## Series editors:

Maria Ganzha (Editor-in-Chief),

*Systems Research Institute Polish Academy of Sciences and Warsaw University of Technology, Poland*

Leszek Maciaszek,

*Wrocław University of Economy, Poland and Macquarie University, Australia*

Marcin Paprzycki,

*Systems Research Institute Polish Academy of Sciences and Management Academy, Poland*

## Senior Editorial Board:

Wil van der Aalst,

*Department of Mathematics & Computer Science, Technische Universiteit Eindhoven (TU/e), Eindhoven, Netherlands*

Marco Aiello,

*Faculty of Mathematics and Natural Sciences, Distributed Systems, University of Groningen, Groningen, Netherlands*

Mohammed Atiquzzaman,

*School of Computer Science, University of Oklahoma, Norman, USA*

Jan Bosch,

*Chalmers University of Technology, Gothenburg, Sweden*

Barrett Bryant,

*Department of Computer Science and Engineering, University of North Texas, Denton, USA*

Włodzisław Duch,

*Department of Informatics, and NeuroCognitive Laboratory, Center for Modern Interdisciplinary Technologies, Nicolaus Copernicus University, Toruń, Poland*

Ana Fred,

*Department of Electrical and Computer Engineering, Instituto Superior Técnico (IST—Technical University of Lisbon), Lisbon, Portugal*

Janusz Górski,

*Department of Software Engineering, Gdańsk University of Technology, Gdańsk, Poland*

Giancarlo Guizzardi,

*Free University of Bolzano-Bozen, Italy, Senior Member of the Ontology and Conceptual Modeling Research Group (NEMO), Brazil*

Francisco Herrera,

*Dept. Computer Sciences and Artificial Intelligence Andalusian Research Institute in Data Science and Computational Intelligence (DaSCI) University of Granada, Spain*

Mike Hinchey,

*Lero—the Irish Software Engineering Research Centre, University of Limerick, Ireland*

Janusz Kacprzyk,

*Systems Research Institute, Polish Academy of Sciences, Warsaw, Poland*

Irwin King,

*The Chinese University of Hong Kong, Hong Kong*

Juliusz L. Kulikowski,

*Nalęcz Institute of Biocybernetics and Biomedical Engineering, Polish Academy of Sciences, Warsaw, Poland*

Michael Luck,

*Department of Informatics, King's College London, London, United Kingdom*

Jan Madey,

*Faculty of Mathematics, Informatics and Mechanics at the University of Warsaw, Poland*

Stan Matwin,

*Dalhousie University, University of Ottawa, Canada and Institute of Computer Science,  
Polish Academy of Science, Poland*

Marjan Mernik,

*University of Maribor, Slovenia*

Michael Segal,

*Ben-Gurion University of the Negev, Israel*

Andrzej Skowron,

*Faculty of Mathematics, Informatics and Mechanics at the University of Warsaw, Poland*

John F. Sowa,

*VivoMind Research, LLC, USA*

George Spanoudakis,

*Research Centre for Adaptive Computing Systems (CeNACS), School of Mathematics,  
Computer Science and Engineering, City, University of London*

**Editorial Associates:**

Katarzyna Wasielewska,

*Systems Research Institute Polish Academy of Sciences, Poland*

Paweł Sitek,

*Kielce University of Technology, Kielce, Poland*

**T<sub>E</sub>Xnical editor:** Aleksander Denisiuk,

DEAR Reader, it is our pleasure to present to you Proceedings of the 2019 Federated Conference on Computer Science and Information Systems (FedCSIS), which took place in Leipzig, Germany, on September 1-4, 2019.

FedCSIS 2019 was Chaired by prof. Bogdan Franczyk, while prof. Rainer Unland acted as the Chair of the Organizing Committee. This year, FedCSIS was organized by the Polish Information Processing Society (Mazovia Chapter), IEEE Poland Section Computer Society Chapter, Systems Research Institute Polish Academy of Sciences, Warsaw University of Technology, Wrocław University of Economics, and Leipzig University, Germany.

FedCSIS 2019 was technically co-sponsored by: IEEE Region 8, IEEE Poland Section, IEEE Computer Society Technical Committee on Intelligent Informatics, IEEE Czechoslovakia Section Computer Society Chapter, IEEE Poland Section Gdańsk Computer Society Chapter, IEEE Poland Section Systems, Man, and Cybernetics Society Chapter, IEEE Poland Section Control System Society Chapter, IEEE Poland Section Computational Intelligence Society Chapter, Committee of Computer Science of the Polish Academy of Sciences, Polish Operational and Systems Research Society, Mazovia Cluster ICT Poland and Eastern Cluster ICT Poland. FedCSIS 2019 was sponsored by Intel.

During FedCSIS 2019, keynote lectures were delivered by:

- Enrique Alba, University of Málaga, Spain, “*Intelligent Systems for Smart Cities*”
- Francisco Herrera, Dept. Computer Sciences and Artificial Intelligence Andalusian Research Institute in Data Science and Computational Intelligence (DaSCI) University of Granada, “*Deep Data and Big Learning: More quality data for better knowledge*”
- George Spanoudakis, Research Centre for Adaptive Computing Systems (CeNACS), School of Mathematics, Computer Science and Engineering, City, University of London, “*Cyber security risks: Comprehensive mitigation through technical, contractual and financial mitigation mechanisms*”

FedCSIS 2019 consisted of five Tracks and a Doctoral Symposium. Tracks were divided into Technical Sessions. Sessions preannounced in Call for Papers as track-related events (conferences, symposia, workshops, special sessions).

- **Track 1: Artificial Intelligence and Applications**
  - Advances in Artificial Intelligence and Applications (14th Symposium AAIA'19)
  - Computational Optimization (12th Workshop WCO'19)
  - Smart Energy Networks & Multi-Agent Systems (7th Workshop SEN-MAS'19)
- **Track 2: Computer Science & Systems**
  - Computer Aspects of Numerical Algorithms (12th Workshop CANA'19)
  - Cryptography and Security Systems (6th Conference C&SS'19)
  - Language Technologies and Applications (4th Workshop LTA'19)
  - Multimedia Applications and Processing

(12th Symposium MMAP'19)

- Advances in Programming Languages (7<sup>th</sup> Workshop WAPL'19)
- Scalable Computing (10th Workshop WSC'19)
- **Track 3: Network Systems and Applications**
  - Advances in Network Systems and Applications (ANSA)
  - Internet of Things - Enablers, Challenges and Applications (3rd Workshop IoT-ECAW'19)
- **Track 4: Information Systems and Technology**
  - Advanced Information Technologies for Management (16th Conference AITM'19)
  - Data Science in Health (1st Special Session DSH'19)
  - Data Analysis and Computation for Digital Ecosystems (1st Workshop InC2Eco'19)
  - Information Systems Management (14th Conference ISM'19)
  - Knowledge Acquisition and Management (25th Conference KAM'19)
- **Track 5: Software and System Engineering**
  - Advances in Software and System Engineering (ASSE)
  - Cyber-Physical Systems (6th Workshop IWCPs-6)
  - Lean and Agile Software Development (3rd International Conference LASD'19)
  - Multimedia, Interaction, Design and Innovation (7th Conference MIDI'19)
  - Software Engineering (39th IEEE Workshop SEW-39)
- **DS-RAIT'19 - 6th Doctoral Symposium on Recent Advances in Information Technology**

The 2019 edition of an AAIA'19 Data Mining Challenge was called *Clash Royale Challenge: How to Select Training Decks for Win-rate*. ~~This year the~~ The task was related to the problem of selecting an optimal training data subset for learning how to predict win-rates of the most popular *Clash Royale decks*. Awards for the winners of the contest were sponsored by: Esensei and the Mazovia Chapter of the Polish Information Processing Society. Papers resulting from the competition are included in the Conference Proceedings (Chapter of Track 1: AAIA).

Each paper, found in this volume, was refereed by at least two referees and the acceptance rate of regular full papers was ~20,8% (62 regular full papers out of 298 general submissions).

The program of FedCSIS required a dedicated effort of many people. Each event constituting FedCSIS had its own Organizing and Program Committee. We would like to express our warmest gratitude to all Committee members for their hard work in attracting and later refereeing 302 submissions (regular and data mining).

We thank the authors of papers for their great contribution to research and practice in computing and information systems. We thank the invited speakers for sharing their knowledge and wisdom with the participants. Finally, we thank all those responsible for staging the conference in Leipzig. Or-

ganizing a conference of this scope and level could only be achieved by the collaborative effort of a highly capable team taking charge of such matters as conference registration system, finances, the venue, social events, catering, handling all sorts of individual requests from the authors, preparing the conference rooms, etc.

We hope you had an inspiring conference and an unforgettable stay in the beautiful city of Leipzig. We also hope to meet you again for FedCSIS 2020 in Sofia, Bulgaria.

**Co-Chairs of the FedCSIS Conference Series**

---

### ARTIFICIAL INTELLIGENCE AND APPLICATIONS

---

---

#### 14<sup>TH</sup> INTERNATIONAL SYMPOSIUM ADVANCES IN ARTIFICIAL INTELLIGENCE AND APPLICATIONS

---

<b>Call For Papers</b>	<b>1</b>
<b>Clash Royale Challenge: How to Select Training Decks for Win-rate Prediction</b> <i>Andrzej Janusz, Łukasz Grad, Marek Grzegorowski</i>	<b>3</b>
<b>Greedy Incremental Support Vector Regression</b> <i>Dymitr Ruta, Ling Cen, Quang Hieu Vu</i>	<b>7</b>
<b>Training Subset Selection for Support Vector Regression</b> <i>Cenru Liu, Jiahao Cen</i>	<b>11</b>
<b>Efficient Support Vector Regression with Reduced Training Data</b> <i>Ling Cen, Quang Hieu Vu, Dymitr Ruta</i>	<b>15</b>
<b>Information granule system induced by a perceptual system</b> <i>Anna Bryniarska</i>	<b>19</b>
<b>Improving Real-Time Performance of U-Nets for Machine Vision in Laser Process Control</b> <i>Przemysław Dolata, Jacek Reiner</i>	<b>29</b>
<b>Predicting blood glucose using an LSTM Neural Network</b> <i>Touria El Idrissi, Ali Idri, Ibtissam Abnane, Zohra Bakkoury</i>	<b>35</b>
<b>Accurate Retrieval of Corporate Reputation from Online Media Using Machine Learning</b> <i>Achim Klein, Martin Riekert, Velizar Dinev</i>	<b>43</b>
<b>A Specialized Evolutionary Approach to the bi-objective Travelling Thief Problem</b> <i>Maciej Laszczyk, Paweł B. Myszkowski</i>	<b>47</b>
<b>Urban Sound Classification using Long Short-Term Memory Neural Network</b> <i>Iurii Lezhenin, Natalia Bogach, Evgeny Pyshkin</i>	<b>57</b>
<b>Quantitative Impact of Label Noise on the Quality of Segmentation of Brain Tumors on MRI scans</b> <i>Michał Marcinkiewicz, Grzegorz Mrukwa</i>	<b>61</b>
<b>Non-dominated Sorting Tournament Genetic Algorithm for Multi-Objective Travelling Salesman Problem</b> <i>Paweł B. Myszkowski, Maciej Laszczyk, Kamil Dziadek</i>	<b>67</b>
<b>Development of a Flexible Mizar Tokenizer and Parser for Information Retrieval System</b> <i>Kazuhisa Nakasho</i>	<b>77</b>

<b>British Sign Language Recognition In The Wild Based On Multi-Class SVM</b>	<b>81</b>
<i>Joanna Isabelle Olszewska, M. Quinn</i>	
<b>Counting Instances of Objects Specified By Vague Locations Using Neural Networks on Example of Honey Bees</b>	<b>87</b>
<i>Jerzy Respondek, Weronika Westwańska</i>	
<b>Generating Human Mobility Route Based on Generative Adversarial Network</b>	<b>91</b>
<i>Ha Yoon Song, Moo Sang Baek, Minsuk Sung</i>	
<b>A Deep Learning and Multimodal Ambient Sensing Framework for Human Activity Recognition</b>	<b>101</b>
<i>Ali Yachir, Abdenour Amamra, Badis Djamaa, Ali Zerrouki, Ahmed khierEddine Amour</i>	
<b>Machine-learning at the service of plastic surgery: a case study evaluating facial attractiveness and emotions using R language</b>	<b>107</b>
<i>Lubomír Štěpánek, Pavel Kasal, Jan Měšťák</i>	

---

## 12<sup>TH</sup> INTERNATIONAL WORKSHOP ON COMPUTATIONAL OPTIMIZATION

---

<b>Call For Papers</b>	<b>113</b>
<b>A Minimum Set-Cover Problem with several constraints</b>	<b>115</b>
<i>Jens Dörpinghaus, Carsten Düing, Vera Weil</i>	
<b>KPIs for Optimal Location of charging stations for Electric Vehicles: the Biella case-study</b>	<b>123</b>
<i>Edoardo Fadda, Daniele Manerba, Roberto Tadei, Paolo Camurati, Gianpiero Cabodi</i>	
<b>A novel integer linear programming model for routing and spectrum assignment in optical networks</b>	<b>127</b>
<i>Youssef Hadhbi, Hervé Kerivin, Annegret Wagler</i>	
<b>An Efficient Exhaustive Search for the Discretizable Distance Geometry Problem with Interval Data</b>	<b>135</b>
<i>Antonio Mucherino, Jung-Hsin Lin</i>	
<b>Models and Algorithms for Natural Disaster Evacuation Problems</b>	<b>143</b>
<i>Alain Quiliot, Christian Artigues, Emmanuel Hebrard, H�el�ene Toussaint</i>	
<b>Best Response Dynamics for VLSI Physical Design Placement</b>	<b>147</b>
<i>Michael Rapoport, Tami Tamir</i>	
<b>Integration of Polynomials over n-Dimensional Simplices</b>	<b>157</b>
<i>Abdenebi Rouigueb, Mohamed Maiza, Abderahmane Tkourt, Imed Cherchour</i>	
<b>Customized Genetic Algorithm for Facility Allocation using p-median</b>	<b>165</b>
<i>Sergio Silva, Marly Costa, Cicero Costa Filho</i>	
<b>An algorithm for 1-space bounded cube packing</b>	<b>171</b>
<i>Lukasz Zielonka</i>	
<b>Ant Colony Optimization Algorithm for Workforce Planning: Influence of the Evaporation Parameter</b>	<b>177</b>
<i>Stefka Fidanova, Gabriel Luque, Olympia Roeva, Maria Ganzha</i>	

---

## 7<sup>TH</sup> INTERNATIONAL WORKSHOP ON SMART ENERGY NETWORKS & MULTI-AGENT SYSTEMS

---

<b>Call For Papers</b>	<b>183</b>
<b>Tool-assisted Surrogate Selection for Simulation Models in Energy Systems</b>	<b>185</b>
<i>Stephan Balduin, Frauke Oest, Marita Blank-Babazadeh, Astrid Nie�e, Sebastian Lehnhoff</i>	
<b>Towards fully Decentralized Multi-Objective Energy Scheduling</b>	<b>193</b>
<i>Joerg Bremer, Sebastian Lehnhoff</i>	

---

## COMPUTER SCIENCE & SYSTEMS

---

<b>Call For Papers</b>	<b>203</b>
------------------------	------------

---

## 12<sup>TH</sup> WORKSHOP ON COMPUTER ASPECTS OF NUMERICAL ALGORITHMS

---

<b>Call For Papers</b>	<b>205</b>
<b>Parallel cache-efficient code for computing the McCaskill partition functions</b> <i>Marek Pałkowski, Włodzimierz Bielecki</i>	<b>207</b>

---

## 6<sup>TH</sup> INTERNATIONAL CONFERENCE ON CRYPTOGRAPHY AND SECURITY SYSTEMS

---

<b>Call For Papers</b>	<b>211</b>
<b>The Low-Area FPGA Design for the Post-Quantum Cryptography Proposal Round5</b> <i>Michał Andrzejczak</i>	<b>213</b>
<b>Accelerating Multivariate Cryptography with Constructive Affine Stream Transformations</b> <i>Michael Carenzo, Monika Polak</i>	<b>221</b>
<b>Spline-Wavelet Bent Robust Codes</b> <i>Alla Levina, Gleb Ryaskin, Igor Zikratov</i>	<b>227</b>
<b>Cryptographic keys management system based on DNA strands</b> <i>Marek Miśkiewicz, Bogdan Książopolski</i>	<b>231</b>
<b>Malicious and Harmless Software in the Domain of System Utilities</b> <i>Jana Št'astná</i>	<b>237</b>

---

## 4<sup>TH</sup> INTERNATIONAL WORKSHOP ON LANGUAGE TECHNOLOGIES AND APPLICATIONS

---

<b>Call For Papers</b>	<b>247</b>
<b>Multilingual Knowledge Base Completion by Cross-lingual Semantic Relation Inference</b> <i>Nadia Bebeshina-Clairet, Mathieu Lafourcade</i>	<b>249</b>
<b>Deep Learning Hyper-parameter Tuning for Sentiment Analysis in Twitter based on Evolutionary Algorithms</b> <i>Eugenio Martínez Cámara, Nuria Rodríguez Barroso, Antonio R. Moya, José Alberto Fernández, Elena Romero, Francisco Herrera</i>	<b>255</b>
<b>Knowledge Extraction and Applications utilizing Context Data in Knowledge Graphs</b> <i>Jens Dörpinghaus, Andreas Stefan</i>	<b>265</b>
<b>Towards semantic-rich word embeddings</b> <i>Grzegorz Beringer, Mateusz Jabłoński, Piotr Januszewski, Andrzej Sobecki, Julian Szymański</i>	<b>273</b>
<b>Languages' Impact on Emotional Classification Methods</b> <i>Alexander Christoffer Eilertsen, Dennis Højbjerg Rose, Peter Langballe Erichsen, Rasmus Engesgaard Christensen, Rudra Pratap Deb Nath</i>	<b>277</b>
<b>Signature analysis system using a convolutional neural network</b> <i>Alicja Winnicka, Karolina Kęsik, Dawid Połap</i>	<b>287</b>

---

## 12<sup>TH</sup> INTERNATIONAL SYMPOSIUM ON MULTIMEDIA APPLICATIONS AND PROCESSING

---

<b>Call For Papers</b>	<b>291</b>
<b>Creating See-Around Scenes using Panorama Stitching</b> <i>Saja Alferidah, Nora Alkhaldi</i>	<b>293</b>
<b>A Social Bonds Integration Approach for Crowd Panic Simulation</b> <i>Imene Bouderbal, Abdenour Amamra</i>	<b>303</b>
<b>GNSS-based Sound Card Synchronization</b> <i>Alexander Carôt, Hasan Mahmood, Christian Hoene</i>	<b>309</b>

<b>Palmprint Recognition Based on Convolutional Neural Network-Alexnet</b>	<b>313</b>
<i>Weyiyong Gong, Xinman Zhang, Bohua Deng, Xuebin Xu</i>	
<b>A Contribution to Workplace Ergonomics Evaluation Using Multimedia Tools and Virtual Reality</b>	<b>317</b>
<i>Roman Leskovský, Erik Kučera, Oto Haffner, Jakub Matišák, Danica Rosinová, Erich Stark</i>	
<b>Information theoretical secure key sharing protocol for noiseless public constant parameter channels without cryptographic assumptions</b>	<b>327</b>
<i>Guillermo Morales-Luna, Valery Korzhik, Vladimir Starostin, Muaed Kabardov, Aleksandr Gerasimovich, Victor Yakovlev, Aleksey Zhuvikin</i>	
<b>License Plate Detection with Machine Learning Without Using Number Recognition</b>	<b>333</b>
<i>Kazuo Ohzeki, Max Geigis, Stefan Schneider</i>	
<b>Depth Map Improvements for Stereo-based Depth Cameras on Drones</b>	<b>341</b>
<i>Daniel Pohl, Sergey Dorodnicov, Markus Ahtelik</i>	
<b>Comparison of singing voice quality from the beginning of the phonation and in the stable phase in the case of choral voices</b>	<b>349</b>
<i>Edward Pótrolniczak, Michał Kramarczyk</i>	
<b>Automatic Assessment of Narrative Answers Using Information Retrieval Techniques</b>	<b>355</b>
<i>Liana Stanescu, Benjamin Savu</i>	
<b>Fuzzy Logic PID Control of a PMDCM Speed Connected to a 10-kW DC PV Array Microgrid - Case Study</b>	<b>359</b>
<i>Roxana-Elena Tudoroiu, Mohammed Zaheeruddin, Nicolae Tudoroiu, Dumitru Dan Burdescu</i>	
<b>Object detection in the police surveillance scenario</b>	<b>363</b>
<i>Artur Wilkowski, Włodzimierz Kasprzak, Maciej Stefańczyk</i>	
<b>Robust Image Forgery Detection Using Point Feature Analysis</b>	<b>373</b>
<i>Youssef William, Sherine Safwat, Mohammed Abdel-Megeed Salem</i>	
<b>Weighted Multimodal Biometric Recognition Algorithm Based on Histogram of Contourlet Oriented Gradient Feature Description</b>	<b>381</b>
<i>Xinman Zhang, Dongxu Cheng, Xuebin Xu</i>	
<b>A GIS Data Realistic Road Generation Approach for Traffic Simulation</b>	<b>385</b>
<i>Yacine Amara, Abdenour Amamra, Yasmine Daheur, Lamia Saichi</i>	
<b>Crime Scene Reconstruction with RGB-D Sensors</b>	<b>391</b>
<i>Abdenour Amamra, Yacine Amara, Khalid Boumaza, Aissa Benayad</i>	
<hr/>	
<b>7<sup>TH</sup> WORKSHOP ON ADVANCES IN PROGRAMMING LANGUAGES</b>	
<hr/>	
<b>Call For Papers</b>	<b>397</b>
<b>Composition of Languages Embedded in Scala</b>	<b>399</b>
<i>Syed Hossein Haeri, Paul Keir</i>	
<b>Supporting Source Code Annotations with Metadata-Aware Development Environment</b>	<b>411</b>
<i>Ján Juhár</i>	
<hr/>	
<b>10<sup>TH</sup> WORKSHOP ON SCALABLE COMPUTING</b>	
<hr/>	
<b>Call For Papers</b>	<b>421</b>
<b>Measure of Adequacy for the Supercomputer Job Management System Model</b>	<b>423</b>
<i>Anton Baranov, Pavel Telegin, Boris Shabanov, Dmitriy Lyakhovets</i>	
<b>Towards Big Data Solutions for Industrial Tomography Data Processing</b>	<b>427</b>
<i>Aleksandra Kowalska, Piotr Łuczak, Dawid Sielski, Tomasz Kowalski, Andrzej Romanowski, Dominik Sankowski</i>	
<b>Whose Fault is It? Correctly Attributing Outages in Cloud Services</b>	<b>433</b>
<i>Maurizio Naldi, Matteo Adriani</i>	

---

## NETWORK SYSTEMS AND APPLICATIONS

---

---

### ADVANCES IN NETWORK SYSTEMS AND APPLICATIONS

---

<b>Call For Papers</b>	<b>441</b>
<b>Formalization of Software Risk Assessment Results in Legal Metrology Based on ISO/IEC 18045 Vulnerability Analysis</b>	<b>443</b>
<i>Marko Esche, Felix Salwiczek, Federico Grasso Toro</i>	
<b>Fane: A Firewall Appliance For The Smart Home</b>	<b>449</b>
<i>Christoph Haar, Erik Buchmann</i>	
<b>Standardized container virtualization approach for collecting host intrusion detection data</b>	<b>459</b>
<i>Martin Max Röhling, Martin Grimmer, Dennis Kreußel, Jörn Hoffmann, Bogdan Franczyk</i>	

---

### 3<sup>RD</sup> WORKSHOP ON INTERNET OF THINGS - ENABLERS, CHALLENGES AND APPLICATIONS

---

<b>Call For Papers</b>	<b>465</b>
<b>Remote Programming and Reconfiguration System for Embedded Devices</b>	<b>467</b>
<i>Robert Brzoza-Woch, Tomasz Michalec, Maksymilian Wojczuk, Tomasz Szydło</i>	
<b>A Framework for Autonomous UAV Swarm Behavior Simulation</b>	<b>471</b>
<i>Piotr Cybulski</i>	
<b>Using Relay Nodes in Wireless Sensor Networks: A Review</b>	<b>479</b>
<i>Mustapha Reda Senouci, Mostefa Zafer, Mohamed Aissani</i>	
<b>Inference of driver behavior using correlated IoT data from the vehicle telemetry and the driver mobile phone</b>	<b>487</b>
<i>Daniel Alves da Silva, José Alberto Sousa Torres, Alexandre Pinheiro, Francisco L. de Caldas Filho, Fabio L. L. Mendonça, Bruno J. G. Praciano, Guilherme Oliveira Kfourir, Rafael T. de Sousa Jr</i>	
<b>Smart Urban Design Space</b>	<b>493</b>
<i>Philipp Skowron, Michael Aleithe, Susanne Wallrafen, Marvin Hubl, Julian Fietkau, Bogdan Franczyk</i>	
<b>An Adaptation of IoT to Improve Parcel Delivery System</b>	<b>497</b>
<i>Ha Yoon Song, Hyo Chang Han</i>	
<b>On Coverage of 3D Terrains by Wireless Sensor Networks</b>	<b>501</b>
<i>Mostefa Zafer, Mustapha Reda Senouci, Mohamed Aissani</i>	
<b>Smart Urban Objects to Enhance Safe Participation in Major Events for the Elderly</b>	<b>505</b>
<i>Tobias Zimpel, Marvin Hubl</i>	

---

## INFORMATION SYSTEMS AND TECHNOLOGY

---

<b>Call For Papers</b>	<b>515</b>
------------------------	------------

---

### 17<sup>TH</sup> CONFERENCE ON ADVANCED INFORMATION TECHNOLOGIES FOR MANAGEMENT

---

<b>Call For Papers</b>	<b>517</b>
<b>Factors Influencing the Intended Adoption of Digital Transformation: A South African Case Study</b>	<b>519</b>
<i>Jean-Paul Van Belle, Rion van Dyk</i>	
<b>Aspects of Mobility of e-Marketing from Customer Perspective</b>	<b>529</b>
<i>Witold Chmielarz, Marek Zborowski, Üyesi Mesut Atasever</i>	

<b>Network Effects in Online Marketplaces: The Case of Kiva</b>	<b>535</b>
<i>Haim Mendelson, Yuanyuan Shen</i>	
<b>The Approach to Applications Integration for World Data Center Interdisciplinary Scientific Investigations</b>	<b>539</b>
<i>Grzegorz Nowakowski, Sergii Telenyk, Kostiantyn Yefremov, Volodymyr Khmeliuk</i>	
<b>Information Systems Development and Usage with Consideration of Privacy and Cyber Security Aspects</b>	<b>547</b>
<i>Janusz Jabłoński, Silva Robak</i>	
<b>Deriving Workflow Privacy Patterns from Legal Documents</b>	<b>555</b>
<i>Marcin Robak, Erik Buchmann</i>	
<b>Using Blockchain to Access Cloud Services: A Case of Financial Service Application</b>	<b>565</b>
<i>Min-Han Tseng, Shuchih Ernest Chang, Tzu-Yin Kuo</i>	
<b>Predicting Automotive Sales using Pre-Purchase Online Search Data</b>	<b>569</b>
<i>Philipp Wachter, Tobias Widmer, Achim Klein</i>	
<b>Exploring Levels of ICT Adoption and Sustainable Development – The Case of Polish Enterprises</b>	<b>579</b>
<i>Ewa Ziemia</i>	
<hr/>	
<b>1<sup>ST</sup> SPECIAL SESSION ON DATA SCIENCE IN HEALTH</b>	
<hr/>	
<b>Call For Papers</b>	<b>589</b>
<b>Medical data exploration based on the heterogeneous data sources aggregation system</b>	<b>591</b>
<i>Andrzej Opaliński, Krzysztof Regulski, Barbara Mrzygłód, Mirosław Głowacki, Aleksander Kania, Paweł Nastalek, Natalia Celejewska-Wójcik, Grażyna Bochenek, Krzysztof Stadek</i>	
<b>Mapping of Dental Care in the Czech Republic: Case Study of Graduates Distribution in Practice</b>	<b>599</b>
<i>Matěj Karolyi, Jakub Šcavnický, Jan Bud'a, Tereza Jurková, Monika Mazalová, Martin Komenda</i>	
<b>Medical prescription classification: a NLP-based approach</b>	<b>605</b>
<i>Vincenza Carchiolo, Alessandro Longheu, Giuseppa Reitano, Luca Zagarella</i>	
<hr/>	
<b>1<sup>ST</sup> WORKSHOP ON DATA ANALYSIS AND COMPUTATION FOR DIGITAL ECOSYSTEMS</b>	
<hr/>	
<b>Call For Papers</b>	<b>611</b>
<b>Location Intelligence in Cogenerated Heating Potential Data</b>	<b>613</b>
<i>Almir Karabegovic, Mirza Ponjavic, Neven Duic, Tomislav Novosel</i>

# 14<sup>th</sup> International Symposium Advances in Artificial Intelligence and Applications

**A** AIA'19 brings together scientists and practitioners to discuss their latest results and ideas in all areas of Artificial Intelligence. We hope that successful applications presented at AAIA'19 will be of interest to researchers who want to know about both theoretical advances and latest applied developments in AI.

## TOPICS

Papers related to theories, methodologies, and applications in science and technology in the field of AI are especially solicited. Topics covering industrial applications and academic research are included, but not limited to:

- Decision Support
- Machine Learning
- Fuzzy Sets and Soft Computing
- Rough Sets and Approximate Reasoning
- Data Mining and Knowledge Discovery
- Data Modeling and Feature Engineering
- Data Integration and Information Fusion
- Hybrid and Hierarchical Intelligent Systems
- Neural Networks and Deep Learning
- Bayesian Networks and Bayesian Reasoning
- Case-based Reasoning and Similarity
- Web Mining and Social Networks
- Business Intelligence and Online Analytics
- Robotics and Cyber-Physical Systems
- AI-centered Systems and Large-Scale Applications

## PROFESSOR ZDZISŁAW PAWLAK BEST PAPER AWARDS

We are proud to continue the tradition started at the AAIA'06 and grant two "Professor Zdzisław Pawlak Best Paper Awards" for contributions which are outstanding in their scientific quality. The two award categories are:

- Best Student Paper. Papers qualifying for this award must be marked as "Student full paper" to be eligible.
- Best Paper Award.

Each award carries a prize of 300 EUR funded by the Mazowsze Chapter of the Polish Information Processing Society.

## EVENT CHAIRS

- **Kwaśnicka, Halina**, Wrocław University of Science and Technology, Poland
- **Markowska-Kaczmar, Urszula**, Wrocław University of Science and Technology, Poland

## ADVISORY BOARD

- **Kacprzyk, Janusz**, Polish Academy of Sciences, Poland
- **Marek, Victor**, University of Kentucky, United States
- **Matwin, Stan**, Dalhousie University, Canada
- **Michalewicz, Zbigniew**, University of Adelaide, Australia
- **Skowron, Andrzej**, University of Warsaw, Poland
- **Ślęzak, Dominik**, University of Warsaw, Poland

## TRACK PROGRAM COMMITTEE

- **Derksen, Christian**, SEN-MAS'19
- **Lasek, Piotr**, AIMA'19
- **Loukanova, Roussanka**, AIRLangComp'19
- **Markowska-Kaczmar, Urszula**, AAIA'19
- **Mozgovoy, Maxim**, ASIR'19
- **Zaharie, Daniela**, WCO'19

## PROGRAM COMMITTEE

- **AbdelRaouf, Ashraf**, Misr International University, Egypt
- **Abiyev, Rahib**, Near East University, Turkey
- **Al-Mardini, Mamoun**, University of Florida, United States
- **Alirezaie, Javad**
- **Antonelli, Michela**
- **Baron, Grzegorz**
- **Bartkowiak, Anna**, Wrocław University, Poland
- **Bembenik, Robert**
- **Betliński, Paweł**, Security On Demand, Poland
- **Boryczka, Mariusz**
- **Bouguelia, Mohamed-Rafik**
- **Bryniarska, Anna**, Opole University of Technology, Poland

**Abstract**—We summarize the sixth data mining competition organized at the Knowledge Pit platform in association with the Federated Conference on Computer Science and Information Systems series, titled Clash Royale Challenge: How to Select Training Decks for Win-rate Prediction. We outline the scope of this challenge and briefly present its results. We also discuss the problem of acquiring knowledge about new notions from video games through an active learning cycle. We explain how this task is related to the problem considered in the challenge and share results of experiments that we conducted to demonstrate usefulness of the active learning approach in practice.

**Keywords**—Data Mining Contest; Training Subset Selection; Win-rates Prediction; Active Learning; Clash Royale

## I. INTRODUCTION

Video games, and especially mobile games, are considered as one of the domains in which a huge amount of data is generated by players on a daily basis. Utilization of such data in practical applications requires complex analysis towards a proper understanding of hidden concepts and time-consuming data preparation process. In particular, it is often necessary to provide labels of data records that we want to use for model training. Even though it is very laborious, this process is necessary to train intelligent models that could provide value to end-users. Due to limited time and budget, it is usually possible to label only a small amount of data. The “as-is” market standard is to manually label data records. To handle this, a number of corporations utilize crowd-computing services to outsource data-labeling capability. However, it seems that the labeling process could be optimized using approaches related to active learning (AL) [1]. An alternative way could be, so-called weak supervision, where less reliable labels are generated using simple heuristics using domain knowledge [2].

In this research, we use as an example a popular mobile collectible card video game – Clash Royale – which combines elements of collectible card game and tower defense genres (<https://clashroyale.com/>). In this game, players build decks consisting of 8 cards that represent playable troops, buildings, and spells, which they use to attack opponent’s towers and defend against their cards. Using good decks is one of the critical abilities of successful Clash Royale players. We describe a challenge in which we take on a problem of measuring and predicting the deck effectiveness in 1v1 ladder games. In particular, we would like to find out whether it is possible to train an efficient win-rate prediction model on a relatively

small subset of decks, whose win-rates were estimated in the past. Such a task can also be considered in the context of active learning, as a selection of a data batch that should be labeled and used for training a win-rate prediction model.

The remaining of the paper is organized as follows: In Section II, we discuss a context for the competition, i.e. the problem of active learning from video game data. In Section III, we briefly describe the competition and summarize its results. In Section IV, we present a framework for predicting win-rates of Clash Royale decks. In Section V, we conclude the paper and draw some directions for future research.

## II. ACTIVE LEARNING FROM VIDEO GAME DATA

Active learning is a domain within the field of machine learning, in which the learning algorithm can interactively query an oracle about labels (or more generally, target attribute values) of some limited number of training records [3]. Its applications are particularly suitable when the availability of labeled data is limited. In such cases, to train reliable prediction models, it is often necessary to perform a laborious and costly process of manual data labeling. Through the use of AL, it is possible to facilitate this process by allowing the algorithm to choose records which seem the most beneficial for learning [4]. Such a selection of training examples is performed based on results of a model constructed in a previous iteration of the AL cycle (Figure 1). The importance of unlabeled examples is determined by the confidence of their classification or by the expected model change after including the instances to the training data [5]. To deal with the cold-start problem, the first training batch is typically selected at random or by using some clustering technique to find a diverse yet representative set of initial examples for labeling [6]. Then, in subsequent iterations of the AL cycle, additional examples are selected and the prediction model is continuously improved [7].

In practice, the data is usually labeled by a committee of experts and the oracle is implemented as a voting system. Since humans are prone to errors, several experts assign labels to each data record, and the final labeling is determined by voting [1]. Research in the AL field focus mainly on algorithms for selecting a single data record for labeling in each iteration of the AL cycle. However, when there are many available experts, it is more efficient to choose larger batches. In this way, experts who label faster do not have to wait until others finish their tasks and the prediction model is updated.

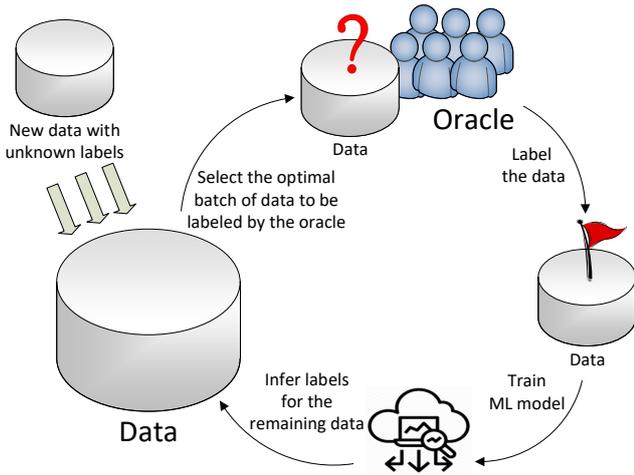

Fig. 1. An active learning cycle. The oracle is interactively queried about labels of records which are selected as the most beneficial for learning by the algorithm.

In a context of video game data, the role of experts can be assumed by the community of players. As a consequence, the committee which assigns labels can be quite large and diverse. This fact impacts the active learning setup in two main aspects:

- 1) In order to optimize the efficiency of the AL cycle and avoid lags in the labeling process, algorithms need to select many data records for labeling at a time.
- 2) Each of selected records should be shown to a subset of available labelers. The voting algorithm should take into account the diversity of labelers and remain robust, even in a presence of a large number of noisy labels.

The system governing the AL cycle should be able to guarantee that whenever there is an available labeler, it can provide a new example for labeling. Moreover, the oracle should be able to find a consensus among contradicting assignments of labels and be able to discard those whose quality is likely to be low. This can be done through the estimation of labelers' expertise, combined with a weighted voting schema [8].

### III. CLASH ROYALE CHALLENGE

The task in Clash Royale Challenge was related to the first of the two problems mentioned in Section II, namely, the selection of a data subset that allows to construct an efficient model for predicting win-rates of Clash Royale decks. The competition took place between April 24, 2019 and June 12, 2019, under the auspices of 14<sup>th</sup> Federated Conference on Computer Science and Information Systems. It was organized on the KnowledgePit platform which underwent a significant lift-up shortly before the start of the challenge (<https://knowledgepit.ml/clash-royale-challenge/>).

The competition's task could also be viewed as a continuation of the topic started in the previous year, i.e. the prediction of win-rates of decks from collectible card video games [9]. The ability to assess quality of decks in a continuously

evolving game is one of core features of an advisory system for players, called SENSEI, which is being developed by one of the competition's sponsors [10].

Data in this challenge consisted of 100.000 Clash Royale decks that were most commonly used by players during three consecutive league seasons in 1v1 ladder games. They were provided in a tabular format. Each row the training set corresponded to a Clash Royale deck and was described by four columns. The first one listed eight cards that constitute the deck. The second and third column showed the number of games played with the deck, and the number of players that were using it, respectively. These values were computed based on over 160.000.000 game results obtained using the RoyaleAPI service (<https://royaleapi.com/>) and SENSEI's data acquisition module. The last column indicated estimations of win-rates of the decks, that were calculated based on games played in the given time window. Participants were asked to indicate ten subsets of those decks, with sizes fixed to 600, 700, . . . , 1500. These subsets were ought to allow training efficient support vector regression models (SVR) with radial kernels [11] for a purpose of win-rate prediction (one model for each training data subset). Competitors could also tune hyper-parameters of the models.

#### A. Evaluation of results and participation in the challenge

The quality of solutions was assessed by measuring the prediction performance of the models trained on data subsets indicated by the participants. This evaluation step was conducted on a separate set of decks. This test data consisted of decks that were popular during the three game seasons after the training data period. This set was not revealed to participants before the end of the challenge. However, a small subset of decks from the test period (a validation data set) was given to participants. It is also worth noticing that the same decks could appear in both the training and evaluation data, but they were likely to have different win-rates. The cause of those differences is the fact that the game evolves in time, players adapt to new strategies, and the balance of individual cards (and their popularity) changes from one season to another.

During the competition, submitted solutions were evaluated online, and the preliminary results were published on Leaderboard. The preliminary score was computed on a randomly selected set of 2000 test records, fixed for all participants. The final evaluation was performed after completion of the competition using the remaining part of the test data. Each teams was oblige to submit a report describing their approach before the end of the challenge.

The measure chosen for the assessment of solutions was the R-squared. If we denote a prediction for a test instance  $i$  as  $f_i$ , and its reference win-rate as  $y_i$ , the R-squared metric is:

$$R^2 = 1 - \frac{RSS}{TSS} \quad (1)$$

where  $RSS$  and  $TSS$  are the residual and total sum of squares, respectively:

$$RSS = \sum_i (y_i - f_i)^2, \quad TSS = \sum_i (y_i - \bar{y})^2$$

TABLE I. FINAL R-SQUARED VALUES AND NUMBER OF SUBMISSIONS FROM TOP-RANKED TEAMS. THE LAST ROW SHOWS THE RESULT OBTAINED BY THE BASELINE SOLUTION.

team name	rank	number of submissions	final result
Dymitr	1	144	0.2552
amy	2	123	0.2530
ru	3	25	0.2257
ms	4	51	0.2241
--	5	30	0.2215
...	...	...	...
baseline	14	1	0.1564

and  $\bar{y} = \frac{1}{N} \sum_i y_i$ .

A value of this metric was computed independently for predictions made by SVR models trained on each of the subsets indicated in the submitted solutions. The final score was an average of the obtained results.

**B. Summary of the competition results**

The scores obtained by top-ranked teams are presented in Table I. The baseline in this challenge was obtained using a simple algorithm that utilizes basic properties of the SVR model, i.e., only records which correspond to the support vectors have any impact on the model. A  $\nu$ -regression SVR was trained on a subset of the most popular training decks with the parameter values set such that the number of selected support vectors corresponded the the desired sizes of target sets. These vectors were taken as the baseline solution.

Participants of the challenge were able to significantly improve over the baseline score. Unfortunately, no team from the top 10 was using an approach that could be applied to the considered problem in practice. The winners were using a greedy search heuristic to limit the candidate decks. Then, they fine-tuned the final sets using exhaustive search. In both cases, the quality of fit was computed as the R-squared value obtained on the validation data. In practice, such data would not be available. Thus any supervised search heuristic would not be feasible. More detailed description of the winning approach can be found in [12]. In Section IV, we propose an alternative method which solves the competition problem without a need for a validation sample. It uses an approach inspired by active learning and can be utilized in a way similar to the AL cycle to continuously adapt to a changing game.

**IV. ESTIMATION OF WIN-RATES USING LIMITED DATA**

We approach the problem of win-rate estimation in Clash Royale using limited training data from a pool-based active learning perspective. Specifically, we propose a solution based on density weighted batch uncertainty sampling. For uncertainty sampling, we provide an informativeness function tailored to the case of known, but noisy labels. Such an approach is viable in the context of win-rate prediction because they change in time due to balance changes in the game. Even though we can always estimate win-rates using historical data (e.g. data from a previous game season), such estimates are likely to be invalid for new game seasons.

**A. An informativeness measure**

Formally, given a training data set  $T$  consisting of records  $(x_i, y_i)_{i=1}^N$  with known label noise  $Var[y_i] = \sigma_i^2$  and a model  $M$ , we search for a training subset of given size  $K$ , such that the model trained on this subset achieves the lowest generalization error, i.e.:

$$A^* = \operatorname{argmin}_{A:|A|=K} \mathbb{E}_{(X,Y)} [l(Y, f_A^M(X))] \tag{2}$$

where  $f_A^M$  is the mapping induced by the model  $M$  trained on subset  $A$  and  $l$  is the mean squared error loss function.

In our method, we begin by choosing an initial training subset  $A_0$  of size  $m$  at random. Then, at each step, we greedily select a sample that maximizes the importance:

$$x^* = \operatorname{argmax}_{x:T} [\phi(x)^\alpha \times Sim(x)^\beta \times Dis(x)^\gamma] \tag{3}$$

where  $\phi$  measures the informativeness of samples,  $Sim(x) = (\frac{1}{u} \sum_{i=1}^u sim(x, x_i))$  is a measure of a representativeness, and  $Dis(x) = (\frac{1}{b} \sum_{i=1}^b dis(x, x_i^B))$  measures the dissimilarity in the current batch, assuming that we have already chosen samples  $(x_0^B, \dots, x_b^B)$ . Parameters  $\alpha, \beta, \gamma$  control the relative importance of each factor. In this work, we set each of the parameters to 1. Similarity measure used in all our experiments was the Jaccard index:  $sim(x_1, x_2) = \frac{|x_1 \cap x_2|}{|x_1 \cup x_2|}$  and  $dis(x_1, x_2) = 1 - sim(x_1, x_2)$ .

To derive the measure of informativeness  $\phi$ , we assume normality of the response  $Y$ . Given a trained model  $M$  and the posterior distribution of the response  $g_M(X_i) \sim \mathcal{N}(\mu_i, \tau_i^2)$ , we obtain the posterior predictive distribution  $\hat{Y}_i \sim \mathcal{N}(\mu_i, \tau_i^2 + \sigma_i^2)$ . This is valid, since noise process and the posterior distribution are independent Gaussians. Now, given a sample  $(x_i, y_i)$  we define the informativeness as

$$\begin{aligned} \phi(x_i) &= 1 - \mathbb{P}(|\hat{Y}_i - \mu_i| > |d_i|) \\ &= 1 - \mathbb{P}((\hat{Y}_i - \mu_i) > |d_i|) - \mathbb{P}((\hat{Y}_i - \mu_i) < -|d_i|) \\ &= 1 - \mathbb{P}\left(Z_i > \frac{|d_i|}{\sqrt{\sigma_i^2 + \tau_i^2}}\right) - \mathbb{P}\left(Z_i < \frac{-|d_i|}{\sqrt{\sigma_i^2 + \tau_i^2}}\right) \\ &= 1 - (1 - \Phi(|d_i|)) - \Phi(-|d_i|) \\ &= 1 - 2\Phi(-|d_i|) \end{aligned}$$

where  $d_i = y_i - \mu_i$ ,  $Z_i$  denotes a standard normal variable and  $\Phi$  is a standard normal CDF.

In our experiments, we used Gaussian Process Regression model [13], along with absolute exponential covariance kernel:

$$K_{\kappa^2, \lambda}(x, x^*) = \kappa^2 \exp\left(-\frac{|x - x^*|}{\lambda}\right) \tag{4}$$

where  $\kappa^2$  and  $\lambda$  are kernel hyper-parameters optimized during model fitting.

**B. Experimental results**

We compared the results obtained using our approach to the best solution from the winners of the challenge [12]. Instead of computing the R-squared metric, we simply measured the root mean squared error (RMSE) of SVR models trained on

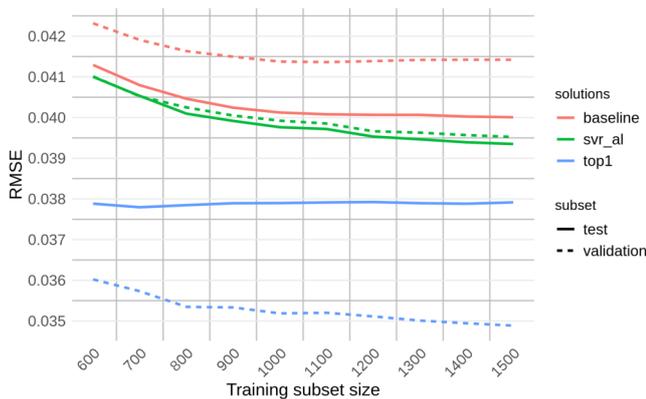

Fig. 2. Results of the compared training subset selection methods. The dotted lines indicate RMSE values obtained on the validation data, whereas the solid lines correspond to the final test set.

each data subset from the winner’s solution, and on subsets of corresponding sizes found using our method. We checked errors of the trained models on the final test set from the challenge, as well as on the validation set which was fully available to competing teams during the competition. Figure 2 shows those results. To provide a better reference, we also computed RMSE values achieved by the baseline method.

Even though our method achieved lower scores than the winner’s for all subset sizes, it is important to notice that in practice, when the validation set is not available, it would be much more useful. For the largest subset size the difference between is lower than 0.002, which seems negligible considering the variance of predicted win-rates. Furthermore, the AL-inspired method is always better than the baseline. The plot also shows that our method is not over-fitted to any particular data subset, whereas the winners achieved much better results on the validation set than on the final test set. Interestingly, RMSE of the winning solution on the final set does not decrease with the growing size of training data subset (it is even slightly higher). This could be regarded as another argument in favour of our method.

## V. SUMMARY

In this paper, we described Clash Royale Challenge organized at the KnowledgePit platform, whose scope was on finding an optimal data subset for training win-rate prediction models. Our competition attracted 115 teams from 18 countries. Among the participating teams, 68 submitted at least one solution file which was ranked on the public Leaderboard. More than 40 of those teams decided to disclose their approach by uploading short reports.

A dominating approach used by competitors was based on a greedy search heuristic with a fit function that used an additional validation set. As an alternative, we proposed a method inspired by active learning, which is more suitable to solve the considered problem in practical applications. In the presented experiments, we showed that it can be effective. In the future, we will focus on extending our approach in the

context of large batch sampling, e.g. by effectively utilizing a predictive covariance matrix for computing the informativeness function utilized by our method.

**Abstract**—Support Vector Regression (SVR) is a powerful supervised machine learning model especially well suited to the normalized or binarized data. However, its quadratic complexity in the number of training examples eliminates it from training on large datasets, especially high dimensional with frequent retraining requirement. We propose a simple two-stage greedy selection of training data for SVR to maximize its validation set accuracy at the minimum number of training examples and illustrate the performance of such strategy in the context of Clash Royale Challenge 2019, concerned with efficient decks’ win rate prediction. Hundreds of thousands of labelled data examples were reduced to hundreds, optimized SVR was trained on to maximize the validation  $R^2$  score. The proposed model scored the first place in the Cash Royale 2019 challenge, outperforming over hundred of competitive teams from around the world.

**Index Terms**—Support vector regression, greedy backward-forward search, data editing, hyperparameters optimization

## I. INTRODUCTION

Support Vector Machine (SVM) is a supervised machine learning (ML) model developed as far back as in 1963 [1] on the basis of Vapnik-Chervonenkis computational theory of learning [2]. Its introduction brought a breakthrough in back then emerging machine learning domain through the proposition of wide-margin linear separation of classes of data in higher-dimensional input space that otherwise were not separable. Since its original proposal multiple incarnations and advancements have been added, most notably introduction of the non-linear SVM classifier with the kernel trick in [3] and soft margin maximization in [4], [5], shaping SVM to more or less the model we see and use till today.

Support Vector Regression (SVR) extends the original capability of the SVM model into the regression space, while sharing the same model fundamental and properties as SVM does for classification: for instance in margin-maximizing hyper-plane characterization, tolerance of errors etc. With its ground breaking wide-margin generalization capabilities SVM as well as SVR dominated the ML field for decades demonstrating significant improvements in supervised learning problems across many application areas: [1]-[7]

In the face of exponential growth of data in terms of its variety, dimensionality and size, we observe today, SVM (SVR) quadratic complexity in the number of training examples, practically eliminates it from direct applications on large datasets starting from hundreds of thousands of data points, especially if frequent retraining is required [7], [8]. High cost involved in computing large number of support vectors in SVR training process is a critical drawback compared to simpler

supervised ML models, which although unable to demonstrate such generalization ingenuity, are simply able to complete in a reasonable time: [9], [10], [11].

Many SVM (SVR) model efficiency improvements have been proposed recently in an attempt to re-enable the model for the big data world: from simplifications like elimination of linearly dependent support vectors [12], through selective probabilistic examples removal [13], up to support vectors elimination through smoothed separable case approximation [11] or k-mean clustering [8] and more related techniques.

Based on the observation that a vast majority of the SVM (SVR) predictive power comes from fairly small number of key data-structure-capturing examples, an obvious attempt to eliminate huge computational cost of training SVR could be reduced by carefully selecting a small set of the critical training data points. In an attempt to address this challenge we have proposed a simple two-stage greedy search process that returns an ordered list of most predictive data points offering the most predictive SVR model based on incrementally added number of training examples. Combined with automated robust SVR hyper-parameter selection we aspire to achieve a fully automated SVR model construction with a flexible complexity control mechanism. The strength of our model has been thoroughly evaluated in the context of Clash Royale Challenge 2019. This international contest was concerned with construction of the most efficient SVR model to predict win rates of the most popular decks of Clash Royale: a card-based online video game that surpassed 2.5B revenue in the three years since launch. Our parallelizable double-search process was able to reduce the original set of 100000 examples down to 1500 key training data points, which SVR can be trained with near-optimal validation  $R^2$  score. Our method scored the first place in the challenge outperforming more than hundred of participating competitive teams from around the world and offering the gaming platforms an efficient new model for rapid accurate estimation of players win chances to better stimulate their immersion and maintain challenging and immersive engagement.

The remainder of the paper is organized as follows. The Clash Royale Challenge 2019 is described in Section II. The two-stage greedy data selection strategy is presented in Section III, followed with experimental results’ discussion in Section IV and the concluding remarks in Section V.

## II. COMPETITION DESCRIPTION

Clash Royale is a popular video game combining the elements of collectible card game and tower defense genres (<https://clashroyale.com/>). The game involves selecting a deck of 8 playable cards used to attack opponents as well as defend against their cards. The Clash Royale Challenge 2019 is focused on efficient prediction of win rates of the most popular Clash Royale decks in the 1v1 ladder games using support vector regression model. Specifically the intention was to find out whether it is possible to build an efficient win-rate prediction model on a relatively small subset of decks, whose win rates were estimated in the past.

The competition training dataset included 100000 decks comprising exactly 8 cards out of the total of 90 unique possible cards with accompanied win rates computed over 160 million games. The validation set of just 6000 randomly selected decks with win rates was also provided and crucially was extracted from the same period as the true testing set to be used as final evaluation in the competition.

The objective of the competition was to provide 10 subsets of 600,700,...,1500 decks from the training set along with the SVR hyper-parameters of omega, C and gamma, that once trained would result in the highest average  $R^2$  score (Eq. 1) obtained on the testing set unavailable to the competitors. Only preliminary results obtained on the small fraction of the testing set are published on the leaderboard during the competition.

$$R^2 = 1 - \frac{\sum_i (y_i - f_i)^2}{\sum_i (y_i - \bar{y}_i)^2} \quad (1)$$

## III. GREEDY 2-STAGE DATA SELECTION FOR SVR

### A. Data preparation

Estimation of future average win rates for every deck was enforced to be done with support vector regression model trained on the bag-of-cards represented decks and their historically computed win rates. Given 90 unique cards the training dataset was transformed to a binary matrix  $X^{[100k \times 90]}$  of 100k (examples) by 90 (card presence indicators), while the output vector  $Y^{[100k \times 1]}$  contained corresponding win rates. Similarly, the validation set  $X_V^{[6000 \times 90]}$  and its corresponding outputs  $Y_V^{[6000 \times 1]}$  were prepared in the same way. Since the validation set was collected from the same period as the unseen testing set it has been decided that the evaluation of any model performance will be obtained using  $R^2$  score computed exclusively on the validation set  $X_V$  against its outputs  $Y_V$ . What it means is that at any point none of the data examples the model is build on will be used to evaluate its performance. Subsequent tests and the leaderboard score feedback positively validated this design choice as a robust generalization feature.

### B. Hyperparameters' setting

The support vector regression model used in the competition used radial basis function (RBF) kernel of the form:

$$G(x_i, x_j) = \exp(-\gamma \|x_i - x_j\|^2) \quad (2)$$

In the light of big discrepancies between the training, validation and the leaderboard sets used in the competition we have decided not to optimize  $\gamma$  parameter to the data during training, but rather use the recommended heuristic of setting it to the median distance to the nearest neighbor among randomly selected small subset of the training data.

The constraint to the alpha coefficients, C, was set to the outlier-free estimate of the response  $Y$  standard deviation by setting  $C = IQR(Y)/1.349$ , where  $IQR(Y)$  is the interquartile range of the response variable  $Y$ .

Similarly the  $\epsilon$  parameter is set to 0.1 of the outlier-free estimate of  $Y$ 's standard deviation  $\epsilon = IQR(Y)/13.49$ .

### C. Greedy online backward-forward data selection

SVR training works the fastest with the small number of examples, hence it appears the best option is to ensure the addition of the new data point to the training set maximally improves model's validation performance. Selecting the best new data point requires, however, an exhaustive evaluation of all available remaining data points, which is computationally expensive. A balanced strategy, which we called greedy online backward-forward selection involves a round of sequential additions of any points that improve the current SVR performance followed with rounds of removals that do the same, i.e. improve the current SVR validation performance. To strengthen the reduction side of the process the backward search for removals is repeated until not a single data point's removal improves SVR performance. Such imbalance ensures quicker accumulation of valuable data points and pruning the dataset to the bare minimum, before resuming with the addition, that overall further speeds up SVR training. The advantage of such search is its ability to very quickly find fairly well performing set of training points. The drawback is that it is sequential - hence not parallelizable and lacking the high performance quality of the full exhaustive addition / reduction process. In the competition this search was applied initially to reduce the original set of 100k examples down to 8000 most predictive data points.

### D. Greedy round-exhaustive forward data selection

Greedy round-exhaustive forward data selection follows the simple strategy of adding the best possible data point at each round i.e. adding the point that maximally improves the SVR validation performance. Such search ensures near-optimal performance at the higher computational cost of testing the addition of all other remaining data points before selecting the best at each round. The advantage of such search is also the fact that it is deterministic hence parallelizable at each round. Unlike the greedy online search, it also ensures the important property of incrementally monotonic set performance i.e. its first  $n$  data points are the best  $n$  points of the set. While it is near-intractable to perform such search on the whole set of 100k data points, after reducing it with the fast but sub-optimal greedy online search and together with the parallelized evaluation implementation, it resulted in a relatively fast process of finding incrementally best performing set of 1500

data points. From this set, exploiting the above-mentioned property of incremental performance monotonicity, choosing the best subsets of 600,700,...,1500 was readily given by taking the incrementally growing chunk of the data. The backward side of the greedy backward-forward search was abandoned for this search simply due to its much higher computational cost and relatively low effectiveness since high quality forward search left very little improvement capability for the backward search at the too high computational cost.

#### E. Fine-tuning for further generalization improvements

Despite model's leading leaderboard score, further attempts have been made to further improve its generalization abilities encouraged by still rather big  $R^2$  score discrepancies obtained for training, validation and leaderboard sets. Beside already mentioned robust data-dependent hyper-parameters setting, significant improvement has been also achieved through injecting a little bit of the training set into the validation set such that the validation set gained extra 4000 data points and now amounted to 10000 points in total. The added data have been naturally removed from the training set to avoid training and validating on the same data points. Injection of the data chunk from different period improved validation set diversity and boosted its representativeness, which was reflected in a slight improvement of the leaderboard  $R^2$  score by about 0.01. The increase in the evaluation cost on the larger validation set was to a degree offset by selection from the smaller training set. The composition balance between the training and validation set sizes in the extended validation set was guided by an intuition but certainly further research on optimality of this balance could be conducted with likely further improvements.

### IV. EXPERIMENTAL RESULTS

The above described 2-stage data selection process has been executed on the standalone PC/laptop. The faster greedy online b-f selection has been executed on average performance laptop since it is not parallelizable and yielded fairly quickly the results in a form of about 8000 preselected data points. Throughout this fast search various fine-tuning and generalization boosting strategies in the section above have been tested that led to the chosen automated setting of the SVR hyperparameters and blending the validation set with a small chunk (4000 points) of the training set. Then the greedy round-exhaustive forward search has been executed on the pre-selected 8000 data points to select incrementally near-optimal set of best 1500 points. It has been executed on the standalone DELL PC with 20-cores Xeon processor and the 20-workers *parfor* parallelization utilized to train and evaluate SVR models in each round of data addition. With such setup the execution was also relatively fast and most importantly yielded intermediate results that were mixed with simple complementary selection that yielded incremental score progress on the leaderboard, reassuring the generalization validity of the strategy. The validation set  $R^2$  score obtained on the subset of preselected 8000 points reached in excess of

Table I  
TIMELINE OF MODEL PERFORMANCE IMPROVEMENTS

Component	online	exhaustive	hyperparameters	validation mix
$R^2$ score	0.237	0.258	0.266	0.274

0.6, while the validation scores obtained for the submission-ready 10 solutions of 600, 700, ..., 1500 were in the range of 0.4–0.5. The final leaderboard score of the best solution was almost 0.275 and was the top score among over 100 teams submissions. Although a huge model overfitting has been observed - evident in a form of big differences between the validation set and leaderboard set scores, the consistency and monotonicity of the score improvements achieved throughout submission of the intermediate search results reassured the strategy validity and allow to expect good results.

Based on the feedback from the leaderboard during the competition, Table I reflects the incremental improvements of the  $R^2$  score of the proposed model with gradually added component features throughout the contest duration.

### V. CONCLUSIONS

We have proposed a simple yet robust 2-stage greedy search strategy for selecting a small subset of the incrementally most predictive data points tested with SVR model deployed to learn decks' win rates within Cash Royale Challenge 2019. With the 1<sup>st</sup> place scored by our model we have demonstrated an extreme efficiency of the proposed data editing strategy, which relatively quickly squeezed out the winning accuracy out of only essential 1% of the original 100k dataset, SVR model would otherwise be completely intractable to train on.

# Training Subset Selection for Support Vector Regression

Cenru Liu

Ngee Ann Polytechnic, Singapore  
liucenru@gmail.com

Jiahao Cen

Nanyang Polytechnic, Singapore  
cenjiahao456@gmail.com

**Abstract**—As more and more data are available, training a machine learning model can be extremely intractable, especially for complex models like Support Vector Regression (SVR) training of which requires solving a large quadratic programming optimization problem. Selecting a small data subset that can effectively represent the characteristic features of training data and preserve their distribution is an efficient way to solve this problem. This paper proposes a systematic approach to select the best representative data for SVR training. The distributions of both predictor and response variables are preserved in the selected subset via a 2-layer data clustering strategy. A 2-layer step-wise greedy algorithm is introduced to select best data points for constructing a reduced training set. The proposed method has been applied for predicting deck’s win rates in the Clash Royale Challenge, in which 10 subsets containing hundreds of data examples were selected from 100k for training 10 SVR models to maximize their prediction performance evaluated using R-squared metric. Our final submission having a  $R^2$  score of 0.225682 won the 3<sup>rd</sup> place among over 1200 solutions submitted by 115 teams.

**Index Terms**—Clash Royal, Support Vector Regression (SVR), R-squared metric ( $R^2$ ), Radial Basis Function kernel (RBF), k-means clustering

## I. INTRODUCTION

NOWADAYS with the growth of the Internet of Things (IoT), 2.5 quintillion bytes of data are produced every day at our current speed [1]. As 2 sides of a coin, a large amount of available data help to build complex and robust machine learning models, while data processing and model training can be rather intractable. Among all data collected, some of them are irrelevant to targets, inter-dependent, and noisy with outliers, leading to inefficient or even intractable training procedure, and more seriously, poor generalization capability.

Support Vector machine (SVM), developed at AT & T Bell Laboratories by Vladimir Vapnik and his co-workers [2], [3], [4], [5], [6], [7] based on the statistical learning theory (or VC theory) [8], [9], [10]. The SVM has shown competitive generalization over many existing machine learning models in various fields, e.g. optical character recognition (OCR), object recognition, time series prediction, etc. [6], [11], [12], [13], [14], as well as in regression, denoted as Support Vector Regression (SVR) [15], [16], [17], [18]. As we know, training a SVR model needs to solve a large quadratic programming optimization problem, which becomes computation intractable on large datasets.

To overcome this disadvantage, it is useful to identify a representative and discriminative data subset from full training data, which is the intention of the Clash Royale Challenge 2019. Clash Royale is a popular video game which combines elements of collectible card game and tower defense genres. In the game, players build decks having 8 cards representing playable troops, buildings, and spells to attack opponent’s towers and defend against their cards. Wining a game is highly dependent on decks. The task of the challenge is to select small data subsets from a large training dataset, on which SVR models can be trained to predict win rates of decks.

To address this problem, a systematic approach is proposed in this paper. The major advantages of our proposed method can be summarized as follows:

- 1) Selecting data points on the clustered space of response variables helps to preserve response distribution, allow parallel implementation, and reduce computational cost.
- 2) Selecting data points from cluster centers of predictor variables can largely speed up search procedure by removing most of training examples from the selection candidates pool, meanwhile reserving predictors’ distribution and their characteristic features.
- 3) Although no guarantee of global optimality, the systematic approach can deterministically find near-optimal solutions.

By using our method in the challenge, 10 subsets containing only hundreds of examples were selected from 100k data points, on which 10 SVR models were trained to predict win rates of decks. The average R-squared metric of the 10 models on unknown testing data is 0.225682, wining 3<sup>rd</sup> place among over 1200 solutions submitted by 115 teams.

This paper is organized as follows. The challenge is described in Section II. The details of the proposed method are presented in Section III. Section IV discusses the experiment results. Conclusions are given in Section V.

## II. CLASH ROYALE CHALLENGE

### A. Challenge task

The intention of the Clash Royale Challenge is to find a small subset from a large training dataset, on which a SVR model with Radial basis function (RBF) kernel can be efficiently trained for predicting win rates of decks. Specifically, competition participants are required to submit 10 subsets of

decks, including 600, 700, 800, 900, 1000, 1100, 1200, 1300, 1400, and 1500 decks, respectively, each of which allows training an efficient SVR based win rate prediction model, and the hyper-parameters of the SVR trained on the these subsets, i.e.  $\epsilon$ ,  $C$ , and  $\gamma$ .

### B. Database

The data used in the challenge are divided into training, validation, and testing sets. The training data consist of 100k Clash Royale decks that were most commonly used by players during 3 consecutive league seasons in 1v1 ladder games. The decks in the validation and testing data were popular during the three next game seasons after the training data period. The validation dataset consists of 6k decks, which was provided to competitors for self-evaluation of their solutions, while the test set was not revealed to participants. The win rates of decks were also provided in the training and validation datasets. Since the decks in the 2 sets were collected from different game seasons, the same decks in different sets may have different win rates.

### C. Solution evaluation

The quality of solutions is assessed using prediction performance measured in the R-squared metric of the models trained on the indicated subsets and the associated hyper-parameters. The R-squared metric is defined as

$$R^2 = 1 - \frac{RSS}{TSS}, \quad (1)$$

where  $RSS$  is the residual sum of squares and  $TSS$  is the total sum of squares, which can be expressed as

$$RSS = \sum_i (y_i - f_i)^2, \quad (2)$$

and

$$TSS = \sum_i (y_i - \frac{1}{N} \sum_i y_i)^2, \quad (3)$$

where  $y_i$  and  $f_i$  are the ground truth label of the  $i^{th}$  data example and its prediction, respectively, and  $N$  is the number of data records in the dataset. The score of a solution is the average  $R^2$  metric of the 10 SVR models.

Leaderboard scores were provided in the preliminary stage of the challenge, which were calculated based on a small subset of the testing data fixed to all participants. The final scores of the 2 best solutions submitted by a competitor evaluated on the full testing set were provided at the end of the challenge.

## III. METHOD FOR SUBSET SELECTION

### A. Method overview

A systemic method is proposed to select a small subset of data for training an efficient SVR model, which consists of 5 parts concluded as follows, as shown in Fig. 1.

- 1) Dividing training data into  $k_y$  groups according to the response variable, denoted as  $y$ , e.g. win rates in the challenge.

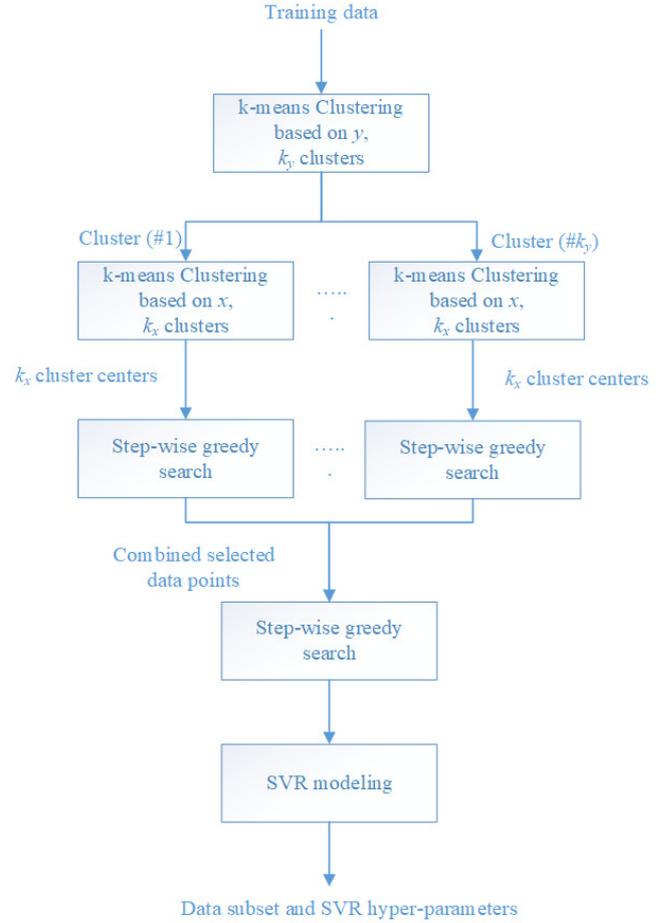

Figure 1. Flowchart of the proposed method.

- 2) Dividing each of  $k_y$  groups into  $k_x$  clusters according to predictor variables, denoted as  $x$ , e.g. decks in the challenge, and constructing  $k_y$  sets of cluster centers.
- 3) Selecting a specific number of data points individually from each of  $k_y$  center-sets by step-wise greedy search. The number is dependent on the sizes of the full dataset, center-set and the subset to be constructed, which will be discussed later. Note that the total number of selected points should be much more than the desired size of the subset.
- 4) Combining all points selected from the  $k_y$  center-sets and selecting exact number of points to construct the required subset by applying again the step-wise greedy algorithm.
- 5) Obtaining the settings of hyper-parameters ( $\epsilon$ ,  $C$ , and  $\gamma$ ) for the SVM model trained on the selected subset.

### B. Data representation

A data example is represented using a binary vector with a length of 90 representing 90 unique cards. Each value in the vector indicates whether or not a card is in the deck, i.e.

- 1- the associated card is used in the deck,

- 0- the associated card is not used in the deck.

The training data containing 100k examples are represented using a matrix with a dimension of  $100000 \times 90$  and the validation data having 6000 examples are represented using a matrix with a dimension of  $6000 \times 90$ . The response variable of the training data, i.e. win rates, is represented using a vector with a length of 100000, and similarly, the win rates of the validation set are represented using a vector with a length of 6000.

It has been mentioned in Section II that the decks in training and validation sets were extracted from different game seasons. Although the same decks may exist in both sets, their win rates are likely different because the game evolves in time, players adapt to new strategies, and the balance of individual cards and their popularity changes slightly from one season to another. Removing the training examples having the same decks as the validation set but with different win rates can avoid uncertainty of such gap, which, however, cannot yield significant improvement on prediction accuracy. This indicates, from a certain of view, the robustness of our selection method.

### C. Two-layer clustering analysis

Clustering analysis is firstly applied to guild data selection. Specifically, a 2-layer clustering strategy inspired by the work presented in [19] is employed to divide training data into groups, as illustrated in Fig. 1. In our method, data clustering is performed by using the K-means clustering algorithm that is a classical and popular unsupervised machine learning algorithm [20]. The aim of clustering analysis here is to preserve the distribution of the full training dataset and reflect their characteristic features in a reduced dataset.

Clustering analysis is performed independent on predictor and response variables, e.g. decks and win rates in the challenge.

- 1) The training dataset is firstly separated into  $k_y$  clusters according to the response variable. The value of  $k_y$  can be set empirically based on the distribution of  $y$ , e.g.  $k_y = 2$  in win rate prediction. In this way, the distribution of  $y$  can be preserved, and meanwhile the subsequent steps can be implemented in parallel.
- 2) Each of  $y_k$  groups are then further divided into  $k_x$  clusters according to the predictor variables. The value of  $k_x$  is empirically determined according to the distribution of  $x$  as well as the sizes of training dataset and the subset to be selected.

We can finally obtain  $k_y$  groups, each having  $k_x$  cluster centers, via the 2-level clustering strategy. Similarly, the validation dataset can be divided into groups using the same cluster centers as the training data.

### D. Two-layer step-wise greedy search

The data subset is selected to feed to SVR training to maximize the prediction performance of the model via a 2-layer step-wise greedy search strategy .

- 1) First, a specific number of data points are independently selected from each of  $k_y$  center-sets by step-wise greedy search that follows below procedure, where  $X$  denotes the full training set containing  $N$  data points,  $S$  represents the subset to be built and  $R(S)$  is its  $R^2$  score.

- Step 1. The search procedure starts with a full training set of  $X$  and an empty subset of  $S$ .
- Step 2. Adding the data point, denoted as  $p$ , selected from  $X$  to  $S$ , which gives the highest score among all points in  $X$ .
- Step 3. Removing the  $p^{th}$  point from  $X$ , and  $N = N - 1$ .
- Step 4. Going to Step 2 until  $S$  is fully filled.

The score of a SVR model is the R-squared metric given in (1) calculated on the validation dataset.

Let  $N_i$  be the number of data points selected from the  $i^{th}$  center-set, which is set as:

$$N_i = N_{all} \times \left( \frac{c_{ti}}{N_t} + \frac{c_{vi}}{N_v} \right) / 2, \quad (4)$$

for  $i \in [1, 2, \dots, k_y]$ , where

- $N_{all}$  is the approximate total number of data points to be selected from all of  $k_y$  clusters, which can be empirically set to be twice as the desired size of the data subset under selection;
- $c_{ti}$  and  $c_{vi}$  are the sizes of the  $i^{th}$  center-sets of the training and validation sets, respectively;
- $N_t$  and  $N_v$  are the sizes of the full training and validation sets, respectively.

- 2) After the data points are selected from each of  $k_y$  center-sets, they are combined to construct a bigger set, on which the step-wise greedy search is applied again to select best data points based on the same selection criteria as the first layer of greedy search.

### E. SVR hyper-parameters

The hyper-parameters of the non-linear SVR model with a Gaussian radial basis function kernel, including  $\epsilon$ ,  $C$ , and  $\gamma$ , are optimized for each selected subset using a heuristic grid search with a range around the seeds and a grid of 0.00001. The seeds of the hyper-parameters are set as follows.

- 1)  $\epsilon$  in the  $\epsilon$ -insensitive loss function controls the smoothness of the SVR model and the number of support vectors, which can largely affect model complexity and its generalization capability.  $\epsilon$  is set to be an estimate of a tenth of the standard deviation using the inter-quartile range of the response variable  $y$ , expressed as:

$$\epsilon = iqr(y) / 13.49, \quad (5)$$

where  $iqr(y)$  is the inter-quartile range of  $y$ .

- 2) The parameter  $C$  controls the trade off between training error and model complexity, i.e. margin maximization, e.g.  $C = \infty$  yielding a hard margin SVR model. In our method,  $C$  is set to be an estimate of the standard deviation of the response variable, expressed as:

$$C = iqr(y) / 1.349. \quad (6)$$

- 3)  $\gamma$  is a free parameter used in the radial kernel. The radial basis function kernel, or RBF kernel on two samples  $x_i$  and  $x_j$  is defined as

$$K(x_i, x_j) = \exp(-\gamma \|x_i - x_j\|^2). \quad (7)$$

The value of  $\gamma$  is optimized by the heuristic procedure using sub-sampling [21].

#### IV. EXPERIMENT RESULTS

The numbers of clusters in the 2-layer clustering analysis were set to be:

$$k_y = 2, \quad (8)$$

i.e. the data were divided into 2 clusters according to win rates, and

$$k_x = 5000, \quad (9)$$

i.e. the data in each of the 2 groups were divided into 5000 clusters. The full training dataset containing 100k examples were reduced into 10k cluster centers from 2-layer clustering analysis, among which 10 relative small subsets containing the required numbers of data examples were selected by using the 2-layer step-wise greedy search strategy.

The best solution that we submitted to the competition as the final solution has a preliminary R-squared metric of 0.2352 evaluated on a subset of testing data and a final score of 0.225682 evaluated on the full testing set, which was scored the 3<sup>rd</sup> place in the challenge among over 1200 solutions submitted by 115 teams.

Although the current version of the proposed method was designed to select a best data subset for SVR model training, our method can be easily extended for other machine learning methods without many modifications. The search procedure followed in our method adding data points in a recursive way cannot guarantee global-optimal performance. Improvement can be expected with suitable implementation of global search.

#### V. CONCLUSIONS

It is useful to select a subset from full labeled data for efficiently training machine learning models, in order to maximize prediction performance at a small number of data examples. This cannot only reduce computational cost but also lead to better generalization capability. To address this, a systematic approach is proposed for data selection, the performance of which has been shown in the Clash Royale Challenge, in which 100k data points were reduced to 600-1500 inputted to train Support Vector Regression (SVR) based win rate prediction models, winning the 3<sup>rd</sup> place in the challenge. This method, although developed for data selection in SVR training, can be easily modified for other machine learning methods. Future work will also improve the search procedure by introducing global optimization methods like evolutionary algorithms.

**Abstract**—Support Vector Regression (SVR) as a supervised machine learning algorithm have gained popularity in various fields. However, the quadratic complexity of the SVR in the number of training examples prevents it from many practical applications with large training datasets. This paper aims to explore efficient ways that maximize prediction accuracy of the SVR at the minimum number of training examples. For this purpose, a clustered greedy strategy and a Genetic Algorithm (GA) based approach are proposed for optimal subset selection. The performance of the developed methods has been illustrated in the context of Clash Royale Challenge 2019, concerned with decks' win rate prediction. The training dataset with 100,000 examples were reduced to hundreds, which were fed to SVR training to maximize model prediction performance measured in validation  $R^2$  score. Our approach achieved the second highest score among over hundred participating teams in this challenge.

**Index Terms**—Support Vector Regression (SVR), K-means clustering, greedy search, R-squared metric, Clash Royale

context of Clash Royale Challenge 2019 with an aim to build an efficient win-rate prediction model on a relatively small subset of decks. The 100,000 labelled data examples in the training dataset were reduced to hundreds, over which a SVR model can be trained with near-maximal validation  $R^2$  score. Our method achieved the second highest score among over hundred participating teams. In addition, a Genetic Algorithm (GA) based approach is also proposed for subset selection to explore global search in training data reduction.

The remainder of the paper is organized as follows. The Clash Royale Challenge 2019 is described in Section II. The clustered greedy selection strategy is elaborated in Section III, followed with the GA based selection approach in Section IV. The experiment results are discussed in Section V. Finally, concluding remarks are given in Section VI.

## I. INTRODUCTION

Support Vector Regression (SVR) shares the same set of properties as Support Vector Machine (SVM) does for classification. Examples include tolerating some errors, characterizing hyper-plane that maximizes the margin, etc. Because of these good properties, during the past decades, SVR as well as SVM have attracted increasing interest and successfully solved supervised machine learning problems in various fields [1], [2], [3]. Its quadratic complexity in the number of training examples, however, eliminates the SVR from training on large datasets, especially if frequent retraining is required [4], [5]. High computational cost associated with the large number of support vectors is a critical drawbacks in comparison with other supervised machine learning algorithms [6], [7], [8].

To improve model efficiency, some approaches for model simplification have been proposed in the literature, e.g. eliminating support vectors linearly dependent on the other support vectors [9], selectively removing examples from training data using probabilistic estimates related to editing algorithms [10], reducing the number of support vectors using smoothed separable case approximation [8] or k-mean clustering [5], etc.

One efficient way for fast SVR training is to maximize its prediction accuracy at the minimum number of training examples. To address this challenge, a multi-step clustered greedy strategy is proposed for selecting a small data subset fed to SVR training fitted with automated robust hyper-parameter selection. Its performance has been illustrated in the

## II. COMPETITION DESCRIPTION

Clash Royale is a popular video game, where players build decks consisting of 8 cards representing playable troops, buildings, and spells to attack opponent's towers and defend against their cards. Building good decks is, therefore, critical to win the game. The intention of the challenge is to find out whether it is possible to build an efficient win-rate prediction model on a relatively small subset of decks, whose win rates were estimated in the past.

The competition training dataset includes 100,000 decks comprising 8 cards out of the total of 90 unique possible cards, which were most commonly used by players during 3 consecutive league seasons in 1v1 ladder games, with accompanied win-rates computed over 160m games. The validation set contains 6000 randomly selected decks with their corresponding win-rates, which was extracted from the 3 next game seasons after the training data period. The testing data extracted from the same period as the validation set, which were unrevealed to participants, were used to evaluate the solutions submitted to the competition,

The task of the competition was to select 10 subsets from the 100,000 training decks, on which 10 efficient SVR models can be trained with best performance of win-rate prediction. Besides the 10 subsets, the hyper-parameter values of the SVR models with radial kernels, including  $\epsilon$ ,  $C$ , and  $\gamma$ , were required together.

The Performance of a SVR model is assessed by the  $R^2$  metric of the model, which is defined as

$$R^2 = 1 - \frac{\sum_i (y_i - p_i)^2}{\sum_i (y_i - \frac{1}{N} \sum_i y_i)^2}, \quad (1)$$

where  $y_i$  and  $p_i$  are the true and predicted values of the win-rate of the  $i^{th}$  data point, respectively, and  $N$  is the size of the testing dataset. The score of a solution is the average of the  $R^2$  scores of the 10 SVR models.

The facility to score derived model solutions on a part of the testing set was provided via the web-based KnowledgePit platform. Although the submission had to be evaluated for the whole testing set, the feedback in a form of the  $R^2$  score was received based on a small subset of the testing examples, fixed for the competitors in the preliminary stage

### III. CLUSTERED GREEDY SELECTION STRATEGY

The clustered greedy strategy has been developed for selecting optimal training subsets, which consists of 4 steps, i.e. k-means clustering, forward greedy search, sequence optimization, and fine-tuning process. The implementation details of the method will be elaborated in this section.

#### A. Data preparation

Estimation of future average win-rates for every deck are enforced to be done with the SVR model trained on the bag-of-cards represented decks and their historically computed win-rates. Given 90 unique cards the training dataset is transformed to a binary matrix with a dimension of  $100k \times 90$  representing 100k (examples) by 90 (card presence indicators), while the output vector with a dimension of  $100k \times 1$  contains corresponding win-rates. Similarly, the validation set ( $6000 \times 90$ ) and its corresponding outputs ( $6000 \times 1$ ) are prepared in the same way.

There is a big gap between the validation  $R^2$  values of our submission-ready solutions and the leaderboard scores, e.g. the former is in the range of 0.4-0.5 while the latter is in 0.2-0.25. To avoid over-fitting and achieve robust models, the validation dataset are extended by combining the original validation set and training data in 4 ways, denoted as E1, E2, E3, and E4, which are:

- E1: 6000 data examples in the original validation dataset;
- E2: 6000 data examples in the original validation dataset and 6000 examples having the largest number of games in the training dataset;
- E3: all data examples in the training dataset, and 16 copies of the original validation dataset for balanced involvement of training and evaluation dataset;
- E4: removing the training points having the same decks as those in the validation set from E3 due to the big discrepancies between the two sets.

The performance of SVR models obtained during search will be evaluated on one of the 4 validation sets.

#### B. Hyper-parameters of SVR

The hyper-parameters of the SVR models with radial basis function (RBF) kernel, including  $\epsilon$ ,  $C$ , and  $\gamma$ , are achieved in below ways:

- $C$ , the constraint to the alpha coefficients, is set as  $C = iqr(Y)/1.349$ , where  $iqr(Y)$  is the inter-quartile range of the response variable,  $Y$ .
- $\epsilon$  is set to be an estimate of 0.1 of  $Y$ 's standard deviation, i.e.  $\epsilon = iqr(Y)/13.49$ .
- $\gamma$  is selected using the heuristic procedure internally implemented in MATLAB.

#### C. k-means clustering

The idea here is to constitute a subset with the data points distributed in the full space of training data. To achieve this, the data are firstly divided into  $k$  groups by k-means clustering. A subset is composed by selecting data points equally from each of the  $k$  clusters. Smaller  $k$  leads to high computational cost and possibly over-fitting caused by concentrated distribution of the selected data, while bigger  $k$  may overlook unique distribution of the training data. We have made a comparison on different values of  $k$ , e.g. 20, 50, and 100, from which it can be seen that  $k = 50$  gives the best results.

#### D. Forward greedy search (FGS)

After dividing the training data into  $k$  clusters, a forward greedy algorithm is applied to select the best subset, which follows a simple strategy of adding the best possible data point from one cluster at each time. After a round is completed, in which  $k$  points have been added respectively from  $k$  clusters, a new round is started if the subset is not fully filled. The flowchart of the search process are shown in Fig. 1.

This search ensures near-optimal performance at the high computational cost of testing the addition of all remaining data points before selecting the best at each search. The advantage of our method is exhaustive evaluation is only performed on data points within a cluster, which, compared to testing all points in the full training dataset, reduces computational cost to  $1/k$ . In addition, such search is deterministic hence it can be implemented in parallel.

Below list compares the regression performance of the SVR models trained over the subsets selected with different values of  $k$  and using different validation sets for performance evaluation of any model yielded in search:

- $R^2 = 0.2158$ ,  $k = 100$ , validation set: E1,
- $R^2 = 0.2277$ ,  $k = 50$ , validation set: E1,
- $R^2 = 0.2566$ ,  $k = 20$ , validation set: E2,
- $R^2 = 0.2593$ ,  $k = 50$ , validation set: E2,

where  $R^2$  is the leaderboard score received in the preliminary stage.

#### E. Sequence optimization (SO)

The greedy search that chooses what appears to be the optimal immediate choice at each time cannot ensure global optimal performance since the current best point may not lead to global best path. To improvement this, after 1500 training

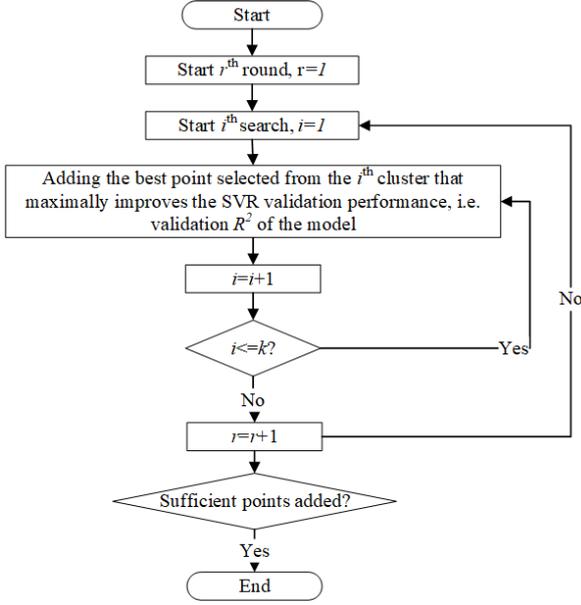

Figure 1. Flowchart of forward greedy search, where  $i$  and  $r$  denote the indices of a search and a round, respectively, i.e. the  $i^{\text{th}}$  search is to find the best point from all available remaining data in the  $i^{\text{th}}$  cluster, and a round is to find  $k$  points in  $k$  clusters respectively.

data points are selected, the sequence of the selected data points are re-arranged by starting a new round of forward greedy search within the 1500 points. Searching within a compressed set, model evaluation can be performed on E3 or E4 validation set at a much lower computational cost than exhaustive evaluation of all available points in a full clustered set. The prediction performance in the steps of FGS and SO are compared below ( $k = 50$ ):

- $R^2 = 0.2277$  in FGS with a validation set of E1  $\rightarrow$   $R^2 = 0.2445$  in SO with a validation set of E3;
- $R^2 = 0.2593$  in FGS with a validation set of E2  $\rightarrow$   $R^2 = 0.2655$  in SO with a validation set of E3;
- $R^2 = 0.2593$  in FGS with a validation set of E2  $\rightarrow$   $R^2 = 0.2702$  in SO with a validation set of E4.

After sequence optimization, the first  $n$  data points in the selected subset are the best  $n$  points of the set. From this set choosing the best 600,700,...,1500 is readily given by taking the incrementally growing chunk of the data.

#### F. Fine-tuning process

The final step of our selection approach is a fine-tuning process, which constitutes a new subset by combining the support vectors of the SVR model from the previous step with the training examples outside  $\epsilon$ -intensive band with smaller deviation between ground truth and corresponding prediction. The improvement, however, is not always quite obvious. The solution with  $R^2 = 0.2702$  can only be improved to  $R^2 = 0.2703$ , while some solutions achieved in previous steps can be improved a little more, e.g. the solution with  $R^2 = 0.2593$  can be improved to  $R^2 = 0.2606$ .

## IV. GA BASED SELECTION APPROACH

In addition to the main method that was presented in the previous section, we also implemented another approach using Genetic Algorithm (GA). In this section, we will present our GA based approach to select training decks.

### A. Population, individual (chromosome), and gene

In GA, at any point of time, there is a population consisting of individuals each of which is a possible solution that includes ten different sets of training decks together with the three required parameters to train an SVM:  $\epsilon$ ,  $C$ , and  $\gamma$ . In other words, an individual in our GA population is a possible solution or submission to the competition.

Given the above definition for an individual in GA, we can see that there are a couple of ways to define a gene in the individual (as an individual is a chromosome that contains a set of genes).

- A possible definition is to consider each training set of deck indices together with the parameters  $\epsilon$ ,  $C$ , and  $\gamma$  as a gene. In this way, we have exactly 10 genes from 10 training sets of decks in each individual. This definition, however, has an issue as the gene is too big to efficiently and effectively perform different variation operations.
- Instead of applying the above definition, the smallest unit of the individual is considered as a gene in which a gene could be a specific  $\epsilon$ ,  $C$ , and  $\gamma$  to train a model with a set of training decks, or even a training deck in this training set. While this definition gives us a finer granulation for the gene, it requires some tricks to support crossover and mutation that we will discuss later to make generation evolve.

### B. First generation

As in a typical approach, the first generation of GA should be generated randomly.

- A random  $\epsilon$  in the range: 0.0 to 1.0
- A random  $C$  in the range: 0.0 to 1000.0
- A random  $\gamma$  in the range: 0.0 to 10.0
- A random set of indices in the range: 1.0 to 100000.0

However, in order to help the GA involve faster, in addition to randomly generated individuals, we also employ few simple approaches to get some seed (good) individuals for the first generation. Note that these approaches are only used to select (possible) better training decks (indices). For  $\epsilon$ ,  $C$ , and  $\gamma$ , we use default values (specifically,  $\epsilon = 0.1$ ,  $C = 1.0$ , and  $\gamma = 1.0/90$ ). Training deck indices were generated for the seed individuals in the following approaches

- Using indices from decks having the highest number of games in the training data.
- Using indices from decks having the highest number of players in the training data.
- Using k-means algorithm to cluster training data into different groups (e.g. 60  $\rightarrow$  150) and again selecting the top-10 indices from each group having the highest number of games or the highest number of players.

### C. Fitness measurement

As each individual in our GA is a possible solution or submission, the straightforward fitness score is the prediction score of the validation data using model trained by parameters and indexed data specified in the individual. In addition to this fitness measurement, another way is to evaluate the model using both training and validation data sets (using different way to give higher weights to the validation data than the training data – as ultimately, we still need to mainly rely on the validation data set). While this validation seems to be better to avoid over-fitting, the trade-off, however, is that it takes significantly more time for the evaluation as the model needs to be evaluated for a much bigger set of data.

### D. Mutation

Given an individual, we first randomly select a set of training decks for the mutation. Then, we will choose to change one of the following components:

- Changing  $\epsilon$  to a random number between 0.0 and 1.0, changing  $C$  to a random number between 0.0 and 1000.0, and changing  $\gamma$  to a random number between 0.0 and 10.0 all with a grid of  $10^{-6}$ .
- Initially, we randomly selected a single training deck to be replaced by another one outside the training set. However, this approach makes the GA extremely slow in progress. Thus, instead of selecting one training deck, to make the GA evolve faster, we chose to randomly select 5% of training decks from the existing indices for replacement.

Note that in each generation, we randomly select 25% of the population to apply mutation for generating new individuals.

### E. Crossover

Given a pair of individuals, we first randomly select a set of training decks for crossover. Then, we choose to perform crossover in the following components:

- Choosing an  $\epsilon$ ,  $C$ ,  $\gamma$  independently from a randomly selected individual.
- We first randomly select a training set of indices having the same size from both individual (e.g. training set of 1000 indices from both sides). Then, from the two training set of indices, we select half of them from each individual. Note that there could be overlapping in the selected indices from both individual, and hence generate less than the number of required indices. In this case, we have two ways to fill the missing indices: to continuously select indices from two individuals to fill or randomly select new indices from outside to fill. In our approach, we randomly use one of the two methods.

Note that in each generation, we randomly select 50% of the population to apply crossover for generating new individuals.

### F. Selection

We follow the traditional approach to select individuals from a generation to the next one. Basically, the probability of an

individual to be selected is proportional to the fitness score it has. It means that the stronger (higher fitness score) of an individual, the higher chance it is being selected to be in the next generation. In our implementation, we choose to maintain a population of 50 individuals in each generation.

## V. EXPERIMENT RESULTS

By applying the proposed methods, the best solution was achieved by clustered greedy selection with below settings:

- $k = 50$  in clustering,
- validation set: E2 in the step of FGS,
- validation set: E4 in the step of SO.

Its leaderboard  $R^2$  score is 0.2593 from forward greedy search and improved to 0.2703 via sequence optimization and fine-tuning. The SO contributes most to score improvement from 0.2593 to 0.2702. The final score evaluated on the full testing dataset is 0.253017. Both the preliminary and final scores of the solution are the 2<sup>nd</sup> highest among over hundred participating teams, showing robustness of the method against over-fitting.

## VI. CONCLUSIONS

This paper explores the possibility of training a Support Vector Regression (SVR) model using a minimal number of training data samples. Two approaches, i.e. clustered greedy strategy, and Genetic Algorithm (GA) based method, are proposed for the selection of data subset fed to SVR training to maximize validation performance. The details of the implementation are elaborated in the paper. The proposed methods successfully selected hundreds of points from 100,000 labeled data samples for efficient SVR training in decks' win-rate prediction and scored 2<sup>nd</sup> place among over hundred participating teams in the Clash Royale Challenge 2019.

**Abstract**—Knowledge represented in the semantic network, especially in the Semantic Web, can be expressed in attributive language *AL*. Expressions of this language are interpreted in different theories of information granules: set theory, probability theory, possible data sets in the evidence systems, shadowed sets, fuzzy sets or rough sets. In order to unify the interpretations of expressions for different theories, it is assumed that expressions of the *AL* language can be interpreted in a chosen relational system called a granule system. In this paper, it is proposed to use information granule database and it is also demonstrated that this database can be induced by the measurement system of the adequacy of information retrieval, called a perceptual system. It can simplify previous formal description of the information granule system significantly. This paper also shows some examples of inducing rough and fuzzy granule databases by some perceptual systems.

## I. INTRODUCTION

IT IS intuitively assumed that **conceiving of information**, represented by descriptions of something, is to discern, distinguish, and identify this thing. Conceiving of information about an object is preceded by **the perception** of the description of this object. The perception consists of a degree of compliance between certain information resources about the object and precisely determined knowledge represented in the set of object descriptions called **the thesaurus** [9], [24]. Thus, object perception determines the weight, rank, and importance of object descriptions representing information about this object. This also applies to sources of information about objects, pointing to these objects, called in the computer science **entities**, i.e. such signs of these objects, which are different from their descriptions. Each such reference is called **the information granule** [24], [25] and its instance is called *data* about the object that this information is concerned with. The description of the information granule indicates what this information is about. In the Web, any description, and thus the description of the information granule, has the address of information in the memory of computers connected to this network. This address indicates the sign for human of what the information relates to, including a specific description of the object. These are, for example, natural language expressions describing these objects, data representative about these objects, their image or their sound characteristics. Granules are grouped into granule systems in which **granular calculations** are made, i.e. the information about objects is interpreted. For

well-established knowledge, granules are *data sets*. When, for knowledge representation, incorrect classification of objects is used, i.e. knowledge about them is probable, uncertain, unclear, or vague, then information granules can not be described by abstract data sets. In such situation, to determine the information granules it is proposed to use the following nonstandard formalisms of the set theory [22]: interval analysis [14], fuzzy sets [29], [30], [31], rough sets [15], [16], [17], [18], [19] and shadowed sets [20], [21], [22]. In the papers mentioned above, as well as in other papers on granular calculations, there is a lack of uniform methods of using abstraction in order to interpret the expressions of the attributive language *AL* in the information granule theories.

It should be noted that in computer science, from the beginning of its existence, abstraction has been used to reduce the complexity of the problem and achieve greater transparency [27]. The elementary form of abstraction introduces a distinction between the level of a concrete (instance, instance of data) and its type. With abstraction, the class type of similar concretes can be specified. The lowest level of abstraction is one that does not require skipping (abstaining from) significant differences between objects. The abstraction model is an abstract set of data about objects, described in the terminology of the set theory in the Cantor sense. At present, the sets are understood as such abstractions in which the formal language of the Zermelo-Frenkel *ZF* set theory can be interpreted, e.g. sets of decidable data strings in the alternative Vopenka theory of sets [28], such as: extended sets [3] and multi sets [2]. For these sets, formal axiomatic set theories have been built, i.e. precise descriptions of these sets.

For any abstraction there is a relational structure called a **granule system**. In this system defines: the set of the universe elements of this structure, the atomic sets determined by the universe elements (singletons), relationships like membership of elements to sets, sets conclusion, sets equality. Furthermore, any set is a sum of atomic sets and analogously to standard one, all operations on sets are specified. In any granule system, the *ZF* set theory language is interpreted. However, not all axioms (except from the axioms of the granule system) and not all *ZF* theorems must be met in this system. The granule system, at a higher level of abstraction, specifies knowledge that is inaccurate, uncertain or unclear at a lower level of abstraction. For fifty years, for fuzzy sets, no such system has

been defined and no formal theory has been built. In 1981, Pawlak [15] described the approximated set at a higher level of abstraction as an abstract class of the relation of the equal approximation of sets and proposed to build an axiomatic rough set theory. A solution to this problem is proposed in the Bryniarski's papers [10], [11].

Recently, *the information retrieval IR* in the semantic network, especially in the Semantic Web, usually means looking for a reliable source of this information. So far, information retrieval systems and information interpretations have only indicated semantically the nearest, described in the thesaurus, sources of searched information. However, this is not always the case. Often, when searching for information about an object in a language deviating from the thesaurus, uncertain, unclear or inaccurate knowledge is obtained. Nevertheless, this uncertainty may lead to the unequivocal establishment of sources of knowledge about this object, i.e. precise knowledge. In this way, compliance with the description of the object model is obtained (compatibility with the thesaurus). The situation described above is called **the information disambiguation paradox** of information retrieval [5].

Searching information in the Semantic Web is to find data copies which are:

- one-argument values of attributes – data representing knowledge about some features or types of objects,
- two-argument values of attributes – data representing knowledge about some properties of objects or relations between two objects..

In first case, data are called *concepts*, and in the second one they are called *roles*. To describe concepts and roles, *the Description Logic (DL)* language [1], [4] is used. The *DL* language describing concepts and roles can be extended to some formulas of the first order logic. In the extended language, a *thesaurus* is created, which describes model concepts and roles, while *the ontology* is a language which describes searched concepts and roles. For the searched data described in the ontology and the recommendations (criteria and knowledge) of experts, there may be a certain degree of compliance of these data with the data described in the thesaurus. This is the assessment of the compatibility of data with the thesaurus accepted by experts. The conceiving rule determining the paradox of accuracy appearing here is called **the residuum rule** [5].

This paper presents a perception model of descriptions representing information in semantic networks. In this model, accepted methods to the description perceptions are used, in order to use the residuum rule. It is the perception of references information resources about the object to the degree of compliance of this information with the precisely determined knowledge represented in the set of object descriptions called the thesaurus. Such perceptual system for descriptions will be called **the residuum system**.

The model of information granule systems represented in semantic networks was formulated at the syntactic and semantic level in the papers [7], [9]. Continuing this research, only

the method of inducing information granules by the residuum system will be presented in this paper.

In this paper firstly is presented the semantic network and the perception in the residuum systems in this network. Further is definition of the information granule database and its extension to the information granule system. The perceptual system defined by the information granule database is novel in this paper. At the end there are two examples of such system – rough and fuzzy one.

## II. THE SEMANTIC NETWORK

The semantic network, or the Semantic Web, most commonly is considered to be a graph schema of knowledge representation. It can be identified with an ordered, indexed graph. In the semantic network the vertices and edges are described by some attributes: one or two-argument. In this paper, a more general graphical scheme of knowledge representation is given in which edges can have more than two vertices [7], [8], [9].

*Definition 2.1:* The semantic network is a system:

$$\text{SN} = \langle U, AS, DS \rangle, \quad (1)$$

where:

- $U$  – is a finite set of individual names, object names of represented knowledge (in the Semantic Web it is a set of names which have the Web address). Elements of  $U$  are called **vertices** of the semantic network.
- $DS$  is a family of nonempty sets of vertices descriptions, and also certain systems of these vertices, called **edges**. The number  $n$  is the largest number of vertices in edges.

Let  $\text{card}(U) = n$  and  $U_{gen} = U \cup U^2 \cup \dots \cup U^n$ . Then:

$$AS \subseteq DS \times U_{gen}, \quad (2)$$

Elements of the set  $AS$  are called **assertions**.  $AS$  includes all vertices  $U$ :

$$U = \{x : \text{exists } (ds_k, (x_1, \dots, x_i, \dots, x_k)) \in AS, x = x_i\} \quad (3)$$

When  $ds \in DS$ , then exists a set  $X(ds) \subseteq U_{gen}$ , such that:

$$\{ds\} \times X(ds) = (\{ds\} \times U_{gen}) \cap AS. \quad (4)$$

Such set and its any subset  $X$  is called a *subject  $X$  with description  $ds$*  (shortly: **subject**), and pair  $\langle ds, X \rangle$  is called a *conceiving subject of description  $ds$* . The subject  $X$  with description  $ds$  will be identified with the conceiving subject  $\langle ds, X \rangle$  of description  $ds$ .

For example, let the conceiving subject of description  $ds$  be  $\langle ds, X \rangle$ , where  $R$  is  $k$ -th argument relation such that:

$$\{ds\} \times R = (\{ds\} \times U^k) \cap X(ds). \quad (5)$$

The set  $X(ds)$  is a relation or sum of relations  $R$  defined as above for any number of arguments. About subject  $X(ds)$ , it is said that, it is a *maximum subject* of the description  $ds$ , and about the description  $ds$ , that it is an *instance of the subject*  $X \subseteq X(ds)$ .

$\text{SN}$  is called *full*, if sum of all such sets is equal  $U_{gen}$ .

Any element of  $U_{gen}$  is called *an instance* of the **SN**, and when this element belongs to some subject  $X$  with some description, it is called *an instance occurrence in the SN network*.

Sets  $\{ds\} \times X(ds) = (\{ds\} \times U_{gen}) \cap AS$  are called *attributes* of subjects  $X \subseteq X(ds)$  with descriptions  $ds$ , and these descriptions will be identified with the instance of this attribute. The family of all such subjects  $X(ds)$  is denoted by  $C_0$ . This set is sometimes a division of  $U_{gen}$  set. The elements of  $X(ds)$  are called *an instance occurrence of attribute ds*, and elements of  $AS$  are *assertions*. The following notary agreement is accepted:

For attribute  $ds$  the instance occurrence set about this attribute is denoted as:

- $\|ds\| =_{df} X(ds)$ .
- the assertion occurrence  $(ds, u) \in AS$ , is denoted as  $u : ds$ , eg. instead of '6 < 9' it will be written '(6, 9) : <'.

One-argument relations will be called *concepts*, and at least two-argument relations will be called *roles*, i.e. concepts and roles are subjects of conceiving certain descriptions.

Due to the fact that for any  $X$  subject, uniquely designated by the attribute  $\{ds\} \times X$ , the description  $ds$  corresponds only to one relationship  $R \subseteq X$ ,  $\{ds\} \times R = (\{ds\} \times U^k) \cap X$  with a given number  $k$  of arguments. Therefore, in the further part of this paper, with a fixed number of arguments of these relations, *concepts and roles will be identified with the corresponding descriptions*.

Occurrences of instances with some attribute, occurrence of attributes, subjects with this attribute, concepts, roles and assertions are described in attributive language  $AL$ . Basic syntax and semantic of  $AL$  language are formulated in the paper [1], and the generalized construction of this language is presented in papers [4], [5], [6], [7], [8], [9].

For example, a role *sonhood* connecting a person named *John* with a person named *Simon*, who is his father, leads to assertion:  $\langle sonhood, John, Simon \rangle$ , what can be denoted as:  $sonhood(John, Simon)$  or  $(John, Simon) : sonhood$ .

To join the concept *sonhood* with the time *current year*, we need two assertions  $\langle sonhood, John, Simon \rangle$  and  $\langle sonhood, current\_year \rangle$ , what can be written as a set of descriptions  $\{(John, Simon) : sonhood, (current\_year) : sonhood\}$ .

An assertion which is expressed in a sentence *Eva sits between John and Simon* can be denoted as:  $sit\_between(Eva, John, Simon)$  or  $(Eva, John, Simon) : sit\_between$ . Roles which are functions, in terms of the last component, are called **operations**, for example in the assertion *drive\_to (John, New York)*.

It is significant to notice that in a triple  $(Eva, John, Simon)$  the cyclic inverse of names can be used, and then the following triple is created:  $(John, Simon, Eva)$ , which is also an instance of some role. This new assertion can be expressed in a sentence *John and Simon sit next to Eva* and can be denoted as:  $(John, Simon, Eva) : sit\_nextto$ . The role *sit\_nextto* is **cyclically inverse** to the role *sit\_between*.

When a triple  $(Eva, John, Simon)$ , which is an occurrence of an assertion *sit\_between*, is reduced by

the first component, then a pair  $(John, Simon)$  is also an instance of some assertion, for example expressed in a sentence: *someone sits between John and Simon* –  $(John, Simon) : someone\_sits\_between$ . This role is called **a reduction** of a role *sit\_between*.

Distinguished by experts subsystem of **SN** is denoted as  $SN^+$  in which concepts and roles are considered to be accurate – experts have confidence in this knowledge.  $SN^+ = \langle U^+, AS^+, DS^+ \rangle$  is called a **confidence range** for the **SN**. In the confidence range is  $U_{gen}^+ = U^+ \cup (U^+)^2 \cup \dots \cup (U^+)^n$ . The set  $SN_{tez} = DS^+ \cup SN_{inst}^+$  of all attribute descriptions and instances of these attributes in the  $SN^+$  is called a **thesaurus** of the semantic network **SN** [8], [9].

### III. DESCRIPTION PERCEPTION IN THE RESIDUUM SYSTEMS

In this paper, some aspects of the perceptual proximity theory are used in the context of the proximity of knowledge searched in the semantic Web to the adequate knowledge represented in the thesaurus. A certain view of nearness perception is accepted, combining the basic understanding of perception in psychophysics with the view of the perception described in the Merleau-Ponty paper [13]. This means that the perception of nearness of knowledge about reality to adequate knowledge – and as a result to human knowledge about objects – depends on the signals of sensors, i.e. signals of the senses or measuring systems [12].

But it is known that these signals from measuring systems are received by our senses, and then, as descriptions of objects, are analyzed in the mind. In this approach, our senses are compared to the sampling function. They mimic the impressions describing the features on the numerical values recognized by the mind. Human sensors (senses) collect data samples and measure the physical characteristics of objects in our environment. The physical properties of the object that are read are described and identified with the features of the object. It is our mind that identifies the relations between the values of the features of the object, creating the perception of the detected objects [13]. Object perception is a measure of the adequacy of the information resource that defines this object. As it was written earlier, such a measurement of the adequacy of the information resource will be hereinafter referred to as *a granule of information*. In this sense, by searching for information about certain objects in the Semantic Web, *the perception of object descriptions* and descriptions representing information about these objects are made. In this way a certain set of information granules is obtained [8], [9].

Thus, the definition of algorithms for granular calculations should begin with the definition that is a part of the definition of *the perceptual system*.

#### A. The residuum system

*Definition 3.1:* The system

$$\mathbf{S_P} = \langle S_P, \bullet_P, \rightarrow_P, 0_P, 1_P \rangle \quad (6)$$

is a **residuum system**, where a set  $S_P$  is called *the set of perception values*, and it includes two different elements  $0_P, 1_P$ , called values of *truth* and *false*. An operation  $\bullet_P : S_P \times S_P \rightarrow S_P$  is called *the operation of perception combination*, an operation  $\rightarrow_P : S_P \times S_P \rightarrow S_P$  is called the operation of *perception residuum*.

Operations of the residuum system satisfy following conditions (for any  $z \in S_P$ ):

$$\text{if } z \neq 0_P, \text{ then } (0_P \rightarrow_P z) = 1_P, (z \rightarrow_P 0_P) = 0_P. \quad (7)$$

In addition, there is such an operation  $\sum_P : \wp(S_P) \rightarrow S_P, \wp(S_P) = \{X : X \subseteq S_P\}$ , called *the generalized combination of perception*, such that for any  $x \in S_P$  and for any nonempty disjoint sets  $A, B \subseteq S_P$ :

$$\sum_P \emptyset = 0_P, \quad (8)$$

$$\sum_P \{x\} = x, \quad (9)$$

$$\sum_P (A \cup B) = \sum_P (A) \bullet_P \sum_P (B), \quad (10)$$

Hence, for any  $x, y \in S_P$ :

$$\sum_P \{x, y\} = (x \bullet_P y). \quad (11)$$

A differentiated operation  $(\cdot^d) : S_P \rightarrow S_P$ , such that  $(0_P)^d = 1_P$  and  $(1_P)^d = 0_P$ ,  $(x^d)^d = x$ , is called *the dual value operation* in the system  $\mathbf{S}_P$ , such that if  $x, y \in S_P$  and  $x < y$ , then  $y^d < x^d$ .

- If  $(z \rightarrow_P z) = 1_P$ , then the residuum operation is called *the t-residuum*.
- If  $(z \rightarrow_P z) = 0_P$ , then the residuum operation is called *the s-residuum*.

With the above definitions results:

*Fact 3.1:* Perception combination is a commutative and associative operation.

Let in the residuum system  $\mathbf{S}_P = \langle S_P, \bullet_P, \rightarrow_P, 0_P, 1_P \rangle$ , for the operation  $(\cdot^d)$  of dual value in the system  $\mathbf{S}_P$ , exist such operation  $\sum_{P'} : \wp(S_P) \rightarrow S_P$ , that (for any  $x \in S_P$  and  $A, B \subseteq S_P$ ):

$$\sum_{P'} \emptyset = 0_P, \quad (12)$$

$$\sum_{P'} \{x\} = x, \quad (13)$$

$$\sum_{P'} (A \cup B) = (\sum_{P'} (A)^d \bullet_P \sum_{P'} (B)^d)^d, \quad (14)$$

Then, for any numbers  $x, y \in S_P$  it is assumed that:

$$x \bullet_{P'} y =_{df} (x^d \bullet_P y^d)^d, \quad (15)$$

for any nonempty, disjoint sets  $A, B \subseteq S_P$ :

$$\sum_{P'} (A \cup B) = \sum_{P'} (A) \bullet_{P'} \sum_{P'} (B). \quad (16)$$

Let  $x \rightarrow_{P'} y =_{df} (x^d \rightarrow_P y^d)^d$ .

If  $z \neq 0_{P'}$ , then  $(0_P \rightarrow_{P'} z) = 1_P, (z \rightarrow_{P'} 0_P) = 0_P$ . Therefore:

*Fact 3.2:* The algebra system  $\mathbf{S}_{P'} = \langle S_P, \bullet_{P'}, \rightarrow_{P'}, 0_P, 1_P \rangle$  is the residuum system.

*Definition 3.2:* The residuum system

$\mathbf{S}_{P'} = \langle S_P, \bullet_{P'}, \rightarrow_{P'}, 0_P, 1_P \rangle$  is called **the dual system** for the  $\mathbf{S}_P$  system.

*Fact 3.3:* The operation  $\rightarrow_{P'}$  in the residuum system  $\mathbf{S}_P$  is the s-residuum operation.

**B. T-norm and s-norm systems in the partially ordered set**

*Theorem 3.1:* The algebra system  $\mathbf{S}_t = \langle L, \bullet_t, \rightarrow_t, 0_L, 1_L \rangle$ , is called **the t-norm system** in the set  $L$  partially ordered by the relation  $\leq$ , in which any subset has infimum and supremum, where  $0_L = \inf L$ , and  $1_L = \sup L$ . It is the residuum system, if the operation  $\bullet_t : L \times L \rightarrow L$ , called *the t-norm* in the  $L$ , satisfies following conditions (for any numbers  $w, x, y, z \in L$ ):

- boundary conditions

$$0_L \bullet_t y = 0_L, y \bullet_t 1_L = y \quad (17)$$

- uniform value increase, monotonicity

$$x \bullet_t y \leq z \bullet_t y, \text{ when } x \leq z \quad (18)$$

- uniform value limitation

$$w \leq x \bullet_t y \leq z, \text{ when } w \leq x \leq z \text{ or } w \leq y \leq z \quad (19)$$

- commutativity

$$x \bullet_t y = y \bullet_t x \quad (20)$$

- associativity

$$x \bullet_t (y \bullet_t z) = (x \bullet_t y) \bullet_t z \quad (21)$$

- and

$$\text{exist } x \rightarrow_t y = \sup\{t \in L : x \bullet_t t \leq y\}. \quad (22)$$

Such described operation  $\rightarrow_t : L \times L \rightarrow L$  is *the t-residuum* in the set  $L$ .

Let operation  $\cdot^d : L \rightarrow L$  be an operation of the dual values in the  $\mathbf{S}_t$  system, then the system  $\mathbf{S}_s = \langle L, \bullet_s, \rightarrow_s, 0_L, 1_L \rangle$  is defined as follows (for any numbers  $x, y \in L$ ):

$$x \bullet_s y = (x^d \bullet_t y^d)^d, \quad (23)$$

$$x \rightarrow_s y = (x^d \rightarrow_t y^d)^d, \quad (24)$$

Then:

*Theorem 3.2:* In the system  $\mathbf{S}_s = \langle L, \bullet_s, \rightarrow_s, 0_L, 1_L \rangle$ , the following conditions are satisfied (for any numbers  $w, x, y, z \in L$ ):

- boundary conditions

$$0_L \bullet_s y = y, y \bullet_s 1_L = 1_L \quad (25)$$

- uniform value increase, monotonicity

$$x \bullet_s y \leq z \bullet_s y, \text{ when } x \leq z \quad (26)$$

- uniform value limitation

$$w \leq x \bullet_s y \leq z, \text{ when } w \leq x \leq z \text{ or } w \leq y \leq z \quad (27)$$

- commutativity

$$x \bullet_s y = y \bullet_s x \quad (28)$$

- associativity

$$x \bullet_s (y \bullet_s z) = (x \bullet_s y) \bullet_s z \quad (29)$$

- and

$$x \rightarrow_s y = \inf\{t \in L : y \leq x \bullet_s t\}. \quad (30)$$

*Definition 3.3:* The system  $\mathbf{S}_s = \langle L, \bullet_s, \rightarrow_s, 0_L, 1_L \rangle$  is called **the s-norm system** in the set  $L$  partially ordered by the relation  $\leq$ , and the operation  $\bullet_s : L \times L \rightarrow L$  is called *the s-norm* in the  $L$  for the operation  $(\cdot^d)$  of dual values in the system  $\mathbf{S}_t$ .

*Example 3.1:* Let range of numbers  $L = [0, 1]$  be ordered by the relation  $\leq$ . The operation  $\bullet_t : [0, 1] \times [0, 1] \rightarrow [0, 1]$ , for any  $x, y \in [0, 1]$ , is the t-norm and is defined by formula:

$$x \bullet_t y = \inf\{x, y\} = \min\{x, y\}. \quad (31)$$

Its generalized form determines the formula, for any set  $X \subseteq [0, 1]$

$$\sum_t X = \inf X. \quad (32)$$

It can be determined that:

$$x \rightarrow_t y = \sup\{t \in [0, 1] : \min\{x, t\} \leq y\}. \quad (33)$$

*Example 3.2:* Let range of numbers  $L = [0, 1]$  be ordered by the relation  $\leq$ . The operation  $\bullet_s : [0, 1] \times [0, 1] \rightarrow [0, 1]$  for any  $x, y \in [0, 1]$ , is the s-norm and is defined by formula:

$$x \bullet_s y = \sup\{x, y\} = \max\{x, y\} \quad (34)$$

Its generalized form determines the formula, for any set  $X \subseteq [0, 1]$ :

$$\sum_s X = \sup X. \quad (35)$$

It can be determined that:

$$\begin{aligned} x \rightarrow_s y &= 1 - (1 - x) \rightarrow_t (1 - y) = \\ &= 1 - \sup\{t \in [0, 1] : \min\{1 - x, t\} \leq 1 - y\} = \\ &= \inf\{t \in [0, 1] : y \leq x \bullet_s t\}. \end{aligned} \quad (36)$$

Having t-norm and s-norm systems can be determined:

*Definition 3.4:* The system  $\mathbf{S}_{\text{logic}} = \langle L, \bullet_s, \rightarrow_t, 0_L, 1_L \rangle$  is called **the logical residuum system**.

#### IV. THE INFORMATION GRANULE DATABASE

Firstly, the definition of the perceptual system is given in order to define the information granule database. Then, it is shown how this database is induced by this system.

##### A. The perceptual system

*Definition 4.1:* For the semantic network  $\mathbf{SN} = \langle U, AS, DS \rangle$ , a **perceptual object** is an instance which was given a certain value in the residuum system  $\mathbf{S}_{\text{logic}} = \langle L, \bullet_s, \rightarrow_t, 0_L, 1_L \rangle$ , i.e. perceptual objects are elements of some set  $O = U_{gen}$ , where the set  $L_0 \subseteq L$  is a set of values of instances in the residuum system  $\mathbf{S}_{\text{logic}}$ .

Giving certain values in the  $\mathbf{S}_{\text{logic}}$  residuum system also has some interpretation in  $\mathbf{S}_{\text{logic}}$ . This interpretation is defined by the definition:

*Definition 4.2:* A **probe function** or a **perception** is a function that  $\phi : O \rightarrow L_0$  represents a feature of a perceptual object [23], [26].

Further, for the  $\mathbf{SN}$ , it is assumed that any description  $\phi \in DS$  corresponds to a certain perception  $\phi : O \rightarrow L_0$  determined by this description  $\phi$ .

Extending the perceptual system definition [26], for the concept of the logical residuum system  $\mathbf{S}_{\text{logic}}$ , it is assumed that:

*Definition 4.3:* A **perceptual system**  $\mathbf{PS} = \langle O, F, \mathbf{S}_{\text{logic}} \rangle$  consists of a nonempty set  $O$  of sample perceptual objects and the set  $F$  of chosen perceptions  $\phi : O \rightarrow L_0$ , called *the perceptions of the PS system*. Elements of the  $L_0$  are called then *the perception degrees*.

##### B. The granule information database induced by the perceptual system

*Definition 4.4:* The system:

$$\mathbf{G}_{\text{base}} = \langle G, \{ \}_G, \cup_G, \subseteq_G, =_G, 0_G, 1_G, G_{inst}, G_{set}, G_0 \rangle, \quad (37)$$

is called **the granule information database**, where elements of the set  $G$  are called *granules*,  $G_{inst}$  is a set of *instance granules*,  $G_{set}$  is a set of *set granules* and  $G_0$  is a set of *singletons of granules*, a granule  $0_G$  is called an *empty granule* and a granule  $1_G$  is called a *full granule*, the operations  $\{ \}_G, \cup_G$  and the relations  $\subseteq_G, =_G$  are defined by following conditions:

$$G_0 \subseteq G_{set}, \quad (38)$$

$$G = G_{inst} \cup G_{set}, \quad (39)$$

$$G_{inst} \cap G_{set} = \emptyset. \quad (40)$$

There is some function  $\{ \}_G : G_{inst} \rightarrow G_0$ , such that

$$\text{for any } x \in G_{inst}, \{x\}_G \subseteq_G 1_G, \text{ additionally, if } \{x_0\}_G \subseteq_G \{x\}_G, \text{ then } \{x_0\}_G =_G \{x\}_G, \quad (41)$$

$$G_0 = \{x \in G_{set} : \exists z \in G_{inst} (x = \{z\}_G)\}. \quad (42)$$

There is some function  $\cup_G : \wp(G_{set}) \rightarrow G_{set}$ , such that

$$\cup_G \emptyset = 0_G, \quad (43)$$

$$\cup_G G_{set} = 1_G, \quad (44)$$

$$\cup_G \{z\} = z, \text{ for } z \in G_{set}, \quad (45)$$

$$x \subseteq_G x, \quad (46)$$

$$0_G \subseteq_G x, \quad (47)$$

$$\text{If } x \neq 0_G, \text{ then, it is not true that } x \subseteq_G 0_G, \quad (48)$$

$$y = \cup_G \{x \in G_0 : x \subseteq_G y\}, \quad (49)$$

for any  $x, y \in G_{set}, (x =_G y) \Leftrightarrow_{df}$

$$\cup_G \{z \in G_0 : (z \subseteq_G x) \Leftrightarrow (z \subseteq_G y)\} = 1_G. \quad (50)$$

It is assumed, in the sense of the set theory, that the  $Inst : U_{gen} \rightarrow G_{inst}$  function assigns a certain instance

granule to each instance. Any such function allows to enter a notation agreement for the granule  $Inst(\langle v_1, v_2, \dots, v_k \rangle)$ , when  $\langle v_1, v_2, \dots, v_k \rangle \in U^k$ :

$$\begin{aligned} (Inst)\langle x_1, x_2, \dots, x_k \rangle &= Inst(\langle v_1, v_2, \dots, v_k \rangle) \\ \text{iff } \langle v_1, v_2, \dots, v_k \rangle &\in U^k \text{ and} \\ x_i &= Inst(v_i), \text{ for } i = 2, \dots, k. \end{aligned} \quad (51)$$

**Theorem 4.1:** Let, for any perceptual system  $\mathbf{PS} = \langle O, F, \mathbf{S}_{\text{logic}} \rangle$ ,  $\mathbf{S}_{\text{logic}} = \langle L, \bullet_s, \rightarrow_t, 0_L, 1_L \rangle$ , symbols  $G, \{\}_G, \cup_G, \subseteq_G, =_G, 0_G, 1_G, G_{inst}, G_{set}, G_0$  be interpreted as follows (for any  $\phi_1, \phi_2 \in G_{set}, \phi \in G_0$ ,  $C_0$  is a family of maximum subjects in the semantic network  $\mathbf{SN}$ ):

$$G_{inst} = U_{gen} \times L_0 \cup C_0, \quad (52)$$

where  $C_0 \subseteq \wp(U_{gen})$  and  $L_0 = \{r : \text{exists } a \in U_{gen} \text{ and exists } \phi \in F \text{ such that } r = \phi(a)\}$ ,

$$G_{set} = F, \quad (53)$$

$$G = G_{inst} \cup G_{set}, \quad (54)$$

$$\phi_1 \subseteq_G \phi_2 \text{ iff for any } x \in L, \phi_1(x) \rightarrow_t \phi_2(x) = 1_L, \quad (55)$$

$$\{(a, r)\}_G = \mu \in F, \quad (56)$$

where  $\mu$  is such perception that for  $(a, r) \in G_{inst}, \mu(a) = r \neq 0_L$ , and  $\mu \subseteq_G 1_G$ , additionally, if  $\mu_0 \in F$  and  $\mu_0 \subseteq_G \mu$ , then  $\mu_0 = \mu$ ,

$$\{K\}_G = \mu \in F, \quad (57)$$

where  $\mu$  is such perception that for  $K \in C_0, \mu(a) = 1_L$  for any  $a \in K, \mu(a) \neq 0_L$  for any  $a \notin K$  and  $\mu \subseteq_G 1_G$ , additionally, if  $\mu_0 \in F$  and  $\mu_0 \subseteq_G \mu$ , then  $\mu_0 = \mu$ ,

$$\begin{aligned} G_0 &= \{\phi \in F : \text{exists } u \in G_{inst}, \\ &\text{such that } \phi = \{u\}_G\}. \end{aligned} \quad (58)$$

Additionally, if  $A \subseteq F$ , then:

$$(\cup_G A)(x) = \sum_P \{y \in L : y = \phi(x) \wedge \phi \in A\}, \quad (59)$$

$$\begin{aligned} (\phi_1 =_G \phi_2) &\Leftrightarrow_{df} \cup_G \{\phi \in G_0 : (\phi \subseteq_G \phi_1) \Leftrightarrow \\ &\Leftrightarrow (\phi \subseteq_G \phi_2)\} = 1_G. \end{aligned} \quad (60)$$

Then, the system  $\langle G, \{\}_G, \cup_G, \subseteq_G, =_G, 0_G, 1_G, G_{inst}, G_{set}, G_0 \rangle$  is the granule information database.

**Definition 4.5:** The granule database described in above theorem is called the granule information database induced by the perceptual system  $\mathbf{PS}$ .

## V. EXTENDING THE INFORMATION GRANULE DATABASE TO THE INFORMATION GRANULE SYSTEM

**Definition 5.1:** For any  $x \in G_{inst}$  and  $y \in G_{set}$ ,

$$x \in_G y \text{ iff } \{x\}_G \subseteq_G y. \quad (61)$$

The relation  $\in_G$  is called the **relation of belonging instance granule to the granule set**.

Hence, and from the conditions describing the information granule database:

**Theorem 5.1:**

$$\{x \in G_{inst} : x \in_G 0_G\} = \emptyset, \quad (62)$$

$$\{x \in G_{inst} : \exists z \in G_0 (x \in_G z)\} = G_{inst}, \quad (63)$$

$$\{z \in G_{set} : \exists x \in G_{inst} (x \in_G z)\} = G_{set}, \quad (64)$$

$$y = \cup_G \{\{x\}_G : x \in_G y\}, \quad (65)$$

**Theorem 5.2:** Granules  $y^G, y \cap_G z, y \cup_G z$ , and  $y \setminus_G z$  exist in the granule database, and are defined by formulas:

$$y^G = \cup_G \{z \in G_0 : \exists x \in G_{inst} (x \in_G z \wedge \neg x \in_G y)\}, \quad (66)$$

$$\begin{aligned} y \cap_G z &= \cap_G \{y, z\} = \cup_G \{t \in G_0 : \\ &\exists x \in G_{inst} (x \in_G t \wedge x \in_G y \wedge x \in_G z)\}, \end{aligned} \quad (67)$$

$$\begin{aligned} y \cup_G z &= \cup_G \{y, z\} = \cup_G \{t \in G_0 : \\ &\exists x \in G_{inst} (x \in_G t \wedge (x \in_G y \vee x \in_G z))\}, \end{aligned} \quad (68)$$

$$\begin{aligned} y \setminus_G z &= \cup_G \{t \in G_0 : \\ &\exists x \in G_{inst} (x \in_G t \wedge x \in_G y \wedge \neg x \in_G z)\}. \end{aligned} \quad (69)$$

In order to unify the expressions of the attributive language  $AL$  in various theories of information granules, formulated in theories: set theory, probability theory, possible data sets in the evidence systems, fuzzy set theory, rough sets theory and shadowed sets theory, the expressions of the attributive language are assumed to be interpreted in a chosen relational system  $\mathbf{G}$  [8], [9], [11] given below. A distinction is made between the set of granule instances and the set of granule set instances. In the first set, attribute instances are interpreted and in the second - set of instances (concepts and roles). The important thing is that the granule set instances determine sets of instances. Granule instances are interpreted as elements of granule set instances, analogically to some classical  $\mathbf{G}^+$  algebra.

**Definition 5.2:** Let the granule system for the attributive language be:

$$\begin{aligned} \mathbf{G} &= \langle G, M_G, \cup_G, \cap_G, \setminus_G, 'G, \in_G, \subseteq_G, \\ &=_{=G}, 0_G, 1_G, G_{inst}, G_{set}, G_0 \rangle. \end{aligned} \quad (70)$$

where:

- $G = G_{inst} \cup G_{set}$  is a sum of sets:  $G_{inst}$  – is a set of granule instances and  $G_{set}$  is a set of granule set instances,
- $M_G$  is a set of functions  $m_G : G \rightarrow G$ ,
- operations  $\cup_G, \cap_G$  are generalized operations of sum and product described on the subsets of the granules family  $G$ ,
- $\setminus_G$  is an operation of granules difference,
- $'G$  is an operation of granules closure,
- for an empty set, a value of these generalized operations is an empty granule  $0_G$  and for the  $G$  set it is a full granule  $1_G$ ,

- $\in_G$  is a relation of being a granule element,
- $\subseteq_G$  is a relation of granules inclusion for instance set granules,
- $=_G$  is a relation of granules closeness for instance set granules,
- $G_0$  is a set of chosen granules.

$G_0$  is a set of granules called *granules of instances singletons* such that there is some function  $\{\}_G : G_{inst} \rightarrow G_0$  and  $G_0 = \{x \in G : \exists z \in G_{inst}(x = \{z\}_G)\}$ .

## VI. EXAMPLES OF THE GRANULE SYSTEM

Let consider two examples of the granule system the rough and the fuzzy granule databases.

### A. The rough granule database

Let in the system  $\langle U_{gen}, C \rangle$ , where  $C$  is a partition of  $U_{gen}$ , operations be defined (for any  $X \subseteq U_{gen}$ ):

$$C^-(X) = \cup\{K \in C : K \subseteq X\}, \quad (71)$$

$$C^+(X) = \cup\{K \in C : K \cap X \neq \emptyset\}, \quad (72)$$

Any sets  $X, Y \subseteq U_{gen}$  are indiscernibility, what is written:  $X \sim Y$  iff

$$C^-(X) = C^-(Y), \quad (73)$$

$$C^+(X) = C^+(Y). \quad (74)$$

The relation  $\sim$  is a relation of equivalence. The abstraction classes  $[X]_{\sim}$  of this relation for the representative  $X$  is denoted as  $X_C$ .  $\emptyset_C$  is denoted by  $0_C$  and  $(U_{gen})_C$  is denoted by  $1_C$ .

The abstract classes of the relations  $\sim$  are called **rough sets** in the system  $\langle U_{gen}, C \rangle$ .

The set inclusion relations and the rough membership relation [10] is defined as follows (for any  $X, Y \subseteq U_{gen}$ ):

$$X \subseteq_C Y_C \text{ iff } C^-(X) \subseteq C^-(Y) \text{ and } C^+(X) \subseteq C^+(Y), \quad (75)$$

$$X \in_C Y_C \text{ iff } X \neq \emptyset \text{ and exists such } K \in C, \text{ that } X \subseteq K, C^-(X) \subseteq C^-(Y) \text{ and } K \subseteq C^+(Y). \quad (76)$$

The expression  $X \in_C Y_C$  is read:  $X$  is an element of the rough set  $Y_C$ . Hence:

$$X \in_C Y_C \text{ iff } X \neq \emptyset \text{ and exists such } K \in C, \text{ that } X \subseteq K \text{ and } X \subseteq_C Y_C. \quad (77)$$

Intuitively, due to the fact that the description of  $x \in Y$  cannot be precisely determined, this description is interpreted as follows: indistinguishable from  $x$  elements of the indistinguishable elements from the sets  $Y$ . With the relation  $\in_C$ , the conclusion of rough sets can also be defined. For any  $Y \subseteq U_{gen}$ ,

$$X_C \subseteq_C Y_C \text{ iff for any } Z \subseteq U_{gen}, \text{ if } Z \in_C X_C, \text{ then } Z \in_C Y_C. \quad (78)$$

Using the theorems given by Bryniarski [10], [11], in the family approximate sets, analogically to the classical set theory, the following operations can be defined: the addition  $\cup_C$ , the multiplication  $\cap_C$ , the difference  $\setminus_C$  and the complement  $'_C$  of the rough sets.

For any rough sets  $X_C, Y_C$ , and any  $Z \subseteq U_{gen}$ ,

$$Z \in_C X_C \cup_C Y_C \text{ iff } Z \in_C X_C \text{ or } Z \in_C Y_C, \quad (79)$$

$$Z \in_C X_C \cap_C Y_C \text{ iff } Z \in_C X_C \text{ and } Z \in_C Y_C, \quad (80)$$

$$Z \in_C X_C \setminus_C Y_C \text{ iff } Z \in_C X_C \text{ and not } Z \in_C Y_C, \quad (81)$$

$$Z \in_C (X_C)'_C \text{ iff } Z \in_C (U_{gen})_C \setminus_C X_C, \quad (82)$$

Operations  $\cup_C, \cap_C$  can be generalized and used in the same way as in the set theory.

If the system:

$$\mathbf{G}_{rough} = \langle G, M_G, \cup_G, \cap_G, \setminus_G, '^G, \{\}_G, \in_G, \subseteq_G, =_G, 0_G, 1_G, G_{inst}, G_{set}, G_0 \rangle, \quad (83)$$

is interpreted as follows:

$$G_{set} =_{df} \{X_C : X \subseteq U_{gen}\}, \quad (84)$$

$$G_{inst} =_{df} \{X \subseteq U_{gen} : X = \{x\} \text{ or } X \in C\}, \quad (85)$$

$$G =_{df} G_{inst} \cup G_{set}, \quad (86)$$

$$\cup_G =_{df} \cup_C, \quad (87)$$

$$\cap_G =_{df} \cap_C, \quad (88)$$

$$\setminus_G =_{df} \setminus_C, \quad (89)$$

$$'^G =_{df} ' _C, \quad (90)$$

$$\in_G =_{df} \in_C, \quad (91)$$

$$\subseteq_G =_{df} \subseteq_C, \quad (92)$$

$$=_G =_{df} =, \quad (93)$$

$$0_G =_{df} \emptyset_C = \{\emptyset\}, \quad (94)$$

$$1_G =_{df} (U_{gen})_C, \quad (95)$$

An operation  $\{\}_G : G_{inst} \rightarrow G_0$  such that for any  $X \in G_{inst}$ ,  $\{X\}_G = X_C$ ,  $G_0 = \{X_C : X \in G_{inst}\}$ , and the set of operations  $M_G$  is empty.

Then the system  $\mathbf{G}_{base}$  (equation 37 from definition 4.4) is a granule information database, and the elements of  $G$  are called **the approximate granules**. Moreover, the system  $\mathbf{G}_{rough}$  is **the rough granule system**.

### B. The fuzzy granule database

Let  $\mathbf{PS} = \langle O, F, \mathbf{S}_{logic} \rangle$  be a perceptual system, in which  $O = U_{gen}$ , and the instance values  $L_0 \subseteq [0, 1]$  are in the residuum system  $\mathbf{S}_{logic} = \langle [0, 1], \bullet_s, \rightarrow_t, \{0, 1\} \rangle$ . In the range  $[0, 1]$ , the s-norm  $\bullet_s : [0, 1] \times [0, 1] \rightarrow [0, 1]$  is defined by formula (for any  $x, y \in [0, 1]$ ):

$$x \bullet_s y = \sup\{x, y\} = \max\{x, y\}. \quad (96)$$

Its generalized form determines the formula (for any set  $X \subseteq [0, 1]$ ):

$$\sum_s X = \sup X. \quad (97)$$

It can be determined that:

$$x \rightarrow_t y = \sup\{t \in [0, 1] : \min\{x, t\} \leq y\}. \quad (98)$$

$F$  is a set of symbols  $\mu_A$  of a function  $\mu_A : U_{gen} \rightarrow [0, 1]$ , and also a symbol of some fuzzy sets [29], [30], [31], described for any  $A \subseteq U_{gen}$  as follows (for any  $x \in K$ ) [17]:

$$[x] = K \Leftrightarrow K \in C \text{ and } x \in K, \quad (99)$$

$$\mu_A(x) = |A \cap [x]|/|[x]|, \quad (100)$$

i.e.  $F = \{\mu_Y : Y \subseteq U_{gen}\}$ , where  $|X|$  denotes the cardinality of the  $X$ .

Hence the result:

*Theorem 6.1:* There are (for  $A, B \subseteq U_{gen}$ ):

$$C^-(A) = \{x \in U_{gen} : \mu_A(x) = 1\}, \quad (101)$$

$$C^+(A) = \{x \in U_{gen} : \mu_A(x) > 0\}, \quad (102)$$

$$A_C = B_C \Leftrightarrow \text{for any } x \in U_{gen}, \mu_A(x) = \mu_B(x) \Leftrightarrow \mu_A = \mu_B, \quad (103)$$

$$A_C \subseteq_C B_C \Leftrightarrow \text{for any } x \in U_{gen}, \mu_A(x) \rightarrow_t \mu_B(x) = 1, \quad (104)$$

$$\mu_A(x) \rightarrow_t \mu_B(x) = 1 \Leftrightarrow \mu_A(x) \leq \mu_B(x), \quad (105)$$

$$A_C \subseteq_C B_C \Leftrightarrow \text{for any } x \in U_{gen}, \mu_A(x) \leq \mu_B(x). \quad (106)$$

The perceptual system  $\mathbf{PS} = \langle O, F, \mathbf{S}_{logic} \rangle$ , induces the **fuzzy granule database**  $\mathbf{G}_{base}$  (equation 37 from definition 4.4), where symbols  $G, \{ \}_G, \cup_G, \subseteq_G, =_G, 0_G, 1_G, G_{inst}, G_{set}, G_0$  are interpreted as follows:

$$G_{inst} = U_{gen} \times L_0 \cup C, \quad (107)$$

where  $C$  is a partition of  $U_{gen}$  and  $L_0 = \{r : \text{exists } u \in U_{gen} \text{ and exists } \mu \in F \text{ such that } r = \mu(u)\}$ ,

$$G_{set} = F, \quad (108)$$

$$G = G_{inst} \cup G_{set}, \quad (109)$$

$$\mu_1 \subseteq_G \mu_2 \text{ iff for any } x \in U_{gen}, \mu_1(x) \rightarrow_t \mu_2(x) = 1, \quad (110)$$

$$\{(a, r)\}_G = \mu \in F, \quad (111)$$

where  $\mu$  is such perception that  $\mu(a) = r \neq 0$  and  $\mu \subseteq_G 1_G$ , additionally, if  $\mu_0 \in F$  and  $\mu_0 \subseteq_G \mu$ , then  $\mu_0 = \mu$ ,

$$\{K\}_G = \mu \in F, \quad (112)$$

where  $\mu$  is such perception that for  $K \in C, \mu(a) = 1$  for any  $a \in K, \mu(a) \neq 0$  for any  $a \notin K$  and  $\mu \subseteq_G 1_G$ , additionally, if  $\mu_0 \in F$  and  $\mu_0 \subseteq_G \mu$ , then  $\mu_0 = \mu$ ,

$$G_0 = \{\phi \in F : \text{exists } u \in G_{inst}, \text{ such that } \phi = \{u\}_G\}, \quad (113)$$

Additionally, if  $A \subseteq F$ , then

$$(\cup_G A)(x) = \sup\{y \in [0, 1] : y = \mu(x) \wedge \mu \in A\}, \quad (114)$$

$$(\mu_1 =_G \mu_2) \Leftrightarrow_{df} \cup_G \{\mu \in G_0 : (\mu \subseteq_G \mu_1) \Leftrightarrow (\mu \subseteq_G \mu_2)\} = 1_G. \quad (115)$$

## VII. CONCLUSION

Presented application of abstraction methods in creating concepts allows to describe and solve more complex problems of knowledge representation in the semantic network, especially in the Semantic Web. Following issues are presented in this paper:

- A semantic network having a more general graph representation of the knowledge representation has been specified, i.e. one in which the edges of the network can have more than two vertices [5], [7], [8]. Roles in attribute language  $AL$  can join more than two vertices of the network. In addition, all currently used methods of knowledge representation can be implemented in a certain semantic network understood as in this paper.
- The theory of information granule databases in the semantic network has been formulated, in which axioms meet the standard theorems of the set theory defining the concept of a set. The model of this theory is the granule system.
- It has been shown that very complex constructs of the interpretation of the  $AL$  language expressions in the granule systems [9], at a higher level of abstraction, can be simplified by reducing them to interpretation in the granule databases induced by the perceptual system.
- Due to the fact that any granules are sums of singletons, calculations in granule systems can be simplified by performing them only on certain selected representatives of the elements of these granules. That allows to implement such computational procedures for the most frequently occurring in the processing of knowledge large data sets represented in the Semantic Web.

In further work presented information granule system will be designed also for extended sets, multiset, Borel field of sets and the system of conceiving will be defined.

**Abstract**—Many industrial machine vision problems, particularly real-time control of manufacturing processes such as laser cladding, require robust and fast image processing. The inherent disturbances in images acquired during these processes makes classical segmentation algorithms uncertain. Among many convolutional neural networks introduced recently to solve such difficult problems, *U-Net* balances simplicity with segmentation accuracy. However, it is too computationally intensive for usage in many real-time processing pipelines.

In this work we present a method of identifying the most informative levels of detail in the *U-Net*. By only processing the image at the selected levels, we reduce the total computation time by 80%, while still preserving adequate quality of segmentation.

### I. INTRODUCTION

SEGMENTATION of complex, noisy images is a core problem in many industrial applications of machine vision, especially in monitoring and control of laser additive manufacturing processes, such as laser cladding [1]. Where classical image processing algorithms cannot provide necessary robustness (against, for example, plasma emissions or powder scattering), machine-learning-based solutions are applied – recently, convolutional neural networks in particular. However, they are notoriously computationally heavy. For off-line applications this issue can be trivially solved with using more compute power, but in some on-line, real-time applications it is a critical problem. If the process state changes rapidly, any delay in its measurement degrades performance of the control algorithm.

*U-Net* is a well-known and proven convolutional neural network architecture for image segmentation [2]. Its distinguishing property is a highly modular, symmetric, dual-path structure. In the “down” path, which comprises blocks of max-pooling and convolution layers, features are being extracted from progressively smaller inputs. Those blocks can

be thought of as observing the input at progressively smaller scales. As a result, they produce feature maps with gradually more contextual information, but less spatial resolution. On the other hand, the “up” path integrates the high-context but low-resolution feature maps with intermediate levels of low-context but high-resolution information. This allows producing highly detailed segmentations for objects of different scales.

Training the *U-Net* on laser cladding monitoring images is a relatively straightforward task, even with a small amount of annotated data. The baseline configuration as described by Ronneberger *et al.* [2] outputs segmentations of satisfactory quality without the need to apply any tricks or problem-specific tuning. However, the time of a single image inference, on our in-house hardware, is approximately 250ms. This is unacceptable for any on-line processing purpose – especially for real-time control.

The simplest yet very effective way to decrease processing time is to reduce the size of the input images. This might have an additional benefit of reducing the cost of data acquisition, or allowing higher processing frame rates. A more advanced method would be to downsample the images in the “down” path earlier, skipping some detail scales during inference if the information they contain does not significantly contribute to the overall segmentation quality. However, it is difficult to determine a priori, at which scale should the input be observed and at which intermediate scales should it be processed. Intuitively, this depends on the specific characteristics of a particular problem. Detecting large objects might require more context – hence, deeper “down” path – than small ones. On the other hand, segmenting objects with fuzzy boundaries might not benefit from very high-resolution features as much as when objects have very clear and detailed edges.

In this study, we present a method of determining which blocks in a *U-Net* are really important for correctly segmenting the objects, and which can be removed or skipped to save computation time without significant degradation of prediction quality. Our contribution is primarily a way of optimizing a neural network architecture. However, identifying the levels of detail at which the objects vary can also

This work was supported from the statutory research of Mechanical Faculty of WUST. The source material (images from laser cladding process) for the dataset preparation was supplied by National Centre for Research and Development - Project AMpHOra - Additive Manufacturing Processes and Hybrid Operations Research for Innovative Aircraft Technology Development – INNOLOT/I/6/NCBR/2013.

be seen as an important insight, helpful in better understanding of the problem.

## II. RELATED WORKS

The original U-Net [2] builds on the concepts of Fully Convolutional Networks [3]. While the FCN allowed using only some of the earlier layers to improve the fidelity of segmentation, U-Net's core concept is to merge even the most early blocks to capture high-resolution features. Further development on these ideas included Pyramid Scene Parsing [4] – where the input is sequentially pooled into separately processed streams and then upsampled and merged together before final prediction – and Feature Pyramid Networks [5], similar to U-Nets except that at every scale a complete segmentation is produced.

Optimization of neural network architectures was always of great interest. Early attempts such as Optimal Brain Surgeon [6] were primarily focused on improving the generalization capability of the learner. In more recent days, most architecture optimization work is focused on improving inference performance or energy efficiency [7], but there are also attempts to use these techniques to help extract classification rules [8]. The two major directions in network structure optimization are: architecture search and network pruning. The objective of architecture search is to find the optimal network structure during training, often using genetic algorithms or growing/pruning strategies [9, 10]. Network pruning focuses on removal of inactive or inefficient units from an already trained network in order to preserve its predictive power but reduce inference time [11].

There is not much research examining the influence of particular levels of detail on the object segmentation or detection quality. Chevalier *et al.* [12] studied the influence of input image resolution on classification performance, however they did not investigate the influence of deeper, highly downsampled layers. In this work, we propose a method of optimizing not only the size of the network input, but also its intermediate levels of detail as well.

## III. EXPERIMENT SETUP

### A. Scale-specialized blocks

U-Net consists of distinct “blocks”, comprising two 3x3 convolutional layers of various kernel depths, each followed by ReLU nonlinearity. From here onwards we will refer to them as simply *blocks*. Blocks are usually separated by max-pooling (in the “down” path) or upsampling and merge layers (in the “up” path). Thus, different blocks learn to extract features on different levels of detail.

Intuitively, depending on the characteristics of the problem, some of those blocks might be less useful for segmentation. This would mean that features of the data at these levels of detail are not important for a proper recognition. Blocks detecting those features would therefore waste compute power and memory. However, the problem of identifying them is not trivial.

Naively, one could envision training and comparison of multiple networks with different selection of blocks (e.g. one with 3 blocks and downsampling by a factor of 2, or 2 blocks and downsampling by 4). Such a brute-force ap-

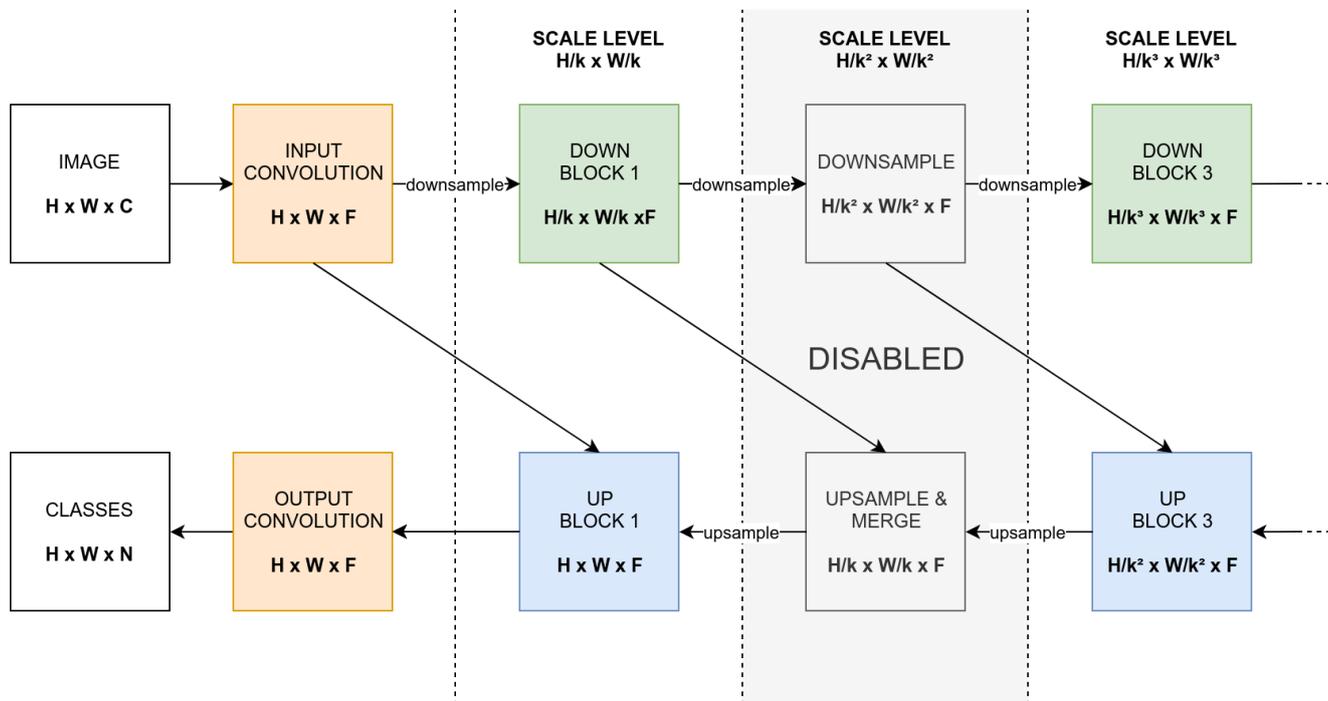

Fig 1. Drop-path regularization algorithm adapted to the general U-Net. In this example, “down” block 1 detects features from data downsampled to some specific resolution (*scale level*), and the corresponding “up” block integrates context extracted the corresponding level. Level 2 is shown in a disabled state – the “down” block only downsamples the data, while the “up” block only upsamples and merges it, both without any other processing.

proach might be infeasible, especially if the dataset is large and the network to be optimized is very deep. Ideally, a single network would be designed and trained in such a way that individual blocks could be freely removed from it without causing a structural failure, but instead only degrading performance – in the case the block was actually useful for prediction. Identifying the useless blocks would then proceed in a manner resembling a structural kind of ablation study.

### B. Drop-path regularization

Larsson *et al.* [13] presented a regularization algorithm, *drop-path*, that allowed them to train a very deep, multi-path network so that it behaves like an ensemble of networks. The core idea of drop-path is that if, during every training iteration, a random subset of individual paths in the network is disabled, the rest of the net will be forced to learn to still produce a correct answer. This allows the network to learn robustness against random removal of some sub-paths. Effectively, even though the network trains as a whole, every sub-path tries to become a fully capable standalone predictor itself. Larsson *et al.* report that they were able to extract even a single path of their FractalNet and it still worked almost as good as the whole.

We adapt the drop-path concept to U-Nets in order to allow them to learn robustness against removal of particular *levels of detail*. In a U-Net, the information from a particular scale is utilized twice during a single pass: once in the “down” path, where the features are extracted, and once again in the “up” path where the features are used to improve prediction resolution. Therefore, in our version of drop-path, whenever we randomly disable a “path”, we actually disable both blocks processing data on a particular scale. Overview of the algorithm is shown in Fig. 1.

To allow uninterrupted flow of the data through the disabled blocks, we replace each disabled “down” block with a simple bilinear downsampling layer, and the corresponding “up” block with a similar upsampling layer. We expect the network to learn to segment the images in the absence of information from particular scales, thus allowing evaluation of their influence on segmentation performance by means of a structural ablation test.

### C. Simplified U-Net

As the original architecture, U-Net does not naturally accommodate images of every size, requiring cropping and matching between “down” and “up” blocks, depending on the input size. However, as a meta-architecture it is very scalable – one can easily add or remove deeper blocks at different scales in order to capture more or less context in the data. We introduce several changes to the U-Net architecture to simplify it and make it more suitable for the drop-path regularization algorithm.

We add zero padding (1px wide border) to every convolutional layer, making each block preserve its input size. This eliminates the need for complex cropping and matching of data tensors throughout the “up” path.

We set every convolution in every block to produce the exact same number of channels (64), making every layer have exactly the same number of parameters. This is crucial in implementing drop-path: if different blocks produced outputs of different depths (as in the original U-Net), skipping a connection would necessitate a non-trivial mapping between the tensors.

Additionally, we introduce BatchNorm [14] after every convolution layer in order to stabilize the gradients. This is particularly important in the “up” path where data from two separate sources is combined.

Finally, following the practice of FPN, we change the type of connections between the “up” and “down” paths from concatenation (as originally in U-Net) to addition. This forms a residual connection between the paths, similar as described in [15]. This is not a critical change, but it reduces the number of parameters in the “up” convolutions by a factor of two, additionally speeding up the computation.

### D. Evaluation by ablation

We expect such a U-Net, trained using drop-path regularization, to behave like an ensemble of smaller networks, each processing data at a particular level of detail. This ensemble should be robust against removal of one member – at most, this should cause the overall performance to degrade, if that member (scale path) strongly contributes to the ensemble’s response. Therefore, we can measure the influence of a particular scale level by a structural ablation study. To test how important a particular level of detail is, we disable its corresponding block and evaluate the network on a validation set, measuring the change in segmentation performance. Additionally, we measure the average inference time to estimate the influence of disabling a block on wall-clock performance of the network.

In the experiment to follow, we use this evaluation strategy to reason about the data – and thus the problem at hand – in two ways.

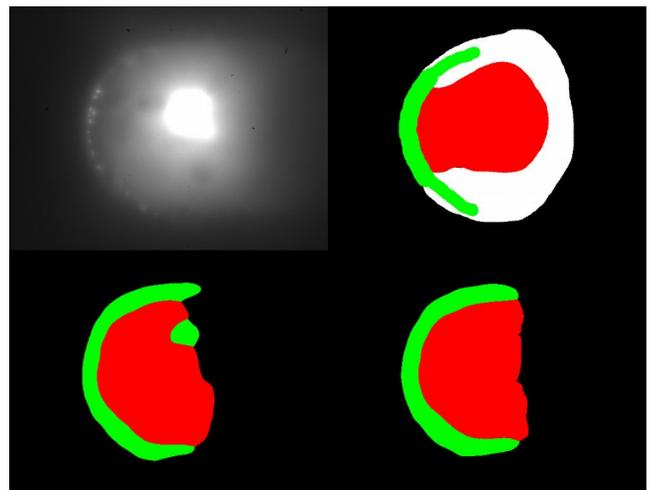

Fig 2. Example data and segmentations. Top row, left to right: source image, ground truth (“ignore” label in white); bottom row: segmentations – left: reduced model (see results, section B), right: full model.

By progressively disabling all blocks starting from the most high-resolution one, we attempt to identify the minimum scale level at which the network can observe the input images while still reliably segmenting the objects. The goal of this experiment is similar to Chevalier *et al.*, except we consider segmentation instead of classification.

By disabling subsequent blocks, starting from some given one, in different combinations, we attempt to find which of the intermediate levels of detail that extract contextual information are actually useful for a correct segmentation. This may provide an insight about how much context and on which level is really necessary, and which levels could be skipped to conserve compute time.

It is important to notice that the initial block of U-Net (on full scale) cannot be disabled – all subsequent layers require the input to be of a certain channel depth, and this first block transforms the original channel to a feature map of a common depth. This means that the initial convolutions will still be performed on the input of original resolution, constituting an approximately constant part of the computation time that cannot be trivially reduced.

#### IV. RESULTS

##### A. Reference network

We conduct the experiments on an in-house dataset of images acquired by coaxial on-line monitoring of a laser cladding process. Images obtained during this process are inherently noisy and blurry due to plasma emissions and powder scattering. However, they carry important information about process status, encoded in the shape of the pool of metal molten by the laser beam. The dataset consists of 250 grayscale images 600x600 pixels, manually annotated in 4 classes: background, two object classes of different shape characteristics (“edge” and “pool”) and an ignore label. Data was split in training and validation sets (150 and 100 im-

Parameter	Value
Learning rate schedule	constant 0.01
Adamax momenta	0.99, 0.999
Weight decay	0.0001
Batch size	64
Total iterations	750 000
Drop-path probability	0.25

ages, respectively). Example data and segmentations shown in Fig. 2.

The reference network consists of 5 levels of feature extraction blocks, at following scale levels: 600px, 300px, 150px, 75px, 25px and 5px. Each block comprises two 3x3 convolutional layers with 64 kernels, each followed by a BatchNorm layer and a ReLU nonlinearity. The network was trained using the Adamax [16] optimizer under the cross-entropy loss function. The complete training parameters are given in Table I.

Due to a small number of data samples and the need to train from scratch, heavy data augmentation routine was used in the form of elastic deformations [17] and horizontal and vertical flips. All augmentations were performed on-line in a random manner, directly before feeding data into the network. For testing, the intersection-over-union (IoU) metric was used. Results are given separately for either object class, due to different characteristics of their shapes.

Experiments were conducted in the PyTorch framework [18] using a single Nvidia RTX 2080 Ti GPU for training and an Nvidia TITAN Z for performance testing.

The reference network trained in approximately 11 hours achieving an IoU metric of 0.654 for the “edge” class and 0.809 for “pool” class. The average inference time (with gradient computation disabled) was 154.5ms, which is already approximately 38% faster than the original U-Net.

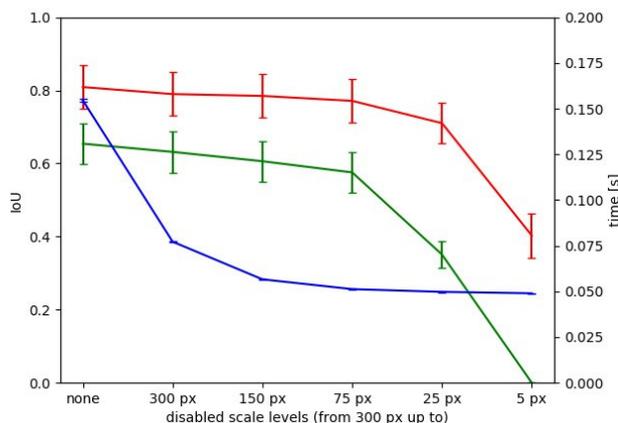

Fig 3. Results of the input size study. Segmentation performance (IoU for both classes, red and green plots) on the left axis, inference time (blue plot) on the right axis.

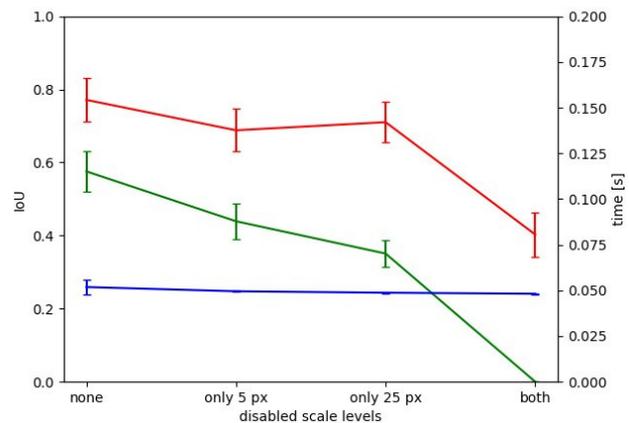

Fig 4. Results of the context levels study. Annotations the same as in Fig. 4.

### B. Input size study

Results of the progressive structural ablation study show relatively small degradation of segmentation quality when disabling the early, high-resolution blocks. As illustrated in Fig. 3, removing only the first block cuts the inference time in half, down to 77.2ms while only reducing the IoU score by 0.02. Performance improvements continue to be significant up until the scale levels of 150-75px, saturating at approximately 50ms (80% reduction with respect to the original U-Net). After that point, any potential speed-up is smaller than the cost of repeatedly downsampling the data to the desired resolution, while segmentation accuracy falls rapidly.

Fig. 2 visually compares segmentations produced by a full model (bottom right) and a model reduced by disabling scale levels 300 px and 150 px (bottom left).

### C. Context levels study

By disabling blocks at lower scale levels, we can determine the influence of particular context sizes. In this example we disable the first 2 levels (300px and 150px scales), fix the 75px scale as enabled and proceed to disable the remaining scale blocks (25px and 5px) in different combinations. We observe that in our case, disabling any level of context beyond the initial scale of 75px causes a rapid deterioration of segmentation quality, while providing zero practical improvement in inference time. Notice in Fig. 4 how disabling scale level 25px has a much more significant effect on the “edge” class (green) than on “pool” (red). Those most contextual blocks operate at very high relative scales (downsampling by the factors of 3 and 5, respectively) – we surmise that due to this, they learn very independent features that are critical to correct segmentation.

## V. CONCLUSION

In this work we presented a simplified and parameterized version of U-Net and adapted the drop-path algorithm to help the network learn as an ensemble of blocks specialized to detect features at specific levels of detail. This allowed us to analyze the importance of individual blocks on the collective network using a structural ablation study. That in turn let us identify blocks that did not contribute significantly to the segmentation, enabling us to make an informed decision to remove them in order to save compute time.

We argue that if the block was deemed unimportant, this might mean that at this particular scale there are no valuable features to be extracted – the data itself contains little valuable information. Therefore, processing inputs at this size is not worth the compute time. Aside from being a useful finding for optimizing a solution, this might also be a valuable insight into the nature of the problem itself.

### ACKNOWLEDGMENT

We wish to thank Mariusz Mrzygłód for valuable comments and discussions.

**Abstract**—Diabetes self-management relies on the blood glucose prediction as it allows taking suitable actions to prevent low or high blood glucose level. In this paper, we propose a deep learning neural network (NN) model for blood glucose prediction. It is a sequential one using a Long-Short-Term Memory (LSTM) layer with two fully connected layers. Several experiments were carried out over data of 10 diabetic patients to decide on the model's parameters in order to identify the best variant of it. The performance of the proposed LSTM NN measured in terms of root mean square error (RMSE) was compared with the ones of an existing LSTM and an autoregressive (AR) models. The results show that our LSTM NN is significantly more accurate; in fact, it outperforms the existing LSTM model for all patients and outperforms the AR model in 9 over 10 patients, besides, the performance differences were assessed by the Wilcoxon statistical test. Furthermore, the mean of the RMSE of our model was 12.38 mg/dl while it was 28.84 mg/dl and 50.69 mg/dl for AR and the existing LSTM respectively.

## I. INTRODUCTION

DATA mining (DM) techniques are useful tools for extracting valuable knowledge from (large) databases that helps in decision making [1], [2]. DM has been fruitfully used in different subfields of medical informatics such as diabetes [1], [3], cardiology [1], [4] and cancer [1], [5].

This paper deals with the application of DM for diabetes which is a chronic illness caused by a disorder in the glucose metabolism. There are mainly two types of diabetes): 1) Type 1 Diabetes Mellitus (T1DM) when the pancreas does not produce enough insulin, and Type 2 Diabetes Mellitus (T2DM) which results from an ineffective use of insulin [6]. If not well managed, this disease can lead to serious problems such as heart attacks, kidney damage, blindness, unconsciousness and even death [6]. The prediction of blood glucose level (BGL) is an important task in the diabetes management and self-management as it can help controlling the BGL by taking appropriate actions ahead of time [7]. To

predict the BGL, the previous glucose measurements are required. The BGL can be measured: 1) Manually by self-monitoring of blood glucose (SMBG) using sticks several times a day or 2) Automatically by continuous glucose monitoring (CGM) using sensors [6], [7].

According to El Idrissi et al. [7], considerable work was done for the BGL prediction and various Data Mining approaches including statistical methods and machine learning techniques were investigated for that purpose; the most used ones are Artificial Neural Networks (NNs) and Auto Regression (AR) [7]. Recently, deep learning modeling is gaining more interest, such as LSTM NN [8] and deep NN [9].

This paper proposes a deep learning NN with one LSTM layer and two fully connected layers for the prediction of BGL using CGM data. Predicting glucose using LSTM Nns is promising [8] since LSTM NNs were successfully applied in other domains such as prediction of water quality [10], electricity consumption [11] and stock prices [12].

This work aims at: (1) Setting the parameters of the model to identify the best configuration of our LSTM NN; and (2) Assessing and comparing the accuracy of the proposed model to existing ones. Toward this aim, two research questions are discussed:

(RQ1): Can the proposed LSTM model achieve good performance?

(RQ2): Is the proposed LSTM model significantly more accurate than existing models?

This paper is structured as follows: Section II presents an overview of LSTM NNs. Section III summarizes the related work on predicting blood glucose. Data used and performance measurement are described in Section IV. Section V describes the experimental design. Results are reported and discussed in Section VI. Threats to validity of this study are presented in Section VII and finally conclusion and future work are presented in Section VIII.

## II. LSTM NNS: AN OVERVIEW

Deep learning in NNs is an emerging method that allows the NN to learn automatically the characteristics of data by selecting the relevant features [10], contrary to the classical NNs that require features' selection based on domain knowledge [9].

LSTM NNs are deep recurrent NNs (RNNs) that were introduced by Hochreiter and Schmidhuber [13] to overcome the problem of exploding or vanishing gradient encountered with traditional RNNs [8]. The LSTM NNs are suitable for sequential data such as speech, video and time series as they can capture long term dependencies [14]. They consist of memory cells with a cell state which is maintained over time, and a gate structure that controls and regulates the information of the cell state.

Fig. 1 illustrates the structure of a memory cell. The index  $t$  refers to time or sequence.  $X_t$ ,  $Y_t$ ,  $h_t$  and  $C_t$  represent respectively the input, the output, the hidden vector and the cell state for  $t$ .

The memory cell contains 3 gates: 1) Input gate selects the information to be retained in the cell; 2) Forget gate decides about the information to be ignored; and 3) Output gate calculates the output and updates the hidden vector. Each of these gates is a NN whose input vector is a concatenation of the hidden vector of the previous cell and the input vector. Let  $W_i$ ,  $W_f$ ,  $W_o$  be the weight matrices corresponding respectively to the input, forget and output gates; and  $b_i$ ,  $b_f$ ,  $b_o$  the corresponding bias vector.  $W_c$  and  $b_c$  are the weight matrix and the bias vector used for updating the cell state.

The result of the input gate is  $i_t$ , which is obtained as follows:

$$i_t = \sigma(W_i * [h_{t-1}, X_t] + b_i) \quad (1)$$

To calculate  $f_t$ , the forget gate uses the following equation:

$$f_t = \sigma(W_f * [h_{t-1}, X_t] + b_f) \quad (2)$$

The output gate uses the equation (3) to obtain  $o_t$ , and the equation (4) to get the hidden vector.

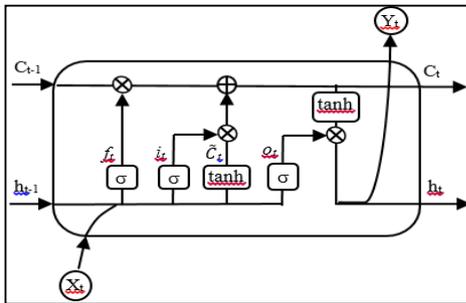

Fig. 1 : Memory cell

$$o_t = \sigma(W_o * [h_{t-1}, X_t] + b_o) \quad (3)$$

$$h_t = o_t * \tanh(C_t) \quad (4)$$

The cell state is updated as follows:

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \quad (5)$$

$$\text{where } \tilde{C}_t = \tanh(W_c * [h_{t-1}, X_t] + b_c) \quad (6)$$

In the Equations (1 to 4 and 6),  $\sigma$  and  $\tanh$  are the activation functions, the former is the sigmoid function defined in Equation (7) and the latter is the hyperbolic tangent function defined in equation (8).

$$\sigma(x) = \frac{e^x}{1+e^x} \quad (7)$$

$$\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}} \quad (8)$$

$\sigma$  and  $\tanh$  are defined on the set of real numbers.  $\sigma$  ranges between 0 and 1 while  $\tanh$  ranges from -1 to 1.

## III. RELATED WORK

El Idrissi et al. [7] investigated by the mean of a systematic map and review the use of predictive techniques in data mining for the diabetes self-management. The study summarized and reviewed 38 studies published from 2000 to April 2017 with regards to: 1) publication's year and source, 2) diabetes' type, 3) investigated clinical tasks, 4) the used predictive techniques and 5) their performance.

The main findings of [7] are the following:

1. There is a growing interest to the use of DM predictive techniques in the last decade. Conferences and Journals are used for publication, nevertheless, the main publication channel is conferences by 76.32% of the selected studies, while just 23.68% were published in journals.

2. T1DM gained more attention for research than T2DM with 84.21% of the selected studies.

3. Considerable work was done for the BGL prediction comparatively to other clinical tasks, in fact, 57.89% of the considered papers investigated BGL prediction.

4. Various DM predictive techniques were investigated, and the most used ones are NNs and AR.

5. NNs and AR models yield the highest accuracies. However, none of the used DM predictive techniques is dominant over the others.

Table I reports the findings of a set of selected studies from the review of El Idrissi et al. [7], in addition to the two recent studies [8], [9]. From Table I, we note that:

1. Various techniques are investigated to the BGL prediction problem: statistical methods such as AR [15], [16] and Kalman Filter (KF) [17]; machine learning methods such as Artificial NNs [18]-[20] and Support Vector Regression (SVR) [21], [22]; and recently deep learning techniques [8], [9].

TABLE I.  
LITERATURE OVERVIEW OF THE BGL PREDICTION

Reference	Technique	Diabetes type	Input Data	Findings
Lu et al., 2010 [15]	AR	T1DM	CGM	AR models yield accurate BGL prediction with short length signals; it is not required to consider exogenous inputs explicitly nor all frequency bands of the glucose signals.
Novara et al., 2016 [16]	AR	T1DM	CGM	A blind identification using AR technique was proposed to predict the BGL and recover the unmeasured inputs.
Wang et al., 2013 [17]	KF	T1DM	CGM	The model based on an extended KF achieves mostly reliable BGL predictions, and made significant improvement compared to zero-order hold.
Zarkogianni et al. 2011 [18]	RNNs	T1DM	CGM	The proposed RNN model to simulate the blood glucose–insulin metabolism makes it possible to personalize the system and to handle the environment’s variations with efficiency.
Allam et al., 2011 [19]	Feedforward NNs	T1DM	CGM	For short prediction horizon, feedforward NN based model gets accurate BGL prediction without time lagging.
Mathiyazhagan & Schechter, 2014 [20]	Fuzzy NNs	T1DM	CGM	This study proposes a soft computing approach which tolerates imprecision by using a fuzzy NN to predict the BGL.
Bunescu et al., 2013 [21]	SVR	T1DM	CGM	The incorporation of physiological features into an existing SVR model for BGL prediction made a significant performance enhancement .
Georga et al., 2010 [22]	SVR	T1DM	CGM	Predicting BGL is possible by compartmental models and SVR with a satisfactory accuracy and a clinical acceptability.
Sun et al, 2018 [8]	LSTM NN	T1DM	CGM	An LSTM network with one LSTM layer followed by one bi-directional LSTM layer and several fully connected layers were proposed for BGL prediction. This LSTM model outperformed the baseline methods ARIMA and SVR.
Mhaskar et al, 2017 [9]	Deep NN	T1DM	CGM	The proposed deep NN for BGL prediction outperforms shallow NN.

2. Different types of Artificial NNs were explored: RNNs [18], feedforward NNs [19], fuzzy NNs [20], and deep NNs [8], [9].

3. Studies are using data coming from CGM for T1DM patients.

#### IV. DATA DESCRIPTION AND PERFORMANCE MEASUREMENT

The data set used in this study is the historical data set DirecNetInpatientAccuracyStudy provided by Diabetes Research in Children Network (DirecNet) [23]. It holds collected data of 110 T1DM patients particularly the recorded data from CGM devices which give the BGLs at intervals of 5 minutes. As we did not specify any prerequisite for our model, we considered randomly a subset of 10 patients. However, a pre-processing of the data was done to eliminate redundancy and outliers between consecutive measurements. Table II summarizes information about the considered patients.

To evaluate the performance of our model, we use the root mean square error (RMSE) which is a common performance metric used to assess BGL prediction [7]. It evaluates the difference between the actual value and the predicted one by means of the Equation (9):

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (\hat{e}_i - e_i)^2} \quad (9)$$

where  $e_i$  and  $\hat{e}_i$  are respectively the actual and the predicted values while  $n$  is the sample’s size. The value of RMSE goes

from 0 to  $+\infty$  and the prediction is better when the RMSE is low.

#### V. EXPERIMENTAL DESIGN

This paper proposes an LSTM NN to predict the BGL of diabetic patients. This NN uses one LSTM layer and two dense layers. To identify the best configuration to adopt, we performed by means of a Grid Search (GS) described in Table III and inspired from [24], the following steps:

Step 1: Train and test the model for each patient by varying the number of LSTM units (LU) according to the GS values of Table III. The chosen value is the one that gives the best RMSE over the patients’ datasets.

TABLE II.  
DATA SET DESCRIPTION. THE BGL IS IN MG/DL

Patient ID	Number of measurements	Min BGL	Max BGL	Mean BGL
PT01	766	40	339	114.78
PT02	278	57	283	120.96
PT03	283	103	322	185.89
PT04	923	40	400	188.44
PT05	562	50	270	179.71
PT06	771	62	400	187.45
PT07	897	42	400	210.26
PT08	546	43	310	152.88
PT09	831	40	400	157.50
PT10	246	72	189	116.51

Step 2: Using the LU obtained in Step 1, we train and evaluate the model for each patient by varying the number of dense units (DU) respecting the GS values of Table III. The chosen value is the one that gives the best RMSE over the patients' datasets.

Step 3: Using the LU and DU obtained in Step 1 and Step 2 respectively, we train and evaluate the model for each patient by varying the length of the input sequences (SL) according to the GS values of Table III. The chosen value is the one that gives the best RMSE over the patients' datasets.

Step 4: We compare in terms of the RMSE criterion our best LSTM model with the LSTM of [8] and an AR model.

Step 5: We evaluate the statistical significance of performance differences between the three models by means of the Wilcoxon statistical test [25].

## VI. RESULTS AND DISCUSSION

This section presents and discusses the obtained results: (1) We present the empirical results of the Steps 1 to 3 of the experimental process related to the parameters' setting. (2) The results of the performance comparison of our model to the two other models are presented. (3) We report the results of the statistical test. And (4), We discuss all the empirical results.

Our LSTM model is developed using Python 3.6 with the framework Keras 2.2.4 and Tensorflow 1.12.0 as backend and under the operating system Windows 10.

### A. Parameters selection

The main objective of this research is to propose an LSTM model that achieves good performance (RQ1). To do that, a phase of parameters selection was carried out. This phase consists of the three first steps of the experimental design of Section V. The results of the first step are shown in Fig. 2 which represents the RMSE for each patient according to the search space of LU defined in Table III. We observe that the RMSE is in general better for LU=50. Therefore, at that step the LU was chosen to be 50 units.

TABLE III.  
PARAMETERS FOR SEARCH GRID

Parameter	Signification	Search space
LSTM Units	Number of neurons in the gates	{5, 10, 20, 30, 40, 50, 60, 70}
Dense Unit	Number of the neurons in the dense layer	{10, 20, 30, 40, 50}
Sequence length	Dimension of the input vector	{5, 10, 15, 20}

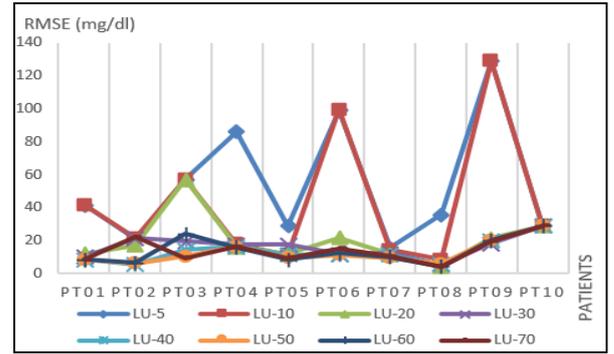

Fig. 2 : RMSE with LU variations

In step 2, we did the same experimentations with LU=50 and we vary DU according to the GS values of Table III. Fig. 3 shows the results obtained: we observe that for DU=40 and DU=50, the RMSE is worse than the others. Furthermore, the values 10, 20 and 30 of DU gave comparable results. However, by considering the times that a configuration (DU is equal to 30, 20 or 10) is better than the others, the minimum RMSE was reached 4 times, 3 times and once respectively. Therefore, the chosen DU value is 30.

The Step 3 uses LU=50, DU=30, and varies the SL according to the GS values of Table III. Fig. 4 shows that SL=10 achieves in general better RMSE values.

To sum up, the best configuration of our LSTM uses LU=50, DU=30 and SL=10. This LSTM variant will be used to compare it with existing BGL predictors.

### B. Models Comparison

To answer RQ2, we applied the LSTM model of [8] referred to as Sun\_LSTM and AR on the same dataset. We carried out the comparison with Sun\_LSTM since it is, according to the best of our knowledge, the only study that proposed an LSTM model for BGL prediction. Regarding the comparison with an AR model, it is motivated by the fact that AR models are suitable for time series prediction and according to [7] they yield along with NNs highest accuracy rates.

The Sun\_LSTM contains one LSTM layer with 4 LU followed by one bi-directional LSTM layer with 4 LU and 3 fully connected dense layers with respectively 8, 64 and 8 DU and finally the output Dense Layer. The SL is set to 4. Regarding the AR model, we used the default model developed in Weka with a lag of 10 similarly to the SL proposed in our model which is equal to 10.

Fig. 5 presents the RMSE got for the three models: we observe that our LSTM model outperforms Sun\_LSTM for all patients and outperforms AR in 9 cases over 10 patients.

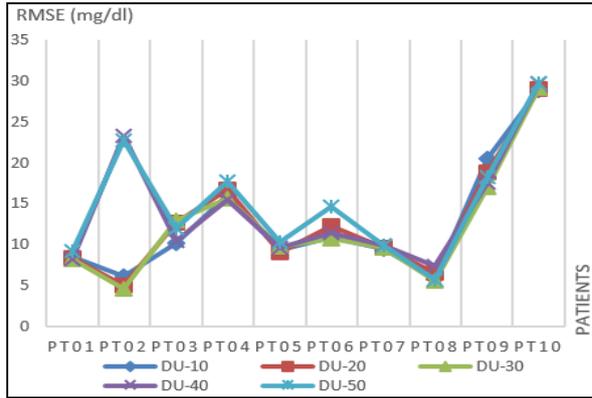

Fig. 3: RMSE with DU variations

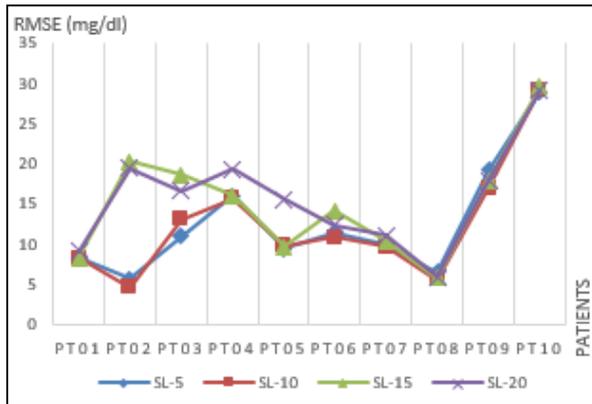

Fig. 4: RMSE with SL variations

Furthermore, we have compared the training time for the two LSTM models presented in Fig. 6. Our model needs overall less time to be trained comparatively to Sun\_LSTM.

Finally, we recorded the number of epochs required for each patient to train the model. Results are presented in Table IV.

The number of epochs is low and ranges between 46 and 260, the mean is equal to 132.8.

TABLE IV.  
NUMBER OF EPOCHS

Patient ID	Number of epochs	Patient ID	Number of epochs
PT01	91	PT06	260
PT02	94	PT07	46
PT03	259	PT08	49
PT04	71	PT09	168
PT05	88	PT10	81

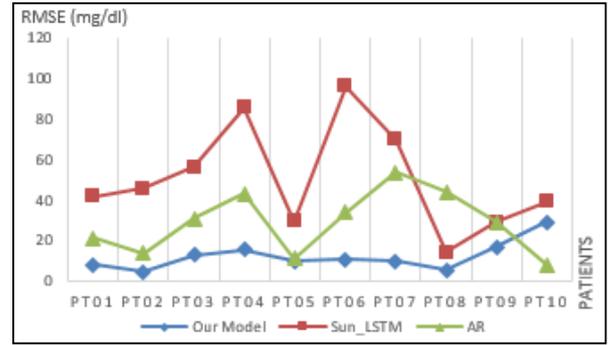

Fig. 5: RMSE for Our model, Sun\_LSTM and AR

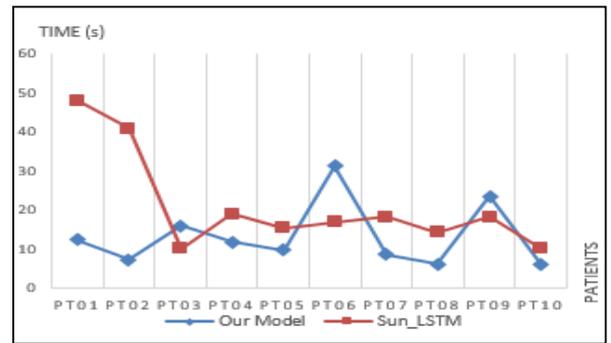

Fig. 6: Training time for Our model and Sun\_LSTM

C. Statistical test

We statistically assessed the results obtained based on the Wilcoxon statistical test. It is a non-parametric test that validates if the differences between the compared models are statistically significant by the means of a statistical hypothesis [25]. In our case, two null hypotheses (NH) were considered to test if our LSTM model is better than Sun\_LSTM and AR. These hypotheses are the following:

- NH1 : Our LSTM model does not outperform Sun\_LSTM.
- NH2 : Our LSTM model does not outperform AR model.

The statistical test was two-tailed considering the significance level  $\alpha$  equals to 0.05. Note that the test is considered significant if the result which is the p-value is less than  $\alpha$ .

For our tests, the p-value of NH1 and NH2 were 0.00512 and 0.0285 which means that the performance differences between our models and respectively the two other models were statistically significant.

D. Discussion

In this study, we propose an LSTM NN to predict BGL. Our first concern was to determine the best configuration by tuning the three following parameters: LU, DU and SL. As we observe from the results of Fig. 2, Fig. 3 and Fig. 4, these parameters have an impact on the model's performance. Thus, when building an LSTM model, one has to determine

the optimal values of these parameters. The final model achieved good accuracy comparatively to what was found in literature by [7]. In fact, for the RMSE, the minimum, maximum and mean values were equal to 4.67, 29.12 and 12.38 respectively. On the other hand, our model outperforms a previous LSTM [8] and AR models. Furthermore, the performance of our model over the two others was assessed by the Wilcoxon statistical test which showed that our model significantly outperformed Sun\_LSTM and AR.

These results show that the use of LSTM NNs for BGL prediction is promising. In fact, LSTM NNs and Deep NNs in general are gaining more interest due to their performances in different fields [26]. Actually, the deep NNs took advantage from their training algorithms that are computationally efficient [27], and from the large hidden neurons' number which results on huge number of free parameters [26]. On another hand, the performance of our model over Sun\_LSTM can be explained by the fact that our LSTM is deeper than Sun\_LSTM: in fact, the former uses 50 LU while the latter uses 4 LU.

However, we believe that the accuracy can be improved by considering: 1) other parameters to tune such as learning rate, the loss function and the optimizer, and 2) more information as input such as medication and exercise.

From another point of view, the training time and the epoch numbers were low, which means that the model can be used on a mobile platform or wearable device [7] which require rapidity [8]. In fact, knowing the importance of the mobile personal health records in health management [28], [29], the deployment of our model on a mobile platform is another direction to explore. Toward that aim, we used TensorFlow as it provides an end-to-end support which goes till the deployment of the models on mobile apps, cloud server and others [30].

#### VII. THREADS TO VALIDITY

Four of threads to validity are identified which are:

**Internal validity:** This thread concerns the evaluation methodology which can be inappropriate. To overcome this limitation, we used 10 data sets, each of them was divided in training and test sets representing respectively 66% and 34% of the whole data set. The model was trained on the former and evaluated on the latter.

**External validity:** This thread is related to the perimeter of validity. This was settled by considering 10 diabetic patients randomly taken from a public dataset. Note that some studies used only one dataset as reported in [7]. Furthermore, the datasets are with different sizes, it goes from 246 to 923 instances.

**Construct validity:** It concerns the measurement validity. To limit this thread, we used the RMSE which is a common performance criterion used to assess BGL prediction [7].

Moreover, it was used by many studies such as [8], [15], [18], [19], [21], [22]. Note that it was used lonely by [15], [21].

**Statistical conclusion validity:** It affects the conclusion related to the comparison performed. To avoid this thread, we used the Wilcoxon statistical test to assess the significance of the performance differences.

#### VIII. CONCLUSION AND FUTURE WORK

This paper considered a deep NN for BGL prediction which is a sequential model with one LSTM layer and two fully connected layers. Multiple runs were done by varying the three parameters: LU, DU and SL to determine the best configuration. The model achieves good accuracy and significantly outperforms, based on RMSE, an existing LSTM model and an AR model.

These promising results encourage to carry out further investigations using the LSTM NNs. Ongoing work aims at building an LSTM model for multi-step prediction by exploring different strategies from literature. Considering more input data such as medication and exercise may improve the accuracy. Furthermore, a problem that can be encountered is the missing data when for example the patient takes off the CGM device, investigating how to handle automatically the missing data is an interesting direction to consider.

**Abstract**—Corporate reputation is an economic asset and its accurate measurement is of increasing interest in practice and science. This measurement task is difficult because reputation depends on numerous factors and stakeholders. Traditional measurement approaches have focused on human ratings and surveys, which are costly, can be conducted only infrequently and emphasize financial aspects of a corporation. Nowadays, online media with comments related to products, services, and corporations provides an abundant source for measuring reputation more comprehensively. Against this backdrop, we propose an information retrieval approach to automatically collect reputation-related text content from online media and analyze this content by machine learning-based sentiment analysis. We contribute an ontology for identifying corporations and a unique dataset of online media texts labelled by corporations' reputation. Our approach achieves an overall accuracy of 84.4%. Our results help corporations to quickly identify their reputation from online media at low cost.

## I. INTRODUCTION

A great variety of firms offer an even greater variety of products and services to consumers and other businesses and strive to build up a strong corporate reputation. Corporate reputation can be defined as the collective perception and judgment of the sentiment (i.e., feeling, opinion) about a corporation and its products or services by its stakeholders. Reputation as a necessary condition for differentiation and corporate success has become one of the central themes in all its facets for both practitioners and the scientific community [1]. The ability to quickly assess current movements in the own and the competitors' corporate reputation is crucial for operative decision making, corporate planning and strategy as well as for external investment decisions.

The important role of corporate reputation has been confirmed through extensive research. Shefrin and Statman show that corporations with good reputation represent good long-term investment opportunities [2]. These corporations with a good corporate reputation are more likely to receive funding on the capital markets at better conditions. The positive relationship between corporate reputation and investor expectations about a firm has been supported again later by Shefrin [3] and MacGregor et al. [4] pointing

toward a stable relationship. Corporate reputation is shown to be positively related to return on sales and assets, sales, earnings per share, price-to earnings ratio, dividend yield, net income of a company, and customer loyalty [5-8].

Studies in the field of corporate reputation [5-8] have in common that authors use either the Fortune magazine's reputation index published in the annual survey "Most admired companies" or conduct a survey on their own to measure corporate reputation. The Fortune magazine's survey is conducted annually among more than 8000 managers and financial analysts. It rates around 700 companies according to their innovativeness, people management, use of corporate assets, social responsibility, global competitiveness, quality of management, financial soundness, value as a long-term investment and product quality or service quality.

The use of surveys for measuring corporate reputation should be assessed critically because it does not cover all stakeholder groups of a company. It has been shown that the resulting reputation ratings reflect mostly the perception of the financial perspectives of a company [9], [10]. Thus, the meaningfulness of such ratings is limited. Furthermore, the low update frequency of the reputation index and the limitation to 700 companies reduces its usability further. Conducting an own survey is costly, time consuming and often covers stakeholders only partly (e.g., [3], [8]).

Nowadays, online media represent a very good source for reputation related comments by customers of companies. However, measuring corporate reputation from online media is a dynamic and challenging problem. The Internet in general extends the reach, speed and intensity of news [11]. There is a great number of online media outlets where people express their opinions about corporations and their products. Because of the volumes of textual data, manual processing is practically impossible. Furthermore, numerous factors that influence reputation need to be considered. However, an automatic retrieval approach using textual content from online media would be an efficient and holistic way to measure corporate reputation.

We propose to combine an information retrieval approach with sentiment analysis methods for automatically analyzing corporate reputation in online media. We contribute an ontology for identifying corporations in the first place. For

analyzing corporate reputation in text, we contribute a unique dataset of human annotated reputation texts. We use the dataset for corporation-specific reputational sentiment analysis using a machine learning classifier. Our work helps corporations to efficiently measure reputation, which is an important factor for the performance of a corporation.

The remainder of this paper is organized as follows. In section 2, corporate reputation is defined and approaches for measuring corporate reputation are presented. Section 3 specifies the problem. In section 4, the proposed reputation measurement approach is described. In section 5, we present our dataset of annotated reputation texts and evaluate our reputational sentiment classifier. Section 6 concludes.

## II. RELATED WORK

### A. Defining Corporate Reputation

Corporate reputation has been a popular topic in different streams of research, leading to a large amount of definitions of corporate reputation (e.g. [12-16]). According to [13,14] we do not use the terms corporate reputation, image and identity interchangeably. Based on [12-16] we define corporate reputation as the collective perception and judgment of the sentiment (i.e., feeling, opinion) about a corporation and its products or services by its stakeholders. Corporate reputation can be positive or negative [17]. Corporate reputation arises from the ability of a corporation to uphold social and institutional norms and values and to satisfy the needs and desires of its stakeholders. Corporate reputation forms through the appealing “character” [15] of a corporation and in the comparison with other entities.

### B. Approaches for Measuring Corporate Reputation

Most of the empirical reputation research uses the Fortune’s magazine “Most Admired Companies” (FMAC) index for measuring reputation [18]. It is based on a survey of senior executives and directors conducted annually. Companies with revenue of at least 10 billion \$ and at least the 15-th biggest revenue in their industry are ranked according to 9 “attributes of reputation”. The use of Fortune’s reputation data is rightfully criticized because it was shown to mostly reflect only the financial performance of a corporation [9], [10]. Surveying only senior executives and directors neglects all other stakeholder groups. The FMAC index also suffers of industry effects because the surveyed managers are explicitly asked to rate the corporations in comparison only to the other corporations in a particular industry [19]. The limited availability and frequency of reputation data (i.e., the reputation index refers to only the largest corporations) further limits the use of Fortune’s index for operative decision making.

“Britain’s most admired companies” (BMAC) of Management Today offers another publicly available reputation index. It is structurally very similar to the FMAC [20]. Similarly to FMAC, managers rate companies according to nine [20]. The critique to FMAC largely applies to BMAC as well because of the similarities between the two surveys.

“Reputation Quotient” (RQ) is a reputation ranking of the 60 “most visible” companies in the U.S. [21]. The companies are rated on 20 attributes distributed over six components of corporate reputation [21]. 22480 randomly selected respondents’ rated one or two companies. Each company is rated by at least 279 people. RQ is theoretically more founded than FMAC/BMAC but its commercial orientation complicates a closer examination. The fact that only the 60 most popular companies *at the time* are rated limits the usability both for research and practice because of resulting gaps in the time series and the small amount of observations.

Reputation can be also measured by conducting an own survey. This technique was employed by [3], [8], [22-24]. Modifications of the classical written (online) surveys like Verbal Protocol Analysis (taping, coding and analyzing the answers of respondents) [23] and the use of personification metaphor (rating a corporation on a five-point scale in regard to 42 items that load onto five orthogonal character factors) [25] have also been proposed.

### C. Research Gap

The reviewed studies on corporate reputation measurement have one major flaw: they do not cover all relevant stakeholder groups. This fact draws attention to the difficulty of conducting a representative survey of corporate reputation: it is very costly and time consuming. Conducting such a survey on a regular basis and for many corporations is practically impossible for smaller corporations.

We propose a different approach to measure corporate reputation in an automatic, efficient, and more holistic way by retrieving corporate reputation-related textual content from online media and using a sentiment analysis approach.

## III. PROBLEM SPECIFICATION

A document from online media may express reputational sentiments on multiple corporations [26]. Sentiments referring to multiple corporations can have different sentiment polarities. The problem is to classify the reputation sentiment polarity contained in a document with respect to each sentiment object separately. By classifying reputation sentiment, all factors influencing reputation should be considered.

## IV. APPROACH

This section describes our approach for extracting corporate reputation from online media texts. A machine learning based classifier is used for reputational sentiment classification. This approach does not require costly and time-consuming optimization of a knowledge base [29]. It is computationally efficient due to the linear classifier [30].

First, each document was pre-processed with natural language processing techniques, similarly to [27]. The preprocessing includes tokenization, sentence splitting, part of speech (POS)-tagging, and morphological analysis for lemmatization. Following [27, 28] the pre-processing was

implemented by GATE’s information extraction system [31].

The pre-processing includes ontology-based entity recognition. For this purpose, an ontology was developed based on [27]. The ontology contains all corporations from the Dow Jones Industrial Average, S&P 500 and S&P 600 indices, and various European and US banks that are also present in our reputation text dataset. For each corporation, hand-curated labels were defined for textual identification.

Second, we extracted relevant text segments that refer to a certain corporation, which were identified by the ontology. Following [32], the relevant text segment is defined as 25 words either side of the mention of a corporation. Then, all text segments referring to the same corporation within one article are concatenated.

Third, a linear kernel soft-margin Support Vector Machine (SVM) is applied successively on each of these text sections, as it has been shown to perform text classification tasks on state-of-the-art level, when given limited training data [30], [33]. We used the default hyperparameter configuration of SVM. The hyperparameter of the SVM for the costs associated with allowing training errors was set to 1. The features used by SVM are frequency counts of unigrams in a document [34]. The feature space of SVM contains only tokens of type “word” normalized by root (i.e., lemmatized words). Feature selection has not been used [35]. The result is a corporation-specific reputational sentiment (positive / negative) on document level.

## V. EVALUATION

The evaluation compares the classifier’s results to the gold standard, provided by a dataset of reputation-related texts, which have been annotated by humans for reputational sentiment.

The dataset consists of 688 text documents from online media related to corporations’ reputation. The documents were annotated by reputation experts from the banking sector, considering all factors that can influence reputation. Each document was annotated with a fuzzy sentiment label, i.e. each document was annotated with a specific degree of membership to the classes of positive and negative sentiment. The positive and negative membership degrees have five values each with an ascending degree of membership. In this work, binary annotations were derived from fuzzy sentiment labels by the following rule: documents with a higher positive than negative degree of membership is part of the positive class and all other document are part of the negative class. The positive class contains 40% of the documents of our dataset and the negative class 60%.

The dataset was annotated in three rounds: The first round consisted of 269 documents and was annotated by three experts. The dataset was randomly divided among the annotators so that each document was annotated by at least one annotator. In the second round, 394 documents were annotated by four annotators. Again, each document was classified by at least one randomly chosen annotator. In a third round, one annotator annotated 25 documents.

TABLE I.  
CLASSIFIER PERFORMANCE

	Precision	Recall	F-Measure	Accuracy
Positive	87.8%	70.8%	78.4%	84.4%
Negative	84.2%	91.1%	87.5%	84.4%
Micro Avg.	85.4%	83.0%	84.2%	

To evaluate the agreement among annotators for the reputational sentiment annotations, Fleiss’ Kapa inter-rater agreement for nominal scaled values with more than two raters was used [36]. In the first round, 27 documents have been annotated by all three annotators and considering only the positive and negative class, Fleiss’ Kappa of these annotations is 0.78. In the second round, all annotators annotated each of 49 documents. The Fleiss’ kappa from these 49 documents’ annotations is 0.66. We consider the level of agreement fairly well, thus the corpus can be used for evaluation of our classification approach.

Following [38, 37], stratified ten-fold cross validation was used. After classifying every document with the classifier on a test subset, we calculated the standard information retrieval metrics and micro averaged them [39].

Table 1 shows the evaluation results. Our approach could not recognize corporations or sentiment in 19 documents, which were not included in the evaluation. Our accuracy of 84.4% is comparable to results from state of the art sentiment classification research [35], [40].

## VI. DISCUSSION

The contribution of this work is an information retrieval approach for efficiently and comprehensively analyzing corporate reputation automatically from online media texts. Our approach builds upon an ontology for identifying all text parts relating to the same corporation. We contribute a unique dataset of labelled corporation reputation texts (see <https://wi2.uni-hohenheim.de/analytics>) and use it for corporation-specific reputational sentiment analysis by a machine learning method. The evaluation of our approach shows an overall accuracy of 84.4%.

A limitation of this work is that the neutral sentiment orientation is omitted, because [32] have found sentiment classification performance to be substantially higher when omitting the neutral class. We deliberately did not use deep learning techniques because the size of our dataset is too small. That is, the size of our dataset is a limitation. However, human annotation is costly and the size of our dataset is not much smaller than related work (e.g., [32]).

From a managerial perspective, our work helps to efficiently measure corporate reputation in on online world where news and opinions travel fast. Thus, managers can make better decisions by constantly monitoring reputation.

Future work points to comparing our measure of corporate reputation for online media with existing survey-based measures to gain insights about measurement validity. Furthermore, our measure of corporate reputation should be empirically validated by its ability to sense impacts on the financial and economic prospects of a corporation.

**Abstract**—In the recent years, it has been shown that real world-problems are often comprised of two, interdependent subproblems. Often, solving them independently does not lead to the solution to the entire problem. In this article, a Travelling Thief Problem is considered, which combines a Travelling Salesman Problem with a Knapsack Problem. A Non-Dominated Sorting Genetic Algorithm II (NSGA-II) is investigated, along with its recent modification - a Non-Dominated Tournament Genetic Algorithm (NTGA). Each method is investigated in two configurations. One, with generic representation, and genetic operators. The other, specialized to the given problem, to show how the specialization of genetic operators leads to better results. The impact of the modifications introduced by NTGA is verified. A set of Quality Measures is used to verify the convergence, and diversity of the resulting PF approximations, and efficiency of the method. A set of experiments is carried out. It is shown that both methods work almost the same when generic representation is used. However, NTGA outperforms classical NSGA-II in the specialized results.

## I. INTRODUCTION

**N**P-HARD optimization problems occur in many real-world scenarios. Be it a lot-sizing problem in economics [1], a transportation problem [2], or a scheduling problem [3]. These problems are ubiquitous and very practical, which makes their solving an important task. In practice, a problem often has multiple objectives. In scheduling problems, both time and cost of the schedule can be considered. In finance, it is desired to maximize the profits, but also to minimize the potential risks. Hence, multi-objective approaches aim to find a set of equally-good solutions, called a Pareto Front (PF).

Recently, authors of paper [4] have pointed out, that real-world problems comprise of multiple subproblems. They contain many dependencies and interwovenness. For that reason, it is not sufficient to find the solution to each of the subproblems. Objectives are interconnected in a way, that the improvement to one objective can lead to the worse value of another objective. Hence, combinations of such solutions do not guarantee the optimal solution to the entire problem. Authors of [5] proposed a Travelling Thief Problem (TTP), which has the features of a real-world problem. In this article, it is used in carried out experiments. It comprises of two constrained problems - a Travelling Salesman Problem (TSP) and a Knapsack Problem (KP). They are interconnected in a way, that makes solving them separately ineffective.

Due to its interdependence and multi-objective nature, evolutionary approaches show great potential in solving the TTP [6], [7], [8]. In [4] it has been shown that, in case of TTP, classical Non-Dominated Sorting Genetic Algorithm (NSGA-II) [9] with specialized operators outperforms other methods. Authors of [10] have introduced a Non-Dominated Tournament Genetic Algorithm. It is based on a NSGA-II, but contains multiple modifications. The authors carry out the research on a scheduling problem to show that these modifications lead to increased effectiveness of the method. This article attempts to verify the effectiveness of modifications introduced by NTGA with the combination of operators specialized for TTP.

A set of quality measures (QMs) proposed in [11] is used to evaluate the multi-objective results. Convergence and diversity of the resulting PF approximations are measured, along with the efficiency of the method.

The rest of the article is structured as follows. Section II presents existing work related to the subject. The TTP is described in section III. Section IV presents both used methods, as well as generic, and specialized representation, and operators. Results of all experiments along with the visualizations are presented in section V. Moreover, a theoretical analysis of the results is given. Lastly, section VI presents the conclusion and outlines the future work.

## II. RELATED WORK

The TTP was first introduced in [5]. The authors pointed out the shortcomings of benchmark problems used in the literature. The important features of a real-world problems were identified, namely existence of the subproblems and their interwovenness. Eventually, a single- and multi-objective versions of TTP were proposed.

Authors of [12] introduced a benchmark dataset for TTP. It contains 9720 instances. Each instance contains a TSP and KP elements. Additionally, the items are assigned to the cities to create the TTP instance. There are three different weight-value correlations present in the dataset. Moreover, instances contain up to 10 items per city.

Many researchers tackled the single-objective version of TTP. Authors of [13] have proposed three exact algorithms based on dynamic programming, branch and bound, and

constraint programming. Moreover, they compared them to the state-of-the-art solvers. In [8] swarm intelligence was used. Additionally, the authors investigated a TTP-specific local search algorithm. A Genetic Algorithm was used in [14]. Authors solve the overall problem instead of solving the subproblems separately. Moreover, the initial population is generated using a TSP specific heuristic. Authors of [18] used a hyperheuristic approach to select the best combination of known heuristics to solve the problem.

A multi-objective approach to TTP is considered less common in literature. However, authors of [15] used a combination of evolutionary computation and dynamic programming for the bi-objective TTP. Additionally, novel indicators were proposed, and the approach was compared to state-of-the-art methods. In [4], an NSGA-II with specialized representation and genetic operators was investigated. Various crossover and mutations method were investigated and the best configuration was identified. The results were compared to Greedy-based approaches. It was shown that NSGA-II outperforms other investigated methods.

NTGA was first proposed in [10]. The authors researched it on a bi-objective scheduling problem. The results were compared to classical NSGA-II and a decomposition based approach.

### III. PROBLEM

TTP is a constrained, combinatorial, NP-hard optimization problem. It comprises of two interwoven subproblems, namely TSP and KP. In the TSP part of the problem, there is a set of cities. Each city must be visited exactly once. In each of the cities there is a set of items, where each item has a weight and a value. Those items represent the KP part of the problem. While travelling a decision must be made which items to pick (if any).

TTP is a bi-objective problem. On one hand, the the goal is to find the quickest route between the cities. On the other, the total value of picked items must be maximized. However, each picked item decreases the speed of travel based on its weight. Hence, an improvement of the profit leads to an increase of the travelling time. TTP can be formally defined by equations 1 and 2.

$$\min f_{\tau}(\pi, z) \quad (1)$$

$$\max f_P(z) \quad (2)$$

where  $\pi$  is the permutation vector of all visited cities, and  $z$  is the picking plan.

The interaction between the subproblems is defined by equation 3. The total travelling time calculated as the sum of travelling times between each pair of consecutive cities plus the travelling time back to the first city. Each of those travelling times is influenced by all the picked items up to the given city.

$$f_{\tau}(\pi, z) = \sum_{i=1}^{n-1} \frac{d_{\pi_i, \pi_{i+1}}}{v(w(\pi_i))} + \frac{d_{\pi_n, \pi_1}}{v(w(\pi_n))} \quad (3)$$

$d_{\pi_i, \pi_{i+1}}$  is the distance between two consecutive cities from the permutation vector.  $n$  is the number of all cities.  $v(w(\pi_i))$  is the velocity in city  $\pi_i$ , considering the current weight  $w$  of picked items, and is defined by equation 4.

$$v(w) = v_{max} - \frac{W_c}{W}(v_{max} - v_{min}) \quad (4)$$

$W_c$  is the current weight, which is the sum of weights of all currently picked items.  $W$  is the capacity of the knapsack.  $v_{max}$  and  $v_{min}$  define the maximum and minimum allowed speed respectively.

The second objective, total profit, is the sum of values of all picked items. It is described by equation 5.

$$f_P(z) = \sum_{j=1}^m z_j z_j^{profit} \quad (5)$$

$m$  is the number of all items,  $z_j$  defines whether  $j$ 'th item has been picked and is equal to either 0 or 1.  $z_j^{profit}$  is the profit of  $j$ 'th item.

Additional constraints must be satisfied for the TTP solution to be *feasible*. The route must contain all cities, and each city must be visited exactly once. The sum of weights of all picked items cannot be greater than the capacity of the knapsack.

### IV. APPROACH

All approaches researched in the article are described in this section. First, definitions of important terms are given, namely dominance relation and a Pareto Front (PF). Next subsection describes used representation of an individual and is divided into two parts. First, a generic representation is described, and then one specialized for TTP. Similarly, the description of genetic operators starts with the operators used with generic representation. Later, the description of operators specialized for TTP is provided. Eventually, descriptions of NSGA-II and NTGA close out the section.

#### A. Definitions of Terms

This subsection contains a description of important terms. They are relevant for all used approaches.

1) *Dominance Relation*: One of the challenges of multi-objective optimization is the comparison of two solutions. Each solution is described by more than one objective, hence a numerical comparison is not sufficient. A Dominance Relation is defined for that purpose. A solution dominates another, if it has the value of at least one objective better and value of no objective worse, that that solution.

2) *Pareto Front*: A true PF contains all globally non-dominated solutions. However, in practice, a true PF is often not known. Hence, in this article, PF refers to the approximation found by the method, which contains all found non-dominated solutions.

### B. Representation

An individual used in evolutionary algorithms consists of a vector of numbers, a genotype. It represents the solution to the given problem. In this article, two representations are used. A generic one, presented in [10], and specialized for TTP, presented in [4].

1) *Generic*: The genome comprises two parts. The first one represents the solution to TSP. It assigns each city a priority. Then, the travelling plan is built by ordering the cities by that priority. The second part of the genome defines the solution to KP. It contains the number of genes equal to the number of items. Each item is assigned either 0 or 1, which defines whether the item should be picked or not.

For example a genome [1, 3, 3, 2, 0, 0, 1, 1] for a problem with 4 cities and 4 items means that the first city is visited first, then the last one, then second, and then third. Additionally, only the last 2 items are picked.

2) *Specialized*: Specialized representation defines the travelling plan with a permutation vector of all cities. The second part of genome is the same as in the case of generic representation.

For example a genome [1, 2, 4, 3, 1, 0, 0, 1] for a problem with 4 cities and 4 items means that the the first city is visited first, then the second one, then the last one, and finally the third one. The first and the last items are picked.

### C. Genetic Operators

This section describes the genetic operators used in the methods, for both representations.

Initial population generation is common for all methods and does not depend on the representation. A random initialization is used.

Selection operator is similarly independent of the representation, but is different for each method and is described in the appropriate method section (IV-D1 and IV-E1).

1) *Generic*: In case of generic representation, a standard single crossover and mutation operator is used for both parts of the genome. In the case of NSGA-II a single-point crossover is used. First, a random cut-point is selected within the genome. The first child is created by copying the genes on the left of that point from the first parent and copying the rest from the second parent. The second child is created similarly, by first copying the genes from the second parent and then from the first one. NTGA utilizes a single-point crossover.

Both methods use the same random mutation operator. First, a random gene is selected. Next, its value is randomly changed to a different, valid domain value.

2) *Specialized*: In the case of specialized representation, to include a problem domain knowledge a different crossover and mutation operator is used for each part of the genome. The Edge Operator (introduced in [16]) is used as the crossover for the part responsible for TSP. It aims to introduce as few as possible additional paths. It does so, by reusing existing edges when generating the children. First, a list is generated, which contains the neighbour cities from both parents for each city. Then, the first city from the first parent is copied to the

child genome and it is removed from the neighbour list. Then, iteratively, neighbours of that city with the fewest neighbours are copied over and removed from the list consecutively. If there are no more neighbours for a given city, a random city is selected. The second child is created similarly, by starting the process with the first city from the second parent. For the KP part of the genome, a uniform crossover is used. Children are created by copying each gene from a random parent with equal probability.

A swap mutation is utilized for the TSP part of the genome. Two random cities are selected and their position in the genome is swapped. For the KP part, a *bitflip* mutation is used. A random item is selected and the value of its gene is flipped.

In generic representation, there may occur a situation that makes an individual, a not *feasible* one. For example, some cities may have the same priority (cities are visited in defined order). In specialized representation crossover/mutation assure the feasibility of TSP-part of genome. However, another situation may exist in both representations when items picked by individual exceed knapsack capacity – items with min profit/weight ratio are removed from the solution.

### D. Non-Dominated Sorting Genetic Algorithm II

This section contains the description of a Non-Dominated Sorting Genetic Algorithm II (NSGA-II). It starts with the description of a pseudocode. Then, the selection and crowding distance, which are unique for this method are described.

NSGA-II is an evolutionary method. It processes a population of individuals in an iterative manner. Each individual represents a single solution to the given problem. The algorithm runs for the predefined number of generations, where a generation is a process of creating an offspring population from the current population. Each generation utilizes genetic operators to select parents and generate children individuals. Eventually, all non-dominated individuals found during the computation constitute a PF approximation. NSGA-II is described in pseudocode 1.

A *PopulationSize* parameter is stored in the first line. Then, in the second line, an initial population of that size is generated. In the third line, the entire population is evaluated. Each individual gets assigned the values of all objectives. Line 4 uses a non-dominated sorting to sort the population based on the rank and crowding distance, which are described in sections IV-D2 and IV-D3 respectively. In line 5, the loop begins, which iterates over all generations. Then, line 6 begins the loop to effectively double the size of the population. First, 2 parents are selected in line 7, using a selection described in IV-D1. In line 8, the crossover is used to create 2 children individuals. They are then mutated in line 9. Finally, the children are evaluated in line 10, and added to the current population in line 11. After the size of population has been doubled, it is again sorted in line 13. The population is truncated to its original size in line 14. Only the better half

**Algorithm 1** Pseudocode of NSGA-II [9]

---

```

1:  $N \leftarrow PopulationSize$ 
2:  $P_{current} \leftarrow generateInitialPopulation(N)$ 
    $evaluate(P_{current})$ 
3:  $nonDominatedSorting(P_{current})$ 
   for  $i \leftarrow 0$  to  $generationLimit$  do
4:   while  $|P_{current}| < 2N$  do
      $parents \leftarrow select(P_{current})$ 
5:    $children \leftarrow crossover(parents)$ 
      $children \leftarrow mutate(children)$ 
6:    $evaluate(children)$ 
      $P_{current} \leftarrow P_{current} \cup children$ 
7:   end while
    $nonDominatedSorting(P_{current})$ 
8:    $truncate(P_{current}, N)$ 
9:   end for
10: return  $P_{current}$ 

```

---

of the population remains. After all the generations have been processed, the last population is returned in line 16.

1) *Selection*: Selection in NSGA-II starts with taking 2 random individuals from the population. Then, those 2 individuals are compared based on the rank and crowding distance, which are described in sections IV-D2 and IV-D3 respectively. The individual with the lower rank is selected. If both have the same rank, individual with the larger crowding distance is selected. Selection returns only one parent, so during the algorithm it is performed twice, to obtain 2 parents.

2) *Rank*: During the NSGA-II each individual is assigned a rank, based on its quality. The lower rank means the individual is better. It is computed in an iterative manner. First, all non-dominated individuals are assigned the rank equal to 1. Then, all individuals that remain-dominated, while not considering the individuals with the rank already set, have the rank set to 2. The process is repeated, until all individuals are assigned a rank. Intuitively, the process divides the population into multiple PF approximations. The rank describes to which of those approximations the individual belongs.

3) *Crowding Distance*: Crowding distance is calculated for each individual. First, the largest possible box is drawn around the individual, that contains only that individual from the population. The crowding distance is the volume of that box. The larger values mean that the individual lies in the poorly explored part of the space. At the same time, lower values mean that there are many individuals around given individual.

### E. Non-Dominated Tournament Genetic Algorithm

This section contains the description of a Non-Dominated Tournament Genetic Algorithm (NTGA). First a pseudocode is given. Then its selection and clone elimination methods are described.

NTGA is based on a classical NSGA-II method. It introduces 4 modifications that aim to improve the effectiveness of the method. First, it separates parent and child populations. Then, it utilizes a selection method with stronger selective

pressure. Finally, it introduces a clone elimination method and archive usage. NTGA is presented in pseudocode 2.

**Algorithm 2** Pseudocode of NTGA [10]

---

```

1:  $N \leftarrow PopulationSize$ 
2:  $archive \leftarrow \emptyset$ 
    $P_{current} \leftarrow generateInitialPopulation(N)$ 
3:  $evaluate(P_{current})$ 
    $updateArchive(P_{current})$ 
4: for  $i \leftarrow 0$  to  $generationLimit$  do
    $P_{next} \leftarrow \emptyset$ 
5:   while  $|P_{next}| < |P_{current}|$  do
      $parents \leftarrow select_{tour}(P_{current})$ 
6:    $children \leftarrow crossover(parents)$ 
      $children \leftarrow mutate(children)$ 
7:   while  $P_{next}$  contains  $children$  do
      $children \leftarrow mutate(children)$ 
8:   end while
    $evaluate(children)$ 
9:    $P_{next} \leftarrow P_{next} \cup children$ 
    $updateArchive(children)$ 
10:  end while
    $P_{current} \leftarrow P_{next}$ 
11: end for
12: return  $archive$ 

```

---

First line stores the *PopulationSize* parameter. An empty archive is initialized in line 2. It is designed to store all found non-dominated individuals. In line 3, an initial population of given size is created. It is then evaluated in line 4. In line 5, the archive is updated with all currently non-dominated individuals. The loop, in line 6, iterate over a predefined number of generations. In line 7, an empty population is initialized, which is going to store the next population. The loop, in line 8, runs until the size of next population is equal to the size of current population. In line 9, parents are selected with the selection method described in IV-E1. Then, the children are created with the crossover in line 10. They are mutated in line 11. The clone elimination method is described between lines 12 and 13. If the next population already contains generated children, they are mutated. After that, the children are evaluated in line 15. Finally, they are added to the next population in line 16. In line 17 the archive is updated. The children are added to it, if they are non-dominated. Then, all individuals, that the children dominate, are removed from the archive. When the next population has been fully generated, it replaces the current population. At the end, the archive of non-dominated individuals is returned. The archive contains the PF approximation.

1) *Selection*: NTGA uses a tournament selection. First, given number of individuals is randomly drawn from the population. Then, they are compared according to their rank (described in IV-D2). The individual with the lowest rank is selected. If there are multiple individuals that match, the first one is selected. It is worth noting that the crowding distance is not considered during the comparison.

2) *Clone Elimination*: Clone elimination aims to increase the diversity of the population. The clones are defined as individuals with the identical genome. Before adding a child individual to the population, a check is performed, to verify whether an identical individual already exists. If so, the child is mutated until it is no longer a clone. Only then, it is added to the next population.

## V. EXPERIMENTS AND RESULTS

The experiments carried out in this article aim to verify the effectiveness of NTGA on TTP. Moreover, it is verified whether the modifications of NTGA are effective in the context of specialized operators. To answer those question the experiments on 4 configurations are carried out. NSGA-II and NTGA are researched with both generic, and specialized representation, and operators. A set of selected QMs is used to verify the convergence and diversity of the resulting PF approximations.

First, selected data instances and quality measures are described. Then, the experimental procedure is presented and selected parameter values are provided. A full set of experiments is carried out on all 4 configurations and the results are presented. Finally, the last subsection contains the theoretical analysis.

### A. Data Instances

A benchmark dataset, first presented in [12], is used in this article. In literature, an *eil51* instances are often used [17] [18], and so they have been selected for the research. 12 instances have been selected with 51 cities and the number of items between 50 and 500. 3 types of correlation between item weight and profit can be identified within the set. A strong correlation, where increased profit also means increased value. No correlation, but all the items have similar weights. The last group has no correlation between the items.

### B. Quality Measures

A set of QMs presented in [11] is used to verify the effectiveness of the methods. Convergence, diversity of the PF approximation, and the efficiency of the method is verified. A Perfect Point and a Nadir Point are used as a reference in 2 of the measures.

1) *Perfect Point*: A Perfect Point contains the best values of all objectives. It does not have to an achievable solution. The value of travelling time is calculated as the length of minimum spanning tree of the tour. A brute force search algorithm is used to calculate the value of profit.

2) *Nadir Point*: A Nadir Point contains the worst values of all objectives from among the non-dominated solutions. It often has to be approximated. Additionally, to make the comparison fair even worse values can be selected [19]. The value of travelling time is calculated by taking the value of travelling time from a Perfect Point and doubling it. It is an upper bound of the TSP. The profit is set to 0 and represents a solution where no items are picked.

3) *Euclidean Distance*: Euclidean Distance (*ED*) is a measure of convergence. It shows how close the PF approximation is to the true PF. Since the true PF is not known, *ED* utilizes the Perfect Point. Value of *ED* is obtained by calculating the average distance between every point on the PF approximation and the Perfect Point. It can be formally defined by equation 6.

$$ED(PF) = \frac{\sum_{i=1}^{|PF|} d_i}{|PF|} \quad (6)$$

*PF* is the Pareto Front,  $d_i$  is the distance from the  $i$ 'th point to the Perfect Point.

4) *Hypervolume*: Hypervolume (*HV*) is a measure of diversity. It is a volume of a hypercube defined by the Nadir Point and the PF approximation. It measures the spread, but is also influenced by the convergence and uniformity of the PF approximation. *HV* can be formally defined by equation 7.

$$HV(PF) = \Lambda\left(\bigcup_{s \in PF} \{s' | s \prec s' \prec s^{nadir}\}\right) \quad (7)$$

*PF* is an approximation of PF.  $s$  is the point of approximated PF.  $s^{nadir}$  is a *Nadir Point*.  $\Lambda$  is a Lebesgue measure, which is the generalization of a volume.  $\prec$  is a domination relation.

5) *Pareto Front Size*: Pareto Front Size (*PFS*) measures the diversity in terms of the cardinality of the PF approximation. It is defined as the number of points on the PF approximation.

6) *Ratio of Non-Dominated Individuals*: Ratio of Non-Dominated Individuals (*RNI*) measure the efficiency of the method. It is defined as the number of points on the PF approximation divided by the number of all visited points.

7) *Spacing*: Spacing (*S*) measures the uniformity of the PF approximation. It ensures that the solutions are evenly distributed and identifies the clustering effect. To calculate it, first, the distances between all consecutive points on the PF approximation are calculated. The standard deviation of those distances is the *S* measure. It can be defined with equation 8.

$$S(PF) = \sqrt{\frac{1}{|PF|} \sum_{i=1}^{|PF|} (d_i - \bar{d})^2} \quad (8)$$

*PF* is the approximation of the PF.  $d_i$  is the distance from the  $i$ -th point the next consecutive point.

The intuition of QMs is: *ED* should be minimized and measures the closeness to the true PF. *HV* should be maximized and it is influenced by both spread of the PF approximation and its distance to the true PF. *PFS* is simply the cardinality of the approximation, while *RNI* measures efficiency, by calculating the ratio of points on the approximation to all explored points. Spacing (*S*) should be minimized and it measures how closely the approximation resembles the uniform distribution.

### C. Experimental Procedure

First, the parameters of all methods have been tuned separately. Then, both NSGA-II and NTGA have been ran with both representations, on every instance. Due to the stochastic nature of evolutionary algorithms, each experiment has been repeated 50 times and results have been averaged. Next, a set of selected QMs has been calculated for each PF approximation. Statistical significance has been verified. Eventually, visualizations for selected instances are presented and theoretical analysis is described.

### D. Parameters

The first step in parameter tuning was to define a set of configurations of different parameter values. Taguchi Orthogonal Arrays have been used for that purpose. Then, each configuration has been ran 10 times and the QMs have been calculated for the resulting PF approximations. Next, a Multi-Objective Grey Relational Grade is calculated and a Taguchi Method is used to identify the impact of the parameters on the results [20]. Finally, the best parameter configuration is selected. This process has been repeated for all 4 configurations. The experiments show that a 1000 generations should be sufficient, however the limit has been set to 2000 to make sure the results converge.

Table I contains the selected configurations of parameter values for each researched method.

### E. Experiments

Tables II and III contain the results of experiments for NSGA-II and NTGA respectively. Both tables show the results on generic representation. Tables IV and V contain the results for NSGA-II and NTGA with specialized representation.

1) *Results*: Comparison of the results for the generic representation shows no significant difference between the results of QMs. The largest difference can be observed for *HV* for the benefit of NSGA-II, but it is within a single standard deviation.

Specialized operators improve the results significantly. The largest difference can again be observed for *HV*. NSGA-II with specialized operators have achieved better values of *HV* for all researched instances. Specialization has improved ED for 6 out of 12 instances. Overall, smaller instances show more improvement in terms of ED. Interestingly, *PFS* has been decreased almost 6 times. However, large values for generic representation might suggest that the solutions are far from local optima. There is no statistical difference in values of *RNI*. Values of *S* have also deteriorated. The largest difference can be seen for instances *eil51\_n250\_uncorr\_01* and *eil51\_n500\_uncorr\_01*. The difference can be justified by much larger spread of the approximation, which can be confirmed by the larger values of *HV*.

NTGA with specialized operators improves the results even further. On average, values of ED have been improved by almost 40%. The largest difference can be observed for larger instances. Values for *eil51\_n50\_bounded-strongly-corr\_01* and *eil51\_n50\_uncorr-similar-weights\_01* are worse than in case of NSGA-II. Better values of *HV* have been achieved for all

12 instances, which suggest much better diversity of the PF approximations. Similarly, larger *PFS* has been achieved for all 12 instances. For *eil51\_n250\_uncorr-similar-weights\_01* the value has been almost tripled. NTGA has also proved to be more efficient. It can be observed by larger values of *RNI*. The only instance that has not been improved is *eil51\_n50\_uncorr-similar-weights\_01*. Achieved values of *S* measure are also lower, however they are still almost 3 times larger than the values achieved for configurations with generic representation. Results compared to specialized versions of NSGA-II and NTGA presented in this section have been statistically confirmed by Wilcoxon signed-rank ( $W_{0.05} = 78 > W_c = 13$ ) for all QM's. All difference are statistically significant.

2) *Visualizations*: This section contains visualization for two selected instances. Figure 1 presents instance *eil51\_n50\_bounded-strongly-corr\_01*. It presents the case, where specialized NTGA has achieved the worse result than specialized NSGA-II in terms of ED measure. ED depends on a Perfect Point, which lies closest to the middle of PF. NSGA-II has achieved a large spread, but its approximation has very few points on the edges. Hence, average distance to the Perfect Point is relatively low. PF approximation generated by NTGA is more evenly distributed, and so many points lie far from the Perfect Point. Hence, ED deteriorates.

Figure 2 presents the second selected instance. For *eil51\_n500\_uncorr-similar-weights\_01* specialized NTGA improved the results the most in comparison to other configurations. Interestingly, specialized NSGA-II has generated the solutions with better profit than specialized NTGA.

Moreover, visualization of all achieved PF approximations for instance *eil51\_n250\_bounded-strongly-corr\_01* is presented in Figure 3. A modified version of empirical attainment function (EAF) [21] is used to get the "averaged" Pareto Front approximations. For clarity, only specialized configurations are shown. It can be seen, that NTGA achieves better results on average. Additionally, the deviations in the results are also smaller. However, NSGA-II has generated points with very high profit, that have not been dominated by any of the runs of NTGA.

### F. Summary

Table VI contains the summary of all obtained results for all configurations. NTGA does not improve the results in case of generic representation. Values of all measures are very similar for both NSGA-II and NTGA.

Specialization has improved the convergence and diversity of the PF approximation. It can be observed by the improved values of *ED* and *HV*. Specialization has decreased the value of *PFS*. However, in case of generic representation, achieved solutions are far from optimal, so their larger number is less significant. Specialized representation also led to increased distances between the points of the PF approximation. It might have been caused by the larger achieved spread.

In case of specialized representation, NTGA has improved the results significantly, even in comparison to specialized

NSGA-II. Both ED and HV values have been improved. Additionally, efficiency of the algorithm has been improved, which can be observed by the increased value of RNI. Value of S measure has been improved in comparison to specialized NSGA-II. However, it remains higher than in case of generic representation.

### G. Theoretical Analysis

In NTGA, parent individuals do not have to compete with children individuals. There is no possibility that an individual will survive for multiple generations. Hence, more unique points are explored by the method. In combination with increased selective pressure it also leads to increased convergence. Interestingly, introduction of clone prevention has not improved the diversity. Larger values of HV are caused by the larger distance from the Nadir Point and not by the larger spread of the approximation. More significant improvement can be observed for larger instances.

Modifications of NTGA lead to no significant improvement in case of generic representation. Non-specialized operators have a low probability of improving the result. In consequence, increased selective pressure has much less significance.

The crowding distance has been removed from NTGA. Instead, each new individual has to be compared with the existing individuals to verify whether it is a clone. In most cases the comparison is done only once. However, if the individual is a clone, it is mutated and the check is performed again. In an edge case the comparison must be done multiple times, which might negatively affect the performance.

## VI. CONCLUSIONS AND FUTURE WORK

In this paper NTGA has been investigated in the context of TTP. A bi-objective problem, which comprises of two subproblems. The subproblems are interconnected, which makes solving them independently ineffective. NTGA has been compared to classical NSGA-II. All experiments have been carried out

in configurations with generic, and specialized representation. It has been shown, that for larger instances specialized NTGA achieves better results than specialized NSGA-II.

Increased selective pressure of NTGA led to improved results. However, more research could be done regarding selection, that would also promote diversity of the PF approximation. An introduction of heuristics, that would further improve the solutions for the subproblems might be worth investigating. Additionally, a hyperheuristic that would combine the benefits of multiple evolutionary methods could prove beneficial to the results. Moreover, many-objective problems are fairly uncommon. An interesting avenue of future work would be to use a benchmark problem with the real-world characteristics, with a larger number of objectives.

**Abstract**—Environmental sound classification has received more attention in recent years. Analysis of environmental sounds is difficult because of its unstructured nature. However, the presence of strong spectro-temporal patterns makes the classification possible. Since LSTM neural networks are efficient at learning temporal dependencies we propose and examine a LSTM model for urban sound classification. The model is trained on magnitude mel-spectrograms extracted from UrbanSound8K dataset audio. The proposed network is evaluated using 5-fold cross-validation and compared with the baseline CNN. It is shown that the LSTM model outperforms a set of existing solutions and is more accurate and confident than the CNN.

**Index Terms**—environmental sound classification, long short-term memory, convolutional neural networks, UrbanSound8K dataset

## I. INTRODUCTION

AUDIO recognition algorithms are traditionally used for the tasks of speech and music signal processing. Meanwhile, the problems of environmental sound recognition and classification have received much attention in recent years. There are multiple applications already proposed in a big variety of industries, including surveillance [1], [2], audio scene recognition for robot navigation [3], acoustic monitoring of natural and artificial environment [4]–[6]. In digitally transformed society [7], soundscape models create a research perspective in smart city domain. City noise managing significantly contributes to a healthy and safe living environment in the big cities [8]. In travel centric systems, city sounds may enter the emerging solutions to develop and share journey experience [9], [10]. Assisting technologies for people with disabilities and, in particular, navigation systems for blind or visually impaired people effectively incorporate urban sound models [11].

Environmental sound analysis is more complex than speech and music processing because of unstructured nature of sounds. There are no meaningful sequences of elementary blocks like phonemes or strong stationary patterns such as melody or rhythm. However, environmental sounds may include strong spectro-temporal signatures. Thus, it is important to consider non-stationary aspects of signal and capture its variation in both time and frequency domains.

The classification of environmental sounds is often split into auditory scene classification and sound classification by

its source. But, both problems share the similar approaches. The methods used involve k-Nearest Neighbors (k-NN) algorithm, Support Vector Machine (SVM), Gaussian Mixture Model (GMM) and Hidden Markov Model (HMM) in combination with features engineered by signal processing techniques, e.g. Mel-Frequency Cepstral Coefficients (MFCC), Discrete Wavelet Transform (DWT) coefficients and Matching Pursuit (MP) features [12]–[14]. In contrast with described approaches, deep neural networks (DNN) allow to facilitate feature engineering keeping classification accuracy and even outperform the conventional solutions [15]. In particular, being able to capture spectro-temporal patterns from spectrogram-like input convolutional neural networks (CNN) have high performance [16]–[19]. Long short-term memory (LSTM) networks is the other type of neural network architectures that is exploited for sound classification [20], as well as the combinations of LSTM and CNN [21], [22].

LSTM networks are recurrent neural networks (RNN) that use the contextual information over long time intervals to map the input sequence to the output. LSTM network is a general solution, efficient at learning temporal dependencies. Its application is beneficial in a variety of tasks, such as phoneme classification [23], speech recognition [24] and speech synthesis [25]. LSTM network combined with CNN was also successfully used for video classification [26].

The applicability of LSTM for sound classification hasn't been fully investigated so far. In this paper we examine a LSTM model to improve understanding of its applicability specifically for urban sounds classification using UrbanSound8K dataset [27]. Table A1 in Appendix summarizes some of the existing solutions where models are evaluated on UrbanSound8K. The baseline accuracy of 70% was obtained with SVM processing mel-bands and MFCC statistically summarized across the time [27]. The unsupervised feature learning using Spherical K-Means (SKM) performed on PCA-whitened log-scaled mel-spectrograms allows to achieve 73.6% accuracy [28]. CNNs of different architectures trained on log-scaled mel-spectrogram frames provide 73% of accuracy and 79% with data augmentation [16], [17]. The LSTM based CRNN for urban sound classification demonstrates 79.06% accuracy using raw waveforms [22]. The accuracy of 93% was shown by GoogLeNet trained on combination

of mel-spectrogram, MFCC and Cross Recurrence Plot (CRP) images [18].

The paper is structured as follows: Section II describes the LSTM model studied and the experimental setup. In Section III we present and discuss our results, and, finally, in Section IV we conclude about the LSTM applicability for urban sound classification and provide directions for future work.

## II. METHOD

### A. Long-short term memory neural network model

LSTM neural network is a special kind of RNN, that doesn't suffer from vanishing gradient problem and is able to learn long-term dependencies. LSTM consists of a set of subnets, known as memory blocks. Each block includes the memory cell and three units: input, output and forget gates.

LSTM layer maps the input sequence  $X = (x_1, x_2, \dots, x_T)$  to the output sequence  $Y = (y_1, y_2, \dots, y_T)$  in according to the equations:

$$i_t = \text{sig}(W_{xi}x_t + W_{yi}y_{t-1} + b_i), \quad (1)$$

$$f_t = \text{sig}(W_{xf}x_t + W_{yf}y_{t-1} + b_f), \quad (2)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot \tanh(W_{xc}x_t + W_{yc}y_{t-1} + b_c), \quad (3)$$

$$o_t = \text{sig}(W_{xo}x_t + W_{yo}y_{t-1} + b_o), \quad (4)$$

$$y_t = o_t \odot \tanh(c_t), \quad (5)$$

where  $c_t$  is the state of the memory cell and  $i_t, f_t, o_t$  are gate outputs at time  $t$ . The network weights  $W$  and biases  $b$  are tuned during learning to minimize the loss function. In case of a multi-layer structure the input of the next layer is the output of the previous one.

Our model for sound classification is composed of two LSTM layers followed by dense layer with *softmax* activation function. Though LSTM produces a sequence, only the last value is propagated to the output layer. The first two layers contain 128 and 64 units, the last layer has 10 units, one per sound class. To reduce overfitting dropout with a rate of 0.25 is applied to the output of the LSTM layers. For training *categorical cross-entropy* loss function is minimized using Adam optimizer. Because of long training time a full search of hyperparameters is infeasible, thus, the most promising combination was found using single fold evaluation.

The input of our model is magnitude mel-spectrogram with 128 bands, that covers a frequency range from 0 Hz to 22050 Hz. Spectrogram is evaluated at sample rate 44100 Hz using 1024 sample window and a hop size of the same width. The length of input sequence is variable and depends upon audio clip duration.

Among the examined variants the proposed model shows the best performance on input data normalized as follows:

$$\mu = \frac{1}{T} \frac{1}{N} \sum_{t=1}^T \sum_{n=1}^N x_t^{(n)}, \quad (6)$$

$$\sigma = \sqrt{\frac{1}{T} \frac{1}{N} \sum_{t=1}^T \sum_{n=1}^N (x_t^{(n)} - \mu)^2}, \quad (7)$$

$$X_{norm} = \frac{X - \mu}{\sigma}, \quad (8)$$

where  $X$  is the input sequence;  $x_t^{(n)}$  is the value of  $n$ -th feature at time  $t$ ;  $N$  is a number of features and  $T$  is a number of time steps. Normalization in both dimensions allows to keep spectro-temporal energy distribution pattern and eliminate the difference between the audio clips across the dataset in terms of linear distortion.

### B. Experimental setup

To evaluate the performance of proposed model we use UrbanSound8K dataset [27], that contains 8732 sound clips of up to 4 s in duration divided into 10 sound classes: air conditioner (AI), car horn (CA), children playing (CH), dog bark (DO), drilling (DR), engine idling (EN), gun shot (GU), jackhammer (JA), siren (SI), street music (ST).

Along with our model we run a baseline CNN [17]. CNN is composed of three convolutional layers followed by two dense layers. Both networks were trained on magnitude mel-spectrogram and CNN model indicated even better performance than was reported in [17] for log-scaled mel-spectrogram. We use a simplified validation algorithm for CNN: in contrast with [17], frame is being extracted from test sample at random, yet the CNN model holds the reported level of accuracy.

We randomly divide the dataset into 5 folds of the same size and carry out cross-validation to evaluate the networks performance. Models were trained on four folds and tested on the last one. The training duration is limited by 64 epochs. The train loss, train accuracy, test loss and test accuracy are saved for each epoch. The final accuracy is taken as the best validation accuracy achieved in the course of training.

Both models were implemented<sup>1</sup> with Keras, a high-level neural network API, written in Python. To resample the audio clips and extract the mel-spectrum we use the Librosa Python library.

## III. RESULTS AND DISCUSSION

Both models show the similar performance, their cross-validation results are presented in Fig. 1. While CNN provides 81.67% average accuracy, the proposed LSTM network

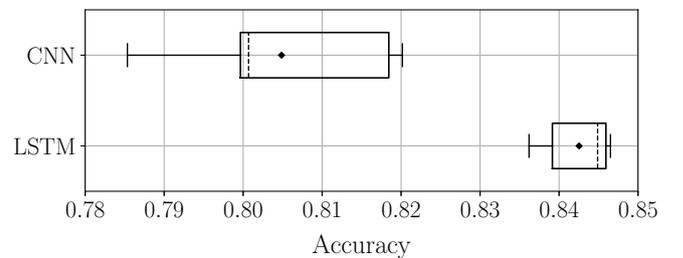

Fig. 1: Classification accuracy. Average accuracy is 80.48% and 84.25% for CNN and LSTM, respectively.

TABLE I: Per-class and averaged Precision, Recall and F1 score for CNN and LSTM.

		AI	CA	CH	DO	DR	EN	GU	JA	SI	ST	Macro-average
LSTM	Precision	0.80	0.82	0.78	0.86	0.87	0.88	0.93	0.89	0.90	0.75	0.85
	Recall	0.88	0.85	0.73	0.83	0.87	0.85	0.94	0.91	0.91	0.73	0.85
	F1	0.84	0.83	0.75	0.84	0.87	0.86	0.94	0.90	0.90	0.74	0.85
CNN	Precision	0.74	0.94	0.63	0.85	0.86	0.80	0.93	0.87	0.95	0.70	0.83
	Recall	0.83	0.79	0.71	0.80	0.81	0.84	0.89	0.84	0.83	0.73	0.81
	F1	0.78	0.86	0.67	0.83	0.83	0.82	0.91	0.85	0.88	0.71	0.82

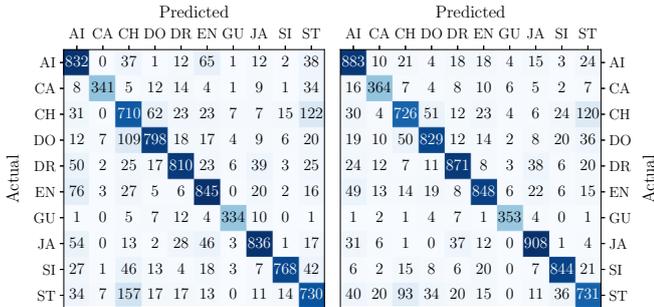

Fig. 2: Confusion matrices for CNN (left) and LSTM (right).

achieves 84.25%. The two models outperform the baseline methods. But LSTM demonstrates less accuracy distribution range and, thus, is more robust.

Confusion matrices obtained on test data during cross-validation is shown in Fig. 2. The same two pairs of classes demonstrate high confusion: street music vs. children playing and children playing vs. dog bark. These sounds may have complex time-frequency structure which impedes their accurate classification.

Precision, recall and F1 calculated for each class using confusion matrices are presented in Table I. LSTM shows slightly higher F1 score for each class, except car horn, and outperforms CNN in average. Also CNN may decrease recall to increase the overall accuracy, especially for unbalanced classes (e.g car horn and siren). Thus, LSTM performs better

keeping not only accuracy but recall and precision as well.

We compare training as accuracy and loss across epochs in Fig. 3. Both networks achieve the ultimate performance on test data approximately at 20-th epoch. Having almost equal accuracy the two models differ in their loss values. LSTM network shows a significantly smaller loss. It means LSTM is more confident in its predictions and has wider margins between classes. Thus, it is more robust.

The CNN holds accuracy and loss over train and test data. In contrast, LSTM model shows the better performance on train data. It doesn't fully generalize from train to unseen test data and memorizes the details that don't affect the overall performance. It may indicate that the model is redundant. Because of its recurrent structure the LSTM is more computationally intensive and prone to overfitting, although has less trainable parameters than CNN: 181K vs. 241K. So, it is highly probable that the model may be simplified without a significant performance degradation. Additional regularization techniques may also be beneficial.

#### IV. CONCLUSION

LSTM network that take magnitude mel-spectrograms was shown to be a reliable classifier in application for urban sounds. It provides the 84.25% of average accuracy and thus exceeds the majority of existing solutions. In comparison with baseline CNN trained on the same data LSTM has a little performance increase and is more confident.

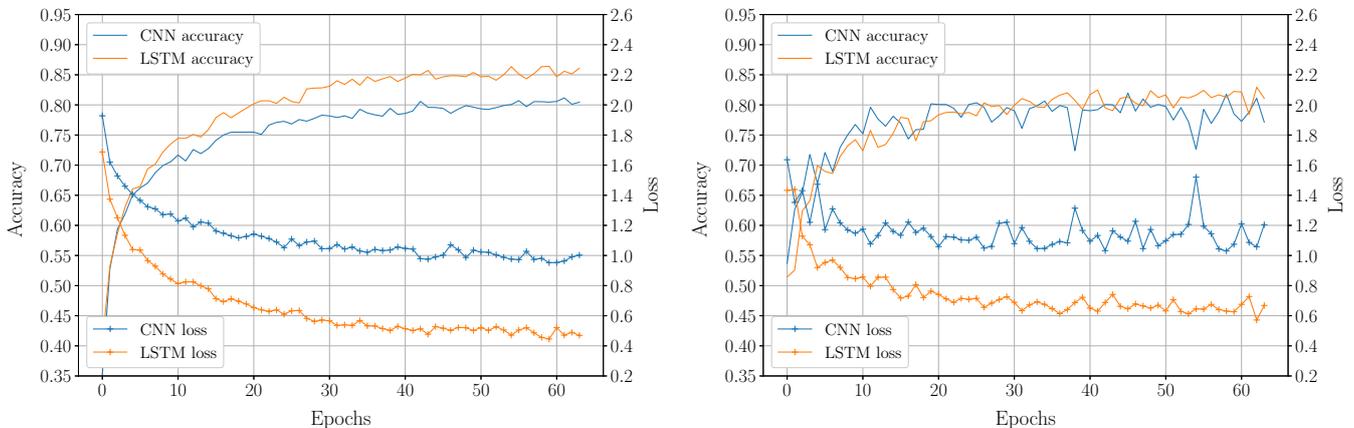

Fig. 3: Accuracy and loss evaluated on train data (left) and test data (right) during training.

The further study may develop towards the model simplification and regularization or involve new data not limited by urban setting.

#### APPENDIX

TABLE A1: Classification accuracy on UrbanSound8K dataset

Reference	Classifier	Features	Accuracy
[27]	SVM	mel-bands and MFCC	70%
[28]	SKM	PCA whitened mel-bands	73%
[16]	CNN	log mel-spectrogram	73%
[17]	CNN	log mel-spectrogram	73%
	CNN + aug		79%
[22]	CRNN	raw waveforms	79%
this paper	LSTM	mel-spectrogram	83%

**Abstract**—Over the last few years, deep learning has proven to be a great solution to many problems, such as image or text classification. Recently, deep learning-based solutions have outperformed humans on selected benchmark datasets, yielding a promising future for scientific and real-world applications. Training of deep learning models requires vast amounts of high quality data to achieve such supreme performance. In real-world scenarios, obtaining a large, coherent, and properly labeled dataset is a challenging task. This is especially true in medical applications, where high-quality data and annotations are scarce and the number of expert annotators is limited. In this paper, we investigate the impact of corrupted ground-truth masks on the performance of a neural network for a brain tumor segmentation task. Our findings suggest that a) the performance degrades about 8% less than it could be expected from simulations, b) a neural network learns the simulated biases of annotators, c) biases can be partially mitigated by using an inversely-biased dice loss function.

## I. INTRODUCTION

**T**HE HUMAN brain is proficient in recognizing patterns in a variety of domains: visual, auditory, etc. Its performance is always treated as the golden standard for the assessment and a level to beat using machine learning (ML) and deep learning (DL) models. As it stands, datasets are labeled by human annotators, with different levels of training, predispositions, and of course, also harbor their own biases, which have an impact on the quality of their annotations. Reducing the errors in datasets, also called label noise, calls for double- and triple-checking (usually done by different annotators), which requires a vast amount of work.

For example, in the classification of natural images – such as the ones included in the famous ImageNet dataset [1] – the human classification error rate was estimated at 5.1% by Russakovsky et al. [2]. However, the authors suggested that the labels provided by two human annotators did not exhibit strong overlap (one annotator's score was much lower – around 80%), and a significant amount of training was needed to achieve high-quality annotations.

The situation is even worse for more specialized domains, such as the diagnosis based on medical imaging, which requires years of training and experience. Moreover, due to the nature of the field, in some cases there is no clear way to classify a given observation correctly – studies showed that

medical diagnosis tests are not 100% accurate and cannot be considered the gold standard [3] [4]. This may be an effect of frequently occurring disagreements between medical experts interpreting test and imaging results [5] [6] [7] [8].

Image segmentation poses an even more severe problem. Reaching an agreement whether the object of interest is present in an image is relatively easy – what is challenging is to reach a consensus on its exact, pixel-wise location. In cases where more than one segmentation is available (which is seldom the case) there are multiple ways of handling such lack of consensus. An example of such method is the STAPLE algorithm [9], which automatically assigns confidence scores to each segmentation to merge multiple segmentations into one that is more accurate.

The presence of noise in annotations may even be more pronounced in real-world datasets, which are not carefully curated and annotated. Intuition tells us that training of a deep neural network (DNN) using a dataset with non-zero annotation noise can hurt the performance of a model, since loss function calculations provide "partially incorrect" gradients, which impair the learning process. Zhu et al. [10] investigated the effect of class label noise on the performance of a Decision Tree (DT) classifier in a classification task performed on various datasets. The study revealed that the performance of a DT classifier decays rapidly as the level of noise increases. Our recent investigation on a smaller scale (unpublished yet) revealed that classifiers based on DNNs can handle the rising amount of class label noise much better, even without applying any noise-filtering mechanisms.

## II. CONTRIBUTION

Another very important application of computer vision, besides image classification, is image segmentation. Image segmentation is often used in medical image processing, where segmentation masks provide a visual aid for physicians. In the future, it could become the first step of automatic or semi-automatic diagnosis processes. However, we must bear in mind that the annotations provided by DL-based models are heavily dependent on the quality of the data they were trained on. Our contribution presented in this paper is three-fold: a) we show the results of our investigation of the impact of various

levels of simulated noise in ground-truth segmentations on the performance of a DNN in brain tumor segmentation; b) a comparison of the DNN with a "perfect model", which learns perfectly the distribution of the simulated biases present in the data; c) the first results showing that an incorporation of bias into the loss function can partially combat a bias present in the data.

### III. DATA

In our study, we performed experiments on the BraTS2018 dataset [11], [12], [13], [14], which consists of MRI-DCE scans of 285 patients with diagnosed gliomas: 210 patients with high-grade glioblastomas, and 75 patients with low-grade gliomas. Each study was manually labeled by one to four expert readers. The data of each patient consists of 155 frames of size  $240 \times 240$  px, with four co-registered modalities: native pre-contrast T1-weighted (T1), post-contrast T1-weighted (T1c), T2-weighted (T2), and Fluid Attenuated Inversion Recovery (FLAIR). The scans were skull-stripped and interpolated to the same shape (155, 240, 240) with the voxel size of  $1 \text{ mm}^3$ . Each pixel was assigned one of the following four labels: healthy tissue (background), Gd-enhancing tumor (ET), peritumoral edema (ED), and necrotic and non-enhancing tumor core (NCR/NET) [12], [13], [14]. An example frame (T1c and T2) and the corresponding multiclass segmentation is shown in Fig 1. For the purpose of this work, all classes were merged into one – whole tumor (for a binary segmentation task).

Our pre-processing followed the methodology from the BraTS2018 competition presented in [15] – a volume-wise  $z$ -score normalization was applied to the brain region of each modality separately.

### IV. EXPERIMENT DETAILS

Our training was performed on a machine equipped with an Intel Core i7-7700 CPU, 64 GB RAM, and a NVIDIA GTX 1080 GPU. All experiments were performed with the PyTorch 1.0 framework in Python 3.6. In all experiments, we exploited a variation of U-net [16] with residual blocks [17] consisting of just under 1M parameters. The network consisted of 3 levels with 2 residual block on contracting path (CP) and expanding path (EP), for total of 12 residual blocks. Each residual block had 3 convolutional layers with 32, 48, and 64 filters on the first, second, and third level, respectively. The data from bridge connections (used between equivalent blocks on CP and EP) was concatenated in the channel dimension with the data coming from lower level, and a single convolutional layer was used to reduce the dimensionality. Parameters of the network were optimized by a SGD optimizer with the momentum of 0.9 and initial learning rate of 0.01. The learning rate was decreased by a factor of 5 after 10 and 16 epochs. The total length of training was 20 epochs, with batch size 14 (due to memory constraints). One epoch took around 22 minutes to train. For regularization we used weight decay of  $10^{-4}$ .

As the main objective function, we used the dice score (1), also called the  $f_1$ -score, which is a harmonic mean of *precision*

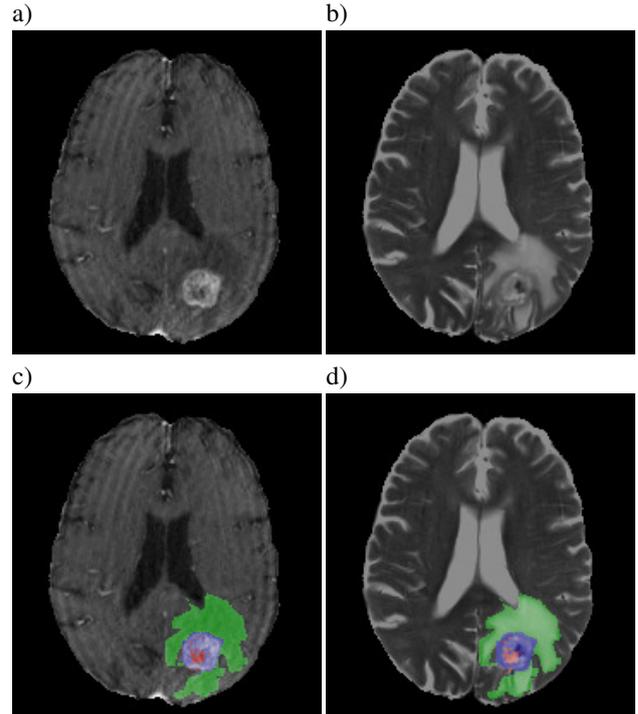

Fig. 1. Examples of images of BraTS2018 dataset in selected two modalities: a) T1c and b) T2. Their corresponding ground-truth segmentations are shown on panels c) and d), with three classes enhancing tumor (blue), peritumoral edema (green), and tumor core (red).

(positive predictive value), and *recall* (sensitivity). For the sake of differentiability we exploited its soft version (without thresholding). The pixel-wise dice score can be expressed as

$$Dice(p, t) = \frac{2 \sum_i p_i t_i + 1.0}{\sum_i p_i + \sum_i t_i + 1.0}, \quad (1)$$

where  $p_i \in [0, 1]$  is the predicted value at pixel  $i$ , and  $t_i \in \{0, 1\}$  is the target value of the same pixel, provided from the ground truth. To assure non-zero gradients and prevent division by zero, a smoothing factor of 1.0 was added to both the numerator and denominator. Since the popular DL frameworks are designed to minimize the objective function instead of maximizing it, we defined our loss function as

$$\mathcal{L}(p, t) = 1.0 - Dice(p, t). \quad (2)$$

The scores obtained on train and validation subsets were calculated for each frame, and then averaged; on the test subset, the scores were calculated volume-wise, which is a form of weighted-average with respect to the size of the ground-truth segmentation.

#### A. Data split

To validate our approach, we split the data into training, validation, and test subsets, containing 205, 40, and 40 data volumes, respectively. This allowed us to have 7 non-overlapping folds to perform cross-validation on. All the results presented are averaged over all folds.

### B. Simulated noise

To imitate sub-optimal segmentations, we assumed that even expert annotators can have their own biases, and their segmentations can have a noticeable variance due to human errors. We introduced biased noise to the train and validation subsets only, since we assumed that the test subset is of sufficiently high quality to be compared against. The bias-introduction routines were based on morphological operations applied to each frame with a binary mask using a  $3 \times 3$  structure one or more times. The morphological operations were incorporated in three ways:

- Dilate: simulates an annotator biased towards recall. The annotations produced tend to be over-segmented (the segmentations encapsulate more pixels than the true tumor), to be sure nothing important is missed. Since the tumor core is usually surrounded by the peritumoral edema, deciding exactly how far the tumor area reaches might be a non-trivial task.
- Erode: simulates an annotator biased towards precision. The annotations produced tend to be under-segmented, ensuring that only the tumor area is included. Because of that, some parts of the tumor can be omitted.
- Random: to simulate a random annotator or a mixture of annotators with different biases (either tending to over- or under-segment), we randomly assigned a dilation or an erosion operation for each frame in an accordingly sampled scale.

The number of iterations of morphological operations, denoted here as a scale of contamination, was sampled from a normal distribution  $\mathcal{N}(0, \sigma^2)$  with a few different values of variance  $\sigma^2 \in \{1, 2, 3, 4, 5\}$ . Since the number of iterations had to be a positive integer number, an absolute value of the number was taken, followed by an integer casting (the *floor* operation). The scale directly influenced the extent to which the original ground-truth mask was modified by a morphological operation (erosion / dilation) — it altered the relative change of size ( $\Delta S = S_{modified}/S_{original}$ ). If scale = 0, the ground-truth was fed into the network unchanged, meaning that  $\Delta S = 1$ . Some example effects of dilation and erosion operations applied to a selected frame of FLAIR modality are presented in Fig. 2 for scales  $\in \{0, 1, 3, 5\}$ . In panels (a) and (e), the ground-truth segmentation is unchanged. The dilation operation (top panels) increased the target segmentation size by 15%, 39%, and 61% for the scales of 1, 3, and 5, as shown in panels (b), (c), and (d), respectively. Erosion (bottom panels) decreased the target segmentation size by 14%, 39%, and 58% for the scales of 1, 3, and 5, as shown in panels (f), (g), and (h), respectively. It is worth pointing out that the magnitude of  $\Delta S$  depends strongly on the initial shape of a mask, thus morphological operations can introduce vastly different surface scaling factors.

## V. RESULTS

The average baseline test scores obtained by our model, without any modifications of the ground-truth segmentations,

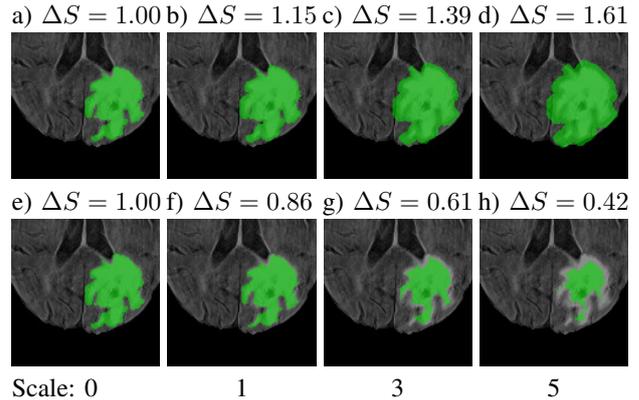

Fig. 2. Examples of biased noise of a binary mask overlaid on a FLAIR image selected from BraTS2018 dataset. Original mask is presented in panels a) and e), marked by the noise scale = 0 and relative change of size  $\Delta S = 1.00$ . Top row (panels b, c, and d) shows examples of dilation operation with scale  $\in \{1, 3, 5\}$ , which translates into  $\Delta S \in \{1.15, 1.39, 1.61\}$ . Bottom row (panels f, g, and h) shows examples of the erosion operation with the same scale, which translates into  $\Delta S \in \{0.86, 0.61, 0.42\}$ .

TABLE I  
BASELINE DICE, PRECISION, AND RECALL SCORES FOR OUR NETWORK TRAINED AND VALIDATED ON BRATS2018 DATASET FOR BINARY SEGMENTATION. MEAN AND STANDARD DEVIATION (STD) WERE CALCULATED OVER ALL FOLDS.

	Val Dice	Val Precision	Val Recall	Test Dice	Test Precision	Test Recall
Mean	0.896	0.906	0.880	0.872	0.902	0.863
Std	0.013	0.009	0.021	0.016	0.020	0.027

were 0.872, 0.902, and 0.863 for dice, precision, and recall, respectively. These values remained relatively consistent across all folds. The scores are comparable with some of the higher scores of the BraTS2018 challenge for the whole-tumor class on the training scoreboard. Unfortunately, since the challenge is over, we were not able to evaluate our results on the validation set or the test set, because the evaluation was carried out by the organizers. Following that, our results could not be compared with these submitted to the challenge by the participants. However, we would like to stress that multiclass segmentation (as in the BraTS2018 challenge) is a much more difficult task; the networks trained for the challenge might not have been optimized for binary segmentation, therefore there is no fair comparison between models trained for multiclass segmentation and our model. However, since our model reaches close to 0.9 of dice, precision, and recall, we are confident that it is good enough to act as a valid baseline.

The main results of this paper are presented in Fig. 3. The panels (a), (b), and (c), present the dice score, precision, and recall as a function of contamination scale, respectively. Solid lines represent the results obtained by our DNN for random (blue), dilation (orange), and erosion (green) contamination modes.

We performed a simulation of a "noise-robust" model – a model which has the same performance on noiseless data as

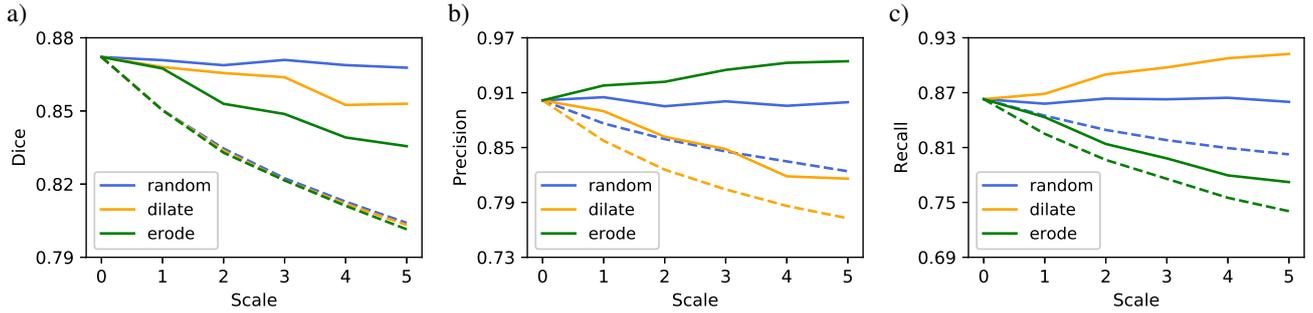

Fig. 3. Performance scores of a deep neural network trained using binary segmentation masks of BraTS2018 dataset with applied morphological noise simulation (erosion – orange, dilation – blue, or randomly chosen one – green) as a function of the scale of the noise. Panel (a) shows the dice score, panel (b) precision, and panel (c) recall.

our DNN, but also learns to mimic the noise-incorporation procedures, yielding the same performance at every scale assuming that the test set is noisy as well. Effectively, we altered the masks of each fold on each scale, and calculated all metrics against the original ground-truth segmentations. The procedure allowed us to verify how our DNN compares with the "noise-robust" model. The results for the simulated "noise-robust" model are presented with dashed lines in Fig. 3. The colors match the modes of the DNN.

#### A. Dice score

The dice score (Fig. 3a) shows a stable behavior for random noise, degrading slightly even for higher values of scale the dice score drops only about 0.004, from 0.872 to 0.868. In the case of dilation and erosion the drop is more significant, down to 0.853 and 0.836. The results obtained by our DNN for each mode are higher than the those obtained by the simulated learner by around 8% (random), 6% (dilate), and 6% (erode).

#### B. Precision

Random noise has a negligible effect on the precision score (Fig. 3b). Erosion biases data towards precision, which is reflected in the increase of the score for that mode, from 0.902 to 0.944. Dilation has an inverse effect – the score drops down to 0.816.

The precision score obtained by our DNN for each mode are higher than the those obtained by the simulated learner by around 8% (random), and 5% (dilate). Since erosion does not misplace any pixels, the noisy mask is contained completely within the original mask – the precision score is unaffected by such noise.

#### C. Recall

Random noise has similarly a negligible effect on the recall score (Fig. 3c). Dilation operation favors higher recall, which is reflected by the increase of the score for that mode from 0.863 to 0.912. Contrarily, the recall score for erosion drops down to 0.772.

The recall score obtained by our DNN for each mode are higher than the those obtained by the simulated learner by around 7% (random), and 4% (erode). Since dilation does not

misplace any pixels, the noisy mask encapsulates completely the original mask – the recall score is unaffected by such noise.

#### D. Reducing bias

We investigated whether biases present in the dataset could be proactively mitigated by altering the loss function (2). We tuned the relative weight of the precision and recall (parameter  $\beta$ ) of the dice score (1), generalizing it to the  $f_\beta$ -score, as in (3). This operation puts more attention of the loss function towards either recall (for  $\beta > 1$ ) or precision (for  $\beta < 1$ ), partially countering the biases present in the data. Particularly, for  $\lim_{\beta \rightarrow \infty} f_\beta$  yields *recall*, while  $\lim_{\beta \rightarrow 0} f_\beta$  *precision*.

$$f_\beta = (1 + \beta^2) \frac{\text{precision} \cdot \text{recall}}{\beta^2 \cdot \text{precision} + \text{recall}}, \quad (3)$$

where

$$\text{precision}(p, t) = \frac{\sum_i p_i t_i + 1.0}{\sum_i p_i t_i + \sum_i p_i (1 - t_i) + 1.0}, \quad (4)$$

and

$$\text{recall}(p, t) = \frac{\sum_i p_i t_i + 1.0}{\sum_i p_i t_i + \sum_i (1 - p_i) t_i + 1.0}. \quad (5)$$

To detect if the bias of the dataset could be mitigated and to what extent, we performed a gridsearch over multiple *beta* values  $\beta \in \{0.0, 0.2, \dots, 0.8\}$ . Lower values *beta* bias the loss function towards precision, so we biased the data towards recall by using dilation. The results of the gridsearch plotted as colormaps are shown in Fig. 4. The values for *beta* = 1.0 were already calculated (Fig. 3).

At no dilation (*scale* = 0) the dice score (Fig. 4a) decreases along with *beta*, which was expected as the network is no longer being trained to maximize the dice score directly. More importantly, the scores obtained for the values of *scale* and *beta* close to the anti-diagonal are visibly higher, especially for higher levels of noise, in comparison with the corresponding results for  $\beta = 1.0$ . For example, at  $\beta = 0.2$ , the network was able to quite consistently (for scale values  $\in \{3, 4, 5\}$ ) score around 1.5 percent higher than for the default dice-based loss function.

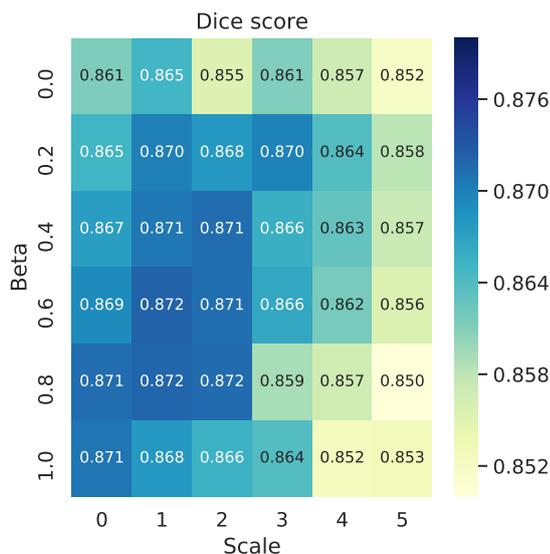

Fig. 4. Dice score of a deep neural network trained using binary segmentation masks of BraTS2018 dataset with applied morphological dilation as a function of the scale of the noise and a parameter  $\beta$ , representing the bias of the objective function towards precision (bias increases with decreasing  $\beta$ ).

Those results confirm that indeed the effect of bias in the dataset can be offset by incorporating an opposite bias in the objective function. Most likely, the optimal performance (obtained using unbiased dataset) cannot be restored completely, but, nevertheless, the gains are non-negligible. This puts the  $\beta$  parameter as a viable hyperparameter for optimizing the performance of a deep neural network in cases where there might be a bias present in a given dataset.

## VI. CONCLUSION

In this paper, we investigated the impact of simulated biases and variances of annotators—reflected in the under- or over-segmentation of binary mask they annotate—on the performance of a DNN trained on such modified image-mask pairs. We employed three types of simulated modifications of original ground-truth segmentation (which we called biased noise): erosion (simulating under-segmentation bias), dilation (simulating over-segmentation bias), and random, which employed randomly either erosion or dilation.

The results suggest that the performance of a DNN decays as the scale of contamination increases. The effect is rapid for both erosion and dilation, while it is slower (but steady) for the random contamination. This is because when training using under-segmented (eroded) segmentation masks, the DNN becomes biased towards precision, while using over-segmented (dilated) makes it biased towards recall. Both modes of contamination degrade the performance of a neural network significantly. However, for random contamination simulating a mixture of annotators with different biases, the decay of performance is less significant.

We also investigated whether the negative effect of a biased dataset on the training of a neural network could be reduced

by incorporating an opposite bias in the objective function. The results confirmed that both biases partially cancel each other, thus improving the performance. We suggest that the  $\beta$  parameter of the  $f_\beta$  score be considered as an important hyperparameter to search for during the optimization. Another option worth considering is to use multiple networks trained with different values of the  $\beta$  parameter in an ensemble. Such ensemble might improve the overall score via voting, just like an "ensemble" of expert annotators improve the score by improving the quality of ground-truth segmentations.

**Abstract**—A Travelling Salesman Problem (TSP) is an NP-hard combinatorial problem that is very important for many real-world applications. In this paper, it is shown, that proposed approach solves multi-objective TSP (mTSP) more effectively than other investigated methods, i.e. Non-dominated Sorting Genetic Algorithm II (NSGA-II). The proposed methods use rank and crowding distance (well-known from NSGA-II), combining those mechanisms in a novel, unique way: competing and co-evolving in the evolution process. The proposed modifications are investigated and verified by the benchmark mTSP instances, and results are compared to other methods.

## I. INTRODUCTION

A TRAVELLING Salesman Problem (TSP) is an NP-hard combinatorial optimization problem. The goal is to find a Hamiltonian cycle, that minimizes the sum of edge weights in a complete weighted graph [1]. Importance of TSP is accentuated by the fact, that it is a part of NP-complete class of problems [2].

A multi-objective Travelling Salesman Problem (mTSP) is an extension of TSP, where more than one objective is considered. It can be cost or time of the travel, the length of the route, etc. All objectives are optimized simultaneously [3]. An mTSP with two objectives is considered in this paper.

In multi-objective optimization, there is no prioritization of the objectives. Hence, to compare different solutions a dominance relation is used. A solution dominates another, if it has the value of at least one objective better, and value of no objectives worse than that solution. The goal of multi-objective optimization is to find all non-dominated solutions, a Pareto Front (PF). In practice, it is often not known whether found solutions comprise a true PF. Hence, the result of each method is called a PF approximation.

A Non-dominated Sorting Genetic Algorithm II (NSGA-II) [4], a classical multi-objective approach, uses two distinct mechanisms in its selection. The first one is the *rank*

comparison, which is based on the dominance relation, and aims to improve the convergence of the results. The second one is the *crowding distance*, which aims to increase the diversity of the results. However, a recent Non-dominated Sorting Tournament Genetic Algorithm (NTGA) [5] does not utilize the crowding distance at all. The authors show increased effectiveness of NTGA. This paper verifies the effectiveness of both *rank* and *crowding distance*. Two methods are presented that combine those mechanisms in a novel, unique way. One that uses them sequentially and forces competition between them. The other that utilizes two populations, where the mechanisms cooperate.

A set of experiments is designed to verify the quality of PF approximations generated by all methods. The Multi-Objective Evolutionary Algorithm integrating NSGA-II, SPEA2, and MOEA/D (MOEA/NSM) [12] is currently the best-known method for mTSP. Hence, it is used to compare the results. The results are evaluated by measuring convergence and diversity of the PF approximation and efficiency of the method. The set of Quality Measures (QMs) proposed in [6] is used. Moreover, visualizations of selected results are provided and a thorough theoretical analysis is presented.

The rest of the article is structured as follows. Section II contains the overview of existing work related to mTSP and multi-objective optimization. Section III provides a formal definition of the problem. All of the proposed approaches are described in section IV. Experiments and their results are presented in section V. The paper is concluded and additional remarks are given in section VI.

## II. RELATED WORK

A TSP is one of the most commonly researched problems. Many modifications to its original definition have been proposed. A TSP with asymmetric distances between the cities

[7], with multiple travelling salesmen [8], with stochastic travel times [9] or a vehicle routing problem [10].

Due to the NP-hard nature of mTSP, researchers often tackle it with metaheuristics. Genetic Algorithms are commonly used (e.g. [11], [12]). Authors of [14] and [15] have used an ant colony optimization methods. In [16] and [17] different memetic algorithms have been researched in the context of mTSP. It is also not uncommon to apply local search based methods [18], [19].

Researches often approach multi-objective optimization with genetic algorithms. They have proven to generate very high-quality PF approximations [20]. NSGA-II [4] is one of the most commonly used methods. It uses only a single population, where parents are forced to compete with children. It utilizes the rank and crowding distance of the individuals in the selection process and to truncate the population after every generation.

NTGA [5] is an extension of classical NSGA-II. The authors have shown its efficiency for a bi-objective scheduling problem – Multi-Skill Resource Constrained Project Scheduling Problem (MS-RCPSP). Modified selection in NTGA no longer utilizes the crowding distance. Instead, a clone elimination method is employed to maintain the diversity of the population. Additionally, the size of the tournament has been adjusted. Moreover, children are created in a new population and no longer have to compete with the parent population. NTGA uses also an archive that contains current approximation of PF. Such approach is a base of considerations in the given paper.

Recently created Multi-Objective Evolutionary Algorithm integrating NSGA-II, SPEA2, and MEA/D (MOEA/NSM) [12] has been successfully applied to mTSP. It uses the crowding distance, decomposition and Pareto strength. The solution space is explored using subpopulation tables, where each subpopulation contains the best results for a given aggregation of criteria. Every individual undergoes a crossover, mutation, and 2-opt optimization. At the end of each generation, subpopulations of SPEA2 and NSGA-II are updated. Rank and crowding distance mechanisms are considered. The authors show that MOEA/NSM outperforms all other methods and is the *state-of-the-art* population-based algorithm for mTSP. Hence, MOEA/NSM is used in this paper for comparison.

Initial multi-objective methods focused mostly on the convergence. However, recent research has shifted the focus onto the diversity [13]. This article tries to find the balance between the two. Two methods are proposed. One that switches the focus between convergence and diversity. The other that emphasizes both in parallel populations.

### III. PROBLEM

A TSP comprises of a set of  $m$  cities. In the problem a salesman must visit every city exactly once and return to the place where the travel started (initial city). The goal is to minimize the cost of travel of that route, given the cost of travel from city  $i$  to city  $j$ , is defined as  $c_{ij}$  and is part of the problem definition. TSP is equivalent to finding the minimum Hamiltonian cycle in a non-directed, weighted graph

[22], where nodes represent the cities, and weights represent the travel costs. Total cost of travel is calculated as the sum of edge weights and should be minimized. A symmetric TSP is considered in this paper, where  $c_{ij} = c_{ji}$  for all cities  $i, j \in \{0, 1, \dots, m-1\}$

In Multi-objective Travelling Salesman Problem (mTSP) multiple aspects of the route are evaluated [12]. It could be cost, time, length or risk of travel. The problem with  $n$  criteria and  $m$  cities is represented by  $n$  weighted graphs. For each  $k \in 1, \dots, n$ , graph  $G_k$  is a weighted graph, that represent  $k$ -th criterion. The edge weight between cities  $i$  and  $j$  in graph  $G_k$  is represented by  $c_{ij}^{(k)}$ . In this paper two criteria are considered.

### IV. EVOLUTIONARY METHODS

This section contains the description of all the investigated methods. First, definitions of important terms related to the work are given. Next, parts that are common for each method are described. Then, reference methods are presented. Finally, two novel modifications are described.

#### A. Definitions of Terms

1) *Dominance Relation*: The comparison of multi-objective solutions is done with the dominance relation. Let  $z, z'$  be two points in the multi-objective solution space.  $z$  dominates  $z'$  when both Eq.1 and Eq.2 are satisfied:

$$\forall_{k=1}^n f_k(z) \leq f_k(z') \quad (1)$$

$$\exists_{k=1}^n f_k(z) < f_k(z') \quad (2)$$

Where  $n$  is the number of criteria,  $f_k$  is the objective function of  $k$ -th criterion.

2) *Pareto Front*: A set of all non-dominated solutions is called a Pareto Front (PF). Since the set of globally non-dominated points is not known, all methods create an approximation of PF.

#### B. Representation

The representation of an individual in genetic algorithm defines how a genome represents the solution in a given problem. It also determines the use of genetic operators. All methods in this paper use the same representation.

An individual, for the problem with  $m$  cities, is represented by the permutation vector  $z = (m_1, m_2, \dots, m_m)$ . Each gene is the number of the next city on the route. In TSP the full route must end on the same city that it started. Hence, in the calculation of the objective functions the cost of travel between  $m_m$  and  $m_1$  must also be considered.

#### C. Initial Population

The first step of a genetic algorithm is the generation of an initial population. A random initialization is used. Every individual is initialized with a random permutation of all  $m$  cities. An additional mechanism enforces the uniqueness of all generated genotypes.

#### D. Genetic Operators

This chapter contains the description of both crossover, and mutation, which allow for exploitation, and exploration of the solution space.

1) *Crossover*: Crossover operator is responsible for the exploitation of space [23]. In the process two parent individuals are used to create two children individuals. In all methods, crossover is performed with a given probability ( $P_x$  parameter). In case of no crossover, parent genomes are copied over to the children individuals.

An Order Crossover (OX) has been selected [24]. It tends to retain the relative order of the genes and has been proven to work well for the ordering problems [25]. First, a part of the route is copied from the first parent, and then the rest of the route is reconstructed based on the genomes of the second parent. The part to copy is selected by randomly choosing two cut-points of the chromosome. The part between those two points is selected and copied to the child individual (in the same place of the genome). The remaining genes are filled, starting with the second cut-point, from the second parent. The order is maintained and already existing cities are skipped.

For example, given two parent individuals  $p_1$  and  $p_2$ :

$$\begin{aligned} p_1 &= (3 \ 2 \ 1 \mid 8 \ 4 \ 6 \ 7 \mid 5 \ 9), \\ p_2 &= (2 \ 3 \ 6 \mid 5 \ 8 \ 4 \ 1 \mid 9 \ 7). \end{aligned}$$

The first child  $c_1$  is:

$$c_1 = (3 \ 5 \ 1 \mid 8 \ 4 \ 6 \ 7 \mid 9 \ 2).$$

The second child  $c_2$  is generated by swapping the roles of two parents in the crossover process:

$$c_2 = (2 \ 6 \ 7 \mid 5 \ 8 \ 4 \ 1 \mid 9 \ 3).$$

2) *Mutation*: Mutation introduces a random perturbation in the genome and is responsible for exploration of the solution space [1]. It introduces one or more small changes within the genome with given probability  $P_m$ . The parameter is a probability of a mutation of a single individual.

An *Inversion* mutation has been selected. It performs an inversion of a randomly selected sequence of genes. The sequence is selected by randomly choosing two cut-points within the genome. All genes between those points are inverted.

For example, let's consider a parent  $p$  with the following genome and selected cut-points:

$$p = (3 \ 2 \ 1 \mid 8 \ 4 \ 6 \ 7 \mid 5 \ 9).$$

Mutation would result in the following genome  $c$ :

$$c = (3 \ 2 \ 1 \mid 7 \ 6 \ 4 \ 8 \mid 5 \ 9).$$

#### E. Selection

Selection operator is used to provide parent individuals for the genetic operators. It pressures the evolutionary process towards the desired results. In the case of multi-objective optimization it is important to find the PF approximation close to the true PF, but also to promote the diversity of the population. However, selection must also allow for the weaker

individuals in order to avoid local optima. In multi-objective optimization the selection is based on the rank and crowding distance [4].

The *rank* is calculated based on the dominance relation. First, all non-dominated individuals within the population gain rank 1. Then those individuals are exempt from further calculations. Rank 2 is assigned to non-dominated individuals from the remaining individuals. The process is iteratively repeated, until every individual has a rank assigned. Higher rank means that the individual is closer to the true PF.

The *crowding distance* is calculated based on the distance to other individuals. It is a volume of the largest cube that contains only that individual. A larger value means that there are fewer individuals in that part of the space.

Researched methods use a *tournament* selection. First, given number of individuals is randomly drawn from the population. They are compared according to given selection operators. The best individual, according to the operators, is returned. NSGA-II originally uses a tournament selection with two individuals, while NTGA allows for higher values of the tournament size. Moreover, in selection method NTGA uses an *archive* that contains all non-dominated individuals found in a given evolution process.

#### F. Evolutionary Process

The same evolutionary process is used in all methods. It is used to generate a new population  $P_{next}$ , from the current population  $P_{current}$ . It also includes a clone prevention method and archive usage introduced by NTGA. The process is described in pseudocode 1.

---

#### Algorithm 1 Pseudocode of the evolutionary process

---

```

1:  $P_{next} \leftarrow \emptyset$ 
2: while  $|P_{next}| < populationSize$  do
3:    $parents \leftarrow select(P_{current} \cup archive, operators)$ 
4:    $children \leftarrow mutate(crossover(parents))$ 
5:   while  $P_{next}$  contains  $children$  do
6:      $children \leftarrow mutate(children)$ 
7:   end while
8:    $evaluate(children)$ 
9:    $P_{next} \leftarrow P_{next} \cup children$ 
10: end while
11: return  $P_{next}$ 

```

---

In line 1 of Pseudocode 1, the next population is initialized to an empty collection. The loop between lines 2 and 10 performs the evolution until the next population reaches the desirable size. In line 3, parents are selected from the current population. NSGA-II does not use archive, but NTGA does (see line 3) in the selection method. The comparison is performed based on selected operators. Then, the children are created by performing crossover and mutation on the parents in line 4. Lines 5 to 7 describe the clone prevention mechanism. As long as the children already exist in the next population, they are mutated. Eventually, the children are evaluated in

line 8, and added to the next population in line 9. The next population is returned in line 11.

### G. Switch Non-Dominated Tournament Genetic Algorithm

The proposed method switches selections (*crowding distance* and *rank*) to obtain an evenly distributed PF approximation with high spread. Switch Non-dominated Tournament Genetic Algorithm (sNTGA) is based on a recent NTGA [5]. It switches between two competing selection operators - primary  $S_{primaryOperator}$  and a temporary one  $S_{switchOperator}$ . The former is used to obtain a diverse PF approximation, while the latter to also guarantee the convergence of the approximation. Both operators work in turns, and they promote different solutions, which allows for a better exploration of the solution space. Additionally, switch of the operators makes it easier to escape local optima. In consequence, improved solutions can be achieved. The time-frame, in which the operators work is defined by the number of births and the following parameters.

- $S_{delay}$  - number of births, after which the temporary operators is switched on. At the very beginning of the evolution, the switch is not necessary, as the population is still diverse, and not yet converged.
- $S_{each}$  - parameter determining a single cycle of the operators
- $S_{duration}$  - number of births after which  $S_{switchOperator}$  should be switch off and  $S_{primaryOperator}$  should be switched back on. It should always be lesser than  $S_{each}$ .

Pseudocode 2 describes the sNTGA.

---

#### Algorithm 2 Pseudocode of sNTGA

---

```

1:  $archive \leftarrow \emptyset$ 
2:  $P_{current} \leftarrow generateInitialPopulation()$ 
3:  $evaluate(P_{current})$ 
4: while  $stoppingCriteria()$  do
5:    $nonDominatedSorting(P_{current})$ 
6:    $crowdingDistanceAssignment(P_{current})$ 
7:    $updateArchive(P_{current})$ 
8:    $operator \leftarrow selectionOperator()$ 
9:    $P_{current} \leftarrow evolve(P_{current} \cup archive, operator)$ 
10: end while
11:  $updateArchive(P_{current})$ 
12: return  $archive$ 

```

---

An empty archive is initialized in line 1. In line 2, the current population is randomly initialized. It is then evaluated in line 3. The loop between lines 4 and 10 runs until the stopping criteria is reached. In the article it has been set to the given number of births. In line 5, the non-dominated sorting is performed and the crowding distance is assigned in line 6. The archive is updated in line 7, by adding all non-dominated individuals, and removing those that became dominated. In line 8 a selection operator is determined (described in pseudocode 3). Then the current population is evolved (described in pseudocode 1), based on the current individuals, the archive, and selection operators. Finally, the archive is again updated

in line 11 and it is returned in line 12, where it contains the PF approximation.

---

#### Algorithm 3 Pseudocode of $selectionOperator$ in sNTGA

---

```

1:  $switchBirthsCount \leftarrow currentBirthsCount - S_{delay}$ 
2: if  $switchBirthsCount < 0$  then
3:    $operator \leftarrow S_{primaryOperator}$ 
4: else if  $switchBirthsCount \bmod S_{each} < S_{duration}$  then
5:    $operator \leftarrow S_{switchOperator}$ 
6: else
7:    $operator \leftarrow S_{primaryOperator}$ 
8: end if
9: return  $operator$ 

```

---

To determine the current selection operators for sNTGA, the moment, at which operator should change is calculated in line 1. A  $switchBirthsCount$  variable is used. It is calculated as the current number of births minus the delay parameter. If that number is smaller than 0 (check in line 2) then the primary operator is selected in line 3. Otherwise, a check is performed to verify, which operator should be used, in line 4. If not enough births have happened, then the temporary operator is used in line 5, otherwise primary operator is used in line 7. The selected operator is returned in line 9.

Researched sNTGA uses the *crowding distance* as the primary operator and *rank* as the temporary operator.

### H. Co-Evolutionary Non-Dominated Tournament Genetic Algorithm

Both *rank* and *crowding distance* operator can be successfully used in multi-objective optimization methods. However, since both operators work on the same population, one operator might diminish the effect of the other operator. Hence, a Co-evolutionary Non-Dominated Tournament Genetic Algorithm (cNTGA) is proposed. The main motivation in cNTGA is to enforce cooperation of selection methods by operating on two separate populations connected in the evaluation process. Thus co-evolution mechanism is applied.

A cNTGA utilizes two populations with different selection operators. The exchange of information is possible due to the use of the same archive. The archive is used in the evaluation and selection process of both populations. Additionally, at the end of each generation, individuals of both populations are added to the archive. The method requires only one additional parameter  $K_{RANK}$  - it defines the percentage of the initial population size, that should be assigned to the population that uses *rank* operator. cNTGA is described in pseudocode 4.

**Algorithm 4** Pseudocode of cNTGA

---

```

1: archive ← ∅
2:  $P_{RANK}, P_{CD} \leftarrow generateInitialPopulation()$ 
3:  $evaluate(P_{RANK})$ 
4:  $evaluate(P_{CD})$ 
5: while  $stoppingCriteria()$  do
6:    $nonDominatedSorting(P_{RANK})$ 
7:    $nonDominatedSorting(P_{CD})$ 
8:    $crowdingDistanceAssignment(P_{CD})$ 
9:    $updateArchive(P_{RANK} \cup P_{CD})$ 
10:   $P_{RANK} \leftarrow evolve(P_{RANK} \cup archive, \geq_{RANK})$ 
11:   $P_{CD} \leftarrow evolve(P_{CD} \cup archive, \geq_{CD})$ 
12: end while
13:  $updateArchive(P_{RANK} \cup P_{CD})$ 
14: return archive

```

---

An empty archive is initialized in line 1. Then two populations  $P_{RANK}$  and  $P_{CD}$  are randomly initialized in line 2. Then, they are evaluated in lines 3 and 4 respectively. The loop between lines 5 and 12 runs until the stopping criteria is reached. In the paper, the number of births is used. In lines 6 and 7, the populations are sorted according to the appropriate operator. The crowding distances are assigned for population  $P_{CD}$  in line 8. Then, the archive is updated in line 9, with the individuals from both populations. The populations are evolved (pseudocode 1) in line 10 and 11 using  $\geq_{RANK}$  and  $\geq_{CD}$  operators. The archive is once again updated in line 13. Finally, the archive containing the PF approximation is returned in line 14.

In cNTGA, co-evolution significantly reduces the number of parameters (comparing to sNTGA) and results in an easier investigation process. Finally, the method decides which selection operator is more “useful” in the given problem, not the researcher in the tuning process.

*I. Reference Methods*

The researched methods are compared to three selected, reference methods. First, a NSGA-II [4] has been selected, as it is the most common method in the literature. NTGA [5] is selected, because approaches described in this paper are based on it. Finally, MOEA/NSM [12] is used as the current best *state-of-the-art* method.

## V. EXPERIMENTS AND RESULTS

This section presents experimental procedure to verify effectiveness of the proposed methods (sNTGA and cNTGA) by empirically comparing results to other reference methods. Thus, used mTSP instances are presented, Quality Measure for multi-objective optimization and methods setup are given. Finally, results and selected visualizations are presented.

*A. Data Instances*

Data instances used in the research are commonly used in literature, e.g. 9 instances *euclid\*\*\** from TSPLIB (e.g. [21]) and {kroAB100, kroAB200} generated from DIMACS code. Instances differ in number of cities, which affects the complexity and size of the solution landscape.

*B. Quality Measures*

To evaluate the results, the QMs proposed in [6] are used. This section contains their description along with the description of reference points required for their calculation.

1) *Euclidean Distance*: Euclidean distance (*ED*) is the average distance between every point on the PF approximation and a so called Perfect Point. Where the Perfect Point comprises of the best values of all objectives. ED can be formally defined by equation 3.

$$ED(PF) = \frac{\sum_{i=1}^{|PF|} d_i}{|PF|} \quad (3)$$

Where  $PF$  is the Pareto Front,  $d_i$  is the distance from the  $i$ 'th point to the Perfect Point.

ED measures the convergence of the PF approximation and should be minimized.

2) *Hypervolume*: Hypervolume (*HV*) is the volume of hypercube defined by the PF approximation and the Nadir Point. Where the Nadir Point comprises of the worst values of all objectives. HV can be formally defined by equation 4.

$$HV(PF) = \Lambda\left(\bigcup_{s \in PF} \{s' | s \prec s' \prec s^{nadir}\}\right) \quad (4)$$

Where  $PF$  is an approximation of PF.  $s$  is the point of approximated PF.  $s^{nadir}$  is a *Nadir Point*.  $\Lambda$  is a Lebesgue measure, which generalizes the a volume.  $\prec$  is a domination relation.

Hypervolume is a measure of spread, but is also influenced by the convergence of the PF approximation. It should be maximized.

3) *Pareto Front Size*: Pareto Front Size (*PFS*) is the number of points on the PF approximation. It is the measure of diversity and should be maximized.

4) *Spacing*: Spacing (*S*) is the average distance between the consecutive points on the PF approximation. S can be formally defined by equation 5.

$$S(PF) = \sqrt{\frac{1}{|PF|} \sum_{i=1}^{|PF|} (d_i - \bar{d})^2} \quad (5)$$

Where  $PF$  is the approximation of the PF.  $d_i$  is the distance from the  $i - th$  point the next consecutive point.

S is the measure of uniformity and should be minimized.

5) *Ratio of Non-dominated Individuals*: Ratio of Non-dominated Individuals (*RNI*) is the value of *PFS* divided by the number of births. It measures efficiency of the method and should be maximized.

6) *Purity*: Purity is used for a direct comparison of two PF approximations. It is the number of points that remain non-dominated, when combined with the PF approximation from another method. Purity should be maximized.

### C. Parameters

Each method is tuned experimentally (like cNTGA, sNTGA) or optimal configuration has been used based on publications (e.g. MOEA/NSM [21] or NTGA [5]). Each method is limited by number of *births* (a number of all visited points). All configurations are presented in Tab. I.

For all investigated methods this value is given according to number of cities as follows:

- 100 cities – 10 mln births,
- 200 cities – 13 mln births,
- 300 cities – 16 mln births,
- 500 cities – 22 mln births,

Such *births* limitations are connected to the size of landscape (number of cities) and limit of computational time required by experimental procedure.

All investigated methods (NTGA, sNTGA, cNTGA and NSGA-II) have been implemented in Java using standard libraries. An exception is MOEA/NSM, where authors of [21] code<sup>1</sup> has been used.

### D. Experiments

Averaged results from 50 runs of 5 methods for 11 instances are presented in Table II. The comparison shows that in each case the best values of *RNI* have been achieved by cNTGA or sNTGA. Proposed methods also outperform others in *PFS* context – they give 2–3 times larger number of points in approx. PF.

NSGA-II created interesting results – in 6/11 cases the best *ED* and *S* values have been achieved – it is connected to the fact, that this method gives very narrow PF approx. that is located in the “centre” (see Fig.1 or Fig.2). Other cases (5/11) are occupied by NTGA, what confirms that *ED* prefers methods that focus on PF “centre”.

In opposite cases (4/11) better *S* values were obtained by cNTGA with much large *PFS* value. Almost every time (9/11 cases) the best value of *HV* was achieved by MOEA/NSM.

All results have been averaged and presented in Table III. Two proposed methods (sNTGA and cNTGA) compete successfully with MOEA/NSM. In case of *ED*, all mentioned methods give results that are almost the same. The Wilcoxon signed-rank test showed that results of these three methods are not statistically different.

Results presented in Table III show that MOEA/NSM gives better approx. PF in *HV* context. The difference between sNTGA and MOEA/NSM results is statistically significant – Wilcoxon signed-rank test ( $W_{0.05} = 66 > W_c = 13$ ) confirmed that.

For other QM’s, two proposed methods – cNTGA and sNTGA – give results (*ED*, *RNI* and *S*) that are not statistically different. The exception is *HV*, where sNTGA outperforms cNTGA and it is statistically significant ( $W_{0.05} = 65 > W_c = 13$ ). However, both methods outperform MOEA/NSM. E.g. comparing results for cNTGA and MOEA/NSM Wilcoxon signed-rank test gives: *PFS* ( $W_{0.05}$

$= 66 > W_c = 13$ ), *RNI* ( $W_{0.05} = 64 > W_c = 13$ ) and *S* ( $W_{0.05} = 66 > W_c = 13$ ).

### E. Visualizations and approx. PF analysis

To visualize approximations of PF, selected graphs have been prepared. They present the “averaged” PF – modified version of empirical attainment function (EAF) [26]. Each graph contains data of PF from 50 independent runs of selected method.

For smaller instances (i.e. euclidAB100) the results of 5 investigated methods are very similar. Hence the visualization has been omitted. Only two methods – NSGA-II and NTGA – give worse results: approx. PF is dominated by others and have larger standard deviation.

Graph presented on Fig.1 shows results for more complex instance, euclidAB300. Methods cNTGA, sNTGA and MOEA/NSM compete successfully. NTGA gives the worst solution. Quite interesting are results of NSGA-II – approx. PF is too short but focused in central region of PF.

The more difficult instance (see Fig.2, euclidAB500) suggests that MOEA/NSM is effective in the central area of PF – QM’s *S* and *HV* confirm that. However, in other areas, sNTGA and cNTGA can compete and give very good results – a large number of points. Moreover, PF approximation created by NSGA-II is very short but of very high quality and focused in the central area.

To get a more detailed image of results **Purity** measure have been (see Tab. IV) used to compare gained approx. PF, where methods are compared in pairs. Results show that it is quite difficult to select the method with the best results. Fig.??- Fig.1 showed that MOEA/NSM gives better results in “centre” region, cNTGA wins in other regions. Using Purity measure, it gives domination of MOEA/NSM in 53.9% but cNTGA dominates in 54.3%. Detailed analysis of the data shows that cNTGA “wins” in instances with 500 cities and fails in 300 cities – it can be a suggestion that *births* limits cNTGA to much and such aspect should be investigated more carefully in further research. It is worth mentioning that cNTGA and sNTGA give significantly larger PF approx. (see *PFS* values in Tab.II or Tab.III) what can disturb a little interpretation of Purity values.

Another conclusion gained from Tab.IV is that cNTGA outperforms results of sNTGA in each instance – approx. PF “dominates” in 62%. Moreover, sNTGA does not compete with MOEA/NSM so successfully, and is “dominated” in 59.8%.

### F. Summary

cNTGA and sNTGA methods are effective and can compete with MOEA/NSM results (e.g. better *PFS* and *S* values). However, there is a strong need to focus the methods in central area of PF. Moreover, proposed methods have better efficiency than MOEA/NSM – the *RNI* confirmed that. The last but not least, is the conceptual aspect – cNTGA and sNTGA are methods that have only few parameters, are easy to understand and tune.

## VI. CONCLUSIONS AND FUTURE WORK

This article introduces two new methods based on recent NTGA. The first one is sNTGA, which uses the rank and crowding distance operators sequentially. The second one - cNTGA utilizes two subpopulations, where one of them uses rank, and the other one uses crowding distance in their respective selection methods. Both subpopulations cooperate by performing the selection on a shared archive of non-dominated individuals.

The methods are compared to the *state-of-the-art* population-based MOEA/NSM. Proposed methods require fewer parameters and it is argued that they are less complex. Additionally, the results are evaluated with a set of QMs on the selected instances of TSP.

Another promising trend in literature is specialization and hybridization of metaheuristics. Proposed methods could be

extended by some local search techniques like 2-opt or/and genetic operators that are considered to be more effective in TSP, like Edge Crossover Operator [27].

It is shown that MOEA/NSM achieves better results in the 'centre' of the PF approximation. A different selection method that would emphasize the convergence in that area could be beneficial. Also, research on the different multi-objective problems in the context of sNTGA and cNTGA is an interesting direction for future work.

 Email: nakasho@yamaguchi-u.ac.jp

**Abstract**—In this paper, we explain the development of a new Mizar tokenizer and parser program as a component of a search system that works on the Mizar Mathematical Library. The existing Mizar tokenizer and parser can handle only an article as a whole written in the Mizar language, however, the newly developed program can deal with a snippet of a Mizar article.

In particular, since it is possible to handle a snippet of an article without specifying a vocabulary section of an environment part, it is expected that user input efforts will be greatly reduced.

## I. MOTIVATION

THE AUTHOR is developing a new information retrieval system that works on the Mizar Mathematical Library (MML) [1]. In this paper, we explain a developed tokenizer and parser program of the Mizar language as a component of our search system.

### A. MML Query

Currently, MML Query [2] developed by Grzegorz Bancerek in 2001 is widely used as an MML theorem search system. MML Query is the forerunner of the search systems for formalized mathematical libraries. Even today, it is the only active system that can search comprehensively large formalized mathematical libraries [3]. MML Query realizes pattern matching according to the grammatical structure of the Mizar language with its own language to specify a search object. This feature allows the users to input search patterns that have more expressive power than that of regular expressions. However, the users have to spend a considerable amount of time to learn the grammar of its own search language. Furthermore, since a mathematical theorem can be transformed into an infinite number of patterns by equivalent rewriting, it often causes retrieval omission in pattern matching. As mentioned above, MML Query has succeeded in reducing laborious retrieval work in the MML, however, there is still rooms for improvement.

### B. Developing search system

In order to learn from the drawbacks of MML Query, the newly developing search system extracts features of the input data and compares them with that of theorems and definitions registered in the MML. For the feature comparison, we use an algorithm designed to output a logical distance between two expressions. In addition, the search history will be collected

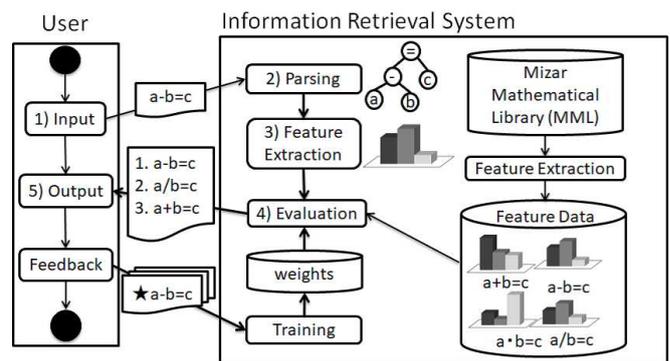

Fig. 1. Diagram of our information retrieval system

and reused as corpus data for machine learning so that the distance calculation algorithm will be tuned to fit user trend.

The flow of our search system is as follows:

- 1) A user inputs a search target such as a theorem in the Mizar language.
- 2) The search system parses the input data.
- 3) The search system calculates the features of the input data such as a number of occurrences and positional relationship of symbols and variables by analyzing the syntax tree.
- 4) The search system compares the above features with that of theorems and definitions registered in the MML, and ranks and displays the matching rates.
- 5) The user of the search system browses the search result displayed on the system.

Fig. 1 shows a diagram of our search system.

### C. Necessity of a new tokenizer and parser

The developed tokenizer and parser program correspond to process 2) in Fig. 1. The existing parser used in the proof verification program of the Mizar system first reads an article and converts it into the Weakly Strict Mizar (WS-Mizar) language [4], [5]. In the WS-Mizar language, all terms are fully parenthesized, therefore, there is no ambiguity in operator precedence. After this process, the article in the WS-Mizar language is converted into XML intermediate representation by a parser program generated with Bison. The existing parser

program is supposed to handle full text of a Mizar article, therefore, it cannot process a snippet like a theorem, which is expected as the main input of our search system. That is the reason why we needed to develop a new tokenizer and parser program for the Mizar language.

## II. REQUIREMENTS OF NEW TOKENIZER AND PARSER

The Mizar language consists of a context sensitive grammar, and a set of valid symbols are determined according to Mizar articles enumerated in a vocabulary section of an environment part. However, in the construction of a Mizar article, it is said that the most difficult process is to create an environment part correctly. Therefore, it is not practical to enforce a search system user to input an environment part for every search. In this project, we aimed at constructing a tokenizer and parser program that works practically without an environment part. However, since the omission of an environment part may cause unexpected syntax errors, our search system needs to provide interfaces that enable the users to grasp and correct any syntax errors easily.

### A. Tokenizer

As mentioned earlier, in the Mizar language, valid symbols are determined according to the Mizar articles enumerated in a vocabulary section. It means that a vocabulary section has an ability to determine word boundaries in lexical analysis. When a vocabulary section is omitted, our tokenizer extracts tokens according to the longest match rule on the assumption that every symbol registered in the MML is valid. As a result, a token that is not an originally valid symbol might be mistakenly recognized as a symbol. However, we succeeded in reducing token recognition errors by implementing special interpretation rules to recognize a token placed immediately after a certain keyword such as *let* or *reserve* as a variable.

### B. Parser

Bison, which is used as a parser generator for the existing Mizar parser, adopts LALR parsing known as one of the most practical bottom-up parsing algorithms. Generally, bottom-up parser generators produce more efficient and smaller programs than top-down parser generators. However, since bottom-up parsers have difficulty in constructing a rough tree structure in the middle of parsing process, they sometimes tend to output meaningless error messages when grammatically incorrect input is given. The existing Mizar proof verification system also tends to output grammatical error messages that are difficult for beginners to understand. Based on these reasons and recent performance improvement of computer hardware, there have been increasing cases where top-down parsers such as LL parser and packrat parser are used in recent years. We also adopted ANTLR, which is based on Adaptive LL (\*) parsing and known as one of the most powerful top-down parser generators, because incomplete input will often be given to our search system. ANTLR supports many output languages such as Java, C++, Python2, Python3, Go, Swift, JavaScript and C#. Whenever we need to develop Mizar tools that work

on Web browser or modern editors such as Atom or Visual Studio Code, it can generate a parser written in JavaScript immediately.

## III. PROGRAM SPECIFICATION

This section explains input, output and the flow of our tokenizer and parser program. Fig. 2 shows the flow chart of our program.

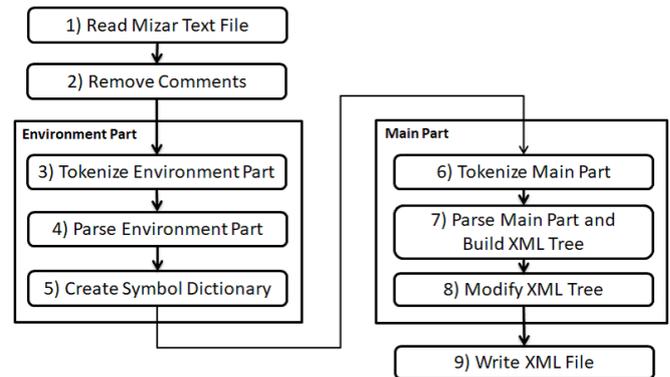

Fig. 2. Flow of our tokenizer and parser program

### A. Input and output

Our program accepts not only full text of a Mizar article but also various types of blocks such as theorem, definition, registration, notation, and scheme as input data. Our program outputs a parsing result in XML format as well as the existing Mizar parser program. The output XML faithfully reproduces the structure of the official BNF grammar provided at [mizar.org](http://mizar.org). Applying the official grammar rules to output XML will promote the secondary use of our tokenizer and parser program.

### B. Tokenizer specification

In lexical analysis, when a vocabulary section is not specified, it is assumed that all the symbols defined in the MML are valid.

All the symbols in the MML are recorded in *mml.vct* attached to Mizar distribution binaries. In our tokenizer program, a symbol dictionary is built by extracting symbol information from *mml.vct* in a pre-processing step.

Our tokenizer program first removes comments. Next, it reads tokens such as symbols, keywords, numbers, identifiers, etc. from the left hand side according to the longest match rule. If the token matches a symbol registered in the symbol dictionary, our tokenizer program appends prefix "`__` «symbol type» «symbol priority» `_`" to the token. Owing to the prefix, the following parser program is able to distinguish symbol types in the parsing process. Table I shows the correspondence between symbol types and their meanings in the Mizar language.

When a token is cut out according to the longest match rule on the assumption that all the MML symbols are valid, there

TABLE I  
CORRESPONDENCE BETWEEN SYMBOL TYPES AND THEIR MEANINGS

Symbol type	Meaning
R	Predicate
O	Functor
M	Mode
G	Structure
U	Selector
V	Attribute
K	Left Functor Bracket
L	Right Functor Bracket

is a risk that a variable is misinterpreted as a symbol. For this reason, when a token comes immediately after a certain keyword such as *let* or *reserve*, our tokenizer regards the token as a variable identifier, and its symbol validity is temporarily turned off within the scope of the variable. Our program writes out token-separated text at the end of the process.

### C. Parser specification

The official syntax of the Mizar language is written in BNF. We transformed the BNF syntax definition into ANTLR grammar form, then passed it to ANTLR parser generator. Normally, LL parsers require left recursion removal, although ANTLR automatically resolves direct left recursions. For this reason, we only needed to remove indirect left recursions. There are only two indirect left recursion in the Mizar official syntax definition. We repaired them and transformed the grammar rules from BNF to ANTLR grammar form.

The Mizar language has a feature that allows users to define prioritized infix operators (functors). While this feature has given a significant advantage of the readability of the Mizar language, it has also made lexical and syntactic analysis more difficult. Historically, this grammatical complexity has often become a bottleneck in the development of support tools for the Mizar system [6]. The existing Mizar system converts the Mizar language into the WS-Mizar language, thus all terms are parenthesized. Thanks to this process, the existing parser can avoid ambiguity in associativity and precedence of infix operators. In our program, its syntax tree structure is re-edited according to infix operator priorities in post-process. This strategy is also used in a parser of Standard ML [7]. At the end of parsing process, our parser removes prefixes attached by a tokenizer to symbols, then outputs an XML file.

### D. Choice of programming languages

We selected C++ for our parser implementation language because the parsing process takes most of the execution time and requires a high performance implementation. On the other hand, we also chose Python3 for other processes to realize smooth linkage with other programs and increase the productivity of the implementation. As for the parser, when we tried both C++ and Python3 as ANTLR output languages, we confirmed that C++ is about 10 times faster than Python3. In the C++ version, the parsing process occupies about 50 to 70 percent of the whole execution time. To bridge the gap

between Python3 and C++, we used the C++ extension feature of Python3 so that the data exchange is performed on memory.

## IV. EVALUATION

The source code of our program is published and managed on GitHub under the MIT license<sup>1</sup>.

### A. Functionality

Most of our program is written in Python3 and is composed of highly extensible modules. Furthermore, since our program faithfully outputs an XML file that follows the official grammar rules written in BNF, it is easy to reuse its source code for development of other support tools of the Mizar system. Currently, although the platform on which our program runs is limited to UNIX, we also plan to support Windows and Mac OS in the future.

### B. Performance

Table II shows a number of words and file size of each Mizar file used for a performance test. *jordan:95* is input data for a test case of our search system so that this file consists of a single theorem and a vocabulary section is not included. The file size of *ring\_1* is standard and that of *jgraph\_4* is the largest in the MML, respectively.

TABLE II  
SPECIFICATION OF MIZAR ARTICLES

	number of words	size
<i>jordan:95</i>	168	0.575 kB
<i>ring_1</i>	11558	37.6 kB
<i>jgraph_4</i>	185895	492 kB

Table III shows the specification of the test environment used in the performance test.

TABLE III  
TEST ENVIRONMENT

Item	Specification
CPU	Intel®Core™i7-7500U @ 2.70 GHz
Memory	16 GB
OS	Ubuntu 16.04 LTS
Compiler	GCC version 7

Table IV shows the execution time of each step of our program. Each item in the list corresponds to the labelled process shown in Fig. 2. From this table, it is confirmed that most of the execution time is occupied by process 7), that is, occupied by an ANTLR generated parser. According to the measurement results, in the case of an article of about 10,000 words like *ring\_1*, the time consumption is less than one second, which means it is enough to be used in practical applications. However, when it comes to an article with more than 100,000 words like *jgraph\_4*, parsing time exceeds 10 seconds. Currently, we suppose the application of our program is limited to the analysis of small input data

TABLE IV  
TIME CONSUMPTION OF EACH PROCESS

like *jordan:95*. Hence, we conclude our program already has enough performance for the application.

Table V shows the comparison result of performance measurement between our program and the existing Mizar parser. Even though this performance comparison is unfair because the existing Mizar parser has additional features such as indexing variables, it is enough to check approximate relative performance of these two programs. This comparison made it clear that our program tends to be slower than the existing parser as the input file size becomes larger. This tendency mainly comes from the difference of parser algorithms between the conventional bottom-up parsing and top-down parsing. The official grammar rules of the Mizar language include a significant number of left recursions that cause backtracking in the process of top-down LL(\*) parsing and performance deterioration. This performance deterioration is a well known issue that occurs when ANTLR generates parsers for languages with complex grammar rules.

## V. REMAINING CHALLENGES

### A. Display of parsing results

Since token interpretation of the Mizar language depends on the entries in a vocabulary section of an environment part, there is a possibility that the program produces incorrect results against user intention when it is applied to input data without a vocabulary section. Therefore, when parsing a snippet by our program, it is necessary to provide a graphical user interface (GUI) that allows users to check the parsed result visually. In the development of our search system, we are planning to build up a component that converts a parsing result into an HTML document with highlights of syntax errors, hyperlinks to symbol definitions, and so on.

<sup>1</sup><https://github.com/mimosa-project/emparser>

### B. Type checking

The Mizar language allows symbol overloading and mode inheritance as well as Java and C++ languages. Therefore, type checking or type inference must be performed in the semantic analysis. Improving the precision of the semantic analysis is expected to greatly contribute to improve on the accuracy of our search system. There is a preceding research on type inference without an environment part by Cezary Kaliszyk et al. [8].

### C. Performance improvement

We are planning to improve the performance for the case where our program is applied to other than our search system in the future. According to the performance measurements, it is supposed that effective remedies are to change the parser algorithm to bottom-up parsing or to optimize a grammar file passed to ANTLR. However, the replacement to a bottom-up parsing makes error handling more difficult, and optimization of the ANTLR grammar file has a disadvantage of impairing readability of the syntax rules. Another improvement plan is to rewrite program components written in Python, such as tokenizer, by using C++ extensions.

### ACKNOWLEDGMENT

I would like to express my gratitude to Adam Naumowicz, Artur Korniłowicz and Radosław Piliszek, who explained the specification of the existing Mizar tokenizer and parser programs and provided a part of their source code.

# British Sign Language Recognition In The Wild Based On Multi-Class SVM

M. Quinn and J.I. Olszewska

School of Computing and Engineering  
 University of the West of Scotland, United Kingdom  
 Email: joanna.olszewska@ieee.org

**Abstract**—Developing assistive, cost-effective, non-invasive technologies to aid communication of people with hearing impairments is of prime importance in our society, in order to widen accessibility and inclusiveness. For this purpose, we have developed an intelligent vision system embedded on a smartphone and deployed in the wild. In particular, it integrates both computer vision methods involving Histogram of Oriented Gradients (HOG) and machine learning techniques such as multi-class Support Vector Machine (SVM) to detect and recognize British Visual Language (BSL) signs automatically. Our system was successfully tested on a real-world dataset containing 13,066 samples and shown an accuracy of over 99% with an average processing time of 170ms, thus appropriate for real-time visual signing.

## I. INTRODUCTION

THERE are 11 million people with hearing loss across the United Kingdom (UK), i.e. 1 in 6 people, with around 900,000 of these persons having profound hearing loss [1]. Users of British Sign Language (BSL) number in the 150,000 range, with more than half of them using BSL as their first language [2]. By stark contrast, there are far less registered BSL interpreters, with 1540 being publicly available on the National Registers of Communication Professionals working with Deaf and Deafblind People (NRCPP) [3].

BSL consists of 26 hand-shapes; one being correlated to each letter of the alphabet, as illustrated in Fig. 1. Each letter is formed using two hands except for the letter ‘C’, using only one hand [4].

With the current expansion of Artificial Intelligence (AI) in daily applications [5], intelligent systems can play an important role for sign language recognition (SLR).

However, despite a number of technologies developed for the automated, visual recognition of gestures within the field of Human Computer Interaction (HCI) [6], [7], only very few studies have tackled with automated BSL translation [8].

In HCI, most of the gesture recognition systems usually require special hardware equipments, such as depth camera [9] or gloves [10], which are usually not available outside a laboratory and/or have limited utility in the wild.

On the other hand, SLR systems integrating machine learning techniques such as genetic algorithms (GA) [11] or convolutional neural networks (CNN) [12] have been mainly focused on the American Sign Language (ASL) [13], which uses static single-hand poses (as opposed to BSL which uses two-handed

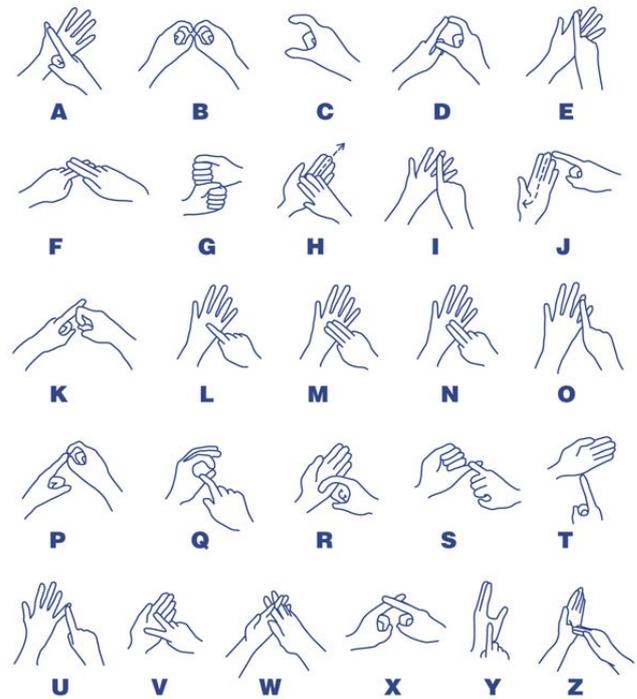

Fig. 1. Schematic overview of the British Visual Language (BSL) alphabet right-handed fingerspelling [2].

ones) to spell individual letters. Most of the available datasets are also only dedicated to ASL. It is worth noting that ASL and BSL languages have little crossover in terms of their actual constituent phonemes and are mutually incomprehensible to one another.

Hence, compared to ASL, BSL has a smaller body of research dedicated to visual recognition and as such, little online BSL datasets exist. Thus, methods based on deep learning [12], which requires hundreds of thousands of training data samples, are not directly available for BSL.

In this work, we propose the development of an accessible, intelligent vision system for real-time, automated BSL recognition in the wild. This assistive technology is inbuilt as a smartphone application, using computer-vision algorithms to process the images captured in real-time by the smartphone

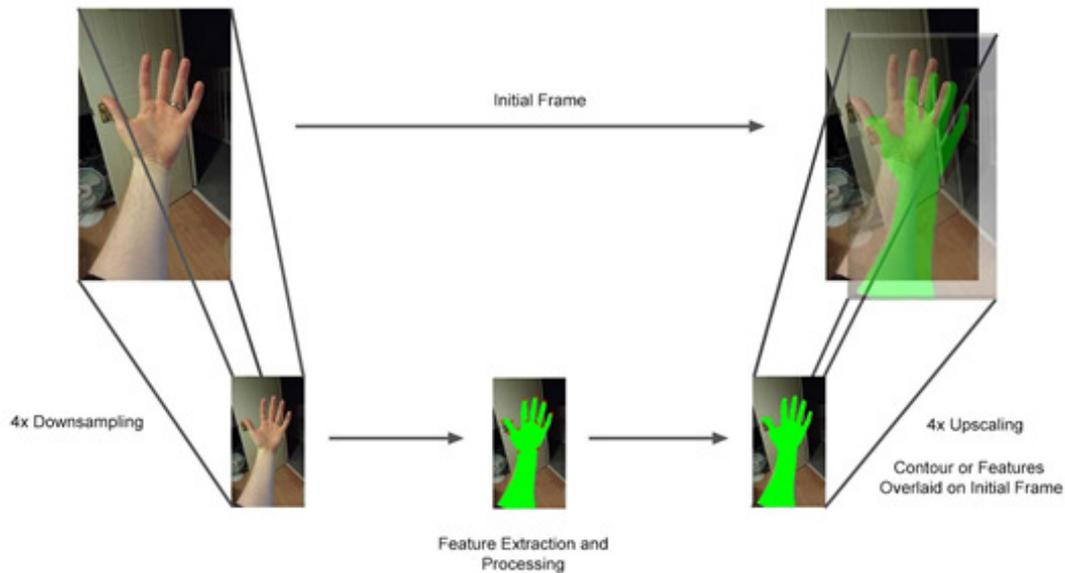

Fig. 2. Overview of our sign detection process.

camera and translating the detected hand pose into a letter using the machine learning technique called Support Vector Machine (SVM).

This intelligent vision system uses a regular optic camera such as a smartphone camera working with RGB flat image data, not requiring any type of calibration or invasive sensors.

On the other hand, our system processes images at an average rate of  $170ms$  per image, addressing successfully the real-time constraint. Indeed, the visual signing rate is of 2.3-2.5 signs per second [14], enforcing real-time SLR systems to process each sign at  $2fps$  or in less than  $400ms$  per image.

The study developed in this work aims to enrich the lives of a wide range of people with hearing and/or speech impairments and their respective circles.

The strict use of free and open source technologies in this project along with the use of cheap, portable hardware such as a smartphone implies that the resultant prototype could be highly accessible to a large number of users.

The original contribution of our work is the study of the automated BSL recognition process and includes the creation of a BSL large-scale dataset of c. 13k samples as well as the design, development, and deployment of a new intelligent vision system for automated BSL recognition in real-world environment.

The paper is structured as follows. In Section II, we present our detection and recognition system for BSL, while in Section III we report and discuss the carried out experiments which results show the developed SLR system has excellent performance on real-world large-scale datasets, both in terms of accuracy and computational efficiency. Conclusions are drawn up in Section IV.

## II. OUR METHOD

The developed intelligent vision system embeds a two-step computational process. The first step involves computer-vision algorithms processing the input image (see Fig. 2) and results in the visual sign detection, as described in Section II-A. The second step consists in machine-learning algorithms using Support Vector Machine (SVM) to recognize the detected visual sign, as explained in Section II-B.

### A. Sign Detection

Let us consider a colour RGB image or video frame  $I(x, y)$  where  $M \times N$  is its size, with  $M$ , its width, and  $N$ , its height, recorded live with the smartphone using the *OpenCV Camera Listener* triggered by our application.

In the first phase, the intelligent vision system running on the smartphone applies to the image  $I(x, y)$  a series of mathematical operations as follows.

Firstly, the RGB image is transformed to the HSV colour space [15]. Secondly, the image is resized and down-sampled based on the Gaussian Pyramid as depicted in Fig. 2. Then, the image is segmented by thresholding [16], and the mask of the hand(s) is extracted by applying mathematical morphologic operations such as eroding and dilation [17]. Next, the Histogram of Oriented Gradients (HOG) [18] is computed as shown in Fig. 3. HOG assembles a histogram of prevailing, aggregated gradients throughout predefined blocks of an image. Because HOG produces such histogram, the number of features per vector is the same every time, given the input image  $I(x, y)$  of a static size.

It is worth noting that through multiple pre-processing and cropping layers, a resultant image of a predictable size, i.e.  $M \times N$ , is given to the HOG detector feature extraction layer.

Post-processing of the image encompasses any upscaling and resizing that may need to be done to render the correct

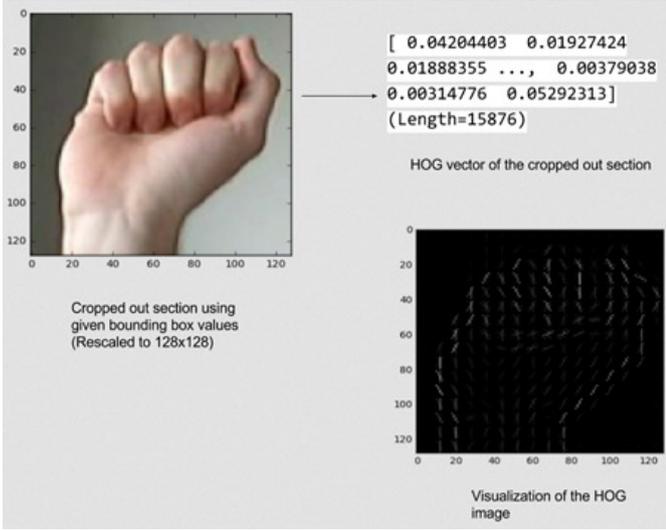

Fig. 3. Histogram of Oriented Gradients (HOG) visualisation.

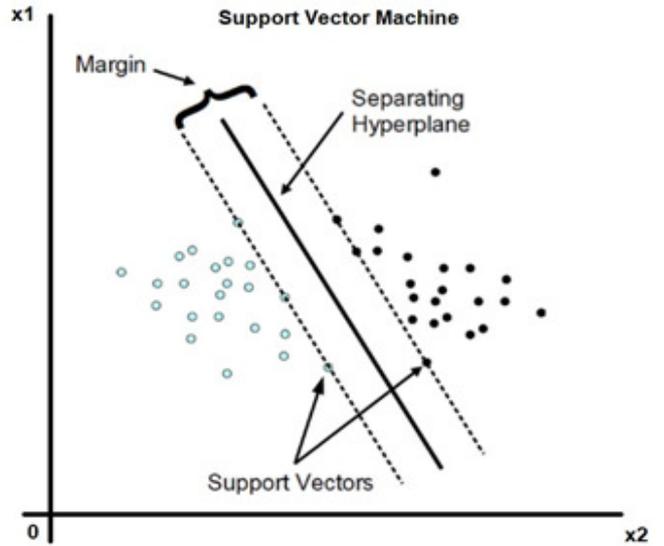

Fig. 4. Support Vector Machine (SVM) hyperplane visualisation.

information. Hence, if contour overlays are required to indicate the detected hand shape (as displayed in Fig. 8), then upscaling the previously down-sampled materials is done in this stage of the process.

*B. Sign Recognition*

Once data has been processed into a set of frames containing only pertinent gesture data as described in Section II-A, these are analysed and fed into a model as explained in this Section II-B, in order to be classified in one of the 26 classes of the BSL alphabet.

In this work, the adopted classifier is a Support Vector Machine (SVM), since SVM is an efficient implementation of a supervised machine learning approach for classification and decision making [19], while requiring only a small sample of training data [20]. SVM method is described in the subsections, as follows.

1) *SVM Hyperplane*: At its core, the SVM method attempts to find an ideal, separating hyperplane  $H_0$  (such as schematized in Fig. 4) to divide a dataset of  $n$  points into separate classes  $y_i$  (e.g. class  $y_i = +1$  and class  $y_i = -1$ ), as follows:

$$H_0 \equiv \mathbf{w}^T \mathbf{x}_i + b = 0, \tag{1}$$

with  $\mathbf{x}_i = (x_1, x_2, \dots, x_n)$ , the input vector,  $\mathbf{w} = (a, -1)$ , the weight factor,  $b$ , the bias, and  $a$  such as  $ax_1x_2 + b = 0$ ; this equation being derived from two-dimensional vectors, but in fact, works for any number  $p$  of dimensions.

The Support Vectors themselves are the data points closest to this plane of division and are therefore critical to segregating classes. Depending on the class (i.e. class +1 or class -1) they are part of, they belong either to  $H_1$  or  $H_2$ , defined as:

$$H_1 \equiv \mathbf{w}^T \mathbf{x}_i + b = 1, \tag{2}$$

$$H_2 \equiv \mathbf{w}^T \mathbf{x}_i + b = -1, \tag{3}$$

with the (hard) margin defined as  $D = H_1 - H_2$  (see Fig. 4); the hyperplane  $H_0$  being the median in between  $H_1$  and  $H_2$ .

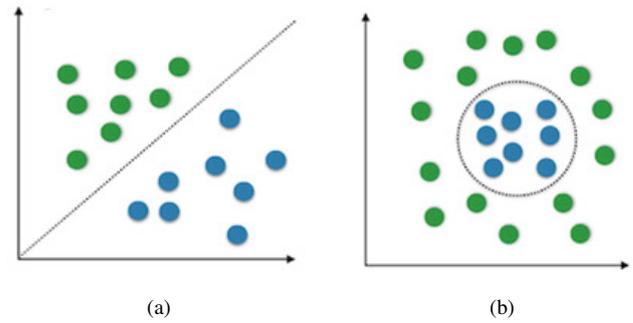

Fig. 5. SVM class separation using: (a) a linear kernel; (b) a radial basis function (RBF) kernel.

Fig. 6. Min-max normalisation performed on feature data before being fed into the SVM layer. It shows new maximum value of 1 on the lower row.

Consequently, each feature vector  $\mathbf{x}_i$  is classified as follows:

$$\text{class } y_i = +1, \text{ if } \mathbf{w}\mathbf{x}_i + b \geq 1, \tag{4}$$

$$\text{class } y_i = -1, \text{ if } \mathbf{w}\mathbf{x}_i + b \leq -1. \tag{5}$$

For SLR, this means finding a hyperplane (Eq. 1) between data from an actual gesture (i.e. class  $y_i = +1$ ) and interstitial hand movements which are not categorised (i.e. class  $y_i = -1$ ), leading to a *one-versus-all* approach, and then using the hyperplane to make predictions as per Eqs. 4-5.

2) *SVM Kernels and Hyperparameters*: The SVM is an integral part of the application, and different possible kernels could be implemented in order to gain linear separation in the data space, in case data is linearly separable (linear SVM), or otherwise (non-linear SVM) in a higher dimensional space. In particular, Linear and Radial Basis Function (RBF) kernels were used to test the application as reported

in Section III. As implied by the name, the linear kernel ( $K(\mathbf{x}_i, \mathbf{x}_j) = (\mathbf{x}_i \cdot \mathbf{x}_j)$ ) attempt to draw a line between class data (see Fig. 5 (a)), whereas the radial kernel ( $K(\mathbf{x}_i, \mathbf{x}_j) = \exp(-\|\mathbf{x}_i - \mathbf{x}_j\|^2/2\sigma^2)$ ) tries to fit a curved or radial shape between classes (see Fig. 5 (b)). These are very different kernels, but can often produce similar results in practice.

In the finalised prototype, the RBF kernel has been adopted based on the resultant test data accuracy (see Table 1). After being trained offline with 20 samples per class, the SVM is run live within the smartphone application. The maximum iterations before terminating the SVM is set to 100. The parameters have been chosen by cross-validation on the training set.

3) *Normalisation*: Min-max normalisation has been performed on feature data before being fed into the SVM layer. Normalisation is important, since it flattens the data to an appropriate scale, in this case from 0 to 1.

The formula given for min-max normalisation is that a data point has the set's minimum subtracted from it, and then this value is divided by the set's maximum minus the set's minimum. Accordingly, a value  $A$  for  $B$  is then derived as:

$$A = \frac{B - \min(B)}{\max(B) - \min(B)}. \quad (6)$$

Figure 6 shows a small example of a row of matrix data being set to new normalised values by applying Eq. 6. Within this example, the far right non-zero, previously maximal value is set to the new scale maximal value which is 1. The other values in the matrix are then scaled according to their relation to this new maximal value.

### III. EXPERIMENTS AND DISCUSSION

Our intelligent vision system was validated by running a series of experiments and assessing them quantitatively as reported below.

The effectiveness of the prototype has been measured using the following metrics [5]:

$$\textit{precision} (P) = \frac{TP}{TP + FP}, \quad (7)$$

$$\textit{recall} (R) = \frac{TP}{TP + FN}, \quad (8)$$

$$\textit{specificity} (S) = \frac{TN}{TN + FP}, \quad (9)$$

$$\textit{accuracy} (ACC) = \frac{TP + TN}{TP + TN + FP + FN}, \quad (10)$$

where  $TP$  is the True positive rate,  $FP$  is the False Positive rate,  $FN$  is the False Negative rate, and  $TN$  is the True Negative rate.

Another common metric is the F1-Measure or F1 score which is the harmonic mean of the precision and recall and which could be used when a balance between precision and recall is needed and when the class distribution is uneven (i.e. high  $TN + FP$ ). F1 score is defined as follows:

$$\textit{F1-Measure} = 2 \frac{P * R}{P + R}. \quad (11)$$

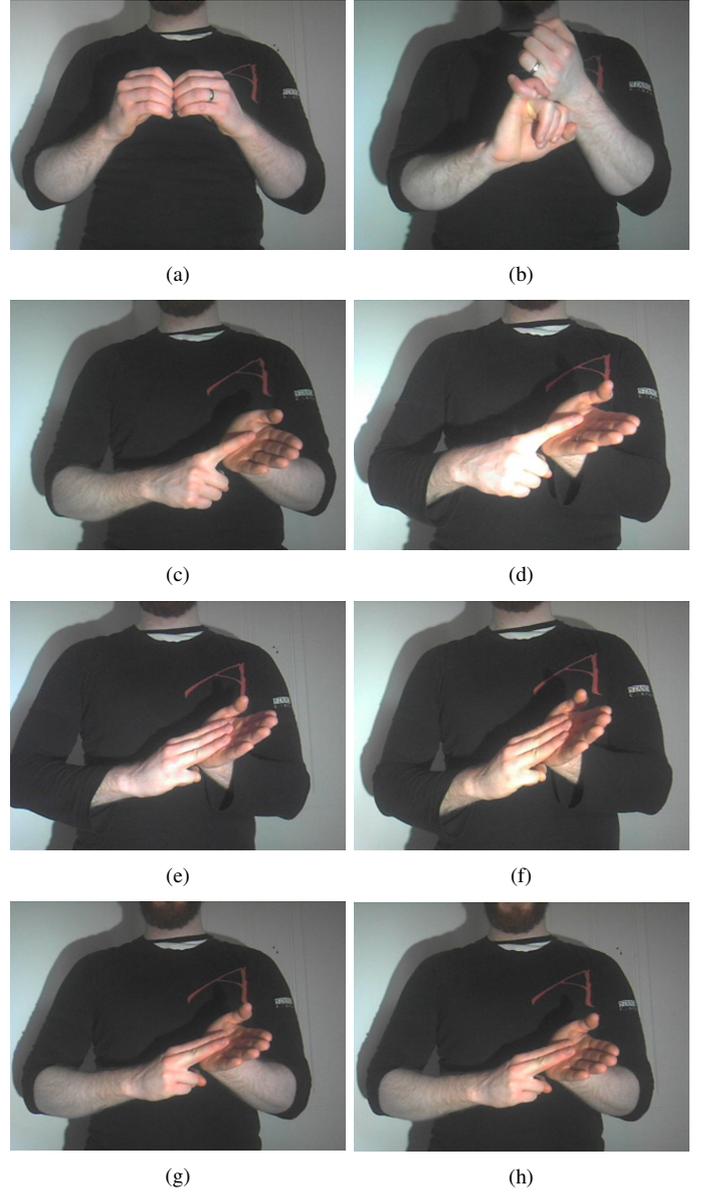

Fig. 7. Samples of our system performing successfully BSL sign recognition of the (a) B letter; (b) S letter; (c)-(d) L letter, in images with different illumination conditions; (e)-(f) M letter in images with different yaw rotations; (g)-(h) N letter in images with different pitch rotations.

As BSL fingerspelling datasets are difficult to find openly, a BSL dataset was created using the dataset creator application developed for this project.

This dataset is unique in the study, as it comprehends BSL phonemes consisting of two-handed gestures. Dataset samples are shown in Fig. 7. This BSL dataset contains 2,600 images of sign classes from  $A$  to  $Z$ . It is worth noting that  $H$  and  $J$  letter images were taken with last endpoint of motion gesture as an approximation. The images are in the Portable Network Graphics (.png) format and have a 640x480 size, a resolution of 72dpi, and a bit depth of 24. Moreover, the lighting is varying, and it also contains an even 50% mixture of signs

Fig. 8. Samples of our system performing hand detection in images with (a) cluttered background; (b) patterned background; (c) high luminance; or (d) high exposure.

with sleeves up and down, in order to introduce variation to the training model.

The dataset has been created in Python language, using the *Dataset Creator* application. The Python language has been chosen due to its lightweight nature and portability, but also because OpenCV wrappers are available for it. Indeed, the OpenCV 'Cv2' library for Python is used to access the webcam data when creating the image dataset and is therefore well suited to the integration with the rest of the project applications.

The prototype is written in Java and uses OpenCV 3.4.3. as well as the Java Native Interface (JNI) platform to enable Java running on the Java Virtual Machine (JVM) to interact with native platform applications written in lower-level languages such as C++. Hence, this JNI interface for the OpenCV dependency provides a critical interface into low-level hardware operations to run OpenCV processes through the C++ library. This interface enables thus the more computationally expensive parts of the application to run more efficiently and thence, provides a better user experience on the low-end phone hardware.

The training of the classifier has been performed using 520 samples (i.e. 26 classes with 20 samples per class) on a computer with features such as AMD FX-8320 3.5GHz (8 cores, 8 threads), 32nm architecture, 8Gb dual-channel DDR3 @ 802MHz, Windows 10 Home, 931Gb Western Digital SATA (7.2k rpm).

For the training function of the Offline Trainer, the datasets used the same imaging kernel as our smartphone application and they were processed image by image using a recursive Image Runner class; this Image Runner taking an input directory and processing each image in the parent folder and any subfolder.

The testing of the prototype has been run on a ZTE Blade V7 smartphone. This is a low-end budget Android phone (sub-£100) for the purposes of encouraging efficient programming and aiding in the overall availability of the end product. This phone model's specifications are as follows: Android 6.0 (Marshmallow) OS, Chipset Mediatek MT6753 (28nm), Octa-core 1.3 GHz Cortex-A53 CPU, Mali-T720MP3 GPU, 16 GB, 2 GB RAM of internal memory, and camera features such as 13 MP, PDAF, Dual-LED dual-tone flash, HDR, panorama, with 1080p @30fps video recorder.

The testing function of the offline trainer is entirely automated. After a training run is complete, the associated test

data is run through the previously trained model. These test images have been subtracted from the initial training dataset in order to not render the testing redundant. Each test image is classified with a predicted letter, and then evaluated against the actual class of the input image. With this data, the outcome of the tests in terms of True Positive ( $TP$ ), True Negative ( $TN$ ), False Positive ( $FP$ ), and False Negative ( $FN$ ) rates are computed. The output of these test operations goes to result log files for analysis and computation of Eqs. 7-11 for each run. Average recognition results can be found in Tables 1-2.

Tests have been carried out in the wild and included 13,066 sample images. BSL uses mainly two hands to represent a letter of the alphabet. However, the letter 'C' is signed using one hand only. Thence, we performed tests for both one and two hands, as illustrated in Fig. 8.

We reported in Tables 1-2 the primary data obtained by processing the approach presented in [21] and our method, respectively, on the BSL large-scale dataset. The approach of [21] involves visual features such as Edge Orientation Histogram features (EOH), whereas our system uses Histogram of Oriented Gradients (HOG) features; the classifier being the Support Vector Machine (SVM), with a linear and a radial basis function (RBF) kernel, respectively.

We can observe that our method combining HOG features and the SVM classifier with a RBF kernel outperforms the state-of-the art approaches in regards of both recognition accuracy and computational efficiency, while performing in the wild.

Furthermore, our method has been compared to available secondary data in the literature. The work of [11] studies Genetic Algorithms (GA) as classifiers for gesture recognition (using only 6 different gesture classes), achieving 98.6% accuracy, but reaching time frameworks in the range of dozens of seconds for the overall image processing. Moreover, [11] requires hundreds of samples for training and has only been tested on 100 samples.

On the other hand, [8] uses a Hidden Markov Model (HMM) and has a BSL recognition accuracy rate per letter of 84.1%, whereas our BSL recognition accuracy rate per letter is 99% and our processing time of 170ms (i.e. less than the 400ms mentioned in the study of [14]) ensures a real-time visual sign recognition pace.

TABLE I

#### IV. CONCLUSIONS

The paper proposes an assistive technology performing British Sign Language (BSL) alphabet translation in real-time and in real-world conditions, with an accuracy of over 99%. The design aims to provide an inclusive and accessible solution consisting in an intelligent vision system for automated BSL fingerspelling recognition, without being invasive or financially expensive. The algorithms developed within this system include Histogram of Oriented Gradients (HOG) method and the Support Vector Machine (SVM) technique. The resulting smartphone application has been successfully tested on a large-scale dataset in the wild. Its excellent performance leads, on one hand, to an accessible, assistive HCI product for non-deaf people wishing to learn BSL and/or to communicate using BSL with deaf persons, and on the other hand, to a potential HRI product for companion robots having the task to assist hearing and/or speech impaired people.

**Abstract**—This article presents a novel approach to segmentation and counting of objects in color digital images. The objects belong to a certain class, which in this case are honey bees. The authors briefly present existing approaches which use Convolutional Neural Networks to solve the problem of image segmentation and object recognition. The focus however is on application of U-Net convolutional neural network in an environment where knowledge about the object of interest is only limited to its rough, single pixel location. The authors provide full access to the details of the code used to implement the algorithms, as well as the data sets used and results obtained. The results show an encouraging low level of counting error at 14.27% for the best experiment.

## I. INTRODUCTION

CONVOLUTIONAL Neural Networks (CNNs) are considered state of the art architectures for object detection and segmentation in color images [1]-[4]. In this article we apply a specific type of CNN, called U-Net CNN (UNETCNN) [5], [6], to count instances of honey bees in color images captured by digital video camera. The dataset was sourced from [7] and is freely available to anyone who wishes to test their own bee counting routines. We are proposing a novel way of preparing data modeling for a UNETCNN, where the only information available, about the object of interest (OOI), is its approximate location, defined as a single point in two dimensional planes. Majority of research in the area of CNNs assumes that an OOI location is provided by a rectangle tightly encompassing its border [4]. We propose to use a circle with its center placed on the OOI. The assumption is: we are not focusing on finding exact boundaries of OOI, but rather on counting instances of the OOI, versus manually provided data in a segmentation set. As we are going to show in this paper, it is not necessary to cover an OOI with a bounding box, to achieve high classification accuracy. Instead we are only considering a location of a pixel lying on the surface of an

OOI. The location of the pixel constitutes a center of a small circle, which contains pixels belonging mostly to OOI and partially to the background. This step is called UNETCNN data generation. Following that, we employ further steps: training of UNETCNN, using the trained model for automatic segmentation of OOI, automatic counting of OOI instances. The final step allows computation of the relative error by comparing the number of OOI instances that were detected automatically versus how many of them were manually labelled by a human.

The article is organized as follows. In section II we discuss recent works in the area of adopting neural network to solve the problem of speed and accuracy in image recognition process including bee detection. We also present UNETCNN architecture and give reasons for adapting it for our own solution. Section III describes in details each stage of our experiment and presents the results. In section IV we summarize our work and discuss future directions which could lead to interesting findings.

## II. EXISTING APPROACHES TO BEE RECOGNITION PROBLEM AND UNET CHARACTERISTIC

### A. Different approaches to OOI detection

The bee detection problem was analyzed in [8] with various scenarios according to diversity of background characteristic, light intensity, bee size, image segmentation and labelling efficiency etc. The experiment evaluation helped us to decide which aspects of image recognition are the most important in our experiment and suggested the way of training set preparation. It also convinced us that Adam optimizer [9] is a good choice for training our neural network.

In [10] bees' recognition problem is discussed in the field of different methods of object recognition. CNNs are compared with Multi-Layer Perceptron (MLP) models. According to the experiments and results presented in that

This work was supported by Statutory Research funds of Institute of Informatics, Silesian University of Technology, Gliwice, Poland (BK/204/RAU2/2019).

paper, it was found that MLP performance is much worse than CNN (taking into account the same dataset). The author stated that ADAM optimizer [9] gave reliable results in comparison to others. In terms of kernel size it was suggested that choosing it as 5x5 pixels, provides better performance of the model. In [10] it was noticed, that one of the problems in proper classifying the bees is a possible presence of bee shadow, which has got the same shape as the bee.

### B. UNet

UNETCNN is a NN architecture designed for image segmentation, characterized by low demand on number of annotated training images, and fast data processing. In [5] the authors use medical images as source of training data and demonstrate state of the art results, compared to manual labelling, making this architecture a de facto standard in medical images segmentation.

A typical UNETCNN consists of two paths. One (the contracting path) is represented by a typical CNN with two operations of convolution and max pooling following one after another. This path reduces spatial information, but provides better information where OOI might be present. The second path (expansive) matches the features extracted in contracting path using a sequence of up-scaling transformations.

A game changing innovation in [5] was the fact that a small set of training images can yield more precise segmentations than larger training sets in other algorithms. For a UNETCNN the training data is sourced from the images by dividing them into smaller windows, and then randomly chosen to be included in a training set.

Another feature of UNETCNN is that the algorithm enables finding the solution not only for diverse data set, but also for relatively similar data. Normally lack of diversity would lead to difficulties in recognizing objects in images which do not present features close to the ones the network was trained on. In order to alleviate this phenomenon and make the results independent of the input data, an excessive data augmentation is used. The network gains the data not only straight from the input data, but also from elastic deformations of the training images. This way the network training process can be invariant to deformations even if the images used in the process do not contain enough OOI. Recent works on UNETCNN [6], [11]–[14] prove that this architecture yields very good results and currently might be the best for solving objects recognition problem not only for 2D but also for 3D data.

In our approach we decided not to segment the training data manually, because of the amount of time it would take. We decided to verify if it would be practical to find a way of solving the problem of manual segmentation, by not providing bounding box or a mask for each object

in the image. We decided to segment images based only on single points for each OOI located in any of the training images.

## III. THE PROPOSED SOLUTION

As we mentioned above, there are 4 stages applied in OOI counting, each described in detail below. For the purpose of our experiments, we decided to use data set downloaded from [7]. At the time of performing experiments, the dataset contained only 550 manually labelled images. We enhanced this data set with a further 1086 images, manually labelled by us, using custom written software. The algorithms examined in this work are publicly available via [15].

### A. Stage 1 – UNETCNN input data generation

As it was commented earlier we decided to adopt a shape of a circle to describe part of an area belonging to each OOI. As the input images are of size 640 x 480 pixels we empirically set the size of the circle to be 16 pixels in radius (which is fully configurable). The idea is that when an OOI is labelled, a point is placed on its surface. We assumed that the pixels lying within the nearest neighborhood of the labelled location belong with a high probability to the OOI itself. We decided to simulate such a neighborhood with a circle of a chosen radius, where the pixels lying more towards the circle's edges are less likely to be part of the OOI itself. A linear probability decrease function is implemented with a minimum probability  $P_{min}$  declared for the edge of the circle and maximum probability  $P_{max}$  for the center of the circle. We set these values to 0.99 and 1.0 respectively for circles with radius of 16 pixels, and to 0.80 and 1.0 for circles with radius of 20 pixels (within different sets of experiments – see Table I). Any pixels lying outside of the circle are considered to belong fully to the background. This approach means that the problem becomes a binary classification one, where we set class 0 as background, and class 1 as an OOI. Any pixel in the generated modelling data has a probability associated with it: background and foreground. Both probabilities sum up to 1.0.

After all the images from the dataset were labelled, and the parameters of the data generation decided (such as circle radius,  $P_{min}$  and  $P_{max}$ ), we could finally create a numeric representation of the modelling data, stored as two separate Python numpy files. The first file described the color RGB channels of the pixels from the labelled images, normalized to values between 0.0 and 1.0. The second file described probability values for non OOI (NOOI) and OOI classes for every pixel, meaning that each pixel has a 2 dimensional feature vector associated with it.

The idea behind such generalization for the shape of an OOI as a circle, was that we were dealing with bees, which are relatively similar in size. We also were using the

fact that NN is working with fuzzy data, where we can assume that a pixel can partially belong to the NOOI and partially to the OOI. Based on that assumption and the fact that training algorithms for NN find local optimal solution we decided to test if this approach worked.

### B. Stage 2 – Training UNETCNN model

In previous stage 1 we created 2 sets: one representing samples X, and the second set Y representing corresponding values mapped to probabilities of all the pixels from modelling set. These sets stored on a hard drive are quite large in size, depending on amount of images in the modeling set. The X and Y sets, stored as Python numpy files, were used as a source for training of the UNETCNN model. The model we used was a slight modification from the original, with last layers changed to use 2 instances of RELU layer, followed by a Dropout layer and SoftMax used for classification. This solution was introduced to minimize the risk of overfitting the network and gave significant improvement according to results of computations. SoftMax layer enabled classification of background and foreground classes and would allow us to use it for classification of more than only two classes in the future.

In order to provide the training data for the UNETCNN, the generated data had to be randomly accessed to retrieve rectangular windows of pixels which contained modelling samples for the OOI and the NOOI classes. We adopted an algorithm, where each modeling image has a total of 80 (configurable value) windows randomly retrieved. Among the 80 windows, a specific amount of windows are considered as OOI windows and the rest are considered as NOOI windows. In order for a window to be OOI based, it has to pass a minimum percentage threshold for OOI pixels count. The amount of OOI windows would vary per image, depending on how many manually labelled OOI samples were present, versus total OOI samples in the modelling set. For example if image IMG1 had 2 OOIs labelled, and image IMG2 had 4 OOIs labelled, then there would have to be 2 times less OOI based windows randomly selected from IMG1 than compared with a number of randomly selected OOI based windows from IMG2. This individual approach was dictated to preserve a balanced number of OOI and NOOI classes in training data. The details of how the modelling set is created from the data generated in Stage 1 are available in [15].

The modelling data collected so far was then further split into training and validation sets (80/20 ratio) to be used in UNETCNN. On average we achieved a decent 96% validation set accuracy.

### C. Stage 3 – OOI Segmentation

After the UNETCNN model was trained we could use it to perform OOI detection on images from segmentation set. As it was mentioned in Stage 2, the model operates on assumption that the input tensor used in classification is of certain dimensions. In our experiments the dimensions were  $N \times 32 \times 32 \times 3$ , where N is the number of windows collected from the segmented image,  $32 \times 32$  are width and height of the window, and 3 stands for RGB channels normalized to [0,1] interval. The value of 32 is also configurable within the source code, and corresponds to diameter of the OOI modelling circle from Stage 1 [15].

We propose a custom approach for segmenting an input image, where a set of windows meshes is created. A single mesh is started at a specific (x, y) offset from the top left corner of a segmented image. The idea is to cover as much of the image as possible with windows tightly attached to each other, where every window needs to be wholly fitting into the image. The windows and their pixel RGB values would create a set which is then classified by the trained UNETCNN model from stage 2. The results of each mesh's classification were then added into a special matrix with values taken for OOI class at corresponding locations to the mesh pixels. Another matrix is also kept to count how many classifications were computed for each pixel from the segmented image. In the end, when all meshes are classified, the accrued classification results are scaled (using the accumulated classification counts), so that a heat map is created. The meshes created for the segmentation process are generated at a specified step of 2 pixels (configurable value) from coordinates of (0, 0) to (32, 32), where 32 is a size of classification window for UNETCNN.

The fore mentioned heat map is later converted to a binary image, where each pixel is decided to be as a part of the OOI or part of the background, based on the scaled voting produced by meshes.

### D. Experiments - Counting OOI

In our experiments we decided to examine how different parameters affect counting error which is expressed as a difference between 100% and a percentage of automatically detected instances of OOI (bees) versus total amount of manually labelled instance of OOI. In Table I we present OOI relative counting error, dependent on modelling size set and window size used for training of U-Net and further segmentation. The error progression is visualized in Fig. 1. Minimum percentage of pixels per window, so that can be considered as an OOI based window, was set as 45 and 50 for Experiment 1 and Experiment 2 respectively. More details can be found in logs provided in [15]. It turns out that the more images are available, the better results. Interestingly, error started dropping dramatically at about 500 images, reaching its

minimum value for full modelling set size of 1096 images with the OOI window size set at 40 pixels (Experiment 1).

TABLE I.

BEES COUNTING ERROR DEPENDING ON AMOUNT OF IMAGES USED IN MODELING SET ALONG WITH WINDOW SIZE

Attempt number	[Modeling images count, window size]	OOI Relative Counting Error
1	[100,40]	75.08%
2	[200, 40]	73.00%
3	[500, 40]	24.23%
4	[1000, 40]	16.83%
5	[1096, 40]	14.27%
6	[100, 32]	75.24%
7	[200, 32]	74.55%
8	[500, 32]	26.35%
9	[1000, 32]	16.87%
10	[1096, 32]	18.17%

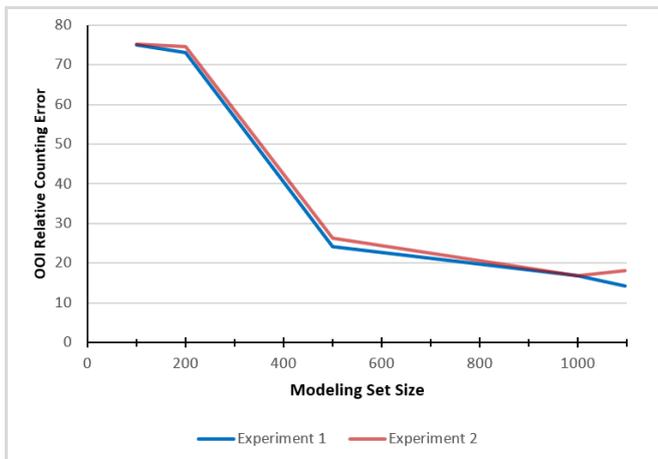

Fig. 1 OOI Counting Relative Error for experiments on parameters set 1 and set 2.

#### IV. CONCLUSIONS

In this article we presented a review of the most recent methods of OOI segmentation and detection. Based on these we chose a UNETCNN architecture which we adapted to a fairly new topic of counting of OOI, based only on their singular locations in the training set. We developed a new approach for generating modeling data, using the trained UNETCNN for segmentation, and further for counting occurrences of OOI in the validation set. We reached a satisfactory level of error at 14.27%, which encourages us to pursue this topic further. The experiments performed show that the training data preparation does not have to be mundane and time consuming and just a few hours spent on the process of labeling images can yield good results, not only in terms of counting error reduction

but also decent outcome in OOI segmentation. The Python code which was developed for the purpose of this research is available freely to anyone from [15]. We would like to thank Mr. Jonathan Byrne for making his data set available in [7].

**Abstract**—Recently, many researches on human mobility are aiming to suggest the personal customized solution in the diverse field, usually by academia and industry. Combined with deep learning methods, it is able to predict and generate novel routes of objects from the mobility data including the given past trends. In this work, Generative Adversarial Network (GAN) model is introduced for creating individual mobility routes based on sets of accumulated personal mobility data. The mobility data had been collected by use of geopositioning system and personal mobile devices. GAN has Discriminator and Generator which are composed of neural networks, and can train and extract geopositioning information. A sequence of longitude and latitude can be geographically mapped, and matrices including all these information can be handled by GAN. The GAN-based model successfully handled individual mobility routes in this way. Consequently, our model can generate and suggest unexplored routes from the existing sets of personal geolocation data.

## I. INTRODUCTION

INDIVIDUAL mobility data has a huge capacity and can provide significant information and knowledge to modern industries. By processing the result of analyzed mobile dataset, enterprises can get human personalities so that they can interact with their customers effectively and set directions in the field of marketing. For instance, the analysis of the consumers' data can help to determine the location of new commercial shop branches and to find the intersected location where their customers visit in common. Therefore, the companies can provide service improving customer satisfaction through the individual preference which is extracted from correlation among distinguished locations analyzed from mobility data.

Normally, personal location data can be divided into location clusters according to the data distribution, and movement patterns in each cluster vary depending on the individual's purpose and desire. It means that the location clusters imply individual lifestyles. By analyzing the correlation between the major location clusters, we could deduce the past visited points and predict the future visitations. This correlation is an important factor which is necessary for creating a new mobility route. Indeed, an appropriate data pre-processing is

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST) (NRF-2019R1F1A1056123).

required for training GAN with human location data. In data pre-processing work, we have partitioned personal mobility data, and utilized 4 layers of Convolutional Neural Networks (CNNs) to deliver features of the partitioned data. In data post-processing work, we adopted CNN to preserve essential location feature in the form of latitude and longitude by improving GAN performance. We introduce GAN for generating mobility routes. In this GAN, there are two representative Discriminator and Generator networks. These networks compare geopositioning features extracted from each mobility data with the generated probability distributions, while backpropagating the differences in each network. Discriminator learns the features extracted from the whole individual mobility route with extra mobility route, and improves ability to discriminate the fake route obtained from Generator and the real route from input dataset. Consequently, the self-creating GAN network, which ensures to enhance the discriminative features, can generate unexplored routes for area size of 3 square kilometer.

Section II will discuss the related researches on human mobility data with diverse approaches. In section III, we analysis our raw data, and section IV explains method we use on the data pre-processing and post-processing. Section V describes detailed methodology with proposed GAN. In section VI presents the result of generation route with our model. Section VII concludes our research and discusses about our future research.

## II. RELATED WORKS

In this section, we review previous investigations on human mobility patterns, which were focused on creating novel mobility route or next location by data mining. It is a typical approach to predict the next location of objects through mobility sequence tree generation by pattern mining the mobility of the object (Pfoser et al. 2000 ; Ying et al. 2011) [1] [2]. A further approach suggests the mobility tree which is expanded gradually by pattern mining (Gorawski and Jureczek. 2010) [3], and there is utilization with Location Based Service(LBS) to generate mobility patterns (Lee et al. 2004) [4]. Through such various methods, including mobility pattern tree generation and next location prediction, the combination of the probabilistic approach and data mining techniques has recently been

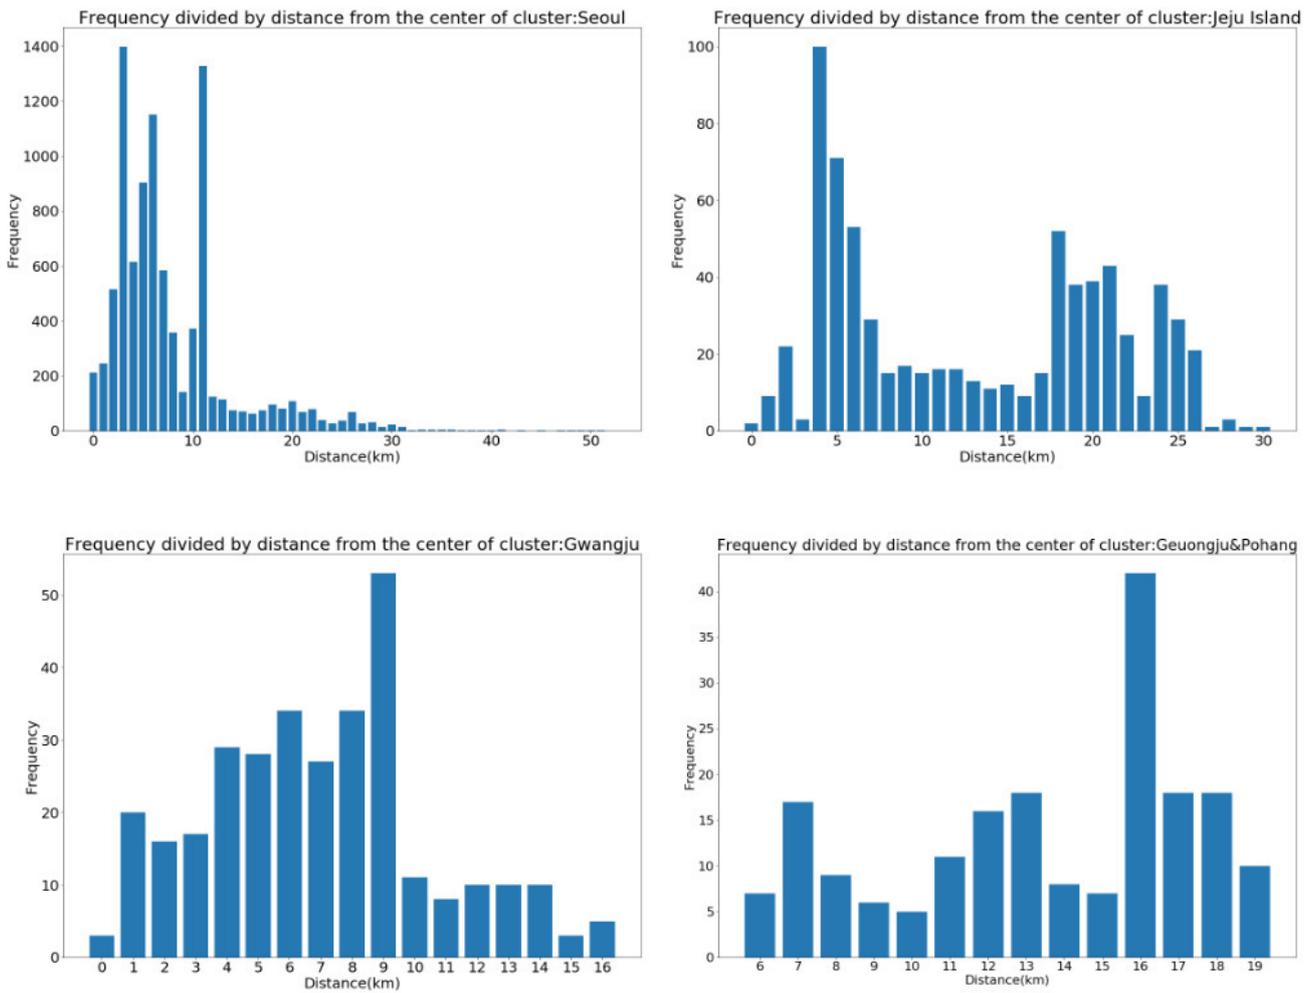

Fig. 1. Location Distribution inside Clusters

applied (Monreale et al. 2009 ; Jeung et al. 2008) [5] [6]. The graphs generated from the data mining results of accumulated trajectory patterns predict the next location (Morzy. 2006 ; Morzy. 2007) [7] [8]. Trajectory pattern can be utilized to mining past trajectories without trees, graphs or probability models (Giannotti et al. 2007) [9]. The success of combination of frequent trajectory and mobility rule for location prediction (Nhan and Ryu. 2006, Song and Choi. 2015) [10] [11] assumes diverse situations, such as disaster from the perspective of location prediction(Sudo et al. 2016) [12]. Markov chain-based approach has been applied on human mobility pattern and achieved remarkable performance on the next location prediction based on human mobility pattern(Baratchi et al. 2014) [13]. In the previous period, researchers have applied the data mining, trajectory pattern tree and Markov chain tools mainly.

From the view of GAN, GAN has achieved impressive outcomes in image generation (Alec Radford, Luke Metz, and Soumith Chintala. 2016) [14], image translation (Yunjey Choi

et al. 2018) [15], and there have been several recent researches to analysis synthetic data generation. Research regarding the activity patterns of neurons using GAN to generate the data can be found in (Molano-Mazon et al. 2018) [16]. Furthermore, movement trajectories based on socially acceptable behavior had been investigated as shown in (Gupta et al. 2018) [17]. Behavior includes passing or meeting of people during walking with parameters such as speed and direction. Current researchers for deep data generation on human mobility are (Alzantot, Chakraborty, and Srivastava. 2017) [18], using an architecture similar with GAN model, which is mixture of density networks to generate the acceleration time series data. However, this research did not use complete GAN architecture, and the input dataset of this research was not geopositioning data of trajectories but solely acceleration data. The purpose of our research is to generate novel mobility routes based on a plenty of daily mobility patterns.

TABLE I  
BASIC PROPERTIES OF LOCATION CLUSTERS

Cluster No.	Location	Center of Cluster(Latitude / Longitude)	Total Number of Data in Cluster
Cluster 0	Seoul	33.48852999 126.47904523	9668
Cluster 1	Jeju Island	33.44230848 126.52364544	728
Cluster 2	Gwangju	35.16296341 126.88780208	317
Cluster 3	KyeongJu, Pohang	35.93293456 129.31300085	191

### III. GEOPOSITIONING DATA ANALYSIS

The mobility data collected by positioning devices, such as smart phones, have the latitude, longitude and time information. The raw data we use are containing the location information of a specific object for more than three years.

#### A. Macroscopic View

In analyzing data from a macro perspective, the K-means clustering method is applied to extract largely four clusters based on location and density from the collected data distribution [19]. The basic properties of each location cluster are shown in table I. Fig. 1 shows histograms of the location points of each cluster. The frequency values are shown according to the distance between a center and positioning data in each location cluster [20]. Cluster 0 contains a relatively large number of location data, and this cluster reflects the location data in lifestyle. On the other hand, a low number of data is collected at cluster 1, 2, 3, and its result shows the irregular mobility pattern of object, such as a trip. This implies that the micro-mobility of an object indicates remarkable differences in each cluster depending on the purpose to visit.

#### B. Microscopic View

Understanding correlation between visited points is a starting point for expanding correlation between day-to-day movement trajectories. In cluster 0, there are mobility patterns on the movement of lifestyle, and the mobility patterns consist of visited points in object's daily life. To analyze correlation among distinguished points in cluster 0, it is necessary to extract past visited points. Distinguished points can be found applying K-means clustering algorithm to each day of the three-year full mobility data. Redundancies of 185 geographical points were eliminated, and the entire mobility pattern in cluster 0, made up of each major point, consists of about 2,700 distinguished points.

Learning connection between distinguished points and connection between each movement pattern, where the points are clustered, is identifying the mobility tendency of an object. Our GAN-based model will put daily movement patterns in Discriminator as input dataset, recognizing the existing patterns as real data, and will train dozens of times for Generator to generate mobility route similar to input dataset. This begins with the notion that a mobility route will be created based on object's mobility tendency.

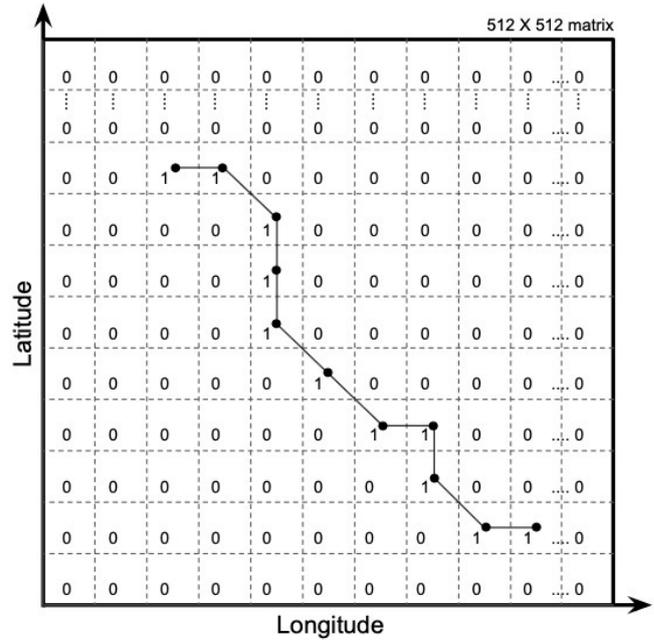

Fig. 2. Area Partitioning and mapping

### IV. GEOPOSITIONING DATA PROCESS

#### A. Data Pre-processing

As the wide range of location dataset is somewhat excessive for GAN model to train, proper data preprocessing is required. The unstructured raw data is initially informal structure, and could not apply to GAN model directly. The area is limited to the size of 3 kilometer in vertical length and 3 kilometer in horizontal length. The input dataset was structured using area partitioning method. The mobility patterns were partitioned as shown in Fig. 2. As a practical approach, area partitioning method can represent daily movement patterns as matrix. In detail, each visited area is mapped from intersection between the trajectory mobility pattern and unit areas. Each unit area size is about 0.06 square kilometer. By the characteristic of the ge positioning data, positioning error, such as value of latitude and longitude, is effectively found from the fifth decimal point of values. That is, eliminating the digits from the 6th to 11th decimal places do not distort the location information. We applied the round function through the area partitioning method. To preserve all positioning information in matrices, the CNN is utilized with 4 layers with each filter size of

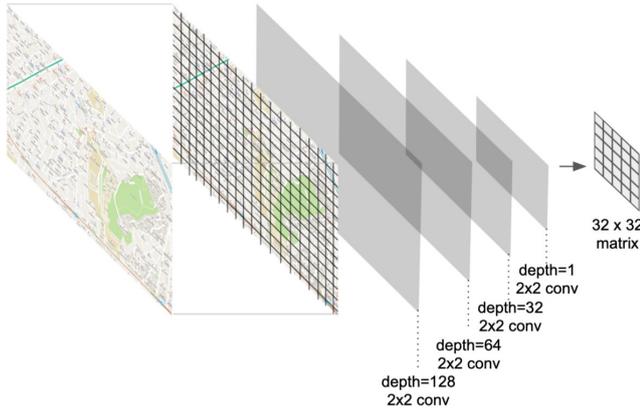

Fig. 3. Process of Convolution

2x2x128, 2x2x64, 2x2x32, and 2x2x1. In data convolution process, input data for GAN model are transformed to 32x32 sized matrices. This problem is solved by making the mobility data to pass multiple CNN layers with Leaky ReLU as an activation function which is convolution stage. Fig. 3 shows the process of convolution. The volume of input dataset was not enough to train the mobility patterns by our model, in detail, the individual accumulated daily mobility pattern. To improve this problem, synthetic inputs, which are extracted by randomly shuffling of 40% to 90% of input data, are duplicated so that GAN model can train various sets of input data. Through this augmentation method, insufficient input dataset amplified 100 times.

### B. Data Post-processing

The output of our GAN model is 32x32 sized matrices. In order to visualize output data on the map, deconvolution as post-processing is required. The CNN as deconvolution layers is used with 4 layers. In this deconvolution process, Nearest Neighbor function is utilized to resize process which transforms the output to 64x64, 128x128, 256x256 and 512x512 size step by step. Fig. 4 shows the steps of deconvolution toward visualization on geographical maps.

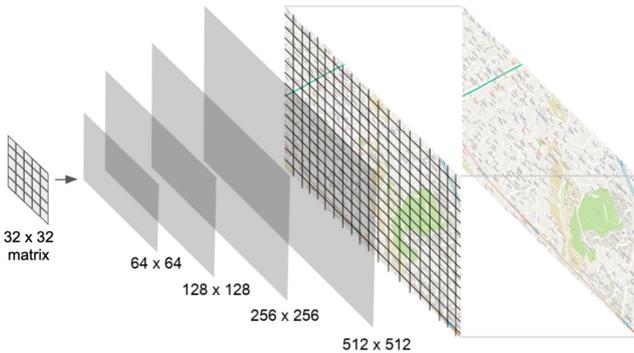

Fig. 4. Process of Deconvolution

## V. METHODOLOGY WITH GAN

GAN was firstly introduced from (Goodfellow et al. 2014) [21], which consists of a Generator and a Discriminator, structured by neural networks. The basic theory of GAN is started below the Non-Saturating game. In detail, the Discriminator minimizes the value of equation 1 and the Generator maximizes the value of equation 2. Generally, GAN model has the saturating issue, which occurs with initialization. Equation 3 will be used as an objective function to solve this issue (Fedus et al. 2017) [22].

$$\max_D \min_G V(D, G) = E_{x \sim p_{data}(x)} [\log D(x)] + E_{z \sim p_z(x)} [\log(1 - D(G(z)))] \quad (1)$$

$$\max_D \min_G V(D, G) = E_{z \sim p_z(x)} [\log(1 - D(G(z)))] \quad (2)$$

$$\min_G E_{z \sim p_z(x)} [\log(1 - D(G(z)))] = \max_G E_{z \sim p_z(x)} [\log D(G(z))] \quad (3)$$

We proposed GAN to generate diverse novel mobility routes. In this GAN, the two neural networks compete each other to improve ability to generate mobility route with latitude and longitude features. Discriminator tries to discriminate the real mobility route, training from the accumulated movement trajectory of object and exporting the probability value which is close to “1”, when the input data is distinguished as real data. On the other hand, the Generator has the random latent vector as input, and generates a matrix. Discriminator tries to compare each matrix generated from Generator with input dataset. When it is indistinguishable if the matrix is from Generator or input dataset, the Generator can suggest a novel route which put together a wide range of daily route. Fig. 6 and Fig. 7 shows our GAN architecture for experiment.

## VI. EXPERIMENT

### A. Test of Convolution and Deconvolution

Despite the data processing, we could find that the geopositioning data are preserved when the data are passed through convolution and deconvolution layer. Fig. 8 shows the original route, convolutionized route and deconvolutionized route as diagram. In test of convolution and deconvolution, fig. 9-(a) shows mapped route from raw data, and fig. 9-(b) shows route after deconvolution process without error. From this result, it is appropriate to apply convolution and deconvolution layer with GAN model.

### B. Experiment for Activation Function

In order to figure out the better result, generating route, we experimented with varying activation functions for Generator and Discriminator. Seven activation functions are applied in this work, such as ReLU, ReLU6, Softplus, Tanh, Softsign and eLU (Fig. 5) with 20,000 and 50,000 epoch. Among

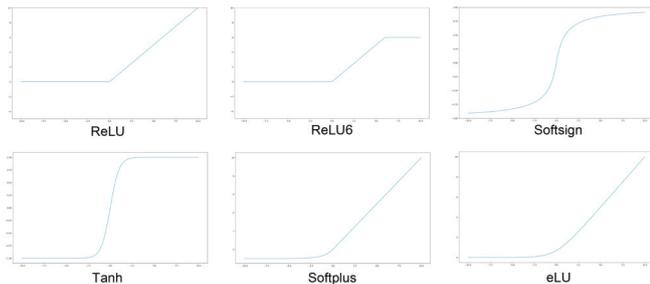

Fig. 5. Activation Functions

the result with the 7 activation functions, ReLU activation function made the worst output, and Tanh activation function made the best output. During training with ReLU, it has possibility to partially miss some positioning data. On the other hand, during training with Tanh, even if Tanh reduce the positioning data, the mobility route can be produced without missing positioning data. This is because the network of the model tends to partially lose its path data as it passes through the ReLU activation function while learning with the input paths. On the other hand, because Tanh minimizes the path as it passes the function and does not make it zero, the path consisting of frequency can be created without missing value. Fig. 10 shows the result with ReLU activation function for 20,000 and 50,000 epochs. Comparing between Fig. 10(a) and Fig. 10(b), ReLU formed accumulated path group. However, ReLU generates clusters rather than generating paths even if epoch increases. Fig. 11 shows the results of two epoch processes with 20,000 and 50,000 epochs with Tanh activation function. About 20,000 epochs, ambiguous paths are created. Approximately more than 50,000 epochs, trained Generator creates a new path. Since the inputs of GAN model are diverse, the outputs seem to be slightly different but suitable paths.

### C. Unexplored Route

Fig. 12 shows two routes generated by GAN. Fig. 12-(a) shows typical output generated. Fig. 12-(b) is not trivial output comparing to output shown in Fig. 10-(a). GAN generated normal routes and it also generated additional routes. That is GAN creates unexplored, new route.

## VII. CONCLUSION

We developed a method to generate human mobility routes based on Generative Adversarial Networks (GANs) which are specialized in image generation. We successfully trained GAN model on individual mobility data, and the model could suggest novel routes in about 3 square kilometer of area, reflecting preference of specific object. In addition, we show the possibility to train any extensive trajectory pattern instead of massive geopositioning data by applying CNN layers in front of the model. The essence of our research is that GAN model can train on the continuous sequential data, such as trajectory pattern and can generate mobility route with additional information. The purpose of this model is

to provide unexplored routes which is based on an object's daily mobile data. By training an object's mobile data, we could generate mobility routes, which the users are likely to explore in their future. Therefore, generated mobility routes are fundamental basis to individual recommendation system. By combining our model with Location Based Service (LBS) and Recommender Systems will allow us to provide whole new service to users. Users will be recommended places such as personalized restaurants, shops, and other utilities within unexplored generated mobility routes.

While the better purpose in our experiment is to create mobile route on random location, the model's ability to generate the route would be bounded with the high randomness. Additionally, we did not interconnect between mobility data and human behavior factor. Further, the biased mobility data, which is adhere to specific location such as school or workplace, caused drawbacks in the model training, and the application based on geolocation system has inherent error. As we mentioned the combination of human behavior factor such as hobby, job, personality, etc., the research that combines with personal factor with our method would be an advanced method to generate mobility route more connected with mobility tendency, offering the personal customized solution. In future work, we aim to apply social media service which includes personal behavior features. It would be possible to identify the purpose of movement and specific time period. This can be expanded from individual to group with similar personality. As a result, it would be possible to create mobility route which is more customer-oriented.

**Abstract**— Human Activity Recognition (HAR) is an important area of research in ambient intelligence for various contexts such as ambient-assisted living. The existing HAR approaches are mostly based either on vision, mobile or wearable sensors. In this paper, we propose a hybrid approach for HAR by combining three types of sensing technologies, namely: smartphone accelerometer, RGB cameras and ambient sensors. Acceleration and video streams are analyzed using multiclass Support Vector Machine (SVM) and Convolutional Neural Networks, respectively. Such an analysis is improved with the ambient sensing data to assign semantics to human activities using description logic rules. For integration, we design and implement a Framework to address human activity recognition pipeline from the data collection phase until activity recognition and visualization. The various use cases and performance evaluations of the proposed approach show clearly its utility and efficiency in several everyday scenarios.

## I. INTRODUCTION

The combination of the Ambient Intelligence and the Internet of Things [1] aims at building smart environments by integrating a variety of interconnected devices such as camera, smartphone, smart watch and actuator. Such a sensing and actuating technology, has allowed to the analysis of human daily activities to become easier and straightforward. Particularly, in smartly controlled environments such as smart home, HAR can be envisioned for several potential applications and different contexts including security, healthcare, ambient assisted living and behavior analysis. For instance, many HAR systems surveyed in [2, 3], where the authors focus on different activities (walking, running, cooking, exercising, etc.) in different application domains.

In practice, there are diverse ways of using sensors for human activity recognition in a smart environment. Hence, the existing approaches can be divided into two main categories, namely: vision-based and sensors-based approaches. In the former approaches, the primitive actions of an activity are detected by analyzing the images transmitted by an RGB camera. Such an analysis can exploit computer vision techniques to recognize patterns. Whereas the latter approaches (sensor-based) use sensors that are either worn by a person or placed on everyday objects. Wearable sensors can be placed on clothing, in a pocket, or stuck directly to the body (wrist, hip or torso) to provide valuable information about an individual's degree of functional ability and lifestyle [4]. Indeed, sensors' position

should be well chosen in order to ensure their usability while offering a maximum comfort to the user. In addition, sensors can be placed seamlessly on ordinary objects to detect and control the environment. They can also be of different types such as: contact detectors to give the state (close/open) of doors and cabinets, pressure mats to indicate the position of the person in the room or to detect if a person is sitting on a sofa or laying on a bed, RFID tags to give the location of objects, etc. According to a recent study [5], the RGB cameras have lower popularity when compared to depth sensors and wearable devices in HAR research.

In order to implement a HAR system, the data collected and transmitted by various cameras and sensors disseminated in the smart environment can be analyzed using several techniques in either vision or sensors-based approaches. Regarding vision-based approaches, a survey of action recognition approaches based on Space-Time Interest Points (STIP) was proposed in [6]. Most recent approaches are based on Convolutional Neural Networks (CNNs) including Deep Convolutional Networks (ConvNets) [7] and TwoStream [8]. These deep learning methods aim to learn automatically the semantic representation of raw videos by using a deep neural network in a discriminatory manner from a large number of tagged data. For analyzing real-time videos, Recurrent Neural Networks (RNN) among which there are Long Short-Term Memory (LSTM) units have been proposed. LSTM networks have proved their effectiveness in several areas such as: images and videos subtitling [9] and temporal information of movements and videos streams. Regarding sensors-based approaches, a deep ConvNet was also used in [10] to perform HAR using smartphone sensors by exploiting the inherent characteristics of activities. In [11], acceleration streamed by a smartphone are analyzed with K-Nearest Neighbors (KNN) for recognizing several types of activities (walking, climbing, sitting, standing and falling down). In [12], data from inertial and pressure sensors placed on the trunk of a patient are used to recognize activities such as walking, sleeping and climbing stairs. In [13], Hidden Markov Model (HMM) is used to classify complex actions such as running, walking or laying, using the accelerometer data of a wristwatch. In [14], simple and complex activities such as cleaning, hand washing, and plant watering are recognized using fixed window lengths with an overlapping halved window. In [15], human activity recognition is analyzed

through the segmentation of the multidimensional time series of acceleration data based on a specific multiple regression model. In [16], a digital low-pass filter is designed to recognize certain types of human physical activities using acceleration data. In [17], the selection and placement of wearable sensors is investigated for classifying sixteen activities of daily living for six healthy subjects.

The aforementioned discussed works show that most of the proposed approaches recognize simple human activities such as laying, sitting, and standing. Moreover, these approaches focus on the data received from either cameras or other sensors without a real combination of the different modalities that can become unavailable due to their temporary or permanent disappearance, and should therefore, be replaced to ensure HAR continuity. Furthermore, contextual information such as localization, acceleration and object state provided by mobile or wearable sensors combined with machine learning methods offer a higher accuracy and diversity for recognizing complex human activities (watching TV, cooking, exercising, etc.).

We propose a hybrid approach for HAR in an ambient environment by combining three types of sensing technologies, namely: smartphone accelerometer, RGB cameras and ambient sensors. First, real time accelerations and video streams are analyzed separately using machine learning algorithms to detect and recognize simple human activities or postures. Video streams are used by default for indoor spaces, but they are replaced by smartphone accelerometer data in the case of inaccessible cameras. Switching between these two modes can considerably increase the reliability of the designed HAR system. Second, additional information is extracted from the available activated ambient sensors to assign semantics to human activity using Description Logic (DL) rules. Finally, the three types of the provided information are combined inside a HAR framework using supervised machine learning algorithms in order to recognize and visualize more complex activities.

The remainder of the paper is organized as follows. In Section 2, we describe our acceleration-based activity recognition method. In Section 3, the video-based activity recognition method is explained. In Section 4, we present the hybrid approach and the designed framework for complex activity recognition. In section 5, we conduct several validation scenarios for the recognition of everyday activities. The paper is concluded with section 6, and potential future works are announced.

## II. ACCELERATION BASED ACTIVITY RECOGNITION

The acceleration data along the three axes ( $x$ ,  $y$ , and  $z$ ) is collected from a smartphone worn on the waistband of the user's pelvis. This data collection operation is performed by an Android application with a sampling rate of 50 Hz, i.e. the data is divided into a window of 50 records per second. We distinguished six (6) classes of elementary actions or postures namely: sitting, standing, running, walking, walking upstairs and walking downstairs. We collected 500 records for each class. For a better distinction between the different classes, we chose, as an input to our machine learning model, a vector of 30 characteristics such as average, variance, and min-max with respect to  $x$ ,  $y$  and  $z$ ; resulting average of the acceleration; AR-

coefficient; Angle Tilt; and Signal Magnitude Area (SMA) [18]. We opted for this choice after performing several tests by combining these different characteristics. For each combination, we calculate classification success rate. These characteristics ensure a high degree of independence between the different classes and minimize the correlation between them. When constructing the learning model, we tested six (06) learning algorithms, which were Naïve Bayes, SVM with linear kernel, SVM with rbf kernel, nonlinear SVM, k-Nearest Neighbors (kNN) and MultiLayer Perceptron (MLP) with a single hidden layer. The success rates obtained from these algorithms are shown in the **Table I**. The latter shows that SVM with linear kernel gives the best performance (93%).

TABLE I. SUCCESS RATE OF THE TESTED ALGORITHMS

Approach	Success rate
Naïve Bayes	92%
SVM with linear kernel	<b>93%</b>
SVM with rbf kernel	90%
Nonlinear SVM	92%
k-Nearest Neighbors (kNN)	87%
MultiLayer Perceptron (MLP)	87%

## III. VISION BASED ACTIVITY RECOGNITION

### A. Dataset construction

The dataset is constructed using two different sources: Multiple Pose Human Body Database (LSP / MPII-MPHB) [19] and other data that we gathered from Google Image search engine. First, the LSP / MPII-MPHB contains 26675 images and 29732 human bodies that are divided into six (06) action categories: curving, knee, laying, occlusion, sitting and standing. For each image, we detect the persons using the Single Shot MultiBox Detector (SSD) method [20], which is a unified Framework for detecting objects with a single neural network. We focus only on three main postures: standing, sitting and laying. Then, we used Google Image search facility to retrieve all possible images for these three main postures.

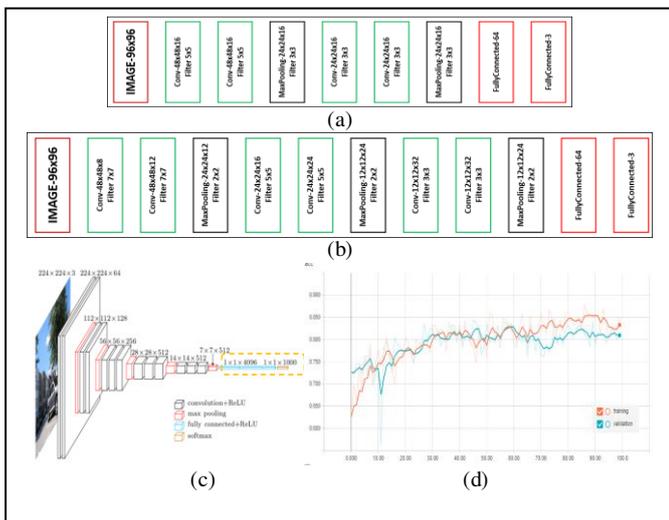

After building the dataset, we obtain a considerable number of images for each action or posture category. The images represent the inputs of the learning model while the actions represent the classes respective to the outputs. Thus, in order to standardize and reduce the size of the training data and to speed up their processing, we perform a pre-processing on all the input images. First, each image is stored with a reduced size of 224x224 pixels and three channels representing the values of the three colors: red, green and blue. Then, the images are normalized and scaled at loading time by a centering and reduction transformation in the interval [-1,1]. Finally, we split the images into three folders: sitting, standing and laying down to assign them to the different classes. In order to feed our learning model, we transformed the set of images into a four-dimensional (height 224 pixels, width 224 pixels and the three-color channels) tensor and the class labels into a one-dimensional vector.

### B. Learning model

We proposed two architectures of convolutional neural networks, where each is composed of several layers of different

types. We also tested a learning method based on the transfer of parameters. These relatively deep architectures have a structure inspired by that of the VGGNet network [20]. The difference between them lies in the depth and the number of hyperparameters. Both architectures are composed of large blocks; where the initial blocks are constituted of two convolutional layers followed by a pooling layer, and the last ones are composed of only dense layers. The depth of the convolutional layers increases from one block to another, although the spatial size of the filters decreases. The choice of convolutional layers comes from the fact that they are the most adapted to image recognition tasks as they consider the multidimensional aspect of images. Moreover, each neuron in these layers is connected to just a small set of neurons in the preceding layer, the number of learnable parameters is therefore smaller due to the parameter sharing property of convolution. The  $z$  outputs of each convolutional layer are filtered by the Rectified Linear Unit (ReLU) activation function.

Fig. 1. Our activity recognition architectures, (a), Architecture 1, (b) Architecture 2, (c) Architecture 3, (d) Results of our activity recognition CNN

A maxpooling layer follows each pair of convolutional layers. These layers lead to the reduction of the dimensions of the feature maps by applying the *max* function on a window of neighboring pixels at a given region of the image. Therefore, the maxpooling reduces the intraclass variance by discarding the unnecessary information. At the last level of the network, a dense layer is considered in order to gather all the features detected throughout the network. The output layer is also a dense layer whose number of neurons is equal to the number of classes (in our case, the number of classes is set to 3). The  $z$  results are passed through a *softmax* function in order to be squashed into the interval  $[0,1]$  leading to a probability distribution over the classes. The reason why the stacked architecture is preferable is that the first layers detect low-level features (such as edges and simple shapes) whereas the deeper ones detect high-level features (such as complex shapes and objects).

In what follows, we present the three architectures that we proposed and tested in the light of this contribution.

### C. Architecture 1

The first block of the network consists of two convolutional layers having each a depth of 16 feature maps and a filter size of  $5 \times 5$ , with stride 1 horizontally and vertically, and zero padding on all four edges. These layers are followed by a maxpooling layer with a filter of size  $2 \times 2$  and a step of 2, meaning that we reduce the dimensions of the input by a half. The second block is identical to the first one except that the depth of each convolutional layer is 32 instead of 16 and the size of the convolution filter is  $3 \times 3$ .

The third block, is a dense layer of 64 neurons connected to all the outputs from the previous maxpooling layer. The output layer is of size 3, where each neuron corresponds to a class. **Figure 1 (a)** illustrates Architecture 1. The green rectangles represent the convolutional layers, the blacks represent the pooling layers, and the reds represent the dense layers.

### D. Architecture 2

This architecture is similar to the first one but it is composed of four main blocks. The first block encompasses two convolutional layers with a filter of  $7 \times 7$  and a depth of 8 and 12, respectively. The second contains similar layers whose filter size is  $5 \times 5$  and depths is 16 and 24, respectively. The two layers of the last block have a  $3 \times 3$  filter and a depth of 32 each. Similarly, a pooling layer follows each pair of convolutional layers in all the blocks. Identically to the previous architecture, this one contains a dense layer of 64 neurons in the last block (see **Figure 1 (b)**).

### E. Architecture 3

The first two architectures, that we proposed, are prone to overfitting because the training dataset is small compared to the size of the network. In order to avoid such a drawback, we used a Transfer Learning approach and we augmented our dataset by applying several image transformations. We initialized the new model with the weights of VGG16 network trained on our dataset. During the training, we maintained a fixed number of layers (the first convolutional layers) and we optimized the parameters of the latter ones. Our purpose is to reduce optimization space dimension, whilst reusing the first convolutional blocks. The latter are most likely to remain similar regardless of the problem at hand, and the model must be able to fit specific top-level layers. We adapted the dense layer with our classes of actions. **Figure 1 (c)** shows the modifications made to the VGG16 architecture for transfer learning. Our best results for activity recognition were obtained with the third architecture (**Figure 1 (c)**).

### F. Cost function and the optimizer

The neural networks are general functions estimators. Nevertheless, their estimation is never perfect as there is always a discrepancy between the output of the network and the ground truth values. Therefore, we define a cost function to measure the error and we adapt an optimization algorithm to minimize its value. Given the transformation of this problem into a classification task, the most appropriate interclass error measure is the cross-entropy function [21]. The learning is achieved by minimizing the norm of the cross-entropy with gradient descent algorithm. Such an algorithm

consists in changing the weights of the network by a factor of a fixed learning rate. We chose the *Adadelta* [22] optimizer as it does not depend.

#### G. Training platform and implementation

One of the major problems in deep learning is the significant requirement for computation resources during the training. In order to alleviate this problem, we trained our algorithm on a machine equipped with a Nvidia GTX 860 GPU and 12Gb of RAM. For the purpose of robustness and versatility, we implemented our CNN in Python3 using TensorFlow library. This library runs a low-level C++ routine, which are able to perform massively parallel computations using all the available processing power and benefiting from the existing hardware vectorization of the GPU. Training and validation progress can be seen in **Figure 1 (d)**

#### IV. HYBRID APPROACH FOR HUMAN ACTIVITY RECOGNITION

The two previously presented models, based on accelerometer and camera, are able to recognize elementary actions or postures of the person (e.g., standing, sitting and laying) while an activity is defined as a task of daily life that the person performs over a given time interval. Thus, other contextual information can complement the information of the posture to deduce the effective activity. The localization of the subject, for example, is an essential attribute, due to the fact that most activities are carried out in a specific room. For instance, the "cooking" activity takes place in the kitchen while "Watching TV" is more likely to appear in the living room. In addition, the posture of the person is a influential factor to recognize an activity. We cannot imagine, for example, a person sleeping in a "standing" posture. It should also be noted that the actions related to a particular activity can activate or deactivate a number of ambient sensors. In order to represent all these causal relationships, we used DL rules to infer five main activities namely: watching TV, sleeping, preparing a meal, communicating (talking on the phone) and working with a laptop or PC. For example, the activity "Sleeping" can be inferred using the two DL rules shown in **Table II**.

TABLE II. EXAMPLE OF DL RULES FOR "SLEEPING" ACTIVITY

$\text{Sleeping} \equiv \text{Posture}(\text{laying\_down}) \cap$ $\text{Location}(\text{bedroom}) \cap$ $\text{AmbientSensors}(\text{Bed}).\text{HasStatus}(\text{On}) \cap$ $\text{AmbientSensors}(\text{Light}).\text{HasStatus}(\text{Off})$
$\text{Sleeping} \equiv \text{Posture}(\text{laying\_down}) \cap$ $\text{Location}(\text{living\_room}) \cap$ $\text{AmbientSensors}(\text{Sofa}).\text{HasStatus}(\text{On}) \cap$ $\text{AmbientSensors}(\text{Light}).\text{HasStatus}(\text{Off}) \cap$ $\text{AmbientSensors}(\text{TV}).\text{HasStatus}(\text{Off})$

Since we can have several rules for the same activity, we transformed these rules to a description vector containing posture, location and the state of the other sensors as shown in **Table III**. Hence, all the data contained in description vectors summarize a temporal window. Such vectors are used as an input for the SVM algorithm with linear kernel and their

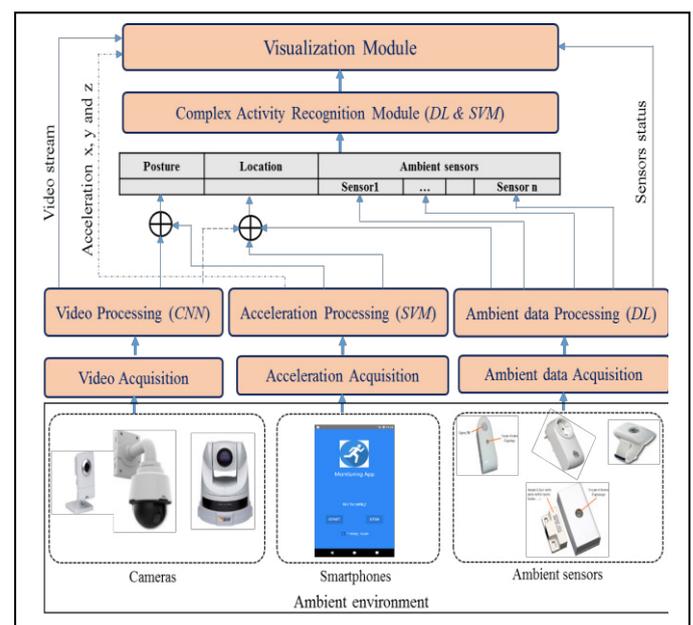

corresponding activities, in DL rules, represent the output. The supervised learning model is constructed by generating a set of input vectors with the identifier of the corresponding class or activity. These vectors contain the different possible combinations of values regarding the considered characteristics. For example, in "Watching TV" activity, the generated posture can be "sitting" or "laying down". If a feature vector does not match any of the existing classes, the person's activity is considered as "Unknown".

TABLE III. STRUCTURE OF THE INPUT LEARNING VECTOR

Posture	Location	Ambient sensors			
		Sensor1	...	Sensor n	

We developed a framework for human activity recognition in ambient environment. As shown in **Figure 2**, the general architecture of the proposed framework allows data acquisition and processing as well as activity recognition and visualization. First, heterogeneous data are collected using different sensing modalities, namely: cameras for real-time video streams, the various sensors of the Smartphone (accelerometer, gyroscope, etc.) as well as the others ambient environment sensors (pressure, temperature, humidity, light, movement, etc.). Then, collected data are processed separately using CNN, SVM and DL respectively for video, acceleration and ambient sensors. We should notice that the posture is recognized, by default, using video stream, but automatic switching to acceleration is performed in case of cameras unavailability to ensure service continuity. The location can be also deduced from cameras and smartphones' position or provided by other sensors. Finally, a description vector is constructed from all the previous processed data and used as input of the machine learning model to recognize more complex activities. The recognized activity along with the collected data from camera, smartphone and ambient sensors are transmitted to the visualization module for display and monitoring in real time.

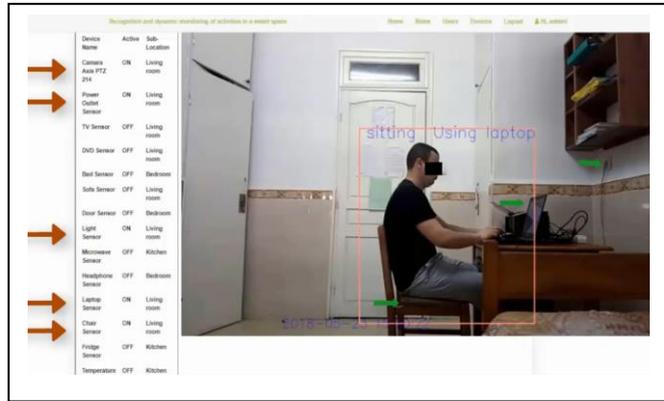

Fig. 2. Global architecture of the designed HAR Framework

V. IMPLEMENTATION AND USE CASES SCENARIOS

The proposed Framework has been applied in several situations for human activity recognition. For example, **Figure 3** shows a person using a personal computer. This activity is recognized with the combination of several information: the posture is "sitting", the location is "office", the pressure sensor on the chair is activated "ON" and the laptop is "ON".

Fig. 3. Example of recognized activity "Working with laptop"

Regarding the performance evaluation, we achieved a success rate of 97% after several classification tests of the proposed HAR approach of the designed framework. As shown in the **Table IV**, our approach gives a better result considering five classes of activities and several multi-source data (ambient sensors, cameras and acceleration). The result of 98.2% obtained in [12] is due to the fact that the authors used the acceleration by considering only three classes of activities which further minimizes the ambiguity between classes.

TABLE IV. COMPARISON OF SUCCESS RATES OF ACTIVITY RECOGNITION

Approach	Devices	Classifier	Success rate
[12]	Inertial and barometric sensor	KNN	98.2%
[13]	Accelerometer of a wristwatch	HMM, CRF	90.4%
[15]	Accelerometer on Chest, Thigh and Ankle	Multiple regression model	90.3%
[16]	Accelerometer on Hand and pocket	digital low-pass filter	91.15%
[17]	Pressure sensor	KNN	89.08%
Our approach	Cameras, smartphone, ambient sensors	CNN, DL and SVM with linear kernel	97%

VI. CONCLUSION AND FUTURE WORK

We proposed a hybrid solution for human activity recognition using smartphone inertial sensors (accelerometers), RGB cameras and ambient sensors (pressure, localization, etc.). Acceleration data and videos were analyzed using machine learning algorithms, SVM and CNN in order to detect the current potential posture of the person. Such an analysis is augmented with ambient sensor data to assign semantics to the human activity based on description logic rules. A HAR framework is also designed to build the whole pipeline from data collection until activity recognition and visualization. We

are currently working to use our approach in the context of ambient-assisted living to assist elderly or dependent persons to improve their quality-of-life. Future works will include further experimentation and combination of other techniques such as automatic image captioning using deep learning.

**Abstract**—Since the plastic surgery should consider that facial impression is always dependent on current facial emotion, it came to be verified how precise classification of facial images into sets of defined facial emotions is.

Multivariate regression was performed using R language to identify indicators increasing facial attractiveness after undergoing rhinoplasty. Bayesian naive classifiers, decision trees (CART) and neural networks, respectively, were applied to assign a landmarked facial image data into one of the facial emotions, based on Ekman-Friesen FACS scale.

Enlargement of nasolabial and nasofrontal angle within rhinoplasty significantly predicts facial attractiveness increasing ( $p < 0.05$ ). Decision trees showed the geometry of a mouth, then eyebrows and finally eyes affect in this descending order an impact on classified emotion. Neural networks proved the highest accuracy of the classification.

Performed machine-learning analyses pointed out which geometric facial features increase facial attractiveness the most and should be consequently treated by plastic surgeries.

## I. INTRODUCTION

**F**ACIAL attractiveness was evaluated far earlier than origins of plastic facial surgery are dated. Whereas origins of plastic facial surgery are related to the First World War (1914–1918), human facial attractiveness received attention from ancient philosophers Polykleitos and Aristotle (4–3 century BC) [1]. Ancient classical rules were defined only subjectively and were strongly limited to the Caucasian race facial appearance as well as based only on viewing of beauty by a naked eye [1].

During the period of Renaissance, Leonardo Da Vinci modernized the classical rules of facial attractiveness viewing and refined them into so-called Neoclassical facial canons, based on the ancient principles. Neoclassical facial canons served mostly for contemporary artists and consisted of nine simple mathematical rules in the terms of *a subtraction or proportion of two linear facial distances should be equaled to a fixed constant*, e. g. “a maximal nose width should be one quarter of overall width of a face” etc.

The rules of the Neoclassical facial canons are still applied – if technically possible – to current plastic facial surgery procedures. An idea that some proportions of selected two different facial distances should be approximately equal to the golden ratio  $\left(\frac{\sqrt{5}-1}{2}\right)$ , is typical for the Neoclassical canons [2]. Similarly, flawlessly or nearly-perfectly axially-symmetric faces [3] and faces very similar to the *mean face of a population*, i. e. morphed facial shapes based on graphical averaging all facial control points of a bunch of faces using the given population, are generally considered as attractive ones [4]. Signs of human faces called *neoteny* (juvenilization), i. e. relative large eye and small mouth sizes, are also associated with a higher level of attractiveness [5]. Finally, sexual dimorphism plays a role in the perception of human facial attractiveness – both male faces with prevailing masculine facial geometry and female faces with prevailing feminine facial geometry are seems to be evaluated as more attractive [6].

All the mentioned rules, the Neoclassical Canon inclusively, are still commonly applied in nowadays plastic facial surgery procedures, including rhinoplasty, and – what is more – they are the principal (or even only) ways of how operational strategies are planned. However, saying this, data-driven approach to techniques covered by plastic facial surgery is the one whose time has to come [7].

Current demands of patients undergoing plastic facial surgeries include wishes handling with a not only improvement of “static” facial features such as corrections of nasal size or shape (rhinoplasty), but also changes for the better of the “dynamic” facial expression, e. g. surgical changes of mouth in order to make a smile more facial-appealing and to increase the facial attractiveness level for only moments when a patient’s face is smiling [7]. This is why movements of facial muscles during emotion expression and their connection to the facial impressions should be taken into account even in plastic facial surgery.

The observation that total human face impression is always dependent on present expressed facial emotion was first taken into consideration by Charles Darwin; Charles Darwin claimed there is a limited and universal set of facial emotions expressed by all higher mammals [8].

American psychologist Silvan Solomon Tomkins extended the idea by analyzing human facial emotions deeper in detail; he declared that specific facial expressions are uniquely linked to individual emotions and, not only but also, asserted that emotions are easily comprehensible across races, ethnic groups, and cultures [9].

In 1971, two psychologists Paul Ekman and Wallace Friesen established a classification of human facial impressions based on six (“clusters” of) emotions, (happiness, sadness, surprise, fear, anger, disgust) [10] and in 90’s they improved their classification of emotions by development of a well-known system called Facial Action Coding System (FACS). The system is based on movements of individual facial muscles which determine the resulting emotion in a form perceived by an observer [11].

In contradiction to the previous, also called *functional* approach how to classify human facial impressions into the appropriate emotions, there is another strategy, a *morphological* way – which is based on simple description of facial geometry [11].

Recognition techniques of human facial emotions come from a general human face image recognition techniques and can be divided into three phases [12]:

- (i) face detection and localization;
- (ii) extraction of appropriate face features;
- (iii) classification of a facial expression into a facial emotion.

The first phase, *face detection and localization*, could apply an *expert method* (e. g. left and right eye are both symmetric and of similar size, etc.) [13], a *feature invariant method* (e. g. eyes, nose, and mouth is detected by human perceiver regardless of an angle of view or intensity of current lighting), an *appearance-based method* (when face image is compared to face templates generated by a machine-learning algorithm) [14], [15].

The second phase, *extraction of appropriate face features*, can be done via *Gabor wavelets method* [16], an *image intensity analysis*, a *principal component analysis* (PCA), an *active appearance model* [17], or *graph models* [17], respectively, including also the well-known Marquardt mask.

Finally, the third phase, *classification of facial expression into emotion cluster*, is one of so-called *classification problem* and belongs to the families of machine-learning algorithms. It can be performed by rule-based classifiers [18], model-comparing classifiers [18] or machine-learning classifiers [18].

To conclude this up, aims of this study therefore are

- (i) to detect which facial geometric features and their surgical corrections are connected with increased facial attractiveness level in patients undergoing rhinoplasty;
- (ii) to work out and test a system of facial expressions based on FACS, so that it could be used for classification

of facial images into facial emotions – this could be a promising starting point for analysis of relations between facial expressions based on facial muscles geometry and movement, and facial emotions, respectively.

The second point (ii) seems to be crucial for planning of facial surgical procedures – whereas real structures such as facial muscles are already objects of surgical interventions, changes for the better in facial expressions should be in fact the desired results of the surgical procedures. However, the relations are not obvious, and machine-learning classification of facial emotions could be one of the first steps in the process of their clarification.

## II. RESEARCH MATERIAL AND METHODOLOGY

Patients who attended the Department of Plastic Surgery, First Faculty of Medicine, Charles University, Prague and Na Bulovce Hospital were asked to join the study and informed enough about all details of the study. There were precisely 30 patients in total who underwent the rhinoplasty surgery and were eligible to join the study. A portrait and profile picture of each of them was taken and stored in a secured database.

There is another sample of 12 patients (all of them are students at the Faculty of Biomedical Engineering, Czech Technical University in Prague) whose portrait and profile images were taken just at the moment they shew a facial expression according to the given incentive. An overview of the facial expressions is in Table I. The total number of their pictures is therefore equal to  $12 \times 14 = 168$ .

TABLE I  
RELATIONS BETWEEN THE FACIAL EMOTIONS AND THE THEIR QUALITY

facial emotion	quality
contact	positive
helpfulness	positive
evocation	positive
defence	negative
aggression	negative
reaction	neutral
decision	neutral
well-being	positive
fun	positive
rejection	negative
depression	negative
fear	negative
deliberation	positive
expectation	positive

*Data of Interests:* Besides the facial image data described one paragraph above, a seven-level Likert scale following the values of  $(-3, -2, -1, 0, +1, +2, +3)$  (the higher score, the more attractive is a face considered to be) was used to evaluate each photography of each patient before and after undergoing the rhinoplasty. There was a board of 14 independent evaluators doing the evaluation.

The facial emotions we used in the study are based on the Facial Action Coding System (FACS), but has been improved a bit. We defined 14 clusters of emotions in total – *contact*, *helpfulness*, *evocation*, *defence*, *aggression*, *reaction*, *decision*,

*well-being, fun, rejection, depression, fear, deliberation, and expectation*, respectively [19], [20].

Furthermore, we defined a *quality* of facial emotions such that each one of the emotions is either positive, negative or neutral, respectively, according to an average effect on a perceiver (and stated by an expert).

Relations between the facial emotions and the quality of the facial emotions, following the way how they were used in the study, are shown in Table I.

*Landmarking:* Landmarks can be defined as morphometrically essential points on a plane of a facial image. Overview of the landmarks of our interest is in the Fig. 1. Landmarks were plotted manually using proprietary program written in C#, by which the coordinates of all of them were collected. The landmarks were also obtained as well using an experimental application written in R language [21] which is able to bridge a well-known C++ library called `dlib` [22]; the `dlib` enables to use automatic facial landmarking. After the gathering of all landmarks' coordinates, for  $i$ -th landmark, where  $i \in \{1, 2, 3, \dots\}$ , with original coordinates  $[x_i, y_i]$ , new standardized coordinates  $[x'_i, y'_i]$  were computed in the terms of

$$x'_i = \frac{x_i - \min_{j \in \{1, 2, 3, \dots\}} \{x_j\}}{\max_{j \in \{1, 2, 3, \dots\}} \{x_j\} - \min_{j \in \{1, 2, 3, \dots\}} \{x_j\}}$$

$$y'_i = \frac{y_i - \min_{j \in \{1, 2, 3, \dots\}} \{y_j\}}{\max_{j \in \{1, 2, 3, \dots\}} \{y_j\} - \min_{j \in \{1, 2, 3, \dots\}} \{y_j\}},$$

assuming that all faces taken in the images are of equal size. The described transformation of coordinates (*standardization*) allows us to compare feasibly enough any two face portraits themselves (their transformed coordinates  $[x'_i, y'_i]$ ), and any two face profiles themselves (their transformed coordinates  $[x'_i, y'_i]$ ), respectively.

There are some of the derived metrics and angles calculated using the transformed coordinates of the landmarks in Table II (definitions of the landmarks are shown in Fig. 1).

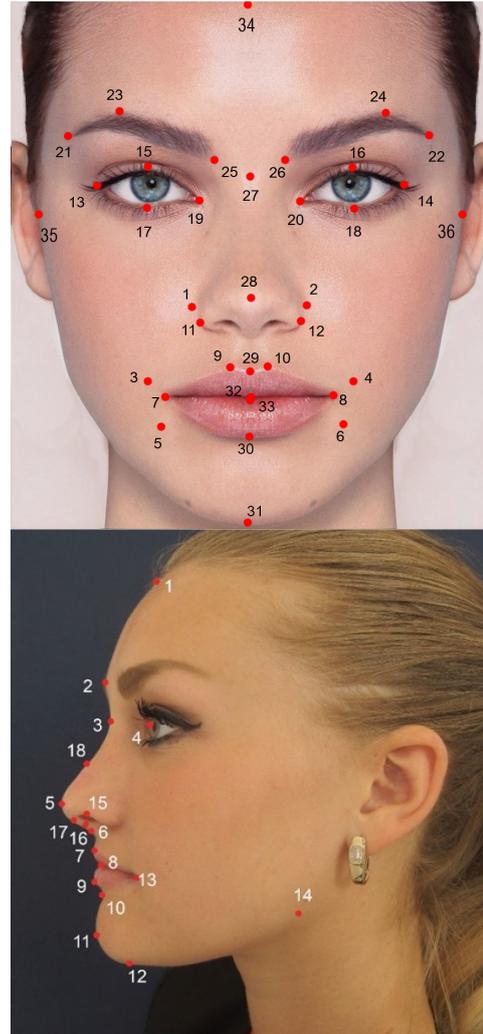

Fig. 1. Landmarks of a face portrait and a face profile

*Statistical Analysis:* Outputs with  $p$ -values below (or very “close” to) 0.05 were considered as statistically significant. All statistical analyses were performed using R language for statistical computing and graphics [21].

A multivariate regression analysis was carried out in order to identify which predictors, i. e. derived metrics or angles (see Table II for more details) statistically significantly affect an average difference of the attractiveness' Likert scores after and before the rhinoplasty undergoing [23].

Additionally, Bayesian naive classifiers [24], CART – classification and regression trees [25] and neural networks using backpropagation with sigmoidal activating function [26] were applied to classify an image of a human face (portrait) into one of the facial emotions, and as well into one of the levels of the quality of facial emotions (and even into some more parameters of emotions not discussed in this paper).

Performances of predictive accuracy of the previously mentioned three methods are reported as confusion matrices or as 95 % confidence intervals. Grant total sum of each of the confusion matrices is equal to  $12 \times 14 = 168$ , i. e. a number of

TABLE II  
SOME OF THE DERIVED METRICS AND ANGLES CALCULATED USING THE TRANSFORMED COORDINATES OF THE LANDMARKS

metrics/angles	definition
nasofrontal angle	angle between landmarks 2, 3, 18 (profile)
nasolabial angle	angle between landmarks 7, 6, 17 (profile)
nasal tip	horizontal Euclidean distance between landmarks 6, 5 (profile)
nostril prominence	Euclidean distance between landmarks 15, 16 (profile)
cornea-nasion distance	horizontal Euclidean distance between landmarks 3, 4 (profile)
outer eyebrow	Euclidean distance between landmarks 21, 22 (portrait)
inner eyebrow	Euclidean distance between landmarks 25, 26 (portrait)

cornea-nasion distance <sub>after-before</sub>	-0.014	0.035	0.694

individuals multiplied by a number of pictures per individual.

### III. RESULTS AND DISCUSSION

A summary of the multivariate linear regression is shown in Table III. As we can see from the Table III, the mean increase of facial attractiveness level after undergoing the rhinoplasty is about 3.8 Likert point,  $p = 0.043$ . Moreover, per each radian of nasofrontal angle enlargement, there is an expectation of mean increase about 0.353 Likert point in facial attractiveness after undergoing the rhinoplasty (when a patient went through this kind of correction),  $p = 0.050$ . Similarly, per each radian of nasolabial angle enlargement, there is an expectation of mean increase about 0.439 Likert point in facial attractiveness after undergoing the rhinoplasty (again, this can be true if and only if this kind of correction is even applied to a patient),  $p = 0.057$ .

As we expected, the larger both nasofrontal and nasolabial angles corrections are, the higher score of attractiveness level such a face obtains. Furthermore, the two mentioned angles are the main corrections which could be done within a routine rhinoplasty procedure. Of course, these results are limited. For instance, if both angles, nasofrontal and nasolabial one would be considered as straight angles, a nose would “disappear” under these conditions instead of expected facial attractiveness level increasing as stated above.

There are confusion matrices of the prediction of the emotional quality based both on Bayesian naive classifier (Table IV) and neural network (Table V). Confusion matrices of the prediction of the facial emotions are not reported due to the fact they oversize the page format.

Point estimate and 95 % confidence interval of mean prediction accuracy of the facial emotions based on Bayesian naive classifier is 0.325 (0.321, 0.329). Point estimate and 95 % confidence interval of mean prediction accuracy of

TABLE IV  
CONFUSION MATRIX OF A PREDICTION OF THE EMOTIONAL QUALITY BASED ON BAYESIAN NAIVE CLASSIFIER

		predicted class		
		negative	neutral	positive
true class	negative	34	16	16
	neutral	11	39	8
	positive	4	10	30

TABLE V  
CONFUSION MATRIX OF A PREDICTION OF THE EMOTIONAL QUALITY BASED ON A NEURAL NETWORK

		predicted class		
		negative	neutral	positive
true class	negative	36	6	6
	neutral	12	54	16
	positive	2	4	32

the emotional quality based on Bayesian naive classifier is 0.413 (0.409, 0.417). Since  $0.325 > \frac{1}{|\text{clusters of emotions}|} = \frac{1}{14}$  and  $0.413 > \frac{1}{|\text{emotional quality}|} = \frac{1}{3}$ , both classifiers predict more precise than random process. Since the target variables (*facial emotions* and *quality of facial emotions*, respectively) contain multiple classes, the classification task here is so-called “multiclass” and even only moderate prediction accuracy is acceptable under this conditions [27], [28].

Point estimate and 95 % confidence interval of mean prediction accuracy of the facial emotions based on decision trees is 0.488 (0.484, 0.492). Point estimate and 95 % confidence interval of mean prediction accuracy of the emotional quality based on decision trees is 0.525 (0.521, 0.529). Similarly, in both cases, the classifier predicts more precise than a random process.

Finally, point estimate and 95 % confidence interval of mean prediction accuracy of the facial emotions based on neural networks is 0.507 (0.503, 0.511). Point estimate and 95 % confidence interval of mean prediction accuracy of the emotional quality based on neural network is 0.726 (0.722, 0.730). Again, in both cases, the classifier predicts far more precise than a random process (and even substantially better than the previous two classifiers, though).

There are examples of decision trees learned in order to predict one of the facial emotions or one of the emotional quality using facial geometry of the photographed facial ex-

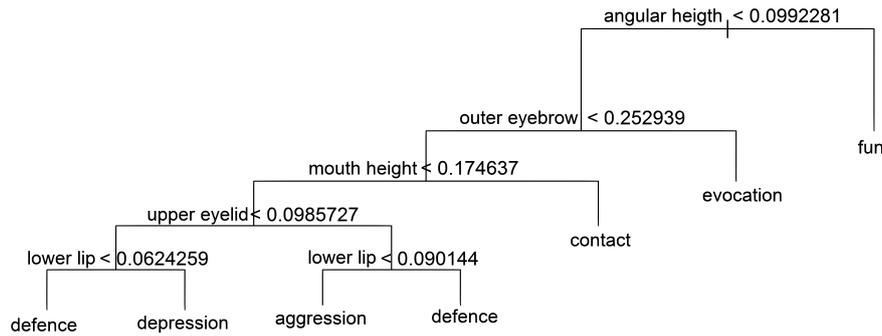

Fig. 2. A decision tree for prediction of the facial emotions (statements in nodes are true for left child nodes)

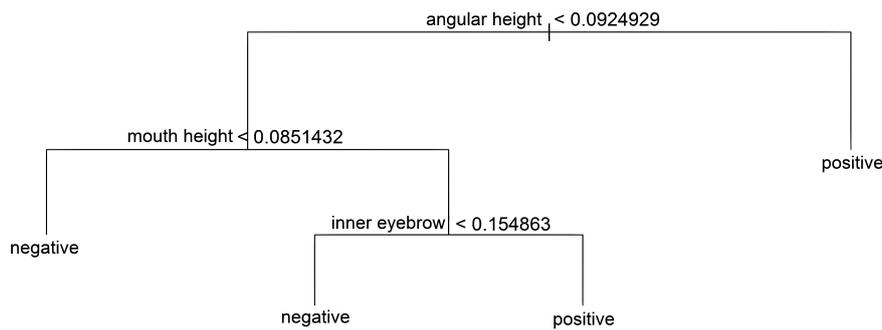

Fig. 3. A decision tree for prediction of the quality of facial emotions (statements in nodes are true for left child nodes)

pression in Fig. 2 and Fig. 3. The closer to the root node the derived geometrical metric or angle in the plot is, the more important seems to be in order to explain a “direction” of the classification into the final class of interest. As we can see, the facial expressions are dominated by geometry of the mouth, then by geometry of the eyes, respectively.

Furthermore, once we would go deeper into results of Fig. 2, we could realize that if the angular height — that is a vertical distance between mouth angles and a horizontal line between the lips — is large enough (more precisely, if the angular height is larger than or eventually equal to 0.0992), and it means that such a face in the image is smiling, then an emotion of that image is classified as a fun, as we can expect. Similar derivations (and still feasible) could be done following the “rules” placed in the next nodes of the trees plotted in Fig. 2 and Fig. 3.

#### IV. CONCLUSION

The performed machine-learning analyses pointed out which geometric facial features, based on significant data evidence, affect facial attractiveness the most — either as predictors increasing facial attractiveness level after undergoing rhinoplasty or as geometric features influencing the classification of facial images into facial emotions —, and therefore should preferentially be treated within rhinoplasty procedures.

Moreover, the learned classification methods confirmed that they are, despite the suggested improvement of FACS scale in terms of increasing the number of facial emotions, able

to classify facial images into the defined facial emotions accurately enough.

#### V. CONFLICT OF INTEREST

The authors declare that they have no conflict of interest regarding the publication of this article.

# 12<sup>th</sup> International Workshop on Computational Optimization

**M**ANY real world problems arising in engineering, economics, medicine and other domains can be formulated as optimization tasks. These problems are frequently characterized by non-convex, non-differentiable, discontinuous, noisy or dynamic objective functions and constraints which ask for adequate computational methods.

The aim of this workshop is to stimulate the communication between researchers working on different fields of optimization and practitioners who need reliable and efficient computational optimization methods.

## TOPICS

The list of topics includes, but is not limited to:

- combinatorial and continuous global optimization
- unconstrained and constrained optimization
- multiobjective and robust optimization
- optimization in dynamic and/or noisy environments
- optimization on graphs
- large-scale optimization, in parallel and distributed computational environments
- meta-heuristics for optimization, nature-inspired approaches and any other derivative-free methods
- exact/heuristic hybrid methods, involving natural computing techniques and other global and local optimization methods
- numerical and heuristic methods for modeling

The applications of interest are included in the list below, but are not limited to:

- classical operational research problems (knapsack, traveling salesman, etc)
- computational biology and distance geometry
- data mining and knowledge discovery
- human motion simulations; crowd simulations
- industrial applications
- optimization in statistics, econometrics, finance, physics, chemistry, biology, medicine, and engineering
- environment modeling and optimization

## BEST PAPER AWARD

The best WCO'19 paper will be awarded during the social dinner of FedCSIS 2019.

The best paper will be selected by WCO'19 co-Chairs by taking into consideration the scores suggested by the reviewers, as well as the quality of the given oral presentation.

## EVENT CHAIRS

- **Fidanova, Stefka**, Bulgarian Academy of Sciences, Bulgaria
- **Mucherino, Antonio**, INRIA, France
- **Zaharie, Daniela**, West University of Timisoara, Romania

## PROGRAM COMMITTEE

- **Abud, Germano**, Universidade Federal de Uberlândia, Brazil
- **Andrei, Stefan**
- **Bonates, Tibérius**, Universidade Federal do Ceará, Brazil
- **Breaban, Mihaela**
- **Gruber, Aritanan**
- **hadj salem, khadija**, University of Tours - LIFAT Laboratory, France
- **Hosobe, Hiroshi**, Hosei University, Japan
- **Lavor, Carlile**, IMECC-UNICAMP, Brazil
- **Marin, Mircea**
- **Micota, Flavia**, West University of Timisora, Romania

**Abstract**—A lot of problems in natural language processing can be interpreted using structures from discrete mathematics. In this paper we will discuss the search query and topic finding problem using a generic context-based approach. This problem can be described as a Minimum Set Cover Problem with several constraints. The goal is to find a minimum covering of documents with the given context for a fixed weight function. The aim of this problem reformulation is a deeper understanding of both the hierarchical problem using union and cut as well as the non-hierarchical problem using the union. We thus choose a modeling using bipartite graphs and suggest a novel reformulation using an integer linear program as well as novel graph-theoretic approaches.

## I. INTRODUCTION

In scientific research, expert systems provide users with several methods for knowledge discovery. They are widely used to find relevant or novel information. For example, medical and biological researchers try to find molecular pathways, mechanisms within living organisms or special occurrences of drugs or diseases. In [1], we discussed a novel approach for describing NLP problems using theoretical computer science. Using this approach, it is possible to obtain the algorithmic core of a NLP problem. Here, we will discuss two  $\mathcal{NP}$ -complete problems: Search Query Finding (SQF) and Topic Finding (TF).

Using expert system as an input, researches usually consider an initial idea and some content like papers or other documents. The most common approach is inquiring a search engine to find closely related information. Thus two question are most frequently asked: "How can I find these documents?" to adjust the search query for knowledge discovery or "What are these documents all about?" to find the topic. Both questions are heavily related to the context of documents. Metadata like authors, keywords and text are used to retrieve results of a query using a search engine.

Semantic searches are usually based on textual data and some meta-data like authors, journals, keywords. In addition, time and complexity play an important role, since often relevant information is not findable or new information is already available. For example, databases such as PubMed [2]

contain around 27 million abstracts and PMC<sup>1</sup> includes around 2 million biomedical-related full-text articles.

Both problems are equivalent (see [1]) and can be described as a Minimum Set Cover Problem with several constraints. Query languages and natural languages are not only highly connected but merge more and more (see [3] or [4]). The goal is to find a minimum covering of documents with the given context for a fixed weight function. The aim of this problem reformulation is a deeper understanding of both the hierarchical as well as the non-hierarchical problem. We thus choose a modeling using bipartite graphs and suggest a novel reformulation using an integer linear program as well as graph-theoretic approaches.

There is a considerable amount of literature on both problems. Many studies have been published on probabilistic or machine-learning-approaches, see [5], [6] or [7]. In addition, in recent years there has been growing interest in providing users with suggestions for more specific or related search queries, see [8].

This paper is divided into six sections. The first section gives a brief overview of the problem formulation and provides the definition of MDC and WMDC. The second section analyses the hierarchical problem formulation and proposes novel heuristics. In the third section, we present a short analysis of the non-hierarchical problem and propose an integer linear program approach and some modified graph heuristics to solve this problem. We present some experimental results on artificial and real-world scenarios in section four. Our conclusions are drawn in the final section.

## II. PROBLEM FORMULATION AND DEFINITION

We follow the notation introduced in [1]. Let  $\mathbb{D}$  be a set of documents and let  $\mathbb{X}$  be a set of context data. Context data is information associated with documents, such as keywords, authors, publication venue, etc. Both  $\mathbb{D}$  and  $\mathbb{X}$  form the vertex set of a graph  $G$ . If and only if a description of a document  $d \in \mathbb{D}$  is associated with context data  $x \in \mathbb{X}$ , we add the edge  $\{d, x\}$  to  $E$ . The graph  $G = (\mathbb{D} \cup \mathbb{X}, E)$  is bipartite and called *document description graph*.

<sup>1</sup><https://www.ncbi.nlm.nih.gov/pmc/>

Given a subset  $R \subset \mathbb{D}$ , the search-query-finding (SQF) or topic-finding (TF) problem tries to find a good description of  $R$  with terms in  $\mathbb{X}$ . In general, we lack a proper definition of what *good* means.

For example, given a search engine  $q : \mathbb{X} \rightarrow \mathbb{D}$  and a description function  $f : \mathbb{D} \rightarrow \mathbb{X}$ , we want a solution  $Z \subset \mathbb{X}$  such that  $q(Z) = R$  and  $Z = f(R)$ . If we want to obtain a human-readable topic for  $R$ , we need a solution  $Z$  of minimum cardinality which precisely describes all documents in  $R$ , hence distinguishing  $R$  from  $\mathbb{D} \setminus R$  without duplication and redundancies. See Figure 1 for an illustration of the relation between the sets  $X, R$  and the mappings  $f, q$ .

To sum up, we need to find a minimum covering of  $R$  with elements in  $\mathbb{X}$  so that whenever we are forced to cover further documents, that is, documents in  $\mathbb{D} \setminus R$ , the number of these further documents is minimal. Depending on the considered problem and the usecase, we have to make a trade-off between the size of the subset in  $\mathbb{X}$  and the number of covered documents in  $\mathbb{D} \setminus R$ . However, these problems are all related to the problem of finding dominating sets in bipartite graphs, see [9]. The latter is  $\mathcal{NP}$ -complete, even for bipartite graphs, see [10].

For  $x_i \in \mathbb{X}$ , we call  $D_i = N(x_i) \subseteq \mathbb{D}$  the cover set of  $x_i$  in  $\mathbb{D}$ . Roughly speaking, just imagine a keyword  $x_i$  and all associated documents  $D_i$ . With this, we reformulate the problem as follows:

**Definition II.1.** (*Document Cover Problem, DC*) Let  $\mathbb{D}$  be a set of documents, let  $\mathbb{X}$  be a set of context data and let  $G = (\mathbb{D} \cup \mathbb{X}, E)$  be the document description graph.

Given a set of documents  $R \subset \mathbb{D}$ , a solution of the DC is a set  $C \subseteq D$  that covers at least  $R$ .

**Definition II.2.** (*Minimum Document Cover Problem, MDC*) Let  $C$  be a solution of the DC and let  $\alpha_2 = |C|$ . Let further  $\alpha_1 = r$  be the number of documents in  $C \setminus R$ .

A solution of MDC is a solution of DC so that  $\alpha = \alpha_1 + \alpha_2$  is minimal.

We can define two objectives for minimization:  $\alpha_1$  and  $\alpha_2$ .

**Definition II.3.** ( $\alpha_2$ -Minimum Document Cover Problem,  $\alpha_2$ -MDC) Given a set of documents  $R \subset \mathbb{D}$ , a solution of the  $\alpha_2$ -MDC is a solution of DC so that  $\alpha = \alpha_2$  is minimal.

**Definition II.4.** ( $\alpha_1$ -Minimum Document Cover Problem,  $\alpha_1$ -MDC) Given a set of documents  $R \subset \mathbb{D}$ , a solution of the  $\alpha_1$ -MDC is a solution  $C$  of DC so that  $\alpha = \alpha_1$  is minimal.

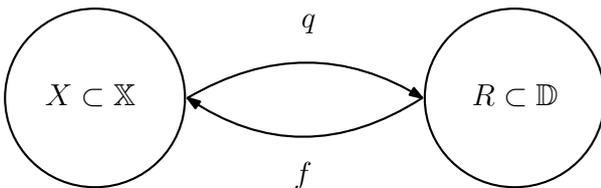

Fig. 1: Relation between the sets  $X \subset \mathbb{X}$  as description set of documents in  $R \subset \mathbb{D}$ .

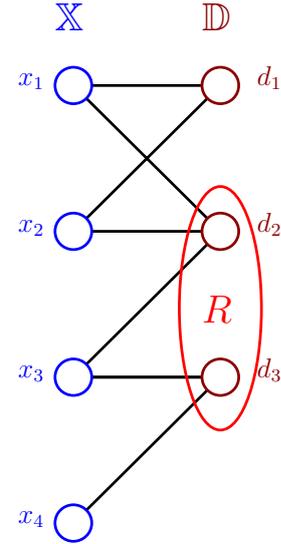

Fig. 2: A graph  $G = (\mathbb{D} \cup \mathbb{X}, E)$  illustrating example II.8

We further introduce a weighted version of this problem:

**Definition II.5.** (*Weighted Minimum Document Cover Problem, WMDC*) Let  $\mathbb{D}$  be a set of documents, let  $\mathbb{X}$  be a set of context data and let  $G = (\mathbb{D} \cup \mathbb{X}, E)$  the document description graph. Let  $w : \mathbb{X} \rightarrow \mathbb{R}$  be a weight function which associates a weight for every element in  $\mathbb{X}$ . Moreover, we set  $D = \{D_1, \dots, D_n\}$ . Let  $\alpha_1 = r$  be the number of documents in  $R \subset \mathbb{D}$  and  $\alpha_2 = |C|$ .

A solution of the WMDC is a set  $C \subseteq D$  which covers  $R$ , such that  $\alpha = \alpha_1 + \alpha_2 + w(C)$  is minimal, where  $w(C) = \sum_{c \in C} w(c)$ .

Again we can find formulations for  $\alpha_1$ -WMDC and  $\alpha_2$ -WMDC. Both problems are  $\mathcal{NP}$ -hard, see [11].

In general, we will focus on the  $\alpha_2$  optimization. Thus, in this paper, we denote this version with the MDC and WMDC.

We have to distinguish between hierarchical and non-hierarchical approaches. Both MDC and WMDC search for a cover set  $c_1, \dots, c_n$  which leads to a solution  $c_1 \cup \dots \cup c_n$ . This is a non-hierarchical approach. Using a search engine this would lead to a solution  $c_1$  or  $\dots$  or  $c_n$ . Utilizing the cut of sets we will need a hierarchical solution  $(c_1 \cup \dots \cup c_n) \cap (c_{n+1} \cup \dots \cup c_m) \cap \dots$ . Using a search engine would lead to a solution  $(c_1$  or  $\dots$  or  $c_n)$  and  $(c_{n+1}$  or  $\dots$  or  $c_m)$  and ....

**Definition II.6.** (*Hierarchical Minimum Document-Cover Problem, HMDC*) Let  $\mathbb{D}$  be a set of documents, let  $\mathbb{X}$  be a set of context data and let  $G = (\mathbb{D} \cup \mathbb{X}, E)$  be the document description graph. Moreover, we set  $D = \{D_1, \dots, D_n\}$ .

A solution of the HMDC problem for  $R \subset \mathbb{D}$  is a minimum cover  $C \subseteq D$  with  $C = C_1 \cap \dots \cap C_n$  and  $C_i = C_1^i \cup \dots \cup C_m^i$  of  $R$  so that  $C \setminus R$  is minimal. We use  $N(x_i)$  as usual for the open neighborhood  $N(x_i) \setminus x_i$ .

**Definition II.7.** (*Hierarchical Weighted Minimum Document-*

*Cover Problem, HWMDP*) Given a set of documents  $\mathbb{D}$ , a set of context data  $\mathbb{X}$  and the document description graph  $G = (\mathbb{D} \cup \mathbb{X}, E)$ . We set  $D = \{D_1, \dots, D_n\}$ . Given a weight function  $w : \mathbb{X} \rightarrow \mathbb{R}$  that defines a weight for every element in  $\mathbb{X}$ .

A solution of the weighted HWMDP problem for  $R \subset \mathbb{D}$  is a minimum cover  $C \subseteq D$  with  $C = C_1 \cap \dots \cap C_n$  and  $C_i = C_1^i \cup \dots \cup C_m^i$  of  $R$ , i.e.  $\sum_{c \in C} w(c)$  is minimal, so that  $C \setminus R$  is minimal.

We will discuss two examples for the non-hierarchical problem:

**Example II.8.** Given an instance of the MDC with  $\mathbb{D} = \{d_1, d_2, d_3\}$ ,  $R = \{d_2, d_3\}$ ,  $\mathbb{X} = \{x_1, \dots, x_4\}$  and  $D_1 = D_2 = \{d_1, d_2\}$ ,  $D_3 = \{d_2, d_3\}$ ,  $D_4 = \{d_3\}$ . See figure 2 for an illustration.

A minimum set cover cannot include  $x_1$  or  $x_2$ , but a solution is  $C = D_3$ .

**Example II.9.** Consider the instance given in example II.8 with additional weights  $w(x_1) = w(x_2) = w(x_3) = 1$  and  $w(x_4) = 0$ . A minimum solution of the weighted MDC can be found with  $Z = \{x_3, x_4\}$ .

Let  $w(x_1) = w(x_3) = 1$  and  $w(x_4) = w(x_2) = 0$ . A minimum solution of weighted MDC can be either found with  $Z = \{x_2, x_4\}$ , here  $w(Z) = 0$  but  $|C \setminus R| = 1$ . If we chose  $Z = \{x_3, x_4\}$   $w(Z) = 1$  but  $|C \setminus R| = 0$ .

We will first of all focus on hierarchical approaches, discussing approaches using dynamic programming and bipartite graph heuristics or spanning trees. After that we will discuss the non-hierarchical problem and solutions using an integer linear program approach as well as some heuristics utilizing the graph structure. We will evaluate the results on some random instances and finish with a conclusion.

### III. HIERARCHICAL APPROACHES

#### A. Problem Description

For some questions it is interesting to find a cover of  $R \subset \mathbb{D}$  with increasing (decreasing) or selectable exactness and the number of named entities  $Z \subset X = f(R)$ . If we have a set of documents and want to obtain more others closely related documents, we may be interested in a modification of the similarity measure for documents or search queries. We build covers  $C_i = q(Z_i)$  of  $R$  and optimize the solution by concatenating them with a logical AND.

#### B. Using unique keyword descriptions on bipartite graphs

From the graph in figure 2 we can see that the graph  $G = (\mathbb{D} \cup \mathbb{X}, E)$  is bipartite. The neighborhood  $N(d) \subset \mathbb{X}$  of every document  $d \in \mathbb{D}$  is not necessarily unique description of this document. Thus we can find a trivial solution of the MDCP on  $R \subset \mathbb{D}$  by

$$\bigvee_{d \in R} (\bigwedge_{x \in N(d)} x)$$

We can eliminate elements with the largest error from this list. This process can be limited by iterations as well as a

precision. For example we may limit the precision to 0.9 which will eliminate at maximum 10% of all keywords, whereas a precision of 0.5 will eliminate at maximum 50%.

---

#### Algorithm 1 KEYWORD-COVER

---

**Require:** Documents  $\{d_1, \dots, d_n\} \subset \mathbb{D}$  and descriptive elements  $f(d_i) = \{x_1, \dots, x_m\} \subset \mathbb{X}$ , a weight function  $w : \mathbb{X} \rightarrow \mathbb{R}$  maxiter as maximum of iterations, prec as precision

**Ensure:** A cover  $Z = (x_i \wedge x_j \wedge \dots) \vee (x_k \wedge x_l \wedge \dots) \vee \dots$  of  $R$  with elements in  $\mathbb{X}$ .

```

1:  $f' = f$ 
2: for every  $d \in R$  do
   while iteration < maxiter AND  $f'(d) > (\text{prec} \cdot f(d))$ 
   do
3:   remove  $x \in f'(d)$  with maximum weight
   end while
6: end for
   return  $Z = \bigvee_{d \in R} (\bigwedge_{x \in f'(d)} x)$ 

```

---

If we set  $w : \mathbb{X} \rightarrow \mathbb{R}$  as the error function  $\text{err}(x) = |q(x) \setminus R|$  we will find a solution for MDCP, otherwise this will return a solution of WMDCP. The function  $\text{err}$  is a less time-consuming approach but highly depended on the distribution of  $\mathbb{X}$ .

#### C. Dynamic programming and bipartite graph heuristic

Here, we describe a heuristic and dynamic method by creating dominating subgraphs of a bipartite graph. Building the bipartite graph  $G_b = (V = R \cup X, E)$ , a subgraph of the document description graph  $G = (\mathbb{D} \cup \mathbb{X}, E)$ , we create a set with documents  $R_a = \{d_1, \dots, d_n\} \subseteq \mathbb{D}$  and all their context data (like keywords, named entities, etc.) in a sorted list  $X_a = \{x_1, \dots, x_m\} \subseteq \mathbb{X}$  for the two sets of nodes. The edges  $(d_i, x_j)$  in  $G_b$  are given for all pairs  $d_i, x_j$  iff  $x_j \in f(d_i)$ . The elements in  $X_a$  should be sorted ascending or descending by their degree. For our example we choose a descending order, which results in an increasing precise cover.

In addition we need to build a second set  $R_b$  as temporary storage for the documents and a sorted list of lists  $Z = \{Z_1, Z_2, \dots, Z_k\}$ , with the covers  $Z_i$  of  $R_a$  for the output. The algorithm in pseudocode can be found in alg. 2. In every execution of the while loop in line 7 a new sublist  $Z_i \subset Z$  is created (see line 13). All of them are complete covers of all documents in  $R_a$ , where  $Z_0$  may contain just one element  $x_i$  with  $N(x_i) = R_a$  and the last  $Z_m$  may contain just all identities, that means  $x_i$  with a single neighbor  $N(x_i) = d_i$ . There are many options to modify the algorithm for special use cases. Choosing the ascending order for  $X_a$  and the minimum in line 9, which is same as in the other case just means the first  $x_j \in X_a$ , will mostly give different results.

If after the last run of the loop  $X_a$  is empty, but there are still documents in  $R_a$ , we receive an incomplete cover  $Z_k$ . To avoid that we add the ID's for the last documents in  $R_a$  (in descending order) to  $Z_k$ , or create and add an all covering  $x_\infty$  (for descending order).

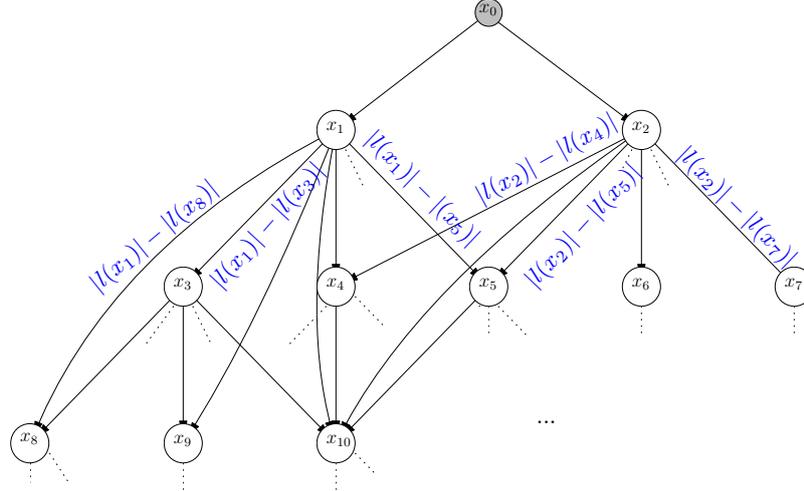

Fig. 4: Illustration of set representative in the graph  $G' = (V, E)$  and weight  $w(x_i, x_j)$  after adding the meta node  $x_0$ , with  $l(x_i) := |N_G(x_i)|$ . Not all edges and nodes have been added.

### B. An Integer Linear Program Approach

Numerous ILP-formulations for the set-cover problem can be found in literature, for example [13] or [14]. To meet definition II.6 of MDC we need to adjust the formulation.

Given a set of documents  $\mathbb{D}$ , a subset  $R \subset \mathbb{D}$ , a set of context data  $f(R) = X \subset \mathbb{X}$  and the document description graph  $G = (\mathbb{D} \cup \mathbb{X}, E)$ . We can define  $\forall x_i \in \mathbb{X} D_i = N(x_i)$  as the cover set of  $x_i$  in  $\mathbb{D}$ . We set  $D = \{D_1, \dots, D_n\}$  and  $e(D_i) = D_i \setminus R$  as the error of the description term  $x_i$ .

A solution of the MDC problem for  $R \subset \mathbb{D}$  is a minimum cover  $C \subseteq D$  of  $R$  so that  $C \setminus R$  is minimal.

$$\begin{aligned} \min \quad & \sum_{i=1}^n x_i + \sum_{i=1}^n x_i e(X_i) \\ \text{subject to} \quad & \sum_{i:v \in X_i} x_i \geq 1, \forall v \in R \\ & x_i \geq 1 \quad \forall i = 1, \dots, n \\ & x_i \in \mathbb{Z} \quad \forall i = 1, \dots, n \end{aligned} \quad (1)$$

Here the vector  $x$  gives a set  $Z \subset X$  which gives a minimum cover  $q(Z) = C \subseteq D$  of  $R$  so that  $C \setminus R$  is minimal.

The weighted MDC problem was introduced in definition II.7. Given a weight function  $w : \mathbb{X} \rightarrow \mathbb{R}$  that defines a weight for every element in  $\mathbb{X}$  the ILP (1) changes as follows:

$$\begin{aligned} \min \quad & \sum_{i=1}^n w(x_i) + \sum_{i=1}^n x_i e(X_i) \\ \text{subject to} \quad & \sum_{i:v \in X_i} x_i \geq 1 \quad \forall v \in R \\ & x_i \geq 1 \quad \forall i = 1, \dots, n \\ & x_i \in \mathbb{Z} \quad \forall i = 1, \dots, n \end{aligned} \quad (2)$$

A solution of the MDC problem for  $R \subset \mathbb{D}$  is a minimum cover  $C \subseteq D$  of  $R$ , i.e.  $\sum_{c \in C} w(c)$  is minimal, so that  $C \setminus D$  is minimal.

### C. Dynamic programming and bipartite graph heuristic

We can use algorithm 2 to construct a non-hierarchical solution. This algorithm has already been used to compute  $k$  covers of  $R_a$ , which can be used to find a cover with minimal

---

### Algorithm 4 BIPARTITE COVER-DESCRIPTION

---

**Require:** Documents  $\{d_1, \dots, d_n\} \subset \mathbb{D}$  and descriptive elements  $f(d_i) = \{x_1, \dots, x_m\} \subset \mathbb{X}$ ,  $R_a$  with all  $d_i$  and empty set  $R_b$ , sorted list  $X$  with all  $x_i$  and empty list  $C$ ,  $G = (R_a \cup X_a, E)$  with  $(d_i, x_j) \in E$  if  $d_i \in N(x_j)$ , maximum iterations  $\text{maxdeep}$

**Ensure:** A minimum covers  $Z$  of  $R_a = \{d_1, \dots, d_n\}$  with elements in  $\mathbb{X}$ .

```

for every  $x_i, x_j \in X$  do
2:   if  $N(x_i) = N(x_j)$  then
        $x_i = \{x_i \text{ OR } x_j\}$ , remove  $x_j$ 
4:   end if
end for
6:  $k \leftarrow 0$ 
while  $|X| > 0$  AND  $k \leq \text{maxdeep}$  do
8:   for every  $d \in R_a$  do
       choose  $x_j \in N(d_i)$  with  $\max |N(x_j)|$ 
10:  for every  $d \in N(x_j)$  do
        $R_b \leftarrow d$ , from  $R_a$ .remove( $d$ )
12:  end for
       move  $x_j$  to  $Z_k$ 
14:  end for
        $R_a = R_b$ ,  $R_b = \emptyset$ ,  $k = k + 1$ 
16: end while
if  $R_a \neq \emptyset$  then
18:  add  $x_\infty$  to last  $Z_k$ 
end if
20: return  $Z = \min_{i \in \{1, \dots, k\}} Z_i$ ,
    
```

---

error  $Z = \min_{e(x_i)} Z_i$ , that means for  $q(Z) = C \setminus R$  is minimal. The pre-sorting of the context data list  $X$  results in covers of ascending cardinality, so the number of iterations  $k$  may be a limit for maximum cardinality. The pre-sorting can be removed, which results in more balanced and random

covers, whereof one with minimum error can be chosen.

## V. EXPERIMENTAL RESULTS

We tested our novel approach within two scenarios. First of all, using an artificial random instances with  $|\mathbb{D}| = 150$  documents and a given subset  $R$  with 20 example documents. We created instances with a fixed number of 80 or 40 normal distributed keywords which had a significant impact on the output. In addition we used  $N$  iterations, which lead to a different precision. The second scenario is a real-world example using set  $R$  of 10 random documents out of a human curated topic. We tested against complete PubMed Database using SCAIView. Thus  $|\mathbb{D}| \approx 29,000,000$ .

Within the random instances we were unable to describe a single document by its random keywords. This approach usually returned more than 100 documents. The reason for this rather contradictory result is still not entirely clear, but the normal distribution of keywords may be responsible for this result. The algorithms Tree-Description and Hierarchical Bipartite Cover-Description performed quite well, see figure 5. In general, we found Hierarchical Bipartite Cover-Description to work better and faster.

Changing to the real-world scenario the situation changes significantly. Given a set of 10 documents, Hierarchical Bipartite Cover-Description usually returned more than 6,000,000 documents, Tree-Description more than 5,000,000 before reaching the search-query length limitations. Vice versa we found, that the combination of keywords described a single document very well – even within nearly 3 million documents in  $\mathbb{D}$ . The keywords using MeSH-terms in PubMed are manually curated and seem not to be normally distributed.

The output of Keyword-Cover for 10 random examples with  $|R| = 10$  is presented in figures 6 and 7. The precision was iterated from 0.9 to 0.4. The output scales very well and is quite stable till precision 0.5 where we found between 12 and 36 documents. For precision 0.4 we found 28 till 676 documents.

We can see, that we have found a novel solution for search query finding on literature that performs quite well on real-world data. Our work clearly has some limitations. It is not clear, why the proposed algorithms perform significantly different in both scenarios. Despite this we believe our work could be the basis for solving the SQF and TD. Further work needs to be performed to the distribution of descriptive elements to documents to establish whether they can be used to generate search queries and topic descriptions that are significant enough.

## VI. CONCLUSIONS

We presented a novel formulation of both search query and topic finding problems as Minimum Set-Cover Problems. We proposed a weighted and unweighted version of the Minimum Document-Cover Problem as well as a hierarchical version using both AND as well as OR and the non-hierarchical version only using and.

With this we get a solution that uses on the one hand as much descriptive elements as possible to get as less documents in  $\mathbb{D}$  but not in  $R$ .

The search queries are not human readable. For example the tree-approach returns queries in the form `MeSH_Terms: D000818" AND ( "MeSH_Terms: D051381" OR "MeSH_Terms: D009538" OR "MeSH_Terms: D017207" OR "MeSH_Terms: Q000494" OR "MeSH_Terms: D006624" OR "MeSH_Terms: D011978" OR "MeSH_Terms: D000109" OR "MeSH_Terms: D008297" OR "MeSH_Terms: Q000187" OR "MeSH_Terms: Q000502" OR "MeSH_Terms: Q000378" OR "MeSH_Terms: D008464" OR "MeSH_Terms: Q000187" OR "MeSH_Terms: Q000187" OR ...`. This can be easily translated into something human-readable. But still it is a good probability that further research has to be done on how to shorten this to be both precise as well as significant.

In general this is both: a correct solution of clustering labeling of  $R$  on  $\mathbb{X}$  obtained by  $f$  as well as a possible solution of a search query so that  $q(Z) = R$ . It is not necessary an optimal solution of SQF or CLF problem, since reordering the keywords may result in better solutions.

The bipartite graph algorithms can be modified for many different use cases. All hierarchical algorithms can also be modified by adding weights. As described, there are many possible variations like sorting the context data list by minimum or maximum degree. The number of iterations  $k$  also has a big impact on the result. Another possible optimization is the pre-sorting by weighting the  $x_i$  with maximum  $|N(x_i)|$  and minimal  $D \setminus R$ .

This paper has underlined the importance of finding the computational core of NLP problems. We have managed to find a Minimum Set-Cover reformulation of SQF and TF which lead to an accurate solving of both on real-world data. The current study was unable to reproduce this success on random input data. Thus it is recommend that further research should be undertaken to examine the impact of keyword (or descriptive elements) distributions on documents. Nevertheless these results have been very encouraging to integrate this feature in SCAIView and to do further research on the optimization and extension of this heuristic.

**Abstract**—Electric vehicles are accelerating the world’s transition to sustainable energy. Nevertheless, the lack of a proper charging station infrastructure in many real implementations still represents an obstacle for the spread of such a technology. In this paper, we present a real case application of optimization techniques in order to solve the location problem of electric charging stations in the district of Biella, Italy. The plan is composed by several progressive installations and decision makers pursue several objectives that might be in contrast. For this reason, we present an innovative framework based on the comparison of several ad-hoc Key Performance Indicators for evaluating many different aspects of a location solution.

## I. INTRODUCTION

Environmental pollution is one of the biggest problems affecting human society, and one of the main source of pollution is represented by motorized vehicles. It has been estimated that they are responsible for 40% of carbon dioxide emissions and 70% of other GHG emissions in urban areas [1]. In order to reduce this kind of pollution, an alternative and promising mobility solution is represented by the adoption of electric vehicles (EVs). Nevertheless, the expansion of this technology is strictly linked with the growth of a proper infrastructure for recharging the vehicles.

In this context, the company *Ener.bit S.r.l.*<sup>1</sup> and the *Department of Control and Computer Engineering* of Politecnico di Torino have recently developed a project for the sustainability of electric mobility in the district of Biella, Piedmont (Italy). The project goal was to plan the type, number, and location of the charging stations over an horizon of about 10 years (2019-2030). It is worthwhile noticing that the number of stations to locate and the number of power plugs for each station depend on an economical analysis related to the forecast number of EVs. Instead, the type of charging stations mainly depends on the features of a selected location. For example, a charging station near working centers can have a low charging system (because workers are assumed to park their vehicle during the entire day), while a charging station near shopping centers is supposed to be faster (cars must be recharged during shopping time). Therefore, the actual decision problem faced in the

project was to select the municipalities in the Biella district where to locate at least one charging station.

In general, location problems consider several different (and possibly conflicting) objectives, e.g., achieving a level of service proportional to the importance of the location, reducing the worst-case service level, maximizing the average service level, etc. Considering all those objectives in the same mathematical problem may end up with a huge amount of solutions that can confuse the decision maker instead of providing help. For this reason, our study provides an innovative analysis based on the comparison of several different aspects of a location solution through the use of a battery of Key Performance Indicators (KPIs). Moreover, since charging infrastructures are commonly supposed to be located through several progressive interventions over a defined time-horizon, we also analyze the trend of the provided KPIs over the interventions to generate long-term managerial insights.

### A. Literature review

Optimal location is a standard topic in operations research. There is a huge amount of different models, and the choice of the most correct model to abstract the problem depends on the objectives set and the constraints imposed by the application itself. In our case, it is fundamental to provide a constraint on the exact number of municipalities where to locate a charging station. Furthermore, the model should aim at optimizing some quality-of-service metrics for the user community.

In the literature, several works are present in this context. In [1], the authors present a study on the location of charging stations for EVs for the city of Lisbon (Portugal), characterized by a strong concentration of population and movements. The methodology is based on a model that maximizes demand coverage while maintaining an acceptable level of service. In [2], instead, the authors use a bilevel model in order to optimize vehicle sharing systems.

After a careful study of the existing approaches, and considering the specific features of the application at hand and the requests by the involved company, we decided to analyze the *p-centdian* model, which represents a combination of the classical *p-center* and *p-median* problems [3].

The rest of this paper is organized as follows. Section II is devoted to present the location model used in the project. In Section III, we propose and discuss several different KPIs of

This work has been supported by Ener.bit S.r.l. (Biella, Italy) under the grants "Studio di fattibilità per la realizzazione di una rete per la mobilità elettrica nella provincia di Biella" and "Analisi per la realizzazione di una rete per la mobilità elettrica nella provincia di Biella".

<sup>1</sup>Official website: <http://www.enerbit.it/>, last accessed: 2019-04-30.

interest for our application. In Section IV, we describe more in details the project and we present the numerical results. Finally, conclusions are drawn in Section V.

## II. THE P-CENTDIAN MODEL

Throughout the paper we use the following notation:

- $G = (N, E)$ : complete undirected graph with a set of nodes  $N$  representing possible locations for the charging stations and a set of edges  $E = \{(i, j) | i, j \in N, i \leq j\}$ ;
- $d_{ij}$ : distance between node  $i$  and node  $j \in N$  (note that distance  $d_{ii}$  may be non-null since it represents the internal distance to travel within municipality  $i \in N$ );
- $Q_i$ : service demand in node  $i \in N$ ;
- $h_i = Q_i / \sum_{j \in N} Q_j$ : demand rate of node  $i \in N$ ;
- $p$ : predefined number of stations to locate, with  $p \leq |N|$ ;
- $\bar{d}$ : coverage radius, i.e. the threshold distance to discriminate the covering. It represents, e.g., the maximum distance that an EV can travel (due to the battery capacity) or that a user is willing to drive to reach a charging station;
- $\mathcal{C}_i = \{j \in N, d_{ij} \leq \bar{d}\}$ : covering set of  $i \in N$ , i.e. the set of all stations nearer than  $\bar{d}$  from node  $i$ .

The *p-centdian* problem is to find  $p$  nodes where to locate charging stations so as to minimize a linear combination among the maximum and the average (weighted) distance between the located stations and the demand nodes. Its formulation is:

$$\min \lambda M + (1 - \lambda) \sum_{i \in N} h_i \sum_{j \in N | (i,j) \in E} d_{ij} x_{ij} \quad (1)$$

subject to

$$M \geq \sum_{j \in N | (i,j) \in E} h_i d_{ij} x_{ij} \quad \forall i \in N \quad (2)$$

$$\sum_{j \in N | (i,j) \in E} x_{ij} = 1 \quad \forall i \in N \quad (3)$$

$$\sum_{j \in N} y_j = p \quad (4)$$

$$\sum_{i \in N | (i,j) \in E} x_{ij} \leq |N| y_j \quad \forall j \in N \quad (5)$$

where  $y_j$  is a binary variable taking value 1 iff a station is located in node  $j \in N$ , and 0 otherwise, while  $x_{ij}$  is a binary variable taking value 1 iff the demand of node  $i \in N$  is served by a charging station located in  $j \in N$ , and 0 otherwise.

The objective function (1) consists of a linear combination of two terms. The first is the auxiliary variable  $M$  that, according to constraints (2), takes the maximum value of the expression  $\sum_{j \in N} h_i d_{ij} x_{ij}$  over all nodes  $i \in N$ . In other words, it is the maximum distance between a demand node and its closest station. The second is the average distance traveled by the total demand flow towards charging stations. Clearly, through the parameter  $0 \leq \lambda \leq 1$  it is possible to define the relative importance of one objective with respect to the other one. In this work, we set the  $\lambda$  parameter dynamically by using

the ratio between the optima of the relative *p*-center and *p*-median subproblems. In this way we ensure that the two terms of (1) are comparable. Constraints (3) ensure that each demand node is served by exactly one station. Constraint (4) ensures to locate exactly  $p$  stations. Finally, logical constraints (5) ensure to locate a station in  $j$  (i.e.,  $y_j = 1$ ) only if it is assigned to serve at least one demand node (i.e.,  $\sum_{i \in N} x_{ij} > 0$ ).

## III. KEY PERFORMANCE INDICATORS

In this section, we define the set of KPIs that were used in the project in order to measure the performance of the solution provided by the model. For simplicity, we define  $\mathcal{L}_i = \{j \in \mathcal{C}_i | y_j = 1\}$  as the set of nodes where a charging station has been located that covers demand node  $i$ , and  $\mathcal{C} = \{i \in N | \exists j \in \mathcal{C}_i \text{ such that } y_j = 1\}$  as the set of demand nodes covered by at least one charging station.

The following proposed KPIs consider topological, coverage, and accessibility measures:

- **WORST-CASE DISTANCE:**

$$D_{max} := \max_{i \in N} \min_{j \in \mathcal{L}} d_{ij} \quad (6)$$

represents the maximum distance between a demand node and its closest charging station.

- **BEST-CASE DISTANCE:**

$$D_{min} := \min_{i \in N} \min_{j \in \mathcal{L}} d_{ij} \quad (7)$$

represents the minimum distance between a demand node and its closest charging station.

- **AVERAGE DISTANCE:**

$$D_{avg} := \frac{1}{|N|} \sum_{i \in N} \min_{j \in \mathcal{L}} d_{ij} \quad (8)$$

represents the average distance between a demand node and its closest charging station.

- **DISPERSION:**

$$Disp := \sum_{i \in \mathcal{L}} \sum_{j \in \mathcal{L}} d_{ij} \quad (9)$$

represents the sum of the distances between all the located stations. It is a measure of homogeneity of the service from a purely topological point of view.

- **ACCESSIBILITY:**

$$Acc := \sum_{i \in N} h_i A_i \quad (10)$$

is the total accessibility of the charging service, where

$$A_i := \sum_{j \in \mathcal{L}} e^{-\beta d_{ij}} \quad (11)$$

is the accessibility of a facility in the sense of [4]. The parameter  $\beta > 0$  must be calibrated and represents the dispersion of the alternatives in the choice process (the calibration has been performed according to [5] and [6]).

- **COVERAGE:**

$$C := 100 * |\mathcal{C}| / |N| \quad (12)$$

represents, in percentage, the number of covered locations with respect to the total.

- WORST-CASE COVERAGE:

$$C_{min} := \min_{i \in N} |\mathcal{L}_i| \quad (13)$$

represents the minimum number of charging stations covering a demand node.

- BEST-CASE COVERAGE:

$$C_{max} := \max_{i \in N} |\mathcal{L}_i| \quad (14)$$

represents the maximum number of charging stations covering a demand node.

- AVERAGE COVERAGE:

$$C_{avg} := \frac{1}{N} \sum_{i \in N} |\mathcal{L}_i| \quad (15)$$

represents the average number of charging stations covering a demand node.

#### IV. THE BIELLA CASE-STUDY

In the aforementioned project, the possible locations are the 78 municipalities of the district of Biella, Italy. From a preceding economical analysis, the company is supposed to install charging stations in one municipality by the end of 2019, in 10 municipalities by the end of 2022, in 37 by the end of 2025, and in all remaining municipalities by the end of 2030. Moreover, the company assumed a coverage radius  $\bar{d} = 25$ , i.e., a municipality is covered if its distance from the nearest charging station is less than 25 kilometers. We remark that each station may have different size, number of plugs, and capacity in terms of charging. However, as already stated in the Introduction, we just focus on selecting the municipalities of Biella district where to locate at least one charging station, while the real characteristics of the stations will be derived in a successive phase. For example, the number of plugs for each municipality can be calculated as a proportion to the demand rate of that particular municipality (and its surroundings).

The p-centdian model, accurately instantiated with the data deriving from the Biella district case study, can be easily solved by exact algorithms as the branch-and-cut implemented in the available commercial and academic solvers. In our particular case, we used the GUROBI solver v.8.1.0. The resolution was performed on a common PC (Intel Core i7-5500U CPU@2.40 GHz with 8 GB RAM) and took on average 12 seconds. Notice how the resolution efficiency obtained allows to possibly perform a large number of experiments with different input data, thus refining the analysis.

The solutions for the different time thresholds studied, obtained using the p-centdian model, are the following (clearly, at each intervention, the locations chosen in the previous steps are forced to remain in the solution):

- one municipality ( $p = 1$ ) by the end of 2019: the only municipality chosen is Biella, the chief town (see Figure 1). This was expected since Biella is the most important city in terms of demand.

- 10 municipalities ( $p = 10$ ) by the end of 2022: some small municipalities close to and other big ones far from Biella are chosen (see Figure 2).
- 37 municipalities ( $p = 37$ ) by the end of 2025: the solution tends to select municipalities close to the previously selected ones, creating clusters (see Figure 3)
- all municipalities ( $p = 78$ ) by the end of 2030 (this corresponds to the trivial solution with  $y_i = 1, \forall i \in N$ ).

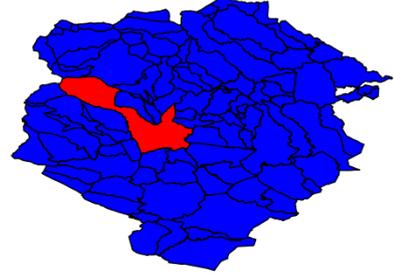

Fig. 1. Optimal location for  $p = 1$  (2019). Chosen locations in red.

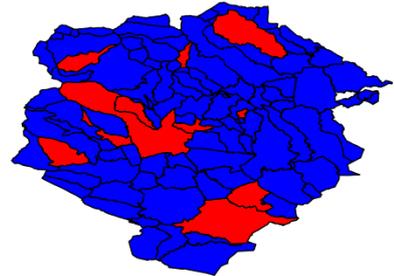

Fig. 2. Optimal location for  $p = 10$  (2022). Chosen locations in red.

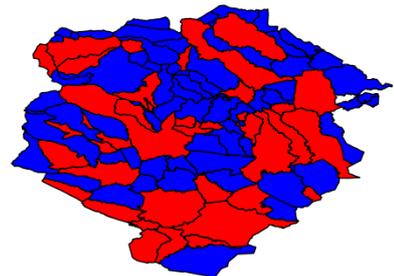

Fig. 3. Optimal location for  $p = 37$  (2025). Chosen locations in red.

The value of all the KPIs, in the various steps of intervention, is calculated and shown in Table I. Note that the last column, corresponding to the case in which all the locations are chosen, contains the best possible value for each KPI. Several observations can be done:

- $D_{max}$  decreases with the increase in the number of municipalities in which at least one charging station has been located and, as it can be seen, it reaches reasonable values from  $p = 10$  onward.
- $D_{min}$  decreases as the number of municipalities in which at least one charging station has been located increases, and it stabilizes at the best value already with  $p = 10$ .
- $D_{avg}$  decreases as the number of municipalities in which at least one charging station has been located increases. It is interesting to note that the percentage improvement in the indicator decreases as the number of selected municipalities increases.
- $Disp$  increases as the number of municipalities in which at least one charging station has been located increases. Its growth is very marked due to the factorial growth of the number of pairs of selected municipalities. The starting value is set to zero since with a single municipality the summation in the definition cannot be calculated.
- $Acc$  increases as the number of municipalities in which at least one charging station has been located increases. Also in this case the improvements are less marked as the number of selected municipalities increases.
- $C$  increases as the number of municipalities in which at least one charging station has been located increases. It can be seen that with only 10 selected municipalities, the coverage reaches very high levels (96% of the municipalities are covered).
- $C_{min}$  increases with the number of municipalities where at least one charging station has been located. Since this is the most pessimistic case, this indicator remains at zero when 1, 10, and 37 selected municipalities are considered. The data then verifies the non-total coverage shown by the KPI previously discussed.
- $C_{max}$  increases as the number of municipalities in which at least one charging station has been located increases. It can be seen that the increase in value grows with the number of selected municipalities. However, it can be noted that already with 10 municipalities the most covered municipality has the choice between 7 charging stations within a 25 kilometers radius.
- $C_{avg}$  increases with the increase in the number of municipalities in which at least one charging station has been located and, as it can be seen, has a much lower value than the  $C_{max}$ . This implies a heterogeneous situation in terms of coverage of the various locations. In fact, we have a large number of municipalities covered by a few charging stations and a small number of municipalities covered by many charging stations. Since the towns that are not covered are those with a lower demand (i.e., with less electric vehicles) this feature is in line with the technical specifications of the problem.

A common trend of almost all the KPIs is that the second intervention is the one providing the highest proportional change with respect to the previous one (e.g.,  $C$  almost doubles its value for  $p = 10$  while it gains only few units for  $p = 37$

TABLE I  
KPIs VALUE IN THE FOUR INTERVENTIONS.

KPI	$p = 1$ (2019)	$p = 10$ (2022)	$p = 37$ (2025)	$p = 78$ (2030)
$D_{max}$	53	24	20	11
$D_{min}$	5.7	2	2	2
$D_{avg}$	20.3	8.9	5.8	4.4
$Disp$	0	2158.2	34663.9	167201.3
$Acc$	0.024769	0.115986	0.329689	0.456748
$C$	55%	96%	98%	100%
$C_{min}$	0	0	0	1
$C_{max}$	1	7	22	43
$C_{avg}$	0.089744	2.653846	8.833333	19.28205

and  $p = 78$ ). Interesting enough,  $D_{min}$  reaches its optimal value even for  $p = 10$ . This represents a very important insight for the company for two main reasons. First, it means that the users will perceive the biggest improvement in terms of service in relatively small amount of time (the first 3-5 years) and in response to a small effort in terms of installed stations. Second, it means that the last interventions, which are the ones affected by the most uncertainty (e.g., in terms of economical sustainability), are not very critical for the process overall quality.

## V. CONCLUSIONS

The implementation of the plan resulting from this study in the district of Biella still needs a detailed urban planning and electrical plant analysis to determine the physical points within the municipalities in which to locate the charging stations identified. However, the described methodologies represent the application of state-of-the-art technology in optimal location to real problems. It is worthwhile noting that the developed analysis can be applied to different location models and to a broader set of KPIs. This way the decision maker can evaluate different solutions and generate insights for the location problem at hand.

**Abstract**—The routing and spectrum assignment problem is an NP-hard problem that receives increasing attention during the last years. Existing integer linear programming models for the problem are either very complex and suffer from tractability issues or are simplified and incomplete so that they can optimize only some objective functions. The majority of models uses edge-path formulations where variables are associated with all possible routing paths so that the number of variables grows exponentially with the size of the instance. An alternative is to use edge-node formulations that allow to devise compact models where the number of variables grows only polynomially with the size of the instance. However, all known edge-node formulations are incomplete as their feasible region is a superset of all feasible solutions of the problem and can, thus, handle only some objective functions.

Our contribution is to provide the first complete edge-node formulation for the routing and spectrum assignment problem which leads to a tractable integer linear programming model. Indeed, computational results show that our complete model is competitive with incomplete models as we can solve instances of the RSA problem larger than instances known in the literature to optimality within reasonable time and w.r.t. several objective functions. We further devise some directions of future research.

## I. INTRODUCTION

TODAY'S communication networks are optical networks where light is used as communication medium between sender and receiver nodes. For over two decades, the Wavelength-Division Multiplexing (WDM) has been the most popular technology used in fiber-optic communication. WDM combines multiple wavelengths to simultaneously transport signals over a single optical fiber, but must select the wavelengths from a rather coarse fixed grid of frequencies specified by the United Nations agency ITU (International Telecommunication Union) and leads to inefficient use of spectral resources and bans allocating more than a single wavelength to a traffic demand.

In response to the sustained growth of data traffic volumes in communication networks, a new generation of optical networks, called flexgrid Elastic Optical Networks (EONs), has been introduced in the last few years to enhance the spectrum efficiency and enlarge the network capacity [7].

In EONs, the frequency spectrum of an optical fiber is divided into many narrow frequency slots of fixed spectrum width. Any sequence of consecutive slots can form a channel

that can be switched in the network nodes to create a lightpath (i.e., an optical connection represented by a route and a channel). EONs enable capacity gain by allocating minimum required bandwidth thanks to a finer spectrum granularity than in the traditional WDM networks.

However, the spectrum assignment in EONs leads to the *Routing and Spectrum Assignment (RSA) problem* that is much harder to handle in practice than its counterpart using Wavelength-Division Multiplexing. In fact, the RSA problem consists of two parts: the routing (to select for each traffic demand a path through the communication network) and the spectrum assignment (to assign for each demand an interval of consecutive frequency slots within the optical spectrum such that the intervals of lightpaths using a same edge in the network are disjoint), see e.g. [15] and Section II for details. Thereby, the following constraints need to be respected when dealing with the RSA problem:

- 1) *spectrum continuity*: the frequency slots allocated to a demand remain the same on all the links of a route;
- 2) *spectrum contiguity*: the frequency slots allocated to a demand must be contiguous;
- 3) *non-overlapping spectrum*: a frequency slot can be allocated to at most one demand.

The RSA problem is a generalization of the well-studied *Routing and Wavelength Assignment (RWA) problem* that is associated with a fixed grid of frequencies [3].

The former problem has started to receive a lot of attention over the last few years. It has been shown to be NP-hard [2], [18]. In fact, if for each demand the route is already known, the RSA problem reduces to the so-called *Spectrum Assignment (SA) problem* and only consists of determining the demands' channels. The SA problem has been shown to be NP-hard on paths [14] which makes the SA problem (and thus also the RSA problem) much harder than the RWA problem which is well-known to be polynomially solvable on paths, see e.g. [3].

To solve the RSA problem, various approaches have been studied in the literature, based on different Integer Linear Programming (ILP) models. Hereby, detailed models aiming at precisely describing all technological aspects of EONs and being able to handle various criteria for optimization typically suffer from tractability issues resulting from their

greater complexity such that the tendency is to use simplified or restricted models.

The majority of the existing models uses an *edge-path formulation* where for each demand, variables are associated either with all possible routing paths or with all possible light-paths for this demand. One characteristic of this formulation is, therefore, an exponential number of variables issued from the total number of all feasible paths between origin-destination pairs in the network, which grows exponentially with the size of the network.

To bypass the exponential number of variables, edge-path formulations with a precomputed subset of all possible paths per demand have been studied e.g. in [8], [9], [16], [19], see [19] for an overview. However, such formulations cannot guarantee optimality of the solutions in general (as only a precomputed subset of paths is considered and, thus, a restricted problem solved). In order to be able to find optimal solutions of the RSA problem w.r.t. any objective function with the help of an edge-path formulation, all possible paths have to be taken into account. As the explicit models are far too big for computation, it is in order to apply column-generation methods. However, computational results from e.g. [10], [11], [13] show that the size of the instances that can be solved that way is rather limited.

An alternative to edge-path formulations is to use *edge-node formulations* that lead to less intuitive models for the routing, but have the advantage that the number of variables grows only polynomially with the size of the instance. Despite this advantage, edge-node formulations are not yet well-studied. Only few authors made use of this type of model, as Cai et al. [1], Velasco et al. [16], Zotkiewicz et al. [19], and Jia et al. who used in [6] an edge-node formulation to treat a more general problem.

All three models from [1], [16], [19] are compact models as both the number of variables and constraints is polynomial in terms of the size of the instance. However, all three models are incomplete as their feasible region is a superset of all feasible solutions of the RSA problem and can, thus, handle only some objective functions (see Section IV for details).

Our contribution is to provide the first complete edge-node formulation for the RSA problem that precisely encodes the set of all feasible solutions and can, therefore, be used to optimize any chosen objective function. For that, we propose an appropriate combination of variables and constraints (partly using new variables and constraints), see Section III for details. Our model uses, as in [1], [16], [19], a polynomial number of variables, but an exponential number of constraints to ensure the exact encoding of feasible solutions. As we are able to separate the exponentially-sized families of constraints in polynomial time, our model is computationally tractable and, therefore, competitive with the compact but incomplete models from [1], [16], [19].

While Zotkiewicz et al. [19] do not give computational results, Velasco et al. [16] tested their formulation on a network topology of Spain with 35 edges (64 slots per edge) and 21 nodes with a very small number of 12 demands and

requested numbers of slots in  $\{1, 2, 4\}$ . The results show that Cplex version 12 could optimally solve the problem after 6 hours by minimizing the number of edges activated for the routing (which can be looked as a network design problem).

Cai et al. [1] tested their formulation on two small network topologies, one with 6 nodes and 9 links and the other with 10 nodes and 22 links, one demand between each pair of nodes in the network and requested numbers of slots in  $\{1, \dots, 3\}, \dots, \{1, \dots, 9\}$ . The results show that Gurobi 5.0 could optimally solve the problem after 1 hour by minimizing the max-slot position for the 6 nodes and 9 links topology (but did not report on time limits to solve the instances on the other network).

Our model allows us to solve instances of the RSA problem larger than the instances in [1], [16] to optimality within reasonable time w.r.t. several objective functions (see Section V for details).

The paper is organized as follows. In Section II, we describe in detail the input and the desired output of the RSA problem together with the studied objective functions. In Section III, we present our new edge-node formulation and compare it in Section IV with existing models from the literature [1], [16], [19]. In Section V, we report on computational results achieved with the help of our formulation. We close with some concluding remarks and future research.

## II. THE RSA PROBLEM

In this section, we formally define the RSA problem by describing in detail the input and the desired output of the RSA problem together with the studied objective functions.

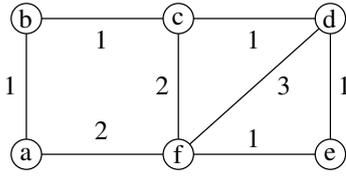

As input of the RSA problem, we are given

- an optical spectrum  $S = \{1, \dots, \bar{s}\}$  of available frequency slots;
- an optical network, represented as an undirected, loopless, connected graph  $G = (V, E)$  that may have parallel edges (if parallel optical fibers are installed between two nodes), and for each edge  $e \in E$  its length  $\ell_e \in \mathbb{R}_+$  (in kms),
- a multiset  $K$  of demands where each demand  $k \in K$  is specified by
  - an origin node  $o_k \in V$  and a destination node  $d_k \in V \setminus \{o_k\}$ ,
  - a requested number  $w_k \in \mathbb{N}_+$  of slots, and
  - a transmission reach  $\bar{\ell}_k \in \mathbb{R}_+$  (in kms).

The task is to determine for each demand  $k \in K$  a lightpath composed of an  $(o_k, d_k)$ -path  $P_k$  in  $G$  respecting the transmission reach  $\bar{\ell}_k$  and a subset  $S_k \subset S$  of  $w_k$  consecutive frequency slots that is available on all edges of  $P_k$  and disjoint from the subsets  $S_{k'}$  of all other demands  $k'$  routed along an edge of  $P_k$ , thereby minimizing some objective function.

Hence, the desired output of the RSA problem is, for each demand  $k \in K$ , a lightpath composed of

- an  $(o_k, d_k)$ -path  $P_k$  in  $G$  with  $\sum_{e \in E(P_k)} \ell_e \leq \bar{\ell}_k$ ,

 Fig. 1. The network  $G$  used in Example 2.1.

- a subset  $S_k \subset \{1, \dots, \bar{s}\}$  of  $w_k$  consecutive slots with  $S_k \cap S_{k'} = \emptyset$  for each demand  $k' \in K$  routed along an edge  $e \in E(P_k)$ .

This output can be given in terms of a matrix  $M \in \mathbb{N}^{|E| \times \bar{s}}$  with

$$M_{e,s} = \begin{cases} k & \text{if slot } s \in S \text{ is allocated to} \\ & \text{demand } k \in K \text{ on edge } e \in E, \\ 0 & \text{otherwise.} \end{cases}$$

In addition, the selected set of lightpaths is supposed to minimize a chosen objective function. In this paper, we will focus on the following objective functions that have been used in [1], [16], [19] to be able to compare our computational results with those from the literature:

- $O_1$ : minimize the sum of hops in paths (where the term hops refers to the number of edges in a path  $P_k$ ) [19],
- $O_2$ : minimize the number of edges from the network used to route the demands [16],
- $O_3$ : minimize the maximal used slot position (and, thus, the width of the subspectrum of  $S$  used for the spectrum assignment) [1].

Note that the first two objective functions are only related to the routing (provided that a feasible spectrum assignment within  $S$  exists for this routing), whereas the third objective function seeks for the most efficient spectrum assignment over all possible routings.

*Example 2.1:* Consider the following small instance of the RSA problem, given by a spectrum of width  $\bar{s} = 10$ , the network  $G$  shown in Figure 1 with edge length as indicated, and the following set  $K$  of demands:

$k$	$o_k \rightarrow d_k$	$w_k$	$\bar{l}_k$
1	$a \rightarrow c$	2	4
2	$a \rightarrow d$	1	4
3	$b \rightarrow f$	2	4
4	$b \rightarrow e$	1	4
5	$d \rightarrow f$	3	4

An optimal solution w.r.t. objective function

- $O_1$  with minimum sum 11 of hops in paths is represented by matrix  $M_1$ ,
- $O_2$  with minimum number 5 of edges from the network used to route the demands is represented by matrix  $M_2$ ,
- $O_3$  with minimum maximal used slot position 4 is represented by matrix  $M_3$ .

$$M_1 = \begin{pmatrix} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\ ab & & & 3 & 3 & & 4 & & & & \\ af & 1 & 1 & 3 & 3 & 2 & 4 & & & & \\ bc & & & & & & & & & & \\ cd & & & & & & & & & & \\ cf & 1 & 1 & & & & & & & & \\ de & & & & & & 2 & & & & \\ df & 5 & 5 & 5 & & & & & & & \\ ef & & & & & & 2 & 4 & & & \end{pmatrix}$$

$$M_2 = \begin{pmatrix} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\ ab & & & 3 & 3 & & 4 & & & & \\ af & 1 & 1 & 3 & 3 & 2 & 4 & & & & \\ bc & & & & & & & & & & \\ cd & & & & & & & & & & \\ cf & 1 & 1 & & & & & & & & \\ de & 5 & 5 & 5 & & & 2 & & & & \\ df & & & & & & & & & & \\ ef & 5 & 5 & 5 & & & 2 & 4 & & & \end{pmatrix}$$

$$M_3 = \begin{pmatrix} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\ ab & & & & 4 & 2 & & & & & \\ af & 1 & 1 & 4 & & & & & & & \\ bc & 3 & 3 & & 2 & & & & & & \\ cd & 3 & 3 & & 2 & & & & & & \\ cf & 1 & 1 & & & & & & & & \\ de & 3 & 3 & & & & & & & & \\ df & 5 & 5 & 5 & & & & & & & \\ ef & 3 & 3 & 4 & & & & & & & \end{pmatrix}$$

### III. A NOVEL EDGE-NODE FORMULATION

In this section we introduce our novel edge-node ILP model for the RSA problem in the general variant where demands may be rejected.

a) *Variables:* For the routing, *demand-edge variables*

$$x_e^k = \begin{cases} 1 & \text{if demand } k \text{ is routed through edge } e, \\ 0 & \text{otherwise,} \end{cases}$$

are used for all  $k \in K$  and all  $e \in E$  as in [17], [19].

For the spectrum assignment, several different variables are necessary. As in [2], [16], *demand-slot variables*

$$z_s^k = \begin{cases} 1 & \text{if slot } s \text{ is the last slot allocated for demand } k, \\ 0 & \text{otherwise,} \end{cases}$$

are used which indicate that  $s$  is the last of the  $w_k$  consecutive slots allocated for the demand  $k \in K$ , with  $s \in S$ . The consecutive slots  $s' \in \{s - w_k + 1, \dots, s\}$  shall form the channel assigned to this demand  $k$  whenever  $z_s^k = 1$ .

We newly propose *demand-edge-slot variables*

$$t_{e,s}^k = \begin{cases} 1 & \text{if slot } s \text{ is assigned to demand } k \text{ on edge } e, \\ 0 & \text{otherwise,} \end{cases}$$

for all demands  $k \in K$ , all edges  $e \in E$  and all slots  $s \in S$ .

When we optimize objective functions involving max-used slot positions, we newly propose *edge-max-slot-position variables*  $p_e \in \mathbb{Z}^+$  for all edges  $e \in E$  (which indicate the position

of the last slot allocated on the edge  $e \in E$ ), as well as a *max-slot-position variable*  $p \in \mathbb{Z}^+$  (which represents the position of the highest slot used over all the edges  $e \in E$  as in [2]).

When we optimize the number of edges used for the routing, we newly propose *edge-activation variables*

$$a_e = \begin{cases} 1 & \text{if some demand } k \text{ is routed through edge } e, \\ 0 & \text{otherwise,} \end{cases}$$

for all edges  $e \in E$ .

*b) Constraints:* To formulate the constraints, we employ the following notations. For any non-empty subset  $X \subset V$ , let  $\delta(X)$  denote the set of edges having one endnode in  $X$  and the other endnode in  $V \setminus X$ . The pair  $(X, V \setminus X)$  is called a cut of  $G$ , the edges in  $\delta(X)$  are said to cross this cut. In the special case  $X = \{v\}$ , we write  $\delta(v)$  instead of  $\delta(\{v\})$ .

For the routing, we use demand-edge variables  $x_e^k$  and have to ensure by appropriate constraints that the subset

$$E(k) = \{e \in E : x_e^k = 1\}$$

of edges selected for the routing of demand  $k$  indeed forms an  $(o_k, d_k)$ -path  $P_k$  in  $G$ , for each demand  $k \in K$ . For that, we use the following constraints. The *origin constraints*

$$\sum_{e \in \delta(o_k)} x_e^k \leq 1, \text{ for all } k \in K \quad (1)$$

ensure that at most one path  $P_k$  can leave the origin  $o_k$  as at most one of the edges  $e \in \delta(o_k)$  incident to  $o_k$  can be selected for  $E(k)$ . Similarly, *destination constraints*

$$\sum_{e \in \delta(d_k)} x_e^k - \sum_{e \in \delta(o_k)} x_e^k = 0, \text{ for all } k \in K \quad (2)$$

force that the path  $P_k$  enters its destination  $d_k$ , provided that there is a path  $P_k$  leaving  $o_k$ . (Note that if no path is selected for demand  $k$ , then  $\sum_{e \in \delta(o_k)} x_e^k = 0$  holds and ensures that no edge from  $\delta(d_k)$  can be selected either for  $E(k)$ .) Origin and destination constraints are used in [1], [16], [19] in a slightly different manner.

In addition, we newly propose *path-continuity constraints*

$$\sum_{e \in \delta(X)} x_e^k - \sum_{e \in \delta(o_k)} x_e^k \geq 0, \forall k \in K, \forall X, o_k \in X, d_k \in V \setminus X. \quad (3)$$

These constraints are important whenever a path  $P_k$  is selected for demand  $k$  (and, thus,  $\sum_{e \in \delta(o_k)} x_e^k = 1$  holds): they guarantee that there is an edge  $e \in \delta(X) \cap E(k)$  such that the path  $P_k$  indeed crosses the cut  $(X, V \setminus X)$  for each  $X$  with  $o_k \in X$  and  $d_k \in V \setminus X$ .

Hence, origin, destination and path-continuity constraints together imply that  $E(k)$  contains an  $(o_k, d_k)$ -path  $P_k$ . It is left to prevent  $E(k)$  from having more edges than needed for  $P_k$  and  $P_k$  from having a length exceeding the transmission reach of demand  $k$ .

For that, we use as in [6], [16] *degree constraints*

$$\sum_{e \in \delta(v)} x_e^k \leq 2, \text{ for all } k \in K, \text{ and all } v \in V \setminus \{o_k, d_k\} \quad (4)$$

to prevent that more than two edges from  $E(k)$  are incident to any node. Furthermore, we newly propose *cycle-elimination constraints*

$$\sum_{e' \in \delta(X_e)} x_{e'}^k \geq \begin{cases} 2x_e^k & \text{if } |X_e \cap \{o_k, d_k\}| = 0 \\ x_e^k & \text{if } |X_e \cap \{o_k, d_k\}| = 1 \end{cases} \quad (5)$$

$$\forall k \in K, \forall e \in E, \forall X_e \subset V$$

where  $X_e \subset V$  denotes a subset of nodes containing both endnodes of edge  $e$ , to avoid cycles isolated from  $P_k$  (note that isolated edges also fall into this case).

Moreover, we newly propose a *transmission-reach constraint*

$$\sum_{e \in E} l_e x_e^k - \bar{l}_k \sum_{e \in \delta(o_k)} x_e^k \leq 0, \text{ for all } k \in K \quad (6)$$

to ensure that the length of  $P_k$  does not exceed the transmission reach of  $k$  if the demand  $k$  is accepted, otherwise all the variables  $x_e^k$  are forced to equal zero.

When we optimize the number of edges used for the routing, we need in addition the following constraints

$$a_e - x_e^k \geq 0, \text{ for all } k \in K, \text{ and all } e \in E \quad (7)$$

to force  $a_e = 1$  when  $x_e^k = 1$  for some  $k \in K$ , and

$$a_e \leq \sum_{k \in K} x_e^k, \text{ for all } e \in E \quad (8)$$

to guarantee  $a_e = 0$  if edge  $e$  is not used in any routing.

For the spectrum assignment, we have to guarantee that, whenever demand  $k$  is accepted and an  $(o_k, d_k)$ -path  $P_k$  has been selected,

- a channel  $S_k \subset S$  of  $w_k$  consecutive frequency slots is assigned to  $k$ ,
- this channel is the same on all edges of  $P_k$  and disjoint from the channels  $S_{k'}$  of all other demands  $k'$  routed along an edge of  $P_k$ .

We newly propose *channel selection constraints*

$$\sum_{s=w_k}^{\bar{s}} z_s^k - \sum_{e \in \delta(o_k)} x_e^k = 0, \text{ for all } k \in K \quad (9)$$

that do not allow to assign a channel to demand  $k$  when no path  $P_k$  is selected (by not allowing to assign a slot  $s$  as last slot in the channel), but force to select such a last slot in the channel whenever a path is leaving  $o_k$ . In addition, we specify the available last slots for the channel of demand  $k$  by *forbidden-slot constraints*

$$\sum_{s=1}^{w_k-1} z_s^k = 0, \text{ for all } k \in K, \quad (10)$$

to prevent demand  $k$  to occupy a slot  $s$  as last slot in the channel whenever  $s < w_k$ . Klinkowski et al. [9] proposed a similar idea using demand-edge-first-slot variables.

We newly propose *edge-slot constraints*

$$\sum_{s \in S} t_{e,s}^k - w_k x_e^k = 0, \text{ for all } k \in K \text{ and all } e \in E \quad (11)$$

to ensure that precisely  $w_k$  slots are allocated on edge  $e$  to demand  $k$  if and only if demand  $k$  is routed through edge  $e$ .

Spectrum contiguity and continuity are handled by the following new *demand-edge-slot constraints*

$$x_e^k + \sum_{s' = s}^{\min(s+w_k-1, \bar{s})} z_{s'}^k - t_{e,s}^k \leq 1, \forall k \in K, \forall e \in E, \forall s \in S \quad (12)$$

to force that slot  $s$  on edge  $e$  is allocated to demand  $k$  if and only if demand  $k$  passes through edge  $e$  and slot  $s$  belongs to the channel assigned to demand  $k$  (which is the case if one slot  $s' \in \{s, \dots, s + w_k - 1\}$  is the last slot of the channel).

We newly propose *non-overlapping constraints*

$$\sum_{k \in K} t_{e,s}^k \leq 1, \text{ for all } e \in E \text{ and all } s \in S \quad (13)$$

to ensure that a slot  $s$  on edge  $e$  can be allocated to at most one demand.

When we optimize objective functions involving max-used slot positions, we newly propose two additional constraints

$$st_{e,s}^k - p_e \leq 0, \text{ for all } k \in K, \text{ all } e \in E \text{ and all } s \in S \quad (14)$$

to guarantee that no slot  $s$  above  $p_e$  is used on edge  $e$  and

$$p_e - \sum_{k \in K} \sum_{s \in S} st_{e,s}^k \leq 0, \text{ for all } e \in E \quad (15)$$

to force the max used slot position on edge  $e$  to equal 0 if no demand is routed through edge  $e$ , set the bounds  $p_e \leq p \leq \bar{s}$ , and force  $p_e \in \mathbb{N}$  for all  $e \in E$  and  $p \in \mathbb{N}$  to be integral. Finally, we force all other variables to be binary and require non-negativity for all variables.

c) *Objective functions*: With the help of these variables, the considered objective functions read as follows:

- $\min \sum_{e \in E, k \in K} x_e^k$  to minimize the sum of number of hops in the paths,
- $\min \sum_{e \in E} a_e$  to minimize the number of edges used for the routing, and
- $\min p$  to minimize the max-used slot position.

Recall that our model encodes the general variant of the RSA problem when demands may be rejected. This situation does not comply with the objective functions studied in [1], [16], [19] (as for all three objective functions, rejecting all demands would yield the optimal solution, with objective function value equal to 0). Our model can be easily adapted to the special case where all demands have to be served, by requiring equality in the origin constraint (1) and simplifying the constraints (2), (3), (6) and (9) by replacing the term  $\sum_{e \in \delta(o_k)} x_e^k$  by 1.

#### IV. COMPARISON OF EDGE-NODE FORMULATIONS

All three edge-node formulations from [1], [16], [19] for the RSA problem are compact models as both the numbers of variables and constraints grow only polynomially in the size of the instance, i.e., in the size of the network  $G = (V, E)$  (measured by  $|V|$  and  $|E|$ ), the width of the optical spectrum  $S$  (measured by  $|S|$ ), and the number of demands (measured by  $|K|$ ). Table I summarizes the order of the number of variables and constraints for the three models<sup>1</sup>.

TABLE I  
THE ORDER OF THE NUMBER OF VARIABLES AND CONSTRAINTS IN THE MODELS FROM THE LITERATURE.

	number of variables	number of constraints
model in [16]	$O( K ^2 E  S )$	$O( K ^2 E  S )$
model in [19]	$O( K ( E  +  S ))$	$O( K ^2 E  S )$
model in [1]	$O( K ( E  +  S  +  K ))$	$O( K ( E  +  V  +  K ))$

Our model uses also a polynomial number of variables, namely  $O(|K||E||S|)$ , but an exponential number of constraints due to

- path-continuity constraints (3) for all subsets  $X \subset V$  with  $o_k \in X, d_k \in V \setminus X$ , for all demands  $k \in K$ ,
- cycle-elimination constraints (5) for all subsets  $X_e \subset V$  containing both endnodes of edge  $e$ , for all edges  $e \in E$  and all demands  $k \in K$ .

Recall that path-continuity constraints (3) are used to force that the set  $E(k)$  of edges selected for the routing of demand  $k$  contains an  $(o_k, d_k)$ -path  $P_k$ , whereas cycle-elimination constraints (5) are used to prevent  $E(k)$  from containing cycles isolated from  $P_k$ , see Figure 2 for illustration. None of the

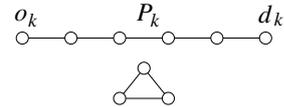

Fig. 2. A set  $E(k)$  containing an  $(o_k, d_k)$ -path  $P_k$  together with a cycle isolated from  $P_k$ .

models from [1], [16], [19] can exclude the occurrence of cycles isolated from  $P_k$ , the model presented in [19] can even not exclude cycles attached to  $P_k$ , see Figure 3 for illustration.

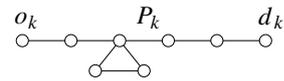

Fig. 3. A set  $E(k)$  containing an  $(o_k, d_k)$ -path  $P_k$  together with a cycle attached to  $P_k$ .

<sup>1</sup>To allow a comparison, we count integer variables with  $n$  possible values as  $n$  binary variables, and express variables encoding possible channels in terms of the spectrum width  $|S|$ .

In addition, none of the three models checks whether the transmission reach of routing paths is respected. Hence, all three models from [1], [16], [19] are incomplete as their feasible region is a superset of all feasible solutions of the RSA problem and can, thus, handle only some objective functions (where the optimal solution does neither contain cycles isolated from  $P_k$  nor cycles attached to  $P_k$ ).

Our model is the first complete edge-node formulation for the RSA problem as it precisely encodes the set of all feasible solutions, i.e., any integral vector satisfying all constraints from our model indeed corresponds to a feasible solution of the RSA problem. Therefore, our model can be used to optimize any objective function chosen as quality measure by the network operator.

In addition, our model is not only complete, but still tractable as we are able to separate the two exponentially-sized families of constraints (3) and (5) in polynomial time.

In fact by the polynomial equivalence between separation and optimization over rational polyhedra [5], the linear relaxations of our model can be solved in polynomial time if and only if the separation problem associated with inequalities (3) and (5) can be solved in polynomial time. The separation problem for the path-continuity constraints (3) reduces to  $O(|K|)$  minimum-cut problems in  $G$  and the separation problem for the cycle-elimination constraints (5) to  $O(|K||E|)$  minimum-cut problems in an auxiliary graph.

Therefore the separation problem associated with (3) and (5) is polynomially solvable using any polynomial-time maximum-flow algorithm (e.g., the preflow-push algorithm of Goldberg and Tarjan [4] running in  $O(|V|^3)$  time). Note that this separation approach provides the most-violated inequality if any w.r.t. a demand or a pair of a demand and an edge.

## V. COMPUTATIONAL RESULTS

In this section we present some preliminary computational results that mainly aim at assessing the empirical performances of a branch-and-cut framework based on our model for the three objectives functions presented in Section II and at comparing them with the results obtained by Velasco et al. [16] for  $O_2$  and by Cai et al. [1] for objective  $O_3$ .

In our experiments we therefore consider the Spanish Telefónica network represented in Figure 4 from [16] and three networks represented in Figure 5 from [1]. The characteristics of the topology of these four networks are given in Table II together with the available numbers of slots per link.

As none of the instances considered in [1], [16] were available, we randomly generated multisets of traffic demands, some of them using Net2Plan [12], while guaranteeing that some of those multisets share the properties described in [1], [16], that is, the same number of traffic demands (12 for Spanish Telefónica and 30 for n6s9) and the same range of values for the requested numbers of slots (in  $\{1, 2, 4\}$  for Spanish Telefónica and in  $\{1, \dots, 3\}, \dots, \{1, \dots, 9\}$  for n6s9). Table III summarizes the different types of traffic-demand multisets we considered for each network.

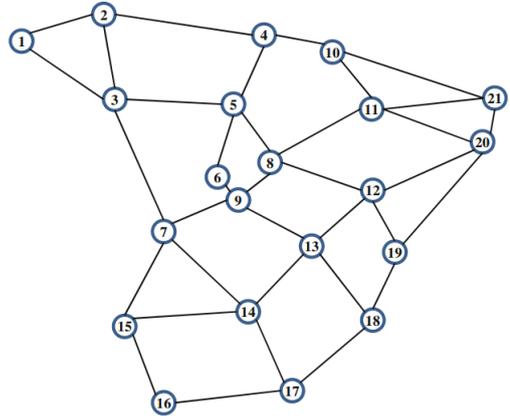

Fig. 4. Spanish Telefónica Network from [16]

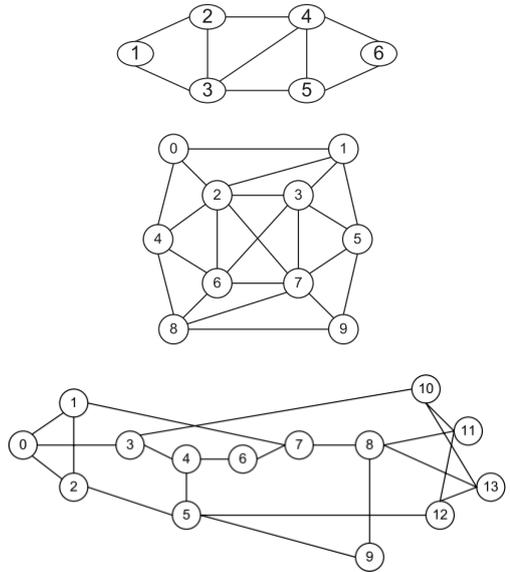

Fig. 5. n6s9, SmallNet, and NSFNET Networks from [1]

All our results were obtained on a laptop, running Microsoft Windows 10 Pro (64-bit), equipped with a 2.5GHz Intel Core i5-7300 HQ processor and 16-GB RAM. The branch-and-cut framework was implemented using IBM ILOG CPLEX Optimization Studio 12.8 C++ library. Note that using user-cut callbacks (needed for the separation of constraints (3) and (5)) in CPLEX 12.8 automatically deactivates the multithreading. To balance some struggles that the default heuristic of CPLEX has to generate good feasible solutions, we implemented a heuristic callback based on

- first decomposing for each demand  $k \in K$  its flow (given by the  $x_e^k$ -variables) into  $(o_k, d_k)$ -paths and
- second using a first-fit greedy approach to assign the best possible channels to the demands,

The first objective function  $O_1$  was considered in neither [1] nor [16]. Within a one-hour time limit, our branch-and-cut framework was able to solve to optimality all our instances

TABLE II  
CHARACTERISTICS OF THE NETWORK TOPOLOGIES

Network's name	number of nodes	number of links	number of slots per link
Spanish Telefónica	21	35	64
n6s9	6	9	80
SmallNet	10	22	{80, 100, 140, 180}
NSFNET	14	21	{120, 160, 210, 285}

TABLE III  
CHARACTERISTICS OF THE TRAFFIC DEMANDS

Network's name	number of demands	number of requested slots
Spanish Telefónica	{12, 15}	{1, 2, 4}
n6s9	{30, 50}	{1, ..., i}, i = 3, ..., 9
SmallNet	{100, 150, ..., 500}	{1, ..., 4}
NSFNET	{100, 150, ..., 250}	{2, ..., 6}

but the ones with 500 demands for which the optimality gap was under 0.5%. Over the course of the solution process, both the lower and upper bounds kept improving and only towards the end, optimal solutions were found.

For the second objective function  $O_2$ , Velasco et al. [16] were able to solve to optimality a single instance of Spanish Telefónica with 12 demands in over 6 hours. It took less than 3 hours for our branch-and-cut framework to solve to optimality the Spanish Telefónica instances with 12 demands and less than 6 hours for the Spanish Telefónica instances with 15 demands. We also ran our branch-and-cut framework on all the instances associated with n6s9 and were able to get optimal solutions within at most 15 minutes. Very early in the solution process, optimal solutions were found meaning that most of the solution time is dedicated to proving the optimality of those solutions (e.g., for the Spanish Telefónica with 12 demands, an optimal solution is found after about 15 minutes but proved optimal after about 2 hours and 40 minutes).

Cai et al. [1] only considered the third objective function  $O_3$  in their experiments with the additional property that given any two distinct nodes  $o$  and  $d$  of  $G$ , the multiset  $K$  of traffic demands contains either both demands having nodes  $o$  and  $d$  as their extremities (with the same requested number of slots) or none of them, and for the former case one assigned route is the reverse of the other one. Some of our generated instances for n6s9 fulfilled that property and were all solved to optimality within 20 minutes while Cai et al. [1] needed up to one hour to solve their similar instances (with CPLEX multithreading being active). We also ran our branch-and-cut framework on n6s9 instances without the reverse-demand property and for most of the instances were able to find optimal solutions within two hours and an optimality gap lower than 5% for the others. We noticed a similar behavior of the lower and upper bounds as for objective function  $O_1$ .

## VI. CONCLUDING REMARKS

The RSA problem in flexgrid elastic optical networks is an NP-hard problem for which various ILP models have been proposed in the literature. Hereby, detailed models aiming at precisely describing all technological aspects and being able to handle different criteria for optimization typically suffer from

tractability issues resulting from their greater complexity such that the tendency is to use simplified models.

The majority of the existing models uses edge-path formulations where the numbers of variables and constraints grow exponentially with the size of the instance, due to the huge number of feasible paths between all origin-destination pairs in the network. Hence, models based on edge-path formulations are often simplified by considering only subsets of precomputed paths (which cannot guarantee optimality, except for few objective functions) or require column-generation techniques (which limits the size of the instances that can be solved to optimality).

An alternative to edge-path formulations is to use edge-node formulations that have the advantage that the number of variables grows only polynomially with the size of the instance. Three compact edge-node formulations are presented in [1], [16], [19] where both the number of variables and constraints is polynomial in terms of the size of the instance. However, all three models are incomplete as their feasible region is a superset of all feasible solutions of the RSA problem and can, thus, handle only some objective functions.

Our contribution is to provide the first complete edge-node formulation for the RSA problem that precisely encodes the set of all feasible solutions and can, therefore, be used to optimize any chosen objective function. For that, we propose an appropriate combination of variables and constraints (partly using new variables and constraints) which results in a model having, as in [1], [16], [19], a polynomial number of variables, but an exponential number of constraints to ensure the exact encoding of feasible solutions.

As we are able to separate the exponentially-sized families of constraints in polynomial time, our model is computationally competitive with the compact but incomplete models from [1], [16], [19]. The computational results support this as our branch-and-cut solver was able, on the one hand, to efficiently handle larger instances and, on the other hand, to find optimal solutions for instances similar to those in [1], [16] in shorter time.

Hereby, we noticed by analyzing the computational results for objective function  $O_2$  that for most instances the optimal solution was found early in the computation process, but that most of the computation time was needed to certify its optimality. Hence, our future research also includes to strengthen lower bounds for the value of different objective functions in order to shorten the time during the computation needed for certifying optimality of a solution.

Therefore, we plan as future research, on the one hand, to strengthen our model further by devising new inequalities, e.g. derived as Chvátal-Gomory cuts from the initial constraints, and, on the other hand, to further improve the separation procedure for the exponentially-sized families of constraints.

Finally, recall that many different objective functions may be considered, depending on the network operator's choice. Besides  $O_1$ ,  $O_2$ ,  $O_3$ , the following objective functions may be of interest:

- $O_4$ : minimize the sum of the total length of paths (taking the edge weights  $l_e$  into account),
- $O_5$ : minimize the maximum load over all edges (where the load of an edge  $e$  is expressed by the number  $s_e$  of slots allocated on edge  $e$ ),
- $O_6$ : minimize the total cost of the solution (where the cost is expressed as the product of the length  $l_e$  and the load  $s_e$  of an edge  $e$ , summed up over all edges  $e$ ).

Hereby, the optimal solutions w.r.t. different objective functions may significantly differ such that an optimal solution for one objective may provide rather bad values according to other optimality criteria. For instance, the three optimal solutions presented in Example 2.1 ( $M_1$  for  $O_1$ ,  $M_2$  for  $O_2$ ,  $M_3$  for  $O_3$  which is also optimal for  $O_5$  minimizing the maximum edge load of 3) differ from each other and from the optimal solution for  $O_4$  and  $O_6$  presented in  $M_4$  (with minimum total length 13 of paths and minimum total cost 22).

$$M_4 = \begin{pmatrix} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\ ab & 1 & 1 & & & 2 & & & & & \\ af & & & & & & & & & & \\ bc & 1 & 1 & 3 & 3 & 2 & 4 & & & & \\ cd & & & & & 2 & 4 & & & & \\ cf & & & 3 & 3 & & & & & & \\ de & 5 & 5 & 5 & & 4 & & & & & \\ df & & & & & & & & & & \\ ef & 5 & 5 & 5 & & & & & & & \end{pmatrix}$$

We notice that the objective functions

- $O_1, O_2, O_4$  for the routing may lead to solutions where some edges are highly loaded (with 6 slots in  $M_1, M_2$  and  $M_4$  where 3 slots suffice as in  $M_3$ ) which also forces a large used spectrum width (6 slots in  $M_1, M_2$  and  $M_4$  where 4 slots suffice as in  $M_3$ ),
- $O_3$  and  $O_5$  for the spectrum assignment may lead to routings along longer paths (total length of 17 in  $M_3$  where 13 suffice as in  $M_4$ ) which may also increase the total cost of the solution (29 for  $M_3$  where 22 suffice as in  $M_4$ ).

Hence, it is also in order to develop strategies to cope simultaneously with different quality measures of solutions.

**Abstract**—The Distance Geometry Problem (DGP) asks whether a simple weighted undirected graph can be realized in a given space (generally Euclidean) so that a given set of distance constraints (associated to the edges of the graph) is satisfied. The Discretizable DGP (DDGP) represents a subclass of instances where the search space can be reduced to a discrete domain having the structure of a tree. In the ideal case where all distances are precise, the tree is binary and one singleton, representing one possible position for a vertex of the graph, is associated to every tree node. When the distance information is however not precise, the uncertainty on the distance values implies that a three-dimensional region of the search space needs to be assigned to some nodes of the tree.

By using a recently proposed coarse-grained representation for DDGP solutions, we extend in this work the branch-and-prune (BP) algorithm so that it can efficiently perform an exhaustive search of the search domain, even when the uncertainty on the distances is important. Instead of associating singletons to nodes, we consider a pair consisting of a box and of a most-likely position for the vertex in this box. Initial estimations of the vertex positions in every box can be subsequently refined by using local optimization.

The aim of this paper is two-fold: (i) we propose a new simple method for the computation of the three-dimensional boxes to be associated to the nodes of the search tree; (ii) we introduce the resolution parameter  $\rho$ , with the aim of controlling the similarity between pairs of solutions in the solution set. Some initial computational experiments show that our algorithm extension, differently from previously proposed variants of the BP algorithm, is actually able to terminate the enumeration of the solution set by providing solutions that differ from one another accordingly to the given resolution parameter.

## I. INTRODUCTION

LET  $G = (V, E, d)$  be a simple weighted undirected graph, where vertices represent objects (whose nature depends on the application at hand), and the existence of an edge  $\{u, v\}$  between two vertices  $u$  and  $v$  indicates that the distance between the two corresponding objects is known [18]. The weight  $d(u, v)$  associated to the edge  $\{u, v\}$  is in general a real-valued interval providing the lower and the upper bound on the distance values. However, the interval  $d(u, v)$  can degenerate to one singleton, and in this situation only one approximation of the distance value is available.

**Definition 1** Given a simple weighted undirected graph  $G = (V, E, d)$  and a positive integer  $K$ , the Distance Geometry Problem (DGP) asks whether a function

$$x : v \in V \longrightarrow x_v \in \mathbb{R}^K$$

exists such that

$$\forall \{u, v\} \in E, \quad \|x_u - x_v\| \in d(u, v), \quad (1)$$

where  $\|\cdot\|$  represents the Euclidean norm.

The function  $x$  is called a *realization* of the graph  $G$ . We say that a realization  $x$  that satisfies all constraints in equ. (1) is a *valid realization*.

The DGP is NP-hard [26], and has several different applications, including: (i) protein structure determination [7] (this is the application we will consider in our experiments in Section IV); (ii) sensor network localization [27]; (iii) multi-dimensional scaling [13]; (iv) clock synchronization [8]; (v) motion adaptation [25]; and others.

We give the following definition of a discretizable subclass of DGP instances [23]. Let  $E'$  be the subset of the edge set  $E$  such that the weight associated to the edges are degenerate intervals.

**Definition 2** A simple weighted undirected graph  $G$  represents an instance of the Discretizable DGP (DDGP) if and only if there exists a vertex ordering on  $V$  such that the following two assumptions are satisfied:

- (a)  $G[\{1, 2, \dots, K\}]$  is a clique whose edges are in  $E'$ ;
- (b)  $\forall v \in \{K + 1, \dots, |V|\}$ , there exist  $u_1, u_2, \dots, u_K \in V$  such that
  - (b.1)  $u_1 < v, u_2 < v, \dots, u_K < v$ ;
  - (b.2)  $\{\{u_1, v\}, \{u_2, v\}, \dots, \{u_{K-1}, v\}\} \subset E'$ ,  
 $\{u_K, v\} \in E$ ;
  - (b.3)  $\mathcal{V}_S(u_1, u_2, \dots, u_K) > 0$  (if  $K > 1$ ),

where  $G[\cdot]$  is the subgraph induced by a subset of vertices of  $V$ , and  $\mathcal{V}_S(\cdot)$  is the volume of the simplex generated by a valid realization of the vertices  $u_1, u_2, \dots, u_K$ .

In the following, we will refer to assumptions **(a)** and **(b)** as the *discretization assumptions*. Such assumptions can be verified only if a vertex ordering is associated to  $V$  [10], which is generally referred to as a *discretization order* when the two assumptions above are satisfied.

Assumption **(a)** allows us to fix a coordinate space where to construct DDGP solutions while making sure that none of them can be obtained from other solutions by applying translations or rotations. Assumption **(b)** ensures that every vertex  $v$  has at least  $K$  *reference vertices*  $u_i$ , with  $1 \leq i \leq K$ , such that the corresponding *reference distance* to  $v$  is known. Since it is supposed (see Assumption **(b.2)**) that only one distance is represented by a non-degenerate interval, the possible positions for  $v$  wrt its reference vertices can be obtained by intersecting  $K - 1$  spheres and one spherical shell, which gives at most two arcs [15]. These assumptions make it possible to reduce the DDGP search space to a discrete domain having the structure of a tree where (possibly degenerate) arcs are associated to its nodes.

In order to simplify the notations, and in accordance with the application that is considered in Section IV, we will suppose in the following that the dimension  $K$  is set to 3.

The branch-and-prune (BP) algorithm [17] can be employed for exploring the search tree obtained with the discretization. In a recent work, we have integrated the BP algorithm with a coarse-grained representation [24]. This representation allows us to deal in an efficient way with the uncertainty of the available distance values, which can have an important impact on the lengths of the arcs obtained with the intersections. Differently from [15], where sample points are selected from the arcs, the coarse-grained representation better deals with uncertainty by assigning to every node of the search tree not only a suitable position  $x_v$  for the corresponding vertex  $v$ , but also a three-dimensional region  $B_v$  where  $v$  is allowed to take its positions. While the initial estimation for  $x_v$  can be very rough, the region  $B_v$  contains all its feasible positions and can therefore be explored for *refining* the position  $x_v$  while searching in a relatively small neighborhood of the search domain. In our first studies, this three-dimensional region is represented by a box inscribing the arcs obtained with the intersections.

This work is a step ahead in the development of an implementation of the BP algorithm that is based on the coarse-grained representation. Our new implementation is the first one that is actually able to enumerate the entire solution set of DDGP instances containing approximated distances (see Section IV). To this final purpose, we propose the integration in the algorithm of the following two features:

- a simple strategy for the definition of the boxes inscribing the arcs obtained with the intersections of the spheres (degenerate intervals) and spherical shell (one non-degenerate interval);
- the introduction of the resolution parameter, which allows to neglect “on-the-fly” all solutions that are *too similar* to solutions that were already computed.

The rest of the paper is organized in three main sections. Section II will be focused on our implementation of the BP algorithm: we will describe the coarse-grained representation, as well as our new method to compute the boxes inscribing the arcs obtained with the discretization process. Section III will introduce the resolution parameter and discuss its impact on the execution of the BP algorithm. Finally, Section IV will present some experiments on DDGP instances of the protein structure determination problem, while Section V will conclude the paper.

## II. AN EXTENDED BP ALGORITHM

We have recently proposed the use of a coarse-grained representation of the DDGP search space in [24]. In the present work, we will extend this approach by introducing some new features in the BP algorithm, so that a *complete* enumeration of the search space will in fact be possible, even in presence of interval distances. This was the main objective of various previous publications (see for example [6]), but it was not completely attained.

In the discussion below, we will focus on the following main points. A general sketch of the BP algorithmic framework will be given in Section II-A, while the coarse-grained representation will be detailed in Section II-B. Then, Section II-C will discuss on how arcs of vertex positions can be computed by exploiting the available distance information, and Section II-D will present our method for the definition of boxes inscribing the arcs.

### A. The BP algorithm

The BP algorithm was formally introduced in [17], and its basic idea is to perform a systematic exploration of the DDGP search tree. This search domain can be explored starting from its top, where the first vertex belonging to the initial clique is placed. Subsequently, all other vertices in the initial clique can be placed in their unique positions [14], and then the search can actually start with the vertex having rank 4 in the associated discretization order. At each step, the candidate positions for the current vertex  $v$  are computed, and the search is branched. This phase of the BP algorithm is named *branching phase*. Depending on the available distance information, represented by one approximated value, or rather by a real-valued interval, the set of candidate positions may either contain two singletons, or two disjoint arcs, respectively. Therefore, an arc is in general associated to every tree node, which can be in some cases degenerate. The distances that are used during the branching phase are called “discretization distances”.

Pruning devices can be employed for discovering infeasible vertex positions. In BP, the main pruning device verifies whether available distances, that are not used for the discretization, are satisfied by candidate vertex positions or not. As soon as a vertex position is found to be infeasible, then the corresponding branch can be pruned and the search can be backtracked [16]. This phase of the BP algorithm is named

**Algorithm 1** The BP algorithm's main framework

*pruning phase*, and the used distances are called “pruning distances”.

Algorithm 1 is a sketch of the main framework for the BP algorithm. In the BP call,  $v \in V$  is the current vertex to be positioned and  $G$  is the simple weighted undirected graph representing a DDGP instance. Once the initial clique has been realized, the BP algorithm can be invoked recursively, starting from the vertex  $v$  having rank 4. As mentioned above, a lot of research has been conducted in recent years to find the best way to implement the line 16 of the algorithm. In [15], for example, a predefined number  $D$  of sample points are extracted from the generated arcs (the parameter  $D$  is the “discretization factor”). However, this strategy for a *lossy discretization* of the arcs has an important impact on the quality of the solutions, with a consequent amplification of error propagation along the search tree [12].

In our current implementation of the BP algorithm, we do not discretize the arcs, but we rather consider the coarse-grained representation presented in Section II-B. Only one vertex position is associated to every node of the tree, but this position is not fixed in one unique position. If necessary, it can rather be refined subsequently when deeper layers of the tree are reached, by exploring other possible positions inside the box that is associated to the node. It is important to remark that, when the generated arcs are larger, the corresponding box becomes bigger, and it might include positions that are feasible with more than one solution.

*B. A coarse-grained representation for BP*

Previous attempts to improve the efficiency of the BP algorithm (see for example [1], [11]) were based on the idea to avoid branching over subsets of positions from the arcs that may be found to be infeasible at the current layer *before* starting the branching phase. While some improvements were observed, these BP variants are however not able to consider distances that appear subsequently at further tree layers.

This is the main motivation for a coarse-grained representation of DDGP solutions. Instead of fixing, on every branch of the tree, all vertices in unique positions, the idea is to rather associate a small *region* of the search space to every vertex, together with a most-likely position. The shape of the region can be chosen on the basis of the methods that are then used for their manipulation.

In our coarse-grained representation, we use the following function:

$$z : v \in V \longrightarrow (x_v, B_v) \in \mathbb{R}^3 \times \mathbb{R}^6,$$

where  $B_v$  is a box defined in the Cartesian system given by the initial clique (see Section II-A). We point out that  $B_v$  has 6 dimensions (in dimension  $K = 3$ , the position of one vertex of the box, plus the corresponding depth, length and height values are necessary for its unique determination). When a new vertex position  $x_v$  is generated for the current vertex  $v$ , the function  $z$  does not only allow to assign a position  $x_v$  to  $v$ , but also to keep track of the feasible region where it belongs to. On further layers, in fact, the position  $x_v$  may not be feasible wrt some other distances, and it could therefore be *refined* in order to ensure global feasibility. This can be done, for example, by employing solvers for local optimization. The position  $x_v$  is naturally constrained to stay in the original box  $B_v$  for two main reasons. Firstly, the (continuous) search space of the local solver is in this way bounded; secondly, the situation where the local solver can move to solutions belonging to other tree branches is avoided.

We motivate the choice of employing a local solver with the fact that, at every layer of the tree where an infeasibility is discovered, there are only a few distances that are not satisfied, and the actual search space consists of the set product of all boxes  $B_v$ . This makes the corresponding subproblem to solve easier to tackle. Naturally, an important point concerning the use of a local solver is also its fast convergence: in fact, when attempting the solution of harder instances, we expect the local solver to be invoked at almost all recursive BP calls.

In this work, we will use a Spectral Projected Gradient (SPG) method [3], [22], [24] for this refinement step. When the BP algorithm reaches a leaf node, a valid realization  $x$  can be extracted from  $z$  by simply extracting the set of positions  $x_v$ , for every  $v \in V$ .

*C. Computing arcs of vertex positions*

When the discretization assumptions are satisfied, the possible positions for a given vertex  $v$  can be computed by exploiting the set of discretization distances, together with the positions, along the same tree branch, of the corresponding

reference vertices. Let  $u_3$ ,  $u_2$ , and  $u_1$  be the three reference vertices for the vertex  $v \in V$ . Since all reference vertices precede  $v$  in the given discretization order, one position for every  $u_i$  is assigned to the current tree branch, and distances between pairs of reference vertices  $u_i$  may be computed (if not already available). Therefore, the subgraph  $G[\{u_3, u_2, u_1, v\}]$ , when completed with missing distances between reference vertices, always induces a clique. As shown in [14], the distance information in the clique can be exploited to represent the possible positions for  $v$  in terms of torsion angles  $\omega$ . More precisely, once the distances  $d(u_3, u_2)$ ,  $d(u_2, u_1)$ ,  $d(u_1, v)$  are fixed, as well as the angles  $\theta_{u_2}$  and  $\theta_{u_1}$  formed, respectively, by the triplets  $(u_3, u_2, u_1)$  and  $(u_2, u_1, v)$ , then the distance  $d(u_3, v)$  corresponds to two possible values for the torsion angle  $\omega$  formed by the quadruplet  $(u_3, u_2, u_1, v)$  [19].

Let us initially suppose that the distance  $d(u_3, v)$  is exact: at most two distinct values  $\omega^+$  and  $\omega^-$  can be computed for the torsion angle (it might happen that they coincide). The two corresponding positions for the vertex  $v$  can therefore be computed with the following formula:

$$\chi(v, \omega) = x(u_1) + Uw(v, \omega), \quad (2)$$

where the matrix  $U$  is a rotation matrix (see [9]) and

$$w(v, \omega) = \begin{bmatrix} -d(u_1, v) \cos \theta_{u_1}, \\ d(u_1, v) \sin \theta_{u_1} \cos \omega, \\ d(u_1, v) \sin \theta_{u_1} \sin \omega. \end{bmatrix}. \quad (3)$$

When the distance  $d(u_3, v)$  is represented by an interval, two intervals of  $\omega$  can be defined [11]. From a geometrical point of view, the interval distance  $d(u_3, v)$  corresponds to two arcs that can be identified over the circle obtained by intersecting two spheres centered in  $u_1$  and  $u_2$  and having as radius, respectively, the corresponding reference distances. We generate a three-dimensional box inscribing every obtained arc, so that it can then be associated to the tree node, together with one position taken from the arc. This chosen position is the one that will be used at further layers when defining spheres or spherical shells for the intersections; however, this position may need to be refined when infeasibilities are detected by the pruning devices. The refinement step is supposed to keep the given position  $x_v$  inside the predetermined box  $B_v$ .

#### D. Computing the boxes

The boxes are defined by using the minimal and maximal possible coordinates associated to a given interval for  $\omega$ . To perform this calculation, we remark that the three components of  $\chi(v, \omega)$  (see equ. (2) and equ. (3)) can be rewritten (we explicitly write only the first component  $\chi'$ ) as:

$$\chi'(v, \omega) = A(v) \cos \omega + B(v) \sin \omega + C(v),$$

where  $C(v)$  is an additive term, and  $A(v)$  and  $B(v)$  are two multiplicative terms. For fixed  $v \in V$ , since  $C(v)$  is an additive constant, the determination of the minimal and maximal values for the first component of  $\chi(v, \omega)$  can be focused on the

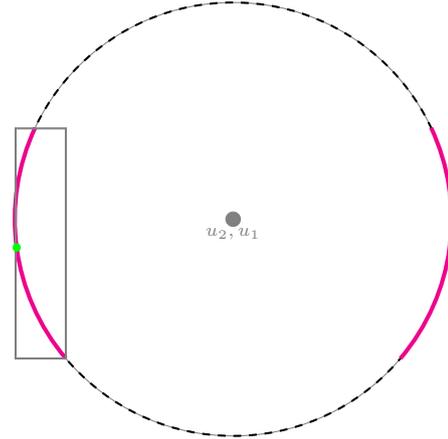

Fig. 1. In dashed line, the circle obtained by intersecting the two spheres centered in  $u_1$  and  $u_2$ . In purple, the arcs on the circle obtained by intersecting this circle with the spherical shell centered in  $u_3$ . For one arc, we show the box inscribing the arc in gray, together with the arc central position in green.

optimization of the remaining terms. By following [11], we remark that

$$A(v) \cos \omega + B(v) \sin \omega = R(v) \cos(\omega - \alpha),$$

where the pair  $(R(v), \alpha)$  corresponds to the polar coordinates of  $(A(v), B(v))$  in dimension 2:

$$\begin{cases} A(v) = R(v) \cos \alpha, \\ B(v) = R(v) \sin \alpha. \end{cases}$$

As a consequence, the problem of finding the minimal and maximal values for  $\chi'(v, \omega)$  reduces to the one of finding the optimal values for the cosine function. Notice that the value of  $\alpha$  can be computed as

$$\alpha = \arctan\left(\frac{B(v)}{A(v)}\right)$$

and that the same strategy can be used for finding the minimal and maximal values for the other components of  $\chi(v, \omega)$  over the given interval for  $\omega$ . A graphical representation of the obtained boxes is given in Fig. 1.

### III. RESOLUTION PARAMETER

At every recursive call of the BP algorithm (see Section II-A), the intersection of two spheres with one spherical shell produces two arcs [11]. The coarse-grained representation (see Section II-B) replaces every arc with a box inscribing the arc (see Section II-D) and a most-likely position, which is initially set at the arc central point. Every generated pair  $(x_v, B_v)$  consisting of a position and a box for the vertex  $v$  can be then assigned to the nodes of the search tree.

The *resolution* parameter  $\rho$  is integrated in the BP algorithm for controlling the size of the boxes associated to the tree nodes. This is done at two different levels:

- 1) If the length of the current arc is larger than the resolution parameter  $\rho$ , then the arc is split in a sufficient number of equally-long sub-arcs whose length is smaller

than  $\rho$ . Naturally, this strategy implies that the search domain is not binary anymore at all layers, for many vertices may need more than two arcs for satisfying the required resolution. On the one hand, this procedure increases the complexity of the search; on the other hand, it allows to assign smaller boxes to the tree nodes, so that the search domain of the local optimizer becomes smaller as well.

- 2) If at least one solution has already been found, and the BP algorithm is currently exploring alternative nodes at a given layer  $v$ , then only positions  $x_v$  whose Euclidean distance from the position of  $v$  in the previously found solution is larger than  $\rho$  are considered. In fact, when this distance is smaller than  $\rho$ , the previous and the current solution are “too” similar, and the current one can therefore be discarded. Notice that, even if this Euclidean distance may be larger than  $\rho$  when the nodes are generated, the local optimizer may modify the positions  $x_v$  so that it subsequently becomes smaller than  $\rho$ . In such a case, the previous and the current solution have the tendency to converge to the same conformation, and thus the current branch can be discarded.

To sum up, the resolution parameter  $\rho$  does not only influence the branching phase of the BP algorithm, but it rather performs two kinds of verification during the execution of the algorithm ensuring that all generated solutions differ from one another in accordance with the chosen resolution parameter.

#### IV. COMPUTATIONAL EXPERIMENTS

We present in this section some initial computational experiments on a set of artificially generated instances. All codes were written in C programming language and all experiments were carried out on an Intel Core i7 2.30GHz with 8GB RAM, running Linux. The codes have been compiled by the GNU C compiler v.4.9.2 with the `-O3` flag.

Before showing our computational experiments, we will briefly present the considered application in structural biology concerning the determination of protein structures (see Section IV-A), and we will explain how we generated our instances (see Section IV-B). Section IV-C will present the experiments.

##### A. Protein structure determination

One of the classical applications of the DGP arises in structural biology [7]. Distances between atom pairs in a given molecule can be estimated through experiments of Nuclear Magnetic Resonance (NMR), so that the possible conformations of the molecule in the three-dimensional space can be identified by solving an instance of the DGP. This application is of relevant interest, especially when dealing with proteins, because the identification of protein conformations can give insights on the dynamics of such molecules, and therefore on their function.

It was proved that protein instances of the DGP belong to the subclass of the DDGP [14], [23]. In many papers cited above (see for example [15], [6], [12]), protein instances are

TABLE I

				2.0	1	3.47e-05	4m 5s

used to perform the experiments. However, as already pointed out in the Introduction, none of such previous works were able to perform an exhaustive search on the domain of the considered instances. Our experiments will show that the BP algorithm, integrated with the new features introduced in this work, is actually able to perform this exhaustive search.

##### B. Generation of the instances

We selected the protein conformations that were considered in the experiments presented in [6] and [24]. We do not use real NMR data, but we rather generate our protein instances from known models of the selected proteins. The three considered proteins, having codes 2jmy, 2kxa and 2ksl in the Protein Data Bank (PDB) [2], have been experimentally determined by NMR experiments, and, as it is usually the case, more than one model for each protein was deposited. In our instance generation, we have simply considered the first model that appears in the corresponding PDB file.

Our instances are generated in a way to resemble NMR data. From the initial conformation model, we compute all inter-atomic distances, and we include in our instance the following distances:

- distances between bonded atoms (only one real value approximated to 3 decimal digits);
- distances between atoms bonded to a common atom (only one real value approximated to 3 decimal digits);
- distances between the first and the last atom forming a torsion angle (distances represented by an interval);
- distances between hydrogen atoms that are shorter than 5Å (distances represented by an interval).

In order to define the interval distances, we create an interval of range  $0.1\text{\AA}$  for the distances related to torsion angles, and an interval of range  $0.5\text{\AA}$  for distances related to hydrogens, and we place the true distance randomly inside such an interval. The atoms are sorted accordingly to the order proposed in [21], which ensures the discretizability of the instance.

##### C. Some initial experiments

We present some initial experiments performed by considering the instances generated as detailed in the previous section. Table I summarizes our experiments: the information about the graph representing the DDGP instance is given together with the chosen resolution  $\rho$ . Moreover, for every experiment, the

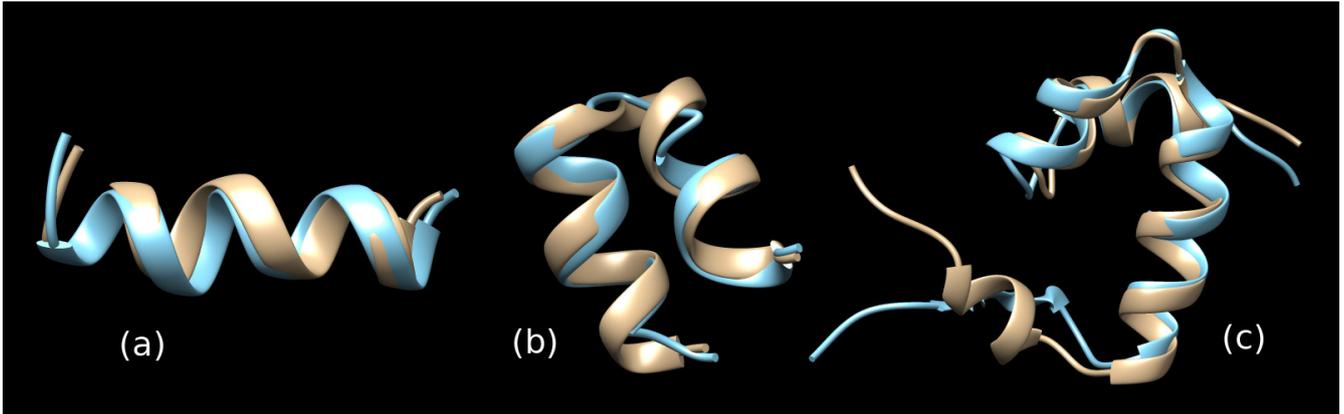

Fig. 2. For every considered protein instance (see Table I), we propose the alignment between the protein model (in gold) that we considered for the generation of the instances, and the best matching solution found by our BP algorithm implementation (in blue). (a) is the alignment obtained for 2jmy; (b) for 2kxa; (c) for 2ks1. The BP solution was subject to energy minimization before the alignment.

total number (#sols) of found solutions is reported, together with the best MDE value:

$$\text{MDE}(x) = \frac{1}{|E|} \sum_{\{u,v\} \in E} \frac{\Delta(\|x_u - x_v\|, d(u,v))}{d(u,v)}, \quad (4)$$

and with the time in minutes (m) and seconds (s). We point out that the given number #sols of solutions is the value of our solution counter at the end of the *complete* enumeration of the search tree, with the specified resolution parameter  $\rho$ . The function  $\Delta(y, I)$  in equ. (4) computes the distance on a line between the real value  $y$  and the real-valued interval  $I$ .

SPG is invoked as a local optimization solver for performing the refinement step (see Section II-B), with the same general settings used in [22]. SPG can terminate because of different criteria: either when the objective function value becomes smaller than  $10^{-6}$ , or when the norm of the search direction becomes smaller than  $10^{-6}$ , or when it reaches the maximum number of allowed interactions, which is set to 10000 in our experiments. Notice that the objective function optimized by SPG is not the MDE function above (MDE is in fact not differentiable in its entire definition domain): more information about SPG and its implementation can be found in [22], [25].

It is easy to see that the newly introduced resolution parameter is able to control the cardinality of the final solution set. The more its value is large, the less are the found solutions (i.e. more solutions are discarded because considered to be too similar to previously obtained solutions). The resolution parameter also influences the total computational time, because it allows to skip all branches potentially leading to similar solutions.

In order to verify how the BP algorithm is able to reconstruct the original protein models used to generate our instances, we have aligned the original structure with the obtained solutions. Before alignment, however, for the two compared structures to be in the same conditions, we optimized the internal energy of the BP structures. To perform such an optimization, the topology/parameter file and the coordinate

file were prepared by the `tLEaP` module of the AMBER 16 program suite [5]. The `GBn` model of Mongan et al. [20] was used for the implicit solvent model; the Bondi radii set was also used [4]. 250 steps of steepest descent minimization were followed by 250 steps of conjugated gradient minimization. The MPI version of `pmemd` program of AMBER 16 suite was used for energy minimization.

Fig. 2 shows the obtained alignments. They show that the BP algorithm is actually able to *reconstruct* the original protein model that was used to generate our instances. We can remark moreover that the quality of the solutions, measured through the MDE function, is independent on the resolution parameter, and has a rather constant magnitude in all experiments. Its value indicates a very good quality for the found solutions (recall that the distances represented by only one approximated value are represented with 3 decimal digits).

## V. CONCLUSION

We have presented an extended version of the BP algorithm which allows an efficient exploration of the search tree obtained with the discretization of the DGP. This extended version is in fact capable of enumerating exhaustively the search tree even when the distance information is given through real-valued intervals. A pair consisting of a three-dimensional box and a selected vertex position in the box is associated to every node of the tree, so that the selected position can be refined at further layers of the search tree when new distance information needs to be verified. The inclusion of a resolution parameter allows to generate boxes with controlled sizes, and to perform the BP branching phase only when the new added branches lead to the generation of solutions that differ, in accordance with the resolution parameter, from solutions that were already computed.

One of the first objectives of our future works will consist in solving DGP instances containing NMR data that are obtained through the experimental technique. To this aim, the main challenge that we will need to face is given by the lower

precision of the distance information. In fact, the intervals related to distances derived from NMR experiments may correspond to ranges up to 3Å. Moreover, the possibility to skip the energy minimization step (that was performed in our computational experiments) will be studied by including more stringent distance constraints for important hydrogen bonding distances.

Finally, work will be performed for formalizing the concepts related to the introduction of the resolution parameter, which will require a complete understanding of the actual impact of this new parameter on the BP algorithm.

#### ACKNOWLEDGMENTS

Most of this work was performed during the visit of AM to Academia Sinica (April 2019), and of JHL to IRISA (May 2019), which were made possible thanks to our CNRS-MoST PRC project entitled “Rapid NMR Protein Structure Determination and Conformational Transition Sampling by a Novel Geometrical Approach” (years 2018–19).

**Abstract**— We deal here, in the context of a H2020 project, with the design of evacuation plans in face of natural disasters: wildfire, flooding... People and goods have to be transferred from endangered places to safe places. So we schedule evacuee moves along pre-computed paths while respecting arc capacities and deadlines. We model this scheduling problem as a kind of multi-mode *Resource Constrained Project Scheduling problem (RCPSP)* and handle it through network flow techniques.

## I. INTRODUCTION

THIS work has been carried on in the context of the H2020 GEOSAFE European project [4], whose overall objective is to develop methods and tools enabling to set up an integrated decision support system to assist authorities in optimizing the resources during the response phase to a natural disaster, mainly a wildfire or a flooding. In such a circumstance, decisions which have to be taken are about fighting the cause of the disaster, adapting standard logistics (food, drinkable water, health...) to the current state of infrastructures, and evacuating endangered areas (see [2]). We focus here on the *late evacuation problem*, that means the evacuation of people and eventually critical goods which have been staying at their place as long as possible.

While evaluation planning remains mostly designed by experts, 2-step optimization approaches have been addressed [2]: the first step (pre-process) involves the identification of the routes that evacuees are going to follow; the second step, which has to be performed in real time, aims at scheduling the evacuation of estimated late evacuees along those routes. As a matter of fact, this last step involves 2 distinct work pieces, one about forecasting, difficult in the case of wildfire, because of their dependence to topography and meteorology [4], and the second one about priority rules and evacuation rates imposed to evacuees [3]. The model which we study here is closed to the one proposed in [1] and called the *non preemptive evacuation planning problem (NEPP)*. According to it, remaining evacuees have been clustered

into groups with same original location and pre-computed route, and once a group starts moving, then it must keep on at the same rate until reaching his target safe area (*Non Preemption* hypothesis, which matches practical concerns of the people who supervise the evacuation process). While authors in [1] address their model while discretizing both the time space and the rate domains and applying constraint propagation techniques, we consider it as an extension of the *Resource Constrained Project Scheduling Problem (RCPSP: [5,6])*, with continuous variables which identify evacuation rates and with an objective function which reflects the safety provided to every evacuee. We use this RCPSP reformulation in order to design a heuristic algorithm which deals with our problem according to network flow like techniques, well-fitted to real-time emergency contexts.

The paper is structured as follows: Section 2 provides the NEPP model. Section 3 describes our RCPSP reformulation. Sections 4, 5 are about algorithms and numerical tests.

## II. NON PREEMPTIVE EVACUATION PLANNING (NPEP)

We consider here a transit network  $H = (N, A)$ :  $N$  is its node set and  $A$  its arc set; Every arc  $e \in A$  is provided with the time  $TIME(e)$  required for some evacuee to move through  $e$  and with the maximum number  $CAP(e)$  of evacuees who may engage themselves  $e$  per time unit. We distinguish:

- The *Evacuation* node subset  $N^+$ , whose nodes are labelled  $i = 1..n$  and related to some population  $P(i)$ .
- The *Safe* node subset  $N$  and the *Relay* node subset  $N^-$ .

Evacuees of the population  $P(i)$  located at  $i \in N^+$  move along a pre-determined path  $I(i)$ , that means a sequence of arcs  $e^1, \dots, e^k(i)$  connecting  $i$  to some *safe* node  $S(i)$ . We set  $L\_TIME(i) = \sum_{k=1..k(i)} TIME(e^k)$ , and, for any  $k =$

1..k(i):  $L(i, k) = \sum_{k \leq j} TIME(e_k^i)$  and  $L^*(i, k) = \sum_{k \geq j} TIME(e_k^i)$ .

We must comply with capacity restrictions: During one time unit, no more than  $Deb(i)$  evacuees may start moving from  $i \in N^+$  and no more than  $CAP(e)$  evacuees may simultaneously engage themselves on a given arc  $e$ . Also, forecast about the way the natural disaster will evolve imposes that for any arc  $e$  of the transit network, nobody may start moving along  $e$  after deadline  $Dead(e)$ , while the whole evacuation process should be over at global deadline  $T-Max$ . Thus all evacuees coming from  $i \in N^+$  should reach related safe node  $S(i)$ , before  $\Delta(i) = \text{Inf}(T-Max, \text{Inf}_{k=1..k(i)}(Dead(e_k^i) + L^*(i, k)))$ .

Besides, authorities impose *Non Preemption*: once evacuees related to evacuation node  $i$  have started moving, they must keep on at the same speed and rate along path  $\Gamma(i)$ , until they all reach safe node  $S(i)$ . We denote by  $v_i$  the related evacuation rate (number of evacuees per time unit which enter on  $\Gamma(i)$  at until  $i$  becomes empty. We derive an upper bound  $v-max(i)$  for  $v_i$  by setting:  $v-max(i) = \text{Inf}(\text{Inf}_j CAP(e_k^i), Deb(i))$ . We also see that if we are provided with the start-date  $T_i$  of  $i$  evacuation process and with its evacuation rate  $v_i$  then we deduce its end-date  $T^*_i = T_i + L\_TIME(i) + P(i)/v_i$ . We deduce from deadline  $\Delta(i)$  a minimal evacuation rate  $v-min(i) = P(i)/(\Delta(i) - L\_TIME(i))$ .

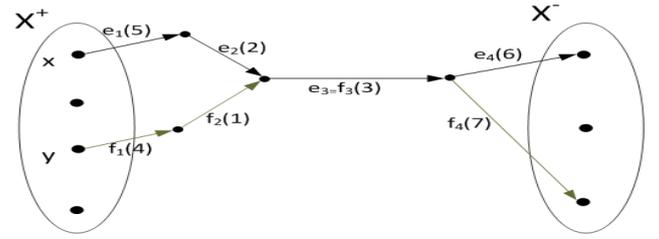

Then, the *Non Preemptive Evacuation Planning Problem* (NEPP) is about the computation of an evacuation schedule, which means of start-times  $T_i$  and evacuation rates  $v_i$ ,  $i \in N^+$ . The quality of such a schedule  $\Lambda = (T, v)$  is going to be the weighted safety margin  $\sum_i P(i) \cdot (\Delta(i) - T^*_i)$ .

### III. A RCPSP ORIENTED REFORMULATION OF NPEP.

We identify evacuation nodes  $i$  of network  $H$  and related evacuation jobs. So the key idea here is to consider the arcs  $e$  of the network  $H$  as resources, likely to be exchanged by evacuation jobs  $i, j$  whose paths  $\Gamma(i)$  and  $\Gamma(j)$  share arc  $e$ . In order to formalize it, we introduce *Conditional Time Lags*:

- If  $\Gamma(i) = \{e^i_1, \dots, e^i_{k(i)}\}$  and  $\Gamma(j) = \{f^j_1, \dots, f^j_{k(j)}\}$  share arc  $e = e^i_k = f^j_l$ , and if evacuees from  $j$  come on  $e$  after evacuees from  $i$ , then delay  $T_j - T_i$  will be no smaller than  $TL-Elem(i, j, e) = L(i, k-1) - L(j, l-1) + P(i)/v_i$ .
- Set  $Arc(i, j) = \{e \in \Gamma(i) \cap \Gamma(j)\}$  and  $TL(i, j, v_i) = \text{Sup}_{e \in Arc(i, j)} (L(i, k-1) - L(j, l-1) + P(i)/v_i) = \text{Conditional Time Lag}$  between  $i$  and  $j$ . If  $Arc(i, j) \neq \text{Nil}$  and evacuees of  $j$  enter after evacuees of  $i$  on the arcs of  $Arc(i, j)$ , then we must have  $T_j \geq T_i + TL(i, j, v_i)$ . We notice  $TL(i, j, v_i)$  depends in a convex way on the evacuation rate  $v_i$  of  $i$ .

This notion is illustrated by following Figure 1:

$$P(x) = 50, v_y = 10; P(y) = 40, v_x = 15 \Rightarrow$$

$$L(x, 2) = 7; L(y, 2) = 5; TL(x, y, v_x) = 7 + 4 - 5 = 6.$$

Figure 1: Conditional Time Lags.

We derive a RCPSP (*Resource Constrained Scheduling*: [5,6]) reformulation of NEPP, which relies on the fact that we consider every evacuation job  $i \in N^+$  as a job, whose execution requires resources which are arcs  $e \in \Gamma(i)$ , constrained by their capacities  $CAP(e)$  and whose start-dates are constrained by conditional time lags:

#### NPEP-RCPSP Model :

{*Preliminary* : We add to the set  $N^+$  two fictitious jobs  $s$  (source) and  $p$  (sink), in order to express the way resources are exchanged between jobs as a flow vector. Then we set, for any  $i \in N^+$ :  $TL(s, i, CAP(e)) = 0$  and  $TL(i, p, v_i) = L\_TIME(i) + P(i)/v_i$ .

*Output Vectors* : For any  $i$  in  $N^+ \cup \{s, p\}$  compute start-date  $T_i$  and evacuation rate  $v_i$ ; In order to do it we involve, for any pair  $(i, j)$  and any arc  $e$  in  $Arc(i, j)$  the part  $w_{i, j, e}$  of access rate to  $e$  which is given by  $i$  to  $j$

#### Constraints :

- o For any  $i \neq p$ ,  $T_i + L\_TIME(i) + P(i)/v_i \leq \Delta(i)$  ; (\*Deadline Constraints\*) (E1)
  - o for any pair  $(i, j)$  and any  $e$  in  $Arc(i, j)$ ,  $w_{i, j, e} \neq 0 \rightarrow T_j \geq T_i + TL(i, j, v_i)$ ; (\*Conditional Time Lag Constraints\*) (E2)
  - o  $T_s = 0$  ; (E3)
  - o For any  $i$  in  $N^+$ ,  $N^+$  and any arc  $e$  in  $\Gamma(i)$ , (\*Flow Constraints\*):  $\sum_j$  such that  $e \in Arc(x, y) w_{i, j, e} = v_i = \sum_j$  such that  $e \in Arc(j, i) w_{j, i, e}$ ; (E4)
  - o For any arc  $e$  of the transit network  $H$ : (\*Flow Constraints\*):  $CAP(e) = \sum_i$  such that  $e \in \Gamma(i) w_{s, i, e} = \sum_i$  such that  $e \in \Gamma(i) w_{i, p, e}$ ; (E5)
  - o For any  $i$  dans  $N^+$ ,  $v-Min(i) \leq v_i \leq v-Max(i)$ . (E6)
- Maximize:  $\sum_i P(i) \cdot (\Delta(i) - T_i - L\_TIME(i) - P(i)/v_i)$

**Explanation:** (E1) tells that every evacuation job  $i$  must be achieved before deadline  $\Delta(i)$ . (E2) means that if job  $i$  provides  $j$  with some access to arc  $e$ , then the conditional time lag inequality holds. (E4, E5) express Flow Kirshoff laws: arcs  $e$  are resources that evacuation jobs exchange between them; so job  $i$  receives  $v_i$  resource (evacuation rate) for any  $e \in \Gamma(i)$  and no more than  $CAP(e)$  such resource may be simultaneously distributed between evacuation jobs .

## IV. ALGORITHMS

NMEP model contains both NP-Hard RCPSP and TSP problems. We have to choose between assigning high rates  $v_i$  to jobs  $i$  or let them monopolize the access to transit arcs, or conversely restricting  $v_i$  in order to make  $i$  share its arcs. In order to do it, we implement a two-step approach: *MNEP-First-Step* searches a feasible schedule satisfying (E1,...,E6), while *MNEP-Second-Step* increases rates  $v_i$  in order to improve the *weighted safety margin*.

## A. The Greedy-NPEP Process.

*Greedy-NPEP* starts from some linear ordering  $\sigma$  defined on  $N^+ \cup \{s,p\}$ , and considers at any time some job  $i_0$  such that for any  $j$  prior to  $i_0$  according to  $\sigma$ ,  $v_j$ ,  $T_j$  and values  $\Pi(j,e)$  = access level to arc  $e$  that job  $j$  can transmit to  $i_0$  are available. Then it applies a 3 stage function *Assign*( $i_0$ ) which computes (see Fig. 1)  $v_{i_0}$ ,  $T_{i_0}$  and flow values  $w_{j,i_0,e}$ ,  $j$  s.t.  $j \sigma i_0$ , and  $e \in \text{Arc}(j,i_0)$ , or, in case of failure, a job  $j$ -fail  $\sigma i_0$  considered as cause of the failure.

- (1) : *Assign* scans path  $\Gamma(i_0)$ , and for any  $e$  in  $\Gamma(i_0)$ , provides  $i_0$  with access rate to  $e$  in such a way resulting *end-date*  $T^*_{i_0} \leq \Delta(i_0)$ . (see Fig. 2):

**Assign1**

For  $e$  in  $\Gamma(i_0)$  do

Let  $L\text{-Job} = \{j \text{ s.t. } (j \sigma i_0) \text{ AND } (e \in \text{Arc}(j, i_0) \text{ AND } (\Pi(j, e) \neq 0)), \text{ ordered according to increasing } T_j + TL(j, i_0, v_j) \text{ values}\}; v \leftarrow 0$ ; Not Stop;

While  $L\text{-Job} \neq \text{Nil}$  AND Not Stop do

If  $T_j + TL(j, i_0, v_j) + L\_TIME(x_0) + P(i_0)/(v + \Pi(j, e)) \leq \Delta(i_0)$  then

Compute  $w$  such that  $T_j + TL(j, i_0, v(j)) + L\_TIME(x_0) + P(i_0)/(v + w) = \Delta(i_0)$ ;

Stop;  $v \leftarrow v + w$ ;  $w_{j,i_0,e} \leftarrow w$ ;

Else  $v \leftarrow \Pi(j,e) + v$ ;  $w_{j,i_0,e} \leftarrow \Pi(j,e)$ ;

If Not Stop then Fail : Choose  $j$ -Fail in  $L\text{-Job}$

Else  $v\text{-aux}(e) \leftarrow v$ ;

If Not Fail then  $V_{i_0} \leftarrow \text{Sup}_e v\text{-aux}(e)$ ;  $e_0 \leftarrow \text{Arg Sup}$ .

$\sigma = s, \dots, x_1, \dots, x_2, \dots, x_3, \dots, x_0, \dots$

$\Gamma(x_0) = \{e_1, e_2\}$ ;  $CAP(e_1) = 20$ ,  $CAP(e_2) = 25$ ;

$\Delta(x_0)$ ;  $P(x_0) = 50$ ;  $L\_TIME(x_0) = 10$ ;  $\text{Arc}(x_2, x_0) = \{e_1\}$ ;  $\text{Arc}(x_1, x_0) = \{e_1, e_2\}$ ;  $\text{Arc}(x_3, x_0) = \{e_2\}$ ;  $TL(s, x_0) = 0$ ;  $TL(x_1, x_0) = 6$ ;  $TL(x_2, x_0) = 3$ ;  $TL(x_3, x_0) = 4$ ;

$s: T(s) = 0, \Pi(s, e_1) = 2, \Pi(s, e_2) = 3$

$x_1: T(x_1) = 5, \Pi(x_1, e_1) = 9$

$x_2: T(x_2) = 8, \Pi(x_2, e_1) = 9, P(x_2, e_2) = 14$

$x_3: T(x_3) = 13, \Pi(x_3, e_2) = 8$

$x_0$

$\Rightarrow$

*Assign-1* ->  $w_{s,x_0,e_1} = 2$ ;  $w_{s,x_0,e_2} = 3$ ;  $w_{x_1,x_0,e_1} = 8$ ;  $v_{x_0} = 10$ ; *Success*; *Assign-2* ->  $w_{x_2,x_0,e_2} = 7$ ; *Success*; *Assign-3* ->  $w_{x_1,x_0,e_1} = 0$ ;  $w_{x_2,x_0,e_1} = 8$ ;  $T_{x_0} = 21$ .

**Figure 2: Assign Process.**

- (2) : *Assign1* computes  $v_{i_0}$  and, for any  $e \neq e_0$  in  $\Gamma(i_0)$  a value  $v\text{-aux}(e)$  which may be less than  $v_{i_0}$ ; So *Assign2* increases the  $w_{j,i_0,e}$  for  $e \neq e_0$  in order to make job  $i_0$  run at the same rate for all arcs  $e$  of  $\Gamma(i_0)$ . This part of the *Assign* process may induce a failure which *Assign2* assign to some job  $j$ -Fail.
- (3) : *Assign3* makes decrease the number of arcs provided with non null  $w_{j,i_0,e}$  values by shifting values  $w_{j,i_0,e}$  which involve, for a given  $j$ , only one arc  $e$ , to another job  $j'$  such that  $e \in \text{Arc}(j', i_0)$ ,  $w_{j',i_0,e} \neq 0$  and  $\Pi(j', e) \geq w_{j,i_0,e} + w_{j',i_0,e}$ .

Then *Greedy-NPEP* comes as follows:

**Greedy-RCPSP-TL( $\sigma$ ) :**

$T_s \leftarrow 0$ ; For any arc  $e$  do  $\Pi(s, e) \leftarrow CAP(e)$ ; Not Stop;

While (Not Stop) and  $\sigma$  no fully scanned do

Apply *Assign* to current  $i_0$  and partial schedule;

If *Success*(*Assign*) then

For  $e$  in  $\Gamma(i_0)$  and  $j$  s.t.  $(j \sigma i_0) \wedge (e \in \text{Arc}(j, i_0))$

do  $\Pi(i_0, e) \leftarrow v_{i_0}$ ;  $\Pi(j, e) \leftarrow \Pi(j, e) - w_{j,i_0,e}$ ;

Else Stop; Return the pair ( $j$ -Fail,  $i_0$ ).

## B. NPEP-First-Step

*Greedy-NPEP* may fail even in the case when a solution  $(T, v, w)$  exists. It raises the question of the way we deal with linear ordering  $\sigma$ .

- Initialization of  $\sigma$** : For any  $i$ , we set  $SME(i) = \Delta(i) - L\_TIME(i) - 2.P(i)/(v\text{-max}(i) + v\text{-min}(i))$ , and compute  $\sigma$  by randomly sorting  $N^+$  in such a way that if  $P(i) < P(j)$  and  $SME(i) < SME(j)$ , then  $i \sigma j$ .
- Making  $\sigma$  evolve**. In case of failure, *Greedy-NPEP* returns a pair ( $j$ -Fail,  $i_0$ ), and this pair is inserted into a *Tabu* like set *FORBID* whose meaning is: If  $(j, i)$  is *FORBID*, then we should have  $(i \sigma j)$ .

So, global process *NPEP-First-Step* comes as follows:

**Procedure NPEP-First-Step(Max-Iter: Threshold)**

Initialize  $\sigma$  as described above; *FORBID*  $\leftarrow$  Nil;

*Iter*  $\leftarrow 0$ ; Not Stop; *Success*  $\leftarrow 0$ ;

While (*Iter*  $\leq$  *Iter-Max*) AND (Not *Success*) do

Generate  $\sigma$  consistent with *FORBID* and Apply *Greedy-NPEP*; If *Failure* then Search a failure responsible ( $j$ -Fail,  $i_0$ ) pair and put into *FORBID*.

### C. NPEP-Second-Step

In case *NPEP-First-Step* yields a feasible solution  $(T, v, w)$  *NPEP-Second-Step* improves it, by acting on rates  $v_i$  in such a way time lags  $L\_TIME(i) + P(i)/v_i$  decrease in an *ad hoc* way. Let us denote by *U-Active*, the set of pairs  $(i, j)$  which are allowed to support non null  $w_{i,j,e}$  flow values. We notice that if *U-Active* is fixed, then resulting restriction of NPEP is a convex optimization problem defined on the  $(v, w)$  polyhedron defined by (E4, E5, E6). So we fix *U-Active* according to the end of *NPEP-First-Step*, and deal with induced convex program:

- We derive from current  $v, w$ , values  $T^*_i$ , related critical paths, and values  $\lambda = \lambda(i), i \in N^+ \geq 0$ , such that  $\sum_i P(i). T^*_i = \sum_i \lambda(i)/v_i + Constant$ : Vector  $Grad = (Grad_i = -\lambda(i)/v_i^2, i \in N^+)$  is a sub-gradient vector;
- Then we modify  $v$  and  $w$  according to (I1):  $v \leftarrow v + V$ ;  $w \leftarrow w + W$ , with  $V$  and  $W$  s.t  $V.Grad < 0$  and  $v + V$  and  $w + W$  comply with (E4, E5, E6) and computed by solving *Project-Grad* following linear program:

**Project-Grad**(*U-Active*,  $v, w, \delta, Grad$ ) LP :  
 {Compute  $V = (V_i, i \in N^+)$ , and  $W = (W_{i,j,e}, (i, j) \in U-Active, e \in Arc(i, j))$  such that;  
 ○  $\forall (i, j, e), w_{i,j,e} + W_{i,j,e} \geq 0$  ;  
 ○  $\forall i \neq s, p, e \in I(i), \sum_j W_{i,j,e} = \sum_j W_{j,i,e} = V_i$  ;  
 ○  $\forall e, \sum_j W_{s,j,e} = \sum_j W_{j,p,e} = 0$  ;  
 ○  $\forall i \neq s, p, v-Min(i) \leq v_i + V_i \leq v-Max(i)$  ;  
 ○  $2.\delta \geq \sum_{i \neq s, p} V_i. Grad(i) \geq \delta$

Then *NPEP-Second-Step* comes as follows:

#### Procedure *NPEP-Second-Step*:

Let  $(T, v, w)$  be the feasible solution computed by *NPEP-First-Step* and  $T^*$  related *end-date* vector;

Derive *U-Active*; Not *Stop* ;  $Val \leftarrow \sum_i P(i). T^*_i$ ;

While Not *Stop* do

  Compute  $\delta$  and coefficients  $\lambda(i), i \in N$ ;

  Solve *Project-Grad*(*U-Active*,  $v, w, \delta, Grad$ );

  If no solution then *Stop* Else

    Apply (I1), update  $T_i, T^*_i$  and related critical paths; If  $Val-Aux = \sum_i P(i). T_i$ ; If  $Val-Aux \geq Val$  then *Stop*.

### V. NUMERICAL EXPERIMENTS.

**Purpose:** Algorithms were implemented on AMD Opteron 2.1GHz. Our goal was to evaluate the ability of *NPEP-First-Step* to deal with tight deadlines and the ability of *NPEP-Second-Step* to improve this solution.

**Instances/outputs:** An instance is a path collection  $\{I(i), i \in N^+\}$ , given together with values  $P(i), \Delta(i)$  and

$TIME(e_k^i)$ . It is summarized by a 3-uple:  $(n, m, \alpha)$ , where  $n = Car(N^+)$ ,  $m =$  number of arc  $e$ , and  $\alpha$  is as above. We both created our own instances and used an instance generator of [1]. In order to get benchmarks, we generated *ad hoc* schedules  $(T, v)$  and derived deadlines  $\Delta(i)$  which made us be provided with almost optimal solutions.

**Outputs:** For every 10 instance package, we compute:

- The number *Trial* of iterations on  $\sigma$  necessary to get a feasible solution through *NPEP-First-Step*;
- The improvement margin (%) *IMPROVE* induced by *NPEP-Second-Step*;
- The gap between *NPEP* and optimal value *VAL*

Table below provides results for  $\alpha \in [1, 2]$ .

Inst. 1: $n = 20, m = 10$	<i>Trial</i>	<i>IMPROVE</i> (%)	<i>GAP</i> (%)	<i>CPU-NPEP</i>
$\alpha = 1.2$	22.30	13.8	4.7	40.4
$\alpha = 1.5$	2.50	29.5	13.0	12.3
$\alpha = 1.7$	1.39	40.8	17.7	8.1
$\alpha = 2.0$	1.08	61.7	19.3	5.2
Inst. 1: $n = 30, m = 15$				
$\alpha = 1.2$	40.6	14.6	5.6	70.5
$\alpha = 1.5$	6.60	30.2	14.5	19.5
$\alpha = 1.7$	2.05	42.3	19.1	12.0
$\alpha = 2.0$	1.19	65.5	22.5	7.9

**Comment:** Tighting deadlines  $\Delta(i)$  improve solutions.

### VI. CONCLUSION

We described here a two-step RCPSP oriented algorithm for the *NPEP* Problem. Remains now to deal with the design of an exact method for small instances and with an integrated computation of routes  $I(i)$ .

**Abstract**—The physical design placement problem is one of the hardest and most important problems in micro chips production. The placement defines how to place the electrical components on the chip. We consider the problem as a combinatorial optimization problem, whose instance is defined by a set of 2-dimensional rectangles, with various sizes and wire connectivity requirements. We focus on minimizing the placement area and the total wire-length.

We propose a local-search method for coping with the problem, based on natural dynamics common in game theory. Specifically, we suggest to perform variants of *Best-Response Dynamics (BRD)*. In our method, we assume that every component is controlled by a selfish agent, who aim at minimizing his individual cost, which depends on his own location and the wire-length of his connections.

We suggest several BRD methods, based on selfish migrations of a single or a cooperative of components. We performed a comprehensive experimental study on various test-benches, and compared our results with commonly known algorithms, in particular, with simulated annealing. The results show that selfish local-search, especially when applied with cooperatives of components, may be beneficial for the placement problem.

## I. INTRODUCTION

**P**HYSICAL DESIGN is a field in Electrical Engineering which deals with *very large scale integration (VLSI)*. Specifically, physical design is the main step in the creation of *Integrated Circuit (IC)*. The basic question is *how to place the electrical components on the chip*. This fundamental question became relevant with the invention of ICs in 1958 [19], and remains critical our days with the development of micro-electricity. Recent developments in micro-electricity enables transistors to reach the size of nanometers, thus a single chip can accommodate thousands of components of different sizes and dispersed connectivity. Bad layout of electrical components leads to expensive production and poor performance. Figure 1 presents the Intel i7 processor [10], and demonstrates how efficient design is crucial in enabling the accommodation of many components on a small area.

The research was supported by THE ISRAEL SCIENCE FOUNDATION (grant No. 1036/17).

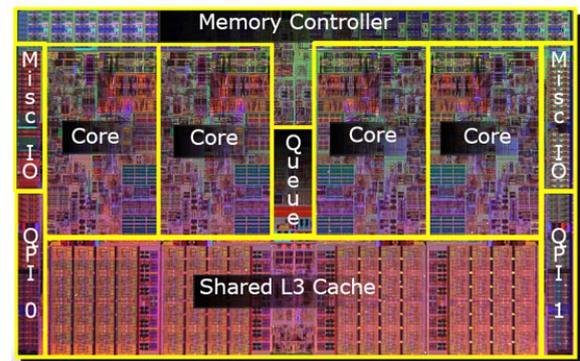

Fig. 1. Intel i7 processor placement.

The complexity of *VLSI physical design* led to the establishment of a design process, in which the problem is divided into several steps, each is an independent NP-complete problem. The most fundamental steps are: (i) *Floorplan*: choose the area of the chip and decide the positions of the building blocks of the chip, (i.e., in Intel processor: cores, graphic processor, cache, memory controller). (ii) *Placement*: Each of the above mentioned building blocks consists of several components. These components should be placed in a way that minimizes area and wire-length. (iii) *Signal and Clock Routing*: route the wires via components white space, which is an extra area assigned for wiring.

In this work, we focus on the *Placement* problem. The floorplan is usually performed manually, and the signal and clock routing is more of a production engineering problem which is tackled using different tools.

Several common methods for coping with the Placement problem are based on local-search. We propose a new class of local-search algorithms that consider the problem as a game played among the components, where each component corresponds to a selfish player who tries to maximize his own welfare. Our algorithms are different from other algorithms based on local search in the way they explore the solution space. Every solution is associated with a global cost, and every component is associated with its individual cost, which is based on its own placement and connections. We move from one solution to another if this move is selfishly beneficial for

a single component or for a small cooperative of components, without considering the effect on the global cost.

In this paper we first review the placement problem, and survey some of the existing techniques to tackle it, in particular local-search algorithms and Simulated Annealing. We then describe our new method of performing selfish Best-Response Dynamics (BRD). In order to evaluate this method, we performed an extensive experimental study in which we simulated and tested several variants of BRD on various test-benches. Our results show that BRD may produce a quick and high quality solution.

#### A. The Placement Problem

The Placement process determines the location of the various circuit components within the chip's core area. The problem, and even simple subclasses of it, were shown to be NP-complete by reductions to the *bin packing* and the *rectangle packing* problems [14], [15]. Moreover, a reduction to the *Quadratic assignment problem* shows that achieving even a constant approximation is NP-hard [9].

Bad placement not only reduces the chip's performance, but might also make it non-manufacturable by forcing very high wire-length, lack of space, or failing timing/power constraints. As demonstrated in Figure 2, good placement involves an optimization of several objectives that together ensure the circuit meets its performance demand [4], [17]:

- 1) *Area*: Minimizing the total area used to accommodate the components reduces the cost of the chip and is crucial for the production.
- 2) *Total wire-length*: Minimizing the total length of the wires connecting the components is the primary objective of the physical design. Long wires require the insertion of additional buffering, to insure synchronization between the components. Short wires decrease the power consumption and the system's leakage.
- 3) *Wire intersection*: Our days, wire intersection is allowed as long as a single wire does not have more than a predefined number of intersections. The manufacturing process enables several routing layers. Nevertheless, a good layout avoids unnecessary intersections.
- 4) *Timing*: The timing cycle of a chip (clock frequency) is determined by the delay induced by the longest wire, usually referred to as the critical path.

Our work considers the initial placement calculation, denoted *global placement*. This stage is followed by the *detailed placement* stage, in which the global placement results are put into use and the cells are actually placed on the die. The detailed placement stage includes small changes to solve local issues such as wire congestion spots, remaining overlaps, layout constrains (such as via locations), connecting to the die pinout, etc.

In the global placement stage, several parameters are optimized. We focus on the total wire-length and placement area. By adjusting the cost function associated with each configuration, our method enables considering additional parameters such as wire congestion, critical path length, and more.

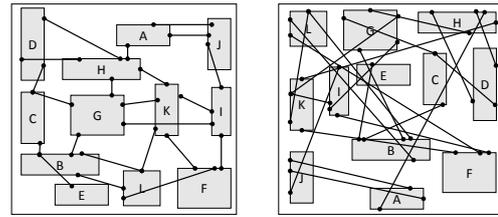

Fig. 2. An example of a good placement (left) v.s a bad placement (right). In the good placement the wires are shorter and there is almost no congestion. In this example, the area of both placements is the same.

#### B. Formal Description of the Placement Problem

We describe the placement problem as a combinatorial optimization problem. The components composing the problem are represented by 2-dimensional rectangles denoted *blocks*. In the placement, they can be rotated by  $90^\circ$ ,  $180^\circ$  or  $270^\circ$ , but not mirrored. The sides of the assigned blocks must be parallel to each other, and to the bounding area. Whenever we refer to a location in a block, we let  $(0, 0)$  be the bottom-left corner, and every other point in the block is given by its  $(x, y)$  coordinates with respect to this corner.

Formally, an instance of the problem is defined by:

- 1) A set of  $n$  blocks  $\{B_1, B_2, \dots, B_n\}$  to be placed on the chip. Every block  $1 \leq i \leq n$ , has associated width  $w_i$  and height  $h_i$ .
- 2) A list of required connections between the blocks,  $\{N_1, N_2, \dots, N_m\}$ . Every connection is given by a pair of blocks, and the locations in which these blocks should be connected. Formally  $N_j = \langle B_j^1, x_j^1, y_j^1, B_j^2, x_j^2, y_j^2 \rangle$ , for  $0 \leq x_j^1 \leq w_j^1, 0 \leq y_j^1 \leq h_j^1$  and  $0 \leq x_j^2 \leq w_j^2, 0 \leq y_j^2 \leq h_j^2$ , corresponds to a request to connect blocks  $B_j^1$  and  $B_j^2$ , such that the wire is connected to coordinate  $(x_j^1, y_j^1)$  in  $B_j^1$  and to coordinate  $(x_j^2, y_j^2)$  in  $B_j^2$ .

The output of the problem is a placement  $F$  given by the locations of the blocks on the plane  $\{L_1, L_2, \dots, L_n\}$ , such that for every  $1 \leq i \leq n$ ,  $L_i = (x_i, y_i, r_i)$ . The parameter  $r_i \in \{0, 1, 2, 3\}$  specifies how block  $B_i$  is rotated corresponding to  $\{0, 90, 180, 270\}$  degrees. Note that a rotation by  $180^\circ$  is not equivalent to not rotating at all, since the location of the required connections is also rotated. Formally, block  $B_i$  is placed in the rectangle whose diagonal endpoints are  $(x_i, y_i)$  (this corner is independent of the value of  $r_i$ ), and  $(x_i + w_i, y_i + h_i)$  if  $r_i = 0$ , or  $(x_i + h_i, y_i + w_i)$  if  $r_i = 1$ , or  $(x_i - w_i, y_i - h_i)$  if  $r_i = 2$ , or  $(x_i - h_i, y_i + w_i)$  if  $r_i = 3$ .

A placement is legal if no two blocks overlap, that is, the rectangles induced by  $L_{i_1}$  and  $L_{i_2}$  are disjoint for all  $i_1 \neq i_2$ .

This condition may be relaxed a bit in the global placement stage, and allow small percentage of overlaps area. These overlaps are resolved later during the detailed placement stage.

The *bounding box* of a Placement  $F$ , is the minimum axis-aligned rectangle which contains all the blocks. The *area* of a placement  $F$  is the area of the bounding box, and is denoted  $A(F)$ .

The blocks' location, together with the required connections, induce the wire-length of a placement. Formally, assume

that blocks  $B_1$  and  $B_2$  are located in  $L_1$  and  $L_2$ , respectively, and let  $N_j = \langle B_j^1, x_j^1, y_j^1, B_j^2, x_j^2, y_j^2 \rangle$ . We first calculate the actual coordinates of the connection points, based on  $L_1, L_2$ , and the values of  $\langle x_j^1, y_j^1 \rangle$  and  $\langle x_j^2, y_j^2 \rangle$ . Let  $\langle \hat{x}_j^1, \hat{y}_j^1 \rangle$  and  $\langle \hat{x}_j^2, \hat{y}_j^2 \rangle$  be the points we need to connect. The wire-length associated with  $N_j$ , denoted  $Len(N_j)$ , is calculated in a way that fits the actual production process, in which all wires are parallel to the blocks and to the bounding area, that is,  $Len(N_j) = \Delta X + \Delta Y = |\hat{x}_j^1 - \hat{x}_j^2| + |\hat{y}_j^1 - \hat{y}_j^2|$ . The total wire-length of a Placement  $F$  is denoted  $L(F)$ , and is given by  $L(F) = \sum_{j=1}^m Len(N_j(F))$ . An example of wire-length calculation is given in Figure 3.

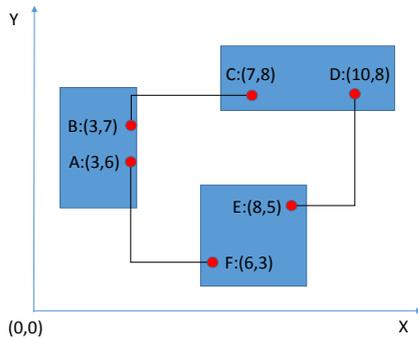

Fig. 3. An Example of wire-length calculation. There are three connections between the pairs of points  $\{A, F\}$ ,  $\{D, E\}$  and  $\{B, C\}$ . The total wire-length is  $(|X_A - X_F| + |Y_A - Y_F|) + (|X_E - X_D| + |Y_E - Y_D|) + (|X_B - X_C| + |Y_B - Y_C|) = (3 + 3) + (2 + 3) + (4 + 1) = 16$ .

The goal in the placement problem is to minimize  $\alpha L(F) + (1 - \alpha)A(F)$  where the parameter  $0 \leq \alpha \leq 1$  weight the importance of the two objectives. These days (as the number of components per chip rises) it is a very common practice to focus on the wire-length of the placement and only when finished optimizing the wire-length, perform small changes in order to gain better area result, with a minimal harm of the achieved wire-length. Thus, in our experiments (to be described in Section III), we give a substantially higher weight to the wire-length.

### C. Current Techniques for Efficient Placement

We now overview the common disciplines to handle the Placement problem. Some algorithms are tailored for simplified classes of instances. Specifically,

- 1) *Standard cell*: Components may have different width, but they all have the same height and are placed in rows. With over-cell routing the goal is to minimize the width of the widest row and the total wire-length.
- 2) *Gate array / FPGA*: The area is discretized to equally sized squares where each square is a possible component location. All the components have the same size and shape but different connections between them, the goal is to minimize the total wire-length.

Both classes induce simplified problems, which are still NP-hard, but can be approximately solved using Linear Programming [22], [7], Greedy Algorithms [25], [2], Slicing Tree

representation [3], or by Divide and Conquer algorithms that allows temporal block overlaps [2], [7].

A different solution approach is to develop heuristics, usually with strong randomness involved. Most heuristics have no assumptions on the problem thus able coping with general instances. Heuristics have no performance guarantee but perform well in practice. Some heuristics were tailored for *Standard cell* and *Gate array* instances [8], [16], [24]. The most commonly used algorithm concept for placement is *simulated annealing* (SA) [23], [20]. Modern algorithms of our days are always compared against it and many of them are based on its concept. While SA is unlikely to find an optimal solution, it can often find a very good one. The name simulated annealing come from annealing in metallurgy, a technique involving heating and controlled cooling of a material to increase the size of its crystals and reduce their defects. Both are attributes of the material that depend on its thermodynamic free energy. Heating and cooling the material affects both the temperature and the thermodynamic free energy. The simulation of annealing as an approach for minimization of a function of large number of variables was first formulated in [13]. Many modern algorithms are based on the concepts of simulated annealing.

Additional widely used placement methods include (i) Force Directed Placement, in which the problem is transformed into a classical mechanics problem of a system of objects attached to springs [21], (ii) Placement by Partitioning, in which the circuit is recursively partitioned into smaller groups [2], [7], (iii) Numerical Optimization Techniques, based on equation solving and eigenvalue calculations [25], [18], and (iv) Placement by Genetic Algorithm, that emulates the natural process of evolution as a means of progressing toward optimum, [25]. Some of these methods are only suited for *Standard cell* or *Gate array* instances, and some are general. A survey of the above and of additional algorithms for placement can be found in [1], [24], [11].

## II. OUR LOCAL-SEARCH METHOD FOR SOLVING THE PLACEMENT PROBLEM

The main challenges involved in solving the Placement problem are the need to optimize several objectives simultaneously, and to achieve even a good approximate solution in reasonable time. Optimizing even a single objective is an NP-hard problem. Naturally, combining several objectives, that may be conflicting, makes the problem more challenging.

Our proposed method not only performs a good placement in a relatively short time, but also copes with the multiple objective challenge.

### A. The Placement Problem as a Game

We propose to tackle the problem by a local-search algorithm, using natural dynamics common in *game theory*. Specifically, we suggest to perform variants of *Best-Response Dynamics* (BRD), assuming the components correspond to strategic selfish agents who strive to optimize their own welfare. In a BRD process, every agent (player) in turn, selects

his best strategy given the strategies of the other players. In our game, the strategy space of a player consists of all the locations his component can be placed in, given the location of the other components. Players keep changing strategies until a Nash equilibrium of the game is reached. A Nash equilibrium is a strategy profile in which no player can benefit from changing his strategy [12]. A lot of attention is given to best-response dynamics in the analysis of non-cooperative games, as this is the natural method by which players proceed toward a NE. The common research questions are whether BRD converges to a NE, the convergence time, and the quality of the solution (e.g. [5], [6]).

BRD can also be performed with coordinated deviations. That is, in each step, a group of players, denoted a *cooperative*, moves simultaneously, such that their total cost is reduced. Note that in a coordinated deviation of a *cooperative*, unlike a *coalition*, some members of the cooperative may be hurt. The deviation is beneficial if the total members' cost is reduced.

In order to consider the placement problem as a game played by selfish agents, we need to associate a value, or cost, for each player in each possible configuration of the game. In our setting, players correspond to blocks and configurations correspond to placements. The BRD process is defined with respect to a cost function that depends on the wire-length connected to the player's block, and the total placement area. The individual cost function is calculated for each block or cooperative, and is relevant only to the currently playing block or cooperative.

Recall that for a configuration  $F$ , the global cost of  $F$  is

$$Global\_cost(F) = \alpha L(F) + (1 - \alpha)A(F),$$

where  $L(F)$  is the total wire-length,  $A(F)$  is the bounding box area, and the parameter  $\alpha$  is used to weight these two components of the cost function. In our algorithms, the global cost function, is used only to evaluate the final configuration - in order to compare different methods and to analyze the progress of the algorithms.

The *individual cost function* is used to evaluate the possible deviations of the currently playing block. For a single block  $B_i$ , let  $L_{B_i}(F)$  denote the total wire-length of  $B_i$ 's connections. By definition,  $L(F) = \frac{1}{2} \sum_{1 \leq i \leq n} L_{B_i}(F)$ . The total individual wire-length is divided by 2, since every wire is counted in the individual wire-length of its two endpoints. For a configuration  $F$  and a block  $B_i$ , the individual cost of  $B_i$  in  $F$  is defined as follows:

$$Ind\_cost(B_i, F) = \alpha \cdot (L_{B_i}(F))^2 + (1 - \alpha) \cdot A(F).$$

Note that in the individual cost function, the corresponding wire-length is squared - for normalization with the area component.

Let  $\Gamma$  be a subset of the blocks. In order to evaluate configurations that are a result of a coordinated deviation, we define, for a cooperative  $\Gamma$  in a configuration  $F$ , the individual cost of  $\Gamma$  in  $F$ :

$$Ind\_cost(\Gamma, F) = \alpha \cdot \sum_{B_i \in \Gamma} (L_{B_i}(F))^2 + (1 - \alpha) \cdot A(F).$$

Since finding the best response is NP-hard in most scenarios and particularly for coordinated deviation, we perform a better-response move, in which the player (or a cooperative) benefits, but not necessarily in the optimal way. In practice, we perform the best response move in a restricted search space. Also, in some algorithms, when there is no local improving step, we may perform a move which harms the cost function. Such moves result in a temporary worse state and are used in order to allow the algorithm to escape from local minima.

In our experiments, we compared our results with those achieved by *Simulated Annealing* (SA), *Greedy Local Search* (GLS) algorithm, based on hill climbing, and *Fast Local Search* (FLS) algorithm (faster version of the greedy local search). For each test-bench we run our algorithms as well as these algorithms, and compared the results. In this paper we only provide the comparison with SA, as it outperformed the other two local-search methods.

### B. Search for a Solution over the Solution Space

Before presenting our algorithms we give an overview of the local search technique, and explain how the search for the solution is performed. A local-search algorithm performs a search over the solution space. Every possible solution (placement  $F$ ) is associated with a score ( $Global\_cost(F)$ ). The global cost function defines a placement-cost multidimensional complex, on which the algorithm advances. Each point on the complex is a placement and the complex includes all possible placements.

Every local-search algorithm moves on the placement-cost complex searching for a point corresponding to a placement having minimum cost. The local-search paradigm implies that the movement along the complex is almost continuous. When the algorithm encounters a heap on the complex which it cannot pass, it may try to bypass it in order to continue the search in that direction.

The main challenge when applying such algorithms, is how to pick the next point to explore and how to decide when to stop the search. As demonstrated in Figure 4, we can continue to search up to some point of worse cost but we do not know what awaits us further down the path of the search. We may attempt to remember each minimum we visit during the search and traverse different search paths from each local minimum detected. However, such methods perform a brute force search, which in turn results in exponential running time. Finding the global minimum means we have found an optimal solution for an NP-hard problem. Hence, such algorithms must have exponential running time (regardless of the algorithm's logic) unless P = NP.

The main difference between our algorithms and previous algorithms based on local search (in particular SA, GLS, FLS), is the way we evaluate each solution in the solution space, and the way we advance to the next solution in the search process. Previous algorithms calculate the cost function for the entire placement, while our algorithms base their progress on the individual cost of a block (or of a cooperative of blocks). The main goal of this work is to examine the quality of local-search algorithms for the placement problem, in which

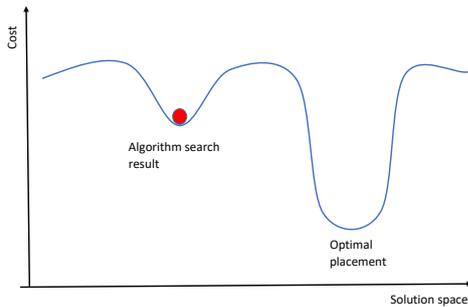

Fig. 4. A general description of a local-search method. The algorithm traverses the cost-placement multidimensional complex. Local search may end-up in a local minimum, unable to escape, thus also unable to find an optimal placement.

the search on the solution space is determined by only a single block (or a small cooperative), in a selfish manner, according to its individual cost-over-time curve. Our method does not use a global cost function; we present the global objective parameters (wire-length, total area, etc.) only for the analysis. As detailed in Section II-C, some of our algorithms accept moves that harm a bit the individual cost function (thus breaking the selfishness to some extent). This possibility allows the algorithms to escape local minimum and the search becomes much more versatile.

### C. Algorithms Based on Best-Response Dynamics

The BRD process proceeds as follows: Every block corresponds to a player. In every step a player or a cooperative of players have a chance to change their current location, in a way that reduces their individual cost in the resulting configuration. In some of our algorithms, a step increasing the individual cost may be accepted with some probability.

Every block can perform one or more of the following moves: {Up, Down, Left, Right, Rotate 90°, Rotate 180°, Rotate 270°}. A step is legal as long as the resulting configuration is legal.

We use three search methods for the block migrations:

1. *Best Response (BRD)*: Each block is controlled by a selfish player. Each player can perform one move per turn, the move is the best local move the block can perform to reduce its individual cost. The algorithm advances in rounds, where in each round, every player gets an opportunity to migrate. Players are allowed to perform only legal moves (no block-overlaps are created).

2. *Constant Perturbations (BRD-ConstPerb)*: In This variant of BRD, when a player does not have a legal improving move to perform, he may, with some non-negligible probability, choose a step which harms its individual cost. In our experiments we found 0.3 to be a good probability for accepting a worse state. It is small enough not to harm the selfishness on one hand, and allows the placement to escape local minima on the other.

3. *Relaxed Search (BRD-RlxSrch)*: This algorithm is another variant of BRD. The difference is that players can select illegal

locations - that involve block overlaps. While blocks are not allowed to overlap beyond a reasonable limit in the final configuration, temporal overlaps may be fruitful. Our relaxed search allows overlaps with varying fines on the area of the overlap. The overlaps fine are added to the block's individual cost. The fines are increased every round - to encourage convergence to a final placement with hardly any overlaps. The Global placement stage can tolerate small overlaps, so the output is accepted if the final placement does include some overlaps.

Each of the above algorithms is ran in two variations: without and with *swap moves*. A swap move is a move in which the active block swaps places with some other block if the swap is legal and reduces the active block's individual cost, as well as the global cost function (this ensures we avoid recurrent swaps between a pair of blocks). Swap moves break the locality of the search and allows another method with which to escape local minima. Instead of attempting to escape a local minimum by accepting a worse state, the algorithm can escape a local minimum by jumping to a better, yet not local neighbor, state. Swap moves do not break the selfishness of our algorithms but rather only the locality, and only to some extent. As our experiments reveal, enabling swap moves improves the quality of the solution.

### D. Coordinated Deviation of a Cooperative

Unlike a unilateral deviation, a coordinated deviation is initiated by a group of players, denoted a *cooperative*, who migrate simultaneously. Such a migration may harm the individual cost of some cooperative members (for example, if they give up good spots for other members), however, the total cost of the cooperative members is strictly reduced. When applying a coordinated deviation, we first determine the cooperative size and then the blocks composing it. A coordinated deviation is therefore defined by (i) the search method, (ii) the cooperative size method, and (iii) the cooperative member selection method.

We simulated three different methods for determining the cooperative's size:

- 1) *Increasing*: Starting from  $k = 1$ , after converging to a  $k$ -NE profile, which is stable against deviations of cooperatives of size  $k$ , we increase the active cooperative size to  $k + 1$ . We keep increasing the cooperative size up to a predefined limit.
- 2) *Iterating*: Each round has a different cooperative size, the sizes are incremented after each round, when the size reaches a predefined limit we reset the size to a single block.
- 3) *Random*: Each cooperative has a random size, the size is uniformly distributed between a single block and a predefined limit.

The cooperative's members are selected in the following way: we iterate over all the blocks, selecting a different *head block* of the cooperative in each round. The head block constructs a cooperative according to one of the following methods:

- 1) *Closest Connected blocks*: in every iteration we add to the cooperative a block with the shortest wire-length to some other block already in the cooperative.
- 2) *Farthest Connected blocks*: in every iteration we add to the cooperative a block with the longest wire-length to some other block already in the cooperative.
- 3) *Closest Geometrically blocks*: in every iteration we add to the cooperative a block with the smallest closest geometrical distance to the head block of the cooperative.
- 4) *Farthest Geometrically blocks*: in every iteration we add to the cooperative a block with the highest geometrical distance to the head block of the cooperative.
- 5) *Random*: Random set of blocks. The cooperative is built by uniformly adding blocks one by one, until the cooperative size is reached.

In our experiments, we run and compared various combinations of search algorithms with cooperative size and formation methods. The algorithms advance as follows: once the cooperative has been formed, all the feasible permutations of possible moves for the cooperative (depending on the search algorithm) are calculated. For each permutation we calculate the individual cost of the cooperative in the resulting placement. The permutation that minimizes this cost is chosen. Only the cooperative cost is taken into account, and we ignore the global cost as well as the internal distribution of the cost among the blocks composing it.

### E. Expected Algorithms' Progress

In this section we review our algorithms by describing their progress in general. A typical cost-over-time progress of BRD-ConstPerb is depicted in Fig 5. Since players can choose a step which harms their individual cost, we expect the algorithm to be able to escape local minima by moving to a more expensive placement and improving it by a sequence of cost-reducing moves, which hopefully lead to a better local minimum.

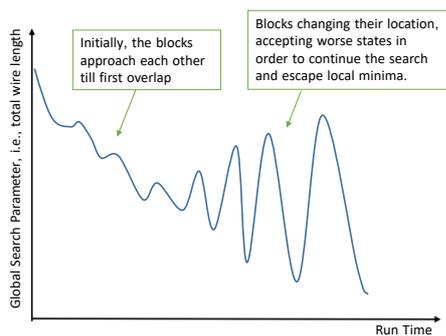

Fig. 5. Expected progress of the *BRD-ConstPerb* search method with unilateral deviations.

The progress of our BRD-RlxSrch method depends heavily on the fines for overlaps. Recall that these fines increase with the run time. As illustrated in Figure 6, this enables the algorithm to explore more areas in the solution space. Once the fines are above some threshold, the algorithm explores

feasible or almost feasible solutions whose cost may be higher than former non-feasible solutions explored earlier.

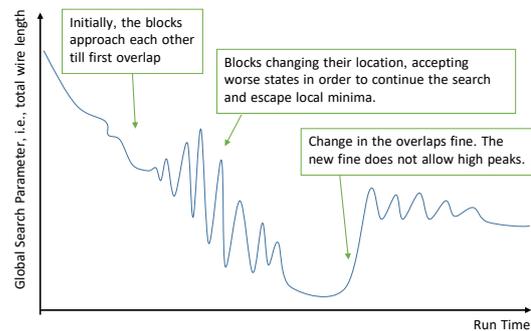

Fig. 6. Expected progress of the *BRD-RlxSrch* method with unilateral deviations. The slope has peaks, the cost function is monotonically decreasing via game of tradeoffs between the search parameters and the overlaps.

Finally, Figure 7 illustrates the typical cost-over-time progress of BRD-RlxSrch and BRD-ConstPerb when coordinated deviations are allowed. The possibility to accept worse or unfeasible solutions enables the algorithm to escape local minima and to advance in the search space towards a better solution.

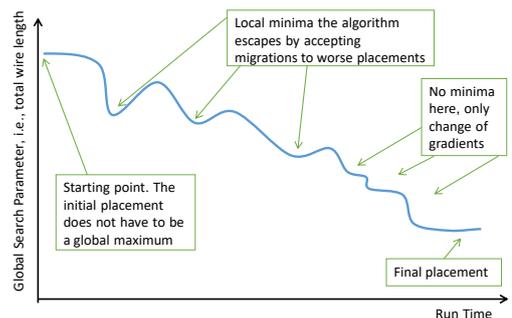

Fig. 7. Expected progress of *BRD-ConstPerb* and *BRD-RlxSrch* with coordinated deviation.

In the above figures we present the slopes as monotonically nicely curved lines, in reality this is not the case. The real lines have various gradient changes, and they are far from being nicely curved over the monotonic movement sections. The figures present the tendency of the algorithm and the overall progress.

## III. EXPERIMENTAL RESULTS

In this section we present our experimental study. Our experiments simulate the global placement stage. This stage is followed by the detailed placement stage, in which the global placement results are applied and the blocks are actually placed on the die. Usually at the detailed placement stage, small changes occur in order to solve some local issues such as wire congestion spots, remaining overlaps, layout constraints, connecting to the die pinout, etc.

We first demonstrate our concept by presenting the results of the unilateral deviation algorithms. Next, we compare some of

our heuristics with the *Simulated annealing* algorithm. Finally, we study coordinated deviations and analyze the effects of the cooperative size and structure. We explore how coordinated deviations improves the results obtained by unilateral deviations, regardless of the selected method for the search algorithm, and also consider algorithms that combine unilateral and coordinated deviations.

#### A. Experiments Setup

All algorithms are ran on the same machine with similar conditions. We sample various parameters during the algorithms run, in order to study not only the final outcome but also the search process. Time measurement is conducted and counted by the algorithms context timers, thus if a context switch occurs the timer pauses. While the time values themselves vary on different machines, the progress of the algorithms and comparison between them is valid and independent of the machine.

Our experiments were performed on 6 different test-benches,  $T_{30}^4, T_{30}^6, T_{30}^8, T_{40}^4, T_{40}^6$  and  $T_{40}^8$ , where  $T_n^c$  corresponds to an instance of  $n$  blocks, with  $c$  connections-per-block. In all instances, the block sizes are randomly distributed, height and width being a random equally distributed number in the range  $[30, 80]$  (pixels). The different connections-per-block parameter enables a good comparison and allows us to isolate and emphasize various aspects of the algorithms.

Recall that the Individual cost of a block  $B_i$  in a placement  $F$  is defined to be  $Ind\_cost(B_i, F) = \alpha \cdot (L_{B_i}(F))^2 + (1 - \alpha) \cdot A(F)$ . We run the search algorithms with various values for  $\alpha$ , and found out that the wire-length component should get much higher weight. Thus, all the results described in this section were obtained with  $\alpha = 0.9$ . This fits the common practice these days to focus on minimizing the wire-length of the placement and only when done optimizing the wire-length, perform small changes in order to gain better area result.

As detailed in Section II-C, we used three local search method: BRD – only legal profitable moves, BRD-ConstPerb – legal but maybe harmful moves, and BRD-RlxSrch – profitable but maybe non-legal moves (overlaps associated with fine). These search methods are constructed into algorithms, combining unilateral players and coordinated deviation players.

Each of these local search methods run in two different variations, without or with *swap moves*. Note that a swap move differs from a cooperative of size 2. The two members of a cooperative may swap places as long as it improves their total cost. However, a swap move is initiated by a single block and may hurt significantly the individual cost of the second block involved.

In order to better evaluate the algorithms, we performed each experiment several times. Specifically, we ran the algorithms on the same instance with 5 different random initial placements. While the initial placement has a strong impact on the results, the final result depends on the progress of the algorithm as much as on the initial placement. If for any test bench one algorithm is better than the other, then it is almost

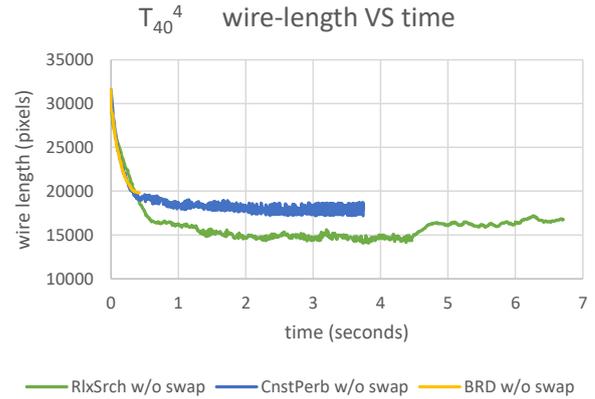

Fig. 8. Progress of total wire-length. No swap moves.

certain better for any initial placement. The variation between the results of different algorithms is consistent for most of the initial placements. In order to compare the algorithms we look at the average results over all initial placements.

#### B. Results for Unilateral Deviations

The first experiment we present is a comparison of the three search methods, when applied without and with swap moves. We run each of these variants on our test-bench  $T_{40}^4$ , that is, an instance consisting of 40 blocks each with 4 connections. All the algorithms were applied starting from the same initial placement. Figures 8 and 9 present the progress of wire-length over running-time without and with swaps, respectively. Figures 10 and 11 present the progress of area over running time with and without swaps, respectively. We can see that the algorithms reach their stopping criteria at different times and have different progress gradient.

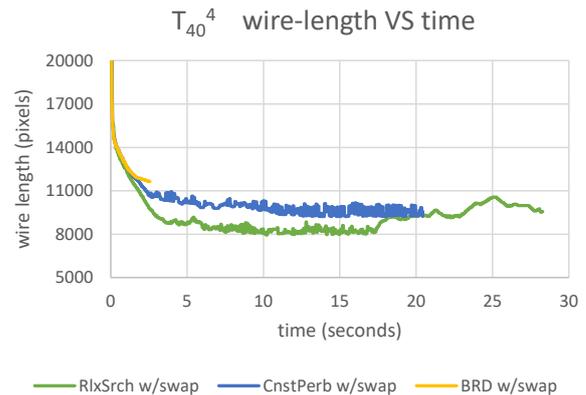

Fig. 9. Progress of total wire-length. Swap moves allowed.

The BRD algorithm is the first to finish - its local search is more restricted and thus, the stopping criteria is reached earlier. Each algorithm has a different progress curve. The gradient of the changes in the cost function according to the time is different. Nevertheless an obvious pattern can be observed: the algorithms that can progress to a worse state

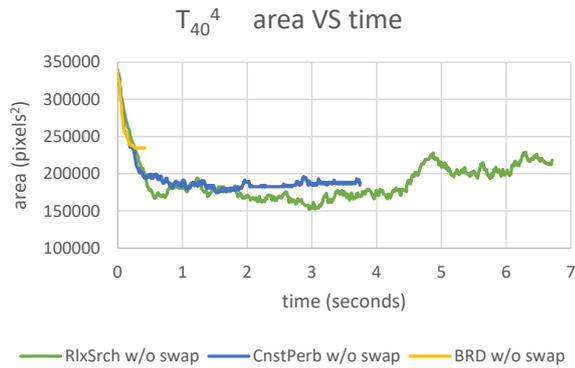

Fig. 10. Progress of Bounding-box area. No swap moves.

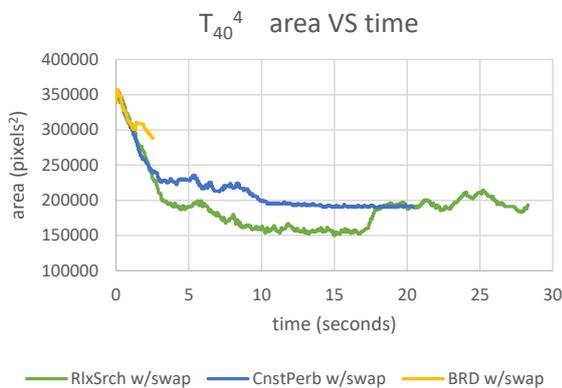

Fig. 11. Progress of Bounding-box area. No swap moves.

tend to continue and improve their result as the algorithm progresses. Such algorithms are able to escape local minima and continue the search, thus obviously the progress gradient is much more moderate. Moreover, we also witness the major influence of swaps. Allowing swaps increases the running time but improves the result. Such behavior leads to having a more moderate gradient of change, but due to the increase in run time, we eventually reach a lower level and a better result.

For BRD-RlxSrch and BRD-ConstPerb we can see peaks and drops in the performance – corresponding to reaching and escaping local minima. In BRD the spikes are limited due to the search method, which always chooses an improving step. Still, the curve is not monotonically decreasing as the improvement are with respect to the deviating block’s individual cost, that may conflict with the global cost.

Due to space constraints we do not present the plot presenting the progress of the overlap area in the BRD-RlxSrch algorithm. In both applications, with or without swaps, the overlap area is not increasing or decreasing monotonically. Initially, the algorithm explores non-feasible solutions, that have low wire-length and bounding box area; however, as the fine for overlaps is increased, the placements become more and more overlap-free. The final placement achieved by the relaxed search algorithm is feasible, and its quality is more or less equivalent to the quality achieved by BRD-ConstPerb.

### C. Comparison with the Simulated Annealing Algorithm

In this section we present a comparison of our unilateral deviation algorithms with the Simulated Annealing (SA) algorithm. We present the results by normalizing the SA result to 1. We ran SA and each of our algorithm on all six test-benches, and normalized the result with respect to the corresponding SA result. For example, if on some instance the SA algorithm produces a placement whose area is 12000 pixel<sup>2</sup>, and our algorithm produces a placement whose area is 9600 pixel<sup>2</sup>, then the result of our algorithm is presented as 9600/12000 = 0.8.

When presenting the results, we distinguish between two groups of algorithms. The first group includes algorithms that are more run-time oriented than result-oriented, while the other aim to achieve a good result. The first group consists of BRD with and without swaps, and BRD-ConstPerb without swaps, while the second group consists of BRD-RlxSrch with and without swaps, and BRD-ConstPerb with swaps.

Figures 12 and 13 present the results for the total wire-length, and Figures 14 and 15 present the results for the placement area. In all the figures, the horizontal black line represents the result achieved by the SA algorithm.

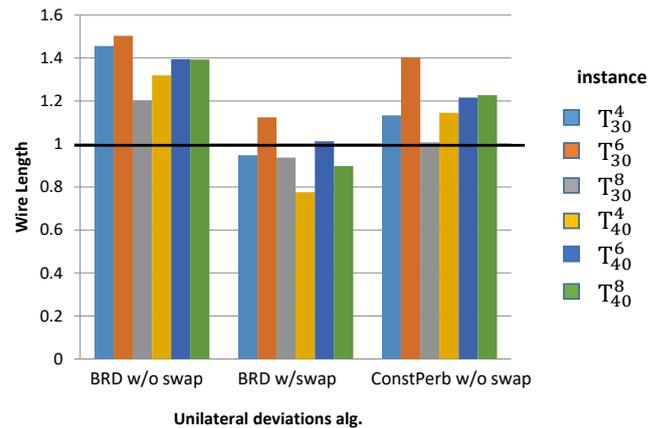

Fig. 12. Wire-length normalized to SA performance – Group I

Figures 16 and 17 present the comparison between the run-times of the algorithms. The algorithm of the first group are indeed much faster than SA. Also, all algorithms when run without swaps are at least 5 times faster than SA.

The experiments reveal that we can achieve better results of both wire-length and placement area while paying with a slightly worse running time. As well as the other way around, that is, slightly worse result can be achieved with a fraction of the running time. We also witness certain algorithms, which on the majority of the test benches, have succeeded to achieve a better result in a lower running time.

### D. Coordinated Deviation

As detailed in Section II-D, coordinated deviations are performed by a cooperative of blocks. In this section we analyze the results achieved by our search algorithms when

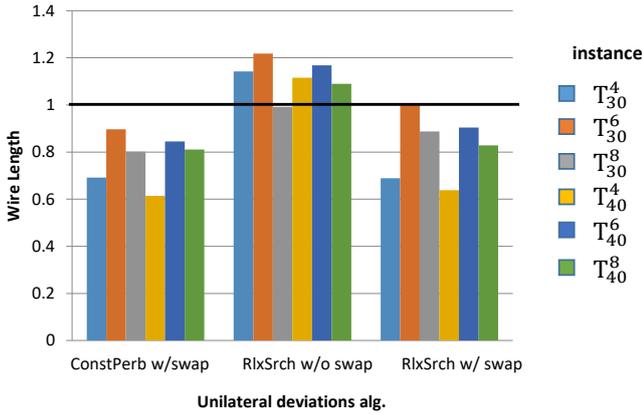

Fig. 13. Wire-length normalized to SA performance – Group II

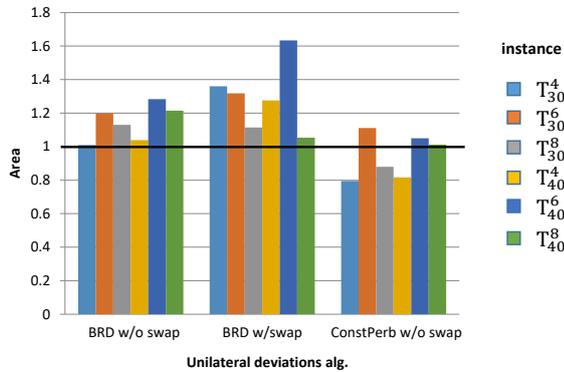

Fig. 14. Area normalized to SA performance – Group I

applied with coordinated deviations. Recall that a deviation of a cooperative is beneficial if the total cost of the cooperative members is strictly reduced. In addition to the local-search method (BRD, BRD-ConstPerb and BRD-RlxSrch), the algorithms are different in the way they determine the active cooperative size and formation. In all the experiments with coordinated deviations, the algorithms were performed on the same instance and the same initial placements.

Due to space constraints, we do not present the results

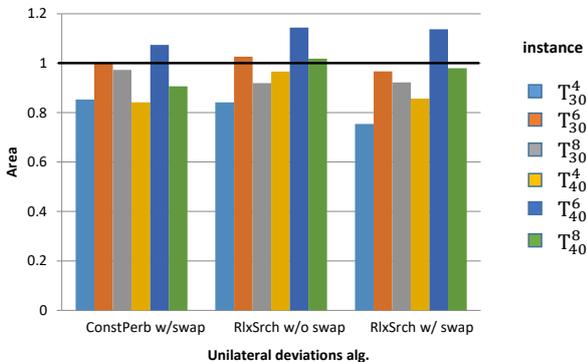

Fig. 15. Area normalized to SA performance – Group II

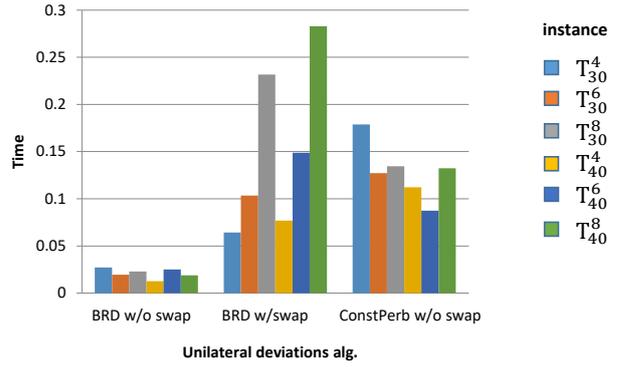

Fig. 16. Running time normalized to SA performance – Group I. The line corresponding to SA (Time = 1) is not shown, as it is way above the shown bars.

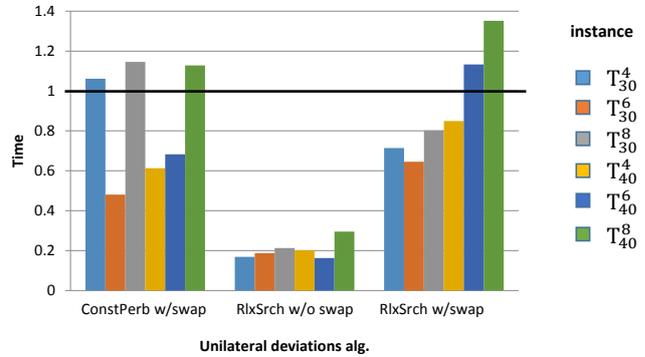

Fig. 17. Running time normalized to SA performance – Group II

using plots, and only summarize our conclusions. Our results show that the cooperative size has the largest influence on the results. The method for determining the cooperative size in each round is not crucial as the predefined limit for the maximal cooperative size. The higher this limit, the better the results. In addition, the experiments do not crown a specific method for selecting the cooperative members - the results vary and depend heavily on the initial placement.

We witnessed a major improvement in the results already with cooperatives of two blocks (compared with unilateral deviations). Further increase in the cooperative size do tend to improve the result, however it involves an exponential increase in the running time. Therefore, the best is to run the algorithm initially with cooperatives of size two, and allow non-frequent rounds in which larger cooperatives are activated. Such executions converge to a final placement much faster than SA, and if performed multiple times, with different initial placements, are expected to produce at least one excellent outcome.

We believe that this unique algorithm, that combines our search methods with a mixture of coordinated and unilateral deviations, is the main result of this work.

#### IV. SUMMARY AND CONCLUSIONS

In this work we examined the performance of local search algorithms for the global placement problem in VLSI physical design. Our algorithms are different from common local search algorithms in the way they explore the solution space. Every solution is associated with a global cost (based on its bounding-box area, the total wire-length, and possibly additional parameters), and every component is associated with its individual cost (based on its own placement and connections). We explore the solution space by moving from one solution to another if this move is selfishly beneficial for a single or for a cooperative of components, without considering the effect on the global cost. Best-response dynamics (BRD) is performed until no component has a beneficial migration. We suggested several methods for selecting the component(s) initiating the next step, and for selecting their migration. In order to evaluate our algorithms, we have tested them on various test-benches, and each test-bench was ran with various initial placements.

Based on our experiments, we can distinguish between two approaches for handling the problem. The first approach is to use algorithms with high run-time that also tend to supply good results. Due to their high run-time, these algorithms can only be ran a small number of times (with several different initial placements). The second approach is to use fast algorithms and ran them many times. We expect to get at least one good output. The first approach rely on the algorithms' ability to consider multiple local minima, thanks to their ability to escape local minimum. In the second approach the algorithms tend to stop at the first local minimum they found, however, this is compensated by the high number of runs, with many different initial placements.

Our algorithms, even for instances on which they perform poorly, achieve results not far from SA with only a fraction of its running time. This feature obviously can be very handy when one tries to get a quick estimation of the results achievable for a given instance. We believe that this work has proved the concept of selfish local search to be valid and efficient. Moreover, this concept may be useful in solving additional optimization problems arising in real-life applications.

**Abstract**—Integrating an arbitrary polynomial function  $f$  of degree  $D$  over a general simplex in dimension  $n$  is well-known in the state of the art to be NP-hard when  $D$  and  $n$  are allowed to vary, but it is time-polynomial when  $D$  or  $n$  are fixed. This paper presents an efficient algorithm to compute the exact value of this integral. The proposed algorithm has a time-polynomial complexity when  $D$  or  $n$  are fixed, and it requires a reasonable time when the values of  $D$  and  $n$  are less than 10 using widely available standard calculators such as desktops.

## I. INTRODUCTION

THE integral evaluation of polynomial functions over  $n$ -dimensional polytopes is essential in many applications. Particularly, it can be used to calculate the probability of a given interval of variables expressed as a polytope and when a polynomial function is used to fit the multivariate probability density function.

In dimension  $n$ , efficient integrating formulas may be set up for some types of polytopes having specific or regular shapes such as hyper-cubes and hyper-parallelepipeds. On the other hand, integrating an arbitrary polynomial function  $f$  of degree  $D$  over an arbitrary general convex polytope is a hard task.

For the simple case  $f = 1$  (when  $D = 0$ ), it turns into volume computing. Even volume computing of polytopes of varying dimension was proven to be NP-hard [2]. Hence, one can conclude that integrating of polynomials over convex polytopes is NP-hard as well, see [1] for more details.

Usually, integration over a general convex polytope is achieved by partitioning it into a finite set of simplices. Then the whole integral value can be obtained by summing the integration results of  $f$  over the resulting simplices. The computational complexity of this approach depends on the: i) triangulation algorithm complexity; ii) number of simplices; iii) integration algorithm complexity of  $f$  over a general simplex.

It has been proven that finding the smallest triangulation is NP-hard [3]. Furthermore, the number of simplices seems to increase exponentially with the dimension for all the known triangulation algorithms. Considering these challenges, it would be suitable to use a fast triangulation algorithm, and

to focus on the improvement of the integration algorithm over general simplices.

The bad news is that even integrating  $f$  over a general simplex  $\Delta$  is shown to be NP-hard [1], but the good news is that integration can be carried out within an acceptable time for some applications when  $n$  and  $D$  values are not too high ( $\leq 10$ ), and time-polynomial for some specific types of  $f$  and  $\Delta$ . For instance, this problem is polynomial time when  $n$  or  $D$  are fixed [1]. Moreover, useful efficient formulas are also given when  $f$  is quadratic and cubic and  $\Delta$  is affinely symmetric [6], when  $\Delta$  is the standard (unit) simplex and  $f$  is expressed as a product of linear forms, etc.

In [5], interesting integration formulas of arbitrary odd degree function for the  $n$ -simplex are derived using combinatorial methods. The key idea consists in employing the known integration formula over the standard simplex [8] by performing an appropriate mapping to a  $n + 1$  variable space. This method involves  $C(n + D + 1, D)$  iterations ( $C$ : combinations number). In [7], a quite similar idea by finding a suitable transformation to the standard simplex is investigated. Based on these two last studies, in this work, we want to propose a new practical algorithm for integrating a high degree (odd and even) polynomial over a general simplex, where the aim is to further accelerate the original problem transforming to another equivalent integration problem over the standard simplex.

The rest of this paper is organized as follows. The next section presents the problem statement. Then, our main contributions are described in section III. Before conclusion, complexity analysis and some experimental results are given in section IV.

## II. PROBLEM STATEMENT

Let  $\Delta \in \mathcal{R}^n$  be a general  $n$ -simplex and  $f \in Q[x_1, \dots, x_n]$  be a multivariate polynomial function of degree  $D$  with real coefficients. Commonly,  $f$  is represented as a sum of  $M$  monomial terms,  $f = \sum_{i=1}^M w_i x_1^{\alpha_1^{(i)}} \dots x_n^{\alpha_n^{(i)}}$ , where  $w_i$  and  $\alpha_j^{(i)} \in N$  ( $\alpha_1^{(i)} + \dots + \alpha_n^{(i)} \leq D$ ) correspond respectively to the coefficient and variables powers for each monomial  $i = 1..M$ .

In this study, we consider the problem of the evaluation of the multiple definite integral of  $f$  over  $\Delta$ , which we denote by  $I_{f\Delta}$ , and it is given by the formula:

$$I_{f\Delta} = \int_{\Delta} f dx_1 \dots dx_n. \quad (1)$$

We aim at providing new practical methods that compute efficiently the *exact* value of  $I_{f\Delta}$  when the coefficients of  $f$  and the vertices of  $\Delta$  are rational numbers as discussed in [1], or compute the *numerical* value when floating-point numbers are used instead. In this second case, no approximations are made and the total error in the evaluation is due only to the floating-point numbers representation precision.

### III. INTEGRATION OVER POLYTOPES

#### A. Integration over the standard simplex

The standard simplex, denoted by  $\Delta_s$ , is the polytope defined by the  $n + 1$  following vertices:  $v_0 = (0, 0, \dots, 0)'$ ,  $v_1 = (1, 0, \dots, 0)'$ ,  $v_2 = (0, 1, \dots, 0)'$ , ...,  $v_n = (0, 0, \dots, 1)'$ . The integral of  $f$  over  $\Delta_s$  is expressed as follows:

$$I_{f\Delta_s} = \int_{x_1=0}^1 \int_{x_2=0}^{1-x_1} \dots \int_{x_n=0}^{1-x_1-\dots-x_{n-1}} f dx_1 \dots dx_n. \quad (2)$$

The integral of one monomial  $x^{(\alpha)} = x_1^{\alpha_1} x_2^{\alpha_2} \dots x_n^{\alpha_n}$  can be computed efficiently using the Stroud formula [8]:

$$I_{x^{(\alpha)}\Delta_s} = \frac{\alpha_1! \dots \alpha_n!}{(n + \alpha_1 + \dots + \alpha_n)!}. \quad (3)$$

Then,  $I_{f\Delta_s}$  can be computed by summing the integral of all  $f$  monomial terms,  $I_{f\Delta_s} = \sum_{i=1}^M w_i I_{x_i^{(\alpha)}\Delta_s}$ .

Note that dynamic programming can accelerate considerably the computation. e.g. factorial terms can be computed and stored just once and used many times.

#### B. Integration over a general simplex

The majority of simplices obtained by triangulation are not standard. Integrating  $f$  over a general simplex  $\Delta$  is an NP-hard problem of varying dimension and degree [1], but it can be solved within an acceptable time for moderate dimension and degree ( $n \leq 10$ ,  $D \leq 10$ ) by the computing means which are nowadays available. To evaluate  $I_{f\Delta}$ , a good option would be to find an affine change of variables from the original space  $[x_1, \dots, x_n]$  to a new space  $[y_1, \dots, y_n]$  such that

$$I_{\Delta} = \int_{\Delta} f dx_1 \dots dx_n = \int_{\Delta_s} h dy_1 \dots dy_n, \quad (4)$$

where  $h$  is a polynomial function with the same degree as  $f$ ,  $\Delta_s$  is the standard simplex. After that, one can utilize formula 3. It is particularly noteworthy that for a non-empty volume simplex  $\Delta$ , this change of variables is always possible. We will show how to determine  $h$  terms in the rest of this section.

Let the vertices of  $\Delta$  be  $v_0 = (v_1^0, \dots, v_n^0)'$ ,  $v_1 = (v_1^1, \dots, v_n^1)'$ , ...,  $v_n = (v_1^n, \dots, v_n^n)'$ . We propose to find an affine transformation  $T : \Delta_s \rightarrow \Delta$  that maps the standard simplex  $\Delta_s$  in the  $y$  space to the general simplex  $\Delta$  in the  $x$  space, as shown in Fig 1 example. Thus,  $T$  maps each vertex

of  $\Delta_s$  to a distinct vertex of  $\Delta$ , the order of vertices is not important. Formally,  $T$  maps a given point  $\mathbf{y}$  to the point  $\mathbf{x}$  given by  $\mathbf{x} = A\mathbf{y} + B$  where  $A$  is an invertible  $n \times n$  matrix that defines the combination effect of rotation, scaling and shearing, and  $B$  is a translation vector.

The correspondence between vertices of  $\Delta_s$  and vertices of  $\Delta$  yields the following linear system  $V = A \times V_s + B$ , which is given by

$$\begin{pmatrix} v_1^0 & v_1^1 & \dots & v_1^n \\ \vdots & \vdots & \ddots & \vdots \\ v_n^0 & v_n^1 & \dots & v_n^n \end{pmatrix} = \begin{pmatrix} A_{1,1} & \dots & A_{1,n} \\ \vdots & \ddots & \vdots \\ A_{n,1} & \dots & A_{n,n} \end{pmatrix} \times \begin{pmatrix} 01 \dots 0 \\ \vdots & \ddots & \vdots \\ 00 \dots 1 \end{pmatrix} + \begin{pmatrix} B_1 \\ \vdots \\ B_n \end{pmatrix} \quad (5)$$

, where columns of matrices  $V$  and  $V_s$  represent the vertices coordinates of  $\Delta$  and  $\Delta_s$ , respectively. The unique solution of the equations system (5) is:

$$B = (v_1^0, \dots, v_n^0)' \text{ and } A_{i,j} = v_i^j - B_i \quad (\forall i, j \in 1 \dots n), \quad (6)$$

which can be computed in linear time. Affine transformations are known to preserve betweenness,  $\mathbf{x} = T(\mathbf{y})$  lies inside  $\Delta$  if and only if  $\mathbf{y}$  is inside  $\Delta_s$ . To compute  $I_{f\Delta}$ , we propose to perform the change of variables  $\mathbf{x} = A \times \mathbf{y} + B$  where the  $i^{th}$  component of  $\mathbf{x}$  is

$$\begin{aligned} x_i &= A_{i,1} \times y_1 + \dots + A_{i,n} \times y_n + B_i \\ &= \sum_{j=1}^n A_{i,j} \times y_j + B_i. \end{aligned} \quad (7)$$

Hence, we have:

$$\begin{aligned} I_{f\Delta} &= \int_{\Delta} f(x_1, \dots, x_n) dx_1 \dots dx_n \\ &= \int_{\Delta_s} f(\sum_{j=1}^n A_{1,j} \times y_j + B_1, \dots, \sum_{j=1}^n A_{n,j} \times y_j + B_n) \\ &\quad |det(Jac_{T(y_1, \dots, y_n)})| dy_1 \dots dy_n, \end{aligned} \quad (8)$$

where  $|det(Jac_{T(y_1, \dots, y_n)})| = |det(A)|$  is the absolute value of the determinant of the Jacobian of  $T$ .

For the simple case of a single monomial term,  $f = x^{(\alpha)} = x_1^{\alpha_1} \dots x_n^{\alpha_n}$  we have:

$$\begin{aligned} I_{x^{(\alpha)}\Delta} &= \int_{\Delta_u} (\sum_{j=1}^n A_{1,j} y_j + B_1)^{\alpha_1} \dots (\sum_{j=1}^n A_{n,j} y_j + B_n)^{\alpha_n} \\ &\quad |det(A)| dy_1 \dots dy_n. \end{aligned} \quad (9)$$

Let  $P_{x_i} = \sum_{j=1}^n A_{i,j} y_j + B_i$  be the dense polynomial of degree one in the  $n$ -dimensional space of  $y$  variables. The desired polynomial function  $h$  is then equal to  $|det(A)| f(P_{x_1}, \dots, P_{x_n})$ .

Therefore, determining  $h$  coefficients can be carried out according to the expression of  $f$  by performing a series of additions and multiplications of dense intermediate polynomials of degree  $d \leq D$  ( $D = \text{degree of } f$ ).

For example, as illustrated in Fig. 1, to integrate  $f = x_1 x_2^3 + x_1^2 x_2 + x_2^2 + 2x_1 x_2 + x_1 + 2$  over the simplex  $\Delta$  defined by

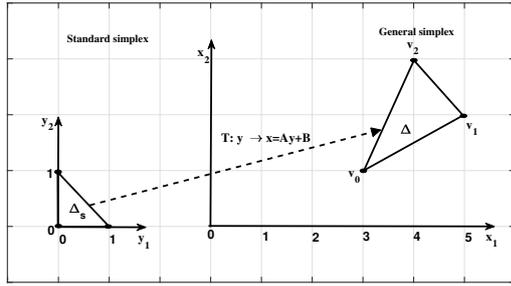

Fig. 1. 2-Dimensional affine transformation example.

the vertices  $V = \{v_0 = (3, 1)', v_1 = (5, 2)', v_2 = (4, 3)'\}$ , by using equations (6,7), we obtain:

$$A = \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}, B = \begin{bmatrix} 3 \\ 1 \end{bmatrix}, \begin{matrix} p_{x_1} = 2y_1 + y_2 + 3 \\ p_{x_2} = y_1 + 2y_2 + 1 \end{matrix}$$

Determining  $h$  depends indeed on the regular expression used to denote  $f$ ; in other words, it depends on the position of brackets and operators '\*', '+' in  $f$  expression. For this example,  $h$  can be built efficiently according to the scheme shown in Fig. 2:(a) when  $f$  is expressed as a sum of monomials, or according to the scheme of Fig. 2:(b) when  $f$  is factorized as follows  $f = (x_1x_2 + 1) * (x_2^2 + x_1 + 2)$ . As you can see in Fig. 2:(a), terms  $x_1x_2$  and  $x_2^2$  are computed just once, and used to compute the four first terms of  $f : x_1x_2^3, x_1^2x_2, x_2^2, 2x_1x_2$

For this approach, integration efficiency depends conjointly on : i) the factorization tree of  $f$  and ii) the complexity of addition and multiplication of intermediate polynomials. Finding the optimal factorization tree for an arbitrary dense polynomial is a difficult combinatorial problem because the search space of all possible factorization schemes is large; e.g. using straight-line-programs [1] may be useful. In this study, our main contribution is focused on the second point; on the proposition of new methods to accelerate furthermore addition and particularly multiplication of intermediate polynomials involved during the construction of  $h$ .

### C. Discussion

In the proposed method, computing  $I_{f\Delta}$  is achieved by performing a suitable change of variables from  $x$  to  $y$  space such that equation (4) holds. And then, integrating the monomial terms of  $h$  over the standard simplex  $\Delta_s$  using formula (3) in a polynomial time.  $h$  terms are determined by accomplishing a long sequence of addition and multiplication of *dense* intermediate polynomials of degree up to  $D$ . Almost all obtained polynomials are dense because the matrix transformation  $A$  is often not sparse for general simplices resulting from the triangulation process. The big part of the computational complexity is due to multiplication rather than addition of intermediate polynomials. Indeed, the multiplication  $P = P_1 \times P_2$  of two polynomials represented as a sum of monomial terms can be carried out in two steps: i) distribution and monomial multiplication (a Cartesian product) and ii) simplification of

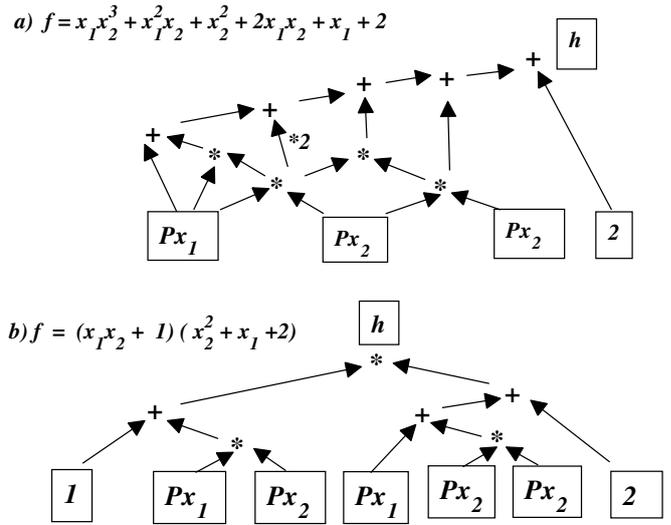

Fig. 2. Example of variables change according to 2 different factorizations.

result terms having the same degree. It should be emphasized that the simplification (step ii) requires more of computational complexity than the distribution and multiplication (step i). Let  $k_1, k_2$  be sizes of  $P_1, P_2$ , respectively. Consequently, we need  $k_1 \times k_2$  elementary operations of multiplication in step i), but we need  $k_1 \times k_2 \times C$  operations where  $C$  is the cost of the simplification of a given monomial term  $m$ .  $C$  is equal to the cost of search plus the cost of insertion of term  $m$  within the structure of  $P$ .

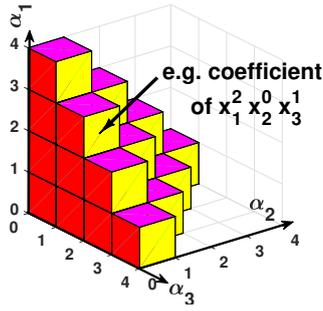

Therefore, it is interesting to improve monomial simplification by the proposition of suitable polynomial representation and efficient algorithms for multiplication.

### D. Proposition 1: accelerating variables change

The physical memory can in fact be seen as a continuous sequence of cells and all intermediate polynomials terms are stored of course in that space. During the variables change process, we need to find efficiently many times the location of a monomial given their variable powers, hence the order of monomials in memory is important.

As all the polynomials obtained are dense, we propose to represent a given polynomial  $P$  as a triplet  $(n, d, W)$  where  $n$  is the dimension,  $d$  is its degree ( $d \leq D$ ), and  $W$  is a vector of floats containing the monomial coefficients of  $P$ . The size of  $W$  is then equal to  $(n + d)! / (n!d!)$ . It is a good idea to save only the monomial coefficients into a compact structure according to a *particular order* and to not save variables powers ( $\alpha$  vectors). The desired order must allow a fast mapping in both directions between variables powers vector and the monomial position in the structure of  $P$ . Consequently, space complexity will be reduced because variables powers ( $\alpha$  vectors) are not saved.

The memory position (index) of the coefficient of a given monomial  $x^{(\alpha)} = x_1^{\alpha_1} \dots x_n^{\alpha_n}$  must be calculated efficiently based on the values of  $n, d, \alpha$  and the chosen order. To this end, we consider that  $w x_1^{\alpha_1} \dots x_n^{\alpha_n}$  is ordered before (on the

Fig. 3. VOIS structure example ( $D=3, n=3$ ).**Procedure 1** Mapping powers to index ( $Pow2Ind$ )

degree  $d$  and dimension  $n$  of the polynomial

**Output:**  $Ind$  (the corresponding index memory of  $x^{(\alpha)}$ )  
 $Ind \leftarrow 0$ ;

- 2:  $j \leftarrow n - 1$ ;  $i \leftarrow d$ ; start cell in Pascal square  
 $k \leftarrow 0$ ; variable index in vector  $\alpha$
- 4: **while**  $\alpha \neq (0, \dots, 0)$  **do**
- 6:   **if**  $\alpha[k] > 0$  **then**  
       $Ind \leftarrow Ind + Pascal[j, i]$ ; increment  $Ind$   
       $i \leftarrow i - 1$ ; shift left in Pascal  
       $\alpha[k] \leftarrow \alpha[k] - 1$ ;
- 8:   **else**  
       $j \leftarrow j - 1$ ; shift up in Pascal  
       $k \leftarrow k + 1$ ; shift right in  $\alpha$
- 10:   **end if**

**end while**

---

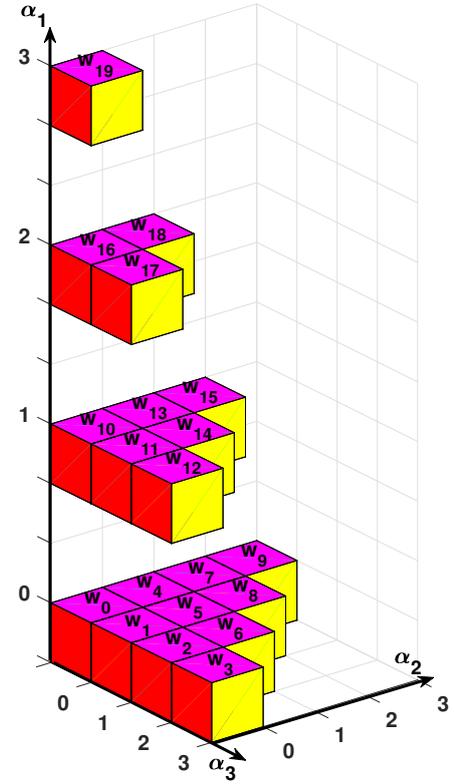

left) of  $w'x_1^{\alpha'_1} \dots x_n^{\alpha'_n}$  if  $[\alpha_1 \dots \alpha_n] < [\alpha'_1 \dots \alpha'_n]$ , which can be evaluated recursively as follows:

$$[\alpha_1 \dots \alpha_n] < [\alpha'_1 \dots \alpha'_n] \text{ if } \begin{cases} \alpha_i < \alpha'_i \text{ or } (\alpha_i = \alpha'_i \text{ and} \\ [\alpha_{i+1} \dots \alpha_n] < [\alpha'_{i+1} \dots \alpha'_n]) \end{cases}$$

We propose to represent the coefficients  $W$  of a dense polynomial of degree  $d$  and  $n$  variables as a Virtual Ordering Integer Simplex which we refer to as VOIS structure in this paper. The coefficient of the monomial  $x_1^{\alpha_1} \dots x_n^{\alpha_n}$  is stored in the cell  $(\alpha_1, \dots, \alpha_n)$  of the VOIS structure. Fig 3 illustrates an example for  $d=3$  and  $n=3$ . The coefficients of  $P$  are stored in the physical memory as a flat vector according to the VOIS order as follows:  $[w_0, w_1, \dots, w_k]$  where  $k = (n + d)! / n! * d!$  is the size of  $P$ , as illustrated in Fig 4.

For polynomial multiplication, we need both to handle monomials powers  $(\alpha_1, \dots, \alpha_n)$ , and to access directly to their memory location. The principal aim of the VOIS structure is to speed up conversion between monomial powers vectors and theirs corresponding memory indices.

The proposed functions that map powers vector to the corresponding memory index ( $pow2ind$ ) and the inverse mapping ( $ind2pow$ ) are displayed in Algorithms 1 and 2, respectively.

$$\leq O(n^{D+2})$$

, which is polynomial with a varying  $n$ . The complexity of polynomial addition is also polynomial in time; it is lesser than the multiplication complexity. According to the used polynomial factorization, we need at most to compute  $(D+n)!/(D!n!)$  multiplications and  $(D+n)!/(D!n!)$  additions which is polynomial for a fixed  $D$ . The total complexity of integrating is then polynomial because the composition of two polynomial functions is also polynomial.

The permutation between  $D$  and  $n$  in the given proof allows us to conclude that the complexity is polynomial for a fixed number of variables. This result agrees with results given recently in [1].

Table II shows the measured integration time using the proposed VOIS method for some examples of polynomials and simplices generated randomly when varying  $D$  and  $n$ . Experiment are carried out on a standard computer. The best integration results for less than a second are highlighted in bold and the worst results exceeding 10 hours are not displayed. One can notice that time-complexity increases very fast as an exponential when augmenting together  $D$  and  $n$ , but it increases with a lower rate when either  $D$  or  $n$  are low. We also notice that saving indices allows reducing time by a factor nearby 5.

## V. CONCLUSION

In this paper, we have proposed an integration method of high dimensional polynomial functions with high degree over a general simplex by performing an affine change of variables to the standard simplex where efficient formulas are already known.

The suggested variables change turns into making addition and multiplication operations over intermediate polynomials many times. To this end, we have proposed a compact data structure for polynomial representation, that we have called VOIS, in order to optimize the different operations involved during the polynomial transforming from the general simplex integration problem to an equivalent standard simplex integration problem.

For a fixed degree (and a varying dimension) or for a fixed dimension (and a varying degree) the integration computational complexity of our algorithm over a general simplex

output polynomial  $P$  of multiplication. One can see that our proposition (methods 4 and 5) overcomes incontestably the three first classical methods in terms of the trade-off between time and space complexity.

Another finding was that the global complexity of our algorithm for the integration over a general simplex is polynomial in time when the degree  $D$  or the dimension  $n$  are fixed. The proof of this result is as follows. In our proposition, all polynomial multiplications are carried out between a polynomial  $p_1$  ( $d_1 \leq D$ ) with a one degree polynomial  $P_2$  ( $d_2 = 1$ ).

For a fixed degree  $D$ , the complexity of multiplication  $P_1 \times P_2$  is:  $\text{CompMul} = \text{size of } P_1 * \text{size of } P_2 * O(n+d)$ , where  $O(n + d)$  is the search-insertion time complexity of a one monomial term (see row 4 in Table I). Hence, we have:

$$\text{CompMul} = (d_1 + n)!/(d_1!n!) * (n + 1) * O(n + d)$$

In experiments, only one core of the Processor Intel i7 3.7 GHz is used.

is polynomial. However, when varying both dimension and degree, the complexity in experiments that we have carried out seems to increase exponentially. In this last case, we recall that integration of a general polynomial function over a general simplex is shown to be NP hard [1].

A second aspect not fully examined in this work relates to the representation of the input polynomial; more precisely to the regular expression used to represent the polynomial that we want to integrate. For instance, we have found in some experiments that representing the polynomial function as a product of lower-degree polynomials, if it is possible, is more efficient than using a dense form expressed as a sum of monomial terms. We recommend orienting future works on the problem of determining the optimal factorization tree of polynomial functions in relation to integration performances.

□ **Abstract**—The  $p$ -median problem is classified as a NP-hard problem, which demands a long time for solution. To increase the use of the method in public management, commercial, military and industrial applications, several heuristic methods has been proposed in literature. In this work, we propose a customized Genetic Algorithm for solving the  $p$ -median problem, and we present its evaluation using benchmark problems of OR-library. The customized method combines parameters used in previous studies and introduces the evolution of solutions in stationary mode for solving PMP problems. The proposed Genetic Algorithm found the optimum solution in 37 of 40 instances of  $p$ -median problem. The mean deviation from the optimal solution was 0.002% and the mean processing time using CPU core i7 was 17.7s.

## I. INTRODUCTION

Facility location problems (FLP) are usually employed for solving public, commercial, industrial and military problems. In these problems, service demand points must be attended by a limited number of facilities. The  $p$ -median problem (PMP) is a type of FLP problem that aims searching a given location that minimizes the sum of the distances between  $N$  demand points and the nearest facility [1].

The computational complexity theory classifies the PMP as a non-polynomial hard problem (NP-hard problem). Meta-heuristic methods are usually used for solving NP-hard problems whose optimal solution method does not exist or is not known: Greedy Interchange (GI) [2], Neighborhood (N) and Exchange [2], Semi-Lagrangian relaxation [3], Simulated Annealing (SA) [4], Tabu Search (TS) [5], Genetic Algorithm (GA) [6-7].

To enable comparative studies of these methods, benchmarking data bases are used. The Operational Research (OR) library [8] and the Traveling Salesman Problem (TSP) [9] are the most used ones [6,7,10,11,12,13].

In the comparisons made in [6] and [11], the GA heuristic stands out as the best one in terms of time and precision of solution. Nevertheless, concerning the precision of the solutions, the GAs presented in these works have a worse result than the customized GAs, presented in [7], as well as when compared to GA combinations with other heuristics, presented in [11].

In [6], the authors used the OR-library [14] and two others more simple databases to evaluate several methods used in PMP solution: ADE (Alp, Drezner and Erkut) GA, Gamma Heuristic (GH), SA, Myopic, Exchange and N. The algorithm known as ADE GA performs a greedy search using the genetic material of two individuals randomly selected, evaluating all the possible combinations of generated offspring. The algorithm found solutions with an average distance from the optimal solution (OPT solution) of 0.41%, in 85% of the OR-library problems, and an average time of 18 seconds.

In [11] the authors performed a comparative study of a GA, an N algorithm and a hybrid GA and N algorithm, using the TSP-library. The GA proposed by the authors is similar to ADE GA, differing only in the use of an algebraic method to select a pair of parents. The GA converged to a solution in less time than the other heuristics. The CPU average time was 126.8min. The GA presented solutions with an average distance from the OPT solution of 0.000016%, and an average time of 391.5min.

In [7], a simple GA was compared to ADE GA, using a subset of OR-library. This GA investigates the use of  $p$  centroids to find the initial solutions of the algorithm. The GA found OPT solutions in 14 of the 15 subset problems. The average CPU time was 60.1s and 0.2s, for the simple GA and ADE GA, respectively. The average deviation was 0.007% and 0.02% for simple GA and ADE GA, respectively.

Table I shows a summary of the main characteristics of the GA used for solving the  $p$ -median problem in [6, 7, 11].

This work aims investigating the customization of GA for solving PMP problems. Three steps of the GA are investigated: selection operator, crossover operator and population updating. This investigation has the objective of generating a best performance of GA in finding OPT solutions for PMP problems.

The random selection operator employed in [6] and [11] does not take into account the individual's fitness when they are selected for crossover. The ranking selection operator employed in [7] assigns a selection probability to individuals directly proportional to their position in a ranking of the fitness function. In this work we investigate the use of the roulette wheel selection operator. The difference between the

GENETIC ALGORITHM CHARACTERISTICS USED FOR SOLVING THE P-MEDIAN PROBLEM IN [6, 7, 11].

Paper	Data base	GA characteristics			Results	
		Selection	Crossover	Heuristics studied	GA Deviation from OPT	Faster Heuristic
[6]	OR - Library, Alberta, Galvão e Koerkel	Random	Merging	ADE, GH, SA, Myopic, Exchange, BV	Up to 0.41% from OPT at 85% of OR problems. 0% at Alberta problems.	ADE
[11]	TSP – Library	Random	Merging	GA [11], BV, Hybrid between GA [11] and N	Up to 0.008% from OPT at 100% of TSP problems.	GA [11]
[7]	OR – Library (15 problems)	Ranking-based	Partial Match	ADE, GA [7]	GA [7]	ADE GA

ranking operator and the roulette wheel selection operator is that, the last one assign individuals a selection probability directly proportional to their fitness value.

We also propose using the single-point crossover operator. Differently from the merging operators [6,11] and partial match operators [7], the single-point crossover operator generate offspring without evaluating the parents. This implies in less processing time demand.

At last, we propose use a steady-state population updating [15]. In this updating mode, the fitness of children is compared to their parent's fitness. When the fitness value of the offspring is lower than their father's fitness, they are discarded. Offspring with better fitness values than their fathers are preserved with a probability of 75%.

The results obtained in this study are compared with the results obtained with the ADE GA [6] and simple GA [7]. For this comparison, we employed PMPs of OR-library and did a benchmark of the machines used for simulations in these previous works.

## II. METHODS

### A. Proposed Genetic Algorithm

Genetic Algorithm is a stochastic optimization algorithm, inspired by the theory of evolution of Charles Darwin [16]. Since its proposition, it has been effectively applied in the solution of complex problems, like TSP [9] and PMP [6,7,11].

In GA, initially, a population of chromosomes is randomly generated. In the sequence, the individuals of this population are modified by applying evolution operators, iteratively. A chromosome represents a solution to the problem. The fitness value of each chromosome is evaluated through an objective function of the problem.

The implementation of GA usually consists of three steps: the definition of the genetic codification model, the definition of the objective function and the parameterization of the evolution operators.

In this work, the genetic codification model uses the facility indexes and the objective function is given by the PMP. The structure of the proposed GA is presented in the steps of Algorithm 1.

### Algorithm 1 Proposed Genetic Algorithm

*Begin*

*Randomly generate the initial population*

*Compute fitness of population*

*Repeat for x generations*

*Roulette wheel selection of 2 parents*

*One-point crossover, at a 95% probability*

*One-gene random mutation, at a 5% probability*

*Compute fitness*

*Replace the parents with lower fitness than the children, at a 75% probability*

*Introduce a random chromosome to the population*

*Until population has converged*

*End*

### Genetic codification

As stated before, the genetic codification uses the facility indexes. The same approach was also used in [6, 7, 11]. Figure 1 shows an encoded chromosome representing a solution in a PMP problem with 8 facilities to be allocated among 100 possible locations.

1	20	31	4	76	91	62	100
---	----	----	---	----	----	----	-----

Fig. 1 Example of an encoded chromosome used in a PMP problem with 8 facilities

### Compute fitness

According to equation 1, the goal of the PMP is minimize  $f$ : the sum of the distances between the demand points and the nearest facility.

$$f = \sum_{i=1}^n \sum_{j=1}^p d_{ij} x_{ij} \quad (1)$$

$d_{ij}$  = distance between point  $i$  and point  $j$

$$x_{ij} = \begin{cases} 1, & \text{if demand } i \text{ is attended by } j \\ 0, & \text{otherwise} \end{cases}$$

$n$  = number of total locations

$p$  = number of medians

*Roulette Wheel Selection*

The selection operator used is the roulette wheel operator [17,18]. In this study, the selection operator assigns a probability value to each individual that is inversely proportional to its fitness value. The inversely dependence is due to the fact that, in the  $p$ -median problem, best individuals are those with lower  $f$  values, given in equation (1). Therefore, fitter individuals are the most likely to have children. This behavior favors the generation of more fit individuals. Table II illustrates the probability values used by different selection operators for four individuals.

TABLE II.  
SELECTION OPERATORS CHARACTERISTICS

Chromosome	Fitness Value	Probability of selection operator (%)		
		Roulette Wheel	Random	Ranking
1	200	28.8	25	30
2	900	6.3	25	20
3	100	57.6	25	40
4	800	7.2	25	10

*One-point Crossover*

The one-point crossover operator is used in this study [18]. This operator randomly generates a reference point to permute genes between fathers. The crossover probability used is 95%. Figure 2 illustrates the genetic permutation performed by the one-point crossover operator. To avoid repeated indexes in the offspring, we do a scan in the genes of each child, and replace the repeated index with another value randomly selected.

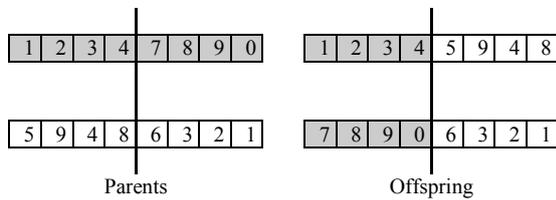

Fig. 2 Illustration of one-point crossover operation

*One-gene random mutation*

The mutation operator used randomly selects one gene [7], with probability of 5%, and performs a mutation. Figure 3 illustrates the mutation operator. One gene with index value of 5 is selected and replaced with the index value of 7. The replacing value is random selected.

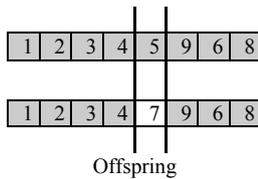

Fig. 3 Illustration of one-gene mutation operation

*B. Metrics*

In this study, the metrics used for performance evaluation of GA algorithms are the number of optimal solutions found, the percentual deviation of a non-optimal solution from the OPT solution, and the algorithm convergence time.

*C. PMP data base for benchmarking*

Aiming to compare the results obtained in this study with the results obtained in other two works [6,7], we use the PMP section of OR-library. For each problem, are given: the number of points,  $N$ ; the number of facilities,  $p$ ; the OPT solution and a matrix with the distances between each pair of points.

*D. CPU benchmarking*

The algorithm convergence time depends on the CPU model and the clock of the machine used for its implementation. Therefore, to compare the results of the GA used in this study with the GAs used in [6,7], we performed the benchmark between CPUs using the Dhrystone (D) method [19].

Using a default algorithm with integer numbers, the D method assigns a numeric value to each CPU. This value represents the number of millions of Dhrystone instructions processed per second (DMIPS) per MHz of clock. The DMIPS value of the machine used in this study (Core I7 7500U) is made equal to 1. The DMIPS values of the machines used in [6,7] are then divided by it and ratio values are obtained. The last column of Table III shows these ratio values. As shown, the machines used in [6] and [7] process 15.1% and 104.1%, respectively, of the DMIPS processed by the machine used in this study.

TABLE III.  
BENCHMARK COMPARISON OF THREE DIGITAL COMPUTERS

CPU	Clock (MHz)	DMIPS/ MHz	Product	Ratio
Pentium III [6]	733	3.4	2492.2	0.151
Core I7 4770K [7]	2000	8.57	17140	1.041

This study				
Product = (Clock*DMIPS/MHz)		Ratio=(Product/16380)		

III. RESULTS

Table IV shows, for the GA proposed in this study, and for the GAs proposed in [6] and [7], the following results: the number of OPT solutions; the percentual deviations from non-optimal solutions to OPT solutions and the GA algorithm processing time. The processing time of the GAs proposed in [6] and [7] are multiplied by the ratio value shown in Table III. Similarly to [6], the results of this study were produced by a C++ code, implementing 10 runs for each one of the 40 OR-library PMP problems. The best results are in bold.

#### IV. DISCUSSION

##### A. Proposed GA vs ADE GA [6]

The GA proposed in this study achieved OPT solutions in 37 of the 40 PMPs shown in Table IV. The non-OPT solutions present a mean deviation of 0.002% from OPT solution, corresponding to a mean time of 17.7s. ADE GA [6] presents OPT solutions in 28 of the 40 PMPs. The non-OPT solutions present a mean deviation of 0.036% from OPT solutions, corresponding to a mean time of 2.7s in a CPU Core I7 7500U at 1.8GHz.

Considering the 28 PMPs that both methods achieved OPT solutions, the proposed GA and the ADE GA [6] achieved best results in 21 and 7 of them, respectively. In the 7 PMPs that ADE GA [6] achieved best results, 6 of them occurred between Pmed1 and Pmed20. This range corresponds to less complex problems. To evaluate the performance difference between the two methods, we applied a Qui-Square test in the following 2x2 contingency table: [21 7; 7 21], and found  $\chi^2 = 14$ . For 1 degree of freedom, and a significance level of 99%, the critical level is  $t_c = 6.63$ . As  $\chi^2 > t_c$ , the difference between the proposed GA algorithm and ADE GA [6] is statistically significant.

From Table IV we also observe that when the ratio  $p/N$  increases, ADE GA [6] presents results significantly lower than the results obtained in this study. In the range Pmed21 to Pmed40, ADE GA [6] achieved OPT solutions in 10 of the 20 PMPs, with mean deviation of 0.046% from the OPT solutions, while the GA proposed in this study achieved OPT solutions in 17 of the PMPs, with mean deviation of 0.004% from the OPT solutions. For the instances Pmed5, Pmed10, Pmed15, Pmed20, Pmed25 and Pmed30, in which the ratio  $p/N$  is around 33%, the GA proposed in this study found all the OPT solutions, while ADE GA [6] found solutions with mean deviation of 0.18% from the OPT solutions. We believe that, for more complex PMP problems ( $N > 900$ ), the GA algorithm proposed in this study would obtain better values than ADE GA [6].

##### B. Proposed GA vs GA proposed in [7]

The GA proposed in [7] obtained solutions only for problems in the range Pmed1 to Pmed15. In this range, it obtained OPT solution in 14 PMPs, with a deviation of 0.07% from the OPT solution. The GA proposed in this study obtained OPT solutions in all this range.

Table IV shows that the GA proposed in this study converged in a shorter time than GA proposed in [7]. The last one is 44 times slower. This result suggests that the centroid technique used for population initialization in [7] as well as the continuous population updating have a negative impact in convergence time of the GA algorithm, making it slower.

#### V. CONCLUSION

A customization of GA operators for solving the  $p$ -median problem is proposed in this study. When applied to solve the

PMPs of OR-library, the proposed algorithm found OPT solutions in 37 of 40 PMPs, with a mean deviation of 0.002% and with a mean time of 17.7s.

**Abstract**—In this paper, we present a 1-space bounded cube packing algorithm with asymptotic competitive ratio 10.872.

**Index Terms**—Online algorithms, bin packing, cube, one-space bounded

## I. INTRODUCTION

IN THE bin packing problem, we receive a sequence of items of different sizes that must be packed into a finite number of bins in a way that minimizes the number of bins used. When all the items are accessible, the packing method is called *offline*. The packing method is called *online*, when items arrive one by one and each item has to be packed irrevocably into a bin before the next item is presented.

In the online version of packing a crucial parameter is the number of bins available for packing, i.e., *active bins*. Each incoming item is packed into one of the active bins; the remaining bins are not available at this moment. If we close one of the current active bins, we open a new active bin. Once an active bin has been closed, it can never become active again. When the method allows at most  $t$  active bins at the same time, it is called *t-space bounded*. Unbounded space model does not impose any limits on the number of active bins. It is natural to expect a packing method to be less efficient with fewer number of active bins. In this paper, we study 1-space bounded 3-dimensional cube packing.

Let  $S$  be a sequence of cubes. Denote by  $A(S)$  the number of bins used by the algorithm  $A$  to pack items from  $S$ . Furthermore, denote by  $OPT(S)$  the minimum possible number of bins used to pack items from  $S$  by the optimal offline algorithm. By the asymptotic competitive ratio for the algorithm  $A$  we mean:

$$R_A^\infty = \limsup_{n \rightarrow \infty} \sup_S \left\{ \frac{A(S)}{OPT(S)} \mid OPT(S) = n \right\}.$$

### A. Related work

The one-dimensional case of the space bounded bin packing problem has been extensively studied and the best possible algorithms are known: the Next-Fit algorithm [5] for the one-space bounded model and the Harmonic algorithm [6] when the number of active bins goes to infinity. The questions concerning  $t$ -space bounded  $d$ -dimensional packing ( $d \geq 2$ ) have been studied in a number of papers. For large number of active bins, Epstein and van Stee [1] presented a  $(\Pi_\infty)^d$ -competitive space bounded algorithm, where  $\Pi_\infty \approx 1.69103$  is the competitive ratio of the one-dimensional algorithm

Harmonic. Algorithms for 2-dimensional bin packing with only one active bin were explored for the first time in [8], where the authors give 8.84-competitive algorithm for 2-dimensional bin packing. An improved result of that case can be found in the paper [7], where a 5.155-competitive method is presented. The last article also contains an algorithm for packing squares with competitive ratio at most 4.5. In [4], a 4.84-competitive 1-space bounded 2-dimensional bin packing algorithm was presented. Grzegorek and Januszewski [3] presented a  $3.5^d$ -competitive as well as a  $12 \cdot 3^d$ -competitive online  $d$ -dimensional hyperbox packing algorithm with one active bin. The  $d$ -dimensional case of 1-space bounded hypercube packing was discussed in [9], where a  $2^{d+1}$ -competitive algorithm was described. The aim of this paper is to improve the upper bound ( $2^{3+1}$ ) in the 3-dimensional case. We present 10.872-competitive 1-space bounded cube packing algorithm.

### B. Our results

The algorithm presented in this article considers packing items (cubes of edges not greater than 1) into one active cube of edge 1. The main packing method is a bit like the classic computer game Tetris. The packing method which we describe is similar to the method presented by Grzegorek and Januszewski in [2]. The algorithm distinguishes types of items what determines a method for packing a specific item in a bin. Items that are considered big enough are packed from top to bottom. Different types of small items are packed from bottom upwards. The algorithm handles small items in a Tetris manner: to determine a place to pack an item a part of a bin is temporarily divided into congruent cuboids of appropriate size. Then an item is packed as low as possible inside a carefully chosen cuboid.

In Section II we give a 1-space bounded cube packing algorithm with the ratio 10.872.

## II. THE one-space-ALGORITHM

Let  $S$  be a sequence of cubes  $Q_1, Q_2, \dots$ . Denote by  $a_i$  the edge length of  $Q_i$ .

- an item  $Q_i$  is *huge*, provided  $a_i > 1/2$ ;
- an item  $Q_i$  is *big*, provided  $1/4 < a_i \leq 1/2$ ;
- an item  $Q_i$  is *small*, provided  $a_i \leq 1/4$ ; a small item  $Q_i$  is of *type k* provided  $2^{-k-1} < a_i \leq 2^{-k}$ .

Let  $\mathcal{B}$  be the active bin. To shorten the notation, a cuboid whose edges have lengths  $a \times a \times b$  will be called an  $(a, b)$ -cuboid.

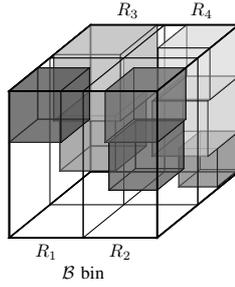

Fig. 1. Big items – the darker an item's colour, the later it arrived

### A. Description of the one-space-algorithm

- In packing items we distinguish coloured and white (not coloured) space. Items are placed only in the white space. Each newly opened bin is white.
- We divide each freshly opened bin into  $(1/2, 1)$ -cuboids. These cuboids are named  $R_1, R_2, R_3, R_4$  in an arbitrary order.
- Huge items (edge  $> 1/2$ ) are packed alone into a bin, i.e., if  $Q_i$  is huge, then we close the active bin and open a new bin to pack this item. After packing  $Q_i$  we close the bin and open a new active bin.
- If  $Q_i$  is big ( $1/4 < \text{edge} \leq 1/2$ ) we find the highest indexed  $R_j$  such that  $Q_i$  can be packed into it. We pack  $Q_i$  into  $R_j$  along the edge of  $\mathcal{B}$  as high as it is possible (see Figs. 1 and 3). If such a packing is not possible, we close the active bin, open a new active bin and pack  $Q_i$  into it.
- If  $Q_i$  is a small item of type  $k$  ( $2^{-k-1} < \text{edge} \leq 2^{-k}$ ) (see Figs. 2 and 3) we find the lowest indexed  $R_j$  such that  $Q_i$  can be packed into it. Since  $j$  is fixed now, we will write  $R$  instead of  $R_j$ .

When a big item is packed, it colours the space covered by itself.

We temporarily divide  $R$  into  $(2^{-k}, 1)$ -cuboids called  $R(1), \dots, R(4^{k-1})$ . Denote by  $t(n)$  the distance between the top of  $R(n)$  and the top of the topmost item packed in  $R(n)$  for  $n = 1, \dots, 4^{k-1}$  (see Fig. 5, right) and let  $\eta$  be an integer such that  $t(\eta) = \max\{t(1), \dots, t(4^{k-1})\}$ . We pack  $Q_i$  into  $R(\eta)$  as low as possible. The result of packing  $Q_i$  is the colouring of the  $(2^{-k}, 1 - t(\eta) + a_i)$ -cuboid contained in the bottom of  $R(\eta)$  (see Fig. 5, right, where  $\eta = 2$  before  $Q_{14}$  was packing).

If such a packing is not possible, then we close the active bin and open a new active bin to pack  $Q_i$ .

### B. Competitive ratio

Let  $P_j$  for  $j = 1, \dots, 16$  be  $(1/4, 1)$ -cuboids with pairwise disjoint interiors. Each cuboid  $R_i$  for  $i \in \{1, 2, 3, 4\}$  is divided into four cuboids  $P_{4i-3}, \dots, P_{4i}$  (see Fig. 4).

**Lemma 1.** Assume that only small items were packed into  $\mathcal{B}$ . Assume that  $j \in \{1, 2, \dots, 16\}$ . Denote by  $n$  the number of items packed into  $P_j$  and by  $t_n$  the distance between the

bottom of  $\mathcal{B}$  and the top of the topmost item packed into  $P_j$ . The total volume  $v_n$  of small items packed into  $P_j$  is greater than

$$f(t_n) = \frac{19}{2048} \cdot t_n - \frac{13}{16384}.$$

Moreover, if the topmost packed item is of type 2, then

$$v_n > f_+(t_n) = \frac{19}{2048} \cdot t_n.$$

*Proof.* Without loss of generality we can assume that  $P_j = [0, 1/4] \times [0, 1/4] \times [0, 1]$ . We will prove the result using induction over the number  $n$  of packed items.

First assume that only one item  $Q_b$  was packed into  $P_j$ . Obviously,  $t_1 = a_b$ . Let

$$\varphi(a) = a^3 - \frac{19}{2048}a.$$

The function  $\varphi(a)$  for  $a > 0$  has a minimum at

$$a_0 = \sqrt{\frac{19}{6144}}.$$

A computation shows that

$$\varphi(a_0) > -\frac{1}{2} \cdot \frac{13}{16384} \quad (1)$$

(this lower bound will be useful in the last part of the proof). We get

$$v_1 = a_b^3 > \frac{19}{2048} \cdot t_1 - \frac{1}{2} \cdot \frac{13}{8192} = f(t_1).$$

Moreover, if  $1/8 < a_b \leq 1/4$ , then  $v_1 = a_b^3 > \frac{19}{2048}a_b = f_+(t_1)$ .

Now assume that the statement holds for at most  $n$  items packed into  $P_j$  (this is our inductive assumption). Let  $Q_u$  be the  $(n+1)$ st item packed into  $P_j$  and let  $t_{n+1}$  be the distance between the bottom of  $P_j$  and the top of the topmost item (from among  $n+1$  items  $Q_b, \dots, Q_u$ ) packed into  $P_j$ .

If  $a_u > 1/8$ , then  $t_{n+1} = t_n + a_u$ . Using the inductive assumption,

$$v_{n+1} = v_n + a_u^3 > f(t_n) + a_u^3 = \frac{19}{2048} \cdot t_n - \frac{13}{16384} + a_u^3.$$

Since

$$\varphi'(a) = 3a^2 - \frac{19}{2048} > 3 \cdot \frac{1}{64} - \frac{19}{2048} > 0$$

for  $a > 1/8$ , we get

$$\varphi(a) > \varphi\left(\frac{1}{8}\right) = \frac{13}{16384}$$

for  $a > 1/8$ . Consequently,

$$\begin{aligned} v_{n+1} &> f(t_n) + a_u^3 = \frac{19}{2048}(t_n + a_u) + \varphi(a_u) - \frac{13}{16384} \\ &\geq \frac{19}{2048}(t_n + a_u) = f_+(t_n + a_u) = f_+(t_{n+1}). \end{aligned}$$

Finally, consider the case when  $a_u \leq 1/8$ . First, we choose the topmost packed item  $Q^1$  with edge greater than  $1/8$  and denote by  $\tau$  the distance between the bottom of  $P_j$  and the top of  $Q^1$  (see Fig. 6, left). If there is no such item, then we

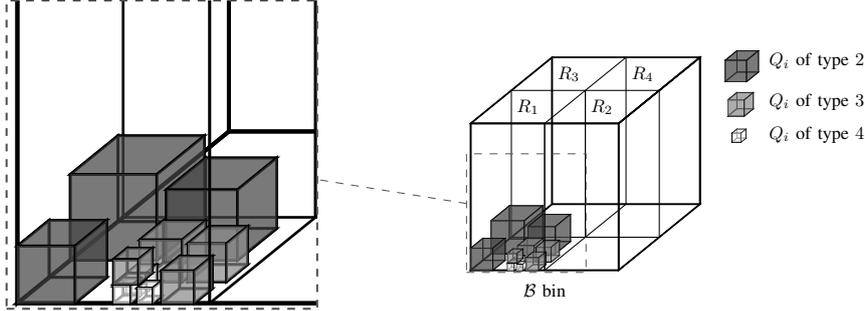

Fig. 2. Small items

take  $\tau = 0$ . The total volume of items packed up to  $\tau$ , by the inductive assumption, is not smaller than  $f_+(\tau)$ . Above  $Q^1$  we divide  $P_j$  into four  $(1/8, 1 - \tau)$ -cuboids  $P_j^1, P_j^2, P_j^3, P_j^4$ . Denote by  $Q_1^l, \dots, Q_{v_l}^l$  the items from among  $Q_b, \dots, Q_{u-1}$  packed into  $P_j^l$  above  $Q^1$  (if any) for each  $l = 1, 2, 3, 4$ . Moreover, denote by  $t_n^l$  the distance between the bottom of  $P_j$  and the top of the topmost item from among  $Q_b, \dots, Q_{u-1}$  packed into  $P_j^l$  and let  $t_n^* = \min(t_n^1, t_n^2, t_n^3, t_n^4)$  (see Fig. 6, right). Clearly,  $t_n^* \geq \tau$  and  $t_n^* \leq t_n$ .

If  $t_n^* + a_u \leq t_n$ , then  $t_{n+1} = t_n$ . Consequently,

$$v_{n+1} \geq v_n + a_u^3 = f(t_n) + a_u^3 = f(t_{n+1}) + a_u^3 > f(t_{n+1}).$$

If  $t_n^* + a_u > t_n$ , then  $t_{n+1} = t_n^* + a_u$ . Items  $Q_1^l, \dots, Q_{v_l}^l$  were packed into  $(1/8, t_n^l - \tau)$ -cuboid  $P_j^l$ . Let  $h(P_j^l) = [0, 1/4] \times [0, 1/4] \times [0, 2t_n^l - 2\tau]$  be the image of  $P_j^l$  in a homothety  $h$  of ratio 2. By the inductive assumption, the total volume of cubes  $h(Q_1^l), \dots, h(Q_{v_l}^l)$  is not smaller than  $\frac{19}{2048}(2t_n^l - 2\tau) - \frac{13}{16384} = f(2t_n^l - 2\tau)$ . Since the volume of each  $h(Q_i^l)$  is 8 times greater than the volume of  $Q_i^l$ , it follows that the total volume of cubes  $Q_1^l, \dots, Q_{v_l}^l$  is not smaller than  $\frac{1}{8}f(2t_n^l - 2\tau)$ .

Consequently,

$$\begin{aligned} v_{n+1} &\geq f_+(\tau) + 4 \cdot \frac{1}{8} f(2t_n^* - 2\tau) + a_u^3 \\ &= a_u^3 + \frac{19}{2048} t_n^* - \frac{1}{2} \cdot \frac{13}{16384}. \end{aligned}$$

By (1) we know that

$$\varphi(a_0) > -\frac{1}{2} \cdot \frac{13}{16384}.$$

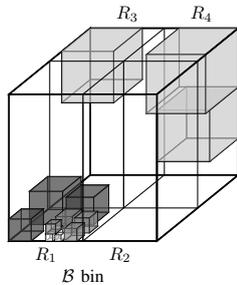

Fig. 3. one-space-algorithm

Consequently,

$$\begin{aligned} v_{n+1} &\geq \varphi(a_u) + \frac{19}{2048}(t_n^* + a_u) - \frac{1}{2} \cdot \frac{13}{16384} \\ &> \frac{19}{2048}(t_n^* + a_u) - \frac{13}{16384} = f(t_{n+1}). \end{aligned}$$

□

**Lemma 2.** Define  $V_3 = 101/1024$ . Let  $S$  be a finite sequence of cubes and let  $\nu$  be the number of bins used to pack items from  $S$  by the one-space-algorithm. Moreover, let  $m$  be the number of huge items in  $S$ . The total volume of items in  $S$  is greater than  $2^{-3} \cdot m + V_3(\nu - 2m - 1)$ .

*Proof.* Among  $\nu$  bins used to pack items from  $S$  by the one-space-algorithm the first  $\nu - 1$  bins will be called full. Let  $Q_z$  be the first item from  $S$  which cannot be packed into a full bin  $\mathcal{B}$  by the one-space-algorithm. Clearly,  $Q_z$  is the first item packed into the next bin.

Denote by  $v_{\mathcal{B}}$  the sum of volumes of items packed into  $\mathcal{B}$ .

If the incoming item  $Q_z$  is huge, then the average occupation ratio in both bins  $\mathcal{B}_j$  and the next bin  $\mathcal{B}_{j+1}$  into which  $Q_z$  was packed is greater than  $1/2^4$ . Obviously, there are  $2m$  such bins.

It is possible that the last bin is almost empty.

To prove Lemma 2 it suffices to show that if  $Q_z$  is not huge and if no huge item was packed into  $\mathcal{B}$ , then  $v_{\mathcal{B}} > V_3$  (the number of such bins equals  $\nu - 2m - 1$ ).

*Case 1:  $Q_z$  is small and all items packed into  $\mathcal{B}$  are small.*

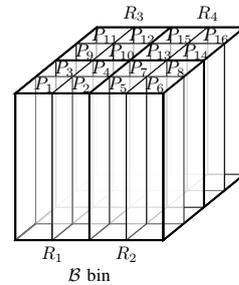

Fig. 4.  $(1/4, 1)$ -cuboids  $P_j$

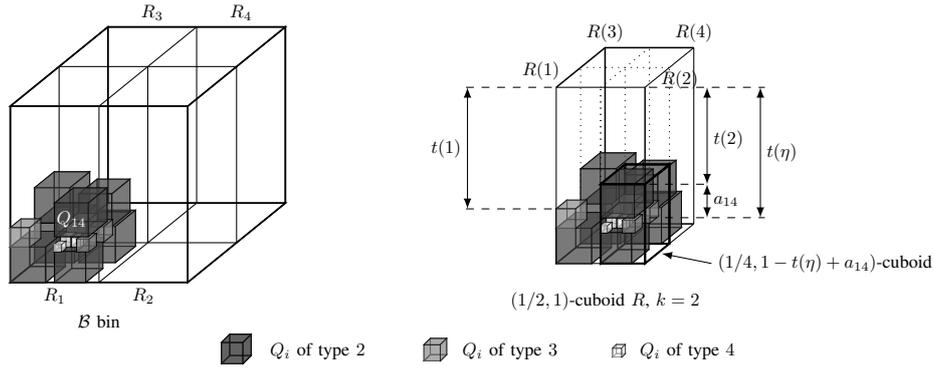

Fig. 5. Packing small items into  $(2^{-k}, 1)$ -cuboids

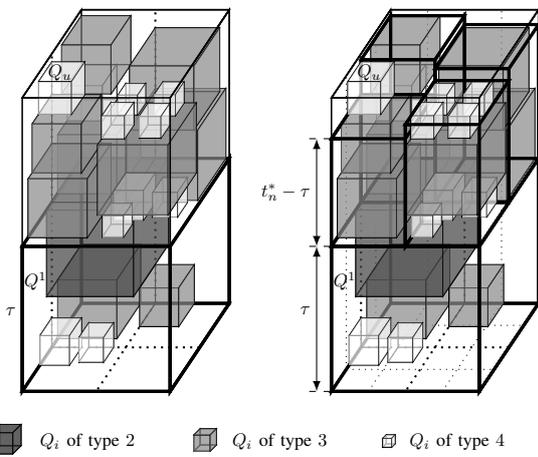

Fig. 6. The division

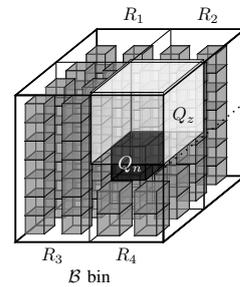

Fig. 7. Case 3

Since  $a_z \leq 1/4$ , it follows that each  $P_i$  is packed up to height at least  $3/4$ . By Lemma 1 we deduce that

$$v_B > 4^2 f\left(\frac{3}{4}\right) = 16 \cdot \left(\frac{19}{2048} \cdot \frac{3}{4} - \frac{13}{4 \cdot 16384}\right) = V_3.$$

Case 2:  $Q_z$  is small and a big item was packed into  $\mathcal{B}$ .

The volume of a big item  $Q_b$  with edge  $t$  is equal to  $t^3 > t \cdot \left(\frac{1}{4}\right)^2$ . In considerations presented in Case 1 we accept that the total volume of small items packed into  $R_j$  up to height  $t$  equals  $4f(t)$ . It is easy to see that

$$4f(t) < \frac{1}{16} \cdot t.$$

As a consequence,  $v_B > V_3$ .

Case 3:  $Q_z$  is a big item and all items packed into  $\mathcal{B}$  are small

Assume that there is  $(2^{-2}, 1)$ -cuboid  $R_j(n)$  ( $j \in \{1, 2, 3\}$ ,  $n \in \{1, 2, 3, 4\}$ ) such that the distance between its top and the top of the topmost item packed into it is greater than  $1/8$  and denote by  $R_+$  first such cuboid. The total volume of items packed into  $R_+$  is greater than  $f(3/4)$ . The total volume of items packed into each cuboid preceding  $R_+$  is greater than  $f(7/8)$ . The total volume of items packed into

each of remaining cuboids is greater than  $\frac{3}{4} \cdot \frac{1}{8^2} > f(7/8)$  (in such a cuboid only items greater than  $1/8$  were packed).

Denote by  $Q_n$  the topmost small item packed in  $R_4$  (as in Fig. 7). Since  $a_z \leq 1/2$  and  $Q_z$  cannot be packed in  $R_4$ , it follows that

$$v_B > (16 - 5)f\left(\frac{7}{8}\right) + f\left(\frac{3}{4}\right) + 4f\left(\frac{1}{2} - a_n\right) + a_n^3.$$

Denote by  $\gamma(a_n)$  the function on the right-hand side of this formula. This function for positive  $a$  has a minimum at  $a_0 = \sqrt{\frac{19}{1536}}$ .

A computation shows that  $\gamma(a_0) > V_3$ . Consequently,  $v_B > V_3$ .

If there is no  $(2^{-2}, 1)$ -cuboid  $R_j(n)$  ( $j \in \{1, 2, 3\}$ ,  $n \in \{1, 2, 3, 4\}$ ) such that the distance between its top and the top of the topmost item packed into it is greater than  $1/8$ , then

$$v_B > (16 - 4)f\left(\frac{7}{8}\right) + 4f\left(\frac{1}{2} - a_n\right) + a_n^3.$$

Since  $f(7/8) > f(3/4)$ , we get  $v_B > \gamma(a_0) > V_3$ .

Case 4:  $Q_z$  is big and a big item was packed into  $\mathcal{B}$

Similarly as in Case 2 we get

$$4f(t) < t^3.$$

We deduce by Case 3 that  $v_B > V_3$ . □

**Theorem 1.** *The asymptotic competitive ratio for the one-space-algorithm is not greater than  $1098/101 \approx 10.8713$ .*

*Proof.* Let  $S$  be a sequence of items of total volume  $v$ , let  $m$  denote the number of huge items in  $S$  and let  $\mu$  be the number of bins used to pack items from  $S$  using the one-space-algorithm. Obviously,  $OPT(S) \geq v$  as well as  $OPT(S) \geq m$ .

By Lemma 2 we get  $v > \frac{1}{2^3} \cdot m + V_3 \cdot (\mu - 2m - 1)$ , i.e.,

$$\mu < \frac{v}{V_3} + m \left( 2 - \frac{1}{2^3 V_3} \right) + 1.$$

It is easy to check that  $2 - \frac{1}{8V_3} > 0$ .

If  $m < v$ , then

$$\frac{\mu}{OPT(S)} \leq \frac{\mu}{v} < \frac{\frac{v}{V_3} + v \left( 2 - \frac{1}{2^3 V_3} \right) + 1}{v} = \frac{2^3 - 1}{2^3 V_3} + 2 + \frac{1}{v}.$$

If  $v \leq m$ , then

$$\frac{\mu}{OPT(S)} \leq \frac{\mu}{m} \leq \frac{\frac{m}{V_3} + m \left( 2 - \frac{1}{2^3 V_3} \right) + 1}{m} = \frac{2^3 - 1}{2^3 V_3} + 2 + \frac{1}{m}.$$

Consequently, the asymptotic competitive ratio for the one-space-algorithm is not greater than

$$\frac{7}{8} \cdot \frac{1024}{101} + 2 = \frac{1098}{101} < 10.872.$$

**Abstract**—Optimization of the production process is important for every factory or organization. The better organization can be done by optimization of the workforce planing. The main goal is decreasing the assignment cost of the workers with the help of which, the work will be done. The problem is NP-hard, therefore it can be solved with algorithms coming from artificial intelligence. The problem is to select employers and to assign them to the jobs to be performed. The constraints of this problem are very strong and for the algorithms is difficult to find feasible solutions. We apply Ant Colony Optimization Algorithm to solve the problem. We investigate the algorithm performance according evaporation parameter. The aim is to find the best parameter setting.

**Index Terms**—Workforce Planning, Ant Colony Optimization, Metaheuristics, Evaporation parameter

## I. INTRODUCTION

**T**HE WORKFORCE planning is a very important decision making problem for branches of the industry. It plays an important role in human resource management. It includes multiple level of complexity, therefore it is a hard optimization problem (NP-hard). The problem can be divided in to two parts: selection and assignment. The first part is selection of employers from the set of available workers. The second part is assignment of the selected workers to jobs, which the worker will perform. The goal is to carry out the work requirements minimizing assignment cost.

As we have noted above the problem is very hard optimization problem and is impossible to be solved with exact methods or traditional numerical methods for instances with realistic size. These types of methods can be applied only on simplified variants of the problem. A deterministic version of workforce planing problem is studied in [12], [18]. In [12] the workforce planning is reformulated as mixed integer programming. It is shown that the mixed integer program is much easier to solve the problem than the non-linear program. In [18] the model includes workers differences and the possibility of workers training and upgrading. A variant with random demands of the problem is considered in [4], [19]. Two stage program of scheduling and allocating with

random demands is proposed in [4]. Other variant of the problem is to include uncertainty [13], [15], [17], [24], [25]. A lot of authors skip some of the constraints to simplify the problem. Mixed linear programming is apply in [6] and in [19] is utilized decomposition method, but for the more complex non-linear workforce planning problems, the convex methods are not applicable.

Last decade, nature-inspired metaheuristic methods receive more and more attention, because they can find close to optimal solutions even for large-scale difficult problems [2], [16], [20], [22], [23]. In the literature can be found various metaheuristic algorithms solving workforce planning problem. They include genetic algorithm [1], [14], memetic algorithm [21], scatter search [1] etc.

Ant Colony Optimization (ACO) algorithm is proved to be very effective solving various complex optimization problems [7], [11]. In our previous work [8], [9] we propose ACO algorithm for workforce planning. We have considered the variant of the workforce planning problem proposed in [1]. Current paper is the continuation of [8] and further develops the ideas behind [8]. We investigate the influence of evaporation parameter on algorithm performance. The aim is to find the best parameter setting.

The rest of the paper is organized as follows. In Section 2 the mathematical description of the problem is presented. In Section 3 ACO algorithm for workforce planing problem is described. Section 4 shows computational results, comparisons and discussion. A conclusion and directions for future work are done in Section 5.

## II. WORKFORCE PLANNING PROBLEM

In this paper we consider the workforce planning problem proposed in [1] and [10]. The set of jobs  $J = \{1, \dots, m\}$  need to be completed during a fixed period of time. The job  $j$  requires  $d_j$  hours to be finished.  $I = \{1, \dots, n\}$  is the set of workers, candidates to be assigned. Every worker must perform every of assigned to him job minimum  $h_{min}$  hours can work in efficient way. The worker  $i$  is available  $s_i$  hours.

One worker can be assigned to maximum  $j_{max}$  jobs. The set  $A_i$  shows the jobs, that worker  $i$  is qualified. Maximum  $t$  workers can be assigned during the planed period, or at most  $t$  workers may be selected from the set  $I$  of workers. The selected workers need to be capable to complete all the jobs they are assigned. The goal is to find feasible solution, that optimizes the objective function.

The cost of assigning the worker  $i$  to the job  $j$  is  $c_{ij}$ . The mathematical model of the workforce planing problem is described as follows:

$$x_{ij} = \begin{cases} 1 & \text{if the worker } i \text{ is assigned to job } j \\ 0 & \text{otherwise} \end{cases}$$

$$y_i = \begin{cases} 1 & \text{if worker } i \text{ is selected} \\ 0 & \text{otherwise} \end{cases}$$

$$z_{ij} = \text{number of hours that worker } i \\ \text{is assigned to perform job } j$$

$$Q_j = \text{set of workers qualified to perform job } j$$

$$\text{Minimize } \sum_{i \in I} \sum_{j \in A_i} c_{ij} \cdot x_{ij} \quad (1)$$

Subject to

$$\sum_{j \in A_i} z_{ij} \leq s_i \cdot y_i \quad i \in I \quad (2)$$

$$\sum_{i \in Q_j} z_{ij} \geq d_j \quad j \in J \quad (3)$$

$$\sum_{j \in A_i} x_{ij} \leq j_{max} \cdot y_i \quad i \in I \quad (4)$$

$$h_{min} \cdot x_{ij} \leq z_{ij} \leq s_i \cdot x_{ij} \quad i \in I, j \in A_i \quad (5)$$

$$\sum_{i \in I} y_i \leq t \quad (6)$$

$$x_{ij} \in \{0, 1\} \quad i \in I, j \in A_i$$

$$y_i \in \{0, 1\} \quad i \in I$$

$$z_{ij} \geq 0 \quad i \in I, j \in A_i$$

The objective function is the minimization of the total assignment cost. The number of hours for each selected worker is limited (inequality 2). The work must be done in full (inequality 3). The number of the jobs, that every worker can perform is limited (inequality 4). There is minimal number of hours that every job must be performed by every assigned worker can work efficiently (inequality 5). The number of assigned workers is limited (inequality 6).

This mathematical model can be used with other objectives too. If  $\tilde{c}_{ij}$  is the cost the worker  $i$  to performs the job  $j$  for one hour, than the objective function can minimize the cost of the hall jobs to be finished.

$$f(x) = \text{Min} \sum_{i \in I} \sum_{j \in A_i} \tilde{c}_{ij} \cdot x_{ij} \quad (7)$$

The preferences of the workers to the jobs can be included. In this case one of the variants of the objective function will be to maximize the satisfaction of the workers preferences.

### III. ANT COLONY OPTIMIZATION ALGORITHM

The ACO is a nature inspired methodology. It is a meta-heuristics, following the real ants behavior when looking for a food. Real ants use chemical substance, called pheromone, to mark their path ant can return back. An ant moves in random way and when it detects a previously laid pheromone it decides whether to follow it and reinforce it with a new added pheromone. Thus the more ants follow a given trail, the more attractive that trail becomes. There is evaporation in a nature and the pheromone evaporates during the time. Thus the pheromone level of not used and less used paths decreases and they become less desirable. In this way the nature prevents the ants to follow some wrong and useless path. The ants can find a shorter path between the source of the food and the nest by their collective intelligence.

#### A. Main ACO Algorithm

It is not practical to solve HP-hard problems with exact methods or traditional numerical methods when the problem is large. An option is to be applied some metaheuristics. The goal is to find a good solution for a reasonable computational resources like time and memory [5].

For a first time, ant behavior is used for solving optimization problems by Marco Dorigo [3]. Later some modifications are proposed, mainly in pheromone updating rules [5]. The basic in ACO methodology is the simulation of ants behavior. The problem is represented by graph. The solutions are represented by paths in a graph and the aim is to find shorter path corresponding to given constraints. The requirements of ACO algorithm are as follows:

- Appropriate representation of the problem by a graph;
- Appropriate pheromone placement on the nodes or on the arcs of the graph;
- Suitable problem-dependent heuristic function, which manage the ants to improve solutions;
- Pheromone updating rules;
- Transition probability rule, which specifies how to include new nodes in the partial solution;
- Appropriate algorithm parameters.

The transition probability  $P_{i,j}$ , is a product of the heuristic information  $\eta_{i,j}$  and the pheromone trail level  $\tau_{i,j}$  related to the move from node  $i$  to the node  $j$ , where  $i, j = 1, \dots, n$ .

$$P_{i,j} = \frac{\tau_{i,j}^a \cdot \eta_{i,j}^b}{\sum_{k \in Unused} \tau_{i,k}^a \cdot \eta_{i,k}^b}, \quad (8)$$

where  $Unused$  is the set of unused nodes of the graph.

The initial pheromone level is the same for all elements of the graph and is set to a positive constant value  $\tau_0$ ,  $0 < \tau_0 < 1$ .

After that at the end of the current iteration the ants update the pheromone level [5]. A node become more desirable if it accumulates more pheromone.

The main update rule for the pheromone is:

$$\tau_{i,j} \leftarrow \rho \cdot \tau_{i,j} + \Delta\tau_{i,j}, \quad (9)$$

where  $\rho$  decreases the value of the pheromone, which mimics evaporation in a nature.  $\Delta\tau_{i,j}$  is a new added pheromone, which is proportional to the quality of the solution. For measurement of the quality of the solution is used the value of the objective function of the ants solution.

The first node of the solution is randomly chosen. With the random start the search process is diversifying and the number of ants may be small according the number of the nodes of the graph and according other population based metaheuristic methods. The heuristic information represents the prior knowledge of the problem, which is used to better manage the algorithm performance. The pheromone is a global history of the ants to find optimal solution. It is a tool for concentration of the search around best so far solutions.

### B. Workforce Planing ACO

An important role for the successes of the ACO algorithm is the representation of the problem by graph. The graph we propose is 3 dimensional and the node  $(i, j, z)$  corresponds to worker  $i$  to be assigned to the job  $j$  for time  $z$ . When an ant begins their tour we generate three random numbers: the first random number is from the interval  $[0, \dots, n]$  and corresponds to the worker we assign; the second random number is from the interval  $[0, \dots, m]$  and shows the job which this worker will perform. The third random number is from the interval  $[h_{min}, \min\{d_j, s_i\}]$  and shows number of hours worker  $i$  is assigned to performs job  $j$ . Next node is included in the solution, applying transition probability rule. We repeat this procedure till the solution is constructed.

The following heuristic information is applied:

$$\eta_{ijl} = \begin{cases} l/c_{ij} & l = z_{ij} \\ 0 & otherwise \end{cases} \quad (10)$$

By this heuristic information the most cheapest unassigned worker, is assigned as longer as possible. The node with highest probability from all possible nodes is chosen to be included in the partial solution. When there are more than one possibilities with the same probability, the next node is chosen in a random way between them.

When a new node is included we take in to account all constraints: how many workers are assigned till now; how many time slots every worker is assigned till now; how many time slots are assigned per job till now. If a move do not meets all constraints, the probability of this move is set to 0. The solution is constructed if there are not more possibilities for including new nodes (the transition probability is 0 for all possible moves). If the constructed solution is feasible the value of the objective function is the sum of the assignment cost of the assigned workers. When the constructed solution

TABLE I: Test instances characteristics

Parameters	Value
$n$	20
$m$	20
$t$	10
$s_i$	[50,70]
$j_{max}$	[3,5]
$h_{min}$	[10,15]

TABLE II: ACO parameter settings

Parameters	Value
Number of iterations	100
$\rho$	{0.1, 0.3, 0.5, 0.7, 0.9}
$\tau_0$	0.5
Number of ants	20
$a$	1
$b$	1

is not feasible, the value of the objective function is set to be equal to  $-1$ .

New pheromone is deposited only on the elements of feasible solutions. The deposited pheromone is proportional to the reciprocal value of the objective function.

$$\Delta\tau_{i,j} = \frac{\rho - 1}{f(x)} \quad (11)$$

Thus the nodes belonging to better solutions accumulate more pheromone than others and will be more attractive in the next iteration. The iteration best solution is compared with the global best solution and if on the current iteration the some of the ants achieves better solution it becomes the new global best. As end condition we use the number of iterations.

In this research we are concentrated on influence of the evaporation parameter on algorithm performance. We tested several values for this parameter and compare the number of needed iterations to find the best solution.

## IV. COMPUTATIONAL RESULTS AND DISCUSSION

In this section we tested our algorithm and evaporation parameter influence on 10 structured problems. The software, which realizes the algorithm is written in C and is run on Pentium desktop computer at 2.8 GHz with 4 GB of memory.

An artificially generated problem instances considered in [1] is used for the tests. The test instances characteristics are shown in Table I.

The parameter settings of our ACO algorithm is shown in Table II and are fixed experimentally after several runs of the algorithm.

In our previous work [8] we show that our ACO algorithm outperforms the genetic and scatter search algorithms proposed in [1]. We perform 30 independent runs with every one of the five values of the evaporation parameter, because the algorithm is stochastic and to guarantee the robustness of the

TABLE III: Evaporation parameter ranking

	$\rho = 0.1$	$\rho = 0.3$	$\rho = 0.5$	$\rho = 0.7$	$\rho = 0.9$
first place	3 times	4 times	1 times	2 times	0 times
second place	2 times	3 times	3 times	2 times	1 times
third place	2 times	1 times	3 times	2 times	1 times
forth place	2 times	1 times	2 times	3 times	2 times
fifth place	1 times	1 times	1 times	1 times	6 times
ranking	26	22	29	31	43

average results. We apply ANOVA test for statistical analysis to guarantee the significance of the difference between the average results. We compare the average number of iterations needed to find the best result for every test problem. The needed number of iterations for every test problem can be very different, because the specificity of the tests. Therefore for comparison we use ranking as more representative. The algorithm with some fixed value for evaporation is on the first place, if it achieves the best solution with less average number of iterations over 30 runs, according other values and we assign to it 1, we assign 2 to the value on the second place, 3 to the value on the third place, 4 to the value of the forth place and 5 to the value with most number of iterations. On some cases can be assigned same numbers if the number of iterations to find the best solution is the same. We sum the ranking of the cases over all 10 test problems to find final ranking of the different values of the evaporation parameter.

Table III shows the ranking of the evaporation parameter. The less number of iterations is needed when the evaporation parameter is equal to 0.3. In this case the algorithm is on the first place four times, on the second place is 3 times and on the third, fourth and fifth is respectively one time. The worst results are achieved when the evaporation parameter is equal to 0.9. The results achieved when the evaporation parameter is 0.1 are a little bit worse than when the evaporation parameter is equal to 0.3. When the value of the evaporation parameter increase the achieved results are getting worse.

## V. CONCLUSION

In this paper we apply ACO algorithm to solve workforce planning problem. We are concentrated on the influence of the evaporation parameter on the algorithm performance, how many iterations are needed to find the best solution. We test the algorithm on 10 structured benchmark problems. The achieved results show that when the value of the evaporation parameter is small, the algorithm needs less number of iterations compared with high value of the evaporation parameter.

# 7<sup>th</sup> International Workshop on Smart Energy Networks & Multi-Agent Systems

**O**UR energy supply infrastructure is in the middle of a transition from a conventional star-like energy supply topology with a manageable number of well-structured power plants towards a grid topology with a myriad of different generation units that are geographically widely distributed. Additionally, the increasing integration of volatile and intermittent renewable energy resources brings massive challenges to grid operations and its composition with respect to power system commitment, dispatching and reserve requirements.

The fact that renewable energy generation units will increase their share in the overall energy production, calls for technologies to be developed in the next decades to deal with the transition of the energy supply system and the distribution of renewable energy generation units. This includes technologies to integrate, handle and intelligently manage energy storage systems, grid load peak-shaving, smart supply system components, more efficient and intelligent coupling of heating with electrical power, heat storage, intelligent load shifting and balancing, to name only a few here.

All these have in common that the future power grid has to be intelligent, where generation and consumption units communicate or even negotiate their offer or their demand of energy through an ‘internet of energy’. Thus, to efficiently design and develop those distributed energy management systems is one of the key challenges to be solved to transform the energy supply system, addressing distributed coordination, as well as different forms of energy like electricity, heat, natural gas and other.

Information and communication technologies are the key enablers of such envisioned systems, where especially the agent-paradigm provides an excellent modelling approach for the distributed character of energy systems. Although significant efforts and investments have already been allocated into the development of smart grids, there are, however, still significant research challenges to be addressed before the promised efficiencies or visions can be realised. This includes distributed, collaborative, autonomous and intelligent software solutions for simulation, monitoring, control and optimization of smart energy networks and interactions between them.

## TOPICS

The SEN-MAS’19 Workshop aims at providing a forum for presenting and discussing recent advances and experiences in building and using multi-agent systems for modelling, simulation and management of smart energy networks. In particular, it includes (but is not limited to) the following topics of interest:

- Experiences of Smart Grid implementations by using MAS
- Applications of Smart Grid technologies
- Distributed energy management of distributed generation and storage based on MAS
- Examples of design patterns for MAS in distributed energy management systems
- Microgrids, Islands Power Systems
- Real time control of energy networks
- Distributed planning process for energy networks by using MAS
- Self-configuring or self-healing energy systems
- Load modelling and control with MAS
- Simulations of Smart Energy Networks
- Software Tools for Smart Energy Networks
- Energy Storage
- Electrical Vehicles
- Charge scheduling for electric vehicles (and fleets) based on MAS
- Interactions and exchange between networks for electricity, gas and heat
- Stability in Energy Networks
- Distributed Optimization in Energy Networks
- Safety and security issues for MAS in Smart Grids

**Abstract**—Surrogate models have proved to be a suitable replacement for complex simulation models in various applications. Runtime considerations, complexity reduction, and privacy concerns play a role in the decision to use a surrogate model. The choice of an appropriate surrogate model though is often tedious and largely dependent on the individual model properties. A tool can help to facilitate this process. To this end, we present a surrogate modeling process supporting tool that simplifies the process of generation and application of surrogate models in a co-simulation framework. We evaluate the tool in our application context, energy system co-simulation, and apply it to different simulation models from that domain with a focus on decentralized energy units.

## I. INTRODUCTION

THE simulation of smart grids is a key step in the deployment process of new technologies and methodologies in the present power system for safety and costs reasons. Co-simulation frameworks like *mosaik*<sup>1</sup> assist the simulation process in the energy domain by providing programmable interfaces for different simulation models and realizing data flow dependencies including synchronization issues. These simulation models can become quite complex and can be provided in different programming languages. This can lead to a slowed down performance of a smart grid simulation. Performance plays a role especially in large-scale setups, such as in the research projects *Smart Nord* [1] or *D-Flex* [2], which are required for the evaluation of new Smart Grid algorithms or sustainability assessments. Furthermore, simulation models might be supplied by industrial stakeholders and thus must be considered as intellectual property that should not be disclosed to partners.

A solution concerning these issues might be the use of a data-driven abstraction of simulation models, so called surrogate models. A surrogate model is a function that maps input values to one or more output values. For this purpose, machine learning algorithms can be used to determine the relation between input and output by training with sample data generated by the original simulation model [3]. The creation of those surrogate models underlies several degrees of freedom like the choice of a sampling strategy for the input data and the choice of the surrogate algorithm. The performance of a surrogate for a particular simulation model

depends not only on the specific type of that model but also can be measured differently depending on the evaluation function. An evaluation function measures the similarity of outputs between surrogate and simulation model for a set of input combinations. Based on the number of existing surrogate modeling algorithms, the identification of an appropriate surrogate can be computationally quite intensive and should be (semi-)automated to ensure replicability and comparability of the results.

For these reasons we propose to use a tool to support the selection of appropriate surrogate models. With the help of various evaluation functions, we can then evaluate the performance of different settings from specific sampling strategies and surrogate models. Furthermore, we present the Python-based open source tool *MeMoBuilder*<sup>2</sup> to support this process. *MeMoBuilder* provides a semi-automated surrogate modeling process including comparison with the original simulation model in a time series evaluation.

The rest of this paper is structured as follows. First, in Chapter II we present the surrogate modeling process and highlight the challenges that emerge from this. In Chapter III we look at existing tools and other work in the field of surrogate modeling. Chapter IV focusses on the tool *MeMoBuilder* which is our approach for reducing the complexity of the surrogate modeling process. In Chapter V we will present a case study to evaluate the tool with reflection to the defined challenges. This paper ends with conclusion and outlook on future work in Chapter VI.

## II. CHALLENGES IN SURROGATE MODELING

The process of creating a surrogate model, which is also called meta model or response surface, is well documented in the literature, e.g. in Myers et al. [4]. In the following, we briefly recap the surrogate modeling process as described by Forrester et al. [5] to point out the challenges in this process. We then derive the requirements that are important for a surrogate modeling tool.

### A. Choosing the sampling strategy

The first step of this process starts with the generation of so-called samples through sampling strategies. We use

<sup>1</sup><http://mosaik.offis.de/>

<sup>2</sup><https://github.com/stbalduin/memobuilder>

the term sampling strategy for the application of a sampling design, i.e. the theoretical construction to generate samples. These consist of a set of possible input combinations  $\mathbf{X} = \{\mathbf{x}^{(1)}, \mathbf{x}^{(2)}, \dots, \mathbf{x}^{(n)}\}$  for the original simulation model  $f(\mathbf{x})$  and their corresponding outputs  $\mathbf{y}$  calculated by the simulation model. A sampling strategy defines which input combinations will be chosen to generate samples and it is important to pick the most relevant data to generate a good model. Finding an appropriate sampling strategy can depend on certain problem-specific and often contrary requirements, e.g. being deterministic, well-balanced, guaranteeing to cover the whole sampling space, or to work well with relatively few samples [6]. The goal of these strategies is to cover the relevant sample space, i.e. non-trivial (e.g. non-linear) behavior of the simulation model is included as accurate as possible. A well-balanced sampling design can be generated deterministically, but may require a large number of samples. On the other hand, a non-deterministic sampling design may work well with fewer samples, but there is no guarantee that it will cover the whole sample area. In both cases the orthogonality, i.e. the correlation of inputs, has to be considered. Simpson et al. [6] point out that the information gain of a design is balanced against the cost of experimentation, i.e. the number of samples, and lists several measures of merit which are useful to compare designs.

### B. Choosing the surrogate algorithm

In the following step, the surrogate model  $\hat{f}(\mathbf{x})$  is created by applying so called surrogate algorithms on the previously generated data. We use the term surrogate algorithm for any supervised machine learning algorithms that is capable of creating a surrogate model. A set of samples is used as training data  $(\mathbf{X}, \mathbf{y})$  for the surrogate algorithm to adjust its parameters in order to make the resulting surrogate model as similar as possible to the original simulation model. The surrogate algorithm can be picked from a large variety of machine learning algorithms with trade-offs in their characteristics, e.g. suitability for non-linear problems, suitability for high-dimensional data, complexity in the application, or in the learning phase. The latter is often partially depending on the search for optimal hyperparameters. These kind of parameters have to be set a priori to the learning process. To find the most appropriate parameter values, an exhaustive searching process with cross-validation has to be applied which means that different splits of the samples into training set and test set are evaluated. Furthermore, some surrogate algorithms use kernel functions to build the surrogate model. The choice of kernel functions and the hyperparameter tuning of these functions also have to be optimized to the given problem.

### C. Choosing the evaluation function

To evaluate the quality of the surrogate model an evaluation function is used. In general, the error  $\epsilon$  is used to describe the deviation between original simulation model and surrogate model:  $f(\mathbf{x}) = \hat{f}(\mathbf{x}) + \epsilon$ , but there are also evaluation functions that represent the quality of the model in a different way,

e.g. correlation functions. The quality of the surrogate model approximation can be evaluated by using samples as test data (which should be distinct from the training data) on the surrogate model and as well on the original simulation model. The error  $\epsilon$  can be determined by applying an evaluation function on both resulting outputs. The choice of the evaluation function has a strong influence on the ranking of surrogate models. They can be categorized into optimistic and pessimistic functions [7]. An optimistic evaluation function weights small errors more than large ones, hence might be beneficial if the error fluctuates greatly. Pessimistic evaluation function behaves the other way around, therefore they might be useful if large errors are undesirable. But there are also other characteristics, e.g. interpretability and independence of (physical) units, which should be taken into account when selecting an evaluation function for the model. It is important to know which requirements the model has to fulfill, like how critical small errors are or who will use the model afterwards, to decide which criteria should be prioritized.

### D. Requirements for tool support

Several degrees of freedom can be found in the defined process steps of surrogate model creation and evaluation, namely the choice of the sampling strategy, the choice of the surrogate algorithm, and the choice of an evaluation function used to evaluate this model. Each choice has its benefits and drawbacks. To find the most suitable combination is always depending on the given problem and cannot be generalized [5, p. 18]. For this reason, several iterations of sample generation, model creation, and model evaluation need to be performed during the surrogate modeling process until the results meet the requirements of the application context. The multi-dimensionality of the surrogate modeling process is summarized by Figure 1. For multiple but similar structured

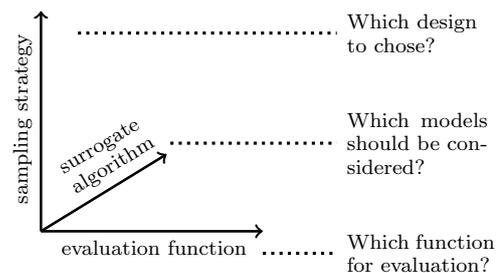

Fig. 1. Dimensions of the surrogate modeling process. Each dimension itself can be optimized quite easily, but it becomes a trade-off when all of these aspects shall be taken into account for optimization.

simulation models this is a quite repetitive process when modeling surrogates, so a tool for assistance is strongly recommended. Such a tool should fulfill the following requirements:

- R1 Support the surrogate modeling process: The tool should allow the surrogate modeler to address all degrees of freedom in experimental design, choice of surrogate algorithm, and evaluation function and thus allow for an

application specific instantiation of the surrogate modeling process.

- R2 Facilitate model exchange: The surrogate modeler is not necessarily the person who will use the model afterwards. Therefore, the tool should allow to create surrogate models which can be easily integrated into an existing environment (e.g. a co-simulation framework) and replace the original simulation models in order to easily integrate these models into smart grid simulation scenarios.
- R3 Allow modularity: In some setups, sampling data may be retrieved from other sources than available simulation models, e.g. in industry driven studies. To allow the surrogate modeler to perform only parts of the process, the tool should support a separation of concerns so that the integration of simulation models for sampling and the construction of surrogate models are independent of each other.

Although not a specific requirement in the choice or development of an appropriate surrogate modeling tool, the long-term perspective of using such a tool should be the (semi-)automatic generation of surrogate models.

### III. RELATED WORK

The whole surrogate modeling process is targeted by the Matlab Surrogate Modeling (SUMO)-Toolbox<sup>3</sup> which automates the single steps of this process. The SUMO-Toolbox builds a surrogate model of a given data source and needs only a few configurations by the user like accuracy and time constraints. However, the resulting surrogate model is bound to the Matlab environment. To deploy the model in a different setup, adaptations may be required and therefore requirement R2 is not fulfilled.

A tool aided surrogate selection is described by Mehmani et al. [8]. The authors developed the Concurrent Surrogate Model Selection (COSMOS) Framework which can be used to select an appropriate surrogate model. This tool focuses on the surrogate selection itself which comprises the optimal model type, the optimal kernel function (if needed), and optimal values of hyperparameter (if present). Despite being an important contribution in the domain of surrogate modeling, some shortcomings arise with respect to requirement R1: An easy comparison of different experimental designs is not possible.

Although not applicable to the problem of generating a surrogate for a given simulation model, the Waikato Environment for Knowledge Analysis<sup>4</sup> (Weka) proposed by Hall et al. [9] is an important open source collection of machine learning algorithms which aims to make these algorithms generally available to solve practical problems. Weka provides both a programmable and a graphical interface where no programming skills are needed when a learnable dataset is given. The focus of this tool is on data mining. Therefore, it does not contain an interface to integrate a simulation model

and automatically generate learnable data. Nonetheless, it does not support to address all degrees of freedom of the surrogate modeling process (requirement R1).

Various applications of surrogate models can be found in Koziel et al. [10], though there are no applications in the energy domain. Other works deal with the construction of a surrogate model for specific (simulation) models within concrete use cases. Pinto et al. [11] constructed a surrogate model for multi-period flexibility provided by a home energy management system. They modeled local microgeneration units, like photovoltaics, combined with flexible storage equipment which can be a battery. In their study the authors proposed an algorithm based on evolutionary particle swarm optimization to generate feasible flexibility trajectories. These trajectories were successfully used as training data for a support vector data description (SVDD) machine learning algorithm.

TABLE I  
SUMMARY OF THE PRESENTED TOOLS COMPARED TO OUR REQUIREMENTS.

In our research (see Table I) we did not find a tool that fulfills all requirements as defined in chapter II.

### IV. MEMOBUILDER

In this chapter we describe the architecture of the proposed Meta Model (MeMo) Builder. Our goal was to integrate surrogate algorithms, sampling strategies, and evaluation functions into one tool (requirement R1). This tool selects the optimal from each of those and generates a surrogate model that can be used within a co-simulation framework (requirement R2) as a replacement for the original simulation model. The model should also be compared with the original simulation model and behave similarly to it. For co-simulation we choose mosaik since it is a flexible tool which provides interfaces to models written in different programming languages. Thus, the surrogate modeling process is applicable regardless of the model at hand and the modeler can concentrate on the modeling process itself rather than integrating the model. The surrogate model itself can also be easily integrated in mosaik.

Mosaik facilitates a time discrete simulation, i.e. each simulation step has the same fixed length and each simulator can decide when it will be activated. Simulation models used in such a framework need to perform their simulation step for a given time interval, and a defined set of inputs and parameters as shown in Figure 2. The same applies to the surrogate models we want to build. We developed the MeMoBuilder as a prototype to identify challenges and benefits of the surrogate modeling process for simulation models in energy system, and adapt the tool to the needs identified in following this process. Further, we wanted to explore the possibilities of (semi-)automatic surrogate model generation of mosaik

<sup>3</sup><http://sumo.intec.ugent.be/>

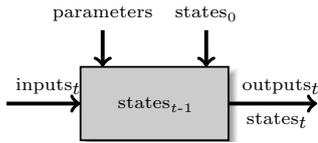

Fig. 2. The simulation model is initialized with parameters and initial states<sub>0</sub>. When simulation starts the model gets inputs<sub>t</sub> for step *t*. The results of each step are the states<sub>t</sub> which will be saved internally and then used in step *t* + 1, and outputs<sub>t</sub>.

component models for power and smart grid simulation scenarios. MeMoBuilder provides a set of sampling strategies, surrogate algorithms, and evaluation functions which can be chosen to generate a surrogate model. In Figure 3 the modular

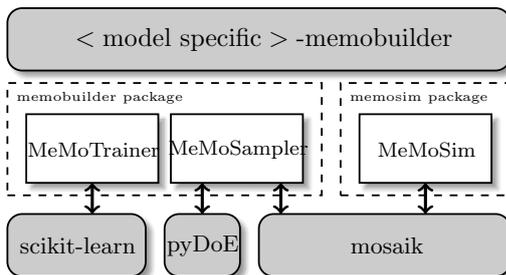

Fig. 3. MeMoBuilder has a modular structure where single components can be left out or be replaced. The core packages are the MeMoSampler and the MeMoTrainer which only need to be adapted if different frameworks for machine learning or design of experiments are used. The MeMoSim package depends on the chosen co-simulation framework which is in this case mosaik.

architecture (requirement R3) and main components of the MeMoBuilder are shown. For each simulation model, a model-specific MeMoBuilder is configured in a YAML<sup>5</sup> (YAML Ain't Markup Language) configuration file. This configuration file is also used for other degrees of freedom like how and which of the other MeMoBuilder components will be used in the surrogate generation process.

In the first step of this process the MeMoSampler uses a framework like pyDoE<sup>6</sup> to generate the sampling designs configured in the YAML file. According to these designs, the simulation model is sampled within a mosaik scenario to create one or more training sets. The use of mosaik at this point ensures that the MeMoSampler can be applied to every model with an existing mosaik adapter regardless for which simulation environment it was built originally.

Next, the training sets are used to create surrogate models. Thereby, it depends on the configuration how many surrogates will be generated. Each training set is used by the MeMoTrainer for all surrogate algorithms that are configured in the model-specific MeMoBuilder. The MeMoTrainer itself uses the scikit-learn library<sup>7</sup> [12] for model fitting and cross validation of optimal hyperparameters, but other frameworks could be integrated as well. It is also possible to use multiple

evaluation functions and in this case MeMoTrainer generates a surrogate for each function.

Ultimately, there can be a whole set of surrogates and each of these will be rated using different evaluation functions. When the surrogate model generation is finished, MeMoBuilder compares the simulation model with the surrogate model in a simple simulation scenario within the chosen co-simulation framework mosaik. The results of each simulation step are stored in a database. Additionally, a visualization of these results is generated and stored. Once the simulation is finished, it is possible to see differences in the output behavior between simulation model and surrogate model.

## V. CASE STUDY

To test the functionality of the MeMoBuilder in a practical environment and check the suitability of this tool against the requirements as defined in Section II, a selection of surrogate algorithms, sampling strategies, and evaluation functions was identified and integrated in the MeMoBuilder environment.

### A. Chosen sampling strategies

We integrated four sampling strategies of both random and deterministic type.

a) *Random based sampling strategies:* Latin Hypercube Sampling (LHS) is probably the most common strategy and has some advantages which possibly lead to the wide acceptance of this method: It is well balanced while only a small number of samples is needed [3, p. 198ff]. LHS is nearly as easy to apply as the other random-based strategy we use, the Monte Carlo Sampling (MCS) which is pure random selection of sample points. Both give the chance, but not the guarantee that the whole sample space will be covered. Furthermore, in some setups the orthogonality of these designs is not given [13, p. 42].

b) *Deterministic sampling strategies:* Besides the random based strategies, we used two deterministic strategies. Both, the sequence of Halton (HSEQ) and the sequence of Sobol (SSEQ) use prime numbers to generate a sequence of numbers, e.g. the prime number 2 generates the sequence  $\frac{1}{2}, \frac{1}{4}, \frac{3}{4}, \frac{1}{8}, \frac{5}{8}, \frac{3}{8}, \dots$ . While HSEQ varies the prime numbers to generate a new sequence, SSEQ permutes this sequence using primitive polynomials. For a more detailed explanation we refer to Lemieux [14, 157ff]. The sample space generated by deterministic designs is typically well-balanced and has only occasionally issues with missing orthogonality [13].

### B. Chosen surrogate algorithms

As surrogate algorithms we selected five heterogeneous algorithms from the field of interpolation, neural networks, and other regression methods. One of the simplest surrogate algorithm is linear regression such as LASSO which constitutes a fast polynomial approximation According to Hastie et al. [15, p. 43] this regression function can outperform more complex methods if the data is structured linearly, a small set of training data, or sparse data is used.

Another approach is to use lazy learners like the k-nearest neighbors (k-NN) algorithm. As described in Yang et al. [16]

<sup>5</sup><http://yaml.org/>

<sup>6</sup><https://pythonhosted.org/pyDOE/>

<sup>7</sup><http://scikit-learn.org/>

the  $k$  nearest neighbors of the learned samples are directly used to estimate missing outputs. According to Ertel [17, p. 199], apart from finding the correct hyperparameters,  $k$ -NN has no actual learning phase therefore it belongs to the lazy learners. For each estimated output,  $k$ -NN calculates the distance of each sample to find the  $k$  nearest samples. Ertel also points out finding the next nearest neighbors according to the given input can be computational intensive if many training samples are used. According to Samaniego and Schulz [18] its strength lies in the flexibility which makes  $k$ -NN an appropriate choice for non-linear data structures [19].

According to Cui et al. [20] Kriging is often used to interpolate data between known data points which is done by a combination of a polynomial model and a realization of a normally distributed Gaussian random process. Simpson et al. [6] state that the strength of Kriging lies in the variety of correlation functions that can be used to shape the Gaussian random process.

Support Vector Regression (SVR) is a type of support vector machines with similarities to Kriging, since the heart of both is a kernel function [21]. This algorithm uses the kernel function in order to transform non-linear regression problems into linear by mapping the original input space to a higher feature dimension space [22].

An ANN is made of several interconnected neurons which process data coming either from outside or from other neurons. The challenge in creating ANN focuses on architectural design and the number of neurons that should be used [6]. A well constructed ANN can be quite powerful in this sense that they can handle non-linear data structures [23] as well as they can handle high-dimensional data, although this can be computationally intensive. A mitigation of computing time could be achieved by parallel computing [6]. For this purpose, multi-layer perceptron regression will be used.

### C. Chosen evaluation functions

To evaluate the generated surrogate models diverse evaluation functions were selected. As a pessimistic evaluation function we choose the mean squared error (MSE) where outliers are weighted quadratically in order to punish large errors more than small errors. The mean absolute error (MAE) is punishing outliers linearly, so it is less pessimistic than the MSE. It is easier to interpret than the MSE since units are not effected by this function.

We also choose the determination function  $R^2$  which is related to the Pearson Correlation Coefficient [3, p. 113]. In contrast to error functions where the error should be minimized, in  $R^2$  a value close to 1 means a high correlation of data and therefore the surrogate is similar to the original model. Hence, an  $R^2$  close to 0 or even negative values can be interpreted as low correlation and thus the surrogate model is not well modeled. The  $R^2$  is free of units which leads to intuitive interpretations of this function. The evaluation functions described above are taken from the scikit-learn library. More information about these functions can be found in their

documentation and user guides<sup>8</sup>. In addition to the scikit-learn evaluation functions, we choose the harmonic average error (HAE), which is shown in Equation 1.

$$\text{HAE}(y, \hat{y}) = \left( \frac{1}{n} \sum_{i=0}^{n-1} \frac{1}{\sqrt{(y_i - \hat{y}_i)^2}} \right)^{-1} \quad (1)$$

Here, the  $n$  is the number of samples,  $y$  the result of the original model, and  $\hat{y}$  the result of the surrogate model as it is the approximation of the original model. This function allows to dominate small errors over large errors which means that this metric allows to have few large errors if there are small errors to compensate. Therefore, the HAE is considered to be optimistic.

### D. Chosen simulation models

We conduct our case study using three simulation models representing different home energy system units that were already in use for different energy system simulation scenarios. These models will be briefly explained in the following without going to much into detail.

The first model is a battery which has an internal state of charge and takes the target electrical power as input. In each step, the electrical power output is calculated depending on the current state of charge. The output has a negative sign if the battery "consumes" energy, otherwise the output has positive sign.

The second model is that of a photovoltaic (PV) plant system. The model has the module temperature as internal state and uses several input variables like time stamp, solar radiation, and air temperature. Based on geo and other information stored in the model, the sun position is calculated depending on the current time stamp which is then used to compute the electrical power output depending on current radiation on the surface of the PV plant.

The last model is the fuel cell (FC) which produces power and heat at the same time. We consider electrically driven operation, i.e. the FC follows a certain power output rather than a thermal profile in thermally driven operation. This model has two inputs, three outputs, and the electrical power as internal state. The inputs are the temperature of the incoming heating water and the target electrical power for the next time interval. The outgoing temperature of the heating water, the thermal power, and the actual electrical power are regarded as outputs of the model. The actual electrical power is divided into discrete fixed electrical power stages whereas the thermal outputs can have continuous values. It should be denoted that the actual electrical power does not need to be the same as the targeted electrical power due to internal restrictions of the model.

All models were build at OFFIS and for each of them we used MeMoBuilder to generate a surrogate model for all combinations of the mentioned methods which results in  $4*5*4 = 80$  surrogate models. We used a uniform sample size of 5,000.

<sup>8</sup>[https://scikit-learn.org/stable/modules/model\\_evaluation.html#regression-metrics](https://scikit-learn.org/stable/modules/model_evaluation.html#regression-metrics)

MeMoBuilder implements methods to apply cross-validation and hyperparameter optimization on this sample size. Since it is easily interpretable, we picked the best surrogate according to the  $R^2$  score [7]. This surrogate model will be compared with the original model in a simulation scenario.

### E. Results for the battery model

The best five surrogate models for the battery are shown in Table II. Note that these are the best models according to the  $R^2$ . Using a different score for sorting may result in a different order of the models. For our battery model, the best combination consists of a Latin Hypercube sampling strategy, an artificial neural network, and the mean squared error for evaluation. But the MeMoBuilder also provides the results for the other combinations. In case of the battery model we see that support vector regression would as well be an appropriate surrogate model. Next, a comparison in a simulation setup is

Sampling Strategy	Surrogate Algorithm	Train Func.	$R^2$ Score	HAE Score	MAE Score	MSE Score
LHS	ANN	MSE	0.998	$2.67 \cdot 10^{-3}$	0.024	0.005
HSEQ	SVR	MSE	0.992	$1.5 \cdot 10^{-10}$	6.535	873.0
MCS	SVR	MSE	0.992	$3.76 \cdot 10^{-3}$	5.872	802.0
MCS	SVR	HAE	0.992	$2.78 \cdot 10^{-3}$	5.909	750.5
LHS	SVR	MSE	0.991	$2.27 \cdot 10^{-2}$	6.766	863.2

TABLE II

BEST FIVE SURROGATE MODELS OF THE BATTERY ACCORDING TO THE  $R^2$  SCORE. THE COMPARISON USING DIFFERENT SCORES REVEALS THAT SVR SCORES POORLY DESPITE A VERY GOOD  $R^2$  SCORE WHEN THE MSE IS CONSIDERED.

done. Both models are supplied with a schedule of electrical power targets. The results are plotted in Figure 4. We see for the electrical output ( $P_{el}$ ) the surrogate model is quite accurate most of the time. Only at the last part the value seems to oscillate. For the internal state of charge, the surrogate model results are accurate for the first 30 - 35 steps. At that point, the target power value is set to zero which is not correctly handled by the surrogate model. After that point the deviation of the prediction increases. At about step 150 the state of charge of the surrogate model reaches zero which may be the reason for the oscillating power output of the surrogate model.

The results show the difficulties of modeling internal states which converge to certain boundaries like minimal and maximal state of charge. Therefore, we could use the MeMoBuilder to investigate further combinations, e. g. other sampling strategies as the peripheral areas of the sample space seem to be not sufficiently covered by the Latin Hypercube strategy, but this is beyond the scope of this paper.

### F. Results for the photovoltaic plant

In Table III the best five surrogate models for the PV plant are shown. The best combination in this case is a Latin Hypercube sampling, an ANN, and the  $R^2$  score, but the same combination with a Monte Carlo sampling differs only very slightly after the decimal point. However, in this case the LHS

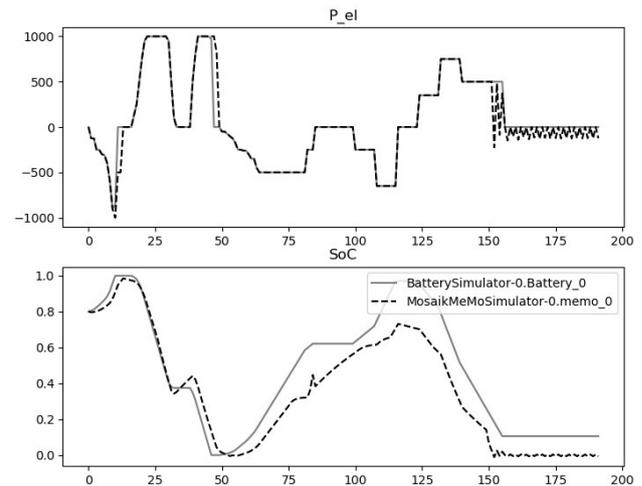

Fig. 4. Co-simulation of surrogate and original battery model comparing their electric power output and the state of charge. The grey line is the original model and the black dashed line is the surrogate model.

model is better not only at  $R^2$ , but also according to MAE and MSE scores. In the simulation, both models are provided

Sampling Strategy	Surrogate Algorithm	Train Func.	$R^2$ Score	HAE Score	MAE Score	MSE Score
LHS	ANN	$R^2$	1.0	$2.21 \cdot 10^{-2}$	0.573	1.168
MCS	ANN	$R^2$	1.0	$1.0 \cdot 10^{-10}$	1.041	3.257
MCS	ANN	MSE	0.999	$1.5 \cdot 10^{-10}$	1.108	3.111
SSEQ	ANN	MSE	0.999	$2.3 \cdot 10^{-1}$	0.639	1.533
HSEQ	ANN	$R^2$	0.999	$2.0 \cdot 10^{-10}$	0.633	1.37

TABLE III

BEST FIVE SURROGATE MODELS OF THE PV PLANT ACCORDING TO THE  $R^2$ . ANNS CONSISTENTLY DELIVER THE BEST RESULTS EVEN WHEN SORTING BY ONE OF THE OTHER SCORES.

with time stamp, radiation, and air temperature. The results are shown in Figure 5. The electrical power output prediction of the surrogate model is very accurate as long as there is actually energy generation. When there is no generation, the surrogate model predicts negative values. The module temperature seems to be captured quite accurate as well. However, the surrogate model is always one step late, but this has no visible influence on the power output.

Overall, the results for the PV plant are satisfactory in our opinion. Small flaws like the negative power output could be handled e. g. applying a  $\max(0, \hat{y})$  function on the output. Therefore, no further investigations are necessary for this model.

### G. Results for the Fuel Cell

The results of the surrogate generation for the fuel cell sorted according to the  $R^2$  score are shown in Table IV. The best combinations in this case are a Monte Carlo sampling with Kriging trained by the mean average error, and a Monte Carlo sampling with Kriging trained by the  $R^2$  score. In the

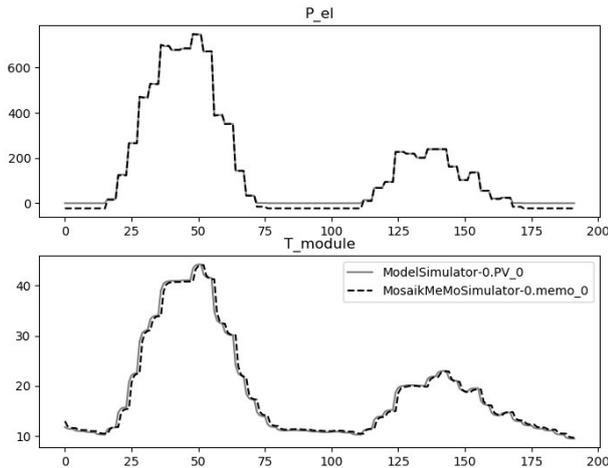

Fig. 5. Co-simulation of surrogate and original PV model comparing their electric power output. Grey line: original model, black dashed line: surrogate model.

simulation, the first configuration is used for comparison with the original model.

Sampling Strategy	Surrogate Algorithm	Train Func.	$R^2$ Score	HAE Score	MAE Score	MSE Score
MC	Kriging	MAE	0.997	$3.3 \cdot 10^{-10}$	1.598	30.72
MC	Kriging	$R^2$	0.997	$3.3 \cdot 10^{-10}$	1.598	30.72
MC	Kriging	MSE	0.996	$4.5 \cdot 10^{-10}$	2.461	43.15
LHS	Kriging	MSE	0.991	$3.5 \cdot 10^{-10}$	1.957	76.74
LHS	Kriging	$R^2$	0.991	$3.3 \cdot 10^{-10}$	1.957	76.74

TABLE IV

BEST FIVE SURROGATE TRAINING FOR THE FUEL CELL SIMULATION MODEL ACCORDING TO THE  $R^2$  SCORE. THIS RANKING SHOWS THAT KRIGING IS DELIVERING THE BEST RESULTS FOR THE  $R^2$  SCORE. .

The input schedule for electrical power is based on the standard load profile for households provided by the BDEW<sup>9</sup> and for heating water we modeled a simplified schedule for the needs of a household.

The simulation result is shown by Figure 6 for the outputs: actual electrically power ( $P_{el}$ ), thermal power ( $P_{th}$ ), and the outgoing heating water temperature ( $T_{out}$ ). The surrogate roughly follows the behavior of the original model in the output variables  $P_{th}$  and  $T_{out}$ . However, since the electrical power  $P_{el}$  is divided into discrete power stages and internally the gradient of the power is restricted so the surrogate has difficulties to reproduce the behavior especially in the transition to other power stages. The example of the fuel cell shows the difficulty of creating adequate surrogate models for models with complex internal states.

Overall, the surrogate model is satisfactory to a limited extent. If thermal power and temperature are the outputs of interest, this model performs well. For the electrical power output, however, further investigations are required.

<sup>9</sup>Bundesverband der Energie- und Wasserwirtschaft e.V

## VI. CONCLUSION AND FUTURE WORK

We motivated why we need surrogate models, what the challenges of the surrogate modeling process are, and which requirements a tool has to meet in order to support this process. We presented the tool MeMoBuilder that semi-automates the surrogate modeling process while testing different combinations of sampling strategies, surrogate algorithms, and training and evaluation functions to face the challenges arising when building an appropriate surrogate model. MeMoBuilder is fully compatible to the co-simulation framework mosaik and can be used on every model which can be integrated into mosaik. An integration with other co-simulation frameworks is possible by implementing the appropriate interface between MeMoBuilder and the target framework.

Further, it is possible to separate the process of sampling and the process of training. So all the requirements as described in Section II are fulfilled. We used this tool to explore the surrogate modeling process for three different simulation models and presented the results as case study.

Our major findings are a) that specific surrogate models are more suitable for concrete simulation models than other and b) the complexity of surrogate modeling can be reduced by using a tool like the MeMoBuilder. The accuracy of the presented models range from bad to good which may depend on the choice of sorting the models according to the  $R^2$ . The MeMoBuilder provides information on which surrogate models perform well according to different criteria and gives recommendations in form of scores by different evaluation

functions.

There are still open issues which need further investigation. All provided sampling strategies and surrogate algorithms are rather generic. For some models this works quite well, for others a more specialized sampling would probably lead to better results (e.g. battery state of charge behavior). Also, the sampling designs itself are not optimized. This will be implemented in the future. Furthermore, only regression models are supported. Original models with discrete output are interpolated in the surrogate model, thus allowing values to be taken that do not exist in the original model, as shown in the fuel cell experiment. A better choice would be a classification model, but that requires training of different surrogate models for different outputs or a manual discretization of the outputs. We tried to construct the artificial neural network as a universal approximator that is generalized for many simulation models and works with a limited amount of samples. Nevertheless, there could be more suitable architectures for the individual simulation models especially with more advanced architectures like long short-term memories or convolutional neural networks.

Future studies will investigate if reducing the sample size still leads to an acceptable result since the dimensionalities of our simulation models are small. Additionally, a more advanced simulation scenario will be developed which tests the surrogate models and possible interactions with other simulation models. The next step will be integrating more specialized sampling strategies, support for classification models, and to use these surrogate models in larger scaled setups.

#### ACKNOWLEDGMENT

This work is supported by the European Community's Horizon 2020 Program (H2020/2014-2020) under project "ERIGrid" (Grant Agreement No. 654113). Further information is available at the corresponding website [www.erigrd.eu](http://www.erigrd.eu). The conception and implementation of the MeMoBuilder tool was mainly done by Thole Klingenberg.

**Abstract**—Future demand for managing a huge number of individually operating small and often volatile energy resources within the smart grid is preponderantly answered by involving decentralized orchestration methods for planning and scheduling. Many planning and scheduling problems are of a multi-objective nature. For the single-objective case – e.g. predictive scheduling with the goal of jointly resembling a wanted target schedule – fully decentralized algorithms with self-organizing agents exist. We extend this paradigm towards fully decentralized agent-based multi-objective scheduling for energy resources e.g. in virtual power plants for which special local constraint-handling techniques are needed. We integrate algorithmic elements from the well-known  $S$ -metric selection evolutionary multi-objective algorithm into a gossiping-based combinatorial optimization heuristic that works with agents for the single-objective case and derive a number of challenges that have to be solved for fully decentralized multi-objective optimization. We present a first solution approach based on the combinatorial optimization heuristics for agents and demonstrate viability and applicability in several simulation scenarios.

## I. INTRODUCTION

The upcoming smart grid gives rise to several multi-objective control tasks. Due to the expected huge number of distributed energy resources (DER) that have to be controlled, self-organized and decentralized algorithms are seen as the most promising solution. On the other hand, surprisingly low effort has been put in developing decentralized multi-objective approaches so far. Here, we go with the example of the predictive scheduling problem [1].

To enable small and individually operated energy devices to responsibly take over control tasks, pooling of different DER is necessary in order to gain enough potential and flexibility. An established concept for such pooling is the virtual power plant (VPP) [2], [3]. Orchestration of such groups of energy units is done by different scheduling procedures that frequently involve multi-objective optimization.

Predictive scheduling [1] describes an optimization problem for day-ahead planning of energy generation in VPPs, where the goal is to select a schedule for each energy unit – from an individual search space of feasible schedules with respect to a future planning horizon – such that as a global objective the distance to a target power profile for the VPP is minimized (e.g. a product from an energy market). Actually, this constitutes a multi-objective problem. Further objectives

like cost minimization, maximization of residual flexibility (for later planning periods) or environmental impact are usually to be achieved concurrently [4]. These goals are often conflicting.

So far, the problem is often reduced to the single objective case for proper solving; if applicable with a combination of different objectives to a single, weighted sum of objectives. We propose a fully decentralized multi-objective algorithm for this problem based on concepts from the combinatorial optimization heuristics for agents (COHDA) and the  $S$ -metric selection evolutionary multi-objective algorithm (SMS-EMOA). The goal is to derive a self-organization approach that results in autonomously acting agents that determine a Pareto front (or at least an approximation) without any central control.

The rest of the paper is organized as follows: We recap multi-objective optimization in general, a centralized solution to the predictive scheduling problem and the single objective approach to the decentralized solution. We define the set of challenges that have to be solved to make algorithms like COHDA multi-objective capable and present a first solution approach that integrates concepts from the SMS-EMOA. We conclude with evaluation results from a simulation study and deduce some further research questions.

## II. RELATED WORK

Decentralized, multi-agent-based multi-objective optimization has so far not gained much attention; at least in the sense of jointly calculating the Pareto front of a given problem. Some approaches have been developed for tuning a multi-agent system or for internal multi-objective decisions. In [5] an example is given for the emergency response planning problem, [6] presents an elevator control. These approaches use centralized algorithms for the multi-objective part. [7] gives an example for multi-objective reinforcement learning. A decision model for objective relationships after intra-agent multi-objective solving is presented in [8].

On the other hand, some approaches have been developed for acceleration by distributing fitness evaluation in multi-objective optimization. An example for a general framework is given in [9]. But, this is not decentralized problem solving by local, agent-based decisions in a collaboration scenario, as we strive for.

### A. Predictive scheduling

We here consider rather small, distributed electricity producers that are supposed to pool together with likewise distributed electricity consumers and prosumers (like batteries) in order to jointly gain more degrees of freedom in choosing load profiles. In this way, they become a controllable entity with sufficient market power. In order to manage such a pool of DER, the following distributed optimization problem has to be frequently solved: A partition of a demanded aggregate schedule has to be determined in order to fairly distribute the load among all participating DER. A schedule  $x$  is a real valued vector with each element  $x_i$  denoting the amount of energy generated or consumed during the  $i$ th time interval withing the planning horizon. Optimality usually refers to local (individual cost) as well as to global (e.g. environmental impact) objectives in addition to the main goal: Resemble the wanted overall load schedule as close as possible.

In [10], a support vector decoder has been introduced to cope with individual constraints of different types of energy units. Constraints may be technically rooted like the state of charge of attached batteries or thermal buffer stores or be economically soft rooted or be due to individual preferences. The basic idea is to learn the enclosing envelope around the set of feasible schedules in data space and to derive a formal description that allows mapping any given schedule to or into the feasible regions. In this way solution repair and space mapping can be achieved. Such constraint handling technique is in general referred to as decoder [11], [12]. Formally, a decoder function  $\gamma$  with

$$\begin{aligned} \gamma : [0, 1]^d &\rightarrow \mathcal{F}_{[0,1]} \subseteq [0, 1]^d \\ x &\mapsto \gamma(x) \end{aligned} \quad (1)$$

transforms any given (maybe in-feasible) schedule (scaled to  $[0, 1]^d$ ) into a feasible one. Thus, the scheduling problem is transformed into an unconstrained formulation when using a decoder:

$$\delta \left( \sum_{i=1}^d s_i \circ \gamma_i(x'_i), \zeta \right) \rightarrow \min, \quad (2)$$

where  $\gamma_i$  denotes the decoder of unit  $i$  that produces feasible schedules  $x'_i \in [0, 1]^d$  and  $s_i$  scales these schedules entrywise to correct power values resulting in schedules that are operable by that unit. Technically, scaling can also be integrated into the decoding process by combining both functions. Thus, for the rest of the paper we refer with  $\gamma$  to a decoder function that maps an infeasible schedule into the feasible region and scales it appropriately to the rated power of the respective energy unit. Please note that this constitutes only a single objective solution and multi-objective scenarios so far have to combine different objectives to a single one by a weighted aggregation. Unfortunately, this is not possible in case of a mixture of global and local objectives.

For the single objective case several solutions exist. In [13] an example for a centralized approach can be found, examples for decentralized approaches are given in [14]–[16]. A centralized multi-objective variant based on parallel

tempering that harnesses a decoder extension to co-encode different key performance indicators can be found in [17]. On the other hand, several approaches neglecting or relaxing individual constraint-handling can be found [2], [18].

For multi-objective optimization in general many approaches exist. In optimization problems with more than one and at least two conflicting objectives, Pareto optimization has become an appropriate means for solving [19]. As improving on one objective degrades each conflicting one, multi-objective optimization deals with finding a set of Pareto optimal solutions as trade-off between opposing solutions. Different algorithms have been designed to find an approximation to the Pareto-optimal set  $M = \{x \in \mathbb{S} \mid \nexists x^* \in \mathbb{S} : x^* \prec x\}$  for a set of objective functions  $f_{1,\dots,n} : \mathbb{S} \rightarrow \mathbb{R}$  defined on some search space  $\mathbb{S}$  [20]; and with  $x \prec x^*$  denoting that  $x$  dominates  $x^*$ , i.e. all objective values of  $x$  are better than  $x^*$ . Different algorithms have been proposed [20]; among them are evolutionary algorithms [21], [22], genetic algorithms including the famous NSGA-II [23], or swarm-based approaches [24].

Predictive scheduling imposes some special needs on constraint handling to ensure that all local schedules are within the feasible phase-space of the individual energy resources [1], [25]. For constraint-handling in multi-objective optimization two general concepts are usually applied [26]. Either a penalty [27], [28] is added to each objective function degrading constraint violating solutions or the definition of Pareto-dominance is extended to take into account constraint violation [26], [29]. Introducing a penalty term changes the objective function and as in multi-objective optimization the impact on different objectives has to be balanced, a too weak set of penalties may lead to infeasible solutions whereas a too strong impact leads to poor distributions of solutions [26].

Nevertheless, all approaches for constraint integration so far need a closed form description of constraints. Constraints are given as a set of (possibly non-linear) in-equalities and equalities as well as a box-constraint demanding all parameters being from a specific range. In the smart grid domain, often no closed form descriptions of constraints are available. Such closed form description does not exist in decentralized energy resource scheduling that includes (at least in general) arbitrary unit types [30].

A first solution approach to hybridizing multi-objective optimization and decoder was given in [31], with a centralized approach based on SMS-EMOA.

### B. SMS-EMOA

Using  $S$ -metric selection for evolutionary multi-objective algorithms has first been proposed by [22]. The  $S$ -metric is based on the hypervolume encapsulated by the set of non-dominated solutions and a reference point [21] and can thus be described as the Lebesgue measure  $\Lambda$  of the union of hypercubes defined by the reference point  $x_r$  and the set of non-dominated points  $m_i$  [19], [22]:

$$S(M) = \Lambda \left( \bigcup \{a_i \mid m \in M\} \right). \quad (3)$$

---

**Algorithm 1** Basic algorithmic scheme of the SMS-EMOA (cf. [22]).

---

```

 $P^{(0)} \leftarrow \text{randomPopulation}()$ 
 $t \leftarrow 0$ 
while  $t < \text{max iterations}$  do
   $o \leftarrow \text{mutate} \circ \text{crossover}(P^{(t)})$ 
   $\{R_1, \dots, R_k\} \leftarrow \text{fast-nondominated-sort}(P^{(t)} \cup \{o\})$ 
   $p \leftarrow \arg \min_{s \in R_k} [\Delta_S(s, R_k)]$ 
   $P^{(t+1)} \leftarrow P^{(t)} \setminus \{p\}$ 
   $t \leftarrow t + 1$ 
end while

```

---

This metric constitutes an unary quality measure by mapping a solution set to a single value in  $\mathbb{R}$ : the size of the dominated space [32]. As it is desirable to have a large  $S$ -metric value for solution sets in multi-objective optimization, [32] first used this measure in a Simulated Annealing approach and [22] developed an evolution strategy (SMS-EMOA) based on this measure. Algorithm 1 shows the basic idea of SMS-EMOA. The algorithm repeatedly evolves a population of  $\mu$  solutions. In each iteration, first a new solution is generated and added to the population. Subsequently, a selection process is started to find the worst individual in the solution which is then removed from the population. Thus, the number of individuals stays constant from a steady state perspective. Selection is done by first issuing a fast non-dominated sort after [23]. In this way, the Pareto fronts are ranked and from the front with the lowest rank the individual with the lowest contribution to the hypervolume (measured by the  $S$ -metric) is removed. This process is repeated until some stopping criterion – e. g. a number of maximum objective evaluations – is met.

In [31] the latter has already been hybridized with a decoder approach for flexibility modeling and constraint-handling in multi-objective energy management.

In general, two types of objective have to be considered. In [30] constraints have been identified on different locality levels. The same holds true for objectives in a VPP. Objectives on a global as well as on a local level have to be integrated. Objectives on a global level have to be achieved jointly. An example is given by the minimization of the deviation of the aggregated joint schedule from a given product schedule that has to be delivered as contracted. These objectives can only be achieved with joint effort. In contrast, local objectives like individual cost minimization are also to be integrated. Although evaluation can only be performed locally (individual cost), help from other to be able to choose a cheaper schedule is often necessary to achieve the goal. In the following we denote with  $f$  local and with  $F$  global objectives.

### C. COHDA

In general, decentralized algorithms are considered advantageous in many fields of smart grid computation [33], [34]. For the case of predictive scheduling, [35] developed a decentralized algorithm for constrained combinatorial problems: The Combinatorial Optimization Heuristics for Distributed

Agents (COHDA). Combined with an appropriate abstraction for individual flexibilities [10]. So far, this fully decentralized approach works with a single objective function and integrates multiple objectives only by combining different objectives into a single one as weighted sum. We extended COHDA to a full-fledged decentralized multi-objective optimization algorithm.

COHDA has been designed as a fully distributed solution to the predictive scheduling problem (as distributed constraint optimization formulation) in smart grid management [36]. Each agent in the multi-agent system is in charge of controlling exactly one distributed energy resource (generator or controllable consumer) with procurement for negotiating the energy. All energy resources are drawn together to a virtual power plant and the controlling agents form a coalition that has to control the VPP in a distributed way.

An agent in COHDA does not represent a complete solution as it is the case for instance in population-based approaches [37], [38]. Each agent represents a class within a multiple choice knapsack combinatorial problem [39]. Applied to predictive scheduling each class refers to the feasible region in the solution space of the respective energy unit. Each agent chooses schedules as solution candidate only from the set of feasible schedules that belongs to the DER controlled by this agent. This selection is done according to local constraints and to a given objective that usually reflects solely the distance (dissimilarity) of the sum of this selection and the schedules of all other agents to the given target schedule.

Each agent is connected with a rather small subset of other agents from the multi-agent system and may only communicate with agents from this limited neighborhood. The neighborhood (communication network) is defined by a small world graph [40]. As long as this graph is at least simply connected, each agent collects information from the direct neighborhood and as each received message also contains (not necessarily up-to-date) information from the transitive neighborhood, each agent may accumulate information about the choices of other agents and thus gains his own local belief of the aggregated schedule that the other agents are going to operate. With this belief each agent may choose a schedule for the own controlled energy unit in a way that the coalition is put forward best while at the same time own constraints are obeyed and own interests are pursued. Thus, we have a multi-objective optimization problem when deciding on the best schedule.

All choices for own schedules are rooted in incomplete knowledge and beliefs in what other agents do; gathered from received messages. The taken choice (together with the basis for decision-making that has been received with prior messages) is communicated to all neighboring agents and, in this way, knowledge is successively spread throughout the coalition without any central memory. Thus, COHDA is a type of gossiping algorithm [41].

Each information update results in recalculating the own best schedule contribution and spreading it to the direct neighbors. By and by all agents accumulate complete information and as soon as no agent is capable of offering a schedule

leading to a better solution, the algorithm converges and terminates. Convergence has been proved in [42].

More formally, each time an agent receives a message, three successive steps are conducted. First, during the perceive phase an agent  $a_j$  updates its own working memory  $\kappa_j$  with the received working memory  $\kappa_i$  from agent  $a_i$ . From the foreign working memory the objective of the optimization (i. e. the target schedule) is imported (if not already known) as well as the configuration that constitutes the calculation base of neighboring agent  $a_i$ . An update is conducted if the received configuration is larger or has achieved a better objective value, what is only directly possible with a single-objective. In this way, schedules that reflect the so far best choices of other agents and that are not already known in the own working memory are imported from the received memory.

During the decision phase agent  $a_j$  has to decide on the best choice for its own schedule based on the updated belief about the system state  $\mathfrak{S}_k^{(a_j)}$ . Index  $k$  indicates the age of the system state information. The agent knows from a subset of (or from all) other agents, which schedules they are going to operate (the system state  $\mathfrak{S}(a_j)_k$ ). Thus, the schedule that fills the gap to the desired target schedule exactly can be easily identified. Due to operational constraints of the controlled DER, this optimal schedule can usually not be operated. In addition, other reasons might render some schedules largely unattractive due to high cost.

Because of this reason, each agent is equipped with a so called decoder that automatically maps the identified optimal schedule to a nearby feasible schedule that is operable by the DER and thus feasible. Based on a set of feasible schedules sampled from an appropriate simulation model for flexibility prediction [43], a decoder can e. g. be based directly on this set (by linearly searching the schedule with the smallest deviation) or be built by learning a support vector model after the approach of [10]. Both approaches have individual advantages and drawbacks regarding computational complexity, search space size and accuracy. Here, we used the support vector version for efficiency reasons.

As the whole procedure is based exclusively on local decisions, each agent decides privately which schedules are taken. Private interest and preferences can be included and all information on the flexibility of the local DER is kept private.

#### D. Challenges

The COHDA approach can be adapted to many different optimization problems as has been demonstrated e. g. in [3], [30], [44], [45]. Basically, solution encoding, objective evaluation and internal, local decision method have to be adapted to the problem at hand. On the other hand, adapting to the multi-objective case entails some additional challenges that have to be solved:

*a) Solution representation:* As the goal now is a Pareto front, each agent will have to manage a set of schedules (a set of own contributions to the joint set of schedules). In the multi-objective case, determining the best own selection will

no longer work by just determining the missing difference to the target and repairing it with a decoder.

*b) Solution quality assessment:* Each time an agent in COHDA decides on a new contribution to a solution (remember: an agent represents just the local contribution, not a full solution) the quality of the solution with the old contribution is compared to the one resulting from the new contribution. This assessment is usually done using the objective function evaluating both candidates. In the multi-objective case an agent represents a set of contributions to a set of solutions, thus it is not possible to compare an old solution directly with a new one using the objective.

This problem can be overcome by using measures that evaluate the quality of a set of solutions with regard to the Pareto front. When using concepts from SMS-EMOA, the achieved hypercube volume can be used.

*c) Incomplete solutions:* During the initial setting time of COHDA, solutions are incomplete by design. COHDA has been developed for predictive scheduling. One agent starts by issuing a schedule (as local solution contribution) for the own energy resource. At this point in time, a solution consists only of this single contribution (as if it was a VPP with just a single energy resource). For the single-objective predictive scheduling case this is admissible as such a solution is always worse regarding the single objective of resembling the wanted target schedule as close as possible. After some negotiation steps, more agents join in and finally a contribution from all agents are on hand. For the multi-objective case it cannot be guaranteed that solutions with incomplete contribution are worse than complete solutions. An example may be given by minimizing cost as objective. Cost dominated by primary energy would deteriorate the objective if more energy resources joint to contribute to the solution; contradicting a minimization.

Several solutions are possible.

- 1) The protocol could be altered and each agent could be requested to calculate an initial contribution in order to avoid incomplete solutions. Depending on the problem at hand these initial contributions might be nonsense as they have been determined without knowledge on the others' decisions.
- 2) A penalty term could be added to the objective in order to deteriorate solutions based on the number of agents that still have to join. In this case the agents would need knowledge on the number of agents that are in the group.
- 3) Solutions with a larger number of contributions are always considered better regardless of the evaluation result. This might not hold for all objectives and may lead to wrong convergence directions.

For some objective functions there seems to be no issue at least if the number of agents is low enough compared with the number of network connections in between them and if the agents join in quick enough. For the simulations conducted with the first approach proposed here, after an initial deterioration of the solution quality a convergence could be observed towards

better solutions. Improved versions should integrate one of the afore mentioned approaches to guarantee convergence.

*d) Localization of objectives:* In standard COHDA each agent knows the global objective function. In multi-objective COHDA all global objective functions might also be known by all agents. On the other hand, not all objectives can be calculated by using the schedules of other agents directly, as it is the case in predictive scheduling. Calculating individual costs for example requires knowledge on private cost factors of other energy resources. Such factors are usually not known publicly nor communicated. Thus essential information for calculating the objectives is missing in a fully decentralized scenario.

In [46], an extension to the decoder approach has been proposed that is capable of annotating individual schedules with performance indicators. In [47] an ontology has been presented to capture and reliably interpret these information in a decentralized scenario. In the first approach presented here, this issue is currently neglected and only objectives that can be calculated without further information are used.

*e) Convergence detection:* In standard COHDA the solution converges to a single solution and eventually all agent represent the same solution. In the multi-objective case, all solution sets converge towards the same Pareto front and eventually all agents represent (an approximation) to the same Pareto front, but with probably different solution sets. Whether this is a problem or not highly depends on the specific problem at hand.

### III. A FIRST APPROACH

#### A. Implementation

We implemented a fully decentralized multi-objective approach for predictive scheduling by extending the COHDA algorithm. First, we had to define the solution format. A solution to the overall problem (Eq. 2) is – in the multi-objective case – a set of sets of schedules for the virtual power plant; each one consisting of a schedule for the respective energy resource in the group:

$$\mathfrak{X} = \{\mathbf{X}_1, \dots, \mathbf{X}_n\}, \quad (4)$$

with

$$\mathbf{X}_k = (x_{ij}) \in \mathbb{R}^{m \times d} \quad (5)$$

where  $x_{ij}$  denotes the mean real power of energy resource  $i$  during the  $j$ th time period. Thus each row of the matrix  $\mathbf{X}_k$  represents a schedule for the respective energy resource. This solution set  $\mathfrak{X}$  is determined in a way that it approximates the Pareto front. In this way, each agent holds and negotiates on a set of schedules for the own energy resource.

Let  $\{\mathbf{x}_1^{(a_j)}, \dots, \mathbf{x}_n^{(a_j)}\}$  denote the set of local schedules (for the own, controlled device) that is negotiated by agent  $a_j$ . Let  $\kappa_j$  be the current working memory of agent  $a_j$  (updated by an incoming message; cf. II-C). Let

$$X_O = \{\mathbf{x}_1^{(a_1)}, \dots, \mathbf{x}_n^{(a_1)}\}, \dots, \{\mathbf{x}_1^{(a_{m-1})}, \dots, \mathbf{x}_n^{(a_{m-1})}\} \in \kappa_j \quad (6)$$

be the currently known schedule selections (local solution candidates) from all the other agents  $a_1, \dots, a_{m-1} \in \mathcal{A} \setminus a_j$ . Basically, this is the system state belief  $\mathfrak{S}(a_j)_k$  without the agent's own contribution from decision  $k$ :

$$X_O = \mathfrak{S}(a_j)_k \setminus \{\mathbf{x}_1^{(a_j)}, \dots, \mathbf{x}_n^{(a_j)}\}. \quad (7)$$

Now the procedure (performed by agent  $a_j$ ) for deciding on the own schedule selection is as follows: The sum of schedules of the other agents is calculated as

$$\mathcal{O} = \{\mathbf{O}, \dots, \mathbf{O}_n\} \quad (8)$$

with

$$\mathbf{O}_i = \sum_{\mathbf{x}_i \in X_O} \mathbf{x}_i. \quad (9)$$

Now a solution of the MAS (cf. Eq. 4) to the joint Problem can be represented as

$$\left[ \begin{array}{c} \mathbf{O}_1 \\ \mathbf{x}_1^{(a_j)} \end{array} \right], \dots, \left[ \begin{array}{c} \mathbf{O}_n \\ \mathbf{x}_n^{(a_j)} \end{array} \right] \quad (10)$$

with  $\mathbf{x}_1^{(a_j)}, \dots, \mathbf{x}_n^{(a_j)}$  being the decision variables of the local problem of deciding on the best local schedules under the assumption that the other agents' schedules are operated as communicated.

Solution candidate  $\mathbf{x}_1^{(a_j)}, \dots, \mathbf{x}_n^{(a_j)}$  is initialized randomly and evolved for some iterations towards the Pareto front. For each evolution step one randomly chosen schedule  $\mathbf{x}_k \in \mathbf{x}_1^{(a_j)}, \dots, \mathbf{x}_n^{(a_j)}$  is mutated to  $\mathbf{x}'_k$  by adding a Gaussian delta  $r \in \mathcal{N}(0, 1)$  to one randomly chosen element of  $\mathbf{x}_k$ . As crossover operator, uniform crossover is applied. Please note, as an agent can only decide on its own schedules, mutation and crossover may not be applied to other agents' schedules from  $\mathbf{O}$ . Then, the agent performs a fast non-dominated sort on  $\mathbf{O} \cup \left[ \begin{array}{c} \mathbf{O}_k \\ \mathbf{x}'_k \end{array} \right]$ .

For applying the fast non-dominance-sort as introduced in [48], from the worst front the worst individual (solution with the lowest hypercube contribution) is removed. For sorting and selecting the worst individual by  $S$ -metric selection, the dominance of solutions has to be determined by using the objective functions. For this purpose, we extend the definition of dominance by integrating the decoder set:

$$\mathbf{y} \prec \mathbf{y}^* \equiv \forall i = 1, \dots, d: y_i < y_i^* \quad (11)$$

in order to keep track of the individual (technical) constraints of the energy resources by setting

$$\mathbf{y} = \left( \begin{array}{c} f_{1,1}(\gamma_1(\mathbf{x}_1)) + \dots + f_{1,n}(\gamma_n(\mathbf{x}_n)) \\ f_{2,1}(\gamma_1(\mathbf{x}_1)) + \dots + f_{2,n}(\gamma_n(\mathbf{x}_n)) \\ \vdots \\ f_{m,1}(\gamma_1(\mathbf{x}_1)) + \dots + f_{m,n}(\gamma_n(\mathbf{x}_n)) \\ F_1(\mathbf{M}) \\ \vdots \\ F_\ell(\mathbf{M}) \end{array} \right) \quad (12)$$

as introduced in [31]. In this way, variations of the previous solutions in the solution set are produced by applying variation

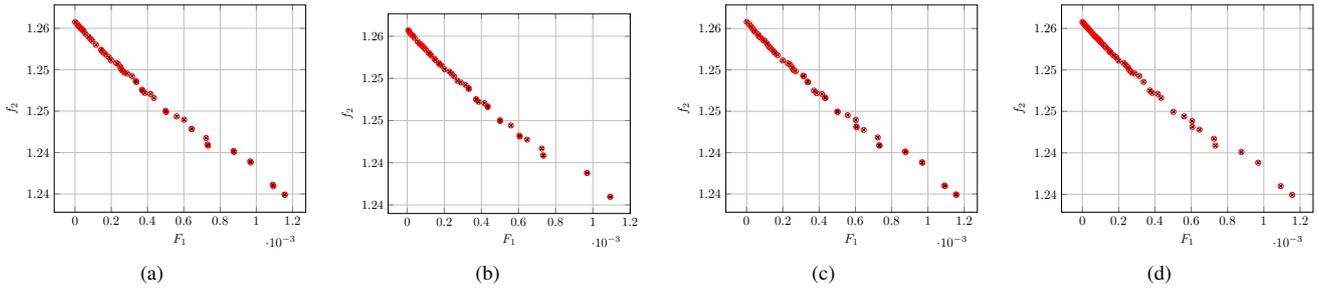

Fig. 1. Resulting solution sets of the 4 agents of the small scenario depicting the individually approximated Pareto fronts.

operators to the genotype. In this way the selection and crossover operators merely have to obey an easy to integrate box constraint that ensures that each value of a solution candidate is kept within  $[0, 1]$  if max power is scaled to 1 (corresponding to 100% rated power). No further constraints have to be integrated. Thus, the problem formulation can be regarded as constraint-free. Constraint-handling is introduced by using decoder functions that abstract from individual capabilities or technical constraints of energy units. The set of decoders ensures that selection is done on feasible solutions only and thus that the solution set approaches a Pareto front without any knowledge about controlled energy units.

The last step in the COHDA process requires comparing the result achieved in the previous round with the current achievement. If the new one is better, it is communicated to the neighboring agents, else it is discarded and the old is kept without communicating any achievement. In the single objective case, the achieved objective values can be compared directly. This is not possible in the multi-objective case as the result constitutes a set of solutions. Thus, we decided to compare both results using the hypervolume between a reference point and the solution set as rather usual in multi-objective algorithms. For fast calculation of exact hypervolumes we applied the WFG (walking fish group) algorithm [49].

With these settings we addressed all challenges identified in section II-D to constitute a fully decentralized, agent-based determination of the Pareto front of a joint multi-objective problem.

### B. Results

For our evaluation we simulated different virtual power plants consisting of different co-generation plants. The model has already been used and evaluated in different projects, e. g. [13], [46], [50], [51]. We started with a rather small setting of four agents and 96-dimensional schedules resulting in a 384-dimensional search space which has already been evaluated to be highly multi-modal and ragged [52]. As goal, two objectives were set:  $F_1$  denotes the deviation of the joint schedule from the desired target schedule ( $\|\cdot\|_2$ ) and  $f_2$  equalizes the run of the co-generation plants by minimizing peak loads:

$$f_2 = \sum_{\mathbf{x}_i \in \mathbf{X}} \sum_{j=1}^d (x_{ij} - \mu)^2, \quad (13)$$

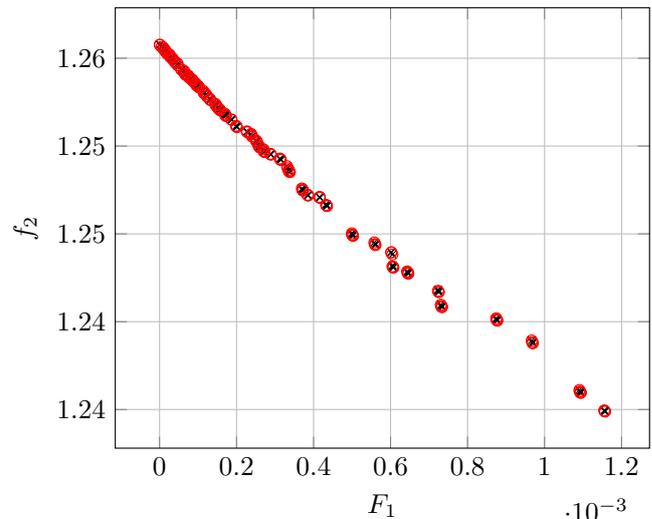

Fig. 2. Combination of local Pareto fronts of agents from solution Fig. 1. Solutions are marked with a cross; non-dominated solutions are marked by a circle. In this example, no solution is dominated by a solution from another agent.

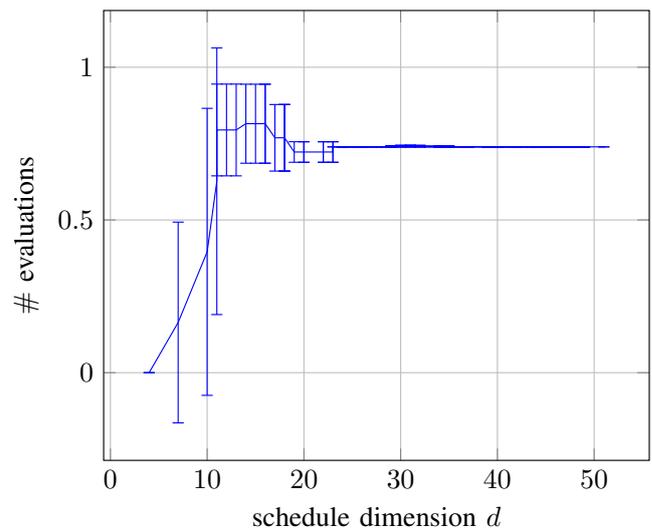

Fig. 3. Convergence and inter-agent variability (error bars) of the small scenario. Only the first 50 (out of  $\sim 1700$ ) measuring points are depicted.

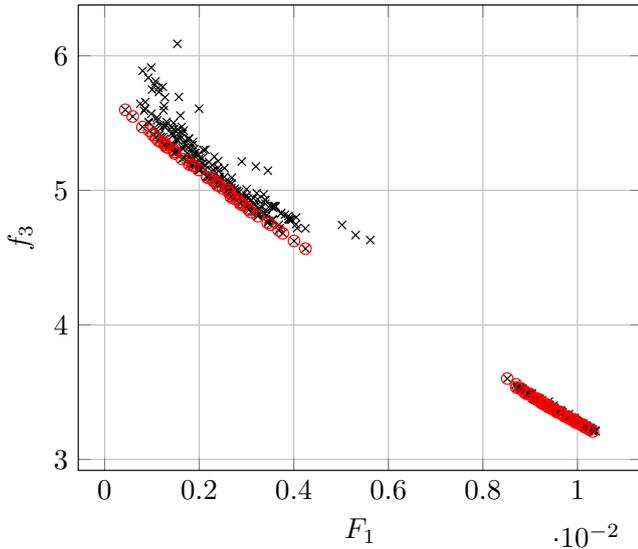

Fig. 4. Consolidated Pareto fronts from the large example. Non-dominated solutions are additionally marked with a circle. As COHDA is a heuristic, this example has obviously not completely reached a common front approximation. Maybe, a post-processing that removes dominated solutions could improve the approach significantly.

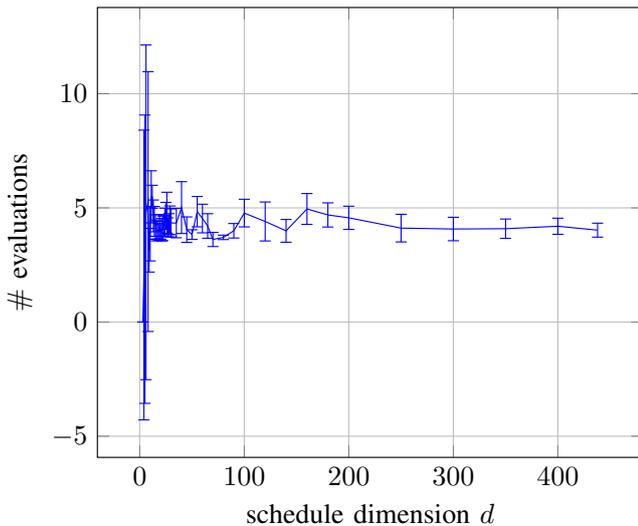

Fig. 5. Convergence and inter-agent variability (error bars) of the large scenario.

with  $\mu$  being the mean power over the whole planning horizon. In this way, the variance in power levels is minimized. Figure 1 shows an example of the resulting Pareto front approximations of the individual 4 agents. The evolutionary part during the decision phase has been run for 500 iterations each. A cross marks an individual for the solution set (50 schedules per agent) and a circle marks a non-dominated solution from the front. Note, that solution here denotes already a solution (joint schedule) for the predictive scheduling problem. Even if all schedules from the individual result sets of the agents are plotted jointly in a single plot, all solutions are non-dominated;

see Figure 2. Thus, all solutions that are individually generated by the agents stem from the same Pareto front approximation, although there are slight differences in the solution sets (regarding distribution on the front) as can be visually seen in Figure 1. The agents approximate the same front but exhibit differences in the individual solution sets.

Some statistics on this scenario with different numbers of evolutionary iterations are given in Table I.

As the proposed approach is still a heuristic, results are as yet not that perfect with growing problem size. Figure 4 shows another example from a scenario with 50 agents approximating a 50 schedule solution set each.

Here another objective has been tested: Achieve a desired state of charge (SOC) for some of the thermal buffer stores that are attached to the co-generation plants.

$$f_3 = \sum \delta(\text{SOC}_i, \text{soc}(x_i)). \quad (14)$$

In this larger scenario some of the solutions in the joint solution set are still dominated by the solutions from others, even though 5000 iterations have been conducted during decision phases. Obviously, the number of necessary iterations quickly grows with problem size: deteriorating needed negotiation time.

On the other hand, the mean hypervolume (as quality measure for a solution) converges quite early to an acceptable value. Figure 3 shows the convergences of the process that led to result 1. Here, the mean (so long achieved) hypervolume of all agents is measured at discrete points in time from the concurrently asynchronously running multi-agent system. Error bars show the inter-agents variance. At the same time the variance among all agents is determined. Depicted are only the first iterations, not the full process. Depending on the specific use case at hand, it might thus be possible to stop the negotiation at an earlier stage with a still acceptably good solution. Some more investigations will be necessary here. Figure 5 shows the situation for the second case.

TABLE I  
PERFORMANCE INDICATORS FOR BOTH TEST SCENARIOS. THIS TIME  $f_2$  WAS USED FOR BOTH.

indicator	4 agents	50 agents
hypervolume	$0.401 \pm 0.213$	$0.533 \pm 0.258$
best $F_1$	$0.103 \pm 0.110$	$0.083 \pm 0.006$
best $f_2$	$1.785 \pm 0.213$	$1.745 \pm 0.142$
# messages	$2191.6 \pm 2407.1$	$679.6 \pm 516.6$
# decisions	$1064.1 \pm 1166.6$	$328.4 \pm 245.3$

Mean achieved results for 100 runs each are depicted in Table I. The achieved hypervolume in the larger scenario larger due to the better aggregated schedule ( $F_1$ ). This observation is consistent with the single-objective case and rooted in the higher flexibility of larger VPPs. The number of exchanged messages and decisions decreases significantly with growing scenario size probably allowing for more complex decision routines of the agents in future improvements.

#### IV. CONCLUSION

For many applications within the smart grid scheduling domain, multi-objective optimization problems have to be solved. As for scalability reasons decentralized (agent-based) algorithms are seen as a promising solution, multi-objective capability has to be integrated into these methods. At the same time, proper constraint-handling is indispensable for acceptance.

With the approach demonstrated here, we integrated multi-objective capabilities taken from SMS-EMOA into fully decentralized energy scheduling.

Applicability and effectiveness of the proposed approach have been demonstrated by simulations. Nevertheless, some questions remain for further research: Replacing the decoder decision by a more complex optimization based decision method entails the need for tuning additional parameters; e. g. the (probably adaptive) number of iterations during each decision procedure. Maybe a substantial acceleration could be reached with additional convergence detection methods. Designing mutation, crossover and selection is also still subject to specialized improvements. Moreover, an integration of indicators into the communicated solution data format could improve privacy as local objectives (and thus their calculation details) would no longer be publicly known. Nevertheless, this first approach demonstrated the general feasibility of fully decentralized multi-objective optimization.

# Advances in Computer Science & Systems

**C**SS is a FedCSIS conference track aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to more technical aspects of computer science and related disciplines. The CSS track spans themes ranging from hardware issues close to the discipline of computer engineering via software issues tackled by the theory and applications of computer science and to communications issues of interest to distributed and network systems. Technical sessions that constitute CSS are:

- CANA'19—12<sup>th</sup> Workshop on Computer Aspects of Numerical Algorithms
- C&SS'19—6<sup>th</sup> International Conference on Cryptography and Security Systems
- LTA'19—4<sup>th</sup> International Workshop on Language Technologies and Applications
- MMAP'19—12<sup>th</sup> International Symposium on Multimedia Applications and Processing
- WAPL'19 7<sup>th</sup> Workshop on Advances in Programming Languages
- WSC'19—10<sup>th</sup> Workshop on Scalable Computing

# 12<sup>th</sup> Workshop on Computer Aspects of Numerical Algorithms

**N**UMERICAL algorithms are widely used by scientists engaged in various areas. There is a special need of highly efficient and easy-to-use scalable tools for solving large scale problems. The workshop is devoted to numerical algorithms with the particular attention to the latest scientific trends in this area and to problems related to implementation of libraries of efficient numerical algorithms. The goal of the workshop is meeting of researchers from various institutes and exchanging of their experience, and integrations of scientific centers.

## TOPICS

- Parallel numerical algorithms
- Novel data formats for dense and sparse matrices
- Libraries for numerical computations
- Numerical algorithms testing and benchmarking
- Analysis of rounding errors of numerical algorithms
- Languages, tools and environments for programming numerical algorithms
- Numerical algorithms on coprocessors (GPU, Intel Xeon Phi, etc.)
- Paradigms of programming numerical algorithms
- Contemporary computer architectures
- Heterogeneous numerical algorithms
- Applications of numerical algorithms in science and technology

## EVENT CHAIRS

- **Bylina, Beata**, Maria Curie-Sklodowska University, Poland
- **Bylina, Jaroslaw**, Maria Curie-Sklodowska University, Poland

- **Stpiczyński, Przemysław**, Maria Curie-Sklodowska University, Poland

## PROGRAM COMMITTEE

- **Amodio, Pierluigi**, Università di Bari, Italy
- **Anastassi, Zacharias**, De Montfort University, United Kingdom
- **Brugnano, Luigi**, Università di Firenze, Italy
- **Fialko, Sergiy**, Tadeusz Kościuszko Cracow University of Technology, Poland
- **Georgiev, Krassimir**, IICT - BAS, Bulgaria
- **Gravvanis, George**, Democritus University of Thrace, Greece
- **Kozielski, Stanislaw**, Silesian University of Technology, Poland
- **Lirkov, Ivan**, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria
- **Luszczek, Piotr**, University of Tennessee, United States
- **Marowka, Ami**, Bar-Ilan University, Israel
- **Petcu, Dana**, West University of Timisoara, Romania
- **Sergeichuk, Vladimir**, Institute of Mathematics of NAS of Ukraine, Ukraine
- **Srinivasan, Natesan**, Indian Institute of Technology, India
- **Tudruj, Marek**, Inst. of Comp. Science Polish Academy of Sciences/Polish-Japanese Institute of Information Technology, Poland

**Abstract**—We present parallel tiled optimized McCaskill’s partition functions computation code. That CPU and memory intensive dynamic programming task is within computational biology. To optimize code, we use the authorial source-to-source TRACO compiler and compare obtained code performance to that generated with the state-of-the-art PLuTo compiler based on the affine transformations framework (ATF). Although PLuTo generates tiled code with outstanding locality, it fails to parallelize tiled code. A TRACO tiling strategy uses the transitive closure of a dependence graph to avoid affine function calculation. The ISL scheduler is used to parallelize tiled loop nests. An experimental study carried out on a multi-core computer demonstrates considerable speed-up of generated code for the larger number of threads.

## I. INTRODUCTION

**D**YNAMIC programming (DP) is typically applied to optimization problems in computational biology. Code implementing such computation-intensive tasks include loop nests within the polyhedral model, which allows us to apply optimization compilers to improve code performance. However, the fact that such problems are within non-serial polyadic dynamic programming (NDPD) leads to existence of non-uniform dependences in corresponding loop nests. This limits many commonly known optimization techniques such as permutation, diamond tiling [1], or index set splitting [2] to improve cache efficiency.

One of such NDPD problems is McCaskill’s algorithm, which requires computing partition functions, which used to fold an RNA secondary structure and to find the probabilities of various sub-structures. McCaskill’s recurrence is quite similar to other NPDP RNA folding algorithms such as Nussinov’s and Zucker’s ones, which are not trivial to be optimized with automatic optimization compilers.

Today, most popular techniques to automatically generate optimal parallel code are based on affine transformations. For a given loop nest statement, an affine transformation can be presented with the following relation  $[I] \rightarrow [t = C * I + c]$ , where  $I$  is the iteration vector of the statement;  $t$  is the discrete time of the execution of iteration  $I$ ;  $C * I + c$  is the affine expression. If two statement instances have the same execution time, they can be run in parallel.

To find the unknown matrix  $C$  and unknown vector  $c$ , for each loop nest statement, on the basis of dependence relations time-partition constraints are created and resolved for elements of matrix  $C$  and elements of vector  $c$ .

State-of-the-art automatic optimizing compilers, such as PLuTo [3], have provided empirical confirmation of the success of polyhedral-based code generation and optimization. PLuTo optimizing compiler is based on the affine transformation framework (ATF), which has demonstrated considerable success in generating high-performance parallel code in particular for stencils.

ATF is also used to generate tiled code. Loop tiling for improving locality groups loop statement instances into smaller blocks (tiles) allowing reuse when the block fits in local memory. In parallel tiled code, tiles are considered as indivisible macro statements. This coarsens the granularity of parallel applications that often leads to improving the performance of an application running in parallel computers with shared memory.

ATF is applied in other compilers such as Apollo and PPCG as well as commercial R-STREAM and IBM-XL. ATF has some drawbacks, papers [4], [5], [6] present its limitations for generation of parallel cache-efficient code for bioinformatics NPDP tasks. Although PLuTo generates outstanding cache-efficient code for McCaskill’s algorithm, it is not able to generate any parallel code.

Wonnacott et al. introduced serial 3-D tiling of “mostly-tileable” loop nests of Nussinov’s RNA secondary structure prediction in paper [5] to overcome some ATF limitations. But they did not present how to parallelize code generated with a proposed technique.

Mullapudi and Bondhugula [6] have also explored automatic techniques for tiling codes that lie outside the domain of standard tiling techniques. 3-D iterative tiling for dynamic scheduling is calculated by means of reorderable reduction chains to eliminate cycles between tiles for Nussinov’s algorithm. Until now, we do not have a precise characterization of the relative domains of those techniques and it is not clear how they can be applied to parallelize McCaskill’s algorithm where target arrays are not a result of reorderable functions such as minimum or maximum.

Paper [7] presents a manual implementation of parallel McCaskill’s algorithm, but the approach is limited only to message passing architectures and does not consider locality improvement for modern multi-core machines.

Li et al. show how to use array transposition to enable better caching for Nussinov’s algorithm [8] with replacing the array reading column order to the row order. The disadvantage of

this approach is the cost of additional memory management, which is overcome by tiling strategies [9]. In paper [10], Li's method was improved, but it allows for generating only serial code.

In this paper, we introduce an alternative approach as a combination of the tile correction algorithm [11] and the ISL scheduler [12] to parallelize tiled loop nests of the McCaskill's algorithm to overcome limitations of the mentioned techniques. This approach is implemented in the TRACO compiler [13].

TRACO does not find and use any affine function to transform the loop nest. It is based on the iteration space slicing framework [14] and applies the transitive closure of a dependence graph to carry out corrections of original rectangular tiles so that all dependences available in the original loop nest are preserved under the lexicographic order of target tiles. The inter-tile dependence graph does not contain any cycle and any technique of loop nest parallelization can be used [11] to generate parallel code. We apply the commonly known loop skewing technique and use the ISL library to implement it and generate parallel tiled code implementing McCaskill's algorithm. We observe high performance and scalability of that code executed on multi-core processors. We compare obtained code performance with that of code generated with PLuTo.

## II. MCCASKILL'S ALGORITHM FOR THE PARTITION FUNCTION COMPUTATION

John S. McCaskill proposed an efficient dynamic programming algorithm to compute the partition function  $Z = \sum_P \exp(-E(P)/RT)$  over all possible nested structures  $P$  that can be formed by a given RNA sequence  $S$  with  $E(P) =$  energy of structure  $P$ ,  $R =$  gas constant, and  $T =$  temperature [15].

In this paper, we study a simplified version of the approach using a Nussinov-like energy scoring scheme, i.e., each base pair of a structure contributes a fixed energy term  $E_{bp}$  independent of its context. Given such an assumption, two dynamic programming tables  $Q$  and  $Q_{bp}$  are populated. The partition function for a sub-sequence from position  $i$  to position  $j$  is provided by  $Q_{i,j}$ . Array  $Q_{bp}$  holds the partition function of the sub-sequences, which form a base pair or 0 if base pairing is not possible.

The following recursions are used to compute the partition functions  $Q$  and  $Q_{bp}$ .

$$Q_{i,j} = Q_{i,j-1} + \sum_{i \leq k < (j-1)} Q_{i,k-1} \cdot Q_{k,j}^{bp},$$

$$Q_{i,j}^{bp} = \begin{cases} Q_{i+1,j-1} \cdot \exp(-E_{bp}/RT) & \text{if } S_i, S_j \text{ can form} \\ & \text{base pair} \\ 0 & \text{otherwise} \end{cases}.$$

Listing 1 presents the implementation of computing  $Q$  and  $Q_{bp}$ . The input data are RNA sequence  $S$  as a chain of nucleotides from the alphabet AUGC (adenine, uracil,

guanine, cytosine), minimal loop length  $l$  (i.e. minimal number of enclosed positions), energy weight of base pair  $E_{bp}$  and normalized temperature  $RT$ . The memory complexity of the arrays is  $\mathcal{O}(n^2)$ , while the time complexity of a direct implementation of this algorithm is  $\mathcal{O}(n^3)$  in the sequence of length  $N$ .

Given these partition function terms, we can find base pair probabilities as well as probabilities that a certain sub-sequence is unpaired, in the manner discussed in [16].

## III. AUTOMATIC CODE OPTIMIZATION

The code presented in Listing 1 was optimized (tiled and parallelized) by means of the TRACO compiler [13]. To tile a loop nest, TRACO forms original rectangular tiles whose size is provided by the user. Then TRACO extracts dependences available in the loop nest applying the Petit tool [17], which returns 19 dependence relations describing all the dependences in the loop nest implementing McCaskill's algorithm. Extracted dependence relations are a mathematical representation of the dependence graph whose nodes are statement instances of the loop nest, while each edge states for a dependence between a pair of nodes.

Using the union of obtained dependence relations, TRACO calculates the transitive dependence of the dependence graph, for this purpose, it uses a function implementing the algorithm presented in paper [18]. The transitive closure of a given graph,  $G$ , is a graph,  $G'$ , such that  $(i, j)$  is an edge in  $G'$  if there exists a directed path from  $i$  to  $j$  in  $G$ . It is worth noting that in general, the dependence graph is parametric – the number of nodes depends on the upper bounds of loop iterators, which are represented with parameters. So, a special algorithm should be applied to calculate the transitive closure of a parametric dependence graph.

TRACO carries out the following calculations according to the algorithm presented in paper [11]. First, applying the transitive closure of the dependence graph, it checks whether the original (rectangular) tiles are valid. A valid tile with identifier  $I$  does not contain any statement instance that is the destination of the dependence whose source belongs to

TABLE I  
EXECUTION TIME (IN SECONDS) OF THE ORIGINAL, TRACO AND PLuTo TILED CODES.

N	1 Thread			2 Threads	4 Threads	8 Threads	16 Threads	32 Threads	48 Threads

the tile whose identifier is lexicographically greater than  $I$ . If all original tiles are valid, it directly generates target code, otherwise, it corrects original tiles so that all target tiles are valid under lexicographical order. Such a correction is realized by means of transitive closure.

It is well-known that if all tiles are valid, then the corresponding inter-tile dependence graph describing dependences among tiles is acyclic, so there exists a schedule that assigns a discrete time to the corresponding tile to execute it [19]. If two or more tiles have the same schedule time, they can be run in parallel.

To extract a valid tile schedule, we need a dependence relation, which describes inter-tile dependences. Using obtained valid tiles, TRACO forms such a relation according to the way described in paper [11]. Then TRACO finds a valid tile schedule applying the ISL scheduler [12], which uses the PLuTo scheduler with Feautrier’s one [19], [20] as fallback. The PLuTo scheduler constructs a set of independent affine schedule functions that guarantee a small dependence distance over the schedule constraints. The basic idea of Feautrier’s scheduler implemented in the ISL library is to carry as many dependences as possible in each level of a multi-dimensional schedule.

For the examined loop nest, the ISL scheduler returns the following tile schedule for each statement:  $[ii, jj, kk] \rightarrow [ii + jj]$ , which means that the tile represented with identifier  $[ii, jj, kk]$  is mapped to execution time  $[ii + jj]$ . Such a schedule corresponds to the well-known loop skewing transformation [21]. It is a convenient method to implement the wavefront method of executing a loop nest in parallel, which creates a “wave” that passes through the iteration space. Skewing changes the iteration vectors for each iteration by adding the outer loop index value to the inner one.

To generate parallel code on the tile level, to each loop statement, we apply the skewing transformation  $(ii + jj)$  to form the following schedule allowing for parallel code generation.

$$SCHED\_PAR := N \rightarrow \{ (i, j, k) \rightarrow (ii + jj, jj, kk, i, j, k) \mid constraints \},$$

where *constraints* are the constraints of a set representing target tiles for a given loop nest statement.

That schedule maps each instance of a statement to a time partition whose all tiles can be executed in parallel. TRACO passes those schedules to the input of the ISL code generator, which generates target pseudo-code. The TRACO

post-processor generates target parallel compilable code in the OpenMP standard [22], which is presented at the repository [https://github.com/markpal/hpc\\_mea](https://github.com/markpal/hpc_mea). In that code, the first loop is serial, it enumerates time partitions including target tiles. The second loop is parallel, it runs tiles belonging to a given time partition, the reminding loops are serial. Intra-tile dependences (dependences within a tile) are honored because within each target tile, statement instances are executed in lexicographical order (serially).

It is worth noting that TRACO code is less regular than that generated with PLuTo because target tiles generated with TRACO are irregular while PLuTo generates regular tiles except from boundary ones.

#### IV. EXPERIMENTAL STUDY

This section presents the results of the comparison of the performance of TRACO and PLuTo tiled codes implementing McCaskill’s algorithm. To carry out experiments, we have used a computer with the following features: Intel Xeon CPU E5-2699 v2, 3.6GHz, 24 cores, 48 Threads, 45 MB Cache, 16 GB RAM. Programs were compiled with the Intel C Compiler (icc 15.0.2) and optimized at the  $-O3$  level (more aggressive optimization recommended for loops involving intensive floating point calculations). Parallelism of target code is represented in the OpenMP standard. We discovered empirically that the best tile size for TRACO code is  $[1 \times 128 \times 16]$ , i.e., the first loop should not be tiled. For tiled code generated with PLuTo, we empirically discover that the best tile size is  $[16 \times 16 \times 16]$ .

The McCaskill loop nest can be tiled by both PLuTo and TRACO, however, only TRACO allows us to parallelize target code. Although the serial code produced with PLuTo is very cache-efficient, the compiler is unable to find any affine schedule allowing for parallel execution of generated tiles. TRACO generates valid tiles applying the transitive closure of the dependence graph built for the McCaskill loop nest, then it forms a relation, which represents inter-tile dependences. Finally, using that relation, it applies the ISL scheduler to get a valid tile schedule to generate parallel code on the tile level.

Table 1 presents execution times (in seconds) for various RNA sequence lengths. Figure 2 depicts the speed-up (a ratio of  $T_1$  over  $T_n$ , elapsed times of 1 and  $n$  threads) of tiled programs for  $N = 5000$  (roughly the size of the longest human mRNA). Analyzing the obtained results, we may conclude that the TRACO code performance overcomes that of the PLuTo serial one for eight and more threads. The worse performance

of the TRACO code for the few number of threads is caused with target code irregularity (see the previous section). The lack of parallelism limits speed-up and scalability of the PLuTo loop nest implementing McCaskill's algorithm on the modern multi-core machine used for experiments.

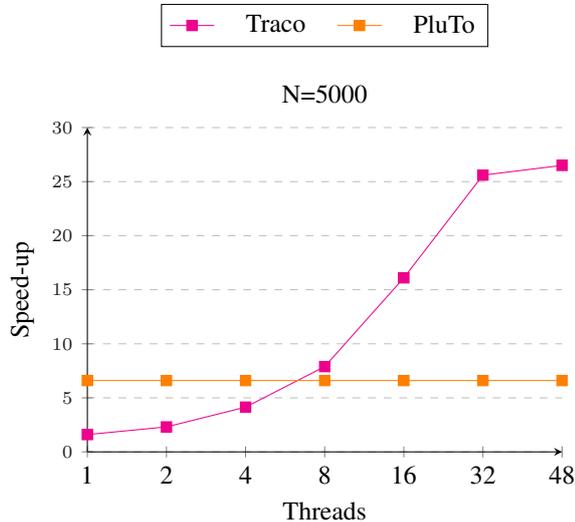

Fig. 1. Speed-up of TRACO and PLuTo codes.

## V. CONCLUSION

In this paper, we presented the usage of the TRACO compiler to optimize the loop nest implementing the McCaskill pattern function calculation. TRACO applies the transitive closure of dependence graphs to generate valid tiles under lexicographical order. Then it forms a relation describing inter-tile dependences and uses the ISL scheduler to obtain a valid tile schedule allowing for generation of parallel tiled code.

Applying optimization techniques based on affine transformations implemented in the PLuTo compiler allows for generation of only serial highly cache efficient code without any parallelism code. The proposed approach outperforms code generated with the PLuTo compiler starting up from eight threads.

It is an ongoing task to find cache efficient optimization for NPDP problems in bioinformatics with  $\mathcal{O}(n^3)$  and  $\mathcal{O}(n^4)$  complexity and non-trivial dependence patterns. In future, we plan to optimize programs implementing base pair probabilities calculation as well as prediction of their structure with maximum expected accuracy (MEA) for a given RNA sequence.

# 6<sup>th</sup> International Conference on Cryptography and Security Systems

**C**RYPTOGRAPHY and security systems are two fields of security research that strongly interact and complement each other. The International Conference on Cryptography and Security Systems (CSS) is a forum of presentation of theoretical, applied research papers, case studies, implementation experiences as well as work-in-progress results in these two disciplines.

## TOPICS

The main topics of interests include:

- network security
- cryptography and data protection
- peer-to-peer security
- security of wireless sensor networks
- security of cyber physical systems
- security of Internet of Things solutions
- heterogeneous networks security
- privacy-enhancing methods
- covert channels
- steganography and watermarking for security applications
- cryptographic protocols
- security as quality of service, quality of protection
- data and application security, software security
- security models, evaluation, and verification
- formal methods in security
- trust and reputation models
- reputation systems for security applications
- intrusion tolerance
- system surveillance and enhanced security
- cybercrime: threats and countermeasures
- 5G Security
- DDoS attacks: detection and mitigation
- Security of Smart Grid systems

## EVENT CHAIRS

# The Low-Area FPGA Design for the Post-Quantum Cryptography Proposal Round5

Michał Andrzejczak

Military University of Technology in Warsaw  
ul. gen. Sylwestra Kaliskiego 2, 00-908 Warszawa, Poland  
Email: [michal.andrzejczak@wat.edu.pl](mailto:michal.andrzejczak@wat.edu.pl)

**Abstract**—Post-Quantum Cryptography (PQC) is getting attention recently. The main reason of this situation is the announcement by the U.S. National Institute for Standard and Technology (NIST) about an opening of the standardization process for PQC. Recently NIST published a list of submissions qualified to the second round of this process. One of the selected algorithms is Round5, offering a key encapsulation mechanism (KEM) and public key encryption (PKE). Due to high complexity of post-quantum cryptosystems, only a few FPGA implementations have been reported to date. In this paper, we report results for low-area purely-hardware implementation of Round5 targeting low-cost FPGAs.

## I. INTRODUCTION

POST-Quantum Cryptography (PQC) is an answer to a threat coming from a full-scale quantum computer able to execute Shor’s algorithm [1]. With this algorithm executed on a quantum computer, currently used public key schemes, such as RSA [2] and elliptic curve cryptosystems, are no longer secure. The U.S. NIST made a step toward mitigating the risk of quantum attacks, by announcing the PQC standardization process [3]. In March 2019, NIST published a list of candidates qualified to the second round of the PQC process [4]. To date, hardware performance of Round 1 candidates was reported for only a small percentage of all submissions.

In this paper, we present the hardware design for low-area implementation of the PQC Round 2 candidate, called Round5. Our design is able to provide both the Key Encapsulation Mechanism (KEM) and Public-Key Encryption (PKE) functionalities. We provide results for all parameter sets of the ring-versions of the respective schemes. Our main goal was to develop the first full-hardware implementation of this PQC submission, able to operate on low-cost FPGAs.

### A. Previous work

Due to complexity of designs, there are only several reports for implementations of PQC candidates in FPGAs. From among lattice-based candidates, Howe et al. [5] reported results for *FrodoKEM*. Kuo et al. [6] and Oder and Güneysu [7] independently reported hardware results for *NewHope*. Aforementioned papers targeted Xilinx Artix-7 FPGA.

In [8], Farahmand et al. proposed a new approach for evaluating PQC candidates by using software/hardware (SW/HW) codesign. They proposed to implement only the most time-consuming functions in the FPGA fabric, while the remaining

parts of the algorithms are implemented in software and run on ARM. Using this SW/HW approach, they reported results for four Round 1 NTRU-based proposals.

For other, non lattice-based candidates, Koziel et al. implemented the isogeny-based SIKE [3], [9]. For multivariate schemes, Ferozपुरi and Gaj reported results for Rainbow [10], implemented using Xilinx Virtex-7 and Kintex-7 FPGAs. From among code-based candidates, Wang et al. reported results for Classic McEliece (a.k.a. classical Niederreiter cryptosystem with binary Goppa codes), implemented using Stratix V FPGAs [11], [12].

### B. Contribution

In this paper, we present a novel hardware design for the ring version of the Round5 submission to the NIST PQC standardization process. Our design is oriented to be a low-area implementation, able to run on low-end FPGAs. The area-performance trade-off is obtained by our customizable architecture for polynomial multiplication.

## II. ROUND5 DESCRIPTION

In the NIST PQC Round 2, there are 26 proposals, with 12 of them belonging to the family of lattice-based schemes. The lattice-based cryptography is a promising option for secure post-quantum KEMs and PKE schemes. It also offers additional novel functionalities, such as homomorphic encryption [13] and identity-based encryption [14].

*Round5* [15] comes from merging two other Round 1 candidates: Round2 [16] and HILA5 [17]. The main underlying problem in *Round5* is Generalized Learning With Rounding (GLWR). In GLWR, the problem randomness comes from rounding, and this feature allows avoiding the necessity of implementing a random bit sampler with any specific distribution, which is a requirement in several other proposals. The submission package contains proposals for indistinguishable under chosen plaintext attack (IND-CPA) KEM and indistinguishable under chosen ciphertext attack (IND-CCA) PKE. Both proposed variants come from the Fujisaki-Okamoto (F-O) transformation [18], by using the main building block of *Round5* — *r5\_cpa\_pke*, the IND-CPA PKE module. Other required modules to perform F-O transformation are a hash function and authenticated encryption with associated data (AEAD). *Round5* comes also in versions with error correcting codes, but our design does not support this functionality.

The package submitted to NIST contains 21 parameters sets, supporting three NIST security levels: 1, 3 and 5. The parameters sets considered in this paper are presented in Table I. We provide results only for the ring version of the schemes, without error correcting codes. The parameter  $n$  describes the polynomial degree,  $p$ ,  $q$ , and  $t$  refer to moduli used in the design for modular reduction and rounding. All moduli are powers of two and must satisfy the requirement  $t < p < q$ .

TABLE I  
PROPOSED PARAMETER SETS FOR THE RING-BASED VERSION OF THE  
ROUND5 PQC CANDIDATE

R5ND Version	$n$	$\log_2(q)$	$\log_2(p)$	$\log_2(t)$
1KEM_0d	618	11	8	4
3KEM_0d	786	13	9	4
5KEM_0d	1018	14	9	4
1PKE_0d	586	13	9	4
3PKE_0d	852	12	9	5
5PKE_0d	1170	13	9	5

#### A. Key generation

In the key generation function, a random seed is expanded by cSHAKE [19]. The use of seed for cSHAKE allows decreasing the size of keys at the expense of an additional cost of expanding the key at the beginning of encryption and decryption. To be compliant with the proposed Hardware API for Post-Quantum Public Key Cryptosystems [20], the key generation function is not a part of the reported design. All long-term keys must be provided to the hardware module from outside, before the main functionality starts.

#### B. Encryption and decryption

Algorithm 1 contains pseudocode for the IND-CPA PKE. The encryption routine starts with expanding a part of the public key and a random input using the cSHAKE function. In the next step, two polynomial multiplications are performed. For polynomial multiplication, one of the polynomials must be lifted to the other's polynomial ring. After the computations, the result is unlifted back. Next, the result is rounded, which is the source of randomness in the GLWR problem.

---

#### Algorithm 1 Round5 Encryption

---

**Require:** public key  $pk$ , message  $msg$ , seed  $\rho$

**Ensure:** ciphertext  $(U, v)$

- 1:  $A \leftarrow \text{Create\_A}(pk.\text{sigma})$
  - 2:  $R \leftarrow \text{Create\_R}(\rho)$
  - 3:  $U \leftarrow \text{Unlift}(\text{Lift}(A) * R)$
  - 4:  $U \leftarrow \text{Round}(U)$
  - 5:  $X \leftarrow \text{Unlift}(\text{Lift}(pk.B) * R)$
  - 6:  $X \leftarrow \text{Round}(X)$
  - 7:  $v \leftarrow msg + X$
  - 8: **return**  $(U, v)$
- 

In Algorithm 2, the pseudocode for decryption is shown. In the first step, the secret key is expanded by using cSHAKE.

Next, only one polynomial multiplication is executed with lifting and unlifting. After the polynomial multiplication, a subtraction from a part of the ciphertext is performed. The last operation is rounding.

---

#### Algorithm 2 Round5 Decryption

---

**Require:** ciphertext  $(U, v)$ , private key  $sk$

**Ensure:** message  $m$

- 1:  $S \leftarrow \text{Create\_S}(sk)$
  - 2:  $X \leftarrow \text{Unlift}(\text{Lift}(U) * S)$
  - 3:  $m \leftarrow v - X$
  - 4:  $m \leftarrow \text{Round}(m)$
  - 5: **return**  $m$
- 

#### C. Supporting functions

Round5 uses three supporting functions during encryption and decryption. First, to obtain an NTRU-like polynomial in the polynomial ring  $\mathbb{Z}_q[x]/(N_{n+1}(x))$  from the key and the random data, the lift function must be applied before multiplication. The lift function is presented in Algorithm 3.

---

#### Algorithm 3 Lift function

---

**Require:** a polynomial  $A$  of length  $n$

**Ensure:** an NTRU-like polynomial  $C$  of length  $n + 1$

- 1:  $C_0 \leftarrow -A_0 \pmod{n}$
  - 2: **for**  $1 \leq i \leq n - 1$  **do**
  - 3:    $C_i \leftarrow A_{i-1} - A_i \pmod{n}$
  - 4: **end for**
  - 5:  $C_n \leftarrow A_{n-1}$ ;
- 

The second function required for proper polynomial multiplication is unlifting, presented in Algorithm 4. Unlifting is applied after polynomial multiplication, and performs polynomial division, taking back the polynomial to  $\mathbb{Z}_q[x]/(\Phi_{n+1}(x))$ .

---

#### Algorithm 4 Unlift function

---

**Require:** a NTRU-like polynomial  $A$  of length  $n + 1$

**Ensure:** a polynomial  $C$  of length  $n$

- 1:  $C_0 \leftarrow -A_0 \pmod{n}$
  - 2: **for**  $1 \leq i \leq n - 1$  **do**
  - 3:    $C_i \leftarrow C_{i-1} - A_i \pmod{n}$
  - 4: **end for**
- 

The last supporting function is rounding, applied to every polynomial coefficient. It is shown in Algorithm 5. It is responsible for rounding elements to smaller values using the exact approach presented in the submission. This function is a source of randomness in the GLWR problem. It is called twice during encryption and once at the end of decryption. Input arguments of rounding are specified in the proposal's documentation.

### III. HARDWARE DESIGN OF ROUND5

We present a low-area architecture of Round5. The implementation follows the proposed hardware API for Post-Quantum Public Key Cryptosystems [20]. The top-level view,

**Algorithm 5** Rounding function

**Require:** an element  $x$  to round, a proper set of  $\{rounding\_constant, shift\_value, mask\}$

**Ensure:** a rounded element  $x$

- 1:  $x \leftarrow x + rounding\_constant$
- 2:  $x \leftarrow x \ll shift\_value$
- 3:  $x \leftarrow x \& mask$
- 4: **return**  $x$

compatible with the aforementioned API, is presented in Fig. 1. The API treats various inputs as public, secret, or random. Thus, three different sets of input ports are used. Each port can handle commands and headers required by the API to control the design.

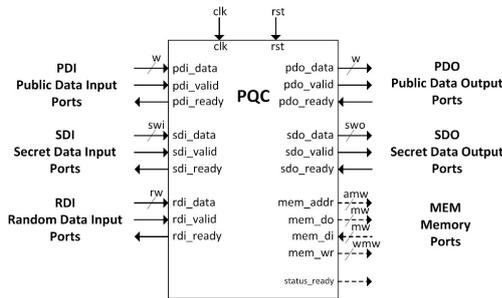

Fig. 1. The PQC Hardware API used in this paper

Going one level down, the architecture of *Round5* is presented in Fig. 2. With the given design, all functionalities of *Round5* are implemented. Each implemented module support all three NIST security levels – 1, 3, and 5. Security level is chosen during compilation and cannot be changed at runtime. The functional modules take input from and write outputs to a shared data bus. The privilege of writing to data bus is granted by the controller’s module.

The main controller is responsible for managing the state of the design and enforcing the proper data flow between modules, depending on a selected operation. It also receives and responds to commands from outside.

The *SHAKE256* module implements the extendable output hash function cSHAKE. It is used for generating pseudo-random polynomials from a given seed. It is also required for the F-O transformation.

The next major component used in our design is the AES-GCM module for authenticated encryption. It is used only in the IND-CCA PKE, as a required part of the F-O transformation. For the IND-CPA KEM, this module can be omitted from the design. The occurrence of AES-GCM is the main difference in the design between the IND-CPA KEM and the IND-CCA PKE versions. In agreement with the F-O transformation, the IND-CCA PKE is build on KEM with additional authenticated encryption.

The most important component is *r5\_cpa\_enc*, providing all arithmetic operations for IND-CPA PKE, the main building

block of all *Round5* proposals.

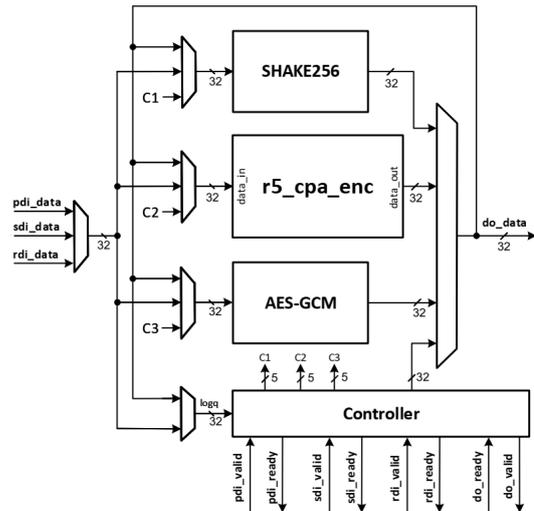

Fig. 2. The proposed top-level architecture of low-area full hardware implementation of Round5

In Fig.3 an arithmetic module responsible for public key encryption and decryption is presented. The important part of this module is the controller, located on the left side of the figure. This controller is responsible for receiving commands from outside, managing the state of the module, and providing proper signals for internal sub-modules. Polynomials required for the operation are stored in separate memory banks. Polynomial multiplication is executed twice during encryption. Thus, two memory banks are able to feed the data to the polynomial multiplier for the first argument. There is some additional memory for the ternary polynomial and for the ciphertext. The ternary polynomial is the same for both multiplications executed during encryption. The message is stored in a register and processed at the end of encryption.

Before polynomial multiplication is executed, one of the polynomials must be lifted to the so called NTRU-ring [21]. This is performed by the *LIFT\_ELEMENT* module, which performs Algorithm 3. Due to the low-area optimization goal, the proposed module lifts elements sequentially, one element at a time. Lifted elements are written back to memory.

The next step is the polynomial multiplication performed by the *POLY\_MUL* module. It requires new data from memory in each cycle. One of the arguments is a coefficient from the lifted polynomial. The second argument is a set of 16 coefficients from the ternary coefficient memory. The module computes results in a sequential fashion, sending further only one coefficient at a time. The first output is ready after  $n$  clock cycles, where  $n$  is a degree of the polynomials. Every next coefficient is ready after  $\lceil n/16 \rceil$  clock cycles.

The computed coefficient follows directly the remaining data path. At first, the coefficient is unlifted to the primary polynomial ring, as shown in Algorithm 4. The next step depends on the operation type. During decryption, subtraction is applied before rounding. During encryption, rounding is

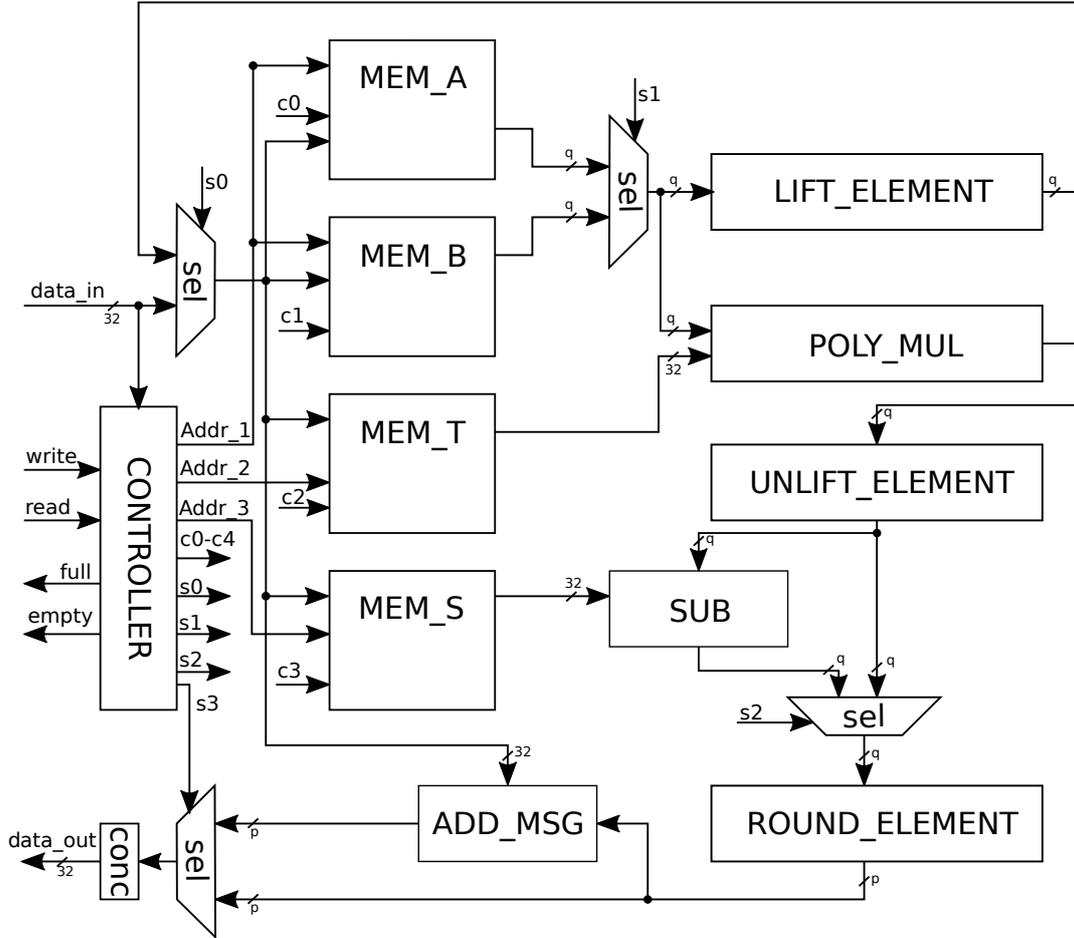

Fig. 3. The arithmetic module for Round5 data encryption and decryption

applied right after unlifting. After rounding, data is stored in the result register directly or with added message bits, depending on the operation type and the state of the encryption process.

Polynomial multiplication has the biggest computational complexity in the *Round5* design. The result is computed by the following formula

$$c_k = \sum_{i+j=k \bmod n} a_i * b_j \quad (1)$$

Due to the form of the polynomial ring and Equation 1, the multiplication can be easily parallelized to speed-up the computations. This is a classical problem of area-performance trade-off, where better performance is achieved by implementing more parallel multipliers, increasing logic usage. Using only one multiplier results in a very large clock cycle latency and slows execution time. On the opposite side of the spectrum, with as many as possible multipliers, the design size is too large to fit in many FPGAs.

We propose a small, in terms of logic utilization, polynomial multiplication module, offering results comparable to those reported for other PQC submissions. Our module executes the

standard schoolbook multiplication with parallel operations. Polynomial multiplication in *Round5* always requires a ternary polynomial and a polynomial with coefficients reduced modulo  $q$ , where  $q$  is a power of 2. Each coefficient in ternary polynomial is from the set  $\{-1, 0, 1\}$ , so only two bits are required to store each coefficient value. All required polynomials are stored separately in internal memory. For polynomials from the ring  $\mathbb{Z}_q[x]$ , each coefficient is accessible directly under different address. Ternary polynomial is stored differently, where one memory cell stores 16 concatenated ternary coefficients. This allows to reduce memory requirements by avoiding only two bits per memory cell utilization. The last memory cell is padded with zeros, if needed.

A new set of coefficients to multiply is loaded from the memory in every clock cycle. The memory address pointers start from the opposite sides, and move in the opposite directions. The ternary polynomial is loaded from the beginning to the end, but the second polynomial is loaded from the last to the first coefficient. The memory pointer for the ternary coefficients is increased by one after each load operation. The second pointer is decreased by the number of parallel multipliers, then the address number is reduced modulo the

polynomial degree. In this scenario, one specific multiplier is computing the same result during one loop over memory. The implemented polynomial multiplication is constant-time.

The proposed polynomial multiplier uses 16 parallel multipliers and is shown in Fig. 4. The number of multipliers is directly linked to the number of coefficients stored in one memory cell. On every memory load, each ternary coefficient is sent to a different multiplier. The second argument is the same for every multiplication unit. The proposed design utilizes the special form of input arguments. The multiplication is done only by addition or subtraction. The value of the accumulator is moved after specific number of multiplications to the next multiplicand. First 15 results are stored in a shift register. This operation is required for computing a proper value. These results are pushed back to multipliers at the end of the computations, to be updated with the remaining multiplication values.

#### IV. RESULTS

We report results for the low-cost DE1-SOC board, manufactured by Terasic. This board is equipped with Intel Cyclone V 5CSEMA5F31C6N FPGA. The chip contains 32,070 adaptive logic modules (ALMs), 128,300 registers, 87 DSP blocks and 3,970 Kb of memory. It contains also the dual-core ARM Cortex-A9 processor. However, in this paper, we focus only on an FPGA part. The post-place and route results were obtained from Intel Quartus Prime v18.1. There is no license requirement for the selected device to perform compilation and deployment.

In Table II, we report results for all security levels and all proposed parameter sets of the IND-CPA KEM and the IND-CCA PKE. We report logic usage for the full design and also for *r5\_cpa\_enc* module separately. This allows us to distinguish the cost of the post-quantum arithmetic module from the remaining costs of the hash-based function and the AEAD module required for the F-O transformation. For presented architecture, the lattice-based arithmetic takes only a small portion of the entire design, several times less than the standard cryptographic elements, such as a hash function or a block cipher. Thus, the implementation goal is achieved. Our design also does not use DSP modules for multiplication, so it can be deployed also with older FPGAs.

The main difference for the logic usage between the IND-CPA KEM and the IND-CCA PKE comes from the additional implementation cost of the AEAD module, not used in the IND-CPA KEM. The logic usage across all security levels is almost the same, as a result of using exactly the same design. The number of multipliers and other arithmetic modules remains always the same.

The memory requirements vary the most among different security levels, due to the necessity of storing significantly larger polynomials. Memory is also used as an input and output buffer to modules in the FIFO queues and in the SHAKE256 implementation. Thus, the overall memory requirements are larger than the sum of all *Round5* elements, such as keys, ciphertext, plaintext, and random data.

All implemented versions of *Round5* run with a similar clock frequency. The reported design is able to perform encapsulation and decapsulation for the highest security level under 1 ms. The encryption and decryption is significantly longer as a result of additional computations required by the F-O transformation and can be performed in around 2 ms also for the highest security level. Only for the lowest security level, the IND-CCA encryption is performed faster than the IND-CPA encapsulation for the parameter set proposed by the submission's authors. These operations are very similar, but for the selected parameter set, the IND-CCA version has smaller polynomial degree. The polynomial degree has the biggest impact on the computational complexity. Thus, faster execution is obtained for the IND-CCA encryption than for the IND-CPA encapsulation.

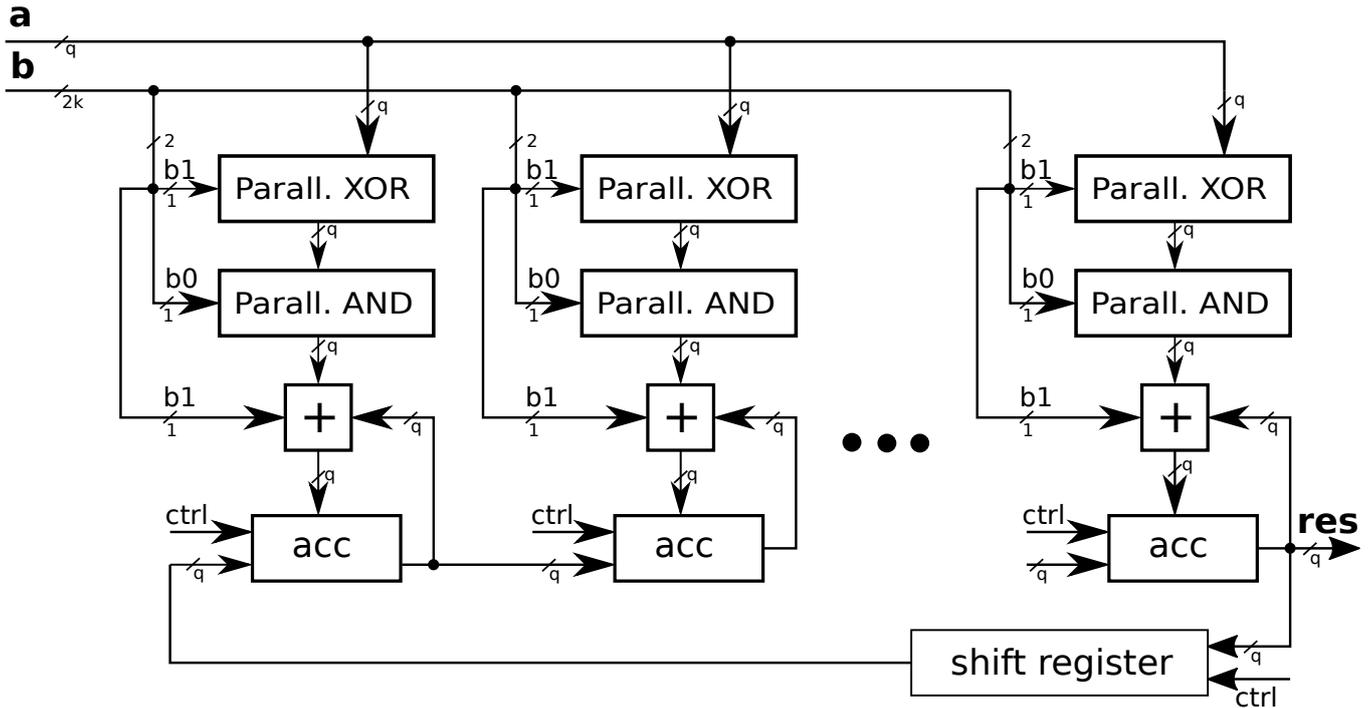

Fig. 4. The parallel polynomial multiplier for Round5

#### A. Comparison to other results

A fair comparison to other results reported to date is hard and complex due to multiple factors directly affecting the obtained results. Moreover, there are no specific guidelines from NIST about proper evaluation of candidates, regarding an FPGA device, implementation goal, API, or compliance criteria. In terms of API and the compliance criteria our design follows the proposal by Ferozpur et al. [20]. As for the FPGA board, we selected one of the least expensive boards, with the free license for the compiler. Any conclusions from comparing logic usage for different FPGA vendors and for different PQC submissions, we are leaving up to the reader.

Howe et al. [5] reported results for full hardware implementation of another lattice-based candidate *FrodoKEM*. They report results for Xilinx Atrix-7 FPGA, and their design balances between area consumption and performance. Their maximum frequency is 167 MHz and is higher than reported in this paper for *Round5*. However, the time required to perform decapsulation is at least an order of magnitude higher, requiring around 20 ms for the execution. Logic requirements are reported for separate modules, not for the entire design able to perform all operations. These modules require around 2,000 slices each.

Most of the other papers reporting results for non-lattice-based PQC candidates, also provide results for Xilinx FPGAs. However, Wang et al. reported results for the Classic McEliece [11], [12] implementation on other high-end Intel FPGA, Stratix V. Their time-optimized implementation uses 121,806 ALM and run at 250 MHz clock, being able to encrypt

and decrypt in less than 0.1 ms.

#### V. CONCLUSIONS AND FUTURE WORK

This paper presented a complete low-area FPGA design for ring version of *Round5*, a lattice-based submission to NIST PQC Standardization process. We reported the post-place and route results for main parameters sets covering all security levels for KEMs and PKEs.

For future work, we consider exploring the area-performance trade-off offered by the proposed polynomial multiplier. A similar polynomial ring is also used by other NTRU-based proposals. Thus, our multiplier can be used for the performance evaluation of other candidates. As for *Round5*, an extension with error correcting codes and the non-ring versions of all schemes is the next big step to provide coverage of all possible parameter sets and versions.

**Abstract**—On December 20th, 2016, the National Institute of Standards and Technology (NIST) formally initiated a competition to solicit, evaluate, and standardize one or more quantum-resistant cryptographic algorithms. Among the current candidates is a cryptographic primitive which has shown much promise in the post-quantum age, Multivariate Cryptography. These schemes compose two affine bijections  $S$  and  $T$  with a system of multivariate polynomials. However, this composition of  $S$  and  $T$  becomes costly as the data encrypted grows in size. Here we present Constructive Affine Stream (CAS) Transformations, a set of algorithms which enable specialized, large-scale, affine transformations in  $O(n)$  space and  $O(n \log n)$  time, without compromising security. The goal of this paper is to address the practical problems related to affine transformations common among almost all multivariate cryptographic schemes.

## I. INTRODUCTION

MULTIVARIATE Cryptography is a, post-quantum, cryptographic primitive based on the difficulty of solving systems of multivariate equations over a finite field [1]. At their core, multivariate schemes define a set of (usually quadratic) polynomials:

$$\begin{pmatrix} p_1(w_1, \dots, w_n) \\ \dots \\ p_m(w_1, \dots, w_n) \end{pmatrix}$$

where all coefficients and variables are in  $\mathbb{F}_q$ , a field with  $q$  elements. Given a plaintext message:  $(x_1, \dots, x_n) \in \mathbb{F}_q^n$  the ciphertext is computed by evaluating:

$$\mathcal{P}(x_1, \dots, x_n) = \begin{pmatrix} p_1(x_1, \dots, x_n) \\ \dots \\ p_m(x_1, \dots, x_n) \end{pmatrix} = \begin{pmatrix} c_1 \\ \dots \\ c_m \end{pmatrix}$$

To decrypt the ciphertext  $(c_1, \dots, c_m)$ , one must hold the *secret key* used to generate the polynomials in  $\mathcal{P}$  in order to invert  $\mathcal{P}$ .

$$\mathcal{P}^{-1}(c_1, \dots, c_m) = (x_1, \dots, x_n)$$

Inverting  $\mathcal{P}$  without the secret key is equivalent to solving a system of multivariate equations over a finite field, known formally as the  $\mathcal{MQ}$ -Problem, and is proven to be NP-Hard. However, modern constructions of these schemes rarely use a set of multivariate polynomials on their own. Modern constructions almost always compose the set of polynomials with two invertible affine maps  $S$  and  $T$  [2]. So, in reality:

$$\mathcal{P} = T \circ Q \circ S : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$$

Where  $Q$  (also known as the *central* or *core map*) is the set of multivariate polynomials and  $S$  and  $T$  are (sometimes linear) affine maps of full-rank. While many papers focus on the design of the central map, few describe how to effectively generate and compose  $S$  and  $T$ , despite the importance of this operation [3], [4], [5], [6], [7]. As the plaintext grows in size, so too do  $S$  and  $T$ . In fact,  $S$  and  $T$  grow so fast that their composition becomes intractable very quickly.

This poses a significant hurdle for symmetric applications of multivariate cryptography. Consider encrypting a 1kB, 500kB, and 1MB file. Because  $S$  and  $T$  are  $n \times n$  matrices where  $n$  is the size of the plaintext, these files require matrices 1MB ( $1\text{kB}^2$ ), 250GB ( $500\text{kB}^2$ ), and 1TB ( $1\text{MB}^2$ ) in size. This rapid inflation of  $S$  and  $T$  restricts these schemes from (reasonably) encrypting anything larger than  $\sim 1\text{kB}$  (without chaining).

In this paper we present Constructive Affine Stream (CAS) Transformations, a set of algorithms capable of efficiently generating and multiplying  $S$  and  $T$  by any arbitrary vector. At the same time, these transformations preserve the post-quantum security of multivariate ciphers. We begin by presenting the theory behind these transformations (Sec. II), followed by a general implementation (Sec. III). We then analyze the asymptotics of the aforementioned implementation (Sec. IV) and conclude by evaluating how these transformations impact the security of multivariate ciphers (Sec. V).

## II. CONSTRUCTIVE AFFINE STREAM TRANSFORMATIONS

Instead of generating, storing, and operating on a matrix outright, a Constructive Affine Stream (CAS) deterministically generates (via some seed derived from the private key) a stream of integers that represent an affine matrix of full-rank. These streams can then be used to transform a vector progressively, in the same way a normal matrix-vector multiplication would, without ever having to store an actual matrix. Furthermore, a stream (if configured with the same seed) can be switched to generate the inverse of a given matrix so that a previous transformation can be undone.

### A. The Structure of an Affine Stream

Constructive Affine Streams (CAS) leverage a basic property of matrix-vector multiplication; each (matrix) row is dotted with the vector term, one at a time, independently of

the other rows. In effect, this property allows the values of each row to be randomly generated over the course of its dot product with the vector term and then “thrown away.” This randomly generated sequence of values is what an affine stream is composed of and allows a vector to be transformed without having to store a matrix.

However, randomly generating matrix rows doesn’t guarantee that the resulting matrix is invertible. Furthermore, even if the matrix was invertible, the values of the rows are generated as needed and never stored, thus each matrix value is “blind” to the values adjacent to it. This limitation prevents a matrix’s inverse from being computed using conventional techniques. In order to solve this problem, matrices generated by a CAS maintain a specific structure.

A CAS generated matrix:

- 1) Takes the form of an upper or lower triangular matrix;
- 2) With non-zero values on the main-diagonal; and
- 3) For every row/column pair which intersect on the main-diagonal, only one of the two (row or column) can contain non-zero values.

While conditions 1 and 2 ensure that the matrix stream produced is always invertible, condition 3 guarantees that the matrix stream is invertible, one row at a time, using only values on the main-diagonal. While the result of condition 3 may not seem intuitive at first, consider inverting the matrix in Fig. 1 via Gauss-Jordan elimination.

A row that only contains zeros (excluding the main-diagonal) can only eliminate values down the column which intersects it on the main-diagonal. For instance, in Fig. 1,  $r_1$  will only be used to eliminate values in  $c_1$ . A row that contains multiple non-zero values has nothing to eliminate in the column which intersects it on the main-diagonal because, by the definition above, that column will always contain zeros. Returning to Fig. 1,  $r_3$  will never need to eliminate anything down  $c_3$  because it is guaranteed to be “zero-valued” by definition. However,  $r_3$ ’s non-zero values 5 and 4 will be eliminated by rows  $r_0$  and  $r_1$  respectively.

Described more generally, the only rows which perform elimination are the ones which contain a single non-zero value: the diagonal-component. Moreover, the only columns which contain non-zero values are the columns which intersect one of the aforementioned rows on its diagonal-component. Consequently, each column can be eliminated independently, without altering adjacent columns.

Because every column can be eliminated on its own, it follows that every column can be inverted on its own. This result is what enables on-the-fly, row-by-row, CAS inversion. The only information needed beforehand are the values of the main-diagonal. With these values, each row can be inverted, one at a time, by mapping its diagonal-component to its multiplicative inverse and all other values (off the main-diagonal) via:

$$-\alpha_{i,j} \times \alpha_{j,j}^{-1} \times \alpha_{i,i}^{-1}$$

where  $\alpha_{i,j}$  is the matrix value at the  $i$ th column and  $j$ th row.

Form	5×5 CAS
Matrix Representation	$\begin{matrix} & c_0 & c_1 & c_2 & c_3 & c_4 \\ r_0 & \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \end{bmatrix} \\ r_1 & \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \end{bmatrix} \\ r_2 & \begin{bmatrix} 8 & 0 & 1 & 0 & 0 \end{bmatrix} \\ r_3 & \begin{bmatrix} 5 & 4 & 0 & 1 & 0 \end{bmatrix} \\ r_4 & \begin{bmatrix} 0 & 7 & 0 & 0 & 1 \end{bmatrix} \end{matrix}$
Stream	[1,0,8,5,0,1,0,4,7,1,1,1]

Fig. 1. An Example CAS Stream

The derivation of this equation is fairly straight forward. Given the following augmented matrix:

$$\left[ \begin{array}{ccc|ccc} \alpha_{i,i} & \cdots & 0 & 1 & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \alpha_{i,j} & \cdots & \alpha_{j,j} & 0 & \cdots & 1 \end{array} \right]$$

we can solve for the inverse matrix value at position  $\alpha_{i,j}$ , via Gauss-Jordan elimination. Here, the rows at  $i$  and  $j$  are normalized:

$$\left[ \begin{array}{ccc|ccc} 1 & \cdots & 0 & \alpha_{i,i}^{-1} & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \alpha_{i,j} \times \alpha_{j,j}^{-1} & \cdots & 1 & 0 & \cdots & \alpha_{j,j}^{-1} \end{array} \right]$$

then the row at  $i$  (multiplied by  $\alpha_{i,j} \times \alpha_{j,j}^{-1}$ ) is subtracted from the row at  $j$ :

$$\left[ \begin{array}{ccc|ccc} 1 & \cdots & 0 & \alpha_{i,i}^{-1} & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 1 & -\alpha_{i,j} \times \alpha_{j,j}^{-1} \times \alpha_{i,i}^{-1} & \cdots & \alpha_{j,j}^{-1} \end{array} \right]$$

Note that in Fig. 1, the main-diagonal only contains ones. This matrix configuration is known formally as a “Semi-Byte” CAS and is one of the three main stream types. A Semi-Byte CAS is trivial to invert because the main-diagonal doesn’t need to be generated beforehand (as it is already known) and each value off of the main-diagonal is mapped via:

$$-\alpha_{i,j} \times 1^{-1} \times 1^{-1} = -\alpha_{i,j}$$

### B. Performing Constructive Affine Stream Transformations

Notice that the affine stream in Fig. 1 is not a consecutive series of matrix rows. These streams take advantage of the aforementioned matrix constraints to generate only the values necessary for vector transformation. Structurally, affine streams are organized by column and do not contain the zeroed half of the triangular matrix. Furthermore, they do not contain the zeros of zero-valued columns, only their diagonal component. For example, in Fig. 1, 8 was generated in  $r_2$ , therefore  $c_2$  must be a zero-valued column. The only value in the stream from  $c_2$  is its diagonal component: 1.

With these streams, a CAS Transformation can be applied to a vector (*vector*) by iterating over a CAS stream and, for each stream value  $v$ , we apply:

$$\text{transform}[r_v] \leftarrow \text{transform}[r_v] + (\text{vector}[c_v] \times v)$$

Where *transform* is an empty vector which stores the transformation and  $r_v$  and  $c_v$  are the row/column matrix coordinates of  $v$ . (e.g. In Fig. 1, 8 has the  $(r_v, c_v)$  coordinates  $(2, 0)$ .)

### III. IMPLEMENTATION

There are three (main) types of CAS: Binary, Semi-Byte and Byte. Each type requires methods for deterministically generating random bits and random non-zero numbers. The bits determine where non-zero values are placed in a matrix while the numbers determine what the values are. If the sequence of bits and numbers can't be regenerated, a transformation can't be inverted. For the sake of our experiments, we leveraged Trivium ([8]) for our bit generator and a simple linear congruential generator (LCG) for our number generator.

Note that in the implementation that follows: *rand* refers to some Pseudo-Random Number Generator (PRNG) initialized with a password which seeds the bit and number generator. (This password can be the same one used for multivariate encryption.) *lowerTriangular* is a Boolean indicating whether the generated CAS matrix is upper or lower triangular. Lastly, the operators  $*$  and  $+$  refer to group multiplication and addition specific to the chosen finite field.

#### A. Semi-Byte CAS Transformations

A Semi-Byte CAS generates an affine stream composed of 1's down the main-diagonal and 8-bit values everywhere else. Despite its name, matrix values aren't limited to 8-bits and should operate in whatever finite field is selected for encryption. (e.g.  $GF(2^8) \rightarrow$  8-bit matrix values,  $GF(2^{16}) \rightarrow$  16-bit matrix values) To save space, the implementation described below performs the vector transformation in-place. However, it could easily be modified to store the values in a new vector.

---

#### Algorithm 1 Semi-Byte CAS Transformation of a *vect*

---

```

1: emptyColumns  $\leftarrow$  [0] * vect.length
2: for  $i = 0$  to vect.length do
3:   if emptyColumns[ $i$ ] == 0 then
4:     for  $j = 1$  to vect.length -  $i$  do
5:       if rand.getBit() == 1 then
6:         scalar  $\leftarrow$  rand.getBytes()
7:         if lowerTriangular then
8:           vect[ $i + j$ ]  $\leftarrow$  vect[ $i + j$ ] + (vect[ $i$ ] * scalar)
9:         else
10:          vect[ $i$ ]  $\leftarrow$  vect[ $i$ ] + (vect[ $i + j$ ] * scalar)
11:        end if
12:        emptyColumns[ $i + j$ ]  $\leftarrow$  1
13:      end if
14:    end for
15:  end if
16: end for

```

---

In order to perform an inverse transformation (relative to a given seed) this implementation would be altered as follows:

- Line 8:  $\text{vect}[i + j] \leftarrow \text{vect}[i + j] - (\text{vect}[i] * \text{scalar})$
- Line 10:  $\text{vect}[i] \leftarrow \text{vect}[i] - (\text{vect}[i + j] * \text{scalar})$

#### B. Binary CAS Transformations

A Binary CAS generates an affine stream composed of only 0's and 1's. Its implementation is practically identical to that of a Semi-Byte CAS Transformation. However, in the case of Binary CAS Transformations, *scalar* is always equal to 1.

#### C. Byte CAS Transformations

A Byte CAS generates an affine stream composed of 8-bit values. (Again, bear in mind that values aren't necessarily fixed to 8-bits and, in reality, are bound by the chosen finite field.) These transformations cannot be done in-place and are the costliest in-terms of space-complexity. Implementation details regarding this transformation type can be found at [9].

### IV. ASYMPTOTIC ANALYSIS & PERFORMANCE

Compared to typical matrix-vector multiplication, CAS Transforms are quite efficient. In terms of space complexity, both Binary and Semi-byte CAS Transforms require only  $\Theta(n)$  space to store the columns flagged as zero-valued (*emptyColumns*). Byte CAS Transforms require  $2n$  space for transformations and  $3n$  for inversions, giving both operations a lower-bound of  $\Omega(n)$ .

Computing time-complexity is slightly more complicated due to the probability involved in CAS generation. While normal matrix-vector multiplication is an  $n^2$  operation (for square matrices), CAS Transformations effectively "skip" zero-valued columns as they only operate on their diagonal component. Because these columns are skipped, we can compute the average upper-bound of a CAS Transform by multiplying the height of the columns by the average number of non-zero columns. However, this requires a function which can approximate the average number of non-zero columns a CAS will generate given a matrix size.

While there are several approaches that could be used to derive this function, we chose a statistical approach as it seemed to yield the best estimates. This approach involved randomly generating 5000 (Binary) CAS matrices at each size ranging from  $1 \times 1$  to  $3000 \times 3000$  and computing the average number of non-zero columns at each size. Each matrix was generated using its own instantiation of Trivium initialized with the first 160-bits of a SHA-256 hash derived from a (randomly generated) alphanumeric password. Plotting these results, it appears that the number of non-zero columns grows in a logarithmic fashion. Indeed, once we fitted a logarithmic curve to the data we found that it fit perfectly (Fig. 2a).

This would seem to indicate that the runtime of a CAS Transformation is on average  $O(n \log n)$ . To verify this result, we plotted the average length of a CAS stream. Using the same parameters, (5000 trials over 3000 sizes) we found that the average length of a CAS stream perfectly fits an  $n \log n$  curve (Fig. 2b). Note, this run-time applies to all CAS types because all types generate their matrix structure using the same bit generation algorithm (in our case, via Trivium).

With the proper implementation, these transformations have the potential to reach impressive speeds and are limited primarily by their chosen bit and number generation algorithms.

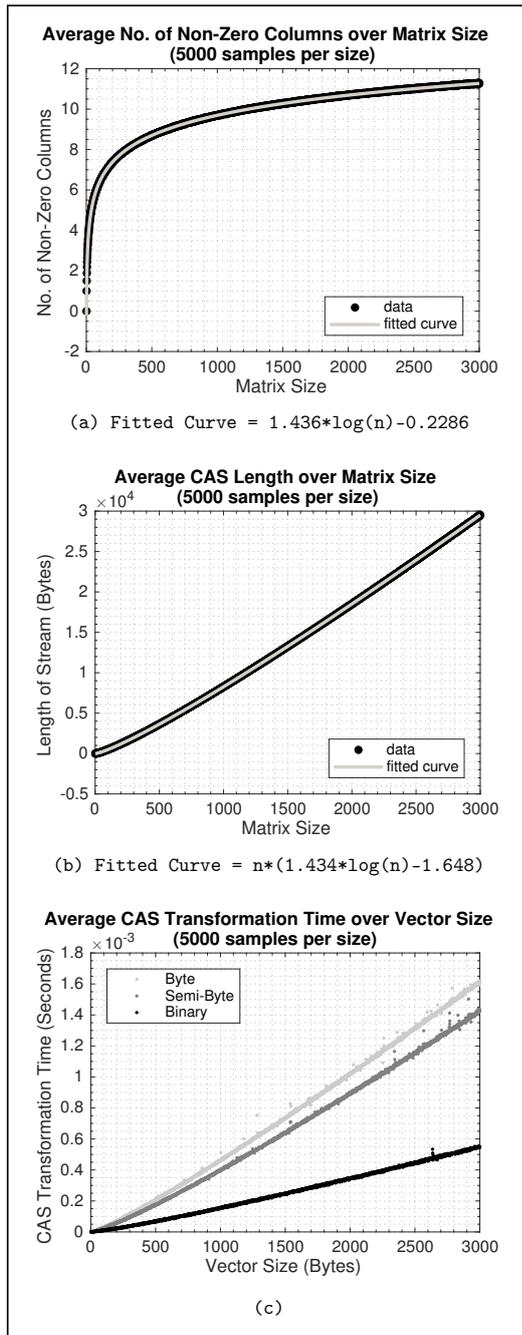

Fig. 2. Runtime Statistics &amp; Time Plots

Our naïve C implementation (run on a computer with an Intel Core i5-3570 processor running at 3.40GHz using 16GB of RAM, with Windows 10 Pro) achieved respectable speeds on its own (Fig. 2c). However, it could be made to operate even faster with an optimized Trivium implementation. In theory a CAS stream could even be cached and applied over blocks. Observe that our speed tests further support our time-complexity analysis as the speed plots reflect our time-complexity plot.

## V. SECURITY

In practice, one CAS Transformation alone isn't enough to sufficiently "mix-up" an input vector. In fact, any triangular matrix on its own isn't enough. The use of single triangular matrices can even break certain multivariate schemes. For example, the multivariate scheme based on the family of expander graphs  $D(n, q)$  is rendered totally insecure when  $S$  and  $T$  take the form of lower-triangular matrices. (For more details about this family of graphs see [10].) To illustrate this insecurity, consider Example 5.1.

*Example 5.1 (The "Poor Mixing" Vulnerability):*

$$\text{Plaintext} = [x_1, x_2, x_3, x_4]$$

$$\text{Password} = [2, 1, 10, 5]$$

$$T = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 \end{bmatrix}, \quad S = T^{-1} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 1 & 0 \\ 1 & -1 & -1 & 1 \end{bmatrix}$$

(Note: Often  $S = T^{-1}$  but it is not a general rule.)

The resulting polynomials produced using  $S$ ,  $T$ , and the polynomials generated from  $D(n = 4, q)$  graphs (traversed with *Password*) are:

$$p_1(x_1) = x_1 + 18$$

$$p_2(x_1, x_2) = -18x_1 + x_2 - 201$$

$$p_3(x_1, x_2, x_3) = -18x_1^2 - 201x_1 - 18x_2 + x_3 - 513$$

$$p_4(x_1, x_2, x_3, x_4) = 36x_1^2 + 621x_1 + 18x_2 + x_4 + 3261$$

For the sake of simplicity, these polynomials are not bound to any specific finite field  $GF(q)$ . (All work is shown at [9].)

Notice that each subsequent polynomial introduces one new variable ( $x_i$ ). So, given the piece of ciphertext  $c_1$  produced by  $p_1(x_1)$ , it would be trivial to compute the plaintext piece  $x_1$  by solving  $x_1 = c_1 - 18$ . Then, given  $x_1$ , we could solve for  $x_2$  in  $p_2(x_1, x_2)$  by plugging in  $x_1$  and  $c_2$ . This process can be repeated until all  $x_i$ 's have been solved for and the plaintext message is revealed (without use of the private key).

To eliminate this vulnerability, a lower and upper triangular CAS Transformation can be combined to form a "Square CAS Transformation." This is simply achieved by applying an upper and lower triangular CAS Transformation to a vector, in any order. Because matrix multiplication is associative, this is equivalent to multiplying a vector by the product of an upper and lower triangular CAS matrix. In fact, simulations have shown that a combined upper and lower CAS Transformation correspond to multiplication by a matrix  $A$ , such that for all  $i \neq j$   $P(a_{i,j} = 0) \approx 0.65$  and  $i = j$   $P(a_{i,j} = 0) \approx 0.35$  [9].

Illustrated below are the corrected polynomials which leverage an upper and lower triangular matrix for both  $S$  and  $T$ :

$$p_1(x_1, x_2, x_3, x_4) = -54x_1^2 - 216x_1x_2 - 108x_1x_3 - \dots$$

$$p_2(x_1, x_2, x_3, x_4) = 18x_1^2 + 72x_1x_2 + 36x_1x_3 + \dots$$

$$p_3(x_1, x_2, x_3, x_4) = -18x_1^2 - 72x_1x_2 - 36x_1x_3 - \dots$$

$$p_4(x_1, x_2, x_3, x_4) = 36x_1^2 + 144x_1x_2 + 72x_1x_3 + \dots$$

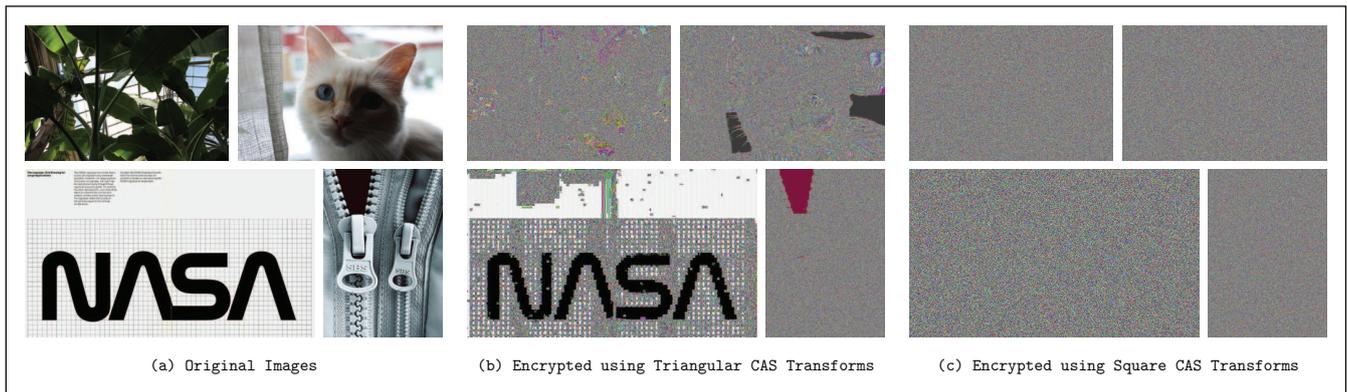

Fig. 3. Image Encryption Tests

A Square CAS Transform can easily be inverted by applying the inverse of its lower and upper triangular components in reverse order. That is, given a vector  $\sigma$ , its transformation  $\sigma'$ , and a triangular CAS Transform  $T(x)$ :

$$T_{lower}(T_{upper}(\sigma)) = \sigma', \quad T_{upper}^{-1}(T_{lower}^{-1}(\sigma')) = \sigma$$

We can visualize this “poor mixing” vulnerability by encrypting image data. In Fig. 3, the images in (a) are composed with an upper-triangular (Semi-Byte) CAS  $T$ , passed through a set of polynomials (from  $D(n, q)$ ), and then composed with another upper-triangular CAS  $S$  to produce the images in (b). Clearly, a large amount of information is exposed. However, if we utilize a square (Semi-Byte) CAS for both  $S$  and  $T$  we produce the images in (c). (Additional tests with alternate configurations can be found at [9].)

While in theory more than two CAS Transformations could be applied to a single vector, Square CAS Transforms on their own have shown to be sufficient.

To further validate the security of Square CAS Transforms, we analyzed the average order of each (square) CAS type. This statistic is of particular interest as there is theoretical evidence which suggests that large order matrices provide better security [11]. (The order of a matrix  $M_{n \times n}$  over a finite field is the smallest positive integer  $k$  such that  $M^k = I_n$ .) At present, the resources required to compute  $k$  over large matrices has restricted our ability to collect large samples of data. However, our initial tests indicate that the order of a Binary matrix rarely exceeds  $k = 120$ . In contrast, Semi-Byte and Byte matrices have both exhibited  $k$ 's in the millions and even billions [9]. This suggests what one might already expect; Semi-Byte and Byte Transforms are considerably stronger than Binary Transforms, making them the preferred choice for most implementations.

## VI. CONCLUSION

As quantum computers march closer towards their full realization we must be prepared with a new set of cryptographic primitives which remain secure in the post-quantum age. Multivariate Cryptography is one of the handful of primitives which has shown real promise but still requires more research

and development before it can be realistically implemented. In this paper we formalized the notion of CAS Transformations, a set of algorithms capable of performing specialized, large-scale, affine transformations in  $O(n)$  space-complexity and  $O(n \log n)$  time-complexity. While there is still more to be learned about these transformations, they have demonstrated real potential; capable of increasing the speed and scale at which Multivariate Cryptography can be applied.

**Abstract.** This paper presents an application of spline-wavelet transformation and bent-functions for the construction of robust codes. To improve the non-linear properties of presented robust codes, bent-functions were used. Bent-functions ensure maximum non-linearity of functions, increasing the probability of detecting an error in the data channel. In the work different designs of codes based on wavelet transform and bent-functions are developed. The difference of constructions consists of using different grids for wavelet transformation and using different bent-functions. The developed robust codes have higher characteristics compared to existing. These codes can be used for ensuring the security of transmitted information.

## I. INTRODUCTION

Wavelet transformation has become well known and widely used in many fields of science [1-3]. The basic concepts of wavelet theory can be found in the work of Daubechies [3]. Also, wavelet theory has found implementation in the technical fields such as data compression, signal analysis, and communication applications [4-7].

One new direction of implementing wavelet theory is error protection codes [6-7, 9-15]. Error detecting codes are used for the protection in telecommunication channels, they ensure the reliability and security of devices from soft, hard errors and side channel attacks [17]. The purpose of error correcting codes is to provide digital communication over the channel in such a way that errors in the transmission of bits can be detected and corrected by the receiver. This goal is achieved by using coding algorithms that convert information before sending it [16-19].

By exercising various effects on the hardware component of a cryptographic device in order to cause distortion of information at some stages of coding, managing and analyzing errors, an attacker can change the information transmitted over the channel. This type of attack is called a calculation error attack [17]. To provide protection against this type of attack, robust codes built on non-linear functions are used because linear functions do not show all errors due to linear properties [16-17]. And often the most interesting are non-linear functions for which the property of non-linearity is bent function [8].

In this article, was investigated the properties of robust codes constructed on bent functions and wavelet decompositions. Will be presented various methods for constructing this class of codes, their advantages and disadvantages are analyzed, and their comparison with existing codes is carried out.

## II. WAVELET TRANSFORM

In this section, will be explained the idea of wavelet transformation [1-7], more detailed information can be found in the works of Daubechies [3].

Let function  $s(t)$  belong to the Hilbert space  $L^2(R)$  with the scalar product  $\langle f(t), g(t) \rangle = \int f(t)g(t)dt$  and the norm  $\int |s(t)|^2 < \infty$ . The idea of the wavelet transform is based on the partition of the signal  $s(t)$  into two components, approximating  $A_m(t)$  and detailing  $D_m(t)$ .

$$s(t) = A_m(t) + \sum_{i=1}^m D_i(t),$$

where  $m$  denotes the decomposition (reconstruction) level.

In this article, will be used wavelet transformation or rather a spline-wavelet transformation for creating an error detection code. In this paper will be explained the idea of spline-wavelet transformation, only for the splines of the first order, which will be used for the construction of codes.

Let  $X$  be a non-uniform grid of elements,  $X = \{x_j\}_{j \in Z}$ , where  $Z$  is the set of integers. Splines of the first order on the grid  $X$  are defined as follows:

$$\begin{aligned} \omega_j(t) &= (t - x_j)(x_{j+1} - x_j)^{-1}, t \in [x_j, x_{j+1}), \\ \omega_j(t) &= (t - x_j)(x_{j+1} - x_j)^{-1}, t \in [x_{j+1}, x_{j+2}), \\ \omega_j(t) &= 0, t \notin [x_j, x_{j+2}), \end{aligned}$$

where  $\omega_j(t)$  – splines,  $x_j$  – elements of  $X$ .

In the process of wavelet decompositions, some element  $x_k$  is thrown out of the grid  $X$ , after this transformation a new grid  $\tilde{X}$ , on the basis of which new splines  $\tilde{\omega}_j(t)$  are constructed. New and old splines are interconnected. This relationship between the elements  $\tilde{\omega}_j(t)$  and  $\omega_j(t)$  can be shown by the formulas:

$$\begin{aligned} \tilde{x}_j &= x_j, \text{ if } j \leq k - 1, \tilde{x}_j = x_{j+1}, \text{ if } j \geq k, \\ \varepsilon &= x_k, \tilde{\omega}_j(t) = \omega_j(t), \text{ if } j \leq k - 3 \\ \tilde{\omega}_j(t) &= \omega_{j+1}(t), \text{ if } j \geq k \\ \tilde{\omega}_{k-2}(t) &= \omega_{k-2}(t) + \tilde{\omega}_{k-2}(x_k)\omega_{k-1}(t) \\ \tilde{\omega}_{k-1}(t) &= \omega_{k-1}(t) + \tilde{\omega}_{k-1}(x_k)\omega_{k-1}(t) \end{aligned}$$

With the help of spline-wavelet decompositions, it is possible to create a large number of different codes constructions among themselves.

## III. BENT FUNCTION

The measure of nonlinearity is an important characteristic of a Boolean function in cryptography. Linearity and properties close to it often indicate a simple (in a certain sense) structure of this function and, as a rule, represent a rich source of information about many of its other properties. The problem of constructing Boolean

functions possessing nonlinear properties naturally arises in many areas of discrete mathematics. And often the most interesting are those functions for which these properties are extreme. Such Boolean functions are called bent functions. A bent function can be defined as a function that is extremely poorly approximated by affine functions [1].

The nonlinearity of a function  $f$  is the distance from  $f$  to a class of affine functions. Let's denote the nonlinearity of the function  $f$  in terms of  $N_f : N_f = d(f, A(n)) = \min_{g \in A(n)} d(f, g)$ , where  $A(n)$  is the class of linear functions.

The function  $f \in P_2(n)$  is called maximally nonlinear if  $N_f = 2^{n-1} - 2^{(n/2)-1}$ .

*Definition:* A bent function is a Boolean function with an even number of variables for which the Hamming distance from the set of affine Boolean functions with the same number of variables is maximal.

Example:  $f(x_0, x_1, x_2, x_3) = x_0x_1 + x_2x_3$

From the point of view of cryptography, the important criteria that a Boolean function  $f$  of  $n$  variables must satisfy are the following:

1) equilibrium — the function  $f$  takes values 0 and 1 equally often;

2) the propagation criterion  $PC(k)$  of order  $k$ - for any nonzero vector  $y \in Z_2^n$  weight at most  $k$ , the function  $f(x+y) + f(x)$  is balanced;

3) the maximum nonlinearity - the function  $f$  is such that the value of its nonlinearity  $NF$  is maximal;

The bent function matches the criteria for propagation and maximum non-linearity, which allows it to detect all errors in the channel and to have a uniform probability of detecting errors, but the function is not balanced.

#### IV. SPLINE-WAVELET ROBUST CODE

In this section, will be described the rules for the formation of code words for a particular code construction, a comparison of these codes with examples of linear and nonlinear codes are also will be given.

Robust codes are nonlinear systematic error-detecting codes that provide uniform protection against all errors without any (or that minimize) assumptions about the error and fault distributions, capabilities and methods of an attacker [12, 16-18].

Let  $M = |C|$ , this is the number of codewords in code  $C$ . By the definition of an  $R$ -robust code, there are no more than  $R$  code words that cannot be detected for any fixed error  $e$ .

$$R = \max \{ |x| \mid x \in C, x + e \in C \}$$

The probability of masking the error  $e$  can be defined as:

$$Q(e) = \frac{|\{x \mid x \in C, x + e \in C\}|}{M}$$

One of the main criteria for evaluating the effectiveness of a robust code is the maximum error masking probability. The maximum error masking probability can be defined as

$$\max Q(e) = \max \frac{|\{x \mid x \in C, x + e \in C\}|}{M} = \frac{R}{M}$$

The following is the construction of robust codes based on bent functions and spline-wavelets with the static grid,

and grid based on the codeword. The additional elements are calculated on the basis of bent functions from information elements and spline-wavelet elements, the result is also a bent function. The function for the additional elements is the bent function (code Kerdock), the elements are the informational elements and wavelet elements. So, the new function is created, because wavelet elements are the function of several informational elements. This function is also bent function, it was checked for all grid values. The new bent function is created, with another properties.

Let  $c = \{c_1, c_2, \dots, c_{n-1}, c_n\}$  denotes the code word of some shared  $(n, k)$  code. Then  $\{c_1, c_2, \dots, c_{k-1}, c_k\}$  is the information part, and  $\{c_{k+1}, \dots, c_n\}$  - additional.

*Construction 1. Spline-wavelet bent robust code with a static grid.*

In this construction, for all code, a grid is selected  $x = \{x_1, x_2, \dots, x_{n-1}, x_k\}$ , any elements are discarded at the discretion of the specialist, the number of discarded items is equal to  $(n-k)/2$ . Number of characters is strictly even and multiple 4, attitudes  $\frac{k}{n} = \frac{2}{3}$ . The ejected elements will be denoted by the set  $z = \{z_1, \dots, z_{(n-k)/2}\}$ . The wavelet elements will be denoted by the set  $b = \{b_1, \dots, b_{(n-k)/2}\}$ . Let  $c = (c_1, c_2, \dots, c_n)$  - vector field  $GF(2^n)$ ,  $1 \leq i \leq n$ . The vector  $c$  belongs to the code if

$$c_{k+j} = b_j = c_{z_i} + c_{z_i+1} + (x_{z_i+2} + x_{z_i-1})(x_{z_i+2} + x_{z_i})^{-1}(c_{z_i-1} + c_{z_i+1})$$

For even  $z_i$ :

$$c_{k+j+(n-k)/2} = c_1 * c_2 + \dots + b_j * c_{z_i-1} + \dots + c_{k-1} * c_k$$

For odd  $z_i$ :

$$c_{k+j+(n-k)/2} = c_1 * c_2 + \dots + b_j * c_{z_i+1} + \dots + c_{k-1} * c_k$$

Where  $1 \leq j \leq (n-k)/2$ ,  $k$  - the number of parity symbols in the code,  $z_i \in z, +$  - addition mod 2,  $c_{k+j+(n-k)/2}$  is the bent function's element.

This construction is built on a static grid, which is not always good, because it will be necessary to transfer the grid between the receiver and the transmitter.

*Construction 2. Spline-wavelet bent robust code with a grid based on the codeword.*

In this construction, for all code, a grid is selected  $x = \{x_1, x_2, \dots, x_{n-1}, x_k\}$ , based on the information part of the codeword, and depending on the number of the ejected element. The grid is equal to the shift relative to the number of the element that is thrown, that is  $x[i] = c[(i-z_i) \pmod{n-k}]$ . The wavelet elements will be denoted by the set  $b = \{b_1, \dots, b_{(n-k)/2}\}$ . Let  $c = (c_1, c_2, \dots, c_n)$  - vector field  $GF(2^n)$ ,  $1 \leq i \leq n$ . The vector  $c$  belongs to the code if

$$c_{k+j} = b_j = c_{z_i} + c_{z_i+1} + (x_{z_i+2} + x_{z_i-1})(x_{z_i+2} + x_{z_i})^{-1}(c_{z_i-1} + c_{z_i+1})$$

For even  $z_i$ :

$$c_{k+j+(n-k)/2} = c_1 * c_2 + \dots + b_j * c_{z_i-1} + \dots + c_{k-1} * c_k$$

For odd  $z_i$ :

$$c_{k+j+(n-k)/2} = c_1 * c_2 + \dots + b_j * c_{z_i+1} + \dots + c_{k-1} * c_k$$

Where  $1 \leq j \leq (n-k)/2$ ,  $k$  - the number of parity symbols in the code,  $z_i \in z, +$  - addition mod 2.

This construction is built on a grid, based on the codeword, and it solves the problem of the transfer grid, but the algorithm is more time consuming. Created constructions have better parameter than existing, presented example will show the difference between created constructions and existing solutions.

*Example:* Consider the composition of construction 1 and construction 2 for  $n=8$  and  $k=4$ .

In order to obtain the code of this kind, we will consider redundant symbols, as a result of the bent-function of the additional stream  $b$  and other information symbols. It is necessary to make sure that the result of the interaction of the main stream and the additional one is also a bent function. The number of the ejected element is taken equal to three (the number of the ejected element does not affect anything, you can throw out other elements, getting other formulas, but this does not affect the final result).

Formulas for decomposition and reconstruction when the element is kicked out under the number  $k$  have the form, provided that  $x_{k+2} \neq x_k$ :

$$b_k = c_k - c_{k+1} - (x_{k+2} - x_{k-1})(x_{k+2} - x_k)^{-1}(c_{k-1} - c_{k+1})$$

$$c_k = b + c_{k+1} - (x_{k+2} - x_{k-1})(x_{k+2} - x_k)^{-1}(c_{k-1} - c_{k+1})$$

As a bent function for the code, will be take the formula  $f = c_1c_2 + c_3c_4 + c_5c_6 + c_7c_8$ . When the third element will be thrown out. The element  $c_3$  will be replaced on the additional flow element  $b_3$ , and  $c_5$  on the additional flow element  $b_5$ . Functions takes the form  $f_1 = c_1c_2 + b_3c_4 + c_5c_6 + c_7c_8$  and  $f_2 = c_1c_2 + c_3c_4 + b_5c_6 + c_7c_8$ , the addition goes modul 2, corresponds to the operation XOR.

Because these functions are bent functions, so, independently of the values of the grid, the function  $f$  is a bent-function. The result of the function  $f$  will be used as a redundant symbol  $r_0 = f_1$ , and the redundant symbol  $r_1 = b_1$  (element of additional stream),  $r_2 = f_2$ ,  $r_3 = b_2$ .

Let's compare this code with different values of a grid with a linear code and a robust code of the same length. In the example, as the linear code was taken Hamming code (8,4). Redundant symbols for a nonlinear code will be equal to  $r_0 = c_1c_2 + c_3c_4 + c_5c_6 + c_7c_8$ ,  $r_1 = c_1c_3 + c_2c_4 + c_6c_8 + c_5c_7$ ,  $r_2 = c_1c_5 + c_2c_6 + c_3c_7 + c_4c_8$ ,  $r_3 = c_1c_3 + c_2c_4 + c_6c_8 + c_5c_7$  (code Kerdock).

Let's draw up a graph of error detection probabilities for a spline-wavelet code with a static grid — construction 1, for a spline-wavelet code with a codeword-based grid — construction 2, for a “robust” Kerdock code and a linear code, the result is displayed in Figure 1.

The Hamming code does not match the equiprobability of the error, which makes this code vulnerable to attack by the attacker, in contrast to the Kerdock code and construct 1.

The average probability of detecting an error is insignificantly different for the construction 1, the construction 2, and the robust Kerdock code. In the case of

linear code, the probability is uneven, which makes this code vulnerable to attacks on third-party channels.

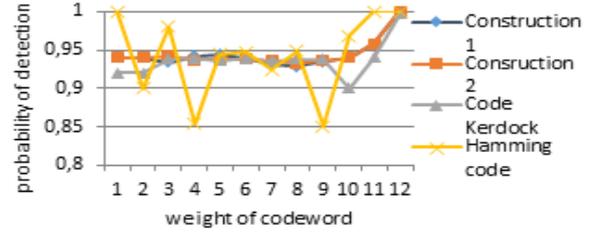

Fig. 1. Error detection probability for different code constructions

Compare the number of the maximum probability of masking errors of these codes and display the results in Table 1, as well as the time, is taken to encode 4000 bytes.

Table 1. Probability of maximum error concealment for different code constructs

Code	maximum probability of error concealment, $Q(e)$	Number of time measurement, sec
Construction 1	0,5	0,045
Robust code Kerdock	0,5	0,067
Hamming code	1	0,037
Construction 2	0,46875	0,067

Codes constructed on the basis of spline-wavelet decompositions using bent functions have a number of advantages in different characteristics compared to other codes. Construction 1 has good coding time, does not have undetectable errors. Construction 2 has the bad coding time, but has no undetected errors, and has the smallest value of the maximum probability of masking the error.

For codes based on bent functions and wavelet transformations, there will always be an even number of information symbols, since bent functions exist only for an even number of variables, and codes have poor coding time scores compared to linear codes.

## V. SPLINE-WAVELET CODE ON BENT FUNCTION WITH DIFFERENT DEGREES

In the case of construction 1, the degree of the bent functions is equal to 2, in the case of the construction 2, the degree of the bent functions is 3 or 2, depending on the symbols to be erased. As a result, an assumption immediately arises that an increase in the degree of the curved function can give the best values for the parameter  $R$ .

The degree of the bent function cannot exceed  $n/2$  [8], and therefore one can not single out a single construction for an arbitrary number of variables.

In this section will be shown functions with different degrees based on spline wavelets and information symbols for  $n = 8$ , they will be compared by the parameter  $R$ . For each number of variables, bent functions were constructed on the basis of spline wavelets. For all functions, the wavelet element is calculated from the same function:

$$Wave_k = c_k - c_{k+1} - (x_{k+2} - x_{k-1})(x_{k+2} - x_k)^{-1}(c_{k-1} - c_{k+1})$$

Functions for n=8 presented in table 2, also given the conditions of the grid and the degree of function.

Table 2. Spline wavelet Bent functions for n=8

Number of function	Grid	Function	Deg(f)
1	$x_i = c_i$	$f_i = c_{i+1} * c_{i+3} * c_{i+4} + c_{i+2} * c_{i+3} * c_{i+5} + Wave_{i+2} * c_{i+6} + c_i * c_{i+3} + c_i * c_{i+5} + c_{i+2} * c_{i+3} + c_{i+2} * c_{i+4} + c_{i+2} * c_{i+5} + c_{i+3} * c_{i+4} + c_{i+3} * c_{i+5} + c_{i+6} * c_{i+7}$	4
2	Static	$f_i = c_i * c_{i+1} * Wave_{i+2} + c_{i+1} * c_{i+3} * Wave_{i+4} + c_i * c_{i+1} + c_i * c_{i+3} + c_{i+1} * c_{i+5} + c_{i+2} * c_{i+4} + c_{i+3} * c_{i+4} + c_{i+6} * c_{i+7}$	3
3	$x_i = c_{7-i}$	$f_i = c_i * c_{i+1} + Wave_{i+2} * c_{i+3} + c_{i+4} * c_{i+5} + c_{i+6} * c_{i+7}$	4
4	Static	$f_i = c_i * Wave_i + c_{i+1} * Wave_{i+2} + c_{i+2} * Wave_{i+4} + c_i * c_{i+3} + c_{i+1} * c_{i+5} + c_{i+2} * c_{i+3} + c_{i+2} * c_{i+4} + c_{i+2} * c_{i+5} + c_{i+3} * c_{i+4} + c_{i+3} * c_{i+5} + c_{i+6} * c_{i+7}$	2

Let's compile the code constructions for all the above functions with 2 redundant symbols  $r_0 = f_0, r_1 = f_1$ . Calculate the parameter R and maximum probability of error concealment, the results are listed in Table 3.

Table 3. Parameter R for n=8

Function	The degree of bent function	R	maximum probability of error concealment, Q(e)
Function №1	4	96	0,375
Function №2	3	120	0,46875
Function №3	4	96	0,375
Function №4	2	128	0,5

The degree of the bent function different from 2 gives a better result for the parameter R. The number of calculations and the time spent on coding information is more compared to the codes built on bent functions with a power of 2. When these codes are used in the case protection against attack by an attacker, then the parameter R is more important. Using spline wavelets, it is possible to build a large number of robust codes, build bent functions and increase their degree, thereby improving the quality of robust codes. So new construction is created with parameter R lower than construction 1 or construction 2.

*Spline-wavelet robust code with lower value R*

Let  $c = \{c_1, c_2, \dots, c_{n-1}, c_n\}$  denotes the code word of some shared  $(n, k)$  code. Then  $\{c_1, c_2, \dots, c_{k-1}, c_k\}$  is the information part, and  $\{c_{k+1}, \dots, c_n\}$  - additional,  $n = k + 2$ . Grid is selected depending on the spline wavelet function,  $f_i(c_1, c_2, \dots, c_{k-1}, c_m)$  is a function from table 2,  $m = 8$ . The vector  $c$  belongs to the code if

$$c_{k+1} = f_0(c_1, \dots, c_m) + c_{m+1} * c_{m+2} + \dots + c_{k-1} * c_k;$$

$$c_{k+2} = f_1(c_1, \dots, c_m) + c_{m+1} * c_{m+2} + \dots + c_{k-1} * c_k.$$

This construction allows better protection against side-channel attacks, because parameter R and maximum probability of error concealment Q(e) lower than existed solutions, but it takes more time for the coding information.

**Conclusion**

In this paper, was described as the error-correcting coding scheme based on wavelet transformation and bent functions. For the proposed scheme, was created wavelet robust codes on bent functions. The robust wavelet code has no undetectable errors, so it ensures reliable protection against the error injection, also has the high values of the parameter R.

**Abstract**—Security of cryptographic keys is one of the most important issues in a key management process. The question arises whether modern technology really allows for a high level of physical protection and security of sensitive data and cryptographic keys. The article considers various contemporary types of threats associated with the storage of secret keys. We present an innovative way to store sensitive data, using DNA strands as a medium, which significantly reduces hazard connected with electronic devices based data storage and makes the key management process independent of third parties.

## I. INTRODUCTION

SECRET keys are usually stored in hard drives placed in computer devices with access secured with a simpler several-character password or on portable flash drives. Such solutions have many disadvantages and really do not guarantee a high level of data security or even in some cases usability. There are a few important reasons why the cryptographic data is not completely safe if it is stored on portable devices (in NAND memory chips) or magnetic storage devices. It is obvious that access to stored cryptographic keys needs at least computer devices with access to wider resources eg. Internet network. With the current complexity of digital systems, we can not fully guarantee security, which to some extent, relies on trust in the integrity of digital system manufacturers and designers. Absolute security, at least theoretically, can only be guaranteed by the lack of participation of third parties in the process of managing and storage of cryptographic keys (creation, storage, use and destruction). If we consider it necessary to use electronic devices, this entails additional risks, in particular, due to the lack of access to stored data during power system failure caused for example by Solar Storm. In the article, the new cryptographic keys management system based on DNA strands is presented. The contributions of our concept are as follows:

- security increase by excluding third parties from the process of storing and reading the key,
- lack of weaknesses and vulnerabilities associated with storing cryptographic keys on portable electronic devices,
- no susceptibility to data destruction caused by strong electromagnetic fields,
- enormous difficulty in accessing data (e.g. cryptographic keys) by unauthorised persons in case of loss of control,

- no need to use DNA sequencing devices to read stored data (minimal resources infrastructure),
- data transferability in a way that can be almost completely undetectable in physical form.

## II. RELATED WORK

In the domain of cryptography key management systems based on biosystems one can analyse three issues: bio cryptography, third-party key management and environmental threats.

### A. Bio cryptography

The use of DNA strands to store information and even perform simple "calculations" is not a completely new idea. Adelman in his work showed the possibility of using fragments of specially prepared DNA strands to solve the problem of Hamilton's path [1]. Gehani together with others created the basis of DNA-based cryptosystem based on the idea of One Time Pad [2]. In the work of Y. Zhang, X. Lui and M. Sun a practical implementation of the problem of key distribution for the OTP method was shown [3]. The sequence of nucleotides in a randomly selected fragment of DNA is used as the key to encrypt the message. The explicit text has been replaced with a sequence of bits and using the XOR function joined with the key string. The key, based on the DNA sequence can be obtained by using one of the possible substitutions of nucleotides: A - 00, C - 01, T - 11, G - 10. Next, the "DNA key" was „glued" to the plasmid and placed in the bacterial cell. The environment inside the bacteria allows you to stably hold the information contained in the DNA strand, which is very sensitive to changes in the temperature and pH of the solution in which it is located. The stability of the DNA accumulated in bacterial cells carried out in the state of spore is impressive. Scientists have been able to read genetic material from *Subtilis* bacteria, which is millions of years old [4], [5]. Modern laboratory techniques allow for stable storage synthetic DNA in Silica for thousands of years [6], [7]. This may be important if it is necessary to store relevant information (in particular cryptographic information) for a very long period of time. Traditional storage technologies such as magnetic devices and optical discs are not reliable for really long-term data storage. Their lifespan is estimated to be about 50 years [8].

Halvorsen and Wong in his paper [9] showed an interesting, simple and secure system for encrypting and decrypting information using self-assembly DNA structures and PCR based decoded information reading method. Tanaka, Okamoto and Saito presented a system for public key distribution based on DNA as a one-way function [10]. Using the methods and algorithms described in the works of A. Leier [11] and H. J. Shiu [12], one can hide the message in a DNA sequence in an encrypted or unencrypted way. Such stenographic techniques require active synthesis of deoxyribonucleic acid chains. The text is encrypted directly in the series of A, C, T and G, or special groups are identified later as counterparts of binary zeros and ones. The presented methods require both synthesis and sequencing devices at almost every stage of work with data stored in DNA, which seems to be an inconvenience in a certain class of applications. Some ideas presented in the last two publications are applied further. The DNA chain can also be successfully used in forensics [13] as well as for invisible product tagging [14].

### B. Third-parties keys management

A user who really cares about the security of his or her data cannot be sure that the data storage devices, produced by third parties, do guarantee real security. This is due to the fact that the average user does not have access to the exact device specification and is not able to check if the electronic systems controlling the memory chips do not allow easy access to data stored by unauthorized entities. In other words, strong cryptography and ultimate cryptographic keys security require the assumption of complete distrust in the devices that are used. The continuous reduction in the size of integrated circuits leads to increased production costs. This forces a vast majority of chip design companies to trust an external third party in chip fabrication, but outsourcing of chip fabrication opens-up hardware to attack. The way of preparing post fabrication tests leave an open door for implementing malicious modifications and backdoors. Even if there are no equipment manufacturers bad intentions there is always a possibility that there has been interference of third parties.

Researchers at the University of Michigan showed in their paper [15], that there is a possibility to create a novel fabrication-time attack based on modifications of the semiconductor structure in integrated circuits. It can be done by adding even single component to "mask" - a blueprint of the chip before its production. Such modifications are hardly detected during the test procedure. This kind of attack is triggered by special *unlike* sequence of commands and allows to give a malicious program the full operating system access.

Other, pernicious fabrication-time attack named dopant-level Trojan bases on conversion trusted circuits into malicious circuitry in chip structure by changing the dopant ratio on the input pins to transistors [16], [17]. Circuits converted to Trojans are very difficult to detect due to the lack of added circuit elements and require imaging with a scanning electron microscope.

Spiegel Online reports in his article [18] that the US National Security Agency (NSA) is in possession of specially prepared "computer buggung" devices that look like typical USB plugs. These devices are capable of sending and receiving data via radio link being undetected.

In October 2018 Bloomberg reported that special microchips were inserted into server motherboards during the production process. The motherboards are components of servers operating in many companies inside their datres. Some of these chips were built as if they were necessary elements for the proper operation of the entire system. Installed chips have enough processing power to carry out an attack or be used to gain unauthorized access to data [19].

### C. Environmental threats

One of the important factors that should be taken into account when cryptographic data is stored on electronic devices and magnetic storage devices is their relatively high sensitivity to strong electromagnetic fields. These kinds of fields can be produced in two ways: as EMP pulses (Electro-Magnetic Pulse) or during the Electromagnetic Solar Storm, especially in the so-called Coronal Mass Ejection.

It is worth to mention at least about two cases of CME, which had a significant impact on the human created infrastructure. The first one is The Solar Storm of 1859 (known as Carrington Effect). During this storm, Earth's magnetic field disturbances caused by CME led to telegraph network failures throughout Europe and North America in some cases giving telegraph operators electric shocks. The second one took place on March 13, 1989. A severe geomagnetic storm struck Earth causing nine hours blackout in Quebec, Canada.

Report prepared by Metatech Corporation [20] describes the threat of the early-time (E1) High-altitude Electromagnetic Pulse (HEMP) produced by nuclear detonations above an altitude of 30 km. The pulse is driven by gamma photons produced in nuclear reactions within the nuclear burst. The main impact has such impulse on the power grid that can be totally damaged, but as the report shows, computers and small electronic devices are also at risk of damage what can make them unusable.

## III. THE METHOD

In this paper, we use and extend the concept presented in the work of [11], where the single bits of information are represented by groups of nucleotides. With certain restrictions, this solution allows to easily generate sequences of data stored in DNA without the need to use synthesis devices. If the prepared data contain secret information, for example, password or cryptographic keys then, as it was mentioned earlier, the lack of third parties engagement during the synthesis process significantly increases data security.

### A. DNA data structure

DNA strand with data stored within, consist of a series of specially prepared components – some kind of building blocks which in fact are shorter fragments of double-stranded DNA

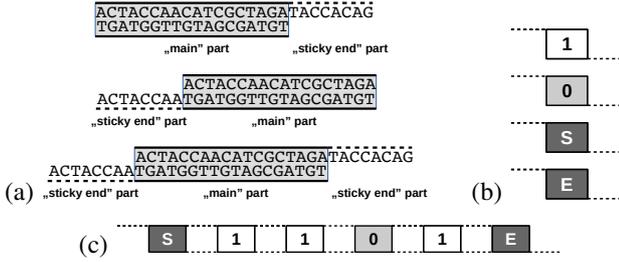

Fig. 1. (a) Structure of simple DNA component. Structural components to build simple DNA data strand. (b) Structural components to build simple DNA data strand. (c) Example of structure of four bit DNA strand.

ended with single-stranded regions called sticky ends. The general shape of a single components is presented in Figure 1 (a). The main part identifies some sort of data stored as a series of nucleotides. These nucleotides can represent a bit or index of extracting parts. Sticky ends are free fragments of one-sided DNA strand that can easily bind to other complementary part connected to the other fragments to producing longer strands.

In the simplest case to store data in DNA as a series of 0 and 1 bits one needs at least four structurally different fragments (see Figure 1 (b)). Two of them named  $S$  and  $E$  starts and ends DNA strand containing data. "0" and "1" fragments represent bis of data. An example of general structure of four bits single DNA strand is shown in the Figure 1 (c).

Every DNA strand containing data bits always starts with  $n$ -numbered  $S$  fragment. Start fragment ( $S_n$ ) is a double-stranded fragment of DNA with length about 30 bp (nucleobase pairs). It consists of the "main" part and sticky end part. The main part (approximately 22 bp) carries information that can be used to identifying bit sequence as a part of a larger amount of data. It can be also used as a primer for the PCR procedure. Sticky end part (length about 8 bp - depended on the total length of the whole strand - explained later in the text) allows binding with next structure fragment - bit fragment.

Bit fragment ( $B_{0k}$  or  $B_{1k}$ ) is a double-stranded fragment of DNA of length about 20 - 30 bp. It consists of Bit identification part and two sticky end parts. There are two different types of Bit identification part - one for bit "1" and the other for bit "0". In the simplest approach the internal structure of every bit "1" and "0" are the same for the whole data strand. In this case, there is no need to use sequencing devices to read data from DNA. Data sequence from the specified strand can be retrieved only by gel electrophoresis.

End fragment is about 20 bp length and it is the last structure element of data DNA strand. Like other fragments, it contains an identification part and a sticky end part.

**B. Sticky ends**

The sticky end is a short single-stranded fragment of DNA placed on its end that allows binding DNA fragments into longer strands. The Special design of the sticky ends nucleotide sequence allows the complementary fragments to join generating a fixed order of components. The idea of how the sticky ends work is presented on Figure 2.

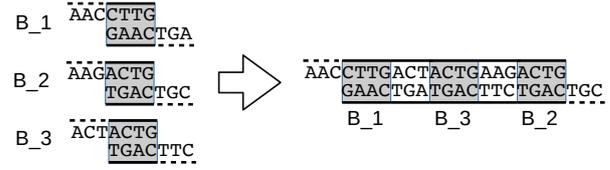

Fig. 2. Shorts three fragments of DNA with complementary sticky ends before ligation.

$N$  bits data string encoded into DNA strand requires at least:

- DNA start component ( $S$ ) with sticky end marked as  $s_0$ ,
- $N$  pair of "Bit" components:
  - first pair of bits with structure:  $s_0 - 0 - s_1$  and  $s_0 - 1 - s_1$ , where  $s_n$  means  $n$ 'th sticky end,
  - second pair of bits with structure:  $s_1 - 0 - s_2$ ,  $s_1 - 1 - s_2$ ,
  - $n$ 'th bits pair structure:  $s_{n-1} - 0 - s_n$ ,  $s_{n-1} - 1 - s_n$ ,
- end component ( $E$ ) with sticky end marked as  $s_n$ .

DNA data strand structure looks like this:  $S - s_0 - B_1 - s_1 - B_2 - s_2 - \dots - s_{n-1} - B_n - s_n - E$ .  $B_n$  denotes "0" or "1" bit component. As one can see  $n$  different sticky ends  $s_i$  are required. Due to the fact that sticky ends consist of  $k$  nucleotides, only  $4k$  different nucleotide sets can be produced. From the statistical point of view, for data strand containing  $n$  bits minimal length of each sticky end should be at least:  $k = \frac{1}{2} \log_2 n$ . For example, 64-bit data strand requires sticky ends that consist of only 3 nucleotides. In fact, as it could be seen in [11], even for 8-bit data strands structure of individual DNA components is more complicated and requires sticky ends of length 10 nt (nucleotides). This is due to the fact that biochemical conditions and processes play a significant role in the problem of sticky end creation and use. The simplest case of minimal required sticky ends length is insufficient and do not lead to the successful creation of longer data strands. Biological limitations related to the procedure of creation data stands from DNA fragment and read them by gel electrophoresis cause that the number of bits carried by DNA strand is not enough to store for example long cryptographic key (1024 to 4096 bits) in a single strand. The reasonable total length of DNA strand that can be used for data storage considered in this paper is about 1000 bp. For such strands number of stored bits is about 32, so 1024 bit keys require 32 different DNA strands. It is, therefore, necessary to introduce a system of indexing individual strands or even individual keys if the multi-key system is introduced.

**C. Single  $n$ -length key DNA data strand preparation**

Let us consider the user that wants to store  $n = 2^k$  bits long cryptographic key in the DNA strand, that can carry only  $m = 2^{k-l}$  bits. Thus he requires  $2^l$  DNA strands, where every one of them contains  $m$  bits of key called subkey. Structure of a single DNA strand from the given set is as follows:  $s_i - S_i - s_0 - B_1 - s_1 - B_2 - s_2 - \dots - s_{m-1} - S_{m-1} - s_m - B - s_m - E_j - s_j$ .  $i$  and  $j$  denote subkey number and vary from 1 to  $2^l$ . As one can see  $2^l$   $S$  and  $E$  fragments must be synthesised with different unique

Fig. 3. Example of 4 bit data strand with Extractor fragments bounded at the ends.

sticky ends. The purpose of that will be explained further. Finally, the procedure of preparation DNA strands for store  $n$  bit length key has following steps:

- 1) Generation and synthesis of  $2^l$  unique DNA Start fragments  $S$ :  $s_i - S_i - s_0$ .
- 2) Generation and synthesis of  $m$  pairs of Bit fragments  $s_0 - 0_1 - s_1$  to  $s_{m-1} - 0_m - s_m$  and  $s_0 - 1_1 - s_1$  to  $s_{m-1} - 1_m - s_m$ . All Bit fragments are called Bit Library.
- 3) Generation and synthesis of  $2^l$  unique DNA End fragments  $E$ :  $s_m - E_i - s_j$ .
- 4) Preparation of subkeys  $K_{m:i}$  for  $i = 1$  to  $2^l$  by splitting key  $K$  into  $2^l$  fragments. Subkey  $K_{m:i} = \{B_1, B_2, \dots, B_m\}_{m:i}$  where  $B_1, B_2, \dots$  represent individual bits of subkey.
- 5) For the first subkey of key  $K$  mix in the reaction tube Start fragments  $S_1$ , End fragments  $E_1$ , and a set of Bit fragments chosen from Bit Library in a way to match the corresponding first subkey bits. Then incubate mixture according to biotechnological protocols to obtain double-stranded DNA.
- 6) Repeat previous step for next subkey of key  $K$ .

After a procedure of generating key  $K$  one should have  $2^l$  reaction tubes with subkeys. Content of reaction tubes can be mixed together in one tube after DNA purification. The final tube contain all the key  $K$  stored in DNA as a series of its bits. Presented procedure can be extended to store more than one key  $K$  just in one tube. Comments require the presence of sticky ends denoted as  $s_i$  and  $s_j$  at the beginning and at the end of the strand. This is straightly connected with subkey extraction and the read procedure described below.

#### D. Subkey extraction

To read a sequence of bits of key  $K$  a sequence of each subkey must be read. All subkey are stored in one tube so the procedure of extraction single subkey must exist. This can be done by preparing a special set of extractors called  $EX$  and  $XE$  which are in fact fragments of double-stranded DNA ended by sticky ends at one side. The extractors are designed to bind to a selected strand representing subkey both at the start ( $EX$ ) and the end ( $XE$ ). It provides to extend the length of the subkey strand as it is shown on a Figure 3.

There is a pair of primers designed to be complementary to extractor pair. Primers are needed for the PCR procedure to increase the number of DNA strands carried extracted subkey. Primers are called  $PEX$  and  $PXE$ . The general procedure to extract subkey  $K_{m:i}$  is as follows: i. get a small amount of mixture containing the key  $K$  and put it into another reaction tube, ii. add pair of extractors  $EX_i$  and  $XE_i$  to the reaction tube and ligate them, iii. prepare and proceed electrophoresis on an agarose gel to separate strands

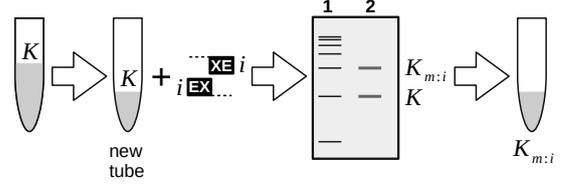

Fig. 4. Schematic process of subkey  $K_{m:i}$  extraction.

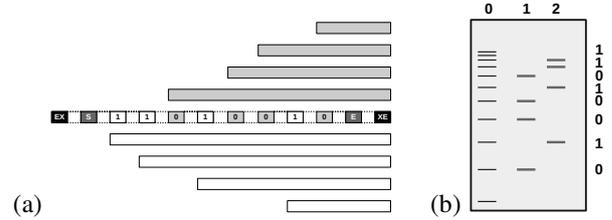

Fig. 5. (a) Expected primer length after elongation in case of 8 bit encoding DNA strand after PCR procedure. (b) An example picture of gel electrophoresis performed for strands set on the left side. Lane 0 symbolize distribution of molecular weight marker, lane 1: distribution of strands length elongated with "0" primer, lane 2: distribution of strands length elongated with primer "1". Reading from bottom to top reveals an encoded bit sequence.

extended by the extractors, vi. isolate from gel DNA strands, that the length corresponds to the length of subkey DNA plus the length of both extractors, v. for extracted DNA material provide the PCR process with primers  $PEX_i$  and  $PXE_i$  relevant to extractors  $EX_i$  and  $XE_i$  to amplify a number of copies of DNA strand.

#### E. Subkey reading

To determine a series of bits in extracted and isolated subkey one must perform two-step procedure used by [11] in his work. The first step is to carry out PCR procedure with two types of primers. Solution with isolated and replicated subkey must be split into two reactions tubes. To the first tube one has to add primers corresponding to "0" bit DNA fragment, to the second reaction tube primers corresponding to "1" bit fragment must be added. Next for both tubes PCR must be performed to elongate the primers. After PCR reaction tubes should contain shorter DNA strands with length matching to the position of "0" and "1" fragments. Figure 5 a. shows example of PCR performed for strand encoding 8 bit sequence: 1 1 0 1 0 0 1 0. The second step requires the implementation of gel electrophoresis for PCR'ed mixture with a subkey. Contents of both reaction tubes must be put into gel separately on different lanes to visualize "0" bit bands and "1" bit bands. Positions of each band are related to DNA strand length in the analysed sample. Due to the fact that Bit fragments forming subkey consist of a determined number of nucleotides, some kind of "quantisation" must occur after electrophoresis. In other way bands on the gel always should come up at the fixed positions indicating positions of zeroes and ones in the analysed subkey. Picture 5 (b) shows expected bands distribution for example from picture 5 (a). To read a sequence of entire key  $K$  every subkey must be read in mentioned way.

### F. Molecular keyring

A tube containing many keys (stored in DNA) could be considered to be "a molecular keyring". The idea of storing multiple keys in DNA bands is not very different from the method of storing a single key, that can be expanded relatively easy. Such approach requires the creation of a revocation key mechanism and an extractors database for keys identification. As it was mentioned earlier, information about the key number and its subkeys is stored in the first segment of each strand containing sticky ends. A user of this system needs to know which extractors use to obtain a chosen key (i.e. subkeys belonging to this key), so the external information binding extractors (with specified sticky ends) with key structure (subkeys sequence) must exist. This could be done for example by signing tubes containing extractors with a signature like this:  $K_{k:m:i}$  that means: extractor for  $i$ -th subkey of length  $m$  of key  $k$ .

For storing, extracting and reading four 1024 bit keys as a series of many 32 bit sequences (which is, in fact, one 4096 bit key - mostly use in e.g. RSA system) user needs in total less than 512 tubes of oligonucleotides to perform simple operations.

A simple revocation mechanism can be proposed for keys that were used and are no longer valid. Other teys for further processing (e.g. reading) need to be extracted by binding them with  $EX$  and  $XE$  extractors. The sticky ends of  $S$  and  $E$  fragments can be blocked against using them as binding sites by adding to the main tube containing keys short single-stranded DNA fragments called caps. Caps are complementary to the sticky ends that need to be blocked. After ligation using ligase enzyme sticky ends at both ends of selected strands (subkeys) should become inactive and no longer can be used for the key extraction. Revocation system for keyring from the above example needs to manage additional  $4 * 32 * 2 = 256$  tubes of oligonucleotides.

### IV. CONCLUSIONS AND FUTURE WORK

A simple cryptographic keys creation and management system based on DNA strands was presented. Despite the considerable complexity due to the relatively large number of necessary elements the system does not require the participation of third parties in very important steps such as the key creation and reading. These features make it resistant to attacks of stealing data through untrusted (unsecured) elements of IT infrastructure or through access by unauthorized entities. In addition, data stored as molecular structures are not susceptible to EMP or SolarStorms and are largely independent of power grids. The next step should focus on experimental verification of the whole process.

# Malicious and Harmless Software in the Domain of System Utilities

Jana Šťastná

Technical university of Košice  
Letná 9, 042 00 Košice, Slovakia  
Email: jana.stastna@tuke.sk

**Abstract**—The focus of malware research is often directed on behaviour and features of malicious samples that stand out the most. However, our previous research led us to see that some features typical for malware may occur in harmless software as well. That finding guided us to direct more attention towards harmless samples and more detailed comparisons of malware and harmless software properties. To eliminate variables that may influence the results, we narrowed down our research study to specific software domain - system maintenance and utility tools. We analysed 100 malicious and 100 harmless samples from this domain and statistically evaluated how they differ regarding packing, program sections and their entropies, amount of code outside common sections and we also looked at differences in behaviour from the high-level view.

## I. INTRODUCTION

WHEN studying research papers in the field of malware research, one may get the impression that harmless software is somehow neglected in research studies. The idea we have specifically in mind is that presence or absence of specific features or differences in their qualities in malware with comparison to harmless software is seldom examined. However, such studies would be of great help.

Many research works use harmless software only as a resource for demonstrating detection rate of new presented detection method. However, selection of harmless samples may considerably influence detection results and thus detection rates. When programs that are part of the default system installation are used as a control group in published research works, they secure lower false-positive ratios, but they do not form complete representative set of harmless software, since many different software products are available and some of them may even resemble malware in some of their features. This idea initiated our first experiments targeted at packing and related properties of programs [1][2]. We discovered that harmless software shares occurrence of packing with malware, together with other related properties. This led us to deeply examine malicious and harmless samples and search for hidden relations.

Our experiment presented in this paper is unique by means of samples selection focused on specific software domain – system utilities and maintenance tools. By this rather narrow selection we aim to eliminate the influence of usage domain of

This work has been supported by the Slovak Research and Development Agency under the contract No. APVV-15-0055 and by project KEGA no. 079TUKE-4/2017.

software which may play important role in exhibited behaviour and properties. In this way we can better compare malicious and harmless samples and look for features that may help in distinguishing them.

## II. BACKGROUND OF THE EXPERIMENT

Detecting that a program is packed is the first step towards its in-depth analysis [3]. Execution of packed program is often inevitable for recovering original program's code and unveiling its behaviour. Dynamic inspection of malware poses a risk that it may escape from analytic environment and spread on more systems, therefore strict security precautions need to be taken when executing malware.

### A. Packing as Analysis and Detection Prevention

Packers employ compression for reduction of program's size and encryption to obstruct program's reverse-engineering [4]. The resulting file comprises an unpacking routine and packed data blocks. When packed program is executed, the unpacking routine recovers the original program code into memory and directs the execution flow to execute it. Program code can be retrieved by virtual machine monitors or emulators [5] but researchers also look for static techniques to distinguish packed malware from goodware [6][3]. Packers are popular for hindering signature-based detection and static analysis.

A general belief is that packing, together with obfuscation, is a common trait in malicious programs and this idea is repeated among malware analysts and researchers [7][8]. Despite that, it is not easy to find current and accurate rates of packer detections. According to Cisco Blog, they estimate around 70-80% of malware is packed and only around 5% of harmless software is modified by packers<sup>1</sup>. Considering the year the article was published (2010) the rates are now outdated, however, a more recent blog article on Malwarebytes from October 31, 2017 states that "*over the last quarter, we've seen an increase in malware using packers, crypters, and protectors*" and "*the growing number of malware authors using these protective packers has triggered an interest in alternative methods for malware analysis*"[9]. As it seems, packers are not on the decline yet, so investigating their occurrence in harmless software may lead to interesting insights.

<sup>1</sup>[https://blogs.cisco.com/security/malware\\_validation\\_techniques](https://blogs.cisco.com/security/malware_validation_techniques)

### B. Introducing Research Hypotheses

Packing is deemed typical for malicious software but results that would confirm and explain reliability of this assumption are not present. We will try to shed some light on this problem and see if assumptions regarding packing match the reality. Our research is evaluated with statistical tests of null hypothesis and two alternative hypotheses for each of analysed features: amount of detected packers, amount of program's sections, entropy of section *.text*, entropy of section *.rest*, and percentage of program's code in section *.rest*.

The null hypothesis reflects the assumption that values detected – low or high – are not related to malicious or harmless origin of samples, so no significant difference in values will be observed in data sets:

*Hypothesis 0 (H0)*: The difference of values measured for analysed feature in harmless software and malicious software is small and insignificant.

Alternative hypotheses reflect the expectation of higher or lower values in malicious samples:

*Hypothesis 1 (H1)*: Analysed feature has higher values in malicious software when comparing to harmless software.

*Hypothesis 2 (H2)*: Analysed feature has lower values in malicious software when comparing to harmless software.

According to hypothesis H2, packing and related features considered typical for malicious software may be detected in harmless software with higher values. Proving the hypothesis for these features may unveil hidden complications in detection mechanisms based on typical malware features.

For statistical analysis, we used two-sample Wilcoxon rank sum test (U test) for comparing the data sets with confidence level 95% ( $\alpha = 0.05$ ).

## III. RESEARCH DATA AND METHODS

### A. Experimental Sets

The set of experimental samples consisted of utility software distributed on the internet for free. Parsons and Oja explain that utility software is a kind of software purposed to assist with monitoring and configuring a computer system and its software [10]. Utility software covers various maintenance tasks, e.g. deleting temporary files, broken links removal, searching for duplicate files, tasks management, memory optimization or personal files encryption. We targeted this specific group of software because of operations that these programs are designated to perform.

We assume that software which legitimately accesses registry entries, processes, file system, etc., may be a promising target for malware writers which create malicious imitations of the original harmless software. With this in mind we aimed at comparing harmless system maintenance tools and their fake malicious counterparts.

We assembled two experimental sets: One containing legitimate applications in a form of executable files (.exe) downloaded from the internet and another containing 100 samples verified as malicious, collected from malware analytic services. We could not obtain all malware .exe files to

analyse them on our own, therefore to unify our resources we used reports from analysis of samples, which were available for both sets. Also, we could not obtain exact malicious counterparts of all harmless programs, but nevertheless we preserved the domain of malicious samples in utility software. We obtained malware in the domain of utility software by looking at application name, e.g. "win defrag", which hints on the intended purpose of the sample. We also focused on high amount of detections by anti-virus (AV) engines and manually selected samples which met our criteria. Data fields and their extraction are described in Section III-C.

### B. Analytic Tools

We performed our experiments with various kinds of tools:

**PEiD** is a tool that allows to identify packers which have been used on programs' code <sup>2</sup>. Packing and encrypting libraries are often used by malware for concealment of suspicious parts of a program and evasion of detection based on malware signatures. PEiD performs the search based on signature-like definition of several hundreds of known packers. While it is reliable to detect commonly used packers, it may fail on custom-made packers whose signatures are yet unknown. The original web page of the tool is discontinued and according to reports it may have been taken over by malicious actors. We obtained our copy of the tool with REMnux <sup>3</sup> distribution for malware analysis.

**UPX** is a packing tool for executable files <sup>4</sup> which is used in the experiment to check whether tested file is packed or not, and to unpack files that are packed. As Davis *et al.* state [11] in their book, numerous computer viruses use specifically UPX packer. A recent case of its malicious usage is presented in blog article by Nick Biasini *et al.* in which cryptocurrency-mining malware *Dark Test* uses UPX as one of its hiding techniques [12]. The packing problem is discussed also in the work of Guo, Ferrie and Chiueh [7]. Therefore, detection of UPX packer being used on analysed sample arises suspicion.

**VirusTotal** is online malware analysis service. We used it to obtain properties and behaviour of malicious and harmless set of samples <sup>5</sup>. In case of harmless samples it was used for safe and reliable analysis of samples that we collected. In case of malware, since we did not possess original malicious files, we used the service to search for reports from analysis by hash codes of samples that we collected beforehand. Reports generated from analysis contain various information, regarding our experiment e.g. scan results form over 50 anti-virus (AV) solutions, detection of packers by analytic tools F-PROT and PEiD, information from PE header, PE sections with their names and properties, and behavioural information with executed system calls.

Tools for static analysis – PEiD, UPX – run as terminal applications which accept arguments that modify settings and set input and output of analysis. This allowed us to create a

<sup>2</sup>PEiD tool: <https://www.aldeid.com/wiki/PEiD>

<sup>3</sup>REMnux: <https://remnux.org/>

<sup>4</sup>UPX: <http://upx.sourceforge.net/>

<sup>5</sup>VirusTotal: <https://www.virustotal.com>

helper program which utilised these features for automation of analysis.

### C. Experimental Procedure

The experiment was performed in two stages: First we analysed harmless set of programs and evaluated results. In the second stage we proceeded with examining malicious samples. The procedure differed for harmless and malicious samples, mainly because original malicious samples were not available, therefore, the second stage leaned on data provided by analytic reports produced by VirusTotal.

In the first stage we employed our helper program which was developed prior to the experiment for automating the usage of analytic tools. Each harmless sample was analysed by PEiD and UPX to check whether it is packed, and if yes, to identify used packers. Results were collected and summarised in a table. Analysis by VirusTotal followed. We collected produced reports and extracted information of interest.

The second stage regarded malicious samples and employed data extracted from reports of analysis obtained by VirusTotal.

Data obtained from analytic reports comprise the following:

- *Detection results of malware scanners.* In case of positive detection, we obtained name of detection signature, for each scanner separately. We summarised the data as quantity of detections per sample.
- *Detection of packers applied to pack analysed sample.* We acquired names of detected packers and summarised the data as quantity of detected packers per sample.
- *Names of program's sections.* We counted the amount of sections and also stored their names for further manual research. Too few or too many sections comprising the executable file suggest that it was packed, encrypted or otherwise modified in order to disguise original code structure<sup>6</sup>.
- *Entropy of program's sections .text and .rest.* A section usually named as *.text* or *.code* contains program's instructions. In some occasions parts of code may occur out of usual sections, in so-called *.rest*. Presence of this quasi-section is characteristic for programs modified with some packer. Entropy of these sections may show whether they were modified by packing or encryption, which typically cause entropy to be very high. Values are measured in the interval  $< 0,8 >$ . Bytes of program's code have some non-random distribution and therefore low entropy. The higher the value, the more random distribution of bytes, suggesting uncommon modifications.
- *The amount of program's code in section .rest.* We calculated percentage amount of bytes in this section. Large portions of code in this section are typical for packed programs.

To objectively evaluate differences between data of malicious and harmless samples we used statistical analysis,

specifically two-sample *Wilcoxon rank sum test (U-test)* with confidence level 95% ( $\alpha = 0.05$ ).

From reports provided by VirusTotal we were able to obtain high-level information about behaviour of analysed samples as a list of executed system calls. We used the data in summative way as quantities of operations in behavioural categories listed in Table I. Each sample was then described by 20 numerical values representing occurrences of 20 types of behaviours.

## IV. RESULTS AND OBSERVATIONS OF THE EXPERIMENT

The following sections present results regarding analysed features and statistical analysis (end of this section, Table II).

### A. Detection Results of Malware Scanners

During our experiment VirusTotal employed usually 56 AV scanners but in some cases, for unknown reasons, few of them were unavailable in the report.

Pie charts in Fig. 1 and 2 show amounts of AV scanners (height of a slice) that positively detected analysed samples (their amount as width of a slice), grouped into ranges for improved visual clarity. Among harmless samples no detection (Fig. 1) prevails, but some were detected as threat nevertheless. Among malware samples (Fig. 2) only one had no detection and the rest of them was detected by multitude of AV scanners.

### B. Detection of Packer Usage

Pie charts in Fig. 3 and 4 show the amounts of detected packers. Height of a slice represents the amount of packers detected in single sample and width shows the amount of samples detected to be packed with given amount of packers.

Only 20% of *harmless samples* were detected as not packed, the rest was modified by packers ranging from 1 to 7.

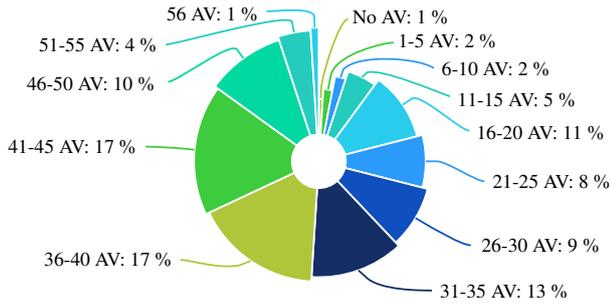

Fig. 2. Pie chart with amount of *malicious samples* that were positively detected by given amount of AV scanners.

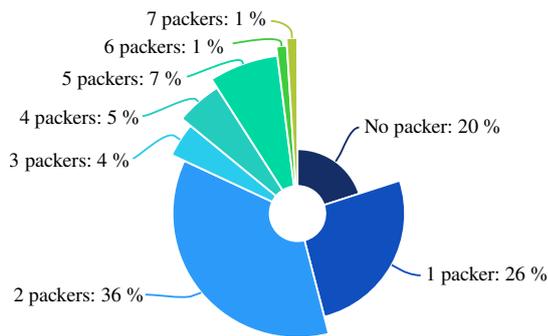

Fig. 3. Pie chart with amount of detected packers in *harmless samples*.

Data from malware samples present more surprises. One malware sample was packed 46 times – that is extreme. However, majority of samples was detected as not packed at all – another surprise, since usual expectations are that malware will be packed massively, not the opposite.

Regarding distribution of amount of packers detected, we can see in Fig. 5 that for *malware* the value of median matches the lower (first) quartile (value 0), and in case of *harmless software* median matches the upper (third) quartile (value 2). From this we can deduce that harmless samples are more prone to being packed, at least with packers that are detectable by available tools. Outliers (extreme values) are not shown in order to prevent plot deformation.

Regarding the hypothesis H1 saying that values of analysed feature – occurrence of packers – is higher in malicious software than in harmless software (Table II, row *Packers amount*, alternative *Higher*), the U-test resulted with p-value  $> 0.99$  which by far exceeds the significance level. As a result, we fail to reject the null hypothesis for this case.

For alternative hypothesis H2 suggesting that occurrence of packers is lower in malicious software, thus prevails in harmless software (Table II, row *Packers amount*, alternative *Lower*), the U-test resulted with p-value  $7.3124 \times 10^{-12}$  which is far below the significance level. As a result, we reject the null hypothesis and accept the alternative hypothesis H2.

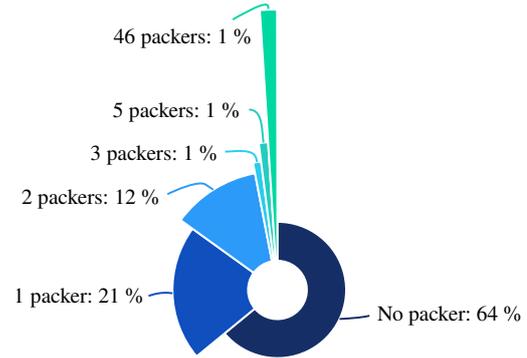

Fig. 4. Pie chart with amount of detected packers in *malicious samples*.

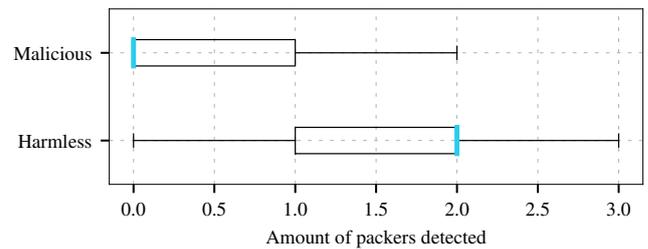

Fig. 5. Boxplots for amounts of packers detected in *harmless* and *malicious* samples. Outliers are not shown in the figure.

### C. Amount of Program's Sections

Pie charts in Fig. 6 and 7 show the amounts of detected sections in analysed programs. Height of a slice represents the amount of sections detected in single sample and width shows the amount of samples with given amount of sections. The amount of sections in majority of harmless samples is quite high – 8 – but the amount in malware is lower.

For *harmless samples*, the interquartile range is higher (Fig. 8) – the box is much wider, in comparison to *malware samples*. Both sets of samples match on the first quartile with value 4. There are 6 *harmless samples* with no section detected. This may be caused by different actual file format than PE so the section table could not be retrieved. While several outliers among *malware samples* may make the impression that the amount of sections is high in malware, values of median clearly show that *harmless samples* tend to have higher amount of sections.

For alternative hypothesis H1 saying that amount of sections is higher in malware than in goodware (Table II, row *Sections amount*, alternative *Higher*), the U-test resulted with p-value  $> 0.99$  which by far exceeds the significance level. As a result, we fail to reject the null hypothesis for this case.

For alternative hypothesis H2 saying that amount of sections is lower in malware, so prevails in harmless software (Table II, row *Sections amount*, alternative *Lower*), the U-test resulted with p-value  $1.9375 \times 10^{-6}$  which is far below the significance level. As a result, we reject the null hypothesis and accept the alternative hypothesis H2 – sections prevailing in goodware.

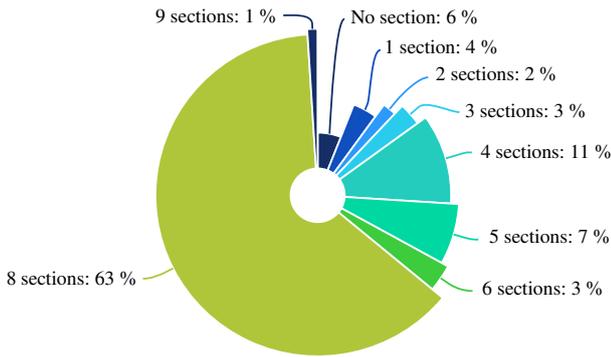

Fig. 6. Pie chart with the amount of detected sections in *harmless samples*.

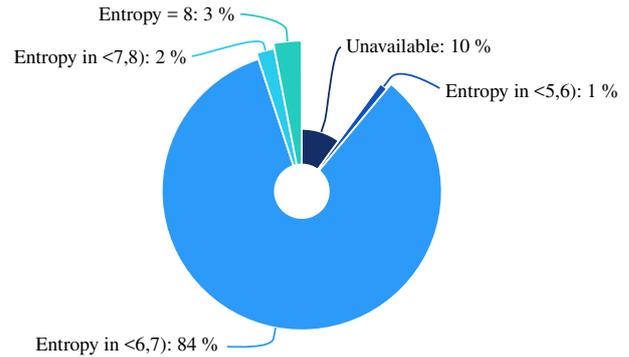

Fig. 9. Pie chart with entropy of section *.text* in *harmless samples*.

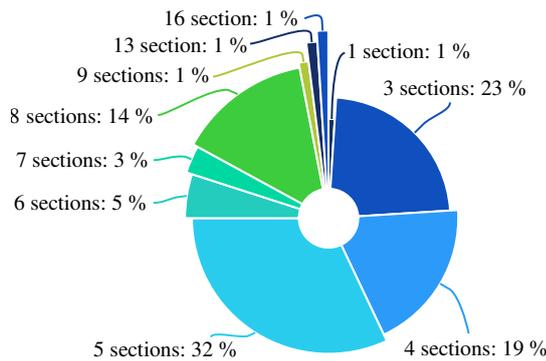

Fig. 7. Pie chart with the amount of detected sections in *malware samples*.

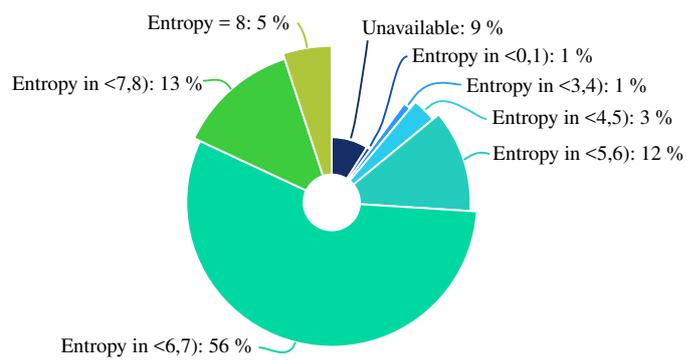

Fig. 10. Pie chart with entropy of section *.text* in *malware samples*.

*D. Entropy of section .text*

Section *.text* (or *.code*) contains executable instructions, therefore its entropy should not be normally very high.

Pie charts in Fig. 9 and 10 show measured entropies. Height of a slice represents range of values of entropy and width shows the amount of samples with given entropy value. We can see that both malicious and harmless group have majority of samples with entropy in range < 6,7). In *harmless samples*, other ranges of entropy occur seldom – only in 6 samples – and the rest comprises samples in which the section could not be precisely identified. *Malware* shows wider variety of entropy, both on the lower and higher spectrum of value ranges.

Boxplot (Fig. 11) shows that inter-quartile range is wider in *malware* and extremes are much more apart. Medians,

however, are close to 6.5 in both malicious and harmless samples. This suggests that the difference in values may not be significant regarding *.text* section entropy.

For alternative hypothesis H1 that values of *.text* section entropy are higher in malware than in goodware (Table II, row *.text entropy*, alternative *Higher*), the U-test resulted with p-value 0.6556 which by far exceeds the significance level. We fail to reject the null hypothesis for this case.

For alternative hypothesis H2 that values of *.text* section entropy are lower in malware (Table II, row *.text entropy*, alternative *Lower*), the U-test resulted with p-value 0.3453 which also exceeds the significance level. We fail to reject the null hypothesis and conclude that differences in values of entropy of section *.text* are not statistically significant.

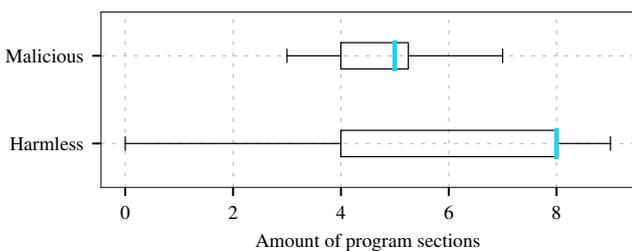

Fig. 8. Boxplots for amount of program's sections in *harmless* and *malicious* samples. Outliers are not shown in the figure.

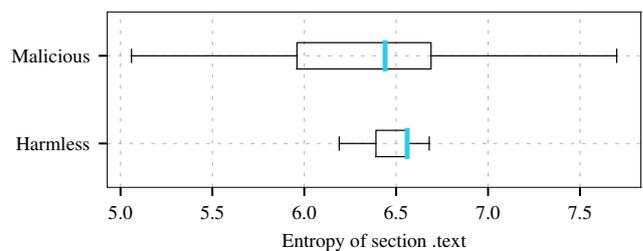

Fig. 11. Boxplots for entropy of section *.text* in *harmless* and *malicious* samples. Outliers are not shown in the figure.

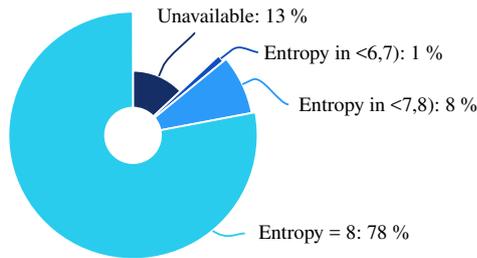

Fig. 12. Pie chart with entropy of section *.rest* in harmless samples.

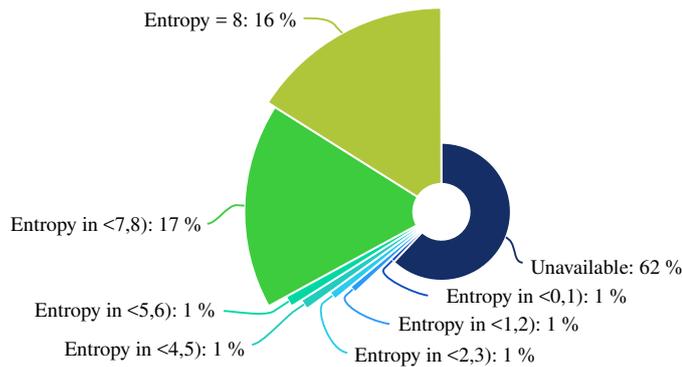

Fig. 13. Pie chart with entropy of section *.rest* in malware samples.

### E. Entropy of section *.rest*

Since *.rest* is not a program section *per se*, it may not be detected in many programs. On the other hand, its presence suggests that special measures have been made to conceal (at least from plain sight) some incriminating portions of code. It comes naturally to assume presence of *.rest* in majority of malware samples, but looking at our previous experiments, assumptions about malware can be quite misleading.

Pie charts in Fig. 12 and 13 show measured entropy of section *.rest*. Height of a slice represents range of values of entropy and width shows the amount of samples with given entropy value. In case of *harmless samples*, 13 programs had no detectable code out of common sections but the rest of them had, with measured entropy from 6 to 8 – which is a maximum. Contrary to that, *malware samples* showed no section *.rest* in majority of cases (62 samples), and in case of its presence, entropy reached value from 6 to 8 only in 33 samples.

Lower quartile, upper quartile and median for *harmless samples* meet at value 8 (Fig. 14) and contrast with values of malware – it has median at zero, mostly due to absence of the section.

For alternative hypothesis H1 that values of *.rest* section entropy are higher in malware than in harmless software (Table II, row *.rest entropy*, alternative *Higher*), the U-test resulted with p-value  $> 0.99$  which by far exceeds the significance level, so we fail to reject the null hypothesis.

For alternative hypothesis H2 that values of *.rest* section entropy are lower in malware (Table II, row *.rest entropy*, alternative *Lower*), the U-test resulted with p-value  $2.7074 \times 10^{-18}$  which is far below the significance level. We reject the null

hypothesis and accept the alternative hypothesis H2 that *.rest* section entropy is lower in malware than in goodware.

### F. Percentage of code in section *.rest*

Percentages that were found among analysed *harmless samples* are shown in Fig. 15 in ascending order.

Surprisingly, large programs' size present in section *.rest* prevails in *harmless software*. We suppose that it may be inflicted by some commonly used packers and application building tools, such as INNO. However, further research needs to be made to confirm this opinion.

Examination of *malware* showed that *.rest* manifested in much fewer samples than in the harmless set. This result corresponds with findings from analysis of entropy of section *.rest* (Sec. IV-E). The percentage of *.rest* section in file's size (Fig. 16) was calculated with data obtained from VirusTotal analytic reports.

62 *malware* samples contained no data outside sections listed in PE file header and so section *.rest* was confirmed to be absent in them. The case of 90% or more of program's bytes was present only in 11 samples. Again, this strongly contrasts with results from harmless samples.

Figure 17 shows that for *harmless samples* the first and the third quartile have high values and samples with less than 80 % percent of code in *.rest* are basically outliers. Quartiles of malware data contrast to that as low – the first quartile and median match at value 0. The boxplot suggests notable differences in values of malicious and harmless samples.

For alternative hypothesis H1 that percentages of code in *.rest* section are higher in malware than in goodware (Table II, row *.rest percentage*, alternative *Higher*), the U-test resulted with p-value  $> 0.99$  which by far exceeds the significance level. As a result, we fail to reject the null hypothesis.

For alternative hypothesis H2 that percentages of code in *.rest* section are lower in malware (Table II, row *.rest percentage*, alternative *Lower*), the U-test resulted with p-value  $3.2413 \times 10^{-17}$  which is far below the significance level. As a result, we reject the null hypothesis and accept the alternative hypothesis H2 about percentage of code in section *.rest* being lower in malware than in harmless software.

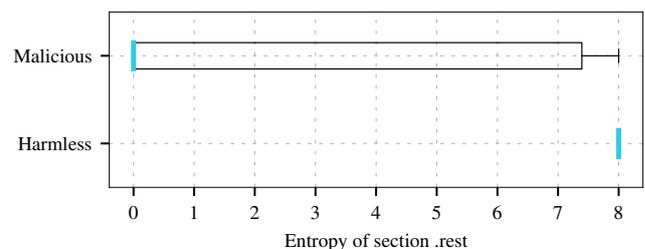

Fig. 14. Boxplots for entropy of section *.rest* in harmless and malicious samples. Outliers are not shown in the figure.

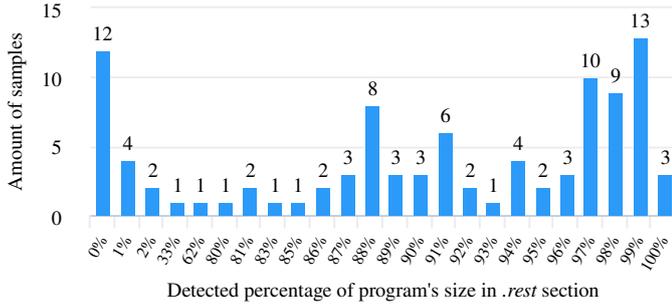

Fig. 15. Measured percentages of .rest section from total size of code in harmless samples, and number of samples with that percentage of code in .rest section.

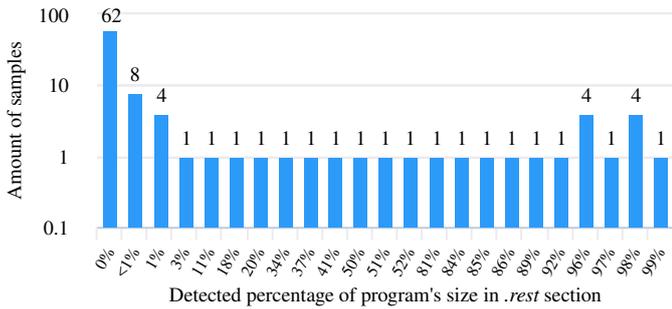

Fig. 16. Measured percentages of .rest section from total size of code in malicious samples, and number of samples with that percentage of code in .rest section. The y-axis with amounts of samples is scaled logarithmically due to great differences among values.

G. Relationships Between Analysed Features

We explored also relationships between analysed features by calculating Pearson's correlation coefficients for each pair of features that were discussed in statistical analysis in previous section. The measure of correlation is described by values from interval  $(-1, 1)$ , with the following interpretation:

- value  $-1$  represents perfect negative correlation, i.e. when values of one feature are high, second feature's values are low, and vice versa,
- value  $0$  represents no measurable linear correlation,
- value  $1$  represents perfect positive correlation, i.e. when value of one feature is high, so is value from the second feature, and vice versa.

Visual representation of correlation matrix as a "heatmap" (Fig. 18, 19) can aid in understanding notable linear relationships between features. We can see that in heatmaps of both malicious and harmless samples only positive correlations were present. For harmless samples the most notable correlation is between amount of detected sections and entropy of section .rest. It seems that when packers are used for hiding program's code the amount of sections is decreased and large portions of code are then in section .rest. We explored the issue further and discovered that it occurred mainly when a sample was packed by packer UPX. If it was the only packer used, it placed all the code into section named .upx.

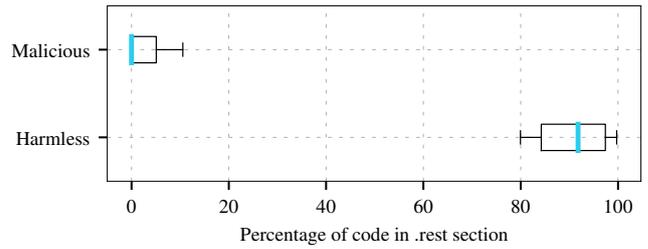

Fig. 17. Boxplots for percentage of program's code in section .rest in harmless samples and malicious samples. Outliers are not shown in the figure.

Data sets		Alternative	Result
Malicious	Harmless		
Packers amount	Lower		$7.3124 \times 10^{-12}$
Packers amount	Higher		$\approx 1$
Sections amount	Lower		$1.9375 \times 10^{-6}$
Sections amount	Higher		$\approx 1$
.text entropy	Lower		0.3453
.text entropy	Higher		0.6556
.rest entropy	Lower		$2.7074 \times 10^{-18}$
.rest entropy	Higher		$\approx 1$
.rest percentage	Lower		$3.2413 \times 10^{-17}$
.rest percentage	Higher		$\approx 1$

TABLE II  
SUMMARY OF RESULTS FROM STATISTICAL ANALYSIS MADE WITH Wilcoxon rank sum test (U-test) WITH CONFIDENCE LEVEL 95% ( $\alpha = 0.05$ ). THE ALTERNATIVE DESCRIBES RELATION BETWEEN VALUES OF MALICIOUS AND HARMLESS SET OF SAMPLES.

Another notable correlations in harmless samples were between amounts of sections and detected packers, and between percentage of code in section .rest and entropy of this section, but values for these correlations are not that high.

Regarding malicious samples, only one correlation is notable and it was measured between values of percentage of code in section .rest and entropy of this section. This relates to finding that numerous malware samples do not have this section so presence of this section with some entropy will cause this correlation to be high.

H. High-Level Behaviours

Beside features related to packing we recorded and measured also quantity of executed system calls which belong to behavioural categories listed in Table I. After observing the values we realised that much more possibilities of analysis are opening ahead of us and thus will require further work. However, to supplement findings from previous sections with at least several interesting insights about behaviour, we analysed correlations between pairs of behaviours and created heatmaps for malicious (Fig. 20) and harmless samples (Fig. 21).

First notable thing is that harmless samples had no occurrence in behavioural categories CI - code injection and FC - file created, therefore lines for these features are blank in Fig. 21.

We can see that heatmap of harmless samples contains more high correlations than heatmap of malware samples. Some of

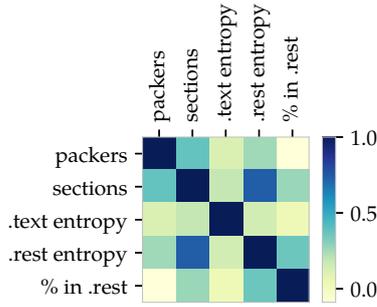

Fig. 18. Correlation matrix heatmap for properties related to packing in *harmless samples*.

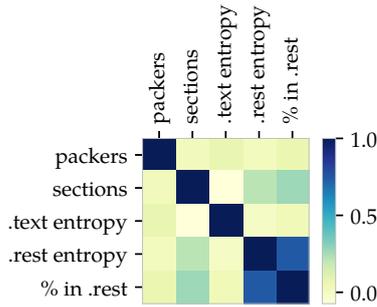

Fig. 19. Correlation matrix heatmap for properties related to packing in *malicious samples*.

them match but for *harmless samples*, these high correlations between pairs of features are unique:

- *FM* - file moved and *FD* - file deleted,
- *FO* - file opened and *FM* - file moved,
- *FO* - file opened and *FD* - file deleted,
- *FW* - file written and *FM* - file moved,
- *FW* - file written and *FD* - file deleted,
- *HG* - HTTP GET request and *DNS* - DNS request,
- *MO* - mutex opened and *MC* - mutex created,
- *SW* - searched window and *MC* - mutex created,
- *TCP* - TCP data flow and *DNS* - DNS request.

It seems that for *harmless samples* operations related to files are often performed and quantitatively relate to each other.

For *malicious samples*, interesting correlations are between following features:

- *MC* - mutex created and *FD* - file deleted,
- *MO* - mutex opened and *DLL* - runtime DLL,
- *REG* - registry entry and *FO* - file opened,
- *REG* - registry entry and *FR* - file read,
- *SS* - service started and *FD* - file deleted,
- *UDP* - UDP data flow and *HG* - HTTP GET request.

*Malware samples* seem to be focused more on mutex, registry and service operations and they are performed similarly often as various operations with files, mainly opening, reading and deleting.

### I. Summary

Entropy of section *.text* was notably high in many malicious and harmless samples, so it seems that concealment is targeted

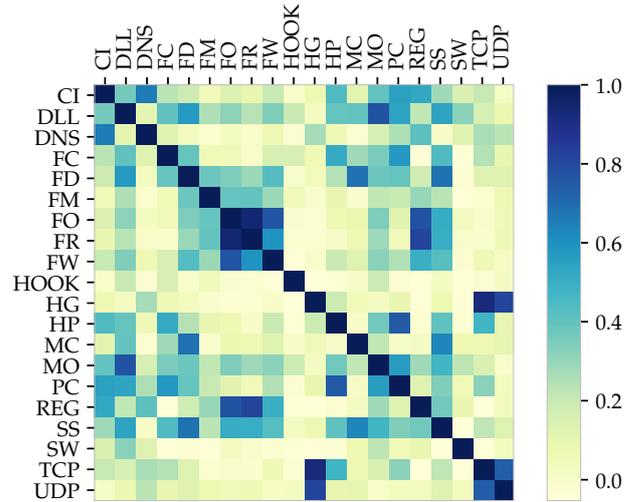

Fig. 20. Correlation matrix heatmap for high-level behaviours of *malicious samples*.

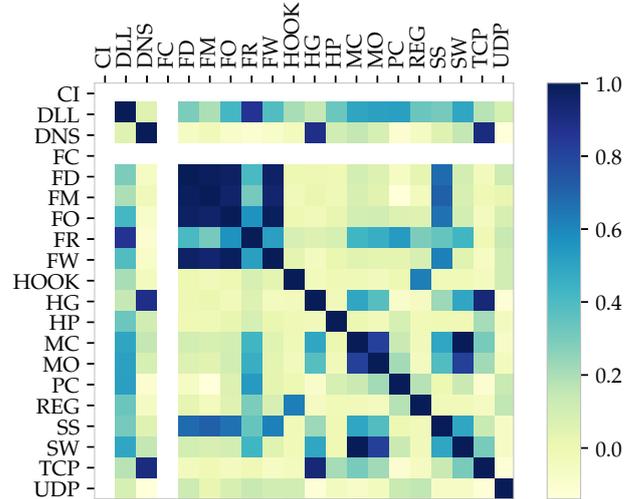

Fig. 21. Correlation matrix heatmap for high-level behaviours of *harmless samples*.

at program's section with executable instructions. Difference between sets resulted as insignificant, but lower amount of detected packers in malware suggests that custom packers are used, which are undetectable by common analytic tools. Section *.rest* was not detected in majority of malware samples. This suggests that malware writers use custom code concealing techniques that do not create this quasi-section.

Regarding the assumptions about malware being packed, they are probably true, however, common tools seem now insufficient for malware packers detection. Information pointing at programs being packed need to be collected from deeper levels of analysis: Amounts and names of packers provided by analytic tools may be incomplete, but dissecting a program into sections and observing their entropy shows the missing

pieces of information.

Correlations between high-level behaviours hint some interesting relationships between types of operations performed during execution of programs and it would be interesting to analyse specific cases of behaviours that are executed together. Also, it would be beneficial to look at behaviours of malware and harmless software from another software domain and examine if there are some repeating patterns present in values.

Insights obtained from experiments that we performed are significant regarding research and implementation of novel detection systems based on machine learning and neural networks, since they utilise quantitatively measurable features of software samples. Our results present options for feature engineering to obtain high-quality training data: Neglecting features that are insignificant or combining closely related features to one for reducing dimensionality of data. Mindful selection of training data will allow to direct more attention and time to selection and experimentation with detection algorithms.

Based on our work new research questions arise. Behavioural and non-behavioural properties of programs vary greatly and as we "zoom in" to specific software domain of malicious and harmless samples, we see that usual assumptions cease to be applicable. For example, results of signature-based detection of packers do not agree with expectations towards malware and goodware (Sec. IV-B) and are therefore unsuitable for machine learning purposes. Clearly, malware writers made it harder to detect packers, so deeper analysis of samples is required to obtain desired data. This opens up a question whether now-so-popular utilisation of massive data is not in fact a limitation in improving malware detection, and we ought to pursue more specific and narrow features for differentiating malware from goodware instead.

## V. DISCUSSION

Beside reports from analysis obtained from VirusTotal we used tools of static analysis in this experiment for the following reasons:

- 1) Although dynamic analysis compared with static analysis indicates smaller issues with malware obfuscation, static analysis allows to detect malicious features which seem to occur randomly during a program execution or in a specific execution environment.
- 2) We could automate the analytic process for large amount of experimental samples in our custom created utilities.
- 3) Automated process of static analysis is less time consuming compared with dynamic analysis, which requires execution of each analysed sample.

Concerning point 1, every program can comprise numerous execution paths, also called *execution traces*. The disadvantage of dynamic analysis is that only one execution trace can be observed at a time. Concerning several traces, also static analysis with reverse engineering is problematic. However, Beaucamps *et al.* addressed this problem in their work [13] and proposed a method for static analysis of execution traces

acquired from control-flow graphs. Macedo and Touili also discuss the issue in their work [14].

UPX packer is commonly known as packing tool often misused for covering malicious code. Marak states, however, that obfuscating effects of the packer are not among its original features and result from altering its original code [15]. A look at licence of UPX packer reveals that modifications and usage of the packer in such way is violating the rules of tool's legal usage <sup>7</sup>. In fact, UPX packer should not be suspicious by itself, like many blogs and papers state, but the illegal modifications made to it are what causes trouble. This fact should be given more attention and researchers should avoid improper simplifications of the matter.

In some cases, PE sections names may reveal name of a packer used for concealing program's code, however, this information is not fully reliable since section names can be modified by various tools, e.g. by PE Explorer <sup>8</sup>. In our observations we also encountered section names being some gibberish or blank—obviously someone removed the original section name on purpose.

### A. Related Work

Malware signatures have still very important role in malware detection, although their effectiveness on malicious samples concealed by techniques that alter syntactic form of a program is questionable. What is more, with rapidly growing number of new malware samples the extraction of signatures requires a lot of precious time. Griffin *et al.* addressed this problem and presented a system for automated generation of malware signatures [16]. An interesting part of their work describes features which they analysed in malicious programs. Concerning syntactic form of a program authors mention patterns emerging in operational code which may represent precursors of non-standard or suspicious behaviour of the program:

- Constant values like IP addresses, email addresses,
- access to memory with unusual offset,
- local function calls, non-library function calls, context of a function call and used parameters,
- suspicious mathematical operations which may indicate obfuscation.

These patterns are used for refining potential malware signatures through, as they call it, *code interestingness check*. In our research they served as an inspiration for comparing features of malicious and harmless programs and looking for patterns which could be employed as indicators of malicious intentions.

### B. Influences on the Study and its Outcomes

Results of our research showed that for special-purpose software packing may be detected more often in harmless samples than in malicious samples, which is in contrast with common assumptions about malware. Nevertheless, several factors could have affected the outcomes even when we made an effort to mitigate them as best we could.

<sup>7</sup>UPX licence: <https://upx.github.io/upx-license.html>

<sup>8</sup>PEexplorer: [http://www.heaventools.com/PE\\_Explorer\\_section\\_editor.htm](http://www.heaventools.com/PE_Explorer_section_editor.htm)

- *Selection of samples.* Commercial paid software was not included in the study but its properties may have been different from what we found in harmless samples. However, obtaining numerous samples of paid maintenance software was not feasible in our research project. Concerning malware samples, it is hard to trace their origin since we worked just with reports from their analysis, not with samples directly. This may have also considerable effect.
- *Collection of samples.* Samples were found on the internet by search engine with specific keywords. Different keywords may have led to different outputs, even when we tried to explore as many various results as we could.
- *The usage domain.* Samples that we experimented with belong to system utility software. Samples from different domains may have different properties regarding packing.
- *Analytic tools.* The tools that we used in our study to gather data of interest do not guarantee 100% correctness of data. There is a chance that detecting fewer packers among malicious samples is caused by inability of tools to unveil usage of hidden, sophisticated custom packer developed by malware creators. This problem, however, is not in our power to mitigate.
- *Other errors.* Several samples had no program sections detected. This may have been caused by an unknown error during analysis performed by tools we used or by difference of actual file format from the format declared by the sample.

## VI. CONCLUSION

We presented a different, novel approach to malware research that is based on narrow selection of experimental samples from specific software domain and statistical evaluation of differences between malicious and harmless software. Several ideas inspired us to perform this experiment:

- 1) Packing is often applied to malicious software with intent to obstruct reverse-engineering, hinder static analysis, and hide incriminating code from malware detectors.
- 2) Although packing is typical for malware, it may be used also on harmless software for protection against intellectual property theft.
- 3) In research circles, a discussion about distinguishing malicious packing from harmless one regards syntactic features of program's operational code, e.g. bytes distribution, entropy, data in so-called *.rest* section.
- 4) Harmless programs have not been given appropriate attention, especially from the context of features relevant for distinguishing between malicious and harmless case of packing, and their reliability.

Although packers are massively used by malware creators, they are also applied for protection of intellectual property in harmless software, making it complicated to separate bad and good intentions behind packer's usage.

In the paper we showed that differences in values between malicious and harmless programs are significant regarding amount of detected packers, amount of program sections,

percentage of code in section *.rest* and its entropy. Entropy of section *.text* together with amounts of packers detected suggest that malware writers create custom packers that are nearly undetectable by common analytic tools.

It is necessary to keep in mind that results presented here concern samples from the domain of maintenance and utility software and samples from other domains may yield different results. In that case, however, it would be interesting to research the influence of software domain selection on values of analysed features, since it may be significant.

# 4<sup>th</sup> International Workshop on Language Technologies and Applications

**D**EVELOPMENT of new technologies and various intelligent systems creates new possibilities for information processing. Natural Language Processing (NLP) addresses problems of automated understanding, processing, evaluation and generation of natural human languages. LTA workshop provides a venue for discussion and presenting innovative research in NLP domain, but not restricted, to: computational and mathematical modeling, analysis and processing of any forms (spoken, handwritten or text) of human language, interactions via Virtual Reality and Augmented Reality, Computational Intelligence models and applications but also other various applications in decision support systems. We welcome papers covering innovative applications and practical usage of theoretical aspects. The LTA workshop will provide an opportunity for researchers and professionals to discuss present and future challenges as well as potential collaboration for future progress in the field.

## TOPICS

The submitted papers shall cover research and developments in all NLP aspects, such as (however this list is not exhaustive):

- Computational Intelligence methods applied to language & text processing
- text analysis
- language networks
- text classification
- language networks, resources and corpora
- document clustering
- various forms of text recognition
- machine translation
- intelligent text-to-speech (TTS) and speech-to-text (STT) methods
- authorship identification and verification
- author profiling
- plagiarism detection
- sentiment analysis
- NLP applications in education
- knowledge extraction and retrieval from text and natural language structures
- multi-modal and natural language interfaces
- innovative language-oriented applications and tools
- interactions models and applications via Virtual Reality and Augmented Reality
- NLP for text analysis in forensic linguistics and cybersecurity

## EVENT CHAIRS

- **Damasevicius, Robertas**, Kaunas University of Technology, Lithuania
- **Martinčić – Ipšić, Sanda**, University of Rijeka, Croatia
- **Napoli, Christian**, Department of Mathematics and Informatics, University of Catania, Italy
- **Sanada, Haruko**, Ritssho University, Japan

**Résumé**—In the present paper, we propose a simple endogenous method for enhancing a multilingual knowledge base through the cross-lingual semantic relation inference. It can be run on multilingual resources prior to semantic representation learning. Multilingual knowledge bases may integrate preexisting structured resources available for resource-rich languages. We aim at performing cross-lingual inference on them to improve the low resource language by creating semantic relationships.

## I. INTRODUCTION

HIGHLY structured knowledge bases (KBs) such as lexical semantic networks (LSNs) contain various connectivity patterns that can be learned as node features using dedicated frameworks i.e. node2vec [10]. However, semantic relations are often unequally distributed over such knowledge resources. Some of the language partitions may benefit from integrating structured resources which are more easily available for "rich" languages i.e. Princeton WordNet (PWN) [7], ConceptNet [21], YAGO [22] for English, RezoJDM [12] for French.

Unlike large factual KBs, the LSNs explicitly represent taxonomic relations (*hyponymy*, *meronymy*), predicate-argument relations, typical characteristic, and possibly other relation types (*entailment*, causal relations) as well as polysemy (through synsets, refinements). A meta-information related to the relation weight (power of association i.e. in RezoJDM), a confidence score linked to the origin of the relations integrated from some existing resources (i.e. in ConceptNet), annotation as well as negatively weighted relations that explicitly model "noise" (relation considered as false, i.e. RezoJDM) may be attached to the LSN relations in the framework of a particular model. Thus, automated semi-structured approaches to the multilingual LSN building represent a hard task : when available, models may vary from one language to another. For instance, the modeling of meronymy relations may reflect different vision of this relation type. In ConceptNet, the meronymy is represented as a *hasPart* relation. PWN introduces the distinction between part (*mammal*→*mouth*), substance (*wine*→*alcohol*), and member (*bee*→*bee colony*) meronymy. RezoJDM model includes all the relations covered by PWN and adds the holonymy relation (*cutlet*→*beef*).

## II. STATE OF THE ART

Cross-lingual relationship inference benefits from active research efforts. State of the art inference in KBs include rule-based and machine learning approaches. In the framework of the large KBs such as NELL [3], several approaches centered on the equivalence between entities and relationships have been introduced. For instance, authors in [11] describe the experience of merging several monolingual editions of NELL. Authors in [14] detail the statistical relational learning on knowledge graphs (KGs) and point out the importance of type constraints and transitivity as well as other statistical patterns or regularities, "which are not universally true but nevertheless have useful predictive power". Similar to [24], they base their method mainly on large scale KBs such as Nell [3], KnowItAll [6], YAGO [22] or DeepDive [20].

The endogenous rule-based inference process has been studied by Zarrouk (2015) and Ramadier (2016) in the framework of RezoJDM, the LSN for French. Their methods rely on the relationships and relationship meta-information that are already present in this LSN in order to propose the new ones following one of the following schemes : deduction, induction (which benefit from taxonomic relations), abduction (exploiting semantic similarity), and inference by refinement. Gelbukh (2018) introduced a comparable inference mechanism to enrich a collocational knowledge base by suggesting new collocations through the inference by abduction (where semantic similarity is calculated on the basis of PWN [7]).

KBs completion can be made using embedding strategies where latent spaces allow modeling candidate facts as resulting from latent factors. RESCAL [15] and TransE [1] propose such approaches. RESCAL performs collective learning using the latent components of the tensor factorization. In other words, the entity neighborhood is used to predict an unknown relation between this entity  $e_1$  and some other entity  $e_2$  knowing that some other entities similar to  $e_1$  (in terms of their neighborhood) are connected to  $e_2$  through the relation type  $t$ . The TransE method models relationships by interpreting them as translations in the embedding space and relies on low-dimensional embeddings of the entities. This system associates some vector depending on the relationship type to the vector of this relationship *tail* (source). This allows learning only one

low-dimensional vector for each entity and each relationship.

Markov Random Fields (MRF) based approach to KBs completion has been proposed with first-order logic representation through a *Markov logic network* in [17]. MRF-based approach with probabilistic logic representation has been introduced in [2]. Path ranking approaches based on random walk i.e. [5] are also being explored.

### III. CONTEXT

To conduct the experiment, we built a multilingual lexical-semantic network (MLSN) inspired by the RezoJDM for the food domain. At the time of our writing, the MLSN contains 821 781 nodes (terms) and 2 231 197 arcs (relationships). It is a directed, typed, and valuated graph. The MLSN  $k$  sub-graphs correspond to each of the  $k$  languages (English, French, Russian, and Spanish). A specific sub-graph fulfills the role of the *interlingual pivot*. The MLSN nodes may correspond to one of the following types : lexical items (i.e. *garlic*); interlingual items (also called *covering terms*) that are not necessarily labeled in a human readable way; relational items (i.e. relationship reifications such as *salad[r\_has\_part]garlic*); category items modeling categories, parts of speech or other morpho-syntactic features (i.e. *Verb :Present, Noun :AccusativeCase*).

During the MLSN set up and building, the hypothesis introduced in [16] concerning the "non separation" between general and domain specific knowledge has been considered. This hypothesis states that during the semantic analysis of domain specific texts that relies on background knowledge, the presence of general common sense knowledge in addition to the domain specific knowledge improves the performance of such analysis. Thus, general commonsense knowledge information has been integrated into our resource from the existing LSNs i.e. PWN, ConceptNet etc. This integration has been "guided" by the domain specific comparable corpora (96 083 cooking recipes, about 8 300 000 words) as its vocabulary has been used as a seed.

A relation  $r \in R$  is a sextuplet  $r = \langle s, t, type, v, l_s, l_t \rangle$  where  $s$  and  $t$  correspond respectively to the source and the target term of the relation. The relation  $type$  is a typical relation type. It may model different features such as taxonomic and part-whole relations ( $r_{isa}$ ,  $r_{hypo}$ ,  $r_{has\_part}$ ,  $r_{matter}$ ,  $r_{holo}$ ), possible predicate-argument relations (typical object  $r_{object}$ , location  $r_{location}$ , instrument  $r_{instr}$  of an action), "modifier" relations (typical characteristic  $r_{carac}$ , typical manner  $r_{manner}$ ) and more<sup>1</sup>. The relationship valuation  $v$  corresponds to the characteristics of the relation which are its weight, confidence score, and annotation. The relation weight may be negative in order to model noise and keep the information about erroneous relations easy to access programmatically so they could not affect the inference processes. The confidence score is a score attributed to a particular data origin (external resource, inference process). In practice, this feature

1. We also introduced more specific relation types such as  $r_{entailment}$ ,  $r_{cause}$ ,  $r_{telic\_role}$ ,  $r_{incompatible}$ ,  $r_{before}$ ,  $r_{after}$  etc.

is an array as different origins may provide the same relation. The confidence information is provided as an argument to the function that maps from some external knowledge resource to the MLSN. In case of relation calculated by an inference process, it corresponds to the precision evaluated on a sample of candidate relations returned by this process. To *annotate* a relation we add a complementary information that allows qualifying this relation. The labels  $l_s$  and  $l_t$  correspond to the language (sub-graph) labels.

As it has been difficult to set up the pivot using a multilingual embedding (joining multiple spaces, one per language) as well as to avoid pairwise alignment based on combinatorial criteria, the pivot has been started as a natural one using the English edition of DBNary [19]. It incrementally evolves based on sense alignments (obtained through external resources or by inference) between the languages of the MLSN to become interlingual. It can be considered as a union of word senses lexicalized or identified in the languages covered by the MLSN. Such progressive pivot building allows reducing the artificial contrast phenomena defined by [18] as a discriminatory information loss linked to the divergent conceptualization and lexicalization observed in different languages. Even though

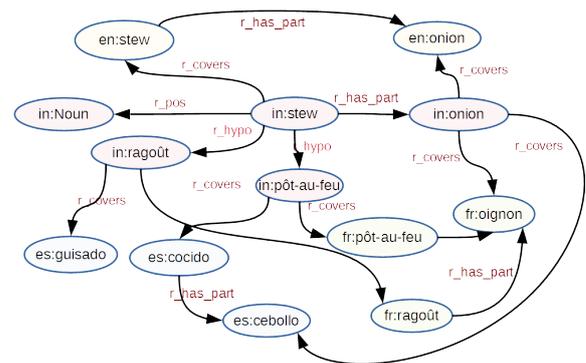

FIGURE 1. Pivoted MLSN architecture. *in* precedes interlingual terms.

we assume the pivot as being interlingual, it is still close to a natural one. As a result, the inference mechanisms we detail are suitable for the architecture by transfer.

The MLSN has been set up and populated through term and relationship extraction from corpora using state of the art pattern based techniques and lexical semantic patterns which add semantic constraints i.e. lookup for semantic relationships in the MLSN to the syntactic pattern; by integrating weakly structured domain specific information (glossaries, vocabulary lists, nutritional composition of food items) as well as structured lexical semantic resources (such as RezoJDM, PWN, ConceptNet) and inference mechanisms.

The table I shows that the global inference impact is higher in the context of the relationship types that are hard to yield by integration from structured resources or identified in corpora. The relationship typed *refinement*( $r_{raff}$ ) connecting terms to their senses will be described in section IV. The pivot coverage (how many terms from a given MLSN sub-graph are connected to the pivot?), the presence of semantic relationships and sense

refinements in a MLSN sub-graph also determine the success of a relationship inference process. Semantic information is easier to obtain from monolingual external resources. Thus, the exogenous data and semantic relationship acquisition are mostly monolingual. As a result, some terms may not be covered by the pivot. As the semantic relationships are used by the inference mechanism for logical filtering, when a MLSN sub-graph has numerous semantic relationships the inference precision is higher.

#### IV. CROSS-LINGUAL SEMANTIC RELATION INFERENCE

**Principle** - In this section we detail the inference of new semantic relations in one lexicalized part of the MLSN from the ones existing in another MLSN part (sub-graph). In a pivoted resource, the relations are first inferred into the pivot (ascending inference). Second, they are inferred in other sub-graphs (descending inference). In transfer-based resources where lexicalized sub-graphs are directly connected to each other, the inference process would directly apply to the source and target languages and rely on translation links between those. Thus, the proposed inference process is independent from the architecture of the resource (transfer or pivot based). It also may be considered as independent from the expressiveness of the multilingual resource as we define for and test it on a very expressive MLSN with numerous relation types. **Monolingual context** - In the monolingual context, the mechanisms of inference by deduction, induction, abduction, and inference with sense refinements apply. These processes have been described in [25]. In case of transitive semantic relations (i.e. hyperonymy, hyponymy), **deduction** and **induction** can be implemented. These inference schemes propose to a term some relevant relations detained by its hypernyms or hyponyms based on the transitivity of these taxonomic relations. For (nearly) synonyms, the **abduction** procedure is chosen. The abduction yields a set of terms similar to the term  $T$  then proposes the neighborhood relations detained by these terms to  $T$ . In order to calculate the similar terms more finely, in addition to calculating Jaccard similarity score, weighted Jaccard such as in [12] or some other similarity measure, we consider semi-relations (Typed ingoing and outgoing relations from/to a neighbor) shared by a pair of similar (synonymous)

terms. **Inference with sense refinements** exploits the sense refinement of polysemous terms. When the senses (we also call *refinements*) are modeled, it is possible to verify whether they are semantically related to the opposite term of the relation to be inferred.

To give an example, we may consider the french term *soupe* and its refinements  $\{soupe>potage, soupe>neige, soupe>repas\}$  ("soup>broth", "soup>melted snow", "soup>meal") and a new candidate relation we want to infer (relation obtained either by deduction, induction or abduction)  $soupe \xrightarrow{r_{carac}} chaud(hot)$ . In order to automatically accept such relation, we may check if one of soup refinements is semantically connected to *chaud* or one of its refinements :  $soupe>potage \xrightarrow{r_{isa}} liquide \& liquide \xrightarrow{r_{carac}} chaud$ .

**Multilingual context** - In the context of the cross-lingual semantic relation inference, we use the *r\_covers* relations to identify the semantic relations that correspond to the premises of the inference rules.

The relations typed *r\_covers* link an interlingual term to the lexicalized terms that it covers. We may suppose that during the ascending ( $language \rightarrow pivot$ ) and the descending ( $pivot \rightarrow language$ ) processes we deal with the equivalent terms. Due to the discrepancies between languages and to the fact that our recent interlingual pivot is still close to the natural one, one lexicalized term may have multiple covering terms and *vice versa*. Therefore, we consider the *r\_covers* relation as a cross-lingual variant of a (possibly) incomplete synonymy. Given that, the case of inference that applies can be either abduction or inference by refinement. For the abduction case in the ascending multilingual context, the relation to be inferred is considered as an abduction rule instance. We transform its source and target terms into the sets which may contain interlingual and lexicalized terms. Then, we explore the neighborhood of the intersection between the obtained sets. If the intersection between the typed semi-relations is sufficient (we empirically set the threshold to 3), the relation from the lexicalized subgraph is proposed for the terms in the interlingual pivot (and *vice versa* while performing a descending inference).

The case of polysemy is processed as if it was an "inference with sense refinements" case. It checks by triangulation the presence of semantic relations between the "refinements" of a term (the different covering or covered terms) and the opposite term of the relation to be inferred. A simplified example of the Russian term *pryanik* for which we are looking to infer relations typed *r\_has\_part* thanks to the "fr" MLSN subgraph illustrates the inference mechanism. The distinction between the sense refinements of *pain d'épices* in French can be modeled at the interlingual level as two interlingual refinements of the interlingual term  $in:gingerbread$  that are  $in:gingerbread>cake$  and  $in:gingerbread>biscuit$ . The inference is a twofold process. The relationships from the "fr" subgraph are inferred into the pivot using the interlingual terms that cover the *pain d'épices* neighbors : such as  $in:sugar \xrightarrow{r_{covers}} fr:sucre$ ,  $in:ginger \xrightarrow{r_{covers}} fr:gingembre$ , etc. Then, the relations are inferred from

the pivot to the "ru" subgraph. As *pryanik* in Russian culinary tradition has the soft cookie texture (this information is available from semantic relations of *pryanik* and from translation links where *pryanik* is linked to both refinements of *pain d'épices*, the distinction observed in French is not relevant for Russian. Thus, the descending inference process proposes candidate relations of the general interlingual term *in:gingerbread* to *pryanik*. As the general term detains the relationships of its refinements, *pryanik* yields all the relationships of *pain d'épices* that can be represented on the interlingual level and persist after logical/statistical filtering.

The abduction scheme generates a lot of candidate relationships. Therefore, a filtering strategy significantly improves the precision. First, we apply part-of-speech pre-filtering can be used depending on relation types. For instance, in the case of the relation typed  $r_{carac}$  (typical characteristic) the source term must be a noun whereas the target term must be an adjective (i.e.  $cake \xrightarrow{r_{carac}} sweet$ ). Second, we use the statistical filtering as the relations of the MLSN can be analyzed in terms of their number, weight, and origin. The weight  $w$  corresponds to the crowd-sourced weight or to the default weight. Similar to ConceptNet, we introduced the information regarding the confidence given to the structured resource from which a given relation has possibly been integrated or to the endogenous inference. Thus we attach the *origin* information to the relationships. It took the form of an array of strings (naming the different processes that provided the relation) to which we associate an array of confidence scores  $\psi = \{i_1, i_2, \dots, i_n\}$  where  $i_j \in [0; 1]$ . The size of the set of semi-relations shared by the terms  $\phi$  is also taken into account. For the positively or negatively weighted relation the filtering function is calculated as follows for  $w \in \mathbb{Z}$  and  $|\psi| > 0$ :

$$f(r) = \phi \times \frac{w}{Max(\psi) \times \log(|\psi|)}$$

In a mature MLSN, the relation inference algorithm becomes a simple lifting and descending algorithm where no significant filtering to be applied.

**Experiment** - We tested our approach on all the semantic relations and languages present in the MLSN. The table II lists the results of the descending inference process. The results are presented in terms of number of relations in the source partition (**#orig**), number of candidate relations (**#cand**), number of accepted relations after filtering (**#acc**), productivity of the algorithm (**prod**), acceptance rate (**%acc**, the percentage candidate relationships that verify the inference rule premises and conclusion and subsist after filtering), and precision (**pr**) which has been manually evaluated on a sample of 500 accepted relations (per type). This type of manual evaluation has been chosen due to the difficulty to find a well balanced reference for evaluation. As we integrated the main LSNs for the languages covered by the MLSN, we presumably infer the relationships that are not explicitly represented in such structured resources. The range **r** has been introduced to express how close a given process is situated to the "gold" productivity (100%). Indeed such "gold" productivity would

mean that the sense based alignment is sufficient for a given term. The table II lists the results for the main semantic relations of the Russian and Spanish sub-graphs and details the evolution of the number of semantic relations.

TABLE II  
DESCENDING INFERENCE OF SEMANTIC RELATIONS.

type	l	#bef	#inf	#aft	ev
$r_{isa}$	ru	46 827	7 036	53 863	+14%
	es	36 807	268 040	304 847	+828%
$r_{has\_p}$	ru	65 772	3 682	69 454	+5%
	es	10 166	56 883	67 049	+559%
$r_{mat}$	ru	5190	4230	9 420	+81%
	es	4013	7 351	7 764	+183%
$r_{man}$	ru	1 265	1 655	2 920	+131%
	es	1 753	9 507	11 260	+542%
$r_{loc}$	ru	640	621	1 261	+97%
	es	90	567	657	+630%
$by\ lang.$	ru	119 694	17 224	136 918	+14%
	es	52 739	342 348	395 087	649%
TOTALS	-	172 433	359 572	532 005	+208%

The logical filtering concerns only a subset of relation types to be checked  $m$  times (according to the branching factor of the term). Thus, the global complexity of the logical filtering would be  $O(m \times n^2)$ . La *average complexity* would correspond to the average degree observed in the MLSN at the time of our writing :  $d_{av} = 4 \Rightarrow O(16 \times m)$ .

**Towards the Sense-based Alignment** - The MLSN refinement relations allow modeling the "use" senses of a term. The refinement corresponds to maximal cliques (calculus) or to the contributions (GWAP). For the french term *baguette*, we distinguish the sense "bread" as opposed to "direction", "stick", and "magic wand". The glossed refinement corresponds to this sense is *baguette > pain*. Thus, we have the following structure in the MLSN :  $baguette \xrightarrow{r_{raff}} baguette > pain \xrightarrow{r_{glose}} pain$ . A glossed refinement may be itself refined and glossed. In the case of a resource that already possesses refinement relations, it is possible to infer some cross-lingual new refinements from the existing ones. The 30% refinement rate of the MLSN pivot has been obtained using this process.

When the term has multiple covering terms, the descending inference pattern can be applied. We consider that the covering terms are potentially linked to the gloss. First, we temporarily label the potential senses using the labels of the covering terms. Second, we group the redundant senses and choose the gloss. the recently started experiment with this pattern allowed producing the first batch of 2 535 sense refinements in Russian whereas 1 800 refinements have been yielded for this language using the glossed refinement technique.

## V. CONCLUSION

We introduced a simple endogenous method for cross-lingual semantic relation inference to improve structured KBs such as MLSN. Given a certain coverage in terms of translation links, it allows enhancing the under-resourced parts of a lexical semantic resource from the rich ones. Even though they benefit from translation resources and tools, some "rare" languages are not covered by any rich lexical semantic resource. To

some extent, the method is beneficial for domain specific MLSNs. It allows rich semantic modeling which provides a semantically structured representation for the fine grained semantic analysis (including word sense disambiguation) and statistical representation learning.

**Abstract**—The state of the art in Sentiment Analysis is defined by deep learning methods, and currently the research efforts are focused on improving the encoding of underlying contextual information in a sequence of text. However, those neural networks with a higher representation capacity are increasingly more complex, which means that they have more hyper-parameters that have to be defined by hand. We argue that the setting of hyper-parameters may be defined as an optimisation task, we thus claim that evolutionary algorithms may be used to the optimisation of the hyper-parameters of a deep learning method. We propose the use of the evolutionary algorithm SHADE for the optimisation of the configuration of a deep learning model for the task of sentiment analysis in Twitter. We evaluate our proposal in a corpus of Spanish tweets, and the results show that the hyper-parameters found by the evolutionary algorithm enhance the performance of the deep learning method.

## I. INTRODUCTION

OPINIONS, sentiments, experiences, private states, broadly speaking subjective information, are continuously posted on micro-blogging sites as Twitter. The processing of this kind of information is crucial for other users and for any kind of organisation, because it offers a valuable source of knowledge to understand the perspectives of users on topics of interest, which eases the process of making decisions [1]. Sentiment Analysis (SA) is the task centred on labelling the opinion meaning of a text, and it is defined as the computational treatment of opinions, sentiments and subjectivity in texts [2].

Since the use of language in Twitter has its own characteristics that make it different from the use of language in formal genre of writing, specific computational methods have to be developed [3]. The main contributions to the processing of the sentiment of tweets can be found in the respective tasks of the workshops SemEval<sup>1</sup> for the English language and TASS<sup>2</sup> for the Spanish language. The state of the art on those workshops has evolved from the use of linear classification systems grounded in the use of a big bunch of hand-crafted linguistic features [4], [5] to the use of deep learning methods

without the need in most of the cases of hand-crafted features [6], [7].

Besides the strong results of deep learning methods in SA in Twitter, we stress out that those deep learning methods has reduced the need of feature engineering, because they are based on the use of unsupervised pre-train features, which the most used are vectors of word embeddings. Deep learning methods depend on the configuration of some parameters that are known as hyper-parameters, such as the number of output units of each neural layer or the dropout rate. Those hyper-parameters must be defined by hand, hence the positive reduction of the effort in the designing of features has been changed to the effort of setting the right hyper-parameters value. The current trend in the development of neural networks for SA is to attempt to encode as much contextual information as possible, which is the aim, for instance, of the self-attentive networks [8] and memory networks [9]. The high complexity of those deep learning architectures entails to define a higher number of hyper-parameters, which means that their configuration would not be an easy task.

We define the process of hyper-parameter setting as an optimisation task, because the optimisation of the value of the hyper-parameters allows to optimise the performance of the neural network. In this paper we thus claim that the use of an optimisation method, as an Evolutionary Algorithm [10], may find out the right hyper-parameters values and consequently optimise the performance of a neural network. We propose the use of the evolutionary algorithm SHADE [11] for optimising the hyper-parameters of a self-attentive neural network for the task of SA in Twitter.

We evaluate our proposal in the task of SA in Twitter in Spanish, and we used the Spanish set of the corpus InterTASS [12]. We define as a baseline model our self-attentive neural network with a set of hyper-parameters values defined by hand, and we compare its performance with the optimised version of the neural model. Likewise, we compare the performance of our proposal with the results reached in the TASS 2018

<sup>1</sup>[https://aclweb.org/aclwiki/SemEval\\_Portal](https://aclweb.org/aclwiki/SemEval_Portal)

<sup>2</sup><http://www.sepln.org/workshops/tass/>

competition,<sup>3</sup> and we show how our proposal without any external knowledge reaches a similar performance than the highest ranked systems in the competition. Moreover, we show how our evolutionary proposal has the ability to improve the learning of minority classes in a imbalanced dataset, as the InterTASS corpus is, and reduces the complexity of the neural model. Although we evaluated our proposal in an imbalanced dataset, we did not conduct any standard data augmentation technique that are usually performed for enhancing the performance of deep learning methods [13], because our aim is to evaluate our claim without the influence of any data pre-processing method.

The reminder of this paper is organised as what follows: Section II exposes some related works to SA in Twitter and hyper-parameter learning. Subsequently, Section III presents our deep learning model for SA in Twitter, which is optimised by an evolutionary algorithm that is detailed in Section IV. Sections V and VI are focused on the description of the experimental set up and the analysis of the results. Finally, Section VII presents the conclusions of our work.

## II. RELATED WORKS

We propose the automatically learning of the hyper-parameters of a deep learning method in order to tackle the task of SA in Twitter. Accordingly, Section II-A describe some works related to SA, and Section II-B is focused on the task of neural networks hyper-parameters learning.

### A. Sentiment Analysis in Twitter

Since the first days of Twitter, this microblogging site has attracted the attention of the research community, although the first works were closer to social sciences [14] than computer science, as well as to the concept of the electronic word of mouth [15]. However, as the popularity of Twitter was increasing, it was becoming in a communication tool in which users exchange their private states, or in other words their experiences, sentiments and opinions.

The first works on SA in Twitter were similar to the first ones in regular texts [16], [17], they were focused on the study of how to represent the opinion meaning of texts and the comparison of linear machine learning classification algorithms. In [18], the first corpus of SA in Twitter is described, and the authors evaluated the performance of three linear classification methods with three different feature vector representations approaches. The following works centred the efforts on feature engineering, broadly speaking, on the use of linguistic features and external knowledge for the representation of the opinion meaning of tweets. For instance, in [19] the tweets were represented with a combination of weighted unigrams and features generated from a sentiment lexicon. Similarly, in [20] the authors used a list of subjective hashtags besides the use of a sentiment lexicon and unigrams to classify the polarity of tweets from different topics. The use of sentiment external knowledge is essential in [21], in which the authors

first represented the tweets as bag of unigrams and bigrams, and each unigram and bigram is represented as a vector of sentiment values aggregated from several sentiment lexicons.

The classification of the polarity of tweets was also used to the prediction of future events, such as the outcome of elections [22], [23]. Likewise, in [24], the authors use the classification of the opinion to predict the evolution of stock markets. As the previous works, the method are based on the representation of the tweets with a great bunch of features and the use of linear classifiers.

Besides the strong results of deep learning methods in Twitter SA, they allow to extremely reduce the efforts in feature engineering and in the use of external knowledge. However, this is caused by the representation of the input sequences of text, in this case, tweets, with unsupervised pre-trained feature vectors. Those feature vectors are known as word embedding that represent the meaning of each word, and they are based on the distributional semantics hypothesis. Accordingly, deep learning methods allow to reach strong results with a low designing effort. For instance, in [25], the authors classify the polarity and the language of tweets with a convolutional neural network (CNN). Likewise, the straightforward neural network described in [26] also reached good results in SA in Twitter in Spanish. Other example of the use of deep learning methods for SA in texts different from English can be read in [27]. However, in some cases, the enhancing of the performance of polarity classification in Twitter forces to use deeper and more complex deep learning methods. In [28], the authors propose the combination of a Long-Short Term Memory (LSTM) Recurrent Neural network (RNN) layer and CNN layer for polarity classification of tweets written in English.

### B. Hyper-parameters Learning

The trend in SA in Twitter is the addition of more encoding layers (CNN, LSTM), and other kind of mechanisms to increase the capacity of the network to represent the contextual information of the input sequence of text. Those layers depend on a set of configuration parameters or hyper-parameters, which their right definition is essential for the global performance of the neural network. Moreover, regularisation layers, as Dropout or penalty rates for the loss function, are key elements of the architecture of neural networks in order to avoid the over-fitting. Consequently, the design of a neural network required of an effort of selecting the right hyper-parameters for each of the layers of the architecture. Therefore, the feature engineering effort has evolved to hyper-parameter engineering.

The definition of the right hyper-parameters is not an easy task, and there is not any rule of thumb to do it. However, there exist some strategies to address it, as well as, some computational approaches, which we indicate as what follows:

- 1) Brute force. It consists in the exhaustive evaluation of all possible values of all the hyper-parameters, which is not feasible because of limitation of time and computational resources.

<sup>3</sup><http://www.sepln.org/workshops/tass/2018/>

- 2) Grid search. It is a brute force approach constrained by a pre-defined set of hyper-parameters values. This is a feasible strategy because the number of evaluations is lower in comparison with the brute force, and it allows to reach good results as show in [29]. However, the hyper-parameters values must be defined by hand.
- 3) Random search. In [30] is shown that the random search of the values of the hyper-parameters allows the neural network to reach good results. However, the random search cannot assure to find out the values that optimise the performance of the network.
- 4) Bayesian approximations [31]. The positive side of this strategies is that they do not have to completely run the neural network to optimise it, because they are grounded in a approximation. However, the complexity of those methods make them close to be unfeasible and difficult to be parallelised.
- 5) Evolutionary algorithms [10]. As the bayesian approximations, these algorithms seek in the hyper-parater values search space those ones that may optimise the performance of the network. Nevertheless, the own definition of evolutionary algorithms has specific strategies for finding the right values in the search space. Moreover, these algorithms are parallelisable in contrast to bayesian approximations, indeed they are parallelisable in GPUs [32]. In [33] is described the use of the CMA-ES [34] for tuning the hyper-parameters of a neural network. In [35] is again used the CMA-ES algorithm for the otpimisation of a neural network, but in this case for the generation of a language model. The use of evolutionary methods for hyper-parameter tuning has not ceased, and recently in [36] a new evolutionary method has been proposed with positive results.

Since evolutionary algorithms are showing a positive performance on the task of hyper-parameter optimisation, we select that strategy for our experimentation, and we propose the use of the algorighm SHADE for the tuning of the hyper-parameters of a self-attentive neural network for the task of SA in Twitter.

### III. DEEP LEARNING MODEL FOR SA

Since our aim is to show the suitability of evolutionary algorithms for tuning the value of hyper-parameters, we propose a deep neural network with several layers with the aim of encoding as much contextual information as possible, which also goes in the line of the proposals of the state of the art (see Section II-A). In the subsequent sections we describe the architecture of our neural network that is composed of three main layers: (1) encoding layer (see Section III-A), self-attention layer (see Section III-B) and classification layer (see Section III-C).

#### A. Encoding layer

Two kind of information may be encoded from a sequence of text: local and temporal. The local information is the underlying one from the inter-dependencies among words in

a local context. On the other hand, the entire sequence of text has also their own meaning which depends on the relation of all the words. Because of these two kind of information, we define an encoding layer composed of a CNN, focused on the local information, and an RNN LSTM layer, centred on the temporal information.

a) *CNN*: We choose a CNN layer in order to focus on the local information motivated by its sparse interactions and the ability to combine features of a local context. CNNs get this ability by implementing the discrete convolution operator (see Equation 1).

$$s(t) = (x * w)(t) = \sum_{a=-\infty}^{\infty} x(a)w(t-a) \quad (1)$$

where  $x$  is the input and  $w$  the kernel. The output is sometimes referred to as the feature map of size  $\text{CNN}_{fm}$ .

The input of a CNN layer is always a grid-structured dataset. For example, the sequence of vectors  $\mathbf{w} = (w_1, w_2, \dots, w_n)$ . This layer performs the convolution function for a fixed kernel size  $\mathbf{k}$ . For an 1-dimensional CNN, the output is another grid-structured dataset of size  $n \times \text{CNN}_{fm}$ . Equation 2 summarise the definition for an 1-dimensional CNN layer:

$$\begin{aligned} \text{CNN}(\mathbf{w}_{1:n}, \mathbf{k}) &= \mathbf{y}_{1:n} \\ \mathbf{y}_i &= s(\mathbf{k}) \\ \mathbf{w}_i &\in \mathbb{R}^d, \mathbf{k} \in [1, 2, \dots, n] \end{aligned} \quad (2)$$

b) *Bidirectional Long-Short Term Memory*: The election of RNN to capture temporal information is due to the fact that they maintain memory based on information history. These networks are defined by a non-linear function  $\sigma$  applied recursively on a sequence of inputs  $(w_1, w_2, \dots, w_n)$ . The input of  $\sigma$  is a state vector  $\mathbf{s}_{i-1}$  and an element of the sequence input  $\mathbf{w}_i$ . The output of the non-linear function  $\sigma$  is a new state vector  $\mathbf{s}_i$ , which is transformed to the output vector  $y_i$  by a deterministic function  $O$ . Equation 3 summarise the definition:

$$\begin{aligned} \text{RNN}(\mathbf{w}_{1:n}, \mathbf{s}_0) &= \mathbf{y}_{1:n} \\ \mathbf{y}_i &= O(\mathbf{s}_i) \\ \mathbf{s}_i &= R(\mathbf{w}_i, \mathbf{s}_{i-1}); \\ \mathbf{w}_i &\in \mathbb{R}^d, \mathbf{s}_i \in \mathbb{R}^{f(h_{lstm})}, \mathbf{y}_i \in \mathbb{R}^{h_{lstm}} \end{aligned} \quad (3)$$

LSTM is a gating-based architecture of RNN that uses several gates in order to solve the gradient vanishing (or exploding) problem of RNN. However, LSTM still has a limitation, the recurrence is only implemented in one direction (from left to right). Nevertheless, the meaning of each word depends on their surrounding context words, broadly speaking, the words in their left and right. Accordingly, we use a bidirectional LSTM (biLSTM). These networks consist in two consecutive LSTM layers, each one in one direction (forward ( $\text{LSTM}^f$ ) and backward ( $\text{LSTM}^b$ )), encoding the full context information. We formally define biLSTM in Equation 4.

$$\text{biLSTM}(\mathbf{w}_{1:n}) = [\text{LSTM}^f(\mathbf{w}_{1:n}, s_0^f), \text{LSTM}^b(\mathbf{w}_{1:n}, s_0^b)] \quad (4)$$

### B. Self-Attention mechanism

The aim of attention mechanisms is to give the neural network the capacity of selecting what to learn from the input data, as humans do. Attention mechanisms have become an essential part of sequence modelling in a wide range of tasks. They are commonly used in conjunction with a RNN.

The attention mechanism in NLP tasks allow to learn what words are the most salient for the global meaning of a sequence of text, but it does not take into account the dependencies that each word has with the others. Self-Attention mechanism [37] calculates the relation of each word with the others, hence it uses more information in order to identify the most salient words. Since Self-Attention allows to use more contextual information of the input data, we chose it in order to automatically learn the set of more prominent words for the polarity classification of the input tweets.

The input of the attention mechanism is a matrix of features, in our case the output of a dense layer immediately after the biLSTM layer,  $H = (\mathbf{h}_1, \mathbf{h}_2, \dots, \mathbf{h}_n)$  where  $h_i \in \mathbb{R}^d$ . This mechanism aims at selecting the best linear combination of the  $n$  hidden vectors in  $H$ . The output of the attention layer is a vector of weights  $\mathbf{a}$ , which are calculated according to Equation 5.

$$\mathbf{a} = \text{sigmoid}(\mathbf{w}_{s2} \tanh(\mathbf{W}_{s1} H^T)) \quad (5)$$

where  $\mathbf{W}_{s1}$  is a matrix of size  $c \times d$  and  $\mathbf{w}_{s2}$  a vector of size  $c$ , with  $c$  arbitrary fixed in  $[1, n]$  (usually equal to  $n$ ). The *sigmoid* function ensures that the output weights are in  $[0, 1]$ .

The output of the attention mechanism has to be combined with the processing pipeline in order to select the most salient words from the input. Accordingly, the output of the attention layer is added up to the output of the dense layer that is immediately after the biLSTM layer.

An extension of the mechanism that performs multiple hops of attention can be used. It is enough to replace the vector  $\mathbf{w}_{s2}$  with a matrix  $\mathbf{W}_{s2}$  of dimension  $r \times n$ , where  $r$  is the number of weighted outputs we want to generate.

$$\mathbf{A} = \text{sigmoid}(\mathbf{W}_{s2} \tanh(\mathbf{W}_{s1} H^T)) \quad (6)$$

Finally, the mechanism encodes the weighted sums by multiplying the matrix  $\mathbf{A}$  and the matrix of features  $\mathbf{H}$ , resulting the matrix  $\mathbf{M} = \mathbf{A}\mathbf{H}$ . To ensure the matrix  $\mathbf{M}$  does not suffer from redundancy problems, the mechanism uses a penalisation term in order to encourage the diversity of the weighted sums across different hops of attention.

### C. Classification layer

The classification starts with the tokenization of the sequence of input text ( $n$ ). The meaning of each word is represented with its corresponding word embedding vector,

which is looked up in a set of pre-trained word embeddings vector. Accordingly, the output of the input layer is  $I_{n \times d}$ .

The output of the input layer is processed by the encoding layer. First, a CNN layer of kernel 2 with feature map of size  $\text{CNN}_{fm}$ . Subsequently, we use an one-dimensional maxpooling operation with pool size as two using padding in order to keep the sentence size. Likewise, we add a dropout layer with rate  $dr^1$  after the maxpooling layer.

After the convolution, we use a biLSTM layer with  $h_{lstm}$  hidden units. We use the L2 kernel regulariser with rate  $L_2r^1$  in each LSTM layer. After that, we reduce the dimension of the output of the biLSTM with a dense layer with  $h^1$  hidden units.

We apply the self-attention mechanism at this point in order to capture the relevance of each word with the generated features. We merge the results of the attention mechanism with the previous output by an addition. We apply a fully-connected layer with output size  $n \times h^1$ .

$$\begin{aligned} \text{sigmoid}(y_{n \times h_2}^9) &= \text{pred}_4 \\ \text{Dropout}(y_{n \times h_1}^8, d_r^3) &= y_{n \times h_2}^9 \\ \text{Dense}(y_{n \times h_1}^7) &= y_{n \times h_2}^8 \\ \text{Attention}(y_{n \times h_1}^6) &= y_{n \times h_1}^7 \\ \text{Dropout}(y_{n \times h_1}^5, d_r^2) &= y_{n \times h_1}^6 \\ \text{Dense}(y_{n \times 2h_{lstm}}^4) &= y_{n \times h_1}^5 \\ \text{biLSTM}(y_{n \times \text{CNN}_{fm}}^3) &= y_{n \times 2h_{lstm}}^4 \\ \text{Dropout}(y_{n \times \text{CNN}_{fm}}^2, d_r^1) &= y_{n \times \text{CNN}_{fm}}^3 \\ \text{MaxPooling}(y_{n \times \text{CNN}_{fm}}^1) &= y_{n \times \text{CNN}_{fm}}^2 \\ \text{CNN}(\mathbf{w}_{n \times d}, 2) &= y_{n \times \text{CNN}_{fm}}^1 \end{aligned} \quad (7)$$

Finally, we use two dense layers. The first one with  $h^2$  hidden units, and the second one matching the number of labels with *sigmoid* activation function.<sup>4</sup>

We show the architecture of our model in Figure 1. Furthermore, we summarise the formal definition in Equation 7.

## IV. EVOLUTIONARY OPTIMISATION OF HYPER-PARAMETERS

The increasing complexity of deep learning models in SA are becoming harder the right configuration of the hyper-parameter values of the neural networks. In this section we describe our proposal grounded in the use of a evolutionary algorithm for tuning the hyper-parameters of a deep learning method.

Evolutionary algorithms (EA) are based on the natural evolution of species, which allows to keep promising individuals, that is, best solutions to our problem. The main steps of these types of algorithms are: (1) Initialisation of a random population, (2) evaluation of the population, (3) selection of the parents, (4) crossover and mutation and (5) replacement of

<sup>4</sup>We decided to use the sigmoid function instead of softmax as activation function of the last layer because the sigmoid function reached better results in previous experiments.

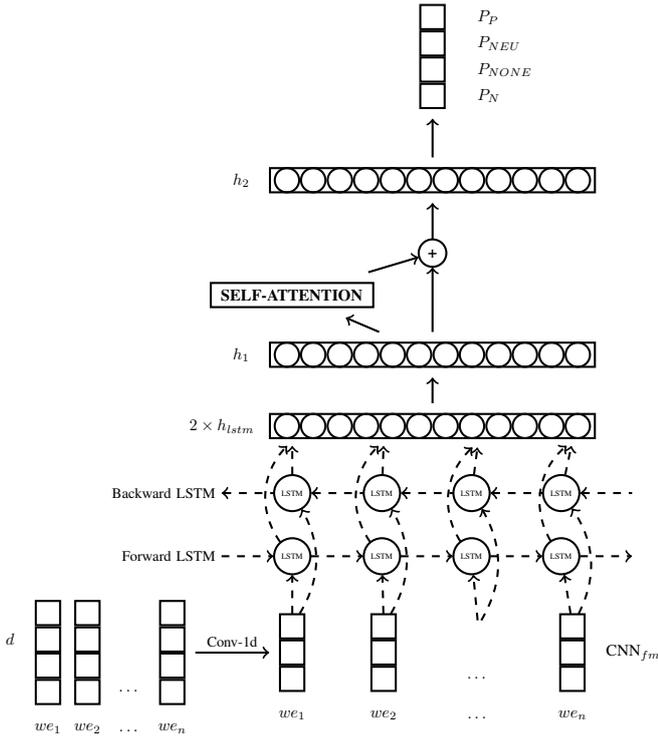

Fig. 1. Architecture of the deep learning model.

the current population by a new generation with individuals selected between parents and offspring. The algorithm is iteratively run until the stopping condition is satisfied.

According to the CEC competition,<sup>5</sup> L-SHADE [38] is in the state of the art of EAs. This algorithm is able to work with large populations of individuals, and it has a mechanism to linearly reduce the population size. The population size of our problem is not large, hence the L-SHADE algorithm is not the most suitable. Consequently, we used the SHADE algorithm [11], which lacks of the linear population size reduction method.

We define as the population of EA the hyper-parameters of some of the layers of our deep learning configuration proposed, specifically: (1) dropout rate ( $dr^1$ ,  $dr^2$  and  $dr^3$ ), (2) regularisation rate (L2) ( $L_2r^1$  and  $L_2r^2$ ) and (3) number of units in the network layers ( $CNN_{f_m}$ ,  $h_{LSTM}$ ,  $h^1$  and  $h^2$ ). Thus, each individual shows a candidate combination of these network hyper-parameters. Figure 2 shows an example of an individual of the population.

110	0.5	64	64	0.0005	0.5	32	0.002	0.5
$CNN_{f_m}$	$dr^1$	$h_{LSTM}$	$h^1$	$L_2r^1$	$dr^2$	$h^2$	$L_2r^2$	$dr^3$

Fig. 2. Example of an individual of the population.

Differential evolution (DE) evolves a population of  $NP$   $D$ -dimensional individual vectors towards the global optimum. We represent as  $x_{i,G}$  the individual  $i$  at generation  $G$  and called it target vector. The initial population should ideally cover the entire search space by randomly distributing each parameter of an individual vector with uniform distribution between prescribed upper and lower parameters bounds.

The main operations of the SHADE algorithm are described as what follows.

#### A. Mutation Operation

Trying to generate diversity in our population, we create a new population which will be crossed in a next step with the current individuals. We define the next mutation operation for this task. For each target vector  $x_{i,G}$  we generate a mutant vector  $v_{i,G}$ . We use the mutation strategy DE/current-to-best/1, which generates a mutant vector using differences between the target vector and the best individual and other random individuals of the current population (see Equation 8).

$$v_{i,G} = x_{i,G} + F(x_{best,G} - x_{i,G}) + F(x_{r_1^i,G} - x_{r_2^i,G}) \quad (8)$$

where the subscripts  $r_1$  and  $r_2$  are random and mutually different integers generated in the range  $[1, NP]$ ,  $F$  is a positive factor for scaling differential vectors and  $x_{best,G}$  is the individual vector with best fitness value in the population at generation  $G$ .

#### B. Crossover Operation

The idea of diversity is needed for seeking the solution. However, we need a balance between exploration of the search-space and exploitation of the current population. Thus, after the mutation operation, crossover operation is used on the individual  $x_{i,G}$  and its corresponding mutant vector  $v_{i,G}$  to generate a trial vector  $u_{i,G}$ , which could be seen as a new individual that allows to keep both properties noted before. For each parameter of the trial vector, we choose between the corresponding parameter of  $x_{i,G}$  or  $v_{i,G}$  depending on crossover rate ( $CR$ ):

$$u_{i,j,G} = \begin{cases} v_{i,j,G} & j = K \text{ or } rand_{i,j}[0, 1] \leq CR \\ x_{i,j,G} & \text{otherwise} \end{cases}$$

where  $CR$  is a value within the range  $[0,1]$ ,  $K$  is a randomly chosen integer in the range  $[1, D]$ . To ensure that the trial vector  $u_{i,G}$  will differ from its corresponding vector  $x_{i,G}$  we add the condition  $j = K$ . As result, we obtain the off-spring population.

#### C. Selection Operation

It selects the best individuals from the population in order to generate a better offspring. The objective function value of each trial vector is compared to its corresponding target vector in the current population. If the trial vector improve the objective function value, the trial vector will replace the target

<sup>5</sup>[http://www3.ntu.edu.sg/home/EPNSugan/index\\_files/cec-benchmarking.htm](http://www3.ntu.edu.sg/home/EPNSugan/index_files/cec-benchmarking.htm)

vector for the next generation. Otherwise, the target vector will remain in the population for the next generation. The selection operation is grounded in the Equation 9

$$x_{i,G+1} = \begin{cases} x_{i,G} & f(x_{i,G}) \leq f(u_{i,G}) \\ u_{i,G} & \text{otherwise} \end{cases} \quad (9)$$

#### D. Parameters self-adaption

The performance of the original DE algorithm is highly dependent on the parameters settings ( $CR$  and  $F$ ). It may require a huge amount of computation time. SHADE can automatically adapt the parameters settings during evolution. For this purpose, SHADE introduce success and failure memories to store different values of  $F$  and  $CR$  within a fixed number of previous generations, hereby named learning period (LP). After the initial LP generations, the probabilities of choosing different parameters values is given by Equation 10.

$$p_{k,G} = \frac{S_{k,G}}{\sum_{k=1}^K S_{k,G}} \quad (10)$$

where  $K$  is the total number of values that we can choose, and  $S_{k,G}$  represents the success rate of the trial vectors generated by the  $k_{th}$  value and successfully entering the next generation within the previous LP generations with respect to generation  $G$ . Equation 11 defines  $S_{k,G}$ .

$$S_{k,G} = \frac{\sum_{g=G-LP}^{G-1} n_{s_{k,G}}}{\sum_{g=G-LP}^{G-1} n_{s_{k,G}} + \sum_{g=G-LP}^{G-1} n_{f_{k,G}}} + \epsilon \quad (11)$$

where  $n_s$  and  $n_f$  are the successful and failures for a certain value in a certain generation.

#### E. Restart mechanism

When an iteration of the evolution is performed, it is possible that our solutions may get stuck in a local search space. Accordingly, we propose to use a restart mechanism in order to avoid to reach a local optimum. When many generations pass without an improvement of the best solution, we opt to restart the population, keeping the best so far. It allows to move our search to new points of the search-space and and test new solutions that could not be evaluated without this approach.

#### F. Objective function

We need an objective function for evaluating the candidate solutions and select best ones. For that, we design a fitness function based on the following requirements:

- We fixed a model (same for each individual).
- Given an individual, each individual parameter is placed adequately in this model.
- We train the model for those values.
- We get predictions and calculate **Macro-F1** (see Section V-C) over a training set.
- With the purpose of minimising the previous value, we use  $1 - MacroF1$  as fitness function for this individual.

Thus, we lead on the evolution of the population towards to the solution with the best results for **Macro-F1** over the evaluation set.

## V. EXPERIMENTS

In this section we show the experiments carried out with our proposed deep learning hyper-parameter tuning based on an EA. We first introduce the dataset used in our experiments, InterTASS Corpus (see Section V-A). Subsequently, we detail the set of pre-train vector of word embeddings used to represent the input tweets (see Section V-B). Then, we compare the results obtained with our method to the ones given by the neural network using the hyper-parameters defined by hand. We also compare our models to the highest ranked model in Task 1 of TASS-2018 Workshop (see Section V-C).

#### A. InterTASS Corpus

The InterTASS Corpus was presented in the *TASS-2018 Workshop* for Task 1, polarity classification at tweet level. The sentiment of the tweets of the corpus are annotated in a scale of 4 levels of polarity intensity: positive (P), Negative (N), neutral (NEU) and no opinion (NONE). The InterTASS Corpus is divided into three datasets: Training (1008 tweets), Development (506 tweets) and Test (1899 tweets). The distribution among the different labels is shown in Table I.

TABLE I  
SIZE OF EACH CLASS IN EACH SUBSET OF THE INTERTASS CORPUS.

	Training	Dev.	Test
P	317	156	642
NEU	133	69	216
N	416	219	767
NONE	138	62	274

According to Table I, the size of the training set is not large, and the distribution of the classes is not balanced, because there is a big difference among the classes P and N and the classes N and NONE. Thus, this two facts will make harder the classification and the optimisation of the model. According to [39], the imbalanced of the data in machine learning may be smoothed by oversampling the minority class. Hence, we slightly reduced the imbalance of the corpus conducting an oversampling method, which consisted in duplicating the instances from the two minority classes. The distribution among the classes in the training set after the oversampling is shown in Table II.

TABLE II  
DISTRIBUTION OF LABELS AFTER OVERSAMPLING THE MINORITY LABELS.

	No Oversample	Oversample
P	317	317
NEU	133	266
N	416	416
NONE	138	276

As we can see from the distribution of classes in table II, NEU and NONE are still the minority classes. However,

the difference with the majority classes has decreased. Establishing the percentage of oversampling is a difficult task, since the amount of data from the minority classes must be increased without losing the representativity of the dataset. For that reason, we choose low oversampling ratios.

### B. Word Embeddings

As we indicated in Section III-A, each word is represented with a vector from a set of pre-trained set of word embeddings. Since the aim is to classify data from Twitter, we trained the embeddings on a set of tweets written in Spanish<sup>6</sup> and using the FastText method [40]. This set of embeddings have a vector representation for some meta-tokens of Twitter, such as: mentions (@user), emojis<sup>7</sup> and for the hashtags of the embeddings training set.

The dimension of the vectors given by these embeddings is  $d = 100$ . Since we used TensorFlow for developing our deep learning method, we had to define a fixed size for the input of the neural network, and to used a zero-padding approach for those tweets shorter and larger to the pre-defined size. The longest tweet in the training set contained 35 tokens, so shorter tweets were filled using padding and truncated in the case of finding a longer tweet in the validation or test set. As the length of the embeddings is 100 and the length of the tweets was set to be 35, the input of the model is a  $35 \times 100$  matrix.

### C. Results

In this section we present the results of the evaluation, that was conducted using the standard evaluation measures in text classification tasks, specifically: F1 score and Accuracy. The F1 is the harmonic mean of the Precision and the Recall, and it provides a trade off among them. Since we are facing up a multi-class classification problem, we used the macro-average version of F1.

We define a set of default values for the hyper-parameters of our deep learning model. Those values were used to configure out the model that was not optimised by the EA algorithm, and they were also used as the initial values of the neural model that was optimised. Table III shows the default hyper-parameters values, which are similar of other deep learning models from the state of the art in SA in Twitter. Likewise, Table III shows the hyper-parameter values returned by the EA algorithm. Some of those values are far from the default ones, and we highlight the value for the second layer of dropout ( $dr^2$ ) that is a very uncommon rate value for a dropout layer, which is usually about 0.5. We also stress out the value for the output units of the biLSTM layer, which is far away from the default value, and it significantly reduces the number of trained parameters of the neural network. Likewise, the size of the output dimension of the CNN was also shortened. Consequently, the SHADE algorithm also optimised the complexity of the neural network.

<sup>6</sup>The tweets to train the set of word embeddings are totally different from the tweets of the training set of InterTASS corpus.

<sup>7</sup>There is an embedding vector for each emoji.

TABLE III  
HYPER-PARAMETER VALUE BEFORE AND AFTER USING EVOLUTIONARY ALGORITHM.

	Starting point	After tuning
CNN $f_m$	128	108
$h_{lstm}$	64	28
$h^1$	32	21
$h^2$	16	21
$dr^1$	0.35	0.471887870
$dr^2$	0.35	0.0706515485
$dr^3$	0.5	0.509543630
$L_2 r^1$	0.0001	0.000410222222
$L_2 r^2$	0.001	0.00173633267

The objective function of the SHADE algorithm was configured out to optimise the F1 score on the validation set. Table IV shows the results reached by the non-optimised deep learning method, our baseline, and the optimised model.

TABLE IV  
RESULTS OBTAINED WITH THE DIFFERENT MODELS.

	Macro-F1	Accuracy
Baseline Model	0.41870	0.60242
Our proposal	0.48352	0.56398

According to Table IV, there is an improvement of more than 6 points in the Macro-F1 after tuning the hyper-parameters with the SHADE algorithm. The use of evolutionary algorithms to tune the hyper-parameters proves to be successful as it improves the Macro-F1 of the initial model. However, the value of the Accuracy in the optimised model is slightly lower than the one reached by the baseline. This is an expected behaviour because of the imbalanced nature of the data. Although the total number of true positives in all the classes is slightly lower in the optimised model, the trade off of correctly tweets classified in all the classes is better in the optimised model as we show in Section VI.

Finally, we use McNemar statistical test [41] in order to study if there are significant differences among the non-optimised model and the optimised one. The test returned that our proposal is significantly better with a  $p$ -value of 0.001 ( $p < 0.001$ ).

Table V shows the position of our proposal in the competition TASS 2018. The first two ranked models elirf-es-run-1 [7] and retuyt-lstm-es-1 [42] are based on deep learning methods, but both of them are grounded in the use of data augmentation techniques. Moreover, the elirf-es-run-1 system also uses external knowledge, such as lists of opinion bearing words in order to enrich with sentiment information of the

TABLE V  
RESULTS OF *InterTass-2018 Workshop task 1*.

	Macro-F1	Accuracy
elirf-es-run-1	0.503	0.612
retuyt-lstm-es-1	0.499	0.549
Our proposal	0.484	0.564
atalaya-ubav3-100-3-syn	0.476	0.544
retuyt-svm-es-2	0.473	0.584

vectors of word embeddings. In contrast, our proposal does not use any amount of external knowledge, and it only uses to train the model the training data. Furthermore, we only duplicated the instances of the minimum classes, which is a less sophisticated data augmentation technique than the one used in *retuyt-lstm-es-1*. Nevertheless, the results of our optimised proposal are close to the first ones.

## VI. ANALYSIS

In this section we study the performance of the experiments explained in the previous section in a more exhaustive way.

In order to explain the results obtained in table IV, we compute the F1 score for each class. We aim to analyse the increases and decreases of the F1 score for each class, which shows the behaviour of the evolutionary algorithm in the task of optimising the F1 score. The F1 for each class can be found in Table VI.

TABLE VI  
RESULTS OBTAINED WITH THE DIFFERENT MODELS SHOWING F1 BY CLASS.

	Baseline Model	Our Model
$F1_P$	0.6691	0.6485
$F1_{NEU}$	0	0.1909
$F1_N$	0.6886	0.67452
$F1_{NONE}$	0.3171	0.4202

Regarding the base model, we see a low performance of the two minority labels (NEU and NONE). We highlight that the base model does not classify any tweet as NEU, which means that the model is not able to learn anything about this label. Likewise, the performance on the NONE label is also reduced, which means that the base model is over-fitted to the labels with more instances. The main improvement of the optimised model is that it improves the performance of the classification in the two minority classes, which improves the performance of the overall system. Consequently, the macro-F1 score of the optimised model is higher, as we indicated in Section V-C.

To go further into this analysis, we examine the behaviour of both models in specific tweets of the different classes. On the first place, we observe that there are some tweets of the majority classes (P and N) that the base model labels correctly and the proposed model does not. We show some of these examples in the table VII. We highlight that the proposed model misclassifies the tweets with the minority classes and, it does not misclassifies among the two majority classes (P and N).

In the same way, there are several examples of tweets of the minority classes (NEU and NONE) that the proposed model labels correctly while the base model does not. We show some examples in table VIII.

This analysis explains the behaviour of the Macro-F1 and accuracy in Table IV. The baseline model (non-optimised) labels correctly more instances but ignoring minority classes while the optimised model deals better with imbalance by giving more importance to minority classes. This illustrates

the importance of choosing a good evaluation measure. Depending on the problem there are evaluation measures that are more representative than others. In our problem, the measure Macro-F1 measures the performance of the models in a more representative way since it takes into account the imbalance. Therefore, according to this measure, we can conclude that the optimised model has provided better results for the imbalanced classification problem.

## VII. CONCLUSIONS

In this paper, we have stress out the difficulty of defining the right hyper-parameters of deep learning method, which makes harder as the complexity of the network increases. We claim that evolutionary algorithms may be used to optimise the value of those hyper-parameters, and we thus propose the use of the SHADE algorithm in order to optimise a self-attentive neural network. We evaluate our proposal in the task of SA in Twitter, specifically of tweets written in Spanish from the InterTASS corpus.

The results show how our optimised proposal allows to improve the performance of the global model and the performance on each of the four classes of the dataset. Likewise, the resultant configuration of the neural network has less parameters than the non-optimised, which is also positive in the sense than optimised the efficiency of the model. Therefore, we conclude that evolutionary algorithms, in our case the SHADE algorithm, are suitable for optimising the configuration of neural networks, broadly speaking, for tuning the hyper-parameter values of deep learning methods. Accordingly, this results open a research line for the meta-learning of hyper-parameters and neural networks, where there a lot of room of improvement.

As future work, we will study the performance of evolutionary algorithms for optimising the number of encoding and classification layers. Likewise, we will evaluate the model with data augmentation approaches to study the synergy between both methodologies.

## ACKNOWLEDGEMENTS

This work was supported by proyect TIN2017-89517-P, by the Spanish “Ministerio de Economía y Competitividad”, the project DeepSCOP-Ayudas Fundación BBVA a Equipos de Investigación Científica en Big Data 2018 and a grant from the Fondo Europeo de Desarrollo Regional (FEDER). Email: \*jens.doerpinghaus@scai.fraunhofer.de, †andreas.stefan@scai.fraunhofer.de

**Abstract**—Context is widely considered for NLP and knowledge discovery since it highly influences the exact meaning of natural language. The scientific challenge is not only to extract such context data, but also to store this data for further NLP approaches. Here, we propose a multiple step knowledge graph-based approach to utilize context data for NLP and knowledge expression and extraction. We introduce the graph-theoretic foundation for a general context concept within semantic networks and show a proof-of-concept-based on biomedical literature and text mining. We discuss the impact of this novel approach on text analysis, various forms of text recognition and knowledge extraction and retrieval.

CONTEXT is a widely discussed topic in text mining and knowledge extraction since it is highly relevant to mine the semantic correct sense of unstructured text. For example in [1], Nenkova and McKeown discuss the influence of context on text summarization. Ambiguity does not only appear for common language words, but especially in scientific context. The scientific challenge is not only to extract such context data, but also to store this data for further NLP approaches. Here, we propose a multiple step knowledge graph-based approach to utilize context data for NLP and knowledge expression. We present a proof of concept based on biomedical literature and show an outlook on further improvements towards next generation knowledge extraction for example for training approaches from artificial intelligence and machine learning.

Knowledge graphs play in general an important role in recent knowledge mining and discovery. A *knowledge graph* (sometimes also called a *semantic network*) is a systematic way to connect information and data to knowledge on a more abstract level than language graphs. It is thus a crucial concept on the way to generate knowledge and wisdom, to search within data, information and knowledge. The context is a significant topic to generate knowledge or even wisdom. Thus, connecting knowledge graphs with context is a crucial feature.

Here, we use a quite general definition of context data. We assume that every information entity can also be a context information for other entities. For example a document can also be a context for other documents (e.g. by citing or referring to the other publication). An author is both a meta information to a document, but also itself context (by other publications, affiliations, co-author networks, ...). Other data is more obvious a context: named entities, topic maps, keywords, etc. extracted with text mining from documents. But already

relations extracted from a text may stand for themselves, occurring in multiple documents and still valuable without the original textual information.

Starting with a simple document graph, in a first step we add context meta information, see figure 1. This will lead to a first knowledge graph which can be used for a first context-based text mining approach. The text mining approach will add more context data, for example from ontologies or relations extracted from the text. The graph with the additional context data can be used as starting basis for more detailed text mining approaches utilizing the novel context data. This step can be redone several time.

In addition using a graph structure has several more advantages for knowledge extraction in biological and medical research. Here scientists are for example interested in exploring the mechanisms of living organisms and gaining a better understanding of underlying fundamental biological processes of life. Today the biomedical field mostly relies on systems biology approaches such as integrative knowledge graphs to decipher mechanism of a disease, by considering system as a whole which is considered as a holistic approach. In that, disease modeling and pathway databases play an important role. Knowledge Graphs built using Biological Expression Language (BEL, see [www.openbel.org](http://www.openbel.org)) is widely applied in biomedical domain to convert unstructured textual knowledge into a computable form. The BEL statements that form knowledge graphs are semantic triples that consist of concepts, functions and relationships [2]. In addition, several databases and ontologies implicitly form a Knowledge Graph. For example Gene Ontology, see [3] or DrugBank, see [4] or [5] cover a huge amount of relations and references to other fields.

Over the last few years new domain specific languages (DSL) and knowledge representations like BEL [6] have been proposed to publish and store this kind of statements and findings. There are still several crucial issues converting literature to knowledge. For example the quality and completeness of such networks has to be evaluated. And with this, to generate new knowledge the context of concepts in a Knowledge Graph has to be considered.

We will first of all give a preliminary overview about information theory and management. With this, we will introduce and discuss the novel approach of managing and mining

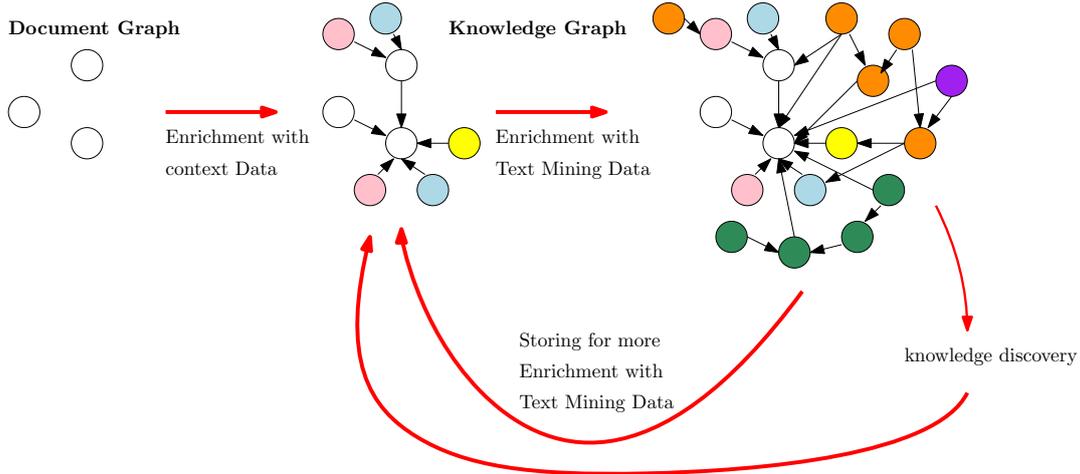

Fig. 1: Proposed workflow to extend a knowledge graph. First starting with a document graph, the basic meta information like authors, keywords etc. are added. This can be used as a basis for text mining which can be used to extend the graph again, for example named entity recognition (NER) may use keywords as a context. Topic detection may also benefit from already assigned keywords, journals or author information. The graph can also be extended by knowledge discovery processes, for example finding parameters of a clinical trial, progression within electronic health records, etc. In any case new context information will be added to the initial graph and improve the input of further algorithms.

the context of knowledge graphs. We demonstrate this novel approach by applying it to common data sources. After that, we will give a detailed list of issues that have to be addressed.

## I. PRELIMINARIES

We define knowledge graphs  $G = (E, R)$  where the set of nodes  $E$  consist of entities  $e \in E$  coming from a formal structure like an ontology  $E_i = (V(E_i), R(E_i))$ .  $E$  is a union of ontologies  $E = \{E_1, \dots, E_n\}$ . The relations  $r \in R$  can be ontology relations, thus in general we can say every ontology  $E_i$  which is part of the data model is a subgraph of  $G$  which means  $E_i \subseteq G$ . In addition, we allow inter-ontology relations between two nodes  $e_1, e_2$  with  $e_1 \in E_1, e_2 \in E_2$  and  $E_1 \neq E_2$ . More general we define  $R = \{R_1, \dots, R_n\}$  as list of either inter-ontology and intra-ontology relations. Both  $E$  as well as  $R$  are finite discrete spaces.

Every entity  $e \in E$  may have some additional meta information which need to be defined with respect to the application of the knowledge graph. For instance there might be several node sets (some ontologies, some document spaces (patents, research data, ...), author sets, journal sets, ...)  $E_1, \dots, E_n$  so that  $E_i \subset E$  and  $E = \cup_{i=1, \dots, n} E_i$ . The same holds for  $R$  where several context relations might come together like "is cited by", "has annotation", "has author", "is published in", etc.

We define a finite, discrete set  $C = \{c_1, \dots, c_m\}$  of contexts  $C_i$ . Every node  $e \in G$  and every edge  $r \in R$  may have one ore more contexts  $c \in C$  denoted by  $con(e)$  or  $con(r)$ . It is also possible to set  $con(e) = \emptyset$ . Thus, we have a mapping  $con : E \cup R \rightarrow \mathcal{P}(C)$  to the power set of  $C$ . If we use a quite general approach towards context, we may set  $C = E$ . Thus, every

inter-ontology relation defines context of two entities, but also the relations within an ontology can be seen as context.

Every node set  $E_i \in \{E_1, \dots, E_n\}$  induces a subgraph  $G[E_i] \subset G$ . With  $G^c[E_i] = G[E_i] \cup N(E_i)$  we denote the extended context subgraph which also contains the neighbours  $N(E_i)$  of each node  $e \in E_i$  in  $G$ , which is the context of that node. For a graph drawing perspective, if  $G^c[E_i]$  defines a proper surface, we can think about a graph embedding of another subgraph  $G^c[E_j]$  on  $G^c[E_i]$ .

We can create the metagraph  $M = (C, R')$  of these contexts. Each context is identified by a node in  $M$ . If there is a connection in  $G$  between two contexts, we add an edge  $(c_1, c_2) \in R'$ . This means if  $\exists(v_1, v_2) \in R : c_1 \in con(v_1), c_2 \in con(v_2) \Rightarrow (c_1, c_2) \in R'$  or  $\exists(v_1, v_2) \in R : c_1 \in con((v_1, v_2)), c_2 \in con(v_2) \Rightarrow (c_1, c_2) \in R'$  or  $\exists(v_1, v_2) \in R : c_1 \in con(v_1), c_2 \in con((v_1, v_2)) \Rightarrow (c_1, c_2) \in R'$ . See figure 2 for an illustration.

Adding edges between the knowledge graph  $G$  or a subgraph  $G' = (E', R') \subseteq G = (E, R)$  and the metagraph  $M$  in  $G \cup M$  will lead to a novel graph. This can be either seen as inverse mapping  $con^{-1}(G')$  or as the hypergraph  $\mathcal{H}(G') = (X, \hat{E})$  given by

$$X = E' \cup G^c[E_i]$$

$$\hat{E} = \{\{e_i, e \forall e \in N(e_i)\} \forall e_i \in X\}$$

This graph can be seen as an extension of the original knowledge graph  $G'$  where contexts connect not only to the initial nodes, but also every two nodes in  $G'$  are connected by a hyperedge if they share the same context. See figure 3 for an illustration.

If  $C = E$ , this will lead to new edges in  $G$  enriching the original graph. This step should be done after every additional extension to the graph  $G$ . Thus we need to update both  $G$  as well as  $M$ .

We will denote this hypergraph  $H$  on a knowledge graph  $G$  and a metagraph  $M$  with  $H_{G|M}$ . We might also add multiple metagraphs  $M_1$  and  $M_2$  which will be denoted by  $H_{G|M_1, M_2}$ .

This graph can be seen as an enrichment of the original knowledge graph  $G$  with contexts. It can be used to answer several research questions and can be utilized to find graph-theoretic formulations of research questions.

If the mapping  $con$  is well defined for the domain set the Graph  $H$  can be generated in polynomial time. Since this is in general not the case, this usually contains a data or text mining task to generate contexts from free texts or knowledge graph entities. With respect to the notation described in [7] this problem  $p$  can be formulated as

$$p = \mathbb{D}|R|f : \mathbb{D} \rightarrow \mathbb{X}|err|\emptyset \quad (1)$$

Here, the domain set  $\mathbb{D}$  is explicitly given by  $\mathbb{D} = G$  or – if additional full-texts  $\hat{D}$  supporting the knowledge Graph  $G$  exist –  $\mathbb{D} = \{G, \hat{D}\}$ . In our case the domain subset  $R = \mathbb{D}$ . In this case we need to find a description function  $f : \mathbb{D} \rightarrow \mathbb{X}$  with a description set  $\mathbb{X} = C$  which holds all contexts. To find relevant contexts we need an error measure  $err : \mathbb{D} \rightarrow [0, 1]$ .

We have to consider several research questions. First of all: What are meta information that can be used to generate a context for a new metagraph? Good candidates are authors, citations, affiliation, journal, and MeSH-terms or rather keywords since they are available in most databases. We also need to discuss text mining results like NER, relationship mining etc. Having more general data like study data, genomics, images, etc. we might also consider side effects; disease labels, population labels (male; female; age; social class; etc.). Here we show a proof of concept for less complex text mining meta data. See figure 1, which describes the process of starting with a simple document graph that can be extended with more context data from text mining. We discuss this in more detail within the next section.

The further research questions address the application of this novel approach for both biomedical research as well as text classification and clustering, NLP and knowledge discovery, also with focus on Artificial Intelligence (AI). How can we use the context metagraph to answer biomedical scientific questions? What can we learn from connections between contexts and how do they look like in the knowledge graph? How can we use efficient graph queries utilizing the context? It may also be useful to filter paths in the knowledge graph according to a given context or to generate novel visualizations. A possible question might be to learn about mechanisms linked to co-morbidities or mechanisms being contextualized by drug information. The meta-graph may also contain information about cause-and-effect relationships in the knowledge graph that are “valid” in a biomedical sense under certain conditions. In addition, a contextualization-based on

demographic information or polypharmacy information. We will discuss several use cases within the last section.

## II. METHOD AND PRACTICAL APPLICATION

The following software was written in Java using Spring Boot (see <http://spring.io/projects/spring-boot>) and Spring Data (see <https://spring.io/projects/spring-data>) and integrated in our SCAIView microservice architecture, see [8]. The database backend is a graph database running Neo4j (see <https://neo4j.com/>).

We will illustrate the following methods with example runs on MedLine and Pubmed data. Both sources are already included in the SCAIView NLP-pipeline. PubMed contains 29 million abstracts from biomedical literature, PMC about 4 million full-text articles.

### A. Creating a document and context graph with basic context extraction

The initial step of creating a document and context graph with basic context extraction needs a basic definition of entity sets  $E_1, \dots, E_n$  and their relations.

The articles and abstracts from PubMed and PMC already come with a lot of contextual data. We may set  $E_{Document}$  as the document set containing nodes, each representing one document. In addition, we may add a set  $E_{Source} = \{\text{PubMed}, \text{PMC}\}$  as the source of a document. Thus, each document can be interpreted as context of a data source.

All meta data are stored in new node sets.  $E_{Author}$  stores the set of authors,  $E_{Affiliation}$  their affiliation which is again context for the authors. Another relevant context is the publisher, in our case  $E_{Journal}$ . PubMed stores several classes, for example Books and Documents, Case Reports, Classical Article, Clinical Study, Clinical Trial, Journal Article, Review etc. We store this in  $E_{PublicationType}$ .

Another important context is  $E_{Annotation}$  storing all kind of annotations like named entities or keywords, which come from the MeSH tree, see [9] and [https://www.nlm.nih.gov/mesh/intro\\_trees.html](https://www.nlm.nih.gov/mesh/intro_trees.html). Thus,  $E_{MeSH} \subset E_{Annotation}$  already comes with a hierarchy and edges  $R_{MeSH}$ . The value of MeSH terms and their hierarchy for knowledge extraction was shown in several recent studies like [10]. We will discuss the value of MeSH as controlled vocabulary within the next section. See figure 4 for an illustration of a single document.

All other relations can be added between the sets  $E_i$ , for example  $R_{isCoAuthor}$ ,  $R_{hasAffiliation}$ , etc. With these information given it is – from an algorithmic point of view – quite easy to add all context relations like  $R_{hasDocument}$ ,  $R_{isAuthor}$ ,  $R_{hasAnnotation}$ ,  $R_{hasCitation}$  etc. Edges must also store additional provenance information. See figure 5 for an illustration.

### B. Extending the knowledge graph using NLP-technologies

The initial knowledge graph can be extended by NLP-technologies.

Terminologies and Ontologies are a widely considered topic in research during the last years. They play an important role in

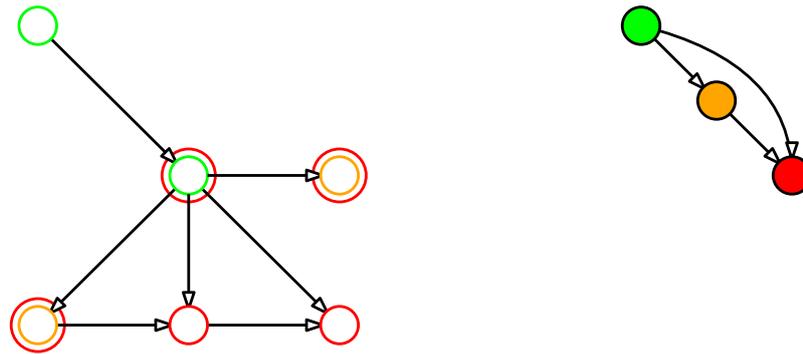

Fig. 2: Illustration of a *knowledge graph with context* (left). The context is illustrated by colors surrounding nodes. At the right the corresponding *context metagraph*. Every context in the knowledge graphs refers to a node in the metagraph and the edges describe if in the original graph a edge from one context to the next exist. Contexts may also be added to edges.

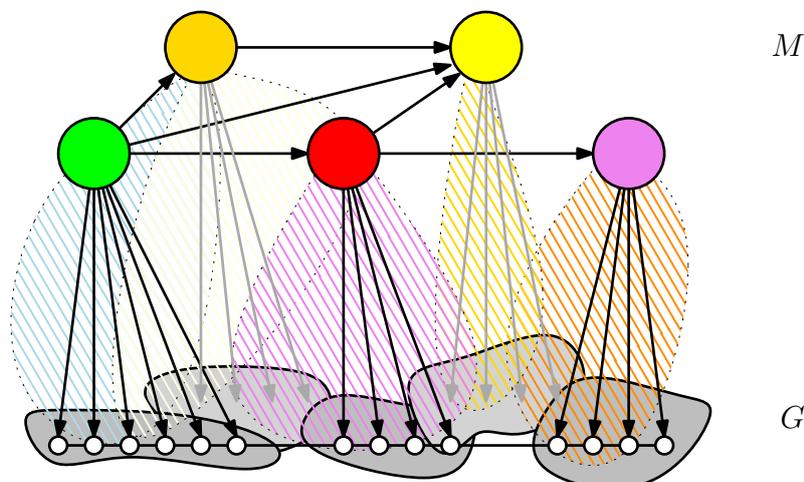

Fig. 3: This figure describes the hypergraph  $\mathcal{H}(G') = (X, \hat{E})$  between the context metagraph  $M$  and the original knowledge graph  $G$  or a subgraph  $G' \subset G$ . This graph is sorted by contexts. The hyperedges, illustrated by sets and indicated by non-hyperedges, connect nodes with context, but also nodes with the same context.

data and text mining as well as knowledge representation in the semantic web. They become more and more important since data provider publish their data in a semantic web formats, namely RDF ([11]) and OWL ([12]), to increase integratability. The term *terminology* refers to the SKOS meta-model [13] which can be summarized as concepts, unit of thoughts which can be identified, labeled with lexical strings, assigned notations (lexical codes), documented with various types of note, linked to other concepts and organized into informal hierarchies and association networks, aggregated, grouped into labeled and/or ordered collections, and mapped to concepts. Several complex models have been proposed in literature and have been implemented in software, see [14]. *Controlled Vocabularies* contain lists of entities which may be completed to a *Synonym Ring* to control synonyms. *Ontologies* also present properties and can establish associative relationships which can also be done by *Thesauri* or *Terminologies*. See [15] and [16] for a complete list of all models.

Here we define Terminologies similar to Thesauri as a set of concepts. They form a *DAG* (Directed Acyclic Graph) with child and parent concepts. In addition, we have an associative relation which identifies similar or somehow related concepts. Each concept has one or more labels. One of them is the preferred identifier, all others are synonyms. To sum up, using ontologies or terminologies for NER, we will have a hierarchy within this ontology. But we may not only consider ontologies and terminologies, but also controlled vocabularies like MeSH. Here we have additional annotations with a different provenance, one coming as keywords with the data, one obtained from NER.

Another example is the Alzheimer's Disease Ontology (ADO, see [17])  $E_{ADO}$  or the Neuro-Image Terminology (NIFT, see [18])  $E_{NIFT}$  coming with their hierarchy  $R_{ADO}$ ,  $R_{NIFT}$ . The process of NER will lead to another context relation  $E_{hasAnnotation}$ . Since not all ontologies or terminologies are described in RDF or OBO format we have to add data from

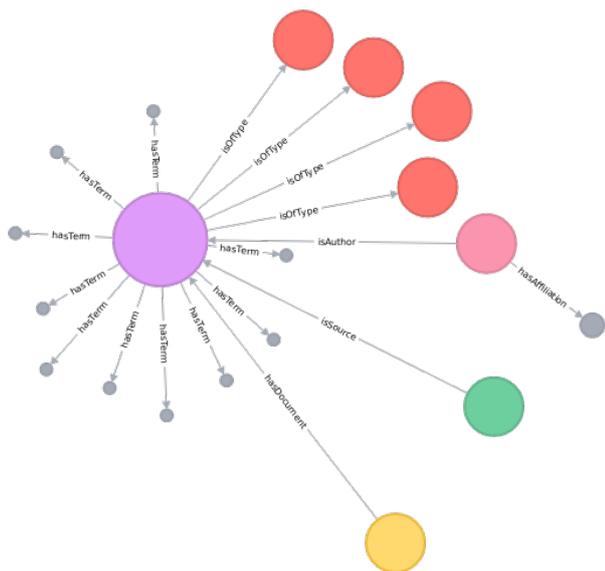

Fig. 4: This figure is an illustration of a single document within the context graph. The document node (purple) has several gray annotation nodes, four red publication type nodes, an orange author node with a gray affiliation. The source (PubMed) is annotated in a green node, the journal in a yellow node.

multiple sources. This is done by a central tool providing all ontology data.

Another context data useful for knowledge extraction are citations, thus edges  $R_{hasCitation}$  between two nodes in  $E_{Document}$ . The data from PMC already stores citation data with unique identifiers (PubMed IDs). Some data is available with WikiData, see [19] and [20]. Other sources are rare, but exist, see [21]. Especially for PubMed a lot of research is working on this difficult topic, see for example [22].

In addition we can consider relational information between entities. For example BEL statements already form knowledge graphs of semantic triples that consist of concepts, functions and relationships [2]. To tackle such complex tasks they constantly gather and accumulate new knowledge by performing experiments, and also studying scientific literature that includes results of further experiments performed by researchers. Existing solutions are mainly based on the methods of biomedical text mining to extract key information from unstructured biomedical text (such as publications, patents, and electronic health records). Several information systems have been introduced to support curators generating these networks. BELIEF, is one workflow generated for this purpose. BELIEF build BEL like statements semi-automatically from retrieving publications from a relevant corpus generation system called SCAIView, see [23] and [24].

Figure 6 illustrates the relations "*Levomilnacipran*" inhibits "*BACE1*", "*BACE1*" improves "*Neuroprotection*" and "*BACE1*" improves "*Memory*" found with relation extraction on named

entities in a document. It is easy to see that context for a document is now also context for the relations and vice versa. If an entity within the relation has synonyms or is found within another document with a different context, this might lead to a deeper knowledge about the statement. Vice versa the context of the document, for example if the knowledge was found within a clinical trial, is a context to the statements.

### III. APPLICATIONS

We will first of all discuss some missing data or data integration problems as well as technical issues which need to be solved. Afterwards we will give an outlook on NLP-based on context information and the impact on answering semantic questions. This is highly related to the FAIRification of research data. This will lead to a short outlook on personalised medicine.

#### A. Missing data

We faced several issues with data integration and missing data. For example some publishers used OCR technologies to convert PDF documents in XML structures. These were usually problematic to process because some fields were missing or wrongly filled.

We have not yet worked on the problem of author and affiliation disambiguation. This is still a widely discussed topic, see [25]. An interesting novel approach – also based on Neo4j database technology – was introduced in [26]. The authors used topological and semantic structures within the graph for author disambiguation. Thus, we plan to integrate state-of-the-art technologies.

In addition performance is a major problem, and the main cause of latency for request. Thus, we had serious problems integrating this framework in our microservice architecture, see [8]. There are several possible explanations for this result, both on technical as well as implementation side. Thus, an important finding was that the storing and retrieval of large knowledge graphs did work. Not surprisingly, for giant and very dense knowledge graphs we need to find another solution. We could either improve the database backend by establishing a polyglot persistence architecture or use existing graph databases like Cray Graph Engine, see [27]. This choice has important implications for the further developing of this architecture, for example SPARQL has more limitations than Cypher. This is an important issue for future research.

However, these results were very encouraging and we will discuss some more topics for further research.

#### B. Context-based NLP

This novel system extends our knowledge and the availability of context data. Context data is a very important foundation for text mining [1]. For example, context-based NER was discussed by [28] and there is still ongoing research, for example on content-aware attributed entity embedding (CAAEE), see [29]. The key strength of our approach is that in every step of text mining and NLP all context data is available and new data will be added. Thus, this system can be used for

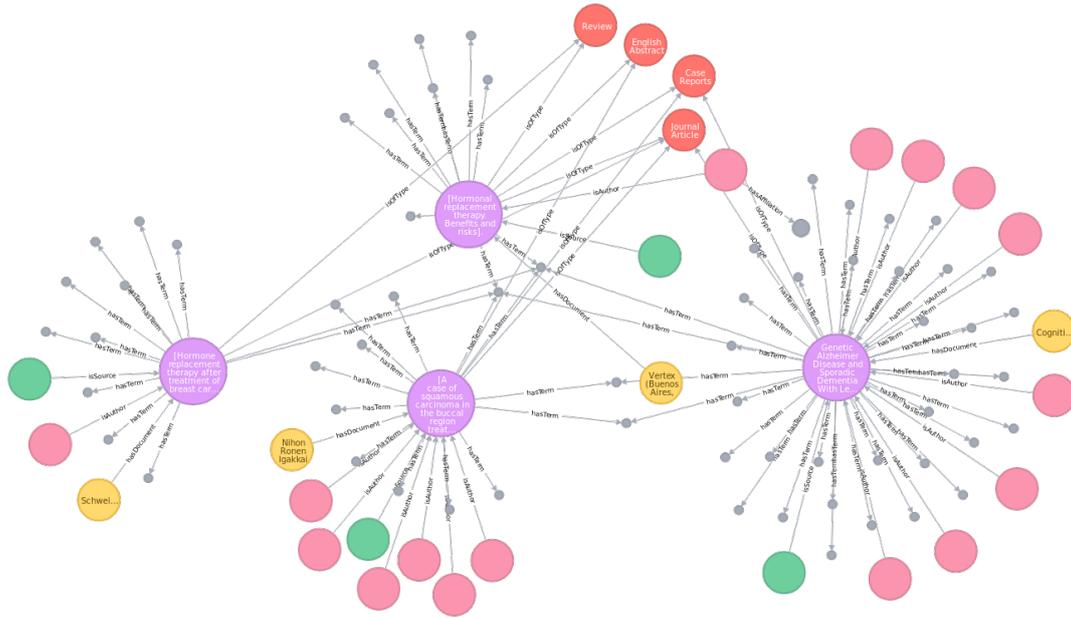

Fig. 5: This figure is an illustration of the initial document and context graph. A PubMed node is the source of document nodes (green). There are several context annotations like article type (red), keywords (gray), authors (orange) and journal (yellow). Authors have additional context (affiliations, gray).

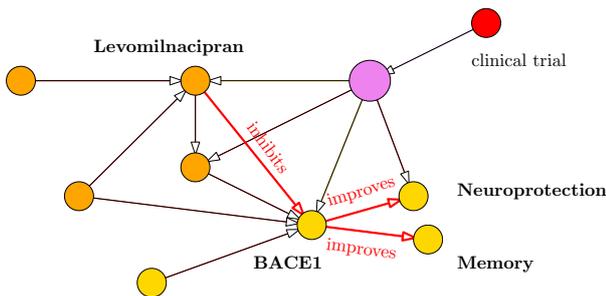

Fig. 6: This figure is an illustration of biological knowledge within the context graph. The document node (purple) has several yellow and orange annotation nodes which come from different terminologies found with NER. The relation extraction task found the relation "Levomilnacipran" inhibits "BACE1", "BACE1" improves "Neuroprotection" and "BACE1" improves "Memory". These relations are illustrated with red edges. Since the document describes a clinical trial, this is also a context for the relations as well.

both building and validating Machine Learning (ML) and AI approaches.

Of course the novel context data is not only suitable for NER, but also for relation extraction. For example [30] proposed a novel approach to context-based relation extraction. Although our example is based on a small data set, the findings suggest that a lot of existing data can be utilized as context data. For example entities annotated by NER or manually curated BEL statements may be applied as context.

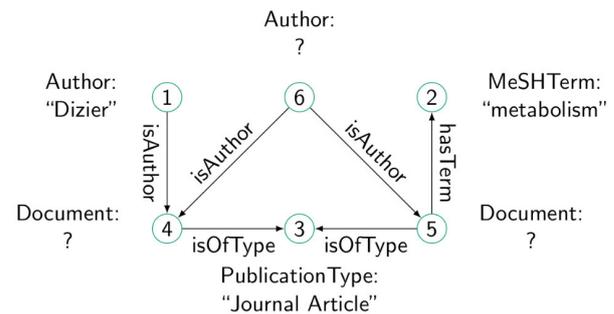

Fig. 7: This figure illustrates a more complex semantic subgraph to query the knowledge graph. We search for two documents having the same author and both of publication type "Journal Article". The first document should have an author called "Dizier", the second one a MeSH Term called "metabolism".

Thus this research has several practical applications. Firstly, it leads to validation and datasets for ML and AI approaches towards text mining. Further work needs to be done to investigate how this data can be used systematically. Secondly, it generalizes the idea of context so that it can be used for semantic questions.

### C. Answering semantic questions and FAIRification of data

Semantic questions can be formulated as subgraph structures of the initial knowledge graphs. For example we may ask: "Which articles have been authored by Pacheco?". This will

lead to a subgraph with two nodes  $v_1, v_2$  where  $v_1 = \text{Pacheco}$  and an edge  $(v_1, v_2) = \text{isAuthor}$ . We may think of much more complex examples, see figure 7 for an example.

In general these semantic subgraph queries (or: graph queries) have an input  $Q = (V, E) \subset G$  and output all subgraphs  $H \subset G$  with  $H \simeq Q$ . Thus, the problem of answering semantic questions is a generalization of the subgraph isomorphism problem. We know already subgraph isomorphism is NP-hard, see [31]. It would be interesting to find a general formulation of the generalization or restrictions that can be applied to this problem. Since Cypher already provides us with the possibility to query graph substructure, further research might explore the runtime or might lead to novel heuristics to solve this efficiently.

Whilst this work did not consider the impact of novel ontologies and terminologies, it did substantiate the impact of them on context data. This is an interesting step towards the FAIRification of data. Wilkinson introduced his FAIR guiding principles in [32] referring to the findability, accessibility, interoperability, and reusability of data, especially for research data. A consequent application of the context idea leads to meta data as context on data which can afterwards be used to make meta data searchable even if the data itself is protected. Thus, the inclusion of context into an information system like SCAIView will make the data findable and accessible. In addition, if interoperable ontologies are available, this data will also be interoperable. This will already solve the three out of four issues addressed by FAIR data.

#### D. Perspectives for Personalised Medicine

Hypothesis generation and knowledge discovery on biomedical data are widely used in medical research and digital health. For example researchers search for genomic or molecular patterns, diagnosis or build longitudinal models. In addition, the massive data available build the basis for a multitude of predictive and personalised medicine ML and AI approaches. A reasonable approach to tackle reproducible research in predictive medicine could be to use a standardized and FAIR context graph for biomedical research data. Thus, it would be necessary to annotate not only biomedical literature but also research data like molecular data, imaging data, genomics and electronic health records (EHR) with context information.

This information system can be used to retrieve data by context (cohort size, settings, results, ...) and by content (imaging data, genomic or molecular measures, ...). For example, this system may answer questions like “Give me a clinical trial to reproduce my results or to apply my model” or “Give me literature for phenotype A, disease B age between C and D and a CT-scan with characteristic E”.

Here we presented a novel approach that annotates research data with context information. The result is a knowledge graph representation of data, the context graph. It contains computable statement representation (e.g. RDF or BEL). This graph allows to compare research data records from different sources as well as the selection of relevant data sets using graph-theoretical algorithms.

## IV. CONCLUSION AND OUTLOOK

Here we discussed a proof-of-concept of a biomedical knowledge graph combining several sources of data as context to each other. We processed data from PubMed and PMC. This initial knowledge graph was extended with results from text mining and NLP-tools already included in our software. Thus, we were able to provide both small datasets as well as large collections of data.

We faced several issues with data integration and missing data, for example because the input data had a bad quality. In addition we have not yet worked on the problem of author and affiliation disambiguation. This directly leads to the question how our approach can be evaluated. For every kind of input data another evaluation method needs to be established. Without this, the quality of the knowledge graph is directly linked to the quality of input data. Before establishing a productive system, this question needs to be properly addressed.

We introduced several applications, for example context-based NLP, answering semantic questions and FAIRification of data, perspectives for Personalised Medicine. The generalisability of these ideas is subject to certain limitations. For instance, the question of interoperable ontologies or ontologies covering the issues of interoperability of data is still not examined. In addition, there is still no FAIR-data information system available.

This has thrown up many questions in need of further investigation. Nevertheless, it is not keen to make an outlook on the impact of such a FAIR and semantic information system and data structure on context data for personalised medicine.

## V. ACKNOWLEDGMENTS

We thank Tim Steinbach for providing some illustrations to this work. In addition, we thank Marc Jacobs and Alexander Esser for carefully revising the manuscript.

**Abstract**—In recent years, word embeddings have been shown to improve the performance in NLP tasks such as syntactic parsing or sentiment analysis. While useful, they are problematic in representing ambiguous words with multiple meanings, since they keep a single representation for each word in the vocabulary. Constructing separate embeddings for meanings of ambiguous words could be useful for solving the Word Sense Disambiguation (WSD) task.

In this work, we present how a word embeddings average-based method can be used to produce semantic-rich meaning embeddings. We also open-source a WSD dataset that was created for the purpose of evaluating methods presented in this research.

## I. INTRODUCTION

Word embedding methods, that map the vocabulary words to low-dimensional continuous space, have been widely applied to various natural language processing (NLP) problems. They are commonly used as the input representation of words, replacing high-dimensional one-hot encodings, and have been shown to improve the performance in tasks such as syntactic parsing[1] and sentiment analysis[2].

In word embedding methods, such as word2vec[3] or GloVe[4], each word in the vocabulary has exactly one representation. While it is enough for most words, it is problematic for ambiguous words, which can contain more than one meaning. For example, consider the following examples with the word *tree*, extracted from Wikipedia articles:

(a) *The olive, known by the botanical name *Olea europaea*, meaning "European olive", is a species of small **tree** in the family Oleaceae [...]*

(b) *Many theories of syntax and grammar illustrate sentence structure using phrase **trees**, which provide schematics of how the words in a sentence are grouped and relate to each other.*

(c) *Upon completion of listing all files and directories found, **tree** returns the total number of files and directories listed.*

All three sentences mention the word *tree* (or *trees*), but the meaning differs based on context - (a) means tree as a forest plant, (b) tree as a parse tree, (c) tree as a command in Unix systems.

For many applications, such as improving relevance of search engines, anaphora resolution or coherence, identifying which meaning is used, based on context, is important. This task is called Word Sense Disambiguation (WSD) and is an open problem in NLP domain. Word embeddings cannot be applied to WSD out-of-the-box, since they cannot differentiate between multiple meanings of an ambiguous word.

In this work, we propose a method to create semantically rich embeddings for each *keyword* (ambiguous word together with meaning, e.g. *tree (structure)*, *pool (computer science)*), by averaging embeddings of the ambiguous word and words describing its meaning. We evaluate this approach on a WSD task, gathered from Wikipedia articles (III). Finally, we discuss our results and propose future work (V-A).

## II. RELATED WORK

There have been many methods of creating semantically meaningful word representations. Global matrix factorization methods, such as latent semantic analysis (LSA)[5], use matrix factorization to perform dimensionality reduction on a large term-frequency matrix, that captures statistical information about the corpus. As the result, we receive word and document embeddings, which are parametrized by the number of topics we want to extract from the documents, and which can be used to find similarities between different words and documents.

Other approach to creating word embeddings is to take only local context into account, without using global statistics. Example of this is word2vec[3], where a shallow neural network is trained to either predict context words based on the current word (skig-gram), or predict current word based on context words (continuous bag-of-words). Continuous representations of words are then extracted from the hidden layer of the trained network. FastText[6] improves upon skip-gram method, by representing each word as a bag of character n-grams, which provides more flexibility and has an added benefit of the ability to compute word representations for words unseen during training.

Global Vectors (GloVe)[4] combine both global matrix factorization and local context window methods, by training word vectors on co-occurrence matrix, so that their differences predict co-occurrence ratios.

Word embeddings can be also extracted from a trained language model[7]. Recently, methods like ELMo[8] or BERT[9] were shown to achieve great results in many NLP tasks. They produce deep contextualized word embeddings by using internal states of a trained language model pretrained on large corpus of text. Since models used are bidirectional (LSTM for ELMo, Transformer for BERT), the word embedding is conditioned on its left and right context, achieving flexible vector representations that could be used to disambiguate words.

Jacobacci et al.[10] were the first to try to use word embeddings for Word Sense Disambiguation. They consider four different strategies for integrating a pre-trained word embeddings as context representation in a supervised WSD system: concatenation, average, fractional and exponential decay of the vectors of the words surrounding a target word. Peters et al.[11] create word representations that differ from traditional word embeddings in that each token is assigned a representation that is a function of the entire input sentence. They use vectors derived from a bidirectional LSTM that is trained with a coupled language model objective on a large text corpus.

The most usual baseline for WSD task is the Most Frequent Sense[12] (MFS) heuristic, which selects for each target word the most frequent sense in the training data. Recent growth of sequence learning techniques using artificial neural networks contributed to WSD research: Raganato et al.[13] propose a series of end-to-end neural architectures directly tailored to the task, from bidirectional Long Short-Term Memory (LSTM) to encoder-decoder models. Melamud et al.[14] also use bidirectional LSTM in their work. They use large plain text corpora to learn a neural model that embeds entire sentential contexts and target words in the same low-dimensional space, which is optimized to reflect inter-dependencies between targets and their entire sentential context as a whole.

### III. DATASET

For the purpose of constructing semantic-rich word embeddings, we manually gathered usage examples for 6 ambiguous words, 4 to 7 meanings each (28 meanings in total). Ambiguous word together with its meaning constitutes a *keyword*, which we use as a separate class when identifying the closest meaning given some context.

We chose ambiguous words based on the number and variety of meanings it had. Meanings themselves were chosen to cover a range of topics (e.g. *tree (forest)*, *tree (family)*, *trees (folk band)*, *tree (command)*). We also tried to look for meanings that are semantically related and can occur in similar context (and in turn be difficult for the model to differentiate between), e.g. *tree (structure)*, *tree (parse)*, *tree (decision)* or *nails (new wave band)*, *nails (hardcore punk band)*. Lastly, we added some keywords, that we suspected to be really underrepresented in the word embedding of the ambiguous word, e.g. *Mars* as the pop singer Bruno Mars (*mars (bruno singer)*) or *pool* as the computer science term (*pool (computer science)*).

Usage examples for keywords were gathered mostly from Wikipedia, using *What links here* utility, which lists all Wikipedia pages that link to a specific article. We used these links to search for usages of our keywords in context. We found that *What links here* utility has some limitations. Many articles linked to the keyword do not use that keyword in text at all or just list it in "See also" section, which does not provide good context around the keyword for the model to improve on. Moreover, some keywords do not have enough usage examples

that can be found on Wikipedia alone. In such cases, other websites were used to find proper usage examples.

The dataset is split into training and test set, with 5 training and 10 test examples for each keyword. Each example is stored in plain text, with the ambiguous word marked with "\*" on both sides. For simplicity, only one word is marked in each text, even if more ambiguous word usages can be found. In case we wanted to mark another word in the same text, we could just add the same example twice, with different words marked each time.

The correct keyword for each example, together with a path to file and a link, where the original text was taken from, are stored in CSV files: *train.csv* for training set, *test.csv* for test set (columns: path,keyword,link). Keywords themselves, together with links to their Wikipedia articles, are stored in *keywords.csv*.

Dataset, together with the code to execute experiments from this paper, can be found on our GitHub repository<sup>1</sup>.

### IV. OUR METHOD

*Keyword* is a sequence of words that is composed of the ambiguous word and words describing its specific meaning, e.g. *tree (forest)* that represents tree as a plant (ambiguous word: *tree*, meaning: *forest*) and *tree (structure)* which represents tree as a mathematical structure (ambiguous word: *tree*, meaning: *structure*).

To get the embedding of the keyword, we average embeddings of all the words in the keyword:

$$\mathbf{k} = e(w_1, w_2, \dots, w_N) = \frac{1}{N} \sum_{i=1}^N e(w_i) \quad (1)$$

where  $e(\cdot)$  is the embedding function used and  $w_1, w_2, \dots, w_N$  is a sequence of  $N$  words that, in this case, constitutes a keyword.

Example for keyword *tree (forest)*:

$$\mathbf{k}_{tree(forest)} = e(tree, forest) = \frac{e(tree) + e(forest)}{2} \quad (2)$$

*Context* is a sequence of words, extracted from some text, which contains an ambiguous word and words surrounding it in text. It is parametrized by **context length**  $l$ , which specifies how many words from both sides of the ambiguous word are taken into consideration.

*Context embedding*  $c$  is also achieved by taking an average of word embeddings (Equation 1). In this case,  $N = 2l + 1$  and  $w_1, w_2, \dots, w_N$  is the context with ambiguous word inside. For some cases  $N < 2l + 1$ , since the ambiguous word may occur at the beginning or end of text example and full context cannot be collected. In this case, we just average the reduced context.

The approach is to use keyword and context embeddings to find the closest keyword given some context, using cosine distance as a similarity metric.

<sup>1</sup><https://github.com/gberinger/automatic-wiki-links>

Table I  
RESULTS ACHIEVED ON THE TEST SET FOR OUR METHOD. COSINE DISTANCE IS MEASURED BETWEEN THE CORRECT KEYWORD AND CONTEXT EMBEDDINGS.

Metric	Our Model
Top-1 accuracy	67%
Top-2 accuracy	85%
Top-3 accuracy	93%

In other words, given an input text and marked ambiguous word within, we extract the context and compute its embedding  $c$ . The keyword, whose embedding is closest to  $c$  w.r.t. cosine distance, is chosen as the ambiguous word’s meaning.

## V. RESULTS OF THE EXPERIMENTS

In our experiments we evaluate how semantic-rich keyword embeddings, perform for the dataset we collected (III), for the our approach. We use a pretrained embedding model from spaCy - *en\_vectors\_web\_lg*, which contains 300-dimensional word vectors trained on Common Crawl with GloVe<sup>2</sup>.

We compare results on the test set with top- $k$  metrics ( $k \in 1, 2, 3$ ), where we check, if the correct keyword is in closest  $k$  keywords given a specific context describe it. We focus mostly on top-1 accuracy, since we are interested if the word is correctly disambiguated.

Due to the high impact of training data order on test results, we take the average score of 30 runs (each with a random order of training data) for each optimization experiment. We evaluate the performance of the proposed model with different context lengths, to see how it affects top- $k$  accuracies (Fig. 1).

We can see, that the model does relatively well. Top-3 accuracy is about 85-90%, which is probably caused by a low number of meanings for each ambiguous word. Top-1 accuracy for shorter context lengths can go as high as 65% but decreases with longer contexts. As suspected (V-A), this is most likely due to the fact, that the average of many word embeddings may make some contexts similar to each other, therefore making it harder to distinguish between some meanings.

The best result w.r.t. top-1 accuracy was achieved with  $l = 3$ , which is why we choose this context length as a starting point for next experiments.

Performance on the test set can be seen in Table I. All metrics improved due to the optimization process of moving correct keywords closer to (and incorrect keywords away from) contexts found in the training set. High top-2 and top-3 accuracies suggest, that the correct keyword is usually relatively close to the context describing it.

It is important to note, that the performance might worsen, if we expand the keyword vocabulary to large-scale experiments, where we have much more possible keywords than 28.

### A. Discussion and future work

We are aware that our method has some limitations. First of all, it may be impossible to achieve the optimal solution, as we can only optimize keyword embeddings, leaving context

embeddings fixed in the multidimensional space. Therefore, it is possible that contexts for specific keyword overlap on contexts for other keyword.

Secondly, the average context embedding may be ambiguous, with a high possibility of two different context being mapped to a similar point in space, especially for longer context lengths. In future work we plan to experiment with different sequence embedding techniques, that might be better suited for this purpose than a flat average.

Finally, we run experiments for a very small number of ambiguous words and meanings. Our method could have problems with a bigger dataset, since it would be much more difficult to separate different keywords.

Constructing semantic-rich embeddings for ambiguous words, by taking the average of embeddings of the ambiguous word and words describing its meaning, and then comparing it with the average embedding of context words describing given keyword, proved to be a surprisingly good approach for the task of disambiguation on the dataset of 28 keywords we collected (III). Our method achieved 67% top-1, 85% top-2 and 93% top-3 accuracy for context length  $l = 3$ . Longer context lengths were shown to decrease the accuracy, since the average of many word embeddings may result in similar embeddings for different contexts.

Further improvements could be sought by using different keyword and context embedding schemes, e.g. weighted average or by using some sentence embedding method. Optimization method itself could be made more stable by applying decay to alpha and beta parameters and by using a validation set for early stopping. It could also be bound to cosine distance between the keyword and context - the bigger the difference, the bigger the update.

It would also be interesting to see, how the suggested approach for constructing semantic-rich embeddings would perform on a large-scale dataset. Such a dataset could be automatically collected from Wikipedia, using disambiguation pages to find ambiguous words and their meanings, and *What links here* utility, to find usage examples for each keyword.

We assume, that the performance of the our model (and thus the quality of keyword embeddings) can be improved, if we provide examples of contexts that the specific keyword appears in. This can be reached by moving keyword embeddings closer to embeddings of contexts they appear in, so for each training example, the correct keyword embedding is shift by a given factor, in the direction of the context embedding, which describes said keyword. Further optimizations can be done, by moving top- $k$  closest keywords that are incorrect given the same context.

## VI. ACKNOWLEDGEMENTS

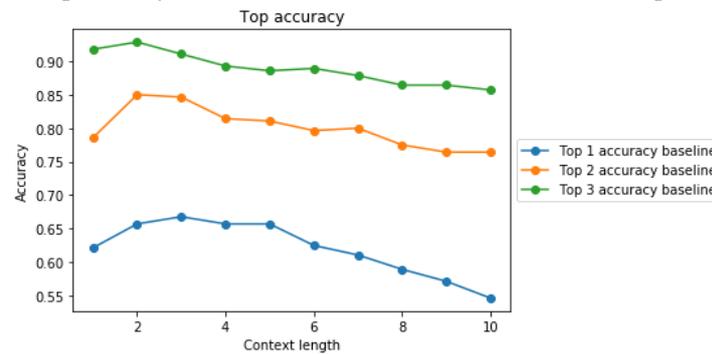

The work has been partially supported by funds of Faculty of Electronics, Telecommunications and Informatics of Gdańsk University of Technology.

**Abstract**—There is currently a lack of research concerning whether Emotional Classification (EC) research on a language is applicable to other languages. If this is the case then we can greatly reduce the amount of research needed for different languages. Therefore, we propose a framework to answer the following null hypothesis: *The change in classification accuracy for Emotional Classification caused by changing a single preprocessor or classifier is independent of the target language within a significance level of  $p = 0.05$ . We test this hypothesis using an English and a Danish data set, and the classification algorithms: Support-Vector Machine, Naive Bayes, and Random Forest. From our statistical test, we got a  $p$ -value of 0.12852 and could therefore not reject our hypothesis. Thus, our hypothesis could still be true. More research is therefore needed within the field of cross-language EC in order to benefit EC for different languages.*

**Keywords:** Sentiment Analysis, Emotional Classification, Text-to-Emotion Analysis, Cross-Language Analysis, Natural Language Processing

## I. INTRODUCTION

The research field of Sentiment Analysis (SA) focuses on textual analysis, concerning the underlying emotions behind language [1]. Emotional information is extracted by using a variety of different methods. This can be used for a number of purposes, e.g. opinion mining during elections.

SA contains the subfield: Emotional Classification (EC), which focuses on classifying the emotions expressed through a medium. For EC, we use the base emotions defined by [2]: joy, trust, fear, surprise, sadness, disgust, anger, and anticipation.

A vast majority of the SA research uses English as the target language. However, it is currently not known whether the results of this research also are applicable to other languages (i.e. cross-language applicability). If the results of SA research based on one target language are applicable to SA for other languages, then that will be very beneficial for SA on non-English languages. We define this area as cross-language EC. To the best of our knowledge no one has conducted research within this area.

Based on this we specify the following null hypothesis: *The change in classification accuracy for Emotional Classification caused by changing a single preprocessor or classifier is independent of the target language within a significance level of  $p = 0.05$ . We test this hypothesis, through an experiment that utilizes a framework we create. This framework consists*

of three overall phases: Preprocessing phase, Classification Phase (CP), and Statical Test Phase (STP). The preprocessing phase consists of three subphases: Common Preprocessing Phase (CPP), Varying Preprocessing Phase (VPP), and Attribute Selection Phase (ASP). This framework serves as a guide for researchers to create experiments with similar structure and purpose as the one we are doing in this study. We do this experiment in order to test whether the effectiveness of different EC methods, trained using tweets, depend on the language being classified.

This experiment uses two data sets; one for Danish and one for English. These data sets consist of posts from the microblogging website *Twitter.com*, called 'tweets'. Tweets are reasonable EC data candidates because they have the purpose of sharing emotions. They are often labeled with keywords, called hashtags, which can be emotional words such as 'happy'. Furthermore, tweets have a character limitation of 280 characters, which entails a higher density of emotions per word.

We compare the differences in impact of changing preprocessors and classifiers on the two data sets, by applying these differences on a two-sided Wilcoxon signed-rank test, from now on referred to as 'Wilcoxon test'.

The result from the Wilcoxon test yields a  $p$ -value of 0.12852, which does not reject our hypothesis. Therefore, it is still possible that EC research on the English language, is applicable to EC on non-English languages. However, since this is only a single experiment, with one non-English language, then more cross-language research is necessary to determine this.

The remainder of the paper is structured in the following way: In Section II we look into previous research within the field of EC. Section III then clarifies the definitions used in this study. Our framework as well as our application of it is defined in Section IV. Details of our experiment are then specified in Section V. In Section VI we present and evaluate our experiment results. The consequences and potential error sources of our results are discussed in Section VII. The conclusion of our study as well as ideas for further research are shown in Section VIII.

## II. RELATED WORKS

During this Section, we introduce a list of EC studies, with a different focus compared to us. We also explain which elements of these studies we use for our experiment.

The main difference between these studies and ours is that while most of these sources examined different preprocessing methods and classification algorithms for the English language, we are comparing preprocessing methods and classification algorithms across multiple languages, in order to check the impact the languages have on their effectiveness.

[3] studied which preprocessing technique yields the highest accuracy using a Naive Bayes Multinomial (NBM) classifier. They used a set of common preprocessors (i.e. preprocessors used in all test cases), and varying preprocessors (i.e. preprocessors which varied whether they were used or not). The combination that yielded the best result, when classifying positive and negative sentences, was the set of common preprocessors and stemming. Using this setup, they were able to achieve an accuracy of 80%.

In [4] they compared accuracies of multiple different  $n$ -gram combinations as well as other features, including preprocessing methods and various lexical resources. Their experiment used LIBLINEAR and NBM as classification algorithms. Based on their research we decided to test the following  $n$ -gram combinations:  $NG = \{1\}$ ,  $NG = \{1, 2\}$ , and  $NG = \{1, 2, 3\}$ .

[5] presented a method for classification using anger, disgust, fear, joy, sadness, and surprise as base emotions, as well as classifying positive, negative, and neutral emotions. The classification was done using a Support-Vector Machine (SVM) classifier with Sequential Minimal Optimization (SMO) calculated on a cluster of computers, and yielded results with accuracies between 65% and 85% depending on the preprocessing methods used. We decided to use some of the preprocessing methods described in [5].

The effectiveness of different SA classification algorithms using tweets was studied by [6]. Based on their research we chose to use Random Forest (RF) and SVM as our classification algorithms. We chose these since we wanted classifiers which performed well and with very different behaviors to cover a wide spectrum of classifiers. RF was overall stable and gave good results, and is chosen as a reliable classifier, whereas SVM showed high performance as a binary classifier, but was shown to be highly data set dependent on 3 class classification.

A framework for detecting emotions in multilingual text was presented by [7]. They developed their emotion extraction system from features that were acquired from different emotional lexicons. Emotions were classified on data gathered from real-time events in different domains, such as sports.

Based on the before mentioned research we chose to use five of the preprocessing methods from [5] and two of the classification algorithms from [6]. We also chose to work with Naive Bayes (NB) as it is a common classification algorithm. We also use the  $n$ -gram preprocessing method with the  $n$ -gram combinations that performed best in [4]:  $NG = \{1\}$ ,  $NG = \{1, 2\}$ , and  $NG = \{1, 2, 3\}$ . While there are many

studies on EC for a single language, there is a lack of research on cross-language EC. The main focus of our research is to address this issue.

## III. PRELIMINARY DEFINITIONS

The definitions we need to clarify are:

- Cross-language: Applying research based on one language to other languages.
- Attribute: Unique word/ $n$ -gram from our data set.
- Instance: A tweet from our data set.
- Class: A base emotion from: {joy, trust, fear, surprise, sadness, disgust, anger, anticipation}[2].
- VPP configuration: A specific combination of preprocessing methods, used in VPP.
- Classification configuration: A combination of a VPP configuration and a classifier.
- Test case configuration: A combination of a classification configuration and a target language.
- Test case: An instance of a test case configuration, including the data set and the results of classifying this data set.

## IV. OUR PROPOSED FRAMEWORK

In this Section, we define the framework for the general point of view as well as how we apply the framework to our experiment.

### A. Framework

The framework is designed to classify a number of test cases. Afterwards, we use a statistical test on these results to evaluate whether the languages used in the data sets have a significant impact on the preprocessors and classifiers being tested.

The input of the framework is a customizable set of data sets in different languages, preprocessing methods, and classification algorithms. Preprocessing methods are divided into common preprocessors and variable preprocessors. Common preprocessors are applied to all test cases, while variable preprocessors are tested as part of the experiment.

We define the framework by three phases: Preprocessing phase, Classification Phase (CP), and Statical Test Phase (STP). The preprocessing phase consists of the following subphases: Common Preprocessing Phase (CPP), Varying Preprocessing Phase (VPP), Attribute Selection Phase (ASP). These phases are visualized in Figure 1. Each test case is going through these phases individually, except STP, which uses the results of the previous phase to evaluate the hypothesis.

The following list provides a general description of each phase, and clarifies its purpose:

- Preprocessing Phase. The purpose of this phase is to make the data sets less complex and faster to classify.
  - Common Preprocessing Phase (CPP). The purpose of this phase is to clean the data set and reduce its size. We do this by removing grammatical elements and combining similar textual elements.
  - Varying Preprocessing Phase (VPP). This phase applies the preprocessing methods that we want to test.

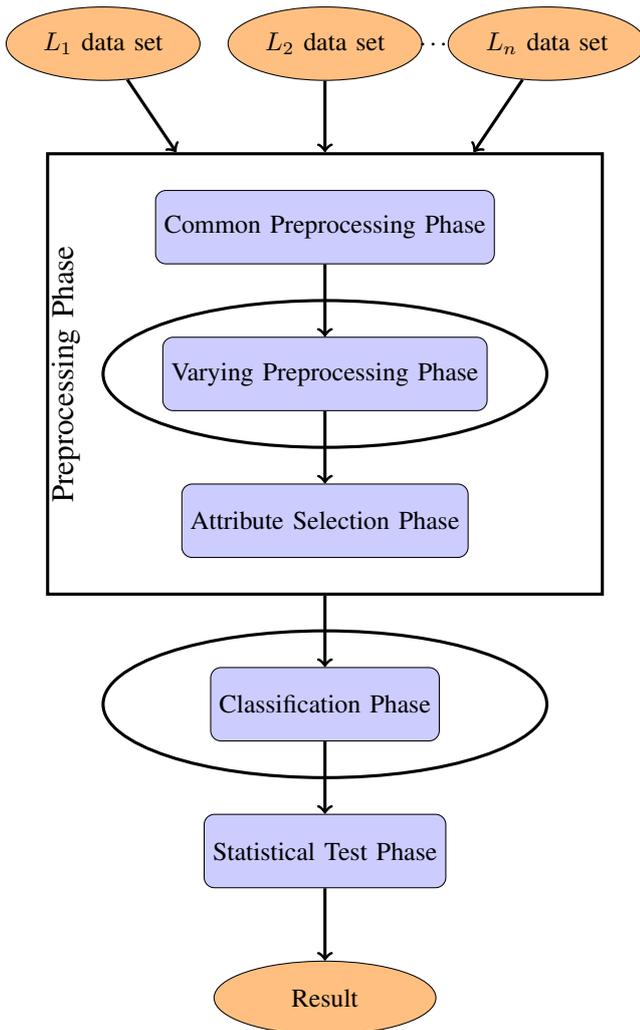

Fig. 1. The process of our framework.  $L_1$  to  $L_n$  represents a minimum of two data sets in different languages to be tested. The black box describes the preprocessing phase which involves the following subphases: CPP, VPP, and ASP. The black ellipses describe the varying parts of our experiment which are changed for each test case.

It consists of multiple preprocessing steps, which are continuously changed based on the VPP configuration of the test case.

- Attribute Selection Phase (ASP). During this phase, we evaluate the preprocessed data set and remove attributes from them in order to reduce classification time.
- Classification Phase (CP). During this phase, we use the preprocessed data set to train and test a classifier.
- Statical Test Phase (STP). During this phase, we use a statistical test on the results gained from CP to evaluate our hypothesis.

### B. Our Application of the Framework

We use a set of Danish tweets and a set of English tweets as the input set for our framework.

Following is a description of the specific methods used for our implementation of each of the phases described in our framework:

1) *Common Preprocessing Phase (CPP)*: Our input for this phase consists of several preprocessing methods which are described below (in execution order):

- **Replace user**  
Replaces a mention of a user, e.g. '@johndoe' with '<user>' in order to unify all references to users.
- **Replace link**  
Replaces a link, e.g. 'pic.twitter.com' with '<link>' in order to unify all references to links, since we do not want to distinguish between links.
- **Remove repeated characters**  
Repeated characters in a word are reduced to a maximum of three repetitions. For example, the word 'happpppppyyy' becomes 'happpyyy'. This is done because a maximum of two adjacent character repetitions can occur naturally, and we assume there is little intensity difference based on the exact amount of repetitions (e.g. 'saaad' and 'saaaaad' have roughly the same intensity). However, we expect a substantial intensity difference between using repeated characters and not which is why up to three repetitions are kept (e.g. 'sad' and 'saaad' have different intensities).
- **Hashtag deletion**  
Hashtags are replaced with the word in the hashtag, e.g. '#sad' becomes 'sad'. Hashtags are often included as words in the text or to summarize the tweet, which is the reason they are kept.
- **Replace emoticons**  
Each emoticon is replaced with an equivalent emoji, thereby reducing the number of attributes. For example, ':D' and ':-D' both become '😊'.
- **Lowercasing**  
All tweets are converted to lowercase.
- **Symbol removal**  
All symbols are removed from the tweets. Commas and semicolons are replaced with <soft>, and additionally <soft> is also added after every string of emojis. Dots, colons, exclamation marks, and question marks are replaced with <hard>. <soft> and <hard> are later used in 'n-gram stop-split' step, described in VPP.

2) *Varying Preprocessing Phase (VPP)*: Our input for this phase consists of the following preprocessing methods (described in execution order):

- **Part-Of-Speech (POS) tagger**  
A POS tagger finds the corresponding word class for each word in the data sets. This is done to focus on typical emotional word classes, i.e. nouns, adjectives, adverbs, and verbs, by removing words from all other classes[8].
- **Stemming**  
Stemming is a process, where each word is converted to its root (e.g. 'walking' becomes 'walk' and 'smiling'

becomes ‘smile’). While some intensity may be lost, the number of attributes are greatly reduced.

- ***n*-gram stop-split**

In this step the *<soft>* and *<hard>* stops are used to split tweets into multiple sets of words, which are split further by *n*-gram before being classified. This means that conjunctions and interposed sentences are taken into account when classifying longer sentences. We use this preprocessor in order to account for the difference in the use of commas between the Danish and the English language. The varying part here is whether *<soft>* is used to split tweets or not while *<hard>* is always used to find splits.

- ***n*-gram**

*n*-gram splits the sets of words acquired in the *n*-gram stop-split preprocessor into smaller sets of words. We test  $NG = \{1\}$ ,  $NG = \{1, 2\}$ , and  $NG = \{1, 2, 3\}$  *n*-gram combination since combinations of multiple *n*-grams received better results than single *n*-grams in [4].

3) *Attribute Selection Phase (ASP)*: Our input for this phase consists of two different methods for removing attributes. Firstly, attributes that only appear in the data set once are removed because they cannot be in the test set and training set at the same time. Besides this we also evaluate the information gain of each attribute, and remove all attributes with an information gain less than 0.00025. This reduced the number of attributes substantially, e.g. for our test case with the most attributes,  $NG = \{1, 2, 3\}$  *English*, we started with 1, 719, 816 attributes, and after running the ASP it had 15, 210 attributes left.

Information gain describes how much information an attribute gives us about the classes. It is calculated using Equation 1, which uses Equation 2 and Equation 3 describing entropy and expected entropy respectively[9].

$$Gain(X) = h(C) - h(C|X) \quad (1)$$

$$h(C) = \sum_{i=1}^n -C_i \cdot \log_2(C_i) \quad (2)$$

$$h(C|X) = \sum_{i=1}^m \frac{|E_i|}{|E|} \cdot h_i(C) \quad (3)$$

In these equations  $C$  is the set of classes  $C = \{C_1, C_2, \dots, C_n\}$ , where  $C_i$  refers to a specific class,  $X$  is an attribute with the domain  $X = \{v_1, v_2, \dots, v_m\}$ , where  $v_i$  refers to a specific value in the domain,  $E_i$  is the set of instances with  $X = v_i$ , and  $h_i(C)$  is the entropy of classes in  $E_i$ .

The domain of our attributes describes how many times the *n*-gram is used in a tweet. However, for the purposes of calculating expected entropy we reduce the domain of all attributes to whether the word is in the tweet or not.

4) *Classification Phase (CP)*: We run all our classifiers using Weka<sup>1</sup>. In order to minimize bias and randomness, we use Weka’s standard parameters, with a 5 fold cross-validation. Which classification algorithm is used depends on the classification configuration from the following options:

- Support-Vector Machine (SVM) - A nonprobabilistic binary classification algorithm. It constructs a hyperplane to separate two classes based on the data points closest to the gap between the classes. We use the SVM optimizer Sequential Minimal Optimization (SMO) for this[10][11].
- Random Forest (RF) - It is also known as random decision forest. RF generates random decision trees which can be used for classification, regression and other purposes[12].
- Naive Bayes (NB) - A simple probabilistic classification algorithm based on applying Bayes’ theorem with strong independence assumptions between the features[13].

5) *Statical Test Phase (STP)*: For our STP, we use a two-sided Wilcoxon signed-rank test[14] on the accuracy difference in pairs of test cases across languages in order to test the following hypothesis:

**Hypothesis:** *The change in classification accuracy for Emotional Classification caused by changing a single preprocessor or classifier is independent of the target language within a significance level of  $p = 0.05$ .*

We cannot use the raw accuracy difference between the languages, since that will only show the difference in difficulty of doing EC on the two languages. Instead we calculate the difference between pairs of classification configurations using our classification results. The difference between the classification configuration pair  $(A, B)$  is calculated as:  $A - B$ . We create a pair of test case configurations  $((A, B)_{Danish}, (A, B)_{English})$  consisting of two pairs of classification configurations.

The test cases representing this test case configuration pair are used as a pair of data points for the Wilcoxon test to make our cross-language comparison. We do this for each pair of classification configurations  $(A, B)$  which only have one difference between them (one varying preprocessor or a different classifier), making up a total of 180 pairs of data points for the Wilcoxon test. These pairs of data points can be seen in Table IV.

We are not using pairs of classification configurations with more than one difference between them since they are already represented through multiple pairs of classification configurations with only one difference;  $(A - C) = (A - B) + (B - C)$ .

## V. EXPERIMENT

During this Section, we specify some details of our experiment, specifically our data extraction process and VPP configurations. We conduct this experiment in order to determine whether the language being classified has impact on the accuracy of EC for a given classification configuration or not.

C18	$NG = \{1, 2, 3\}, ST, NGSS$
C19	$NG = \{1, 2\}, ST, POS, NGSS$
C20	$NG = \{1, 2, 3\}, ST, POS, NGSS$

#### A. VPP Configurations

All possible VPP configurations for our experiment are shown in Table I. We use these configurations both for the Danish and the English data set, and for each classifier. This table uses the following abbreviations for describing the types of VPP methods included in each VPP configuration:

- Stemming = ST
- POS tagger = POS
- $n$ -gram = NG
- $n$ -gram stop-split = NGSS

#### B. Data Extraction

For each base emotion, we manually choose hashtags based on synonyms and similar words from these websites<sup>2,3,4</sup>. Then we manually filter the hashtags, based on whether the tweets using the hashtag show the correct emotion. Examples of these hashtags are shown in Table II. We then download the tweets, which include the remaining hashtags, using the python library 'Twint'<sup>5</sup>.

It is important that the data set for each language are as similar as possible. This is to ensure that any difference we detect in the performance of methods is due to linguistic differences rather than other differences in the data sets. In particular, we want the data sets to have equal size and distribution between classes. The English data set is created based on the size of the Danish data set since there are fewer Danish tweets compared to English tweets. For each English

hashtag, we collected a number of tweets equal to  $\frac{1}{10}$  of the number of Danish tweets for the class which the hashtag belongs to. Then from each class of English tweets a number of random unique tweets, equal to the size of the same class of Danish tweets, are selected. This makes the data sets equal in number of tweets for each class, as well as in the total number of tweets.

## VI. EVALUATION

In this Section, we show and discuss the results from our experiment's CP and STP through trends and phenomena that occur.

#### A. Classification Evaluation

For each test case configuration, we calculate accuracy, precision, recall, and F-measure using Weka. Accuracy is a general measure of the quality of the classification. Precision and recall are both measures of relevance, where precision describes how many retrieved items are relevant, and recall describes how many relevant items are retrieved. The values listed are the average precision and recall of the classes. F-measure is the harmonic mean of precision and recall. The values listed are the average F-measure of the classes. Weka calculates these statistics using the following formulas:

$$Accuracy = \frac{|correct\ results|}{|correct\ results \cup incorrect\ results|} \quad (4)$$

$$Precision = \frac{1}{n} \sum_{i=1}^n \frac{|TP(C_i)|}{|TP(C_i)| + |FP(C_i)|} \quad (5)$$

$$Recall = \frac{1}{n} \sum_{i=1}^n \frac{|TP(C_i)|}{|TP(C_i)| + |FN(C_i)|} \quad (6)$$

$$F - measure = 2 \cdot \frac{Precision + Recall}{Precision \cdot Recall} \quad (7)$$

In the above equations,  $C$  is the set of classes  $C = \{C_1, C_2, \dots, C_n\}$ , where  $C_i$  refers to a specific class of emotions, and  $n$  is the number of classes (eight emotions in our case). *correct results* is the set of all results which are classified as the correct class, while *incorrect results* is the set of all results classified as the wrong class.  $TP(C_i)$ ,  $TN(C_i)$ ,  $FP(C_i)$ , and  $FN(C_i)$  describe the set of: true positive-, true negative-, false positive-, and false negative results respectively, for the class  $C_i$ .

We present the results of the CP in Table III. A row in Table III describes which VPP configuration is used, while the columns describe whether accuracy, F-measure, precision, or recall is shown, and which language and classification algorithm is used.

When we observe the results, the following trends appear:

- The average accuracy of the English data set is lower than the average accuracy of the Danish data set. This might be due to the the higher diversity in English tweets, created by the difference in numbers of hashtags, and that the English tweets are written by many different cultures,

while the Danish tweets primarily are written by Danish people.

- SVM has the highest accuracy, F-measure, precision, and recall, out of all classifiers and across both languages.
- The  $n$ -gram stop-split preprocessor does not make a large difference in the results. There are only a few cases with a noticeable difference, e.g. between C16 and C9, which is  $NG = \{1, 2, 3\}$  POS, with and without NGSS respectively. This might be because most of the  $n$ -grams this preprocessor removes would otherwise have been removed during the ASP.
- The differences in classification effectiveness between  $NG = \{1\}$  and  $NG = \{1, 2, 3\}$  is the opposite of what we expected. The effectiveness of  $NG = \{1\}$  is often higher than the other  $n$ -gram variations for both Danish and English. This suggests that the context gained from adding orders of words is less significant than the noise created by adding more  $n$ -gram attributes.

### B. Statistical Test Evaluation

We compare the classification accuracies, from Table III by applying them on a Wilcoxon test. The basis of this analysis is described in Section IV-B5.

Figure 2 shows the pairs of test case configurations where Table IV shows the setup of each test case configuration i.e. the variables on the x-axis of Figure 2.

In Table IV, test case configuration differences written on the form 'VPP configuration-classifier-classifier' describe two test case configurations with the same VPP configuration but different classifiers. However, test case configuration differences on the form 'VPP configuration-VPP configuration-classifier' describe two test case configurations with one difference in

their VPP configuration but using the same classifier. The corresponding VPP configurations are shown in Table I.

In Figure 2, each point represents the difference between two test cases' accuracy ( $A_{accuracy}, B_{accuracy}$ ), where  $A$  and  $B$  has only one difference between their classification configurations. If a point is positive, then test case  $A$  has a higher accuracy than  $B$ ; if a point is negative, then test case  $A$  has a lower accuracy than  $B$ ; and if a point is 0, then there is no difference between their accuracies.

Each line in Figure 2 represents the accuracy difference between a pair of test case configurations. The red and orange lines represent the English data set, while the blue and cyan lines represent the Danish data set. The special cases where one point is above 0 and the other is below, represent test case configuration pairs where there is a positive accuracy change for one language and a negative change for the other. Orange and cyan represent these special cases. These cases support the rejection of our hypothesis.

Running the Wilcoxon test on our test case configuration pairs results in a  $p$ -value of 0.12852. Our hypothesis is therefore not rejected within a significance level of 0.05. Thus, which classification configuration that performs best might be independent of the languages being classified.

The box plot in Figure 3 shows the variance of the accuracy difference in the data used for the Wilcoxon test. We can see that the English data set has a higher variance, meaning it is more sensitive towards configuration changes. Despite this, both data sets have a median close to 0, which could explain why we cannot reject our hypothesis.

By studying Figure 2, we learn that the biggest differences in accuracy comes from the change of classifier to/from NB. Furthermore, POS tagging on the English data set makes almost

TABLE III

TEST CASE RESULTS: BOLD VALUES ARE THE HIGHEST VALUES WITHIN THE CLASSIFIER AND LANGUAGE COMBINATION WHILE UNDERLINED VALUES ARE THE HIGHEST VALUES WITHIN THE LANGUAGE.

as large a negative change in accuracy difference as changing classifier to NB. The Danish data set however improves slightly when POS tagging is applied. This effect can be seen in the difference between C1 to C7, C2 to C8, and C3 to C9 for all classifiers.

## VII. DISCUSSION

In this Section, we discuss the consequences of the observations in Section VI-B. First we look at the results of the Wilcoxon test, followed by the effects of classifiers, and language specific tools.

As described in Section VI-B, our Wilcoxon test did not yield any significant results. This suggests that classification configurations react similarly to the Danish and the English data set. However, further research is needed to establish the statement “EC research based on one language is applicable to other languages”.

However, there is a significant difference when NB is applied as a classifier. Using NB, the accuracies of the English data set are between 50% – 58% while the Danish data set’s accuracies are between 72% – 80%. This suggests that there is a relevant difference in EC between the two languages.

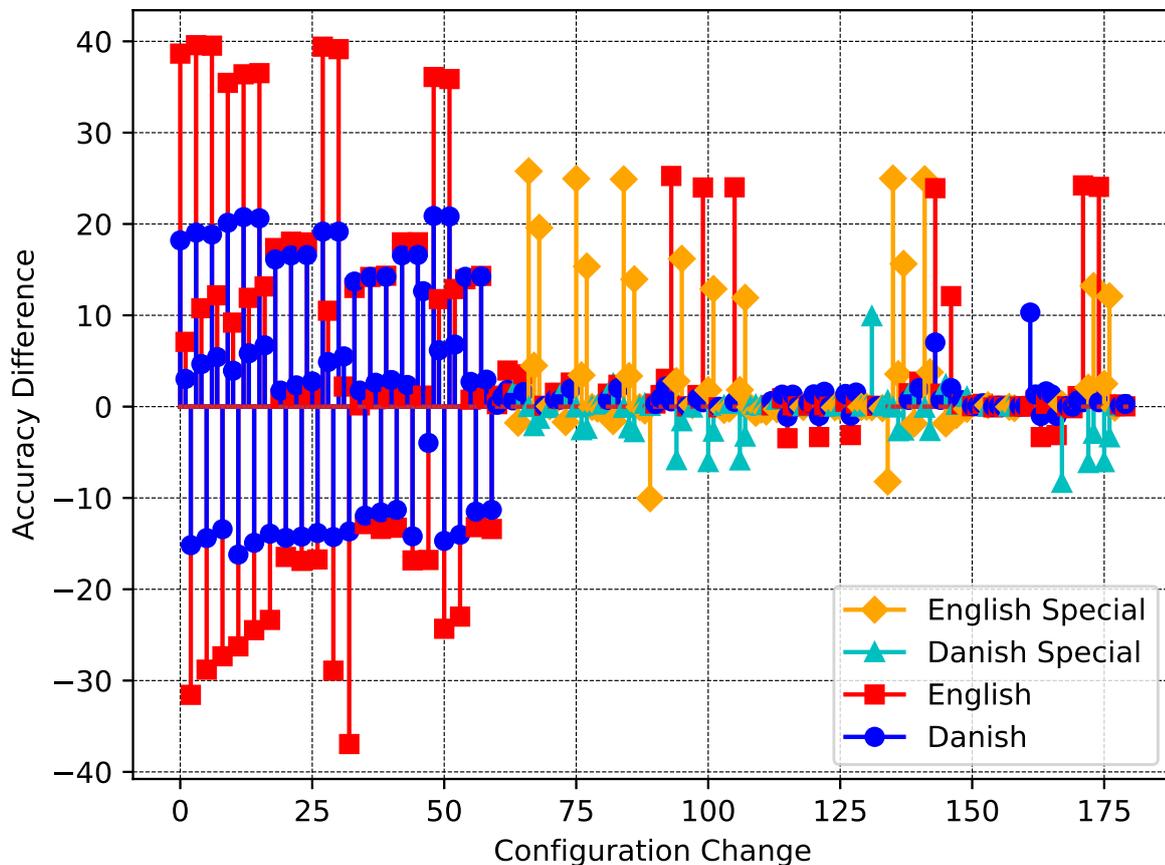

Fig. 2. Data points used in the Wilcoxon test. Configurations can be seen in Table IV. Each data point represents the percentage difference in accuracy between a pair of classification configurations. Data points marked with a blue circle represents the Danish data set and points marked with a red square represents the English data set. The data points with a orange diamonds and cyan triangles represent special cases for Danish and English respectively. These special cases describe where the configuration change had a positive impact on the one language but not with the other.

Another interesting observation we found in Section VI-B is that POS tagging has opposite effects on the two languages. Adding POS tagging made a difference in accuracy between  $-0.58\%$  and  $7.02\%$  on the Danish data set and between  $-1.82\%$  and  $-25.78\%$  on the English data set. The variance is not only higher for the English data set, as shown in Figure 3, the difference is also mostly positive for Danish and always negative for English. This means that the Danish data set benefits from POS tagging while the English data set suffers greatly from it. This suggests that while a lot of the elements of EC are not language dependent, the use of tools designed for a specific language might be language dependent. Therefore, more language specific research in these tools would be beneficial.

#### A. Possible Error Sources

By analyzing our experiment, we find some possible error sources which may have impact on our results.

- There exists non-Danish tweets in the Danish data set since Twitter's language filter is not perfect.
- English tweets are posted more often than Danish tweets, and we download the tweets in chronological descending order of posting time. In order to have the same amount of tweets in the data sets, the Danish data set ends up with a much higher time variance between posts than the English data set. Therefore, the Danish data set probably has a higher variance in how the language is used.
- The hashtags used for gathering tweets have been chosen manually and therefore do not cover all emotional words related to the base emotions.
- There may be differences in how the chosen hashtags are related to the base emotion they are labeled with. There are also 87 more English hashtags than Danish hashtags. This might cause the English data set to be more diverse and therefore possibly harder to classify.
- There are some differences between the Danish and

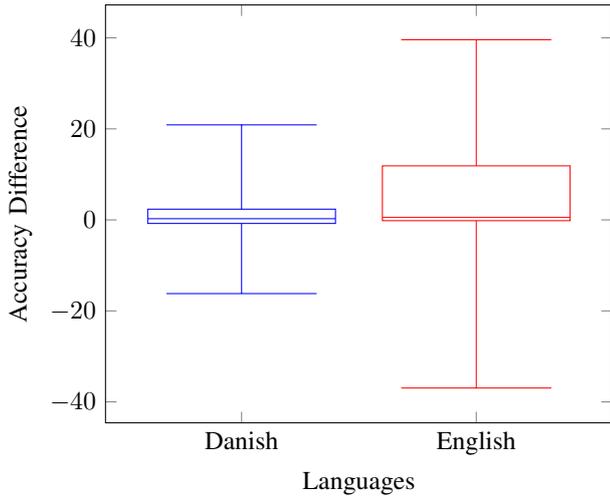

Fig. 3. Boxplot of data in Figure 2 which shows the accuracy difference using the quartiles; {Minimum, Lower Quartile, Median, Upper Quartile, Maximum} for the Danish and English data sets.

English POS tagging and stemming preprocessing methods used in VPP.

- The Danish POS tagger labels nonwords as nouns and the English POS tagger labels nonwords as proper nouns. In the VPP the POS tagging preprocessor keeps nouns but not proper nouns as part of the attributes.

## VIII. CONCLUSION

We have conducted this study in order to test whether the new research field: *cross-language EC* has the potential for reducing the amount of research needed for non-English languages within the field of EC. In Section IV-A, we constructed a framework for testing the classification accuracy of a number of test cases. In Section IV-B, the framework was used to setup our experiment, for the purpose of evaluating our null hypothesis: *The change in classification accuracy for Emotional Classification caused by changing a single preprocessor or classifier is independent of the target language within a significance level of  $p = 0.05$ .* We made this hypothesis in order to answer the more general question: *Do target languages have impact on the effectiveness of EC methods?* Our two-sided Wilcoxon signed-rank test gave a  $p$ -value of 0.12852, and therefore did not reject the hypothesis using data sets constructed from Danish and English tweets. It should be noted that our results are based only on two germanic languages with the common domain Twitter, and thus only covers a small part of the research within cross-language EC. During our experiment, SVM has consistently yielded the best results in contrast to the experiment made by [6], where SVM did not yield consistent results on nonbinary classification. In Section VI, we observed a few interesting characteristics of our results, e.g. POS tagging works well for the Danish data set but not for the English data set. These findings suggest that further research is needed for cross-language EC. We believe our study

is significant as it introduces a new topic within EC with the potential to help other EC research.

#### A. Future Work

The experiment we have conducted is only a small part of cross-language classification research since it only tested on the Danish and English language, a few preprocessing methods, and three classification algorithms. Therefore it is necessary to make similar experiments, e.g. on languages other than Danish and English in order to validate our hypothesis. Researching the cross-language effectiveness of other preprocessors and classifiers is also a possible continuation of our work. It will also be worth testing the differences between languages with different alphabets and/or structure, especially Latin-based and non-Latin-based languages. The framework described in Section IV can serve as a guide for comparing EC methods between languages. Whether languages have impact on the effectiveness of preprocessing and classification methods is still an open problem, that can be tested using other languages, preprocessing methods, classification algorithms, and/or data sets. One possible data set to use would be the SemEval-2019 data set<sup>6</sup>, which is used for a semantic evaluation workshop.

**Abstract**—Identity verification using biometric methods has been used for many years. A special case is a handwritten signature made on a digital device or piece of paper. For the digital analysis and verification of its authenticity, special methods are needed. Unfortunately, this is a rather complicated task that quite often requires complex processing techniques. In this paper, we propose a system of signatures verification consisting of two stages. In the first one, a signature pattern is created. Thanks to this, the first attempt to verify identity takes place. In the case of approval, the second stage is followed by the processing of a graphic sample containing a signature by the convolutional neural network. The proposed technique has been described, tested and discussed due to its practical use.

## I. INTRODUCTION

USING signature, we can confirm our identity. This is particularly important in the case of signing contracts or receiving parcels from couriers. In each of these situations, we confirm something with signature. Of course, such a signature may differ each time we use it. The reason is his elaboration, which means that the more we sign, the more stable it will be. Lawyers, politicians or office workers who often sign on different documents will have a stable and permanent signature very quickly. Consequently, such a signature is very important as an element of our identity.

Unfortunately, there are situations where such a signature is forged for fraud purposes. To prevent this, it is worth having a signature, which minimizes the possibility of counterfeiting. This is possible thanks to a much smoother writing process, pen pressure, or runtime. All these features are often used in the authentication process. In practice, such verification is not an easy thing, which is why the complicated methods of artificial intelligence are often used.

An important element of verification process is the classifier, which makes decisions with a certain probability. The most popular are artificial neural networks which are inspired by the mechanisms occurring in the brain. An important element of scientific research is the improvement and design of new solutions that may later be used in biometrics [1]–[6]. One of the last achievements in this field are papers on the interpretation of the signature in numerical form and the use of so-processed samples in the training process [7], [8]. Interesting approach

was presented in [9], where the authors described a technique that uses a single record with a signature.

The cited works show great effectiveness, however, it is worth paying attention to the mechanism of such software. Quite a frequent mechanism is processing not on the device, but in the computing cloud [10]. Another thing is the front-end of the software and the ways in which the application is displayed to the user [11], [12]. Conducted research is not only related to the signature but also to other elements that can confirm our identity, an example of which are the fingerprint and iris of the eye [13]–[15].

In this paper, we present a system for signature verification based on two stages based on image processing and convolutional neural networks.

## II. SIGNATURE PROCESSING

Each graphic sample containing a signature should be processed. The main reason is the inclination of the signature relative to the straight line. In order to analyze or to compare two signatures, both samples should be arranged on the same straight line without any inclination.

The slope of the signature can be calculated using the linear approximation for the given set in the discrete form. The signature is a graphic file that should be saved in numerical form. The first step is to binarize the image. Each pixel in the image is described in the RGB color system (*Red-Green-Blue*), so the binarization will mean replacing all colors with white or black one using the following equation

$$\begin{cases} \frac{\sum_{i \in \{R,G,B\}} i(p)}{3} < \left\lfloor \frac{255}{2} \right\rfloor & \text{then } R(p) = G(p) = B(p) = 0 \\ \frac{\sum_{i \in \{R,G,B\}} i(p)}{3} > \left\lfloor \frac{255}{2} \right\rfloor & \text{then } R(p) = G(p) = B(p) = 255 \end{cases} \quad (1)$$

where functions  $R(\cdot)$ ,  $G(\cdot)$  and  $B(\cdot)$  are a color component of pixel  $p$ . The value on the right of the inequality means the total value of the center of the color range in the RGB model.

As already mentioned, the image after the binarization process consists of two colors – black and white, where

the black pixels represent the signature. Each pixel can be interpreted as a coordinate  $(x, y)$ . Taking these points, we have a set of points on the Cartesian plane given discreetly. On this basis, it is possible to calculate the slope of the signature using the linear function equation in the following form

$$f(x) = y = a_0 + a_1x \Rightarrow a_0 = \tan(\alpha) \Rightarrow \alpha = \arctan(a_0). \quad (2)$$

It is easy to see that having a coefficient  $a_0$ , the slope can be calculated. However, the value of  $a_0$  must be calculated. Suppose that the set of points has  $n$  elements, then we are looking for such a function  $f(x)$ , for which the following condition will occur

$$f(x_i) = y_i, \quad i = 0, \dots, n-1. \quad (3)$$

Assume that for a set of points  $\{(x_i, y_i)\}$  where  $i \in \{0, n-1\}$ , a function  $S(a_0, a_1)$  will be presented as

$$S(a_0, a_1) = \sum_{i=0}^{n-1} (y_i - a_0 - a_1x_i)^2 \quad (4)$$

Therefore, the system of normal equations has the following form

$$\frac{\partial S(a_0, a_1)}{\partial a_0} = \sum_{i=0}^{n-1} (y_i - a_0 - a_1x_i)(-1) = 0 \quad (5)$$

$$\frac{\partial S(a_0, a_1)}{\partial a_1} = \sum_{i=0}^{n-1} (y_i - a_0 - a_1x_i)(-x_i) = 0 \quad (6)$$

By grouping the above two equations, we get

$$a_0n + a_1 \sum_{i=0}^{n-1} x_i = \sum_{i=0}^{n-1} y_i \quad (7)$$

$$a_0 \sum_{i=0}^{n-1} x_i + a_1 \sum_{i=0}^{n-1} x_i + a_1 \sum_{i=0}^{n-1} x_i^2 = \sum_{i=0}^{n-1} x_i y_i. \quad (8)$$

The above system of equations is linear, so it can be saved in a simpler form as

$$X \cdot A = Y, \quad (9)$$

where  $A, X, Y$  are a matrices defined as

$$A = \begin{pmatrix} a_0 \\ a_1 \end{pmatrix}, X = \begin{pmatrix} \sum_{i=0}^{n-1} 1 & \sum_{i=0}^{n-1} x_i \\ \sum_{i=0}^{n-1} x_i & \sum_{i=0}^{n-1} x_i^2 \end{pmatrix}, Y = \begin{pmatrix} \sum_{i=0}^{n-1} y_i \\ \sum_{i=0}^{n-1} x_i y_i \end{pmatrix} \quad (10)$$

Finally, searched coefficients can be obtained by

$$A = X^{-1} \cdot Y. \quad (11)$$

In this way, we obtain the coefficients of the approximated linear function, and thus using the equation (2), it is possible to find the slope of the signature for which the image with the signature should be rotated.

Having a processed and rotated image, we put together several signatures belonging to the same person. The imposition of images consists in creating matrix with a dimension adequate to the samples (if the samples are of different sizes, they should be normalized to the same one). This matrix should be filled with 0 (which is understood as a white pixel). Then, for each image, pixels are checked. If there is a black pixel at a given position in the image, then the value in this matrix is increased by 1.

Such a matrix allows us to create patterns. The higher the value of a given matrix element, the more often the pixel appears and can be treated as a feature.

The smallest values should be replaced with zeros. The selection of this value depends on the number of samples used in the process of its creation. As part of the experiments to be carried out, the optimal value was determined as  $\frac{n}{2}$  or  $\frac{n-1}{2}$ .

Such a matrix can be applied to a new, processed signature. In this case, we calculate the number of black pixels of the signature that are on the positions in the matrix (where the elements are different from zero). This allows us to calculate the percentage coverage of features.

### III. CONVOLUTIONAL NEURAL NETWORK

The previous stage allowed the creation of a technique that gives the percentage quality of coverage of the main features. Unfortunately, it does not allow the verification process itself. For this purpose, we use Convolutional Neural Network (CNN) [16], which are a mathematical model of action having place in the primary cortex. These structure take the image at the entrance, and at the output they return the class to which the input belongs with a certain probability. Structure construction can be described using three layers. The first two layers are used to feature extraction and are called convolutional and pooling. The first type processes the image using a certain filter  $\omega$  defined as a matrix and a step  $S$  through which this matrix will be moved. The next layer is called pooling which reduces the size of the image using the selected function. If the image is to be reduced to  $t$  times, a matrix of size  $t \times t$  is created, in which only one pixel is selected and this matrix is shifted in the image, resulting in a reduced image. Next, a classic neural network is created that forms the last layer of the network.

The structure itself is quite simple in its model, however, it must be added that the layers are connected to each other thanks to synapses burdened with weights. At the initial stage of creating networks, they are generated in a random way. Using the training algorithm, they are modified due to input data. The most commonly used algorithm is Adaptive Moment Estimation (*Adam*). The algorithm consists in calculating the mean values  $m$  of the gradient and the second momentum (variance)  $v$  in each iteration  $t$ . Let us assume that  $w^{(t)}$  will be understood as a parameters and  $L^{(t)}(\cdot)$  as a loss function. Formally, the equations for these values are as follows

$$m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t, \quad (12)$$

$$v_t = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2, \quad (13)$$

where  $\beta_1$  and  $\beta_2$  are decay coefficients, which values are close to 1. The correction for a given moment is defined as

$$\hat{m}_t = \frac{m_t}{1 - \beta_1^t}, \quad (14)$$

$$\hat{v}_t = \frac{v_t}{1 - \beta_2^t}, \quad (15)$$

which are used to update the value

$$\theta_{t+1} = \theta_t - \frac{\eta}{\sqrt{\hat{v}_t} + \epsilon} \hat{m}_t, \quad (16)$$

where  $\epsilon$  is a constant, small value used to prevent dividing by 0 and  $\eta$  is the learning rate.

#### IV. SIGNATURE VERIFICATION MODEL

The proposed system consists of image processing or normalization of the sample, and then using it in two stages. The first one is to create a matrix or use it to check the percentage of coverage of features. If the obtained value exceeds the threshold value, then this sample is classified by the convolutional neural network. The graphical illustration of the model is shown in Fig. 1. This action reduces the number of operations performed by possibly rejecting the sample due to the feature matrix.

Assuming that the system should enable the identity verification of several people, the signature is analyzed in relation to all matrices in the database. If for any of them, the percentage threshold is exceeded, it is classified by the network. In case the matrix and network return different results, the system will not be able to clearly identify the owner of the sample.

#### V. EXPERIMENTS

For testing purposes, a small signature database of two people was created, consisting of 50 samples (25 per person). In addition, 20 samples (10 for each person) of fake signatures were created (tried to imitate other's signatures). In the classifier learning process, all samples were normalized to the dimension  $150 \times 150$  pixels. Used architecture of CNN is presented in Tab. I.

The features matrix was tested for different values, and the best efficiency (in an empirical way) was obtained for a value equal to  $\frac{n-1}{2}$ . Classifier was trained 10 epochs using 70% : 30% of samples (training to validation number of samples). The history of training is shown in Fig. 2

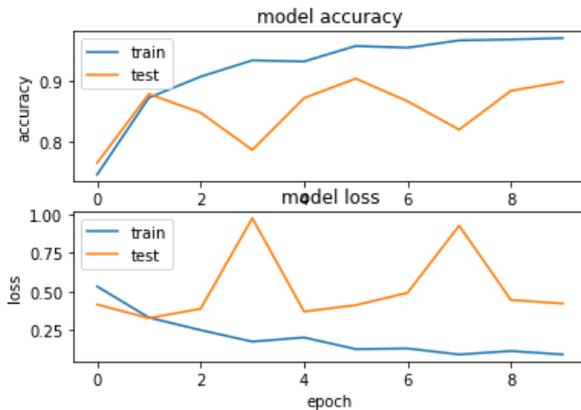

Figure 2: Graphs of training history using 50 samples (35:15 training : validation).

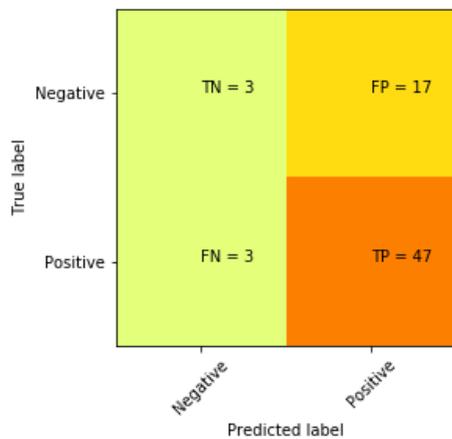

Figure 3: Confusion matrix for average results contained from 10 attempts.

The effectiveness of the classification for two people was achieved at 94%, which is a very good result considering the number of samples in the training process. It is worth noting that after training the classifier, fake samples were used in order to verify the operation of the proposed system. 11 signatures were rejected at the level of the features matrix and the remaining ones were classified by the classifier. The average probability of belonging to these people was in the range 33–90%, what is a good result. The optimistic approach is the result of the fact that the original samples were classified above 83%, what allows to reject counterfeit signatures except for selected images. The network was trained ten times in order to obtain an average classification value, which was achieved at 91%, the average results of classification was presented in confusion matrix in Fig. 3.

## VI. CONCLUSION

The described method of identity verification based on the signature indicates high efficiency. The experiments were

carried out on the basis of a total sum of samples equal to 50, which is quite a small amount. It is worth noting that adding verification using the matrix of features allowed to reduce the operations performed using CNN because it rejected over half of suspicious samples before the verification stage. This solution indicates the possibility of obtaining better efficiency using more extensive techniques for creating matrix pattern using other features.

# 12<sup>th</sup> International Symposium on Multimedia Applications and Processing

**O**RGANIZED by Software Engineering Department, Faculty of Automation, Computers and Electronics, University of Craiova, Romania “Multimedia Applications Development” Research Centre

## BACKGROUND AND GOALS

Multimedia information has become ubiquitous on the web, creating new challenges for indexing, access, search and retrieval. Recent advances in pervasive computers, networks, telecommunications, and information technology, along with the proliferation of multimedia mobile devices—such as laptops, iPods, personal digital assistants (PDA), and cellular telephones—have stimulated the development of intelligent pervasive multimedia applications. These key technologies are creating a multimedia revolution that will have significant impact across a wide spectrum of consumer, business, healthcare, educational and governmental domains. Yet many challenges remain, especially when it comes to efficiently indexing, mining, querying, searching, retrieving, displaying and interacting with multimedia data.

The Multimedia—Processing and Applications 2019 (MMAAP 2019) Symposium addresses several themes related to theory and practice within multimedia domain. The enormous interest in multimedia from many activity areas (medicine, entertainment, education) led researchers and industry to make a continuous effort to create new, innovative multimedia algorithms and applications.

As a result the conference goal is to bring together researchers, engineers, developers and practitioners in order to communicate their newest and original contributions. The key objective of the MMAAP conference is to gather results from academia and industry partners working in all subfields of multimedia: content design, development, authoring and evaluation, systems/tools oriented research and development. We are also interested in looking at service architectures, protocols, and standards for multimedia communications—including middleware—along with the related security issues, such as secure multimedia information sharing. Finally, we encourage submissions describing work on novel applications that exploit the unique set of advantages offered by multimedia computing techniques, including home-networked entertainment and games. However, innovative contributions that don't exactly fit into these areas will also be considered because they might be of benefit to conference attendees.

## CALL FOR PAPERS

MMAAP 2019 is a major forum for researchers and practitioners from academia, industry, and government to present, discuss, and exchange ideas that address real-world problems with real-world solutions.

The MMAAP 2019 Symposium welcomes submissions of original papers concerning all aspects of multimedia domain ranging from concepts and theoretical developments to advanced technologies and innovative applications. MMAAP 2019 invites original previously unpublished contributions that are not submitted concurrently to a journal or another conference. Papers acceptance and publication will be judged based on their relevance to the symposium theme, clarity of presentation, originality and accuracy of results and proposed solutions.

#### BEST PAPER AWARD

A best paper award will be made for work of high quality presented at the MMAP Symposium. The technical committee in conjunction with the organizing/steering committee will decide on the qualifying papers. Award comprises a certificate for the authors and will be announced on time of conference.

#### STEERING COMMITTEE

- **Amy Neustein**, Boston University, USA, Editor of Speech Technology
- **Lakhmi C. Jain**, University of South Australia and University of Canberra, Australia
- **Zurada, Jacek**, University of Louisville, United States
- **Ioannis Pitas**, University of Thessaloniki, Greece
- **Costin Badica**, University of Craiova, Romania
- **Borko Furht**, Florida Atlantic University, USA
- **Harald Kosch**, University of Passau, Germany
- **Vladimir Uskov**, Bradley University, USA
- **Thomas M. Deserno**, Aachen University, Germany

#### HONORARY CHAIR

- **Dumitru Dan Burdescu**, University of Craiova, Romania

#### GENERAL CO-CHAIRS

- **Adriana Schiopoiu Burlea**, University of Craiova, Romania
- **Marius Brezovan**, University of Craiova, Romania
- **Marcin Woźniak**, Institute of Mathematics, Silesian University of Technology, Poland

#### PUBLICITY CHAIR

- **Amelia Badica**, University of Craiova, Romania
- **Milan Simic**, RMIT University, School of Engineering, Australia

#### ORGANIZING

- **Dumitru Dan Burdescu**, University of Craiova, Romania
- **Costin Badica**, University of Craiova, Romania
- **Marius Brezovan**, University of Craiova, Romania
- **Adriana Schiopoiu Burlea**, University of Craiova, Romania
- **Liana Stanescu**, University of Craiova, Romania
- **Cristian Marian Mihaescu**, University of Craiova, Romania

#### PROGRAM COMMITTEE

- **Azevedo, Ana**, CEOS.PP-ISCAP/IPP, Portugal
- **Badica, Amelia**, University of Craiova, Romania
- **Burlea Schiopoiu, Adriana**, University of Craiova, Romania
- **Cano, Alberto**, Virginia Commonwealth University, United States
- **Cordeiro, Jose**, EST Setúbal/I.P.S.

- **Cretu, Vladimir**, Politehnica University of Timisoara, Romania
- **Debono, Carl James**, University of Malta, Malta
- **Fabijańska, Anna**, Lodz University of Technology, Poland - Institute of Applied Computer Science, Poland
- **Fomichov, Vladimir**, National Research University Higher School of Economics, Moscow, Russia., Russia
- **Giurca, Adrian**, Brandenburg University of Technology, Germany
- **Grosu, Daniel**, Wayne State University, United States
- **Kabranov, Ognian**, Cisco Systems, United States
- **Keswani, Dr. Bright**, Suresh Gyan Vihar University, Mahal, Jagatpura, Jaipur
- **Korzhih, Valery**, State University of Telecommunications, Russia
- **Kotenko, Igor**, St. Petersburg Institute for Informatics and Automation of the Russian Academy of Science, Russia
- **Logofatu, Bogdan**, University of Bucharest, Romania
- **Mangioni, Giuseppe**, DIEEI - University of Catania, Italy
- **Marghitu, Daniela**, Auburn University
- **Mihaescu, Cristian**, University of Craiova, Reunion
- **Mocanu, Mihai**, University of Craiova, Romania
- **Ohzeki, Kazuo**, Professor Emeritus at Shibaura Institute of Technology, Japan
- **Pohl, Daniel**, Intel, Germany
- **Popescu, Dan**, CSIRO, Sydney, Australia, Australia
- **Popescu, Daniela E.**, Integrated IT Management Service, University of Oradea
- **Querini, Marco**, Department of Civil Engineering and Computer Science Engineering
- **Radulescu, Florin**, University "Politehnica" of Bucharest
- **Romansky, Radi**, Professor at Technical University of Sofia
- **RUTKAUSKIENE, Danguole**, Kaunas University of Technology
- **Salem, Abdel-Badeeh M.**, Ain Shams University, Egypt
- **Sari, Riri Fitri**, University of Indonesia, Indonesia
- **Scherer, Rafał**, Częstochowa University of Technology, Poland
- **Sousa Pinto, Agostinho**, Instituto Politécnico do Porto, Portugal
- **Stanescu, Liana**, University of Craiova, Romania
- **Stoicu-Tivadar, Vasile**, University Politehnica Timisoara
- **Trausan-Matu, Stefan**, Politehnica University of Bucharest, Romania
- **Trzcielinski, Stefan**, Poznan University of Technology, Poland
- **Tsihrintzis, George**, University of Piraeus, Greece

**Abstract**—Image stitching refers to the process of combining multiple images of the same scene to produce a single high-resolution image, known as panorama stitching. The aim of this paper is to produce a high-quality stitched panorama image with less computation time. This is achieved by proposing four combinations of algorithms. First combination includes FAST corner detector, Brute Force K-Nearest Neighbor (KNN) and Random Sample Consensus (RANSAC). Second combination includes FAST, Brute Force (KNN) and Progressive Sample Consensus (PROSAC). Third combination includes ORB, Brute Force (KNN) and RANSAC. Fourth combination contains ORB, Brute Force (KNN) and PROSAC. Next, each combination involves a calculation of Transformation Matrix. The results demonstrated that the fourth combination produced a panoramic image with the highest performance and better quality compared to other combinations. The processing time is reduced by 67% for the third combination and by 68% for the fourth combination compared to stat-of-the-art.

## I. INTRODUCTION

THE STUDY of panoramic imaging is one of the advanced research topics in the field of computer vision, graphics and image processing [1]. Panorama Stitching is defined when two or more images of the same scene are taken by rotating a camera about its axis. As a result of this process a wider panorama image is created by overlapping the common contents of each component image [2]. In 1997, Szelinski and Shum defined creating a larger panorama image as the integration and overlapping the common contents of two or more images of the same scene by rotating the camera about its axis. In 2017, Wand et al. defined panorama stitching as taking multiple images with an overlapping area and stitching them together into a single wide image [3][4]. In 2015, Hee-kyeong Jeon et al. classified the panorama stitching process as the three core steps of detecting features, matching them, and stitching [2]. Early panorama images were created by sliding a slit-shaped aperture across a photographic film. The digital approach of today extracts thin, vertical strips of pixels from the frames of a sequence captured by a translating video camera. The resulting image is considered as multi-viewpoint (or multi-perspective), because different strips of the image are captured from multiple viewpoints [4]. Strip panoramas are created from a translating camera with many variants, such as "pushbroom panoramas" [5], "adaptive manifolds" [6], and "x-slit" images [7]. Contrary to the hardware-based approach,

many researchers have explored the multi-perspective renderings of 3D models [8][9]. Yu and McMillan presented a model that describes a multi-perspective camera [10]. Panoramic image stitching is used in a variety of environment, including gaming, virtual reality, virtual museums, and map applications [11]. Microsoft Research, for example, is spending on research projects featuring panorama stitching techniques, and many algorithms are designed to efficiently facilitating the creation of panoramic images through stitching [12][13].

## II. BACKGROUND

Most researchers classify panorama stitching as either a direct technique or a feature-based technique [11][14]. The direct technique compares pixel to pixel between images and the feature-based technique compares all features within each image [14]. This paper applies the feature-based technique as it is more advanced, faster, and flexible when compared to the direct technique. Producing a panorama stitching for two or more images of the same object is divided into three steps. First, the process discovers the points of interest between several images (the keypoints) and extract vector features around each of these points of interest (the descriptors). Second, identifies the matching lines between several images using the extracted features after that match the correct features and remove incorrect features. Third, find the transformation matrix that satisfies matching with the other keypoints, and use this transformation to align the two images before merging. Panorama stitching is considered through two perspectives. The first is camera rotation, where images are acquired with the camera positioned at the same point while being rotated to provide multiple views of the same object. The second perspective is camera translation, where the camera is not fixed at the same position but is moved through a linear translation to capture the second image. This paper focuses on the second prospective where two images are taken for the same scene and with a slight linear displacement.

Consider a car moving towards an intersection with a large building on the corner obstructing its view. If an image is taken from a point ahead of its current position and stitched with another image at its current position, such that the integrated image shows the two overlapped as a semi-transparent view, then this image can enable drivers to have a partial view of the scene behind the building. This work helps to create a vision

effect around the image, Figure 1, graphically explains this scenario. The first camera (Camera 1) captures one image of

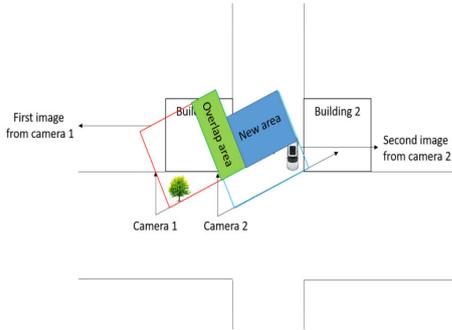

Fig. 1: The panorama stitching problem illustrated

building 1, which is shown as a red square. The blue square is the image captured from the second camera (Camera 2) that captures part of building 1 and part of building 2. The green rectangle represents the overlapping area between the two images and the blue area behind the green rectangle is the portion obscured by the building. This paper employs seven techniques, which are combined into four hybrid models, as shown in Figure 2, to create panoramic images. The four

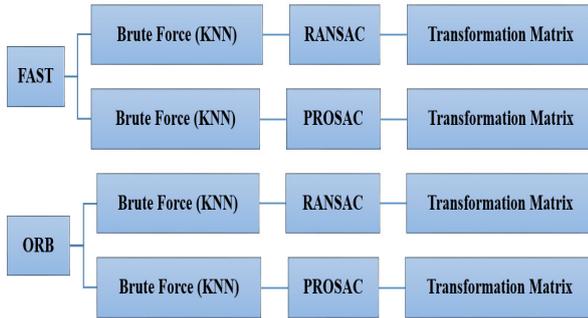

Fig. 2: The selected solution for four hybrid approaches

combinations include: (1) *FAST*, Brute Force (KNN) and *RANSAC*; (2) *FAST*, Brute Force (KNN) and *PROSAC*; (3) *ORB*, Brute Force (KNN) and *RANSAC*; (4) *ORB*, Brute Force (KNN) and *PROSAC*. Then each combination is followed by the calculation of a Transformation Matrix. The results of these models are compared to the model proposed in [2]. Basically, the model in [2] utilized *ORB*, Hamming distance, *PROSAC* and the Transformation Matrix to produce a stitched image. This model will be referred to as the fifth combination here. Next sections will discuss the seven implemented techniques.

#### A. *FAST*

The *FAST* technique is a high-speed corner detector method [15] defined by having a pixel A surrounded by a sufficient quantity of neighborhood pixels with a different grayscale value. In this scenario, the pixel A is recognized as

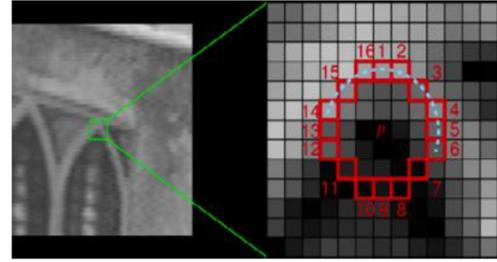

Fig. 3: *FAST* Feature Point Detection [15]

a *FAST* corner and applies to grayscale images. The *FAST* neighborhood must contain enough pixels with values greater than, less than or similar to that of pixel A. We choose an arbitrary pixel as the center to establish a circular area, to be considered as the pixel point's neighborhood [16]. As shown in Figure 3, a discrete circle of radius 3 with pixel p as the central pixel has neighborhood pixels labeled 1 to 16. If pixel 16 has sequential n pixels that satisfy the equation [16]

$$|I_x - I_p| > t, \quad (1)$$

then, we consider p as a candidate feature point, t is a given threshold value,  $I_x$  is the gray value of the sequential n pixel, and  $I_p$  is the gray value of pixel p, [17]. For features extraction and descriptors computation in the first and second hybrid combinations based on using *FAST*, the Binary Robust Invariant Scalable Keypoints (*BRISK*) algorithm is incorporated, [23], because *FAST* can only detect corner features but dose not compute the descriptors. Therefore, this paper uses *BRISK* descriptor with *FAST* keypoints.

#### B. *BRISK*

*BRISK* is a binary descriptor that calculate the weighted Gaussian average over selected points near the keypoint [23]. For specific pairs of Gaussian windows *BRISK* compare values that could be either a 1 or a 0 depending on which window in pair was greater [23]. *BRISK* descriptor applies the sampling pattern around the keypoints [23]. The sampling pattern rotated  $\alpha$  angle around the keypoint k. The  $\alpha$  is calculated by [23]:

$$\alpha = \arctan 2(g_y, g_x), \quad (2)$$

where  $g_x$  and  $g_y$  are the gradients sum. The bit vector descriptor  $d_k$  is collected by execute for all point pairs the short distance intensity comparisons [23].

$$(p_i^\alpha, \sigma_i) \in S, \quad (3)$$

such as every bit b corresponds to:

$$b = \begin{cases} 1, & I(p_j^\alpha, \sigma_j) > I(p_i^\alpha, \sigma_i) \\ 0, & \text{otherwise} \end{cases}, \quad (4)$$

$$\forall (p_i^\alpha, p_j^\alpha) \in S, \quad (5)$$

where  $I(p_i^\alpha, \sigma_i)$  is gray intensity after rotated  $\alpha$  angle around the keypoint k and S is gray intensity for the short distance

pairs set. At the end, *BRISK* uses a deterministic sampling pattern introduce a uniform sampling-point density [23].

### C. ORB

The *ORB* technique is based on improved *FAST* and the Binary Robust Independent Elementary Features *BRIEF* feature detector techniques to extract points of interest by using a binary string [18]. Since *FAST* and *BRIEF* process quickly, the *ORB* will also be fast [15]. While the *FAST* technique is not sensitive to noise and is highly reliable for identifying feature points, it does not provide an orientation. However, *ORB* incorporates orientation into *FAST* with the *oFAST* algorithm. The *BRIEF* approach finds descriptors around each feature point by using a binary coding method [19], which is simple and requires less memory compared to *SIFT* and *SURF* [19]. Consider  $p$  is a smoothed image patch defined on the size of  $S*S$  (Where  $S$  contains the coordinates of pixels) round feature points and a binary random selected test defined as  $\tau$ ,

$$\tau(p; x; y) = \begin{cases} 1, & p(x) < p(y) \\ 0, & \text{otherwise} \end{cases}, \quad (6)$$

where  $P(x)$  is the pixel intensity at the  $x = (u, v)^T$  point [3][20][16]. After filtering is performed, a set of points can uniquely identify one binary detection  $\tau$  [16]. Therefore, the features defined as a vector of  $n$  binary strings is the same as,

$$f_n(p) = \sum_{1 \leq i \leq n} 2^{i-1} \tau(p; x; y), \quad (7)$$

[3][20][16]. Since *BRIEF* is not scale invariant, *ORB* solves this issue by adding a direction into *BRIEF* by defining patch moments as [3][20][16]

$$m_{pq} = \sum_{x,y} x^p y^q I(x, y), \quad (8)$$

where  $p$  and  $q \in \{0, 1\}$  is binary selector for  $x$  and  $y$  direction and  $(x, y)$  is the position of the *FAST* feature point. The circular neighborhood radians are  $r, x, y \in [-r, r]$  [21][22], and the moment is reordered (centroid) as  $C$  [3][20][22], such that

$$C = \left( \frac{m_{10}}{m_{00}}, \frac{m_{01}}{m_{00}} \right). \quad (9)$$

When assuming a center vector  $O$  to the centroid  $\vec{oc}$ , then the offset is defined as

$$\Theta = \arctan\left[\frac{m_{01}}{m_{10}}\right] = \arctan\left[\frac{\sum_{x,y} y I(x, y)}{\sum_{x,y} x I(x, y)}\right], \quad (10)$$

[3][20][16]. Therefore, *ORB* extracts the *BRIEF* descriptor based on the direction performed by Equation 6. The random *ORB* uses a greedy algorithm to find the random pixel block with low correlation and vector length equal to a 256-bit feature descriptor named *BRIEF*, [16], for which some previous research used a different type of test, such as the Gaussian distribution [3].

### D. K-Nearest Neighbor

One image matching algorithm is *KNN* that take a set of query points  $Q$  and set of references point  $R$  [24]. Then, check for each query point  $q \in Q$ , compute distance between  $q$  and all  $r \in R$ , sort the computed distance in list [24]. Finally, select  $K$  nearest reference points corresponding to  $k$  smallest distance [24]. A threshold ratio value is then checked to determine if it is a good matching point, which requires the process to loop until at least four matches are found to compute the Homography [25]. This paper uses the Brute Force matcher, a simple version of the *KNN*, to match the descriptors of the images.

### E. RANSAC

*RANSAC* is a robust technique used to estimate the Homography and remove outlier points randomly from images to provide good matches [11] and increase quality [2]. *RANSAC* randomly select a set of data required to calculate a mathematical model of data parameters [26][16]. Then, with an effective random sample [16], *RANSAC* uses a small number of points to estimate the model and check if it agrees with the remaining points by calculating their distance to the fitted model. *RANSAC* can be performed  $N$  times until a subset of the image is found with a good matching relationship [11].

### F. PROSAC

The *PROSAC* technique is used to remove outliers points progressively from images to obtain good matching results [26]. This algorithm performs the same steps as *RANSAC* gradually and not randomly, which reduces the required operation time and the number of repetition when the sufficient process of verification is completed [2]. Two problems need to be addressed in *PROSAC*, first is the growth function [26],

$$n = g(t), \quad (11)$$

which is defined as the set  $U_n$  of  $n$  (where  $U$  is set of features) arranged progressively and sampled after trials  $t$  are selected [19]. Second, *PROSAC* like *RANSAC* provides guarantees about the stopping criterion for the optimal solution, which must be found [26].

### G. Transformation Matrix

The transformation matrix defines  $x$  in an image  $B$  with  $x'$  as the final panorama image for calculating a new position of pixels [27][3],

$$x' \sim H_x, \quad (12)$$

where  $x$  is a new position of pixels in image  $B$ ,  $x'$  is a position of pixels in the final panorama,  $\sim$  finds the similarity up to scale, and  $H$  is a  $3 \times 3$  matrix that can be calculated using the Direct Linear Transform algorithm [27]

$$H = \begin{pmatrix} h_1 & h_2 & h_3 \\ h_4 & h_5 & h_6 \\ h_7 & h_8 & h_9 \end{pmatrix}, \quad (13)$$

where points  $x$  and  $x'$  are defined as [27]

$$x_i = \begin{pmatrix} x_i \\ y_i \\ w_i \end{pmatrix}, x'_i = \begin{pmatrix} x'_i \\ y'_i \\ w'_i \end{pmatrix}, \quad (14)$$

where  $x_i, y_i$  is the keypoint position and  $w_i$  is set to 1. The final equation after subsequent transformation [27] becomes:

$$\begin{pmatrix} 0^T & -w'_i x_i^T & y'_i x_i^T \\ w'_i x_i^T & 0^T & -x'_i x_i^T \\ -y'_i x_i^T & x'_i x_i^T & 0^T \end{pmatrix} \begin{pmatrix} h_1 \\ h_2 \\ h_3 \end{pmatrix} = 0. \quad (15)$$

Two linearly independent equations. In addition, this can be written as [27]:

$$A \begin{pmatrix} h_1 \\ h_2 \\ h_3 \end{pmatrix} = 0. \quad (16)$$

We add two question on matrix A for each pair of points.

### III. EXPERIMENTAL RESULTS

The machine used in this work is Windows 10 with 64-bit operating system. The application uses two cameras with  $1373 \times 2382$  image resolution to capture sets of images for testing the panorama stitching algorithms. The experiments are performed using 15 different scenes, each with two captured images. Contrast Differences is used to evaluate the quality of the four hybrid combinations to determine if the stitched images are seamless as the seam is considered poor when it is visible.

#### A. Contrast Differences

Contrast differences are the variances in luminance between neighboring pixels that make them distinguishable [28]. In this paper, the differences in the contrast value between the stitched images and the original image check the quality of the four stitched images. Equation 17 shows the image contrast calculation  $I'_k$ , where  $I_k$  is the image in the vertical direction, is determined by:

$$I'_k(i, j) = I_k(i + 1, j) - I_k(i, j), \quad (17)$$

for  $1 \leq i < H$  and  $1 \leq j \leq L$ . To evaluate the quality between the original and the four stitched images, the area of the original image and the four stitched images is divided [28] as illustrated in Figure 4 with the stitched image  $I_{k,k+1}$  and the two halves of the overlapping area from the original images  $A$  and  $B$  and  $t_v$  is the horizontal translation.

The left half of the overlapping area is mainly contributed by the left half of the stitched image from  $A'$ . The right half of overlapping area is mainly contributed by the right half of the stitched image from  $B'$ . So, the contrast values of  $A$  and  $B$  are subtracted from contrast values of  $A'$  and  $B'$  to calculate the contrast difference values. The performance measures  $d_A$  and  $d_B$  for the  $A$  and  $B$  regions are then calculated as [28].

$$d_A = \sum_{i=1}^H \sum_{j=1}^{t_v} |I'_k(i, L_k - t_v + j) - I'_{k,k+1}(i, L_k - t_v + j)| \quad (18)$$

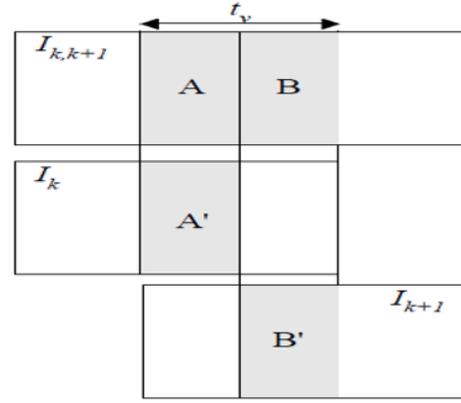

Fig. 4: Regions for comparison [28]

$$d_B = \sum_{i=1}^H \sum_{j=1}^{\frac{t_v}{2}} |I'_{k+1}(i, \frac{t_v}{2} + j) - I'_{k,k+1}(i, L_k - \frac{t_v}{2} + j)| \quad (19)$$

where the  $L$  and  $H$  are the width and height of the images, respectively [28]. Beside using Contrast Differences, this paper use Peak Signal-to-Noise Ratio ( $PSNR$ ) and Root Mean Square Error ( $RMSE$ ) to evaluate quality by calculating the error rate.

- 1) Mean Squared Error ( $MSE$ ).

$$MSE(x, y) = \frac{1}{N} \sum_{i=1}^N (x_i - y_i)^2, \quad (20)$$

where  $N$  is number of pixels,  $x$  and  $y$  are signals, the error signal  $e_i = x_i - y_i$  is differences between two signal [29].

- 2) Peak Signal-to-Noise Ratio ( $PSNR$ ).

$$PSNR = 10 \cdot \log_{10} \left( \frac{L^2}{MSE} \right), \quad (21)$$

where  $L = 2^8 - 1 = 255$  for an 8-bit per pixel image [29]. High value of  $PSNR$  means better quality and less noise.

- 3) Root Mean Square Error ( $RMSE$ ).

$$RMSE(I, J) = \sqrt{MSE(I, J)} \\ = \sqrt{\frac{\sum_{j=1}^m \sum_{i=1}^n (I_{ij} - J_{ij})^2}{m \times n}}, \quad (22)$$

Where  $I, J$  are two image matrices [29].

Figures 5 and 6 show two images for one building from different angle, referred to as Data 0. Figures 7 and 8 show two images captured for same scene, referred to as Data 1. Figures 9, 10, 11 and 12 show the stitched images for the first, second, third and Fourth combinations of Data 1, respectively. Figures 13, 14, 15 and 16 show the stitched images for the first, second, third and Fourth combinations of Data 1, respectively. Figure 17 Provides analysis of the processing time in seconds as shown in (a), the  $PSNR$  as shown in (b) and  $RMSE$  as shown in (c), for the five combinations using 10 different

Fig. 5: First Image of Data 0

Fig. 6: Second Image of Data 0

Fig. 7: First Image of Data 1

Fig. 8: Second Image of Data 1

Two images of the same building were taken from two different angles as shown in Data 0 and Data 1.

scenes. The fifth combination refers to the method proposed in [2], as mentioned earlier. In Figure 17 (a), it is clear that the processing time of third and fourth combination take minimum time to process stitched panorama images. From Figure 17 (b) and Figure 17 (c) it is apparent that the fourth combination produce better result on most *PSNR* and *RMSE*. Table I shows the number of keypoints and matching points from testing Data 0. Table II shows the number of keypoints and matching points from testing Data 1. Table III show the first and second hybrid combinations results for 10 data (i.e. scenes) that contains two set of images with image resolution of  $1373 \times 2382$ . Table IV show the third and fourth hybrid combination results for 10 data. Table V show the fifth hybrid combination results for 10 data.

#### IV. DISCUSSION

This paper provided four different combinations that used for panorama stitching and compared their output images

based on processing time and quality. The third model reduced the processing time by 67% for the *ORB*, Brute Force (KNN), *RANSAC*, and Transformation Matrix compared to the fifth model, [2], that used *ORB*, Hamming distance, *PROSAC*, and the Transformation Matrix. The proposed fourth model reduced the processing time by 68% for the *ORB*, Brute Force (KNN), *PROSAC*, and Transformation Matrix compared to the fifth model, [2]. The fourth model that used *ORB*, Brute Force (KNN), *PROSAC*, and Transformation Matrix is shown better performance and quality results compared to other combinations. In particular, using *ORB*, Brute Force (KNN), *PROSAC*, and Transformation Matrix in the fourth model is shown better results of *PSNR* and *RMSE* compared to other combinations, as illustrated in Tables III, IV and V. Table I and Table II are showing the results for two different scenes that are referred to as Data 0 and Data 1. The four hybrid combinations are compared with regard to detector/descriptor type, where the *FAST* technique is used

in first and second combination and the *ORB* technique is used in the third and fourth combinations. It can be seen that the FAST technique extracted more keypoints compared to the *ORB* technique. As minimum number of keypoints will reduce the processing time.

## V. CONCLUSION AND FUTURE WORKS

Researchers have worked to improve panorama stitching techniques and minimize the computational requirements. This paper focused on a new application of panorama stitching for a 2D scenario. The proposed methods can generate a semi-transparent view as a solution for the project enabling drivers to effectively see around corners. This paper also compared the quality and processing time of the produced 2D views within the scope of state-of-the-art methods. For future work, the presented models can be extended to include 3D scenes. Another future work can provides a real-time processing for similar applications to assist drivers and pedestrians. Finally, additional novel techniques could be implemented to enhance the methods discussed in this work.

## ACKNOWLEDGMENT

We would like to express our special thanks to King Faisal University and to Dr. Syed Afaq Husain, Dr. Muhammad Bilal Ahmad and Dr. Asrar Ul Haque for their feedback which helped to improve the project.

**Abstract**—Crowd panic has incurred massive injuries and deaths throughout history; thus understanding it is particularly important in order to save human lives. Recently, numerous simulation methods have been contributed in order to provide insight into the design of evacuation planning strategies. In this paper, we integrate a social structure to the crowd mobility model for the purpose of investigating the influence of social bonds on collective behavior during panic. A macroscopic crowd panic model based on social science theories was integrated as an internal module to the microscopic mobility model. The resulting framework is tunable and permits the implementation of several panic scenarios. It is also designed to run in different situations for a better comprehension of panic-related phenomena. The results demonstrate the smoothness of our crowd flow model and the realism of evacuation during panic.

**Index Terms**—Panic modeling, Crowd simulation, Human behavior in panic, Evacuation disaster.

## I. INTRODUCTION

THROUGHOUT history, mankind has experienced several disasters and accidents caused by panic in overcrowded spaces (Fig 1a). Hence, simulating crowd with panic has an important value in emergency planning for architectures characterized by a high-density crowd. Special attention should be dedicated to a deeper understanding of the nature of panic during the process of escaping hazardous situations within buildings and public spaces [1]. On the other hand, a clearer understanding of the social interactions in difficult situations would give more insights on how we could prevent casualties beforehand by adapting the design of buildings to the potential course of events during an evacuation situation. The understanding of such behavior brings a significant architectural added value, which in turn would result in safer and more reliable buildings.

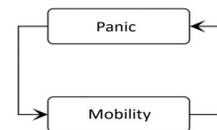

The prediction of the birth of collective panic and the possible actions that might cause material damage and human losses can be difficult. Modeling and simulation constitute a solution to tackle such a problem. These tools allow us to generate virtual environments including both human agents and buildings, an evacuation scenario can then be run under some assumptions on a given emergency scheme.

Our objective is the modeling of panic propagation process and its consequences on human behavior while taking into account the social aspect of the crowd. To this end, the remainder of the paper is structured as follows: in Section

2 we describe the main related works that were contributed in the field of crowd simulation. in Section 3 we present a brief description of crowd behavior during panic situations. Section 4 is the core of our work, where we propose a socially-aware panic model. In Section 5, we present the results of our contribution and we discuss their impact compared to alternative methods. Finally, we conclude the paper, and we trace the potential perspectives that can extend the current work.

## II. RELATED WORKS

Crowd simulation models have roots in different domains such as entertainment, security, urbanism, architecture, management, etc. Since we are interested in panic modeling, we will present the main works that have permitted the modeling of panic evolution phenomenon and its effects on the crowd as well as those which gave consistent results with empirical observations. Indeed, we will focus on conceptual modeling rather than the available software tools. After analyzing collective behaviors literature, three main theoretical approaches were found.

The first one, called *Contagion Theory* [2, 3], it states that an individual in a crowd loses their conscious personality and obeys to all suggestions from the crowd influent members. Works belonging to this category incorporate the concept of social forces, where the model allows a mixture of socio-psychological and physical forces influencing the behaviors within a crowd [4]. Several models based on this approach have been developed so far, the latter proposes an adaptation and hybridization of the model of social forces with other models [5]. These models can reproduce certain phenomena observed in real crowds during panic movements, such as crowd oscillation in a narrow passage, arch formation in front

of an exit, lane formation, etc. However, they neglect the description of panic evolution phenomenon and reproduce only some of its aspects. Moreover, the social structure of the crowd is neglected and the evolution of the emotional state of individuals is not taken into account, which impinges on the realism.

The second approach is based on the *Emergent Norm Theory* [6], which considers that the collective behavior is an outcome of the interactions among individuals, which are able to evaluate the information they receive and to decide on its usage at the present situation. In fact, agents assign positive or negative values to the information, which leads to the development of an interactive cognition. This approach analyzes the agent's micro-properties that help in the social system formation. It also analyzes the behavior patterns at a group level. An example of works based on this approach can be found in [7], where the authors describe an individual behavior model for agents. Although there is no explicit way of interaction or communication, each agent is aware of itself and their peers.

The last approach is a variant of the second one, commonly called *Structuralism*, it inverts the formula and emphasizes the social structure studies and their impact on individuals. It is a macro-to-micro approach since it considers that the changes are triggered by the crowd (macro) to the individuals (micro). Social science research such as [8] embraced the structural theory approach. One of the works that had implemented the macro-to-micro approach for panic crowd situations is [9], where the authors utilized system dynamics and consider that panic is a domino effect. In fact, the movements of individuals result from two complementary models that interact and influence each other mutually, namely the mobility model and the panic model (Fig 1b).

These models are more informative than those based on alternative approaches. In fact, they allow us to describe the beginning and the evolution of panic, thereby to adapt the behaviors to the individual state. However, the solutions that were found model sudden transitions between different states of human emotions. In fact, before an individual behaves in a non-rational fashion, they go through a stage called *Limited Rationality* and can remain in it or calm down without reaching the state of panic. Also, these models do not take into account the social structure of the crowd.

### III. CROWD PANIC

Understanding how crowds behave during critical situations has long been necessary for emergency response and management. In fact, most of the normal behavior vanishes when pedestrians face an emergency situation (it does not always have to be an emergency situation, however, similar actions can be observed for example among crowds trying to get the best seats at a concert or consumers running for sales) and non-adaptive crowd behaviors appear. These behaviors are recognized to be responsible for the death and injury of most victims in crowd disasters. Non-adaptive crowd behaviors refer to the destructive actions that a crowd may experience

in emergency situations, such as stampede, pushing, knocking and trampling on others [1]. Generally, these behaviors are the result of a dangerous psycho-sociological phenomenon, which is *panic*.

Panic is a phenomenon generally studied in psychology and human science and often identified by its consequences. It is triggered whenever a situation of tension worsens, slips or escapes from human control. Panic is defined as an intense fear triggered by the occurrence of a real or imaginary danger felt simultaneously by all individuals in a group, a crowd or a population, characterized by the regression of mentalities to an archaic and gregarious level, leading to primitive reactions of hopeless jumps, indiscriminate agitation of violence or collective suicide [5]. Nevertheless, discrepancies exist between the definition of triggering and propagation processes. This difference gives rise to different social theories [1]. The latter differs in the definition of the relationship between disasters and panic phenomenon, and the type of behavior in a state of panic. Despite the differences, these approaches come together on two important points:

- Panic is a feeling of extreme fear that invades the pedestrian following the perception of possible danger;
- Social interaction in a crowd promotes the spread of panic.

### IV. PROPOSED MODEL

In order to ensure the safety of people and reduce the impact of panic caused by disasters, it is necessary to understand and model this dangerous phenomenon, its propagation process, and its consequences. Panic model presented hereinafter is based on system dynamics. It has been integrated into a mobility model for crowd evacuation simulation during catastrophes. Besides, it uses the same environment and pedestrian modeling (Fig 1b). The proposed mobility model is microscopic, whereas the proposed panic model is macroscopic (Fig 2). Thereby, panic model permits the study of the evolution of panic phenomenon at a different level of granularity than that adopted for the study of mobility. Many types of relations coexist between the individuals of a crowd (family bonds, friendships, professional relations, etc.). Behaviors and decisions made by these individuals depend strongly on the social relations [10, 11]. We added a social model that describes the social structure of the crowd and its evolution during the emergency in order to study their effects on pedestrians mobility and the propagation of panic.

#### A. Social structure of the crowd

In order to build an innovative solution for crowd modeling, we chose to integrate an important aspect into our mobility model which is the *social structure of the crowd*. This latter could be integrated by using a social model [2]. The one we adopted in our work is *Small World* because its generated graphs are the closest to the real representation of contacts between individuals and groups and their evolution in space and time. These graphs allow us to predict the evolution of the epidemic and by analogy the evolution of panic.

We used a new model for generating small world graphs. Transformations and constructions that it orchestrates follow sociological behaviors observed and described in the literature. The generation process provided by this model is divided into three phases, each permits to accomplish a different aspect of links evolution in the crowd.

1) *Initialization*: The model we used is configurable. The generative process behind it permits to create a simple, connected and undirected graph  $G = (V; E)$ , of  $|V|$  nodes and  $|E|$  edges.

2) *Creating nodes (inserting agents into the simulated environment)*: The first step allows the addition of new individuals in the social structure of the crowd. In fact, every time an agent is added to the simulation environment, they join the social structure. The graph thus obtained contains the expected number of nodes but does not reach the expected number of edges. This first step returns a connected simple, acyclic graph, resulting in a topology similar to that of a tree. It represents the initial social links that will evolve during the simulation.

3) *Adding random edges (connecting agents)*: The second phase allows us to link members of the crowd randomly. This step serves to reproduce the process of connecting people that know each other, either before joining the network or afterward. In order to implement different types of social links, we included a weighting strategy to the links. Each edge will be assigned a value that represents its type. We model three types of links: family, friendship link and professional.

4) *Reinforcement of communities*: This stage corresponds to the moment when the members of the network begin to establish relationships with other members who share the same friends. Two persons who didn't know each other beforehand can potentially become friends, which will lead to the creation of new links between them. The creation of edges according to this scheme allows the strengthening of communities, thereby increasing the agglomeration coefficient of the generated network. Unlike the first two phases that run before the launch of the simulation, the latter runs simultaneously with the mobility model.

### B. Adaptation of Susceptible, Infectious and Recovered (SIR) epidemic model for panic propagation

The panic model was integrated into the mobility model and it uses the same environment and pedestrian modeling. The analogy between panic and contagion led us to a propagation model inspired by the epidemiological ones, and strengthened by the work of [12] and [3]. We adapted the SIR compartmental model [13] to describe the evolution and spread of panic within a crowd. Compartmental models are a technique used to simplify the mathematical modeling of infectious disease. For instance, the population is divided into compartments, with the assumption that all the individual within the same compartment share the same properties [13]. These models are usually modeled through ordinary differential equations (which are deterministic), but can also be viewed in a stochastic framework, which is as realistic as complicated to analyze (Fig 2a). Our version of the SIR model consists of four

compartments where individuals are classified according to their emotional state:

- SP: compartment of people susceptible to panic.
- RL: compartment of people who behave with limited rationality. The individuals of this compartment have not yet reached the state of panic but are already disturbed.
- NR (P): compartment of people in a state of panic. The individuals of this compartment have reached the state of panic and behave irrationally.
- NP: compartment containing non-panicked people (calm).

In fact, an individual is not assigned to the compartment NP until he reaches the emergency exit and leaves the simulation environment. Furthermore, we added an intermediate step before the transition to the state of panic, which is modeled via the RL compartment. It was introduced to express the non-spontaneous aspect of panic. This latter appears when the negative emotions of the individual (fear, stress) reach a predefined threshold. This last can be modeled by latency periods in the RL compartment that are randomly chosen to be able to express the heterogeneity among individuals. We also admit that some individuals have personal predispositions to panic. They will be in a panic state at the beginning of the simulation and will represent the initial panic transmission vector.

#### 1) Transitions between compartments:

- Each susceptible individual moves from the compartment SP to the compartment RL with a transition rate ( $\alpha_1$ ) following direct contact with a panicked person.
- ( $\alpha_2$ ) represents the transition rate from the compartment RL to the compartment SP. This transition expresses the possibility that an individual RL can calm down after a certain period of time without reaching the state of panic.
- ( $\beta_1$ ) is the transition rate for which RL individuals transit to the compartment NR (P). In fact, each individual of the RL compartment spends some time in the latter. The choice of this parameter is very important because it allows changing phases in the process of panic propagation between an active phase, when panic spreads, and an inactive phase when it disappears.
- ( $\beta_2$ ) is the transition rate for which panicked people pass to the RL compartment. This transition happens for each individual after being panicked for a certain period of time. This aspect has been added to our model to take into account the ephemeral aspect of panic.

### C. Integration of the intermediate models

In order to test and validate the proposed solutions, we integrated them in our mobility model and we adapt this latter to the modifications added. We start by integrating the social structure of the crowd obtained via the social model Small World in the decision making the process of agents. Afterward, we integrate panic model developed as an internal module in the mobility model.

1) *Integration of the social structure into the decision-making process*: Individuals will, now, adjust their displacement vector so as to evacuate while joining members that

belong to their social group. This strategy was implemented using the distance maps obtained by the *FMM* method and provided by one of the two upper layers of the environment model in Fig 2b. Hence, each agent will have the possibility to identify the positions of individuals with whom they are socially linked and to choose the member to join according to the type of the link. The decision-making process consists of the following iterative steps:

- 1) Collect distance maps provided by the environment layers;
- 2) Collect the map of social links;
- 3) Identify the member to join among those having a social link with it;
- 4) Trigger a movement decision based on the collected data;
- 5) Perceive near environment information;
- 6) Adjust the decision according to the social forces model and behavior rules;
- 7) Take into consideration the individual properties that influence the decision;
- 8) Execute the decision.

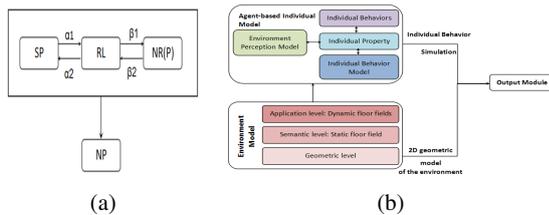

Fig. 2: (a) Proposed panic model, (b) Mobility model architecture.

2) *Integration of panic model*: The integration of panic model will change the system's flow. In fact, mobility and panic interact and influence each other mutually. Panic is nothing more than a structure contained in the crowd that will be activated when certain conditions are met. The general process of unfolding panic model follows two main phases. The first one takes place before the launch of the simulation. It allows the user to initialize the individuals initially panicked. Whereas, the second takes place during the simulation. In fact, it runs in parallel with the mobility model.

3) *Panic consequences modeling*: Once an individual becomes panicked, he behaves in a non-rational manner and adopts a social attitude toward the rest of the crowd, even toward members of their own social group. This behavioral disorder is reflected in our mobility model by the disappearance of social values and the emergence of violence and individualism. Violence was modeled by incrementing repulsive forces and individualism through the non-consideration of the social structure in the decision-making process. Nevertheless, panicked behaviors vary according to the nature of each person. We modeled this heterogeneity through different criteria and individual characteristics such as aggressiveness, restriction of the field of vision, increasing the speed of

movement or reducing the comfort distance.

## V. RESULTS AND DISCUSSION

In this section, we study the flow while taking into account the social structure of the crowd and panic phenomenon. The validation of the mobility model was carried out on two steps: qualitative and quantitative. Several qualitative aspects of pedestrian dynamics were reproduced by our model such as lane formation, the arch phenomenon, oscillations at the bottleneck, etc (Fig 3a), and no more unrealistic congestions are encountered (Fig 3b). The quantitative study that we conducted regards pedestrians' flow through a narrow path (bottleneck) (Fig 3c). The experimental setup that we simulated was inspired by [14]. The results obtained using our mobility model correspond well to the real-world observations (Tab I, II).

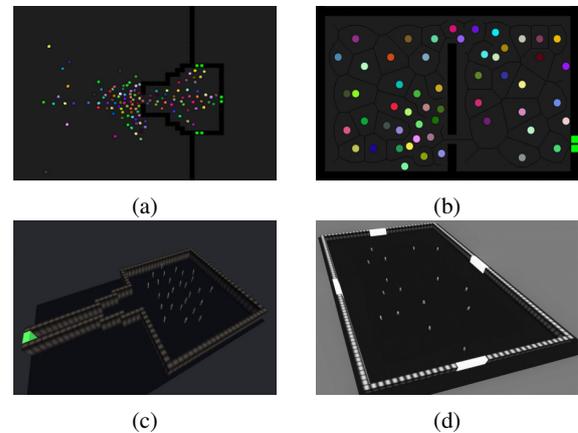

Fig. 3: (a) (b) Qualitative aspects obtained by the mobility model, (c) Bottleneck generation with our simulation framework, (d) Real simulation scenario

### A. Study of social structure impact

First, we start with the simulation results obtained without introducing the social structure into the mobility model in

TABLE I: Experimental specific flow  $J_{s,exp}$  [14]

b(m)	$N_b=20$	$N_b=40$	$N_b=60$
0.8	1.86	1.77	1.61
0.9	2.06	1.91	1.86
1.0	2.19	2.08	1.9
1.1	1.78	1.93	1.93
1.2	2.31	1.81	1.97

TABLE II: Values of the specific flow  $J_s$  obtained using our Framework.

b(m)	$N_b=20$	$N_b=40$	$N_b=60$
0.8	1.73	1.45	1.40
0.9	1.92	1.49	1.53
1.0	2.07	1.63	1.66
1.1	2.26	1.78	1.73
1.2	2.35	1.83	1.86

order to study the impact of this latter on the decision-making process without introducing panic. In order to distinguish social links influence, we run a series of simulations using the same scenario with the new and the old version of the mobility model. The test scenario we used is inspired by that illustrated in (Fig 3d).

Several qualitative aspects of pedestrian dynamics were reproduced by our model. Many of which were already obtained without the social aspect of the crowd such as, lane formation, the arch phenomenon, oscillations at the bottleneck. However, by introducing the social aspect congestion reappears, as well as the formation of reconciliation movements and training groups of different sizes, which is closer to reality.

### B. Study of panic propagation and its effects

In order to simplify the study of panic propagation, we simulate without mobility. Since there is not a method to quantify the growth rates of emotion intensity [3], we vary the latency and infection period from one individual to another to express their emotional and psychological heterogeneity. Nevertheless, the proposed panic model is macroscopic, it describes the evolution of the population and not that of the individuals themselves. This evolution is considered continuous over time, which is reflected mathematically by an ordinary differential equation system :

$$\begin{cases} \frac{dx}{dt} = -\alpha_1 \cdot x + \alpha_2 \cdot y \\ \frac{dy}{dt} = \alpha_1 \cdot x - \left(\frac{\beta_1}{N} \cdot z + \alpha_2\right) \cdot y + \beta_2 \cdot z \\ \frac{dz}{dt} = \left(\frac{\beta_1}{N} \cdot y - \beta_2\right) \cdot z \end{cases} \quad (1)$$

The ratio  $\frac{\beta_1}{N \cdot \beta_2} \cdot y$  defines the basic reproduction number  $R_0$ . According to its value, panic will spread or shrink. Generally, it is the initial value  $R_0$  that is used. We have either:

- $R_0 = \frac{\beta_1}{\beta_2} > 1$  : propagation,
- $R_0 = \frac{\beta_1}{\beta_2} < 1$  : shrinkage.

Several methods exist to solve the differential equations system. We used the approximation obtained by the classical *Runge-Kutta* and we implemented it then integrated it to our simulation platform. In order to validate the hypothesis about panic propagation, we conducted an experiment inspired by the one presented in [3]. We start with a population of 50 individuals susceptible to panic, 70 individuals of limited rationality and 5 panicked individuals. We vary the value of the transition rates  $\beta_1$  and  $\beta_2$  to verify the validity of the expression of the basic reproduction number. Fig 4a and 4b show the evolution of the numbers of individuals in each compartment for  $R_0$ , respectively, greater than and less than 1.0.

The obtained results show that the spread of panic and its shrinkage depend on the choice of the user. Moreover, the behavior of individuals can be defined according to their state. This aspect allows for implementing several cases in order to study and evaluate faithfully safety procedures. By introducing mobility, the social structure of the crowd evolves

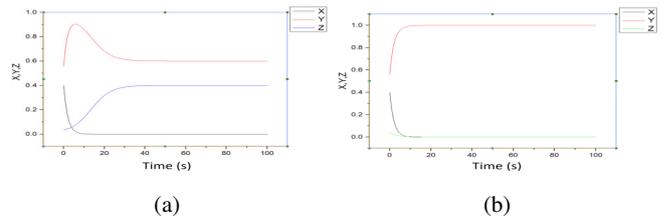

Fig. 4: Graphs showing the evolution of the number of SP, RL and P individuals for a basic reproduction number (a)  $R_0 > 1$  and (b)  $R_0 < 1$ .

and promotes the spread of panic and allows it to reach isolated groups.

In order to position our model among the existing ones, we conducted a comparison between the models [3, 15, 16] and the proposed one according to the following criteria: reactive/cognitive approach, micro-level explicitness, macro-level explicitness, communication forms, and panic behavior explicitness.

The reactive and cognitive approaches are related to how individuals are modeled in the system. Authors in [3, 15] adopted both the cognitive approach, while [16] and the proposed model combine both approaches.

The micro and macro levels parameters refer to the presence of components that represent the collectivity in an explicit fashion. Concerning the micro level explicitness: [16] and [3] deal with it using agent-based models, [15] on the other hand, uses collective agents and our model uses a hybridization of individual behavior model, social forces model, and global rules. The macro level explicitness, however, was addressed using: group formation with social forces by [16], imaginary and group mind formation by [15], without detail in [3] and using a Social crowd model in our solution.

The communication form parameter deals with the interactions among the collectivity of agents. These interactions can happen either directly, indirectly or through the process of perturbation and dissipation. The communication was of this latter type in [15] and, indirect in [16], and [3] as well as in the proposed model.

Finally, panic behavior parameter deals with the usage of the collective behavior formation stage. If such a stage is modeled and the transition is described in detail for each agent, they could behave more realistically, and the simulation could be closer to reality. This aspect was not available in [16], and was modeled using: a framework based on symbolic interactionism in [15], a macroscopic model for panic spread based on an epidemiological approach in [3] and in the proposed solution.

## VI. CONCLUSION AND PERSPECTIVES

In this paper, we developed a macroscopic panic model that permits to study the evolution of a panicked population. This model is based on an epidemiological approach and takes into account the social aspect of the crowd. We also integrated this model as an internal component of a microscopic mobility model to investigate and explore the complementarity between

macroscopic and microscopic models and the possibility of enrichment between them. The obtained results are encouraging and replicate faithfully the real crowd evacuation situations.

As further work, we think there are topics that need to be deeply investigated in order to improve crowd simulation and analysis. First, human emotions represent one of the most important factors that affect the propagation of panic in the crowd. Thus, modeling emotions and their evolution process will systematically enhance the realism of panic propagation. Second, the role of an individual during the emergency situation is also one of the most important factors, which affect the process of decision making. Therefore, modeling the different roles that can be assigned to individuals and computing their influence on the crowd will be necessary for an even more realistic simulation. Third, human behavior depends on the state of each individual in the crowd, the latter can be obtained from sociological studies and empirical observations.

**Abstract**—Audio communication on the public Internet suffers from not synchronized word clocks of the involved audio devices. The resulting clock drift leads to audio dropouts, which is typically compensated by a sample rate conversion (SRC) in standard telecommunication systems. This, however, does not fulfill the requirements of a high-quality audio system, in which all devices share one and the same word clock. Professional IP based network audio systems such as DANTE or AVB with their respective clock synchronization techniques have so been limited to LAN usage, where network jitter and loss have negligible importance regarding the required accuracy in the dimension of several nanoseconds. In a WAN, however, jitter in the millisecond dimension would lead to unacceptable measurement errors for the intended clock synchronization. As a consequence, we decided to investigate alternative clock synchronization techniques for WAN-distributed devices and developed a GNSS-based approach, which leads to precise clock synchronization.

## I. INTRODUCTION AND PROBLEM

The term "distributed music" or "network music performance" describes a scenario, in which at least two dislocated musicians perform together as if being in the same room. This domain has been investigated for more than two decades [3]. However, with the increasing stability of nowadays available broadband networks another quality reducing factor has become relevant: Despite commonly applied standard audio sample rates of 44,1 kHz, 48 kHz or 96 kHz [10] the word clocks of two different devices do not run in precise synchrony for physical reasons. With respect to audio networking, clock drift means that one audio process is running faster than the remote one. As a consequence, the faster process will not receive a sufficient amount of audio samples, which in turn leads to a buffer underrun and a corresponding audio dropout in specific intervals ranging between 10 and 30 seconds depending on the actual amount of drift. On the other side, the slower process receives too many samples, which eventually leads to a buffer overrun in the same interval, which also corresponds to disturbances in the audio signal. In context with low-latency audio networking the network buffers should be adjusted as low as possible, however, due to the described clock drift problem this proportionally increases the probability for audio dropouts.

In LAN-based sound systems (Local Area Network) such as Dante [2] or AVB [7], each device of the audio network

fast-music is part of the fast-project cluster (fast actuators sensors & transceivers), which is funded by the BMBF (Bundesministerium für Bildung und Forschung).

is therefore synchronized to either a dedicated master clock or a specific device on the network, which was previously identified as the clock master. With respect to our Internet-based application, this synchronization process typically cannot be applied due to the existing network jitter in the common dimension of at least one millisecond and rather more. In [4] we presented an approach, which is able to provide WAN-based synchronization (Wide Area Network) by averaging the resulting measurement error, however, the reliability of this approach is limited depending on the actual amount of network jitter.

## II. CONCEPT

In this section, we present a novel concept, which eventually provides reliable sound card synchronization for WAN-distributed devices. Our previous and not perfectly reliable approach uses the WAN itself as the source of synchronization. In contrast, our new concept takes advantage of global navigation satellite systems (GNSS) as the synchronization link between the involved sound devices. We consider GNSS such as the global positioning system (GPS) excellent sources for a grandmaster clock in order to synchronize the word clocks of the involved devices. GNSS transceivers provide a 1-PPS (one pulse per second) output signal, which gives a high pulse at every start of a second [5]. This pulse is our reference point to the absolute start of a second. The UTC (Coordinated Universal Time) time received from GNSS can be used to synchronize the word clocks, but there is a delay between the time received by the GNSS module and time set in the processor, hence it is not accurate up to microsecond level. In order to compensate this offset we take advantage of the time stamping capabilities of IEEE 1588 clocks, which capture the moment of the actual pulse occurrence so that the local time can be set later according to the precise reference. Despite the synchronization with the 1-PPS pulse the local oscillator and the GNSS clock still suffer from the inherent clock drift so that the clocks go out of sync after a couple of seconds. We overcome this problem via a feedback loop and a proportional, derivative and integral (PID) controller that keeps track of the clock drift and adjusts the clock rates respectively. The 1588 clock follows the GNSS clock to a precision and accuracy of greater than one microsecond. Once the 1588 clock is synchronized, we apply the appropriate fine-tuning to an audio clock PLL (phase locked loop) accordingly. Figure 1 illustrates

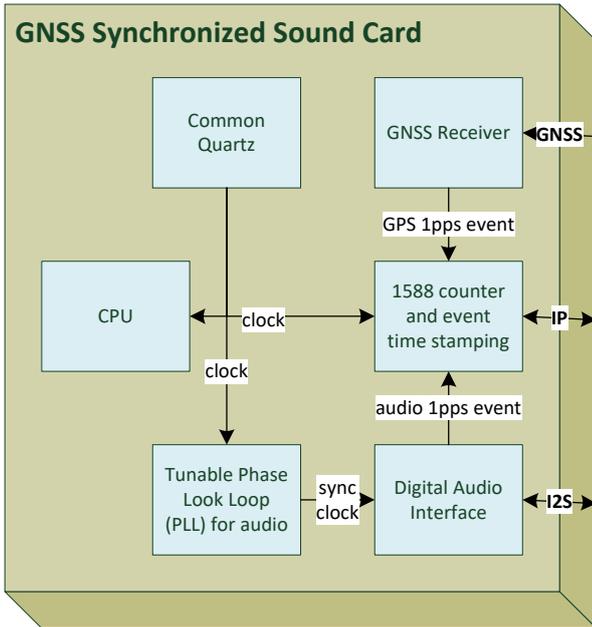

Fig. 1. Block diagram of GNSS synchronized sound card

the described key factors of our theoretical concept. Regarding the upcoming implementation, our concept considers an i.MX7 board by NXP Semiconductors. The i.MX7 series offers a highly integrated processor designed to enable secure and portable applications within the Internet of Things and it suits our demands because it supports the required features with respect to IEEE 1588 and audio word clocking. In that context we will now describe the particular hardware architecture that supports hardware timestamping and time keeping within the Ethernet driver. Afterwards, we will explain how the clocking is realized and how the audio word clock can be controlled and fine-tuned.

#### A. Hardware architecture

To allow for IEEE 1588, the MAC hardware in i.MX7 by NXP Semiconductors is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames and granule control of the IEEE 1588 time [11]. Figure 1 shows the block diagram of the i.MX7 board architecture.

At the centre of the time stamping module is a 32-bit counter register, which keeps track of IEEE 1588 time on the hardware level. It is incremented after every rising edge received from the oscillator by an amount specified by  $ENET\_ATINC[INC]$  register. In our use case, this value is set to 10 nanoseconds because it corresponds to the Ethernet clock with a frequency of 100 MHz. The  $ENET\_ATPER$  register contains the number of nanoseconds after which the counter will wrap around. It is programmed with a value of  $10^9$  so that the counter resets itself in intervals of one second [11].

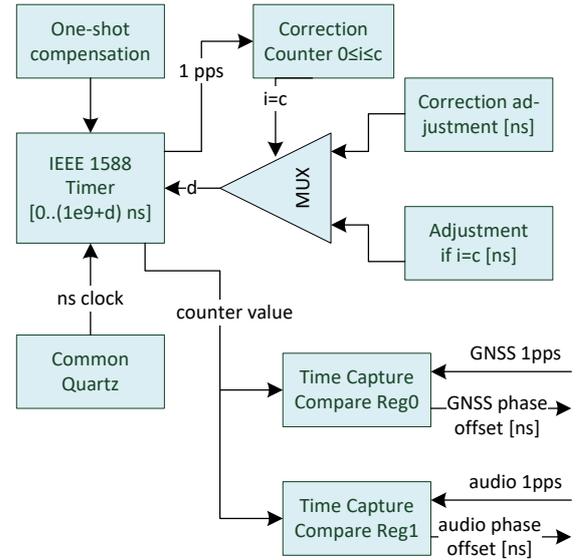

Fig. 2. Block diagram of the adjustable IEEE 1588 counter and the event time stamping

The block diagram of the adjustable timer is illustrated in figure 2.

The  $ENET\_ATCOR$  register is designed for the fine grain tuning of the counter. It defines after how many clock cycles the correction counter should be applied. The amount of correction is specified in  $ENET\_ATINC[INC\_CORR]$ . If the value of  $ENET\_ATINC[INC\_CORR]$  is greater than  $ENET\_ATINC[INC]$  the counter speeds up, if it is less the counter slows down. Furthermore, the system supports a one-shot offset event generation. In that context, the module contains the  $ENET\_ATOFF$  register. It holds the final nanosecond value after which the counter is reset for one single time.

#### B. Audio clocking architecture

The audio word clock in the i.MX7 is derived from the board's main 24 MHz phase-locked loop (PLL) oscillator. In that context, our requirements determine that the audio word clock's frequency must reside in a significantly lower dimension of 44,1 kHz, 48 kHz or 96 kHz and therefore represents a divisor of the board's main frequency of 24 MHz. Furthermore, the final frequency must be adjustable with respect to our previously described synchronization approach. Regarding the fine-tuning functionality the board contains three registers: In the following the  $CCM\_ANALOG\_PLL\_AUDIO[DIV\_SELECT]$  register will be abbreviated with  $Div$ , the  $CCM\_ANALOG\_PLL\_AUDIO\_NUM$  register will be abbreviated with  $Num$  and the  $CCM\_ANALOG\_PLL\_AUDIO\_DENOM$  register will be abbreviated with  $Denom$ . Based on these registers the output of the audio PLL depends on the following calculation:

$$F_{output} = F_{osc} * (Div + Num/Denom)$$

$Div$  multiplies the 24 MHz base clock frequency with the integer specified. The actual granule fine tuning is provided by adding a 32-bit fraction denoted by  $Num$  and  $Denom$ . The resulting audio PLL goes through a pre-divider and a post-divider to get the respective clock frequencies. Pre and post dividers have 64 steps so the frequency change is always an integer multiple of the audio PLL frequency:

$$F_{peripheral} = F_{src} * (Div_{post}/Div_{pre})$$

Afterwards, a so-called Sound Asynchronous Interface root clock (SAI) is derived from the audio PLL, which represents the master for the final audio word clock. The SAI root clock feeds a bit clock generator, which eventually generates the final square-waves-based audio word clock and eventually determines the sample capture and playback of the sound card.

### III. IMPLEMENTATION

This chapter describes the actual implementation of our concept. First, we describe how the synchronization of the local time to UTC time is being realized with an accuracy of one second. Secondly, granule control of the time with nanosecond accuracy is explained and how to keep the clock synchronized with the GNSS time using a PID controller. Eventually, the final audio clock is synchronized with the IEEE 1588 clock, which in turn is in sync with the GNSS clock as intended.

#### A. IEEE 1588 synchronization to UTC time

In order to let the IEEE 1588 clock follow UTC time, first, the local clock must be set to UTC time. This time can be received from the GNSS module periodically once every second [1]. A daemon called *gpsd* is used as an interface between the i.MX7 and the GNSS module. *Gpsd* provides a socket connection between the module and the host [6]. The IEEE 1588 clock ID can be retrieved with the function *phc\_open()* [9]. The definition of this procedure is found in the library *phc2sys* [9]. After the retrieval of the clock ID the POSIX function *clock\_settime (clockid t clockid, const struct timespec \*tp)* [8] is called and the current time is read from the *gpsd* buffer. Hence, the IEEE 1588 time is set to UTC time at the nearest second.

#### B. Granule control of the 1588 clock

Once the 1588 clock time is accurately set at the nearest second, an offset between the start of a second in the UTC time and the local clock time can be observed as described in the concept. The required offset compensation is realized via hardware time stamping. As soon as the 1-PPS pulse occurs on the interrupt line, the current value of the 1588 counter is latched on to the Timer Capture Compare Register *ENET\_TCCR* by the hardware to be inspected later on by the software [11]. This enables a precise calculation of the phase offset. Since the counter is reset in intervals of one second, this value represents the true second offset between the local clock and the absolute start of the second. A one-shot event through *ENET\_ATOFF* is then applied in the

interrupt handler, whose value is set to the value latched in *ENET\_TCCR*, which enables the timer. When the 1588 counter reaches this value, it is set to zero and starts again resulting in the desired offset removal.

After the offset compensation has been applied it is possible to take care of the actual clock drift. The drift can be controlled by an adjustment value that is applied to the counter every second. Ideally, every second would consist of  $10^9$  ns. However, as the clocks are drifting, the GNSS second is not exactly equal to  $10^9$  ns of the i.MX7 quartz. Instead, we see a difference to be equalized. To compensate for this clock drift, the IEEE 1588 timer counts to  $10^9 + d_{normal}$ , where  $d_{normal}$  is the drift offset. This principle compensates the clock drift with a certain degree of precision, however, we further optimize it by using  $d_c$  as a correction value instead of the  $d_{normal}$  value once every  $c$  seconds. This approach is called Proportional-Integral-Derivative (PID).

More precisely, the *ENET\_ATINC[INC\_CORR]* register and the *ENET\_ATCORR* register, which allow granule control over the 1588 counter, can be sped up or slowed down using the Timer Increment. The *ENET\_ATINC[INC\_CORR]* register has the new increment and the *ENET\_ATCORR* register defines its frequency. When the number of clock cycles of the 1588 counter equals the *ENET\_ATCORR* value, the 1588 counter is incremented by the *ENET\_ATINC[INC\_CORR]* nanosecond value instead of the usual *ENET\_ATINC[INC]* value.

The resulting adjustment assumes a difference in time between our 1588 clock start of second and the GNSS start of second. The difference is obtained from the current value latched on to the *ENET\_TCCR* register. Speeding up the 1588 counter is realized by increasing the *ENET\_ATCORR* register value. Decreasing it slows down the timer.

#### C. Synchronizing the audio clock with the IEEE 1588 clock

The final step of synchronizing the audio PLL with the IEEE 1588 clock is realized via a task, which is scheduled in intervals of one second. It receives the clock drift correction from the previous step. According to this value, the audio PLL frequency is changed respectively in order to reflect the change of the audio word clock speed. However, the clock drift compensation of the audio clock is different compared with IEEE 1588: The audio PLL allows to tune the audio bit clock with a very fine grain resolution of less than 0.1 Hz.

Even if the clock drift of the audio signal is compensated, we will need to determine the precise time phase offset of the audio signal with respect to the GNSS clock. Otherwise, the incoming and outgoing audio signals would not be in sync. In order to achieve this, we introduce a special synchronization mode. This synchronization mode is activated only at the startup period because we assume that the time offset does not change if the clocks are running synchronously. Instead of a digital audio output signal, an artificial 1-PPS signal is generated.

In the synchronization mode, the serial audio bit output of the SAI is connected with the serial audio input to a direct

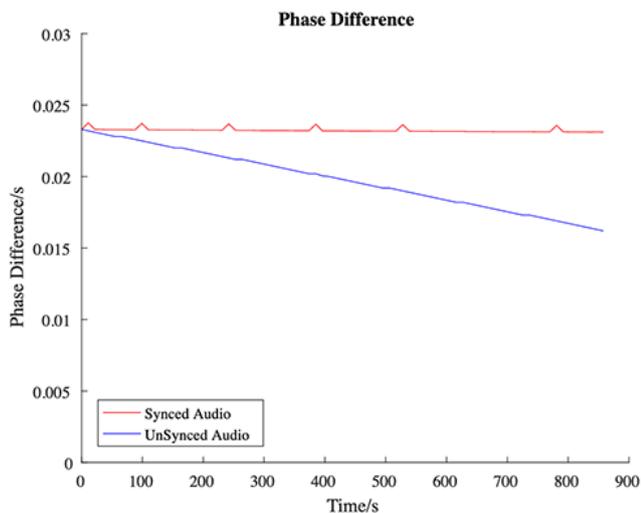

Fig. 3. Audio word clock drift with and without our synchronization

feedback loop. In addition, the SAI data output – filtered by a D flip-flop that is driven by the audio bit clock – is connected to an IEEE 1588 time capture register (similar to the 1-PPS signal of the GNSS receiver). Then, we can measure the delay between sound and GNSS if playing out an artificial digital audio pattern.

#### IV. EVALUATION

The clear and obvious purpose of this paper is the removal of clock drift in remotely distributed sound systems. Therefore we decided to perform our evaluation based on the comparison of two sound card's word clocks with regard to the phase of a low-frequency square wave, which is predestined in that context. In our setup, we generate a 20 Hz square signal with a frequency generator and feed it into two sound cards. The outputs are fed into a 2-channel oscilloscope, which displays both signals at the same time. If the sound card's clocks exhibit a drift the phase of the displayed square waves will drift as well over time. If our implementation is successful we expect the signal to stay in phase and the image on the oscilloscope should stay the same. The duration of the measurement was set to 15 minutes and we retrieved a phase measurement in intervals of 11 seconds. In figure 3 we present our results of this evaluation with and without our developed synchronization approach.

It is clear that without synchronization the phase drift increases proportionally and amounts to 7.5 ms after the final duration of 15 minutes. With our synchronization being applied the phase remains the same because the audio word clocks don't exhibit a drift anymore. In fact we can observe slight phase variations in fixed intervals, however, they are immediately compensated by our applied algorithm and cannot be considered problematic regarding the demands of our described use case.

#### V. CONCLUSIONS AND FUTURE WORK

In this paper, we describe the successful implementation of a GNSS-based sound card synchronization technique for devices distributed in wide-area-networks (WAN) such as the public Internet. Measurement results clearly show the inherent audio word clock drift of approximately 7.5 ms over a duration of 15 minutes without our synchronization technique and precise synchrony of both sound cards and in turn no clock drift when applied. To our knowledge this is the first implementation able to provide the described functionality in the sound card domain. In the near future, we will develop a custom sound card, which benefits from this approach and integrates it into our remote music system. The drawback, however, is that GNSS is not necessarily available in any given environment – especially in basement rehearsal chambers – which is why we will also apply our older approach side-by-side with the new.

**Abstract**—In the classic algorithm, palmprint recognition requires extraction of palmprint features before classification and recognition, which will affect the recognition rate. To solve this problem, this paper uses the convolutional neural network (CNN) structure Alexnet to realize palmprint recognition. First, according to the characteristics of the geometric shape of palmprint, the ROI area of palmprint was cut out. Then the ROI area after processing is taken as input of convolutional neural network. Next the PRelu activation function is used to train the network to select the best learning rate and super parameters. Finally, the palmprint was classified and identified. The method was applied to PolyU Multi-Spectral Palmprint Image Database and PolyU 2D+3D Palmprint Database, and the recognition rate of a single spectrum was up to 99.99%.

## I. INTRODUCTION

WITH the development of network and information technology, the society has put forward higher and higher requirements for the security of information systems. Biometric recognition technology has gradually become one of the important methods to enhance the security and stability of information systems. Biometrics is a technology that uses human physiology or behavioral features for automatic identification [1]. Biometrics are unique personal attributes, which have the characteristics of stability, diversity and individual differences. A number of biometrics have been used, including fingerprint, face, iris, signature,

finger vein, etc. [2]. Meanwhile, palmprint recognition technology is also developing rapidly [3].

Compared with other biological features, palmprint has many unique advantages, and each person's palmprint has different characteristics. Palmprint combines the texture and line features of the palm, and these features do not change over time. In comparison, the collected palmprint is easier to obtain rich personal information due to its larger area than fingerprint. Therefore, palmprint attracts more and more scholars' attention due to its advantages. Traditionally, researchers combine machine learning methods, such as SVM [4], KNN [5], etc., with feature extraction methods, such as LBP [6] and HOG [7], in palmprint recognition. Contrast to machine learning, deep learning achieves automatic feature extraction and classification.

Since 2012, the method based on deep convolutional neural network has achieved remarkable results in various computer vision tasks [9]. In face recognition based on deep learning, researchers have made extensive research [10]. In the aspect of palmprint recognition, researchers have carried out corresponding research experiments with the convolutional neural network method, and achieved good results [11]. In this paper, Alexnet structure is adopted, and experiments and improvements are made on PolyU multispectral Database and PolyU 2D+3D Palmprint Database. The accuracy of each spectrum is quite good, which further proves the effectiveness of the deep learning method in Palmprint recognition.

The rest of the paper is organized as follows: Section II introduces the palmprint preprocessing method and the

---

This work was not supported by any organization

palmpoint recognition method based on deep learning; Section III describes the experimental results obtained by verifying the algorithm on palmpoint database; Section IV concludes the paper.

II. METHODS

A. Image preprocessing

Palmpoint contains rich texture and structural features, such as the main line, wrinkles, triangulation and detail points. When collecting images, images of the same palmpoint collected at different times will have different degrees of rotation and translation, and the size of palmpoint collected at the same time may also be different. Therefore, before feature extraction and recognition of palmpoint, it is necessary to extract the effective ROI area of palmpoint containing main features. The whole processing process is shown in Fig.1. ROI extraction is a key step, and the correct ROI extraction is conducive to image alignment, improving the efficiency of feature matching, and finally giving a positive impact on the recognition results.

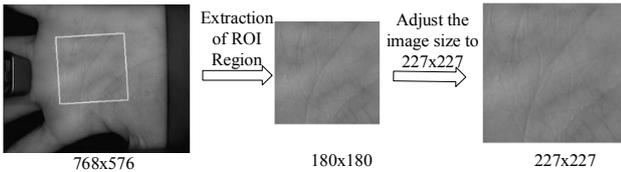

Fig. 1 Image preprocessing

The relative position of the ROI area in the palm is fixed and located in the center of the palm. Zhang et al. proposed edge-based palmpoint positioning processing method [12], which can accurately extract ROI images and thus has been widely used. This article uses this method to process the ROI area with rich features for the following part of the The ROI area of CASIA-Multi-Spectral- PalmpointV1 is shown in Fig. 2

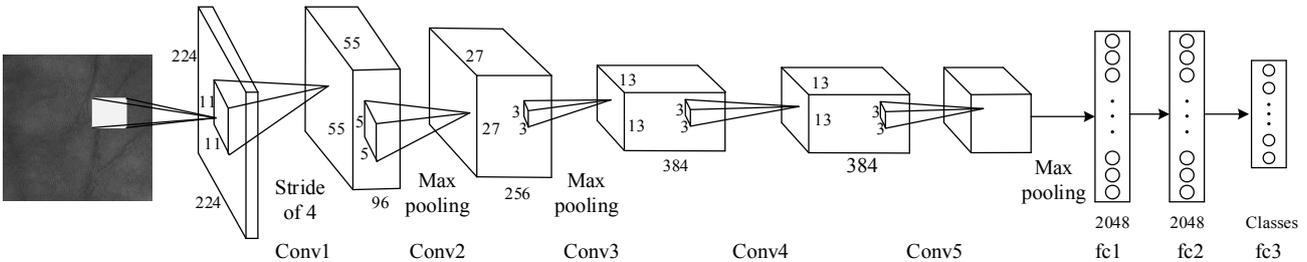

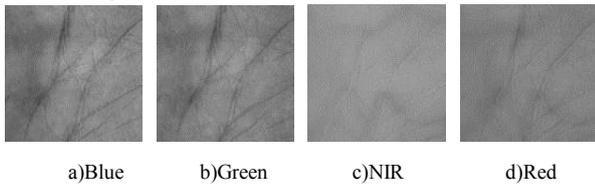

Fig. 3 Structure of Alexnet

Fig. 2 ROI region obtained by image preprocessing

B. Convolutional Neural Network - Alexnet

Convolutional neural network (CNN) is a branch of deep learning which is widely studied and applied. It is not only a multi-layer network model, but also an improvement of BP neural network. They all use forward propagation to output calculated values, and use back propagation to adjust weights and biases. Different from the classical recognition algorithm, CNN repeatedly uses the convolution operation and pooling operation in the original input to obtain increasingly complex feature graphs, and finally directly outputs the results through the full connection. It mainly includes five parts which are input layer, convolution layer, pooling layer, full connection layer and output layer.

In this paper, Alexnet [9] is used and improved. It contains 8 layers of neural network, 5 convolution layers, 3 pooling layers and 3 full connection layers. The structure of the whole system is shown in table 1 and fig.3.

In Alexnet, the author used ReLU activation function and Dropout to improve speed and accuracy. Fig.4 (a) shows the ReLU activation function and the definition is shown in formula (1). Compared with Sigmoid and Tanh activation function, this activation function makes the network converge more rapidly. It can combat the gradient vanishing problem and has high calculation efficiency. When we use ReLU activation function, with the progress of training, there may be a situation where the neurons die and the weight cannot be updated. If that happens, then the gradient through the neuron from this point will always be zero.

$$f(y) = \begin{cases} y, & \text{if } y > 0 \\ 0, & \text{if } y \leq 0 \end{cases} \quad (1)$$

So, He [13] et al. proposed a new nonlinear correction activation function PReLU, whose definition is shown in formula (2). Compared with ReLU, PReLU converges faster. And although PReLU introduces extra parameter "a", it hardly needs to worry about overfitting. In addition, we can achieve learning updates of "a" through back propagation, which enables neurons to select the best gradient in the negative region. So in this article, we use PReLU as an activation function for Alexnet.

$$f(y) = \begin{cases} y_i, & \text{if } y_i > 0 \\ a_i y_i, & \text{if } y_i \leq 0 \end{cases} \quad (2)$$

### III. EXPERIMENT

#### A. Public Palmprint Database

Classic Palmprint recognition technology is mainly based on 2D Palmprint, which is convenient to collect and contains rich texture information. Therefore, we use 2D Database in PolyU 2D+3D Palmprint Database. Multispectral Palmprint can obtain more abundant Palmprint features and a higher recognition effect, because use the spectrum of different wavelengths, skin absorption and reflectance is different, you can collect multiple bands of palmprint images, and these images are not easy to be forged. So we used the PolyU Multi - Spectral Palmprint Image Database.

1) *PolyU 2D+3D Palmprint Database*: PolyU 2D+3D Palmprint Database [14] contains 8000 sample images collected from 400 different palms. Samples of each palmprint were collected in two separate sessions, and 10 samples were collected in each experiment. The average time interval between the two sessions was one month. In the experiment, samples taken from the same palm can be regarded as the same class, and samples taken from different palms can be regarded as different classes. Therefore, this sample base contains a total of 400 classes, with each class

containing 20 samples. Each sample contains its 3D ROI (area of interest) and corresponding 2D ROI. This article uses the part of 2D ROI in the database, and the image size is  $128 \times 128$ .

2) *PolyU Multi-Spectral Palmprint Database*: PolyU Multi-Spectral Palmprint Image Database [15] collected 250 people left hand and right hand, a total of 500 classes of sample. Each palm was collected in two separate sessions, each time 6 palmprint images were collected, and the average time interval between the two sessions was 10 days. Each collection was done under lighting conditions of four different spectra, Red, Green, Blue, and Near Infrared, to collect palmprint images of four bands. The specific four bands are near-infrared (band I, wavelength 880nm), red (band R, wavelength 660nm), green (band G, wavelength 525nm), and blue (band B, wavelength 470nm). Therefore, there are a total of  $4 \times 12 \times 500 = 24000$  palmprint images of all palms in each band. Using the above palmprint processing method, the ROI area of  $128 \times 128$  palmprint was obtained for the next experiment.

#### B. Experimental Environment

The training equipment used in this article includes an eight-core Intel i7 processor, an NVIDIA1060 graphics card, and 16GB of memory. The experiment of this paper is carried out in the open source machine learning library Tensorflow2.0 of Google, and the programming language is Python3.5.

#### C. Experiments Results

In order to test and select the appropriate learning rate, we selected 2D Database in the Palmprint Database of PolyU 2D+3D for the experiment. We selected all 400 classes of data in the database. After data preprocessing, we divided the data into 60% training set, 20% test set and 20% verification set to compare the performance.

We tested the influence of different learning rates on the recognition rate with 2500 iterations, and the results are shown in table II. After comprehensive experiment comparison and selection, we found that the convergence rate and training time synthesis reached the best speed and the maximum recognition rate when the recognition rate was 0.0008.

We divided all the data in the database into 60% training set, 20% test set and 20% verification set. The determined learning rate and network structure are applied to conduct training on the PolyU 2d+3d Palmprint Database and PolyU Multi - Spectral Palmprint Database, the results are shown in table III below. In addition, classical methods such as LBP and HOG are used to extract features from the same training set, and classical algorithms such as KNN and SVM are used for training and classification recognition. Then, we use LDA to reduce the dimension of data after LBP and HOG feature extraction, and then conduct classification and recognition. All results are shown in table III below.

TABLE II.  
PERFORMANCE COMPARISON

Learnin-g rate	Iterations	Loss	Time/s	Accuracy of test data	Recog-nition rates
0.01	500	1.5120	448.98	56.00%	99.94 %
	1000	0.0533	1352.85	90.00%	
	1500	0.0001	2461.74	100.00%	
0.001	500	0.7400	436.48	70.00%	99.95 %
	1000	0.0592	1428.42	92.00%	
	1500	0.0001	2561.06	100.00%	
0.0008	500	0.7454	378.42	90.00%	99.96 %
	1000	0.0147	1226.62	100.00%	
	1500	0.0026	2427.54	100.00%	
0.0005	500	0.9277	444.21	46.00%	99.95 %
	1000	0.0719	1242.87	96.00%	
	1500	0.0048	2449.93	100.00%	
0.0003	500	1.5656	441.12	40.00%	99.56 %
	1000	0.1695	1236.46	86.00%	
	1500	0.0025	2431.89	98.00%	
0.0001	500	2.4503	437.07	78.00%	99.64 %
	1000	0.6367	1227.33	74.00%	
	1500	0.3356	2288.35	92.00%	

TABLE III.  
TEST RESOULT

Methods	Recognition rate of Spectras or Databases (%)				
	Red	Blue	Green	NIR	Sub2D
Alexnet	99.99	99.99	99.97	99.86	99.96
LBP+KNN	88.35	89.55	91.44	87.10	90.31
LBP+SVM					
HOG+KNN	97.90	98.40	95.95	96.45	97.31
HOG+SVM					
LBP+KNN	91.60	87.80	88.25	92.75	94.31
LBP+SVM	89.50	87.40	89.10	93.45	93.81
HOG+KNN					
HOG+SVM	99.65	99.83	99.35	99.35	99.84
HOG+SVM	99.60	99.45	98.30	99.10	99.25

It can be seen from the experiment that the method of deep learning can get a better recognition rate in each spectrum and database, which also proves the effectiveness of the method of deep learning in palmprint recognition. At the same time, the experiment also proves that in the aspect of palmprint recognition, the feature extraction and learning ability of deep learning is slightly stronger than the classic algorithm combination of HOG, LBP, KNN and SVM.

IV. CONCLUSION

The classical palmprint recognition method needs a series of tedious operations such as feature extraction, feature selection and classifier selection, and has great limitations in the process of feature extraction and feature selection. Compared with the classical algorithm, the convolutional neural network has the ability to directly input the image and then obtain the classification result, and it has a good

nonlinear fitting ability. When using convolutional neural network for palmprint recognition, we do not need to construct feature extraction algorithm. In this paper, a classic convolutional neural network Alexnet is used for palmprint recognition, and its recognition rate can reach up to 99.99% on test data, which is another idea of palmprint recognition.

**Abstract**—The paper demonstrates an application developed to help to evaluate ergonomics of a workplace. Ergonomics of a workplace has enormous impact on employees and their long-term work effectiveness, which causes an interest in this field from employers' point of view. The paper describes and compares several attitudes companies use to set up and evaluate workplace metrics, potential of virtual reality (VR) in the process, VR application proposal, implementation within Unity 3D engine and results achieved with implementation of this proposed solution. Current approaches also include motion tracking for ergonomics evaluation. These technologies are often far over smaller companies' budget. Described solution is reasonably priced also for small companies, using cheaper motion capture equipment.

## I. INTRODUCTION

AT THE present time, the interest in health of employees performing monotonous and repetitive routines in industrial companies is increasingly being pursued. One of the new issues is the evaluation of workplace ergonomics in such enterprises. This topic is strongly supported, especially in Germany, where trade unions have an important influence. The paper deals with the proposal of methodology for ergonomics evaluation using modern information-communication technologies (ICT), such as virtual or mixed reality. This vision is fully in line with the European industry revolution - Industry 4.0 [1].

The aim of our work was to contribute to the development of a comprehensive system (application) for the evaluation of workplace ergonomics for medium and small enterprises. As the development of such a system (application) is a complex task that requires a multidisciplinary approach, the work has set out subtasks that relate to computer support for ergonomics evaluation. The project uses a new motion capture suit named Perception Neuron. The advantage of this solution is a system that is less expensive than current solutions. Another benefit is the use of a virtual reality in which individual workplaces can be composed and, if necessary, used for worker training [2].

## II. ERGONOMICS

Ergonomics is the process of designing and deployment of workplaces - objects and systems in an environment so that their layout fits the people who use them. It can be applied to

all processes and locations that include people - workplaces, sports, leisure activities, but also safety and health.

The goal of ergonomics is to refine the layout of environment to minimize the risk of injury or other types of health problems.

Enterprises are concerned with ergonomics because they realize that the better the environment is adapted to the needs of the person, the higher the productivity of person's work is. At the same time, companies try to minimize the costs of illnesses and wounds resulting associated with work at the workplace.

### A. Ergonomics Evaluation

Several disciplines are used to evaluate ergonomics [3], [4]. In the factories, especially in our site, the implementation is predominantly tabulated, with the company prescribing workplace deployment standards, which describe the minimum / maximum table height, desktop size, distance between objects, and so on.

Some of the companies also use innovative technological solutions that are available today. Motion capture methods have been used at the sport sector. Similarly, there are car manufacturers that evaluate the cockpit ergonomics with the aforementioned methods, which record, for example, the movements of people during boarding and disembarking, which are later evaluated.

We attempt to contribute in this area by incorporating current technologies, using motion capture methods in combination with virtual reality [5].

### B. Existing Solutions

The paper [6] lists the basic ergonomic aspects of workplace design. The advantages of the ergonomic design of the working environment are proven by increasing work performance and reducing errors. A turnover of staff is also reduced. Workers are more satisfied at work and have no reason to look for a new job. The benefits can therefore be seen for both organizing the production and the employee:

- 1) For the production organization

- a) reduction of incapacity for work and occupational diseases
  - b) performance improvement
  - c) reducing error and confusion
  - d) improving the mental status of the worker
- 2) For the worker:
- a) improving the mental and physical condition of the worker
  - b) minimizing the signs of mental and physical fatigue
  - c) social benefits - improved self-realization

As stated in [7], the use of virtual reality technology in solutions aimed at increasing workplace ergonomics is an unavoidable trend. Virtual reality applications have these benefits:

- user can enter and walk through the scene on different tracks
- events happen in real time
- scene and objects have 3D character
- scene is not static and objects can be manipulated

Virtual reality models allow:

- replacing physical prototypes with virtual ones
- simulation of the different stages of development in a virtual environment
- improvement and acceleration of product development processes
- scene is not static and objects can be manipulated

The main advantages of human simulation in the 3D environment are:

- shortening development time
- reducing development costs
- improvement of quality and safety
- increase of competitiveness

The use of virtual reality in the design of workplace ergonomics will provide the following functionalities:

- a clearer design of the new work cell
- evaluation of existing assembly line, increasing its efficiency considering the human factor
- energy expenditure for the operation

Tecnomatix Jack is frequently used for ergonomic workplace design [8]. Though, it does not provide a built-in solution that uses VR and its unquestionable benefits. Existing solutions for employee ergonomics analysis in VR are mostly developed by big companies. These software and hardware solutions are often developed for automakers [9].

So far, there is no affordable solution for small and medium-sized companies. For example, these are commercially available virtual reality headsets and affordable motion capture suits. Our proposed solution described in this paper is priced at a maximum of thousands of USD / USD. Existing solutions for large companies are priced at hundreds of thousands.

### III. PROPOSED VISION

The impulse for the project was the idea of connecting motion capture methodology with the visualization capabilities

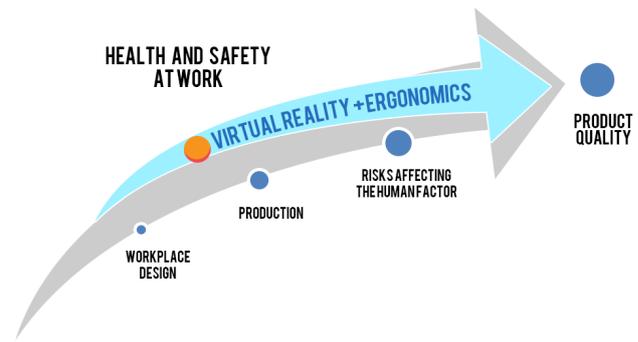

Fig. 1. Impact of involving innovative procedures to enhance product reliability [7]

of VR applications [10] [11], giving users new perspective to the spatial body movement in a virtual workplace.

Recording worker's movements via motion capture technology and then providing users with tools for controlling recorded live movement data similarly as a movie player with functions to control play speed or pause whole moment and also providing tools for modifying environments in way of building custom workplaces, would granted users with full control of those aspects which would make it easy to recognize critical spots of the workplace.

Application use is intended mainly for those kinds of workplaces, where inappropriate ergonomics may cause an increase of wounds. There are connected with manual repetitive actions, that are common e.g. in factories, so it is compulsory that it includes industrial equipment, that could be used to build industrial workplaces. Considering the fact that application should be reasonably priced also for small companies, proper support of inexpensive variants of technologies is required.

### IV. MAIN ASPECTS OF PROPOSED APPLICATION

Based on the vision, our application was proposed. The proposal was divided into several different independent parts, each dealing with different problematics. Application was divided into:

- Supported technologies
- User input / movement
- Environment
- User interface
- Workplace building
- Work simulation
- Limitations

#### A. Supported Technologies

As it was stated in the proposed vision, the application should offer virtual reality environment, which includes the use of a VR headset. It relies on use of a motion capture technology and 3D engine which is a powerful environment when dealing with 3D rendering [12].

There are a lot of VR headsets to choose from. Support for more than one device often meant device dependent development and writing code for each device separately. It was caused by differences in controllers and input. Some of the headsets provides only gestures, others one or two controllers of different types.

Acer WMR (Windows Mixed Reality) was the best candidate for the application and for testing of the proposed system. Its system requirements and performance tests were better on our computers than it was with the other virtual reality headsets considered for use (including HTC Vive, Oculus Rift). Advantages of this headset is lack of external sensors for tracking of headset’s orientation. Tracking sensors are internal – in a form of two cameras detecting movement of the device relative to the room or other surroundings by the changes of positions of referral points in the environment in each image. In addition to performance and saving one HDMI port and not using external sensors, also the price is lower than the price of the other devices. Headset belongs into the family of Windows Mixed Reality headsets. These devices share uniform controllers, which makes the application compatible with each type of headset of this type.

For motion capture technology, price was the key feature that matters as this could be the most expensive part of the whole project. Also used tracking technology was important as motion should be captured right in and during real work process. Some of the workplaces could provide only very constrained setting, making it impossible to capture movement with cameras detecting markers on worker.

Considering mentioned facts, Perception Neuron was selected. Developed by Noitom, this motion capture suit consists of individual sensors called Neurons. Each neuron houses an Inertial Measurement Unit with a accelerometer, gyroscope and magnetometer [13]. This units should provide decent measurement values with reasonable price. Suit allows full body tracking. Noitom also provides a SW in the form of environment, where editing, real-time preview of animations and export to various formats are possible. The only limitations are warnings about wearing suit near the electric devices, which is not always possible in a factory.

*B. User Input and Movement*

A design of user input was not an easy task. It is always important to realize, what are the actions that we need to cover and how many different types and keys will be available for the users.

Using WMR controllers, we got four buttons (one reserved for return to Windows), one joystick and one touchpad per controller. Considering left and right hand-oriented users, it may cause difficulties, if each of the buttons on the left and right controller had different functions. It would be also not possible to completely control the application with just one controller. Because of this, functions of buttons on both controllers will be mirrored. This left only five input keys for genuine actions as buttons on the left controller should call the same actions as the opposite buttons on the right controller.

As defined in the vision, main actions could consist of:

- movement
- displaying/hiding the menu
- selecting items in menu / environment
- confirming action
- playing the simulation
- changing simulation play speed

Reserving joystick for movement works great and feels natural as axis of joystick movement corresponds to the direction of movement in a virtual environment. Touchpad was reserved for scrolling in menus on vertical axis and changing play speed on horizontal axis.

As a specific method of location input, application will use controllers as pointers used to select options in menu panels or position in environment.

All buttons setup proposal is described in Fig. 2.

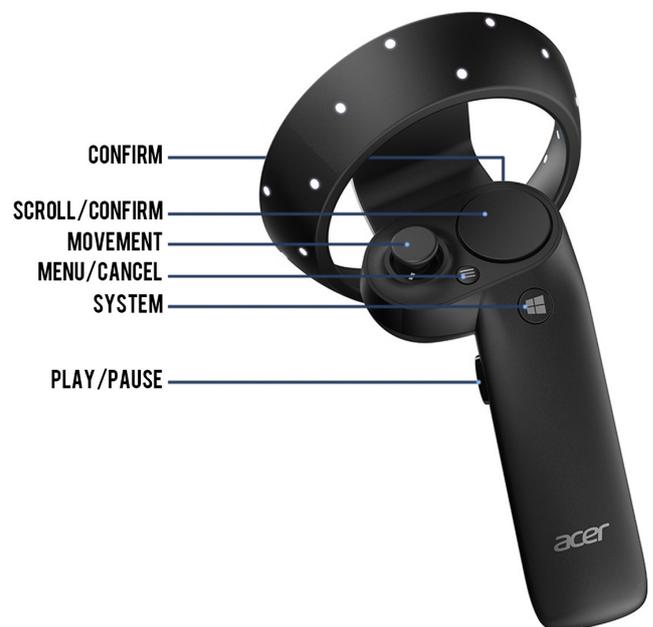

Fig. 2. Controller key bindings

Movement itself was a problem since of appearance of first virtual reality applications. Movement caused disorientation and nausea. Now we know, that this was caused by unnatural movements in virtual environment that human brain had problem to process. Most of the problems were caused by absention acceleration and deceleration forces present while moving in real life. This would be impossible to do by code, as every person’s movement pattern is different from others. Therefore, modern VR applications relies on real physical movement that is detected through inside or outside sensors and then it is transferred into the VR, which is more natural and not causing problems like older applications.

Natural movement is often limited by real surroundings, as user may need to move in larger area but that’s not possible in real setting. In this case application provides procedure of teleportation, where user can change location instantly for

longer distances by pointing at the new location and pushing joystick forward. When user releases the joystick, application moves him/her to the new location.

Application also provides "step back" function, used go back and turning joystick left or right rotates user in desired direction.

### C. User Interface

User interface (UI) should consist of selection menus or panels with additional information to user's visual experience.

Since UI will be presented in VR, there are specific rules for text to be easily readable and provide understandable options.

Important text information should be kept in user's field of view (FOV) as it is something users should be aware of in whatever direction they are looking at. Displayed panels should be far enough, not blocking the view, but fitting in. The size of font of every text information should be large enough so users will be able to read it. Aiming at the buttons should not be challenging task to feel selection more natural, achieved by selecting proper size of buttons.

Providing information in more different panels step by step also works better for VR than displaying everything all at once.

Curved menus (Fig. 3) for bigger panels are preferred unlike straight menu panels where content on the sides is in greater distance, which results in unequal feel of presented options from side of user.

Curve angle should not be too high to avoid claustrophobic feeling. This could be done by moving the center of an imaginary circle, where lies curved menu panel, behind user's back.

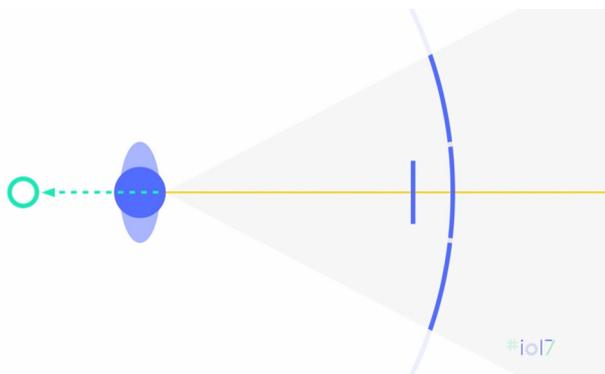

Fig. 3. Layout of curved menu with circle center shifted behind users back [14]

### D. Environment

Environment needs to provide enough space for users to simulate physical body movement actions and also free space where custom workplaces will be built.

Both indoor and outdoor scenes (Fig. IV-D) can be used for the simulation. Indoor scenes would need correct lightning settings and outdoor scene raised skyline to make scene look infinite. Illusion of no boundaries improves user experience (UX).

Fig. 4. Outdoor / Indoor scene examples

## V. WORKPLACE BUILDING

Building of a scene in the application will be a process, where user selects an object from a set of provided 3D models and places these objects to desired location in order to build either a replica of existing workplace or to create and test a new workplace.

Provided items will be sorted into categories to make selection faster. Each item should provide detailed look before selection. Item position in environment will be selected by pointing a controller and pushing button for accept (Fig. 5).

Fig. 5. Proposal of item selection menu

## VI. WORK SIMULATION

Simulation consists of playing recorded body movements of a worker during his/her work.

Users will be able to load film box format (.FBX), which, in addition to polygon and material data of 3D model, also contains animation data. This data will be automatically processed and mapped to 3D engine's animation component.

Loaded animation will be bound to the 3D model of a human figure used as a mannequin. Playing the animation will move mannequin accordingly.

The applications will also provide a control mechanism for control play speed of an animation based on music or video players (Fig. 6).

### A. Limitations

Setting up limits is important to maintain performance of the application.

This could be done by restricting of number of objects that can be placed in single workplace. The application should also focus on polygon optimization of 3D models. Reducing

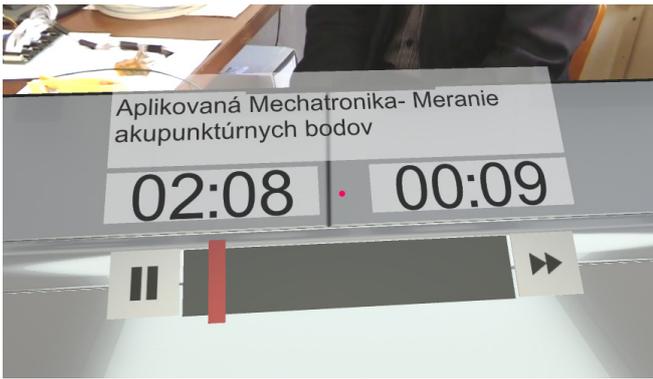

Fig. 6. Video player as an idea for animation player

polygon count in scene will reduce calculation count needed for rendering. Polygon optimization is useful when working with 3D models from CAD. CAD models provides too many details that are not needed in virtual reality visualization (Fig. 7).

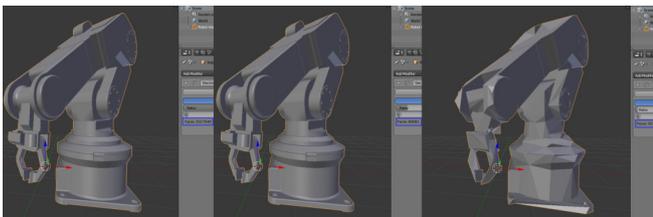

Fig. 7. Example of reducing number of polygons of a 3D model

Another restriction may be setting up a movement area boundary, which defines location, where user can freely move and those places, that are not accessible.

VII. IMPLEMENTATION AND RESULTS

The vision of application was implemented and built by Unity 3D engine. Unity provides build for a lot of platforms including Windows, Mac, Linux, Android, iOS, etc. WMR headsets are bound to operating system Windows as it is the only operating system supported by these devices.

Unity 3D engine is perfect choice for this type of application. The 3D engine has tools and components created for use with virtual reality. Great advantages of this 3D engine are low learning curve, easy scripting system and simplicity of engine’s GUI.

A. Scenes

The application itself is divided into two scenes. The first scene provides simple menu with options of loading animations or workplaces while the second scene is used for building and simulation.

Menu-selection scene is a starting point, where user can load animations and open workplaces. This is a small scene where users find themselves inside a room with reflections to optically enlarge surrounding area.

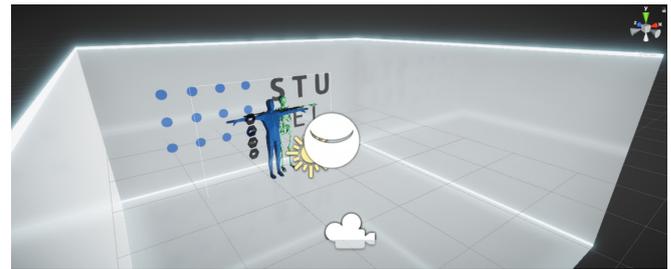

Fig. 8. Main menu scene

Loading of animations is done via system file browser panel, which has similar functions to the traditional Windows file browser. Selection is confirmed by aiming at desired option and clicking the confirm button on virtual reality controllers.

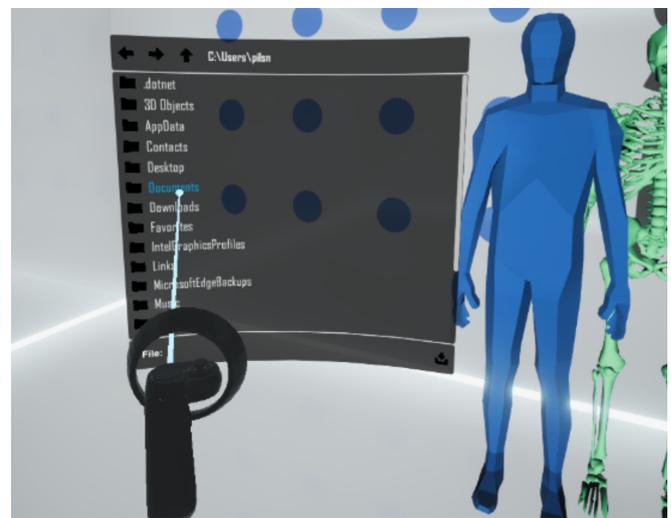

Fig. 9. File browser

Second scene is loaded after animations and workplace are selected. User spawns inside a hangar building. This scene serves for building virtual replicas of actual workplaces. Hangar should provide enough space also for larger workplaces. The door on one of the sides of the building are opened.

Fig. 10. Simulation scene

Outside area contains grass and trees. Also bird sounds can be heard. Even though outside area is not accessible, it creates a relaxed atmosphere.

Fig. 11. Outdoor environment of the simulation scene

### B. Controllers

During application runtime, virtual models of controllers are being rendered for users, if they are turned on and paired with computer. Virtual controllers increase amount of interactivity. Selection ray is displayed with a dot on its end which works as a mouse cursor. Aiming and hovering over buttons and objects with scripted actions will result in selecting these components.

#### REAL CONTROLLER

#### 3D MODEL

Fig. 12. Real and virtual controller

Movement realization is done exactly as proposed. The application provides four types of movements:

- Real movement projected into application – whatever move user do with headset same change is performed by in-game camera
- Teleport – pushing joystick forward and aiming at the ground, users can teleport to a new location
- Step back – pushing joystick back will result at camera moving back a little
- Turn left/right – turn by 30 degrees by pushing joystick left or right

While requested teleporting by pushing joystick forward, markers to indicate ongoing action are displayed to the user.

### C. Raycasting

Method of raycasting is used for collision detection. During detection a ray is cast in a certain direction for specified length and first found interception is returned as a collision point.

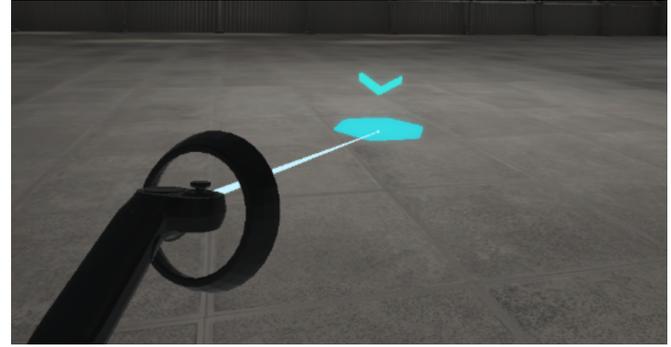

Fig. 13. Teleportation sign

In this case, rays are cast from controllers, checking for editable objects and menu item detections. If confirm button is pressed and user is aiming at such object or menu item at that moment, its action is called in form of C# method written in abstract editable object class overridden for specific use of specific object user is currently clicking on.

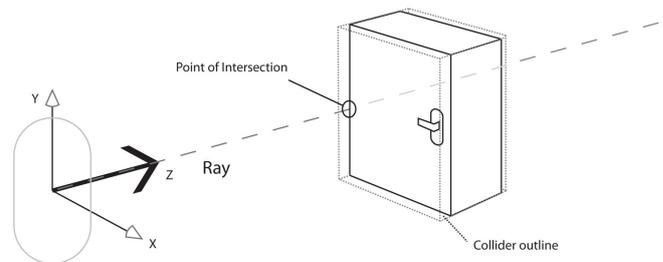

Fig. 14. Raycasting method [15]

As some of the meshes can have too many polygons and complex shapes, colliders are used to simplify these shapes and to receive the collisions. This approach reduces the quantity of calculations needed, although collisions are not always that precise as simplified shape cannot always perfectly align complicated shape.

In Fig. 15, green lines represent edges of a chair collider around its mesh. Colliders at the top of the objects are defining mesh better than those at the base. Reason is that higher parts of collider are more likely to stand in front of other object from user's perspective, which causes blocking rays and detecting object at the front when aiming its direction. When these colliders are better defining its mesh, change-over the objects while moving the controllers is more accurate, representing what user really see. At the bottom areas, while aiming at the ground, there is unlikely that collider could block another object, so those can be simplified so that they don't correspond with actual mesh.

### D. Object Selection And Building

Building of a workplace is done by selecting an object by object from application menu and placing and positioning the object to fit user needs. Objects provided are categorized.

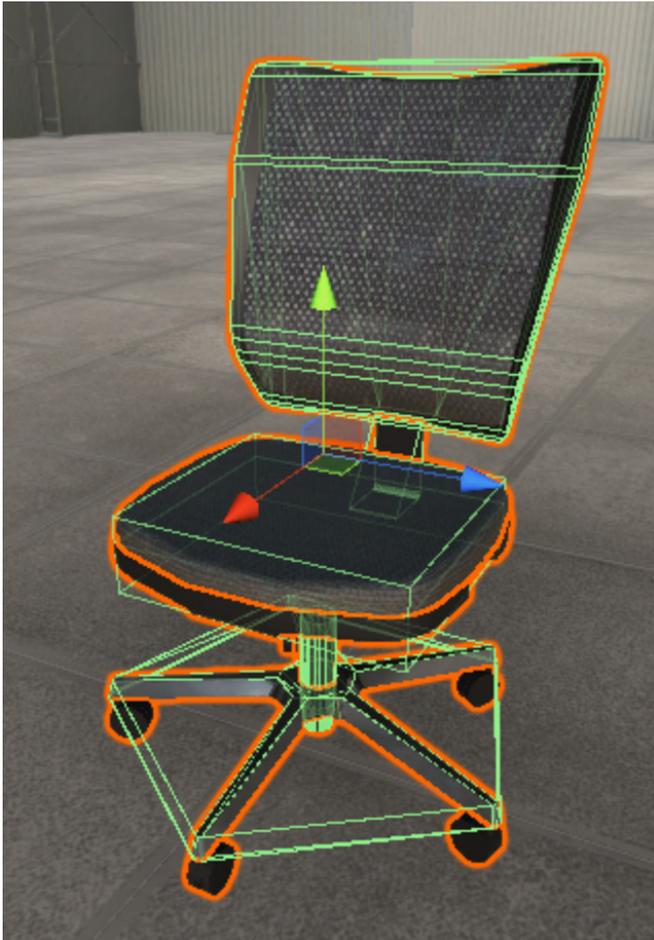

Fig. 15. Object collider example

Menu provides these categories as buttons. Each category contains several optimized objects prepared for use. Items are loaded automatically from application resources based on the folder names. After clicking on category button, objects of selected category are displayed to the user.

Provided categories are:

- Machinery
- Conveyor belts
- Racks
- Tables
- Chairs
- Cabinets
- Electronics
- Other – other objects that do not belong to any of mentioned categories like decoration objects, boxes, walls, etc.
- Primitives – if users cannot find suitable object of those provided by the application, they can replace it with this simple primitive 3D objects as cube or sphere
- Functional – this section contains physical animation player that can be used to control the movement simulation. Category was also prepared for objects like doors

- or elevators that was not implemented yet
- Mannequin – contains humanoid 3D model

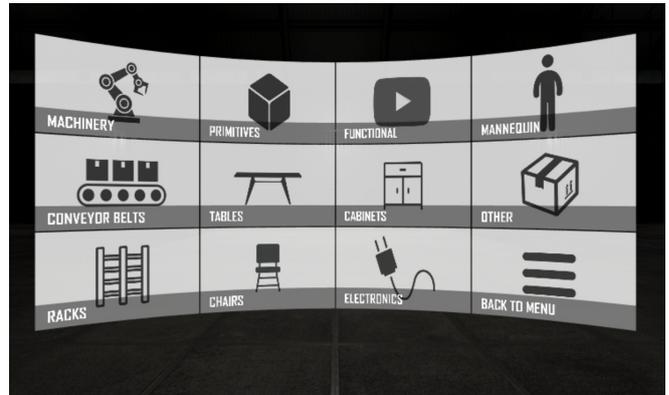

Fig. 16. Build menu

Providing limited number of objects users can use to build their workplaces, it can be hard to create something that looks similar to the real environments. If application contained only very specific 3D models, it would be impossible task.

Due to this cause, whole specific assembly lines were split into smaller reusable parts that can be used multiple times with different setup (size or colour). Doing this, users create their own specific solution themselves using the principle of modularity (Fig. 17) by combining several objects in many ways.

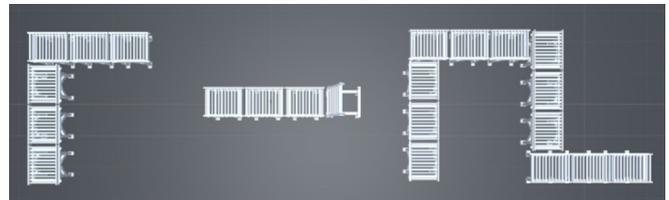

Fig. 17. Modularity principle

### E. Object Detail

When object category in build menu is selected, objects that belong to the category are displayed to the user. There are several objects in each section which could get confusing when showing all at once, especially when also visual of every object has to be displayed. Instead, application presents one object at a time, providing name of the object and detailed look. Arrows on both sides of the object detail can be used to cycle through all objects.

Preview of each object is rendered dynamically. The detail canvas contains a render texture, which can be used to display an image from a camera. Whenever user opens a selection menu, selected item is placed under the whole scene in front of prepared detail camera, where user cannot see it. This camera renders an image, that is projected in the detail canvas of selection menu. When changing the object, old object selected

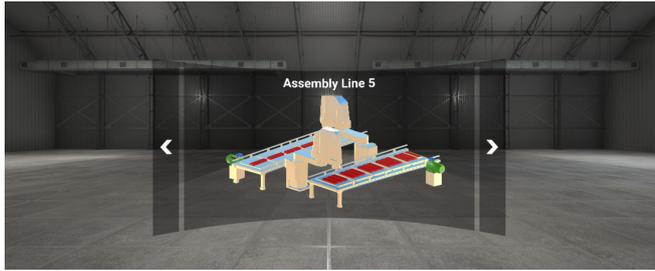

Fig. 18. Selection menu

before is deleted and replaced by the new one just being selected. This will result in change of camera view, which also renders whole new image on the menu canvas.

Detail camera uses orthogonal view, which makes 3D object look more like an image.

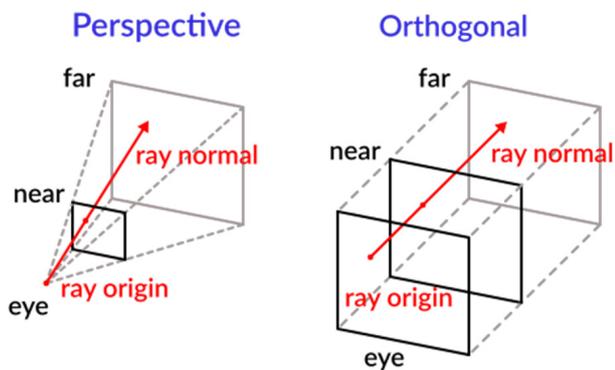

Fig. 19. Orthogonal camera render principle [16]

User confirms the selection by clicking the object image in the canvas, which results in closing the menu and sticking the object to the end of the ray casted from controller, changing its position whenever controller is moved and casted ray collides with the ground. At this moment, object can be rotated moving the joystick right or left. Aiming at desired position and by clicking the submit button, object stops following the ray and becomes solid part of the virtual environment.

#### F. Object Set-Up Options

After selecting the object and confirming its position it stays still. But sometimes it is necessary to be able to change object's rotation or position again or delete the object after its building.

All possible modifications of each object are presented by the setup menu. This menu can be accessed by aiming at the built object and pressing the submit button. When aiming at the object, name of the object and the action are automatically displayed to let user know about the action.

Setup menu provides numerous object settings:

- Change rotation – buttons can be used to change the rotation of placed object. Rotation is changed on three euler axes.

- Change scale – rescaling the object on three axes.
- Materials – preview of all mesh materials – clicking the material will open a material menu
- Detail – similar to the selection menu, creates a copy of modified object. All of the modifications are done affecting only this copy and only by clicking the confirm button copy replaces old object in scene. If not confirmed and cancel/back button is pressed, menu closed and object copy is deleted, preserving original object.
- Buttons
  - Confirm – confirms the changes
  - Move – closes the menu and sticks the object to the end of the ray, user can move object again to its new location
  - Delete – deletes object from scene

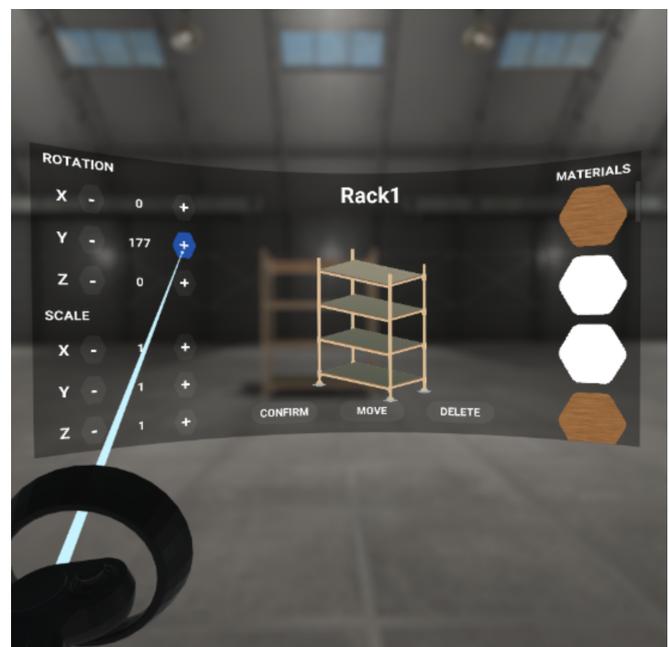

Fig. 20. Object editing menu

Selecting the material from the setup menu opens other menu with all the materials grouped by their type. Clicking on new material will replace the original one. All the materials can be changed. Provided material groups are:

- Simple color
- Fabric
- Glass
- Metal
- Plastic
- Stone
- Wood

Setup menu provides only few options to customize objects, however it can be used to produce totally different object with the identical base 3D model. As an example, here is a cabinet that was rescaled, and materials were changed.

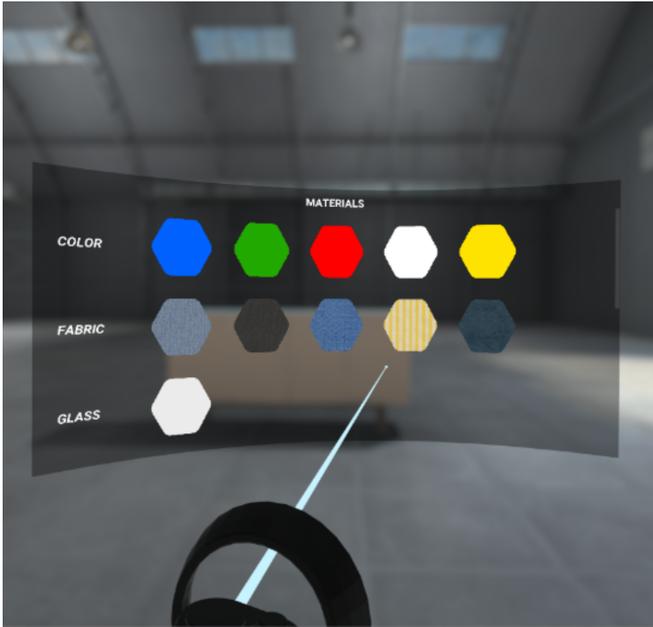

Fig. 21. Material selection menu

Fig. 22. Example of original and edited object

*G. Motion Simulation*

The application provides tools for the simulation which is in this case done by playing recorded motion data as an animation bound to the humanoid 3D model. At first, motion data needs to be captured using motion tracking technology. Data have to be stored as .FBX format which can describe also animation data stored in time frames. This file is then loaded through the application using the file browser.

Unity 3D engine does not provide tools for runtime load of an animation or model to the application (except for asset bundles, which is not suitable for this solution, due to the need of the Unity editor to create a bundle), so an external library is used and included to the application.

Asset Import library is an open-source library dedicated for the import of multiple 3D model data formats into the form, it can be easily processed in third-party applications.

With use of mentioned library, animation data is extracted from loaded .FBX file, stored into animation time frames that form whole animation. Each frame has information about positions, rotations and scales of animated object at a specific moment in time. Changing object position and rotation according to this information continuously, frame by frame,

will create a visual animation. After animation was loaded, user is informed about animation statistics like total number of frames, framerate (frames per second) and duration of loaded animation. Then users may select an environment in which simulation takes place.

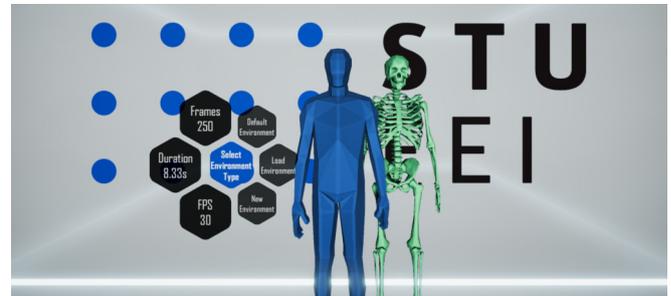

Fig. 23. Animation information after load

In environment, animation is automatically bound to the mannequin – 3D humanoid. To perform the simulation, its necessary to play the animation, which can be done by the controllers as there are keys for play/pause as well as controls for controlling the play speed. In section “functional” of build menu, users can also find physical controller composed of buttons. This controller provides additional information about play speed, animation name, duration and actual time and buttons with the same functionality as described for VR controllers.

Fig. 24. Motion simulation

*H. Results*

Many kinds of environments can be built within the proposed application using / editing provided objects.

VIII. CONCLUSION

The application was developed to help evaluate ergonomics of workplaces with focus on manual repetitive monotonous working activities. One of the main goals was to make the application affordable for small and medium enterprises. The application allows use of affordable motion tracking solutions, which ensures a price drop.

Fig. 25. Office workplace example

Fig. 26. Industrial workplace example

Main purpose of this application is to provide an alternative original look at the working process, create new points of view using the virtual reality technology and provide tools for managing environment and working process in it.

The application can also be used for workplace adjustments and modifications to fit the ergonomics standards or to change design of evaluated environment to solve its deficiencies. It can also be used for designing entire new environments and in some limited way for training of new employees.

The application is not evaluating ergonomics itself, as it needs specialist in this field to do the evaluation. Automatic machine evaluation of workplaces is one of the improvements we are considering to the future. There is also software like Biomechanics of Bodies, that can automatically evaluate ergonomics of human body based on human joints positions and rotations, counting muscle stress and much more. Using software like this, the application could provide users with evaluated data, directly displaying critical human body parts or exact muscles that suffer the most and marking critical area where unnatural movements occur.

Other improvements can provide more user actions and customization to make it suitable for employee training and augmented reality support could bring evaluation to the real workplace.

## ACKNOWLEDGMENT

**Abstract**— We propose a new key sharing protocol executed through any constant parameter noiseless public channel (as Internet itself) without any cryptographic assumptions and protocol restrictions on SNR in the eavesdropper channels. This protocol is based on extraction by legitimate users of eigenvalues from randomly generated matrices. A similar protocol was proposed recently by G. Qin and Z. Ding. But we prove that, in fact, this protocol is insecure and we modify it to be both reliable and secure using artificial noise and privacy amplification procedure. Results of simulation prove these statements.

**Index terms:** key sharing protocol, physical layer security, privacy amplification, Shannon information.

## I. INTRODUCTION

Solving the key sharing problem between legitimate users, connected by some telecommunication channels, has been in research focus within many years and it is still completely unsolved.

A protocol based on some cryptographic assumption (factoring problem, discrete log problem, error correction algorithm ctr. [1]) has been proposed by Diffie and Hellman [2] many years ago. There are known key distribution protocols based on “key commutative property” of the encryption algorithms [3]. But the corresponding protocol requires to hide the identity of the message sender [4], which is indeed a further cryptographic assumption.

It was developed in recent years a new approach to key distribution problem based on the notion of *physical layer security* (PHY) (see excellent survey [5]). This approach exploits some physical properties of real communication channels connecting legitimate users sharing a secret key in the presence of eavesdroppers. In line with this setting it was published a pioneer paper by A. Wyner [6] and its extension in the papers [7, 8], where legitimate channels were superior to eavesdropper ones on the SNR parameter.

Next, due to advanced Maurer’s papers [9, 10], such approach was extended with the use of so-called *public discussion* and privacy amplification. It enables to transform disadvantage on SNR for legitimate users against eavesdroppers into advantage at the cost of exchange by additional information on public channels.

Other PHY-based protocols execute channels with random parameters (say, fading channels with multipath wave propagation) [9, 10, 11]. And this technique was used also in MIMO-based systems intended for a communication between mobile units [12, 13]. Effective key distribution problem can be solved also in frame of the so-called *quantum cryptography* where special quantum channels and devices [14] should be executed. But it is worth to note that all the key sharing methods mentioned above have been designed for known SNR in the eavesdropper channels or for the case where the number of antennas in the eavesdropper MIMO-based system is limited by some value. However such requirements to enemy system is obviously unrealistic.

Also there is a demand to share secret keys between users connected by constant (practically noiseless) channels (as Internet itself) and without any cryptographic assumption due to a risk of quantum computers to be applied in the future.

In section 2 we remind the key sharing protocol based on extraction of matrix eigenvalues described in [15] as Scheme EVSKey and confirm that it is in fact insecure [16]. Next, we extend this protocol in order to provide the upper bound for SNR in eavesdropper channel. In section 3 we present some channels transform primitives. Section 4 is devoted to results of simulation. In section 5 we optimize protocol parameters to provide both security and reliability of the shared key. Section 6 concludes the paper and proposes some open problem for further investigation.

## II. KEY SHARING PROTOCOL BASED ON EXTRACTION OF MATRIX CHARACTERISTIC POLYNOMIALS

Let us remind the scheme EVSKey [15] used in the current paper in order to generate the binary raw sequence for further creation of the shared key. The scenario corresponding to this scheme is presented in Fig. 1.

Before a transmission, Alice (A) and Bob (B) generate their own reference matrices  $X_A, X_B \in \mathbb{C}^{n \times m}$  with independent matrix elements distributed according to  $CN(0, \sigma_X^2)$  as well as random unitary matrices  $G_A, G_B \in \mathbb{C}^{n \times n}$  where  $n$  is number of antennas employed by each user and  $m$  is the length of pilot signal.

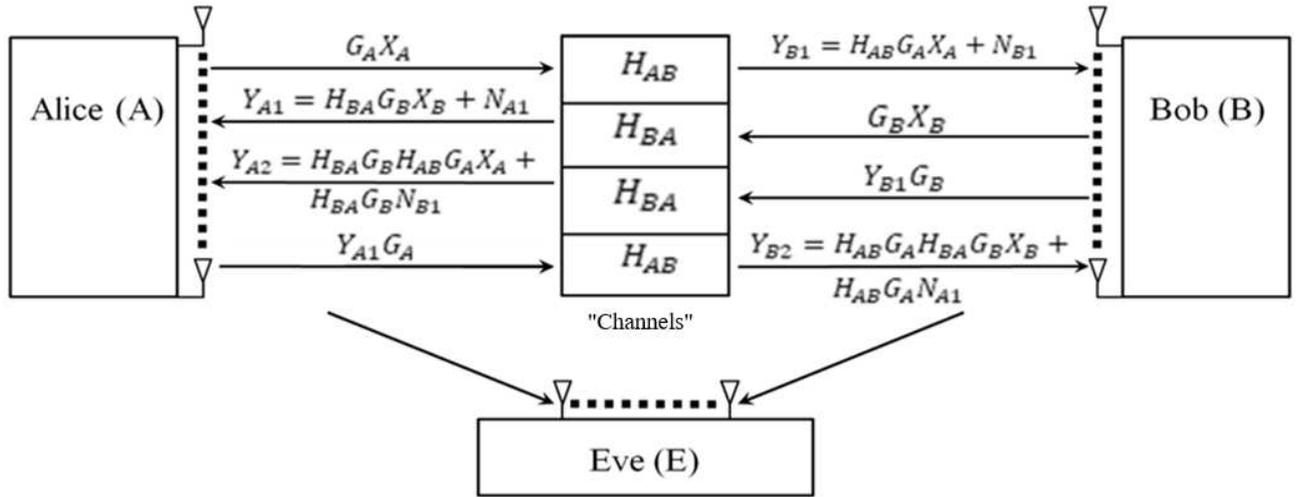

Fig. 1. The scenario corresponding to Scheme EVSKey.

Since in our case A and B are connected by constant noiseless public channels, the original channel matrices  $H_{AB}, H_{BA}$  are generated by A and B as random matrices  $(h_{ABij})_{ij}, (h_{BAij})_{ij} \sim CN(0, \sigma_w^2)$ .  $N_{A1}, N_{B1}$  are AWGN matrices  $(n_{A1ij})_{ij}, (n_{B1ij})_{ij} \sim CN(0, \sigma_e^2)$  generated by users A and B, respectively, as matrices of *artificially created Gaussian noises*. We let further  $\sigma_w^2 = \sigma_x^2 = 1$ ,  $\sigma_e^2 = \sigma^2$ . Let us introduce the following matrices:  $P = H_{BA} G_B$ ,  $Q = H_{AB} G_A$ . Then  $PQ$  and  $QP$  can be estimated by users via the least square method as:

$$PQ = Y_{A2} (X_A)^{-1} \quad (1)$$

$$QP = Y_{B2} (X_B)^{-1} \quad (2)$$

In [15] it was proved that matrices  $PQ$  and  $QP$  have the same non-zero eigenvalues. In [16], it has been proved an extension of such statement, that in fact they have the same *characteristic polynomials* (CP):

$$CP[PQ] = CP[QP] \quad (3)$$

Thus, from (3), we have that the legitimate users A and B are able to extract the same characteristic polynomials after a completion of protocol through noiseless channels although matrices  $PQ$  and  $QP$  can be different. The artificially added noises  $N_{A1}, N_{B1}$  result in errors between shared key bits extracted from quantized characteristic polynomial coefficients, eigenvalues or traces. Therefore, these errors have to be corrected by an additional procedure. Hence, the following question arises – what is the goal of adding artificial noises? The reason is a noising of eavesdropper channel in such a way that power of this noise cannot be decreased by any eavesdropper E!

But firstly we should demonstrate that E is able to intercept even noisy key bits because it was claimed in [15] that it is impossible. Unfortunately the last statement is wrong and in [16] there has been described the procedure about how E is able to intercept key bits, not necessary in the case when she has a close location to legitimate users. In fact, for noiseless channels, if E intercepts  $Y_{A1}, Y_{A2}, Y_{B1}, Y_{B2}$ , where  $Y_{A1} =$

$H_{BA} G_B X_B$ ,  $Y_{A2} = H_{BA} G_B H_{AB} G_A X_A$ ,  $Y_{B1} = H_{AB} G_A X_A$ ,  $Y_{B2} = H_{AB} G_A H_{BA} G_B X_B$ , she can compute the matrix Y:

$$Y = Y_{A2} (Y_{B1})^{-1} Y_{B2} (Y_{A1})^{-1} \quad (4)$$

(We note that pseudo-inverse matrices can be found by Penrose's procedure [17] as

$$(X_p)^{-1} = X^\dagger (X X^\dagger)^{-1}. \quad (5)$$

Here “ $\dagger$ ” is conjugate transpose. It was proved in [16] that matrix Y is *similar* to matrix  $QP$ , thus they have the same characteristic polynomials for nonsingular matrices [18].

Hence the original scheme EVSKey is useless for key sharing but fortunately it can be used as a primary protocol providing lower noisy bound for eavesdropper that cannot be decreased because it is controlled by the legitimate users.

But before we present the following part of key sharing protocol, it is important to show that both artificial noises  $N_{A1}, N_{B1}$  should be added, otherwise eavesdropper can be able to intercept the legitimate key without any errors. Indeed, let us assume that only B creates artificial noise. Then we get:

$$Y_{B1} = Q X_A + N_{B1}, \quad Y_{A2} = P Y_{B1} \\ Y_{A1} = P X_B, \quad Y_{B2} = Q Y_{A1} \quad (6)$$

Next, A extracts CP from the matrix:

$$Y_{A2} X_A^{-1} = P Y_{B1} X_A^{-1} = PQ + P N_{B1} X_A^{-1}, \quad (7)$$

whereas B extracts the key from CP of the matrix:

$$Y_{B2} X_B^{-1} = Q Y_{A1} X_B^{-1} = QP \quad (8)$$

The eavesdropper E extracts the key from CP of the matrix:

$$Y_{A2} (Y_{B1})^{-1} Y_{B2} (Y_{A1})^{-1} = PQ \quad (9)$$

Thus (3) implies that E gets exactly the same key as legitimate user B. This means that such situation has to be excluded.

### III. DESCRIPTION OF CHANNEL TRANSFORM PRIMITIVES

In the following section there will be presented the results of simulation regarding the key bit errors under the provision of two artificial noises  $N_{A1}, N_{B1}$ . If such results give advantage to legitimate users against eavesdroppers, that is  $P_l < P_e$ , where  $P_l, P_e$  are the key *basic bit error rate* (BER) for legitimate users and eavesdropper, respectively, then we

can apply privacy amplification theorem [11]. It states that such algorithm exists which provides an approaching to zero both key BER for legitimate users and Shannon information leaking to eavesdropper with the *key generation rate*:

$$R = h(P_e) - h(P_l), \quad (10)$$

where

$$h(x) = -(x \log_2 x + (1-x) \log_2 (1-x))$$

is the entropy function. But, for opposite situation when it occurs that the key BER's satisfy to inequality  $P_l > P_e$ , it is necessary to apply in advance some additional protocol (primitive) that reduces the previous inequality to opposite one ( $P_l < P_e$ ).

In [11] several examples of such primitives are given. It seems that the best of them is protocol known as "a preference improvement of the main channel" (PIMC). Let us consider the protocol PIMC in more detail, when there are two binary statistically independent symmetric channels without memory (BSC: *binary symmetric channels*): one with BER  $P_l$  and another with BER  $P_e$  and  $P_l > P_e$ . Then legitimate user A has to repeat  $S$  times each bit transmitting over main channel with BER equal to  $P_l$ . Another legitimate user B receives only such  $S$ -blocks which consist of all zeros or ones and takes corresponding decision. He informs over public noiseless channel about blocks that he has accepted and erases other blocks. It is easy to see that such protocol forms the following BER for B:

$$\tilde{P}_l = \frac{P_l^S}{P_l^S + (1-P_l)^S} \quad (11)$$

At the same time eavesdropper E intercepts  $S$ -blocks over BSC with BER  $P_e$  and controls public noiseless channels. E knows exactly which  $S$ -blocks are accepted by B. But because E's channel is statistically independent with the main channel (A→B), she should take decision about bits corresponding to  $S$ -block using *majority rule*. This means that she takes a decision that  $S$ -block carries bit "0", if this block has more zeros than ones and decision about bit "1", if the number of ones in that  $S$ -block is larger than the number of zeros. Then the BER after such decision will be for odd  $S$  the following:

$$\tilde{P}_e = \sum_{i=\frac{S+1}{2}}^S \binom{S}{i} P_e^i (1-P_e)^{S-i} \quad (12)$$

But unfortunately, it seems to be impossible to repeat bits if they were extracted from CP's of the matrices PQ and QP!

In order to avoid this problem let us modify slightly our previous protocol as it is shown in Fig. 2. We can see that just after a generation of "raw" bits from matrices PQ and QP, user B generates truly random binary string  $\gamma$  that is XOR-ed with B's raw bits  $K_B$  and it is transmitted over public and noiseless channel to user A that adds this string with her raw bits  $K_A$  in order to get:

$$\tilde{K}_A = K_B \oplus \gamma \oplus K_A = K_A \oplus \varepsilon_{AB} \oplus K_A \oplus \gamma = \gamma \oplus \varepsilon_{AB}, \quad (13)$$

where  $\varepsilon_{AB}$  is discrete noise string between raw key strings  $K_A$  and  $K_B$ . It is easy to see that in such setting the user B is able already to repeat  $S$ -times each bit of  $\gamma$  in order to perform the previous protocol. From now on we consider just  $\gamma$  as a new key string, transmitted to A over BSC with BER equal to  $P_l$ .

At the same time E, having received  $K_B \oplus \gamma$  and her raw key  $K_e$ , extracted by (4), sums these sequences up. This gives:

$$\tilde{K}_e = K_e \oplus \gamma \oplus K_B = K_B \oplus \varepsilon_{BE} \oplus \gamma \oplus K_B = \gamma \oplus \varepsilon_{BE}, \quad (14)$$

where  $\varepsilon_{BE}$  is discrete noise string between raw key strings  $K_B$  and  $K_e$ , that is equivalently to a transmission of key string  $\gamma$  to eavesdropper E over BSC with BER equal to  $\tilde{P}_e$ .

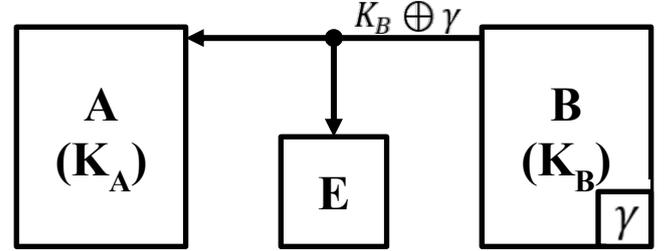

Fig. 2. Modified key sharing protocol.

#### IV. RESULTS OF SIMULATION

##### A. Using quantized matrix traces as the raw key bits

Since the traces of matrices are complex, they can be quantized both on amplitude and on phase. It was proved in [16] that the quantized intervals on amplitude of the traces providing equal probabilities of their occurrence should be chosen as follows:

$$r_{k-1} \leq |Z| < r_k, \quad k = 1, 2, \dots, N, \quad (15)$$

where  $Z$  is the trace of the matrices,  $r_k = \sigma_z \sqrt{-\ln(1 - \frac{k}{N})}$ ,  $\sigma_z^2 = n^2 \sigma_w^2 (\sigma_w^2 + \sigma_e^2) + n \sigma_e^2$ ,  $N$  is the number of intervals. In table 1 there are presented the results of BER simulation for  $N = 16$ , different values of NSR, and different matrix sizes  $n \times m$ . We see from this Table that for all parameters  $P_l > P_e$  and hence it is necessary to execute the protocol PIMC (see section III) in order to reduce to opposite situation  $P_l < P_e$ , that will be demonstrated in the sequel.

##### B. Using quantized matrix eigenvalues as the raw key bits

Unfortunately, there appears one problem in this case – how to compare the numbering of eigenvalues adopted by different users? Let us denote by  $N_p$ ,  $N_A$  the numbers of quantization intervals on phase and on amplitude respectively.

TABLE 1.

SIMULATION RESULTS OF THE BER FOR EXTRACTION THEM FROM MATRICES TRACES BOTH LEGAL USERS ( $P_l$ ) AND EAVESDROPPER ( $P_e$ ) WITH 8 SECTORS AND 8 RINGS, UNIFORM PHASE QUANTIZATION AND AMPLITUDE STEP QUANTIZATION BY (15)

$\sigma^2$ \ n/m	4x4	4x6	4x12	8x8	8x16	16x16
	$P_l, P_e$					
0.1	0.348 0.274	0.255 0.191	0.155 0.116	0.363 0.291	0.152 0.118	0.364 0.303
0.01	0.212 0.157	0.104 0.075	0.058 0.044	0.209 0.139	0.055 0.043	0.219 0.158
0.001	0.098 0.063	0.032 0.022	0.013 0.011	0.085 0.063	0.015 0.012	0.098 0.064

Let  $N = N_p \times N_A$  be total number of quantization intervals. Then we find the number of eigenvalues that hits each of the  $N$  interval (cells). After a completion of eigenvalues extraction, we get a string of integers  $g_1, g_2, \dots, g_i, \dots$ , where  $g_i$  is the number of the  $i$ -th cell containing at least one eigenvalue. If several eigenvalues occur in the same cell, then the cell number is repeated as  $g_i, g_i, \dots$ . Next each number  $g_i$  is presented as a bit string and such strings are connected in a consecutive binary manner. The final binary string forms the raw shared key. It is easy to see that the total number of bits for each session of protocol can be computed as [16]

$$\log_2 \binom{N+n-1}{n} = \log_2 \frac{(N+n-1)(N+n-2)\dots N}{n!} \quad (16)$$

In Table 2 there are presented the results of BER simulation for different matrix sizes and different NSR for eigenvalues extracted from matrices where each eigenvalue is quantized on 8 sectors and 8 rings.

TABLE 2.

SIMULATION RESULTS OF THE BER FOR EXTRACTION OF THEM FROM MATRIX EIGENVALUES BOTH LEGAL USERS ( $P_l$ ) AND EAVESDROPPER ( $P_e$ ), WITH 8 SECTORS AND 8 RINGS FOR EACH EIGENVALUE

$\sigma^2$	n/m	4x4	4x6	4x12	8x8	8x16	16x16
		$P_l, P_e$					
0.1		0.348	0.262	0.170	0.350	0.207	0.207
		0.288	0.204	0.121	0.302	0.159	0.159
0.01		0.215	0.115	0.069	0.235	0.085	0.085
		0.156	0.080	0.049	0.175	0.057	0.057
0.001		0.104	0.037	0.022	0.127	0.029	0.029
		0.068	0.027	0.014	0.082	0.021	0.021

We see from this Table also that, as before, for all BER parameters,  $P_l > P_e$ , hence it is necessary to execute the protocol PIMC in order to provide the opposite situation ( $\tilde{P}_l < \tilde{P}_e$ ). We show in the sequel how to do it.

#### V. OPTIMIZATION OF KEY-SHARING PROTOCOL PARAMETERS IN ORDER TO PROVIDE GIVEN SECURITY AND RELIABILITY

It has been proved by the *Enhanced Privacy Amplification Theorem* [19], that the eavesdropper's expected Shannon information  $I_o$  about the final key sequence shared by legitimate users, satisfies the inequality:

$$I_o \leq \frac{2^{-(k-t_c-l_0-r)}}{\alpha \ln 2}, \quad (17)$$

where  $k$  is the length of the string  $x$  generated by A and B after a completion of the protocol PIMC,  $t_c$  is the Renyi (or collision) information obtained by eavesdropper E about the string  $x$  received by E through a BSC with BER equal to  $\tilde{P}_e$ ,  $r$  is the number of check bits sent by one of legitimate users to another one in order to reconcile their string,  $l_0$  is the length of the final key,  $\alpha$  is a coefficient that approaches to 0.42 for any fixed  $r$ , as  $k$ ,  $r$  and  $k-r$  are increasing (we recall that the *privacy amplification procedure*, providing the inequality (17), can be performed in two stages: firstly with the use of a hash function chosen randomly from universal<sub>2</sub> class and, secondly, by special "puncturing" of hash string [19]).

Let us consider a scenario, that allows to optimize parameters:  $k, r, S$  (see (11), (12)) for given prior values  $l_0, I_o$

and  $\tilde{P}_{ed}$  – the probability of incorrect decoding of final key string.

1. Given  $I_o$ , find the bound value

$$k - t_c - l_0 - r = -\log_2(I_o \alpha \ln 2) = \lambda_1 \quad (18)$$

2. Calculate the value Renyi entropy [19]:

$$H_c = -\log_2(\tilde{P}_e^2 + (1 - \tilde{P}_e)^2) \quad (19)$$

3. Taking into account the relation

$$t_c = k - kH_c, \quad (20)$$

we get by (18)

$$kH_c - r = \lambda_1 + l_0. \quad (21)$$

4. In order to provide a decreasing of  $\tilde{P}_{ed}$  for bit string of length  $k$  and with execution of  $r$  check bits it is necessary to satisfy Shannon's inequality [21]:

$$\frac{k}{k+r} < C, \quad (22)$$

where

$$C = 1 + \tilde{P}_l \log_2 \tilde{P}_l + (1 - \tilde{P}_l) \log_2 (1 - \tilde{P}_l) \quad (23)$$

5. Substituting (19) into (20) and considering (21) jointly with (22) (taken as equality) it is possible to solve the linear system of equations with respect to  $k$  and  $r$ .

We can take different values  $P_l, P_e$  from simulation results (see Tables 1, 2) and, by varying the parameter  $S$  into (11), (12), to obtain the new values  $\tilde{P}_l, \tilde{P}_e$ , that would improve our protocol. For example one could increase the length of final key  $l_0$  or to make it more secure by decreasing the value  $I_o$ . It is worth to note that we do not find so far a final key reliability in terms of the value  $\tilde{P}_{ed}$  but *we only guaranty* (due to Shannon's theorem) the existence of such encoding and decoding procedures that provide an approaching of this probability to zero.

Selection of the constructive encoding/decoding procedures requires further research. Seemingly, it should be of well known class of codes like LDPC. The later approaches *the Shannon limit* for large block lengths [20]. But before we face with some examples, it is necessary to fix the value  $I_o$  by a reasonable manner. Let us present a lower bound for  $\tilde{P}_{ed}$  based on Fano's inequality [21]:

$$H(U/V) \leq h(\tilde{P}_{ed}) + \tilde{P}_{ed} \log_2(M-1), \quad (24)$$

where  $H(U/V)$  is *conditional entropy* for eavesdropper E;

$$h(x) = -x \log_2 x - (1-x) \log_2 (1-x), 0 \leq x \leq 1 \quad (25)$$

$M$  is the number of possible keys (in our case it is equal to  $2^{l_0}$ );  $\tilde{P}_{ed}$  is the probability of incorrect decoding that means a transition of the key string to another one (it is worth to note that the meaning of inequality (24) is the following: if entropy  $H(U/V)$  is large, then the probability  $\tilde{P}_{ed}$  of incorrect decoding cannot be small). The graph of the function  $\mu(\tilde{P}_{ed}) = h(\tilde{P}_{ed}) + \tilde{P}_{ed} \log_2(M-1)$  is shown in Fig. 3.

We can see from Fig. 3 that if  $H(U/V)$  is larger than some value, say  $H_0$ , then  $\tilde{P}_{ed}$  should be at least  $P_{ed}^0$  (see Fig. 3). Thus for given  $M = 2^{l_0}$  and  $I_o$ , we can find the lower bound

for  $\widetilde{P}_{ed}$  and if it occurs very close to the value  $(M-1)/M$  (the probability of a *random key string guessing*) then it is assumed that the key sharing protocol is secure. If we let  $I_0 = 10^{-3}$ ,  $M = 2^{64}$ , then  $H(U/V) = 64 - 0.001 = 63.999$ . Using the graph of  $\mu(\widetilde{P}_{ed})$  we get that  $\widetilde{P}_{ed}$  is sufficiently close to the case of random guessing  $(M-1)/M$ .

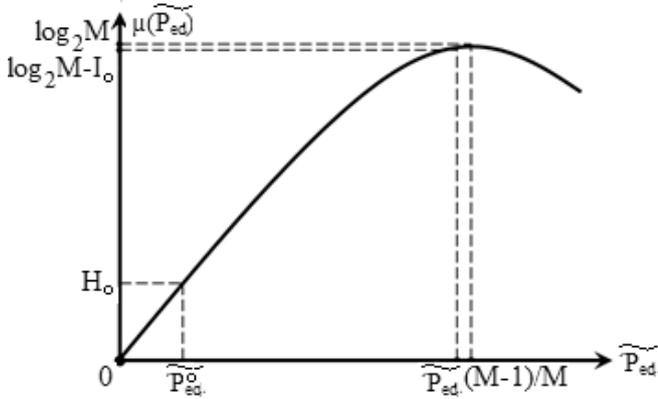

Fig. 3. Graph of function  $\mu(\widetilde{P}_{ed})$  against  $\widetilde{P}_{ed}$ .

*Examples:*

1. Let us take from Table 2 the parameters  $n \times m = 4 \times 4$ ,  $\sigma^2 = 0.1$ . Then  $P_e = 0.29$ ,  $P_l = 0.35$ . Select  $S = 5$  in (12), (13). Then we get by (12, 13)  $\widetilde{P}_l = 0.043$ ,  $\widetilde{P}_e = 0.15$ ,  $H_c = 0.425$  and  $C = 0.439$  by (20) and (24). Selecting  $\lambda_1 = 10$ ,  $l_0 = 64$  and following to the scenario steps 1÷5, we get finally for key size 64 bit  $k = 1058$ ,  $r = 374$ ,  $I_0 \leq 2^{-10} \approx 10^{-3}$ .

2. Let us take the same as in Example 1 initial parameters  $P_l$ ,  $P_e$  and the same  $S = 5$ . But let us increase  $\lambda_1$  till 30. Then we get finally  $k = 1337$ ,  $r = 472$ ,  $I_0 \leq 2^{-30} \approx 10^{-9}$ .

So we can see that it is possible to provide better security by changing protocol parameters. Because in this case the inequality (23) coincides with equality, it is necessary to decrease slightly the parameter  $k$  in order to provide approaching of  $P_{ed}$  to zero by Shannon theorem.

3. Let us increase the key size  $l_0$  up to 128, because the most of contemporary encryption standards (like GOSI-2015 and AES) have namely such key sizes. We assume the same initial probabilities  $P_l$ ,  $P_e$  as before and the same  $S = 5$ . Following to scenario steps 1÷5 we get the parameters:  $k = 2228$ ,  $r = 787$ .  $I_0 \leq 2^{-30} \approx 10^{-9}$ . We can see from this example that it is possible to share more longer key with a good security at the cost more longer error correcting code.

4. In this example we consider the case of key bit extraction from matrix traces (see Table 1).

Let us select the parameters  $n \times m = 4 \times 4$ ,  $\sigma^2 = 0.1$ . Then we can see from Table 1 that  $P_l = 0.348$ ,  $P_e = 0.274$ . Selecting parameter  $S = 7$ , we get by (12), (13) that  $\widetilde{P}_l = 0.012$ ,  $\widetilde{P}_e = 0.095$ . Following to scenario steps 1÷5 we compute for  $l_0 = 128$ , that  $k = 962$ ,  $r = 101$ ,  $I_0 \approx 10^{-9}$ .

We can see that having selected such protocol parameters  $n \times m$  and  $NSR = \sigma^2$ , we can perform a tradeoff between

security ( $I_0$ ), reliability ( $P_{ed}$ ) and error correction procedure complexity that is proportional to  $k$  and  $r$ .

In Fig. 4 there is presented a diagram of all procedures that must be executed in order to complete the key sharing protocol among legitimate users connected by noiseless, public and constant parameter communication channel. There is a new block (verification of key string authenticity) that has not been discussed before. In fact, this procedure is requested for any key sharing protocol in presence of an active adversary (eavesdropper). Otherwise the adversary can impersonate legitimate users and eventually share with them common key. It is common to use authentication method based on the so-called *short-key* [22]. The Needham-Schroder authentication protocol [23] can be used if users have initially distributed, by some trusted center, short keys.

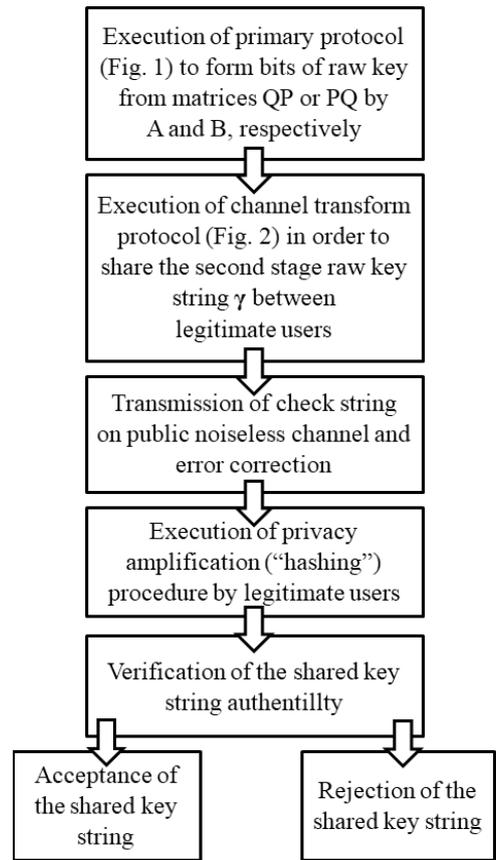

Fig. 4. Diagram of the whole key sharing protocol.

Another way is if users can provide the so-called *paring procedure* during their “face to face” meeting (like Mag Pairing or Physical vibration [24, 25]).

It is interesting to estimate (at least roughly) the length of the whole protocol (in transmitting channel bytes). Our computations show that the whole key sharing protocol requires about 100 Kbytes channel uses to produce 128 key bits.

## VI. CONCLUSION

We have proposed key sharing protocol for noiseless public constant parameter communication channels (like Internet or “Direct seen”). The main novelty of our scenario is that *it is not based on some unrealistic assumptions* like given SNR, cryptographic assumption for eavesdropper (hard factoring problem) or multipath wave propagation, that is different for legitimate users and eavesdropper. The core of our protocol is the *Scheme EVSKey* proposed in [15]. But we proved that such protocol itself is insecure. Therefore we modified it by introducing artificial noise by legitimate users that does not allow to decrease this noise power by eavesdropper. Next we apply effective procedure of privacy amplification that provides both security and reliability for legitimate users. It is worth to note that good statistical properties of the final key string follow directly from such properties of truly random generated  $\gamma$  (see Fig. 2). It seems at a first glance that the paper [26] was devoted also to a solution of the same problem as our paper. In fact, it has only one common notion – “artificial noise”, but many differences, namely:

- we consider key sharing problem, instead of secure information transmission as in [26],
- in [26] it is executed either a MIMO system in fading channels or a set of “helpers”; our protocol is used in constant parameter public channel due to information exchange between two users,
- in [26] it is created noise in “zero-space”, whereas we execute special protocol imposing to eavesdropper artificial noise,
- in [26] it is provided zero noise by “zero-forcing”, but we provide a lower bound only for noise power,
- finally, in [26] it is guaranteed only some given *secrecy capacity*, but it is unknown how to realize it, namely how to provide constructive encoding/decoding procedures? But we on the contrary calculate Shannon information leakage to eavesdropper after application of the known privacy amplification procedure and find the parameters  $n$  and  $k$  for linear error correcting codes. Next investigations in the direction of artificial noise can be found in [27, 28].

The problems for further investigation are:

- consideration of constructive error correction procedures and
- elaboration of effective authentication algorithm against an active adversary.

**Abstract**—In autonomous driving, detecting vehicles together with their parts, such as a license plate is important. Many methods with using deep learning detect the license plate based on number recognition. However, there is an idea that the method using deep learning is difficult to use for autonomous driving because of the complexity in realizing deterministic verification. Therefore, development of a method that does not use deep learning (DL) has become important again. Although the authors have made the world's best performance in 2018 for Caltech data with using DL, this concept has now turned to another research without using DL. The CT5L method is the latest type, that includes techniques of the continuity of vertical and horizontal black-and-white pixel values inside the plate, unique Hough transform, only vertical and horizontal lines are detected, the top five in the order of the number of votes to ensure good performance. In this paper, a method to determine the threshold value for binarizing input by machine learning is proposed, and good results are obtained. The detection rate is improved by about 20 points in percent as compared to the fixed case. It achieves the best performance among the conventional fixed threshold method, Otsu's method, and the conventional method of JavaANPR.

## I. INTRODUCTION

THE issue of practical use of automatic driving is discussed in ROAD2016 [1]. With the advancement of technology, the number of test cases is said to be huge and to be  $10^{12}$ . Because of this, Virtual Test becomes more important. With the addition of AI technology, this type of test case is expected to become even more extensive, and it is also pointed out that the deterministic test becomes more difficult.

With the technology that processes images obtained from camera sensors and recognizes them in the external world, many methods can be developed and studied by software development on a computer. Our group has been promoting the Samurai Project on ADAS since 2016, and has developed image processing technologies such as license plate detection, lane detection, vehicle detection, vehicle maker logo detection, front grill detection, etc. . Among them, LPD by deep learning has developed an improved method that surpasses the highest performance of the past [2]. Currently, many LPDs detect plate areas by number and character recognition.

Among the technologies related to autonomous driving, we are especially developing technologies for vehicle detection and license plate detection. In addition to vehicle detection, the significance of plate detection will be described. As a second step after vehicle detection, for example, plates, lights, etc. of the vehicle elements are individually detected. The verification of the element by this detection makes it possible to verify whether the event that detected the vehicle was correct. This can increase the reliability of vehicle detection. In the vehicle detection, as a detection result, both a correct detection of a vehicle (True Positive: TP) and a false detection (False Positive: FP) in which a non-vehicle is recognized as a vehicle are output. That is, detection of precision =  $TP / (TP + FP)$  is performed. In this equation, if the detection result of the vehicle element such as plate detection is evaluated as the reliability in the second stage processing and the false detection (FP) is eliminated, the FP value of the equation can be reduced and the precision rises. This is the significance of performing license plate detection in addition to vehicle detection.

Deep learning is also effective in license plate detection [2]. Convolutional Neural Network (CNN), which is used in deep learning, performs effective computations, but it is difficult to clearly describe the process of generating the correct result by including the multiplication of many coefficients and non-linearity. Therefore, there is a high possibility that the test of the autonomous driving vehicle using deep learning can not estimate the total number within the feasible range, which is a problem [3]. It has also been pointed out that there are problems with AI and safety assurance by the Cyber-Physical System research group and the researchers of software engineering. [4] Therefore, developing a scheme that does not use CNN is effective as one method to avoid the risk arising from such an indication.

Estimated power consumption of PCs in electric vehicles is 40% of the total increase [5], and a decrease is required. Low power consumption is desired. Methods of non-deep learning etc. are also becoming more important as a study target.

Another background is that the illegality of ANPR was pointed out in 2008 [6] [7]. The use for the crime prevention such as the police is established as a legitimate use even after that. However, there is a move that appeals to identify personal information from the number as a privacy issue, and it remains unsolved, and there is a possibility that the future controversy will continue. It is unpredictable how future laws will change, and insurance technology development and development of backup technology are necessary to cope with the uncertainty. Therefore, in consideration of the privacy problem, we have taken measures to detect the plate only from the features of the license plate without using number recognition.

In this paper, considering such background, it is characterized by examining in the range of methods that do not use number recognition and do not use deep learning such as CNN.

In our group, we are conducting research and development on practical application of automatic driving in the Samurai Project. Regarding license plate detection, Samurai Project has developed both statistical and deterministic methods, as shown in Table 1. Although Linear Regression used to determine the threshold is due to machine learning, it is a fixed factor, a finite number of realizable deterministic processes, and not deep learning. The reason that deep learning can only be performed by statistical test is considered to be due to the large number of coefficients and the fact that the circuit contains nonlinearity. Along with the development of test environment in the future, in addition to pursuing high performance using deep learning, it is also necessary to carry out technological development without deep learning and secure flexibility in technology integration .

Further structure of this paper is as follows. Section II provides the overview of the relevant works. Section III provides our number plate detection algorithm. Section IV describes machine learning tools used in this paper. Section V demonstrates the experimental results. Evaluation, Conclusions and future research directions are outlined in section VI.

## II. RELATED WORKS

### A. Methods by Conventional Image Processing

The license plate detection of a vehicle includes a method by conventional image processing and a method by recent deep learning, which are respectively useful techniques. First, as a conventional method of image processing, there is a method using Rectangle Detection by Rosito et al. [8]. They made it possible to detect a generalized rectangle including the case of tilting using the rectangle and symmetry of the rectangle in the Hough transform. This is used to detect License Plate and Rectangle-like semiconductor chips.

There is a scheme of Frequency of Luminance changes in the Vertical and horizontal direction, which has been studied by Martinsky [9]. The surface of the vehicle is flat, and in the area of the License Plate, there are large brightness changes in numbers, letters, and the like. If scanning horizontally, the place where the change is large corresponds to the plate area. Also, if scanning vertically, the plate part will be the place of large change as well.

### B. Methods Using Deep Learning

Next, we describe a high-performance method using deep learning. Zang et al use a CNN for three datasets of RGB color channels, and integrates the results by majority decision [10]. They show the advantage of three channel integration. Montazzolli et al. detect Brazilian plates using YOLO in real-time [11]. There are three stages, cropping small region around plate, detecting plate region, and character recognition on the plate by adjusting parameters of YOLO.

Dong et al. also present two-stage detection of Chinese plates [12]. At the first stage, it detects plate region using Region Proposal Network in low resolution, then replaces by a high resolution image, and detects four vertices of the plate using Faster R-CNN, then obtains corrected plate region using affine transform. At the second stage, seven STN and CNN units work in parallel for seven characters for separation and recognition.

The highest performance using Deep learning for standard dataset of Caltech is presented by Kim et al. [13], together with the search from the second to the seventh results. They use the faster R-CNN for the vehicle region detection and candidates for license plates in each detected region with the hierarchical sampling method (CNN) are generated. Finally, non-plate candidates are filtered out by training a deep convolutional neural network. Training two different CNN's for plates and non-plates, they remove FP results using non-plate CNN. For Caltech standard dataset, precision of 98.39% and recall of 96.83% are performed, which are the best world records at the time of publication 2017. But the method by our group, which was announced in

2018, surpasses the method of Kim et al. Achieved performance [2].

By improving accuracy of character recognition, a method to detect character region at the first stage without vehicle region detection has become effective. Among them, [14] is an ambitious paper using deep learning of character recognition. At the first stage, from candidate region detected by weak character detection making saliency map, rectangle plate region is detected after removing FP by two-class CNN. At the second stage, using character separation and character recognition, together with labeling results based on connectivity, numbers and characters on the plate are confirmed. In total 37 class CNN is constructed with ten numbers and 26 uppercase letters and a single non character. Region detection at the first stage should be improved, while character recognition at the second stage improves by adding connectivity process. Using ten numbers and 26 uppercase letters for CNN, the recognition rate can be advanced, though more kinds of characters are needed depending on each country specification. For the first stage of region detection of a plate, character recognition may fail to produce FP's for logos and advertisements other than plates. In the case of serial construction, total performance is a product of each performance of each stage. Accuracy of each stage must be the highest. Even in the case of so-called Coarse-to-Fine serial construction, the first stage of Coarse should not be coarse but fine in accuracy, excluding FP and removing FN.

ANPR software vendors have published Accuracy results based on image benchmarks. In 2017, Sighthound announced an accuracy of 93.6% for original images [15]. In 2017, OpenALPR's commercial software announced 95-98% accuracy rates in public images [16]. The Brazilian team announced a scheme with an average recognition rate of 93.53% in April 2018, showing a significant improvement from the 81.8% obtained in the previous paper [17].

In the paper by Silva et al. at the 2018 ECCV, an example of detection in a moving picture is shown, but in the comparison of Accuracy, the result changes depending on the data set used [18]. As quoted in Table 2-1, the data averages 81-89% with the lowest at 57-75% and the highest at 96-98%.

Looking at these results, LPD for autonomous operation is still in development, and future performance improvement is expected. In deep learning, it is expected that the amount of computation is large and thus the power consumption will also increase. According to materials of Michigan University [5], 40% of the power consumption in the vehicle is the processing of PC, and the reduction is an issue. Development of LPD by conventional image processing technology not using deep

learning adapted to such a requirement is required in the menu of the autonomous driving system. Further, a method using a technique for recognizing numbers and characters on a plate as a key is in conflict with German precedents, and a method for performing feature detection of a plate that does not perform number or character recognition is required. For these reasons, in this paper, we will develop LPD by Image Processing.

### III. PROPOSED METHOD CT5L

In addition to vehicle detection, the significance of plate detection is to individually identify vehicle elements such as plates, lights, radiators, logos, tires, window glasses, shadows, tail lamps, etc., as a second step after vehicle detection. Thus, it is possible to verify whether the event that detected the vehicle was correct. This can increase the reliability of vehicle detection (see Fig. 1). Vehicle detection includes, as detection results, both correct vehicle detection (True Positive: TP) and false detection (False Positive: FP) in which a non-vehicle is recognized as a vehicle. That is, precision =  $TP / (TP + FP)$ . In this equation, detection results of vehicle elements such as plate detection are evaluated as reliability in the second stage processing. Specifically, if detection of each element is confirmed, one point is added, and if the sum becomes larger than  $n$ , it is regarded as correct detection, otherwise it is regarded that vehicle detection is erroneous. Eliminating false positives (FPs) can reduce the FP value of the equation and

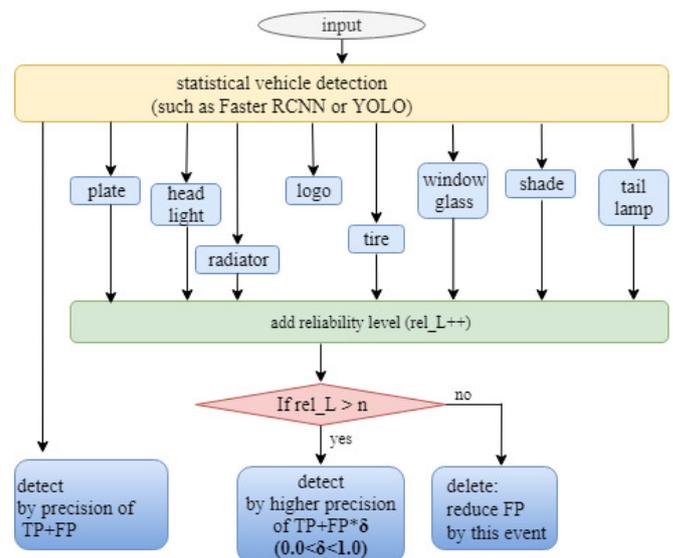

Fig.1 Integration of vehicle and element detection

raise the precision value. This is the significance of performing license plate detection in addition to vehicle detection.

We will describe the "Combining Top Five Lines (CT5L) Method" of the proposed method. This method is an improvement of the basic method presented in [19] and [20]. In the process of development, there were several branched versions, such as the oblique detection compensation method by Okunuki and the 3D compensation method by Max Geigis. In this paper, based on the examination of variations of this, we constructed a high-performance and stable method. Fig. 2 shows a block diagram of CT5L Method.

The number plate area determined from the vehicle area of the input image is compared with the threshold value and binarized (binary image). The binarized data is evaluated as to vertical change and continuation length, horizontal change and continuation length as processing before Hough transform. Based on this evaluation result, points that are candidates for plate boundaries are registered, and points that are not so are deleted (VH continuous condition).

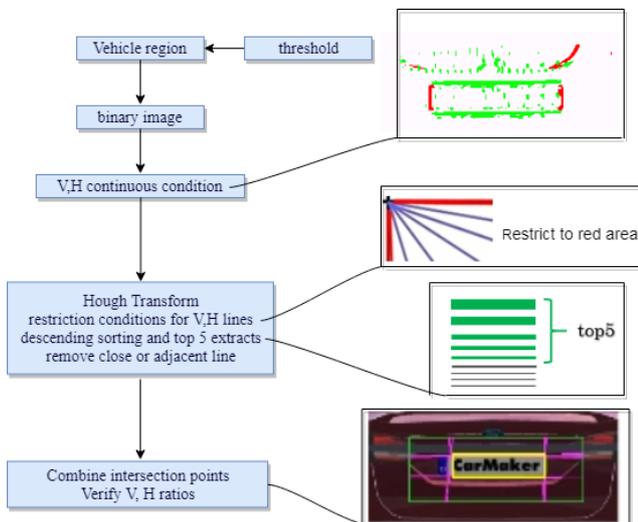

Fig.2 CT5L Method Block Diagram.

Next, Hough transform is performed in the "Hough Transform" section. The Hough transform is performed only within a range in which the angles are limited to  $0 \pm \epsilon$  degrees and  $270 \pm \epsilon$  degrees. The transform is performed only on the red area shown in Fig. 2. As a result, unnecessary calculations are not performed, and thus speeding up can be achieved. When the search range is limited to plus and minus 3 degrees, the amount of operation is reduced to  $12/360 = 1/30$ . Sorting is performed in descending order of the number of votes of distribution after transform, and the upper five lines are selected for each of vertical and horizontal. At this time, close lines may be dense, so if the absolute value of the difference between the line detected later and the upper-rank line up to that time is less than  $\delta$ , it

will be regarded as the same line and removed from the ranking process. In this way, five valid lines are extracted as candidates for the plate outline. Next, in the "Combination of intersection point", select a pair that forms a rectangle by the combination of 5 vertical lines and 5 horizontal lines, verify the aspect ratio and size, and determine the rectangle closest to the plate. If no candidate rectangle is established, no detection is made.

Fig.3 shows how plate candidate areas are extracted from the input image. The region of the vehicle is extracted as a candidate of the object region by Faster-RCNN [21] or the like. This is also demonstrated by Kido [22] and shows good results. Also, YOLO [23] can be used. The vehicle area is normalized to a size of  $400 \times 300$  pixels as shown in Fig.4. An area  $200 \times 75$  pixels including the plate candidate is set in this area. An example of the detected plate is shown in Fig.5.

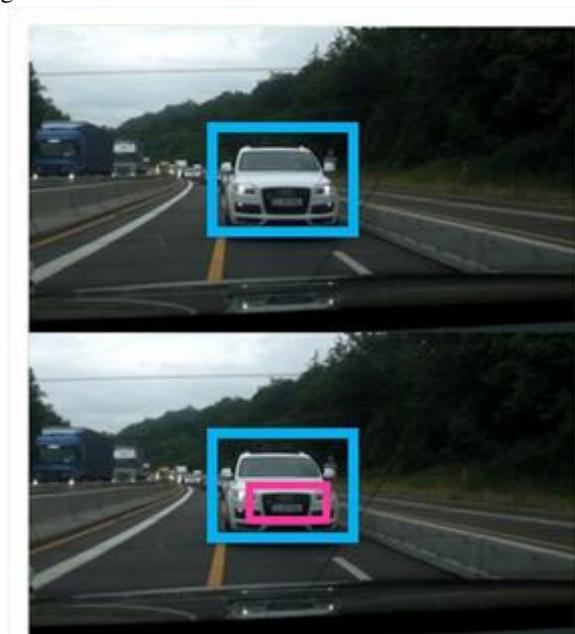

Fig.3 Vehicle area (upper) and license plate candidate area (lower).

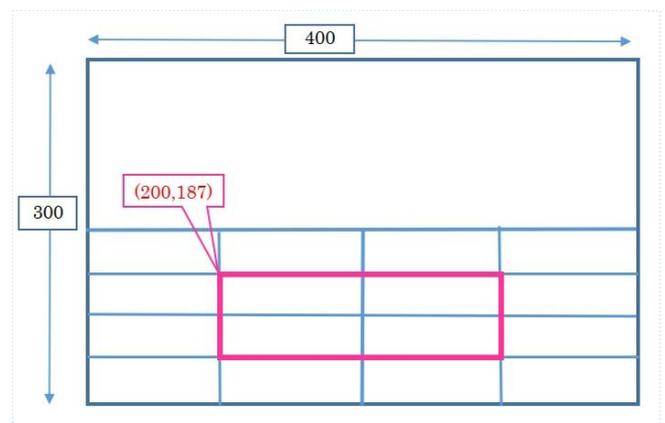

Fig. 4 Whole vehicle area(400x300) and candidate area of license plate(200x75).

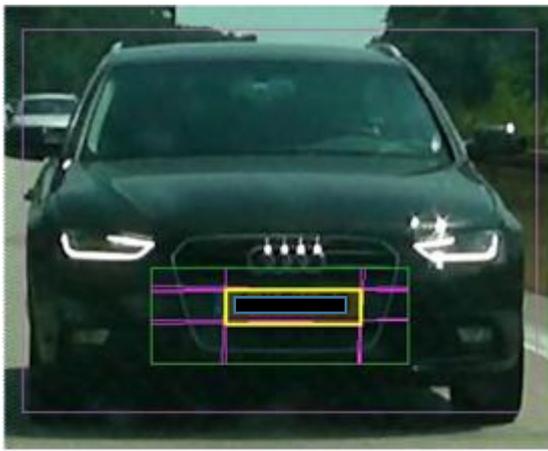

Fig.5 An example of detected plate in this paper.

IV. MACHINE LEARNING FOR THRESHOLD VALUE

Machine learning for threshold value applied to input image to get binary images is introduced. The binary images are important to be used in the following process. The threshold value was at the beginning of this project, the center value of luminance which is 127 or 128. Then, taking into account of input change of luminance, average value of input luminance or shifted average value by a fixed value are tried. But through experiments, detection ratio is affected by changing threshold values. The threshold may be affected by input environment which is beyond average luminance. To cope with this problem, automatic learning by machine learning tool is effective. In this paper a machine learning method is newly introduced to derive more effective threshold from input whole image, vehicle region image, or plate candidate region.

Fig.6 shows the upper and lower two areas of the vehicle area and the lower area divided into 16 areas. As the explanatory variables used in machine learning, the average value and the variance value of the luminance of the area numbered in Fig. 6 are used. The threshold value was changed as the correct value for supervised learning, and the value at which the software was able to detect the plate normally was allocated. Therefore, a predicted value of threshold is set as an objective function. If the correct data

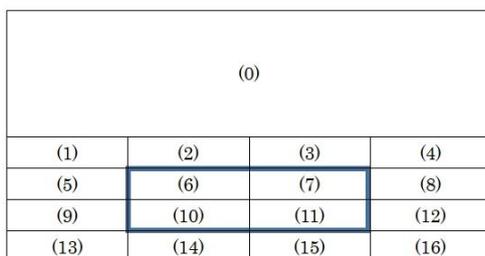

Fig.6. shows the upper(0) and lower(1)-(16) two areas of the vehicle area. The lower area divided into 16 areas.

has a width, the center value is taken as the correct value of the objective function. As a whole, machine learning system with at most 34 explanatory variables can be configured. Table 2 shows the sequence of data used. ML is a regression that predicts a threshold value, and in this case, a frequently used linear multiple regression function is used.

V. EXPERIMENTS

The experiment was divided into three types.

- (1) Basic method: In the case of a fixed threshold as the basic configuration,
- (2) ML method: When ML is introduced and threshold is automatically determined,
- (3) Otsu method: The case where the famous Otsu's method is used as a method of binarization, will be described.

As the input image, a road image taken using an on-vehicle camera and a vehicle image on the road synthesized by software for performing a virtual test were used. The road images are selected from the real images [24] on the road in the front and rear of a vehicle traveling in Europe, especially in Germany (see Fig. 5). The synthesized images were generated using IPG Automotive's CarMaker® [25], which is widely used as Virtual Test Software (Fig. 6). Images are collected that are difficult to detect. Also, the size is Hi-definition (HD: 1920x1080) standard. The correct value "thr" (in Table 2) which is teacher data was obtained by changing threshold over the entire range for each image. In this preliminary experiment to obtain correct data, the median value of the threshold value when normal plate detection can be performed is determined, and up to 66 correct data can be obtained at present(n=66 in Table 2).

Table 3 is the result of performing a detection experiment by JavaANPR of the prior art [9]. In the case of HD size, in the first column, in the second column when vertical and horizontal are reduced to 1/2, and in the third column, the vehicle region size (400 × 300) is cut out. Because we use JavaANPR's software as is in Table 3, it is not possible to compare the same lines simply with the detection situation proposed in this paper. The images used in this paper are with increased levels of difficulty, such as those that are shot in backlight, dark images, bright images, artificial synthesized images by CarMaker®, and so on. Common

road images achieved precision = 0.923 in the old version of CT5L in the experiment by Okunuki.

Table 3 results by JavaANPR [9]

	1	2	3
images	original full_size 1920x1080	quarter 960x540	cropped 400x300
TP	0.303030303	0.015151515	0.272727273

Fig.6 A car Image generated by IPG CarMaker

(1) Basic method: CT5L method was executed with threshold fixed. In the experiments up to now, as the threshold value, for example, the intermediate value (127 or 128) of luminance, a value of 95 or the like have been used in the preliminary experiment with a fixed value. In this Basic experiment, changes in the detection rate of the entire search were examined in which the threshold was changed from 0 to 255 on the obtained input image. As a result, as shown in Fig.7, using 89 as the fixed threshold value was the best result. As for the other values, it can be seen that the detection rate randomly fluctuates and gradually decreases as it gets away from 89. Also, there is a second peak at 104, 105.

Fig.7 The case of fixed threshold

(2) ML method: The implementation of ML used the Linear Regression function of Scikit-learn included in the Library of Python. The explanatory variable is extracted

from the numerical data described in Section 4, and learning is performed by Linear\_Regression. When the predicted value of threshold output as a result is included in the range of the correct answer, it is regarded as the correct answer. That is to minimize the sum of squares of errors with the correct answer. The learning used Leave-One-Out Cross-Validation method (LOOCV) [26] which is a type of cross-validation [27]. In LOOCV, one test data is separated from learning data, and all remaining data are used for learning. Using the regression coefficient after learning, test data that has been isolated without being used for learning is input, a predicted value is determined, and the accuracy rate is measured. First of all, the performance was evaluated when the explanatory variable was limited to one. This is useful because it evaluates the effectiveness of each explanatory variable and is also a source of feature variable selection in subsequent multiple regression experiments.

Fig.8 shows the result when there is one explanatory variable. Using the luminance average value as an explanatory variable is better than using the standard deviation value, and the range is about 0.46 to 0.6. COD is also better for average than that for Sd. Also, as the position of the variable, 2, 6, 10, etc. are bad, and 4, 5, 8, 9, 11, 12, 13, etc. are good in results.

he combination which takes out several explanatory variables from 34 explanatory variables becomes huge. In fact, the total number of combinations that extract n from 34 is  $2^{34}-1$ , if n = 34 from the formula  $2^n = \sum_{k=0}^n nCk$ . Taking out multiple explanatory variables is called "Feature Selection", and methods to reduce the number of searches have been studied for a long time. The method of selecting the one with good performance in the case of one explanatory variable and sequentially increasing the combination is called "Forward Method" [28]. In addition, when increasing sequentially, it is considered as a bad effect that it can not be removed after registration once, and a flexible method of adding p pieces and excluding r pieces

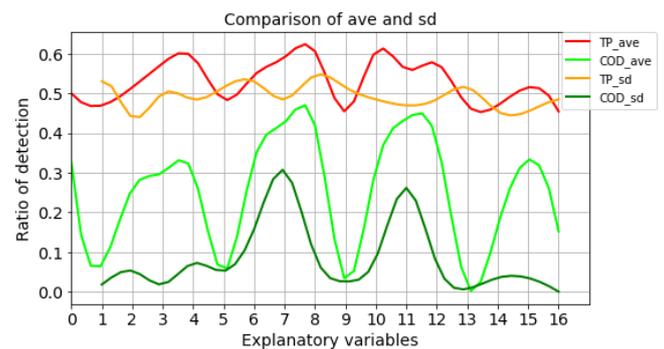

Fig.8 The case of a single explanatory variable.

For each explanatory variable, detection ratio is evaluated by average or variance. TP\_ave=True positive rate, ave means average of detection ratio, sd=Standard deviation, and COD=Coefficient Of Determination. Other than grid points are interpolated by the spline function. The same is true for the graphs below.

has been proposed as "+p-r method" [29]. Here, based on the Forward method, while increasing sequentially from the high precision explanatory variables, we will try to replace as appropriate when increasing the number. Similarly, Fig. 9., Fig. 10, Fig. 11, Table 4, Table 5 and Table 6 show the results when 3, 4, 5, 6 and 7 explanatory variables are used.

TP	0.712121212
COD	0.695194388

(3) Otsu method: There is a famous Otsu's method as a scheme of binarization. Here, image data is given, and experiments are performed in the case of plate detection using a threshold value obtained by the Otsu binarization method [29\_Otsu] as a predicted value. Otsu's method is to automatically find the optimum threshold iteratively so as to maximize the ratio of the interclass variance divided by the intraclass variance. The implementation of Otsu's binarization used the threshold function in OpenCV2. The image was given in three ways: an original image (1920x1080), a vehicle area (400x300) and a plate candidate. The fixed threshold used in the past (95, etc.) has been improved in some cases, but has not reached a good example by ML.

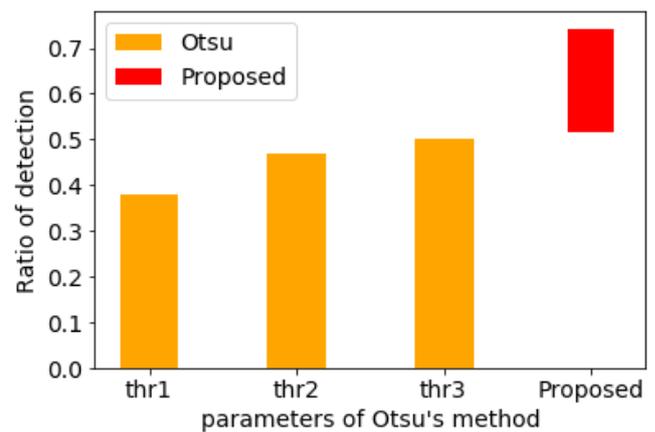

Fig. 12 ratio(TP) vs. area of threshold calculation. thr1=1920x1080, thr2=960x540, thr3=400x300.

## VI EVALUATION AND CONCLUSION

Table 7 shows the best results of for fixed threshold values case, for Otsu's automatic optimization method case and for proposed Machine Learning method case. In Otsu's

method, in addition to the automatically determined threshold value, the value when improved manually is added. In ML, the proposed method with seven variables at present is the best, and it is improved by 0.227 points in rate representation compared to the conventional fixed case.

In the field of deterministic verification, that is, in the field of the method that does not use deep learning at present, optimization of threshold is performed by fixed ML in the method of detecting features of the plate region. It is possible to construct the method which surpasses the conventional automatic optimization method Otsu Method and JavaANPR.

In the future, we will investigate the possibility of further performance improvement, such as mitigation for over-detection from the data distribution obtained during optimization. We will also incorporate and implement Virtual Test's LPD detection function as reference software.

Table 7 Comparison of the best value of three methods

	Fixed threshold	Otsu Method	ML(proposed)
param.	thr=89	thr3(200x75)	ave5,6,7,8,9,11, sd11
rate (TP)	0.515152	0.5 (automatic) 0.68(plus manual adjustment)	0.742424242

**Abstract**—Using stereo-based depth cameras outdoors on drones can lead to challenging situations for stereo algorithms calculating a depth map. A false depth value indicating an object close to the drone can confuse obstacle avoidance algorithms and lead to erratic behavior during the drone flight. We analyze the encountered issues from real-world tests together with practical solutions including a post-processing method to modify depth maps against outliers with wrong depth values.

**Index Terms**—depth camera, stereo, computer vision

## I. INTRODUCTION

In the last decade, depth cameras have become available in more affordable versions which increased the usage both in the industrial as well as in the consumer space. One interesting use case is on drones, where stereo-based depth cameras generate data for obstacle avoidance algorithms to keep the drone safe. However, the algorithms used to calculate depth information are trying to solve an under-determined problem. From two-dimensional images, data in three dimensions is reconstructed. Therefore, it seems only natural that in certain cases the generated depth images might contain wrong data as shown in Figure 1. Specifically, when used in larger outdoor environments at different weather conditions like drones would exhibit, the set of parameters and requirements might be very different from other common use cases for depth sensors as found in indoor scenarios like finger tracking or gesture recognition.

In this paper, we present the encountered challenges of using depth cameras on drones and how we overcame them. **Our contributions are:**

- Description of stereo camera issues on drones
- Solutions to minimize the encountered problems
- Release of the solutions as highly optimized open source code

In the following, we will first give an overview of related work in the space of drones with different depth cameras. Next, we describe the use case of the depth sensor on our drone and issues observed for enabling automatic obstacle avoidance. After specifying the hardware and software system, we take a look at incorrect depth values from the used depth cameras. Having all of this laid out, we provide improvements against depth outliers through a variety of methods like calibration, depth camera settings and post-processing methods.

Figure 1. The top image shows the depth map from the scene at the bottom. The colors are applied depending on the distance in meters as shown in the scale on the right part of the image. At the light gray wall with thin horizontal stripes, the algorithm of the depth sensor wrongly estimates an object close to the camera.

We compare the results of the post-processing steps and provide a performance analysis of the used algorithms. We discuss current limitations and give an outlook on further improvements. Last, we conclude and link to our open source implementation.

## II. RELATED WORK

There are various devices to measure depth to other objects. Options which have also been used on drones include ultrasonic [1], lidar [2], [3], radar [4] or depth camera-based systems [5]–[8]. While all of these have their advantages and drawbacks, we focus in this work on depth camera-based

systems due to their light weight, detailed depth information and relatively low cost.

In the category of depth cameras, we describe two very common types and their differences [9].

**Time Of Flight (TOF) cameras:** a laser or LED is used to illuminate where the camera is pointing at [10]. As the constant speed of light is known, the round-trip time of such a light signal returning to the camera sensor can be used to calculate an approximate distance. Common advantages of these depth sensors are simplicity, efficient distance algorithm and their speed. Their drawbacks show in bright outdoor usage where the background light might interfere with measurements, potential interference with other TOF devices and issues at reflections.

**Stereo-based depth sensors:** these devices are taking two images with a fixed, known offset between the two image cameras. Using stereo matching algorithms [11], [12] together with the known intrinsic and extrinsic parameters of the camera, they can generate approximate depth values for the image. Usually, these sensors consume less power compared to TOF cameras.

### III. DRONE USE CASE

To avoid accidents, injuries and crashes, it is very important for drones to avoid flying into obstacles. Depth cameras help the drone to "see" the environment. The obstacle avoidance algorithms that we use are taking the depth image from one or more depth cameras. As we know the mounted camera position and orientation on the drone and the GPS location of the drone, we transform the data from the depth image into world space. We map those depth values to 3D voxel locations. For the voxel value, we update the probability of that space to be occupied. Having the voxel map available, we check the drone's heading and velocity against potential obstacles in that direction. If we find any, we redirect to avoid a collision.

As we found in real-world usage of drones with depth sensors, there are sometimes issues that the depth values are not correct and can therefore lead to problems. For example, suddenly, a wrong, very close depth value appears in front of the drone. This might be interpreted as an obstacle to which our safety distance is not kept and strongly violated. A common reaction might be to move the drone quickly away from that obstacle or to at least not move further into the direction of the obstacle. For a drone operator on the ground observing what happens in the sky, such behavior of the drone is not comprehensive. The operator sees that there is no obstacle, yet the drone behaves in an undesired way trying to avoid invisible objects.

### IV. SYSTEM

In the following scenarios, we use the Intel NUC7i7BNH platform with the Intel Core i7-7567U (2 cores, 4 threads) at a base frequency of 3.5 GHz with 16 GB memory. Given the requirements of being able to work outside in bright environments and the goal of having a low power consumption, we decided to use a stereo-based depth sensor. The model is Intel RealSense [13] D435i with the firmware 5.11.6.250.

Figure 2. Drone with depth sensor

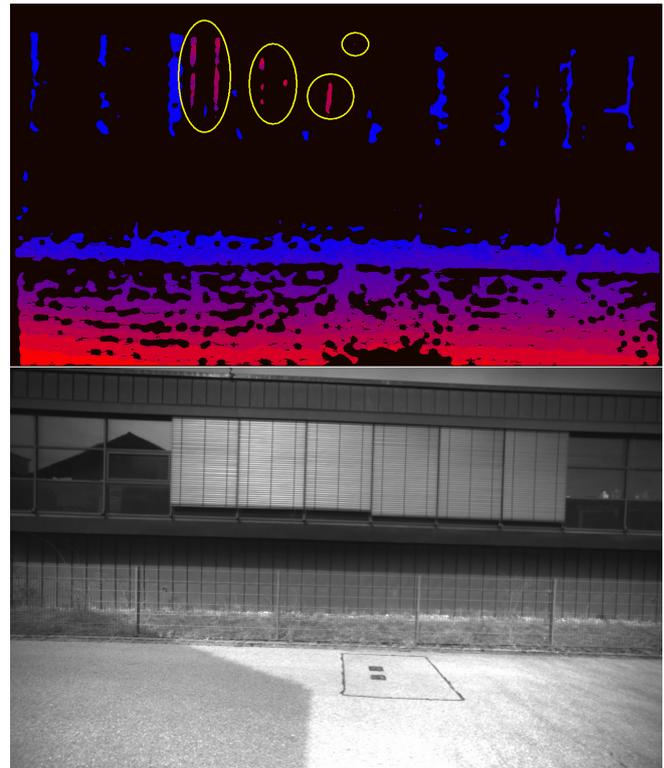

Figure 3. A case in which parts of the blinds on the windows are wrongly indicating depth which is very close to the camera. Near distances are represented in an intense red, while the farther away it gets, the coloring changes to blue.

The system runs Ubuntu 18.04 with the Intel RealSense SDK 2.0 (build 2.23.0). Some of the visualizations are generated with the RealSense Viewer 2.23.0. For image operations, we use OpenCV 3.4.5. The depth camera is mounted on an Intel Falcon 8+ octocopter (Figure 2). We use a camera resolution of  $848 \times 480$  pixels at 30 frames per second.

### V. INCORRECT DEPTH VALUES

As mentioned in Section III, we discovered some cases in which depth values in the depth map were not accurate and disturb the obstacle avoidance algorithms. Figure 1 shows one example. We provide another case in Figure 3.

Both cases have in common that there is a structure with repetitive content which can easily disturb stereo feature matching as almost the same color values are frequently repeated in neighboring areas.

## VI. IMPROVEMENTS

In this section, we provide improvements for the previously described depth maps with some incorrect depth values.

### A. Calibration

Depth cameras are shipped with a previously executed factory calibration. Due to the stress on the modules endured by a potential air freight delivery with different pressure conditions at such high altitudes and potential shaking during transportation, it can happen that physical properties of the device slightly differ from the state it was during calibration.

At least in one case we found significant improvements when running a local calibration on the device. As test setup, we used a carpet intended for children to play with small toy vehicles on it. The carpet provides strong features which can be picked up by the stereo algorithm. For this test, we used very strict camera settings which rejected depth values if their confidence was not extremely high.

For the Intel RealSense D435i camera, there are tools that allow a recalibration within a few minutes. As shown in Figure 4, this can increase the confidence in depth values and therefore provide more valid inputs. In most real-world cases the differences will not be as high as illustrated here, but this shows how important an accurate camera calibration is.

### B. Depth Camera Settings

As a guideline for outdoor depth sensing as used on drones, we prefer having fewer depth values at a high confidence compared to receiving many values which are less certain to be valid. In the RealSense D435i camera, there are various settings affecting this which can be modified through visual tools like the RealSense Viewer and can be stored in .json files. Those configuration files can be uploaded in the application via API calls. We describe the most relevant changes in the settings that we made compared to the default. To give a better understanding of the parameters on the resulting images, we show different settings in the Appendix.

**texturecountthresh, texturedifferencethresh:** These settings describe how much difference in intensity in the gray scale stereo image needs to be to determine a valid feature. In outdoor usage, the sky and clouds provide an almost similar color with only small deviations. Walls captured during inspection flights might have areas of the same color which do not make strong features. To increase the confidence on depth values, we increased the values of *texturecountthresh*, which sets how many pixels of evidence of texture are required from 0 to 4 and set the value of *texturedifferencethresh*, how big a difference is required for evidence of texture, to 50.

**secondpeakdelta:** When analyzing the disparities of an area in the stereo images for a match, there might be one clear candidate indicating a large peak in terms of correlation. In some cases, multiple candidates could be viable at different peak levels. The second peak threshold determines how big the difference from another peak needs to be, in order to have confidence in the current peak being the correct one. We increased this value from a default of 645 to 775.

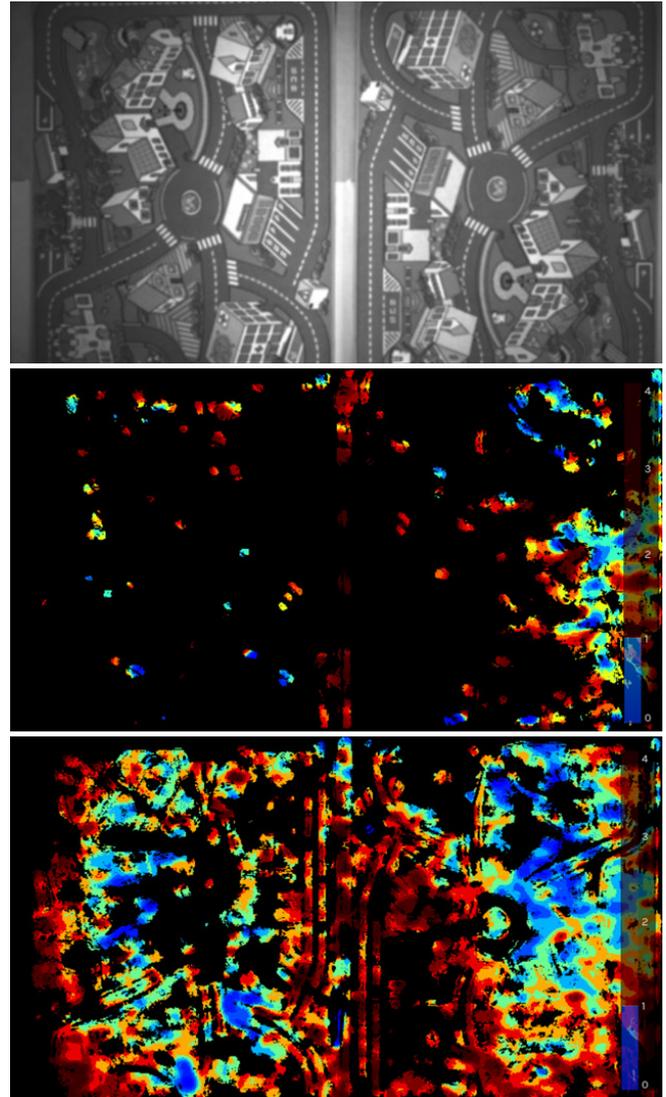

Figure 4. The top gray scale image shows the carpet for toys as target in a test setup. The middle image shows the depth values before manual calibration with camera settings for very high confidence of depth values. The bottom image shows the depth values after recalibration.

**scanlinep1, scanlinep1onediscon, ...:** For finding the best correlation form the disparities, a penalty model is used as described in [14]. In addition to estimating the validity of a current correlation, neighboring areas with their estimate are analyzed and taken into account. A small difference can be expressed in a small penalty (*scanlinep1* = 30) while a larger difference leads to a second penalty value (*scanlinep2* = 98). Both penalties are added together in an internal cost model for the likelihood of a correlation to be the correct one. Further fine tuning on large color or intensity differences between the left and right image can be set with *scanlinep1onediscon* and *scanlinep1twodiscon*.

**medianthreshold:** When looking for a peak regarding correlation, we want it to have a significantly large value

to clearly differ from the median of other correlation values. While the default is set to 796, we found that we were able to lower this value safely to 625. This did not introduce any noticeable artefacts, but made more valid depth values available.

**autoexposure-setpoint:** The autoexposure setting can be changed to deliver a darker (lower value) or brighter image. It is set to 1500 by default. For outdoor usages, we found the brighter value of 2000 to work better. Details in the sky like clouds are not relevant for us, so if this part is overexposed, it has no negative effect. On the positive side, increasing brightness makes darker objects like the bark on a tree brighter and enables better feature detection on it.

We present the full .json file with all settings in the Appendix.

### C. Post-processing of Depth Images

With a good depth camera calibration and the modified parameters, we are able to get good images with relatively high confidence features. However, for our purpose this is still not enough and cases with invalid depth values have still been observed. We tried many different other parameter settings, but in the end, we were not able to remove the outliers just through parameters without losing almost all other valid depth data. Instead, to handle the invalid depth values, we are applying post-processing steps to the received depth image. As described in [15], there are various known methods for post-processing like downsizing the image in certain ways to smooth out camera noise, applying edge-preserving filtering techniques or doing temporal filtering across multiple frames.

In our outdoor drone use case, we apply different post-processing methods. For the ones we describe, we additionally require reading out the left rectified camera image stream which is synchronized with the depth image. In our depth camera model this image is in an 8-bit gray scale format. The pseudo-code for our post-processing operations is in this listing:

```

1  const int reduceX = 4;
2  const int reduceY = 4;
3  cvResizeGrayscaleImage(reduceX, reduceY);
4  resizeDepthImageToMinimumInBlock(reduceX, reduceY);
5
6  // create edge mask
7  cvScharrX(grayImage, maskEdgeX);
8  cvScharrY(grayImage, maskEdgeY);
9
10 convertScaleAbsX(maskEdgeX);
11 convertScaleAbsY(maskEdgeY);
12
13 cvAddWeighted(maskEdgeX, maskEdgeY, maskEdge, 0.5);
14 cvThreshold(maskEdge, 192, 255, THRESH_BINARY);
15
16 // create corner mask
17 cvHarris(grayImageFloat, maskCorners, 2, 3, 0.04);
18 cvThreshold(maskCorners, 300, 255, THRESH_BINARY);
19
20 // combine both masks
21 cvBitwiseOr(maskCombined, maskEdge, maskCorners);
22
23 // apply morphological opening
24 cvMorphOpen(maskCombined, MORPH_ELLIPSE(3, 3));
25
26 // use mask on depth image
27 depthImage.cvCopy(depthImageFinal, maskCombined);

```

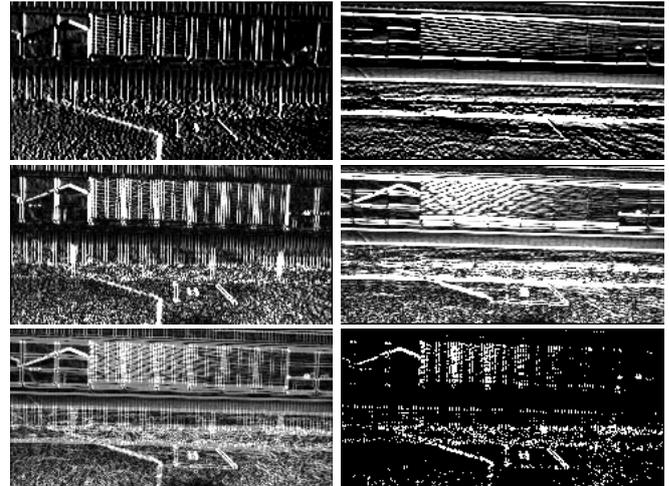

Figure 5. Steps for creating the edge mask. The top row shows the Scharr images in X and Y dimension. The second row applies the absolute function to the values from the top row. The last row shows left the added images from the middle row. On the right, it shows the final mask with the applied binary threshold function.

In the lines 1-4, we are downsizing both the depth and the camera image by a factor of four in each dimension. For the depth map, we search within a 4x4 pixel block for the closest depth value which is not zero, meaning not invalid. We take this value as the downsized pixel value. The reason for this selection is that for obstacle avoidance our most important information is which object might be the closest to us. For the gray scale image, we can use regular OpenCV downsizing. In our case, nearest-neighbor downsizing was sufficient, but, depending on the performance budget, bilinear filtering might be chosen as well. After resizing, the depth image and camera image have been lowered from a resolution of  $848 \times 480$  pixels to  $242 \times 120$  pixels. With 16 times fewer pixels, further processing on the images will be much faster.

Edges and corners are very robust features for stereo matching. To achieve even higher confidence in the depth values, we want to mask out all depth values which do not have edges or corners in the corresponding area of the gray scale image. To do this, we create an image mask for edges and one for corners. For edge detection, we use the OpenCV Scharr operator [16] as shown in lines 7 and 8 of the pseudo-code listing. For the intermediate images in X and Y dimension, we apply the absolute function and convert them into an 8-bit format (line 10, 11). We add both images together and apply a binary threshold on the mask (lines 13, 14). Using the case from Figure 3, we visualize these processing steps in Figure 5.

For creating the corner mask, we use the Harris Corner Detector [17] in OpenCV (line 17). Again, we apply a threshold in the line below. We combine the mask for edges with the mask for corners in line 21. To eliminate too small areas in the mask, we apply the morphological opening operation on the mask which applies an erosion followed by a dilation on the image (line 24). We apply the final mask to the resized depth image. Only where positive values are in the mask, the

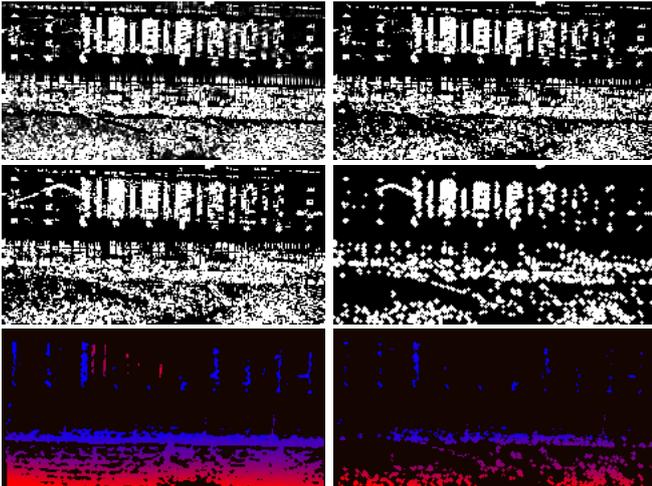

Figure 6. Steps for creating the corner mask. Top left shows the corners as detected by Harris. On the right, the binary threshold is applied to that. In the second row on the left, the combined edge and corner mask is shown. On the right side the final mask is shown after the opening function has been applied. The bottom row shows left the original, resized depth map. On the right, the mask has been applied to it. This is the final version of the depth map without outliers of wrong depth.

depth value will be copied into the final image, otherwise it will be set to zero, indicating no valid depth information (line 27). We visualize these steps in Figure 6.

#### D. Results

Using recalibration, tuning of the depth camera parameters and applying the post-processing steps as described, we got a much higher quality depth map as the example with the result in Figure 6 (bottom right) shows. A comparison between the before and after images with a resolution of  $242 \times 120 = 29040$  pixels, is shown in Table I.

Table I

COMPARING THE BEFORE AND AFTER IMAGE FROM FIGURE 6 (BOTTOM). THE FIRST NUMBER INDICATES THE AMOUNT OF PIXELS IN AN IMAGE WITH A RESOLUTION OF  $242 \times 120$  PIXELS. THE SECOND NUMBER SHOWS THE PERCENTAGE OF PIXELS IN THAT IMAGE.

	original	our method
number of depth values	7375 (25%)	2802 (10%)
number of outliers	94 (0.3%)	0 (0%)

While the image loses more than half of its valid depth information with our method, it also eliminates all outliers. As it can be seen in comparing both images, the loss happens relatively evenly across areas. For our obstacle avoidance this means that we still have enough information in these areas to be aware of potential objects in our path. To repeat the statement we made before: we prefer having fewer depth values at a high confidence compared to receiving many values which are less certain to be valid. Using our method, this goal is achieved.

We tested our method on multiple hours of log files from various drone flights. In almost all cases, we were able to

filter out wrong depth measures that would have impacted the drone’s obstacle avoidance to work correctly.

#### E. Performance

The post processing steps will increase the required compute load. We optimized our code to make use of AVX2 functions for our custom-written resizing function which we make available as open source. OpenCV, compiled with the right flags, will use AVX2 intrinsics for the relevant functions. We measured how much time the individual steps for post-processing took for processing 30 frames (the amount of frames we receive within one second from the depth camera) and show this in Table II.

Table II  
TIME IN MS FOR POST-PROCESSING STEPS FOR 30 FRAMES.

resize gray scale	1.2
resize depth map	1.5
create edge mask	2.9
create corner mask	9.3
combine masks	1.8
opening mask	1.3
apply mask	0.3

**total** 18.3

## VII. LIMITATIONS AND OUTLOOK

There are still some rare cases in which wrong depth makes it through all the suggested methods. The area of pixels with wrong depth is already much smaller with our methods. To increase the robustness against these rare outliers, we recommend using the depth data in a spatial mapping like in a 3D voxel map. Popular libraries like Octomap [18] are a good starting point. Before values are entered into such a spatial structure, it might be required to have multiple positive hits for occupancy over multiple frames and/or observations of obstacles from slightly different perspectives. In the case of drones, movement is pretty common and even when holding the position, minimal movements from wind might already change what the depth camera delivers. The position of a wrong depth value and its corresponding 3D space might change by such a small movement. As the incorrect depth values are not geometrically consistent, they might be filtered out through the spatial mapping technique.

While the performance impact of our routines is already relatively low for a modern PC-based system, the overhead might still hurt performance on highly embedded systems. In future versions of depth cameras, it might be a desired step to have our described methods directly implemented in hardware.

## VIII. CONCLUSION

In this work, we described the issues of receiving wrong depth data that was observed in some drone flights outdoors. Through proper calibration, modification of internal depth camera parameters and a series of post-processing steps on the depth map, we were able to clean up almost all outliers with wrong

depth. The resulting depth data can be used for robust obstacle avoidance with spatial mapping of the environment. Our highly optimized algorithms for post-processing are released as open source under <https://github.com/IntelRealSense/librealsense>.

#### APPENDIX

To give a better overview of the impact of changing some of the mentioned RealSense depth camera parameters, we provide examples of the resulting images from Figure 7 to Figure 11. In order to find the best matching values, this was tested and fine-tuned on various environments: natural, industrial, residential and mixtures of those. The height was varied between looking at objects almost at the same height and from a much higher perspective, e.g. 30 to 50 meters above ground. When testing different parameters on the ground, we recommend using the Intel RealSense Viewer in which the parameters can be changed in real-time through sliders to directly see the impact on the images.

**Abstract**—In the process of acoustic voice analysis, in this case of singing, it is important that the sound samples contain a stable phase of phonation. Sometimes, however, it is not possible. This study was prepared to determine how big are the differences between the values of the acoustic parameters obtained for the initial phase of phonation and for the stable phase of phonation. The values of acoustic parameters, such as, among others shimmer, jitter, RAP, PPQ, APQ, HNR or SPR were estimated for registered singing samples in the initial phase of phonation and in the middle phase. The analysis were performed over the samples of singing of the vowel 'a' recorded many times for different pitches. In the process of analyzing of the obtained results, it was found that the impact of the selection phase of phonation for analysis is crucial in assessing the singing voice quality.

## I. INTRODUCTION

**T**HE motivation for taking up the research on the singing voice acoustic parameters analysis was the need of assessment of singing quality. It may be useful for training lessons of voice production. It can be useful to help singers make a progress and it may allow for self-correction of selected voice parameters. It can be also very important for the choirs constantly working on the voice.

To analyse singing voice a must is to determine intonation or vibrato [1]. Some authors try to analyse the singing voice based on mel-cepstral features [2] or voice and speech features like Singing Power Ratio [3]. Anyway, there are many available acoustic parameters which may be investigated in the singing voice quality assessment.

One of the problems in the case of singing voice analysis is to obtain stable values of the parameters from the samples of singing. Due to the character of the singing signal envelope, it seems that determining the values based on the initial fragments of the singing recording may have an impact on the analytical process. So if it turns out that the values of the parameters from the beginning and the middle of the phrase differ significantly, it means that short signals for which a significant part is the attack and decay phase should not be applied to analysis.

During the creation of the database, the authors of this work paid attention to the quality of the samples. The recordings were carried out in appropriate conditions, the samples were subjected to precise segmentation. The samples obtained by us last for 3-4 seconds so they ensure that the middle part is the most valuable. In order to determine the analysed parameters, the samples were cut at an additional 5% from the beginning and the end. Regardless of these treatments, the authors were not sure if the samples throughout the entire run have similar quality or maybe the initial fragments are out of quality from the middle ones. This doubt was behind the undertaking of the described research and observations.

The voice, in general, is produced by a vocal instrument consisting of three elements: a breathing apparatus, oscillating vocal folds and a vocal tract. Breathing has a decisive impact on all activities related to voice emission. The entire phonation process can be represented using the ADSR (Attack-Decay-Sustain-Release) model that describes production of a single sound. It can be used for sound analysis [4], [5] and synthesis [6]. It is also the description of the sound waveform in the MIDI standard [7].

The sound attack is first part of the ADSR envelope. The attack ('on the sound') is used to modify the first phase of the amplitude envelope [8] of the generated sound, in which the sound gains the highest amplitude. This is followed by decay section during which the amplitude is reduced. As the next a sustain stage characterized by a stable pitch amplitude is visible. The ADSR envelope is completed at the release stage. The ADSR sections are illustrated in fig. 1.

The quality of singing is related to breathing. The proper breath before the phonation results in a good beginning of each phrase [9]. This is especially important in singing phrases that start with a vowel. The attack is more precise in the case of professional singers. Choral singers are less precise at this stage of voice production. The practice can solve this problem, but choir members usually develop their voice in groups, making their vocal abilities are similar in the group. It should be kept in mind that the presented investigation concerns the choral voices analysis.

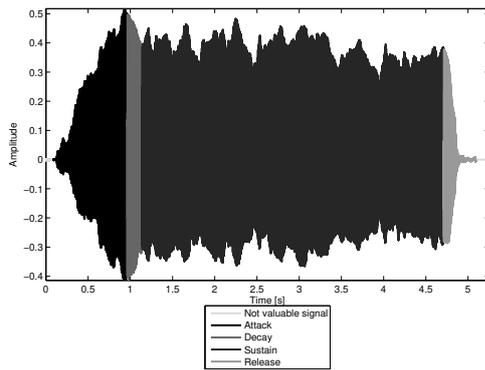

Figure 1. Example of a sung phrase divided into ADSR sections

The first phase of voice production perceived from the point of view of the ADSR envelope looks highly variable as its values increase from 0 up to the highest envelope value. However, if to take into account the physiological aspects of the human body, it will turn out that the production of sound with varying loudness and stable fundamental frequency requires a lot of effort and experience. This leads to the suggestion that greater differences in the qualitative parameters between the initial phase of voice emission and the phase with stable amplitude may be more visible in people with less vocal experience - which should also be noted when analysing the obtained values.

## II. RESEARCH CONDITIONS

The database used here was created as part of the research project of the West Pomeranian University of Technology: 'Computer methods to support the process of choral voice training' quote [10] and expanded at a later time. The content of the database allows to estimate selected parameters of the sung voice. It is possible to examine, for example, the intonation [11], the function vibrato [1], tremolo, sonority, noise [12] and other variables. It is possible to carry out more general database research, such as for example the voice quality evaluation [13], [14].

For this study, recordings containing the vowel /a/ sung on one pitch for a few seconds, were selected. In the further part of the analysis, the subsection will be the initial part of the signal and the middle part (sustain) of the samples.

The recordings used in this article were made in a specially arranged environment, with appropriate conditions for the recording session. All recordings were done with a resolution of 24 bits and with a sampling rate of 48 kHz. All singers were provided with referential signal at the beginning of recording of each sample. The process was carried out under the supervision of an expert to ensure the best quality of the samples.

The analysed group of singers consists of 16 men and 7 women. All these people have so much vocal experience that they are able to sing the sound at a given frequency. The examined persons are characterized by a varied work experience

in the team (1-20 years). The pitches range recorded for each person reflects their vocal abilities - recorded sound represents the person's voice scale.

## III. RESEARCH IDEA

The aim of the research was to confirm or reject the hypothesis that that values of the quality parameters estimated for the first part of the signal present worse quality of the singing comparing to the middle part of the signal.

To reach the goal of the study a number of acoustic (vocal) parameters can be used. Some of them are: SPR, LTAS. Another popular are: jitter and shimmer measures, harmonic-to-noise-ratio (HNR), formants (including singer's formant (SF)), Spectra Centroid, energy ratio (ER), percentual variability (PV) [15] and others.

Many of those mentioned above are used in this study. Analysing acoustic parameters we were observing a differences in values estimated for the Entry of phonation and the middle.

The chosen acoustic parameters have been estimated and analysed based on the recorded vowel /a/. The set of the estimated parameters consisted of the most recognized by the scientists in the field of voice analysis:

- Jitter,
- Shimmer,
- HNR35,
- SPR.

Above were implemented and calculated using Praat [16] (via Parselmouth [17]) and Matlab using dedicated libraries (VoiceSauce [18], YIN [19]) or our own implementations.

Jitter and shimmer are the two common perturbation measures in acoustic analysis. Jitter is a measure of frequency instability, while shimmer is a measure of amplitude instability. In Praat we have access to multiple kinds of jitters (local and local absolute, RAP, PPQ5, Jitter DDP) and shimmers (local and local in dB, APQ3, APQ5 and APQ11, Shimmer DDP)

Harmonics to Noise Ratio (estimated here in Matlab via VoiceSauce [18]) indicates ratio of harmonics values comparing to noise level. In our case HNR35 is ratio measured between 0-3500Hz.

SPR (Singing Power Ratio), for the needs of this publication, was calculated in Matlab on the basis of [20].

For each sample we omit 5% of signal from both endings of file just to be sure it contains valid signal. Remaining signal was divided equally in to five parts and for each of them we calculated total set of parameters. They were named as SET 1, SET 2 and so on. For the analysis we've chosen SET 1 which we believe is the most unstable and SET 3, which we believe that it is the most stable part of the signal in the context of parameters fluctuations.

## IV. THE RESULTS

As mentioned earlier, the study consisted in determining advanced voice parameters for acquired voice samples in the initial and middle part, and then on observing general trends.

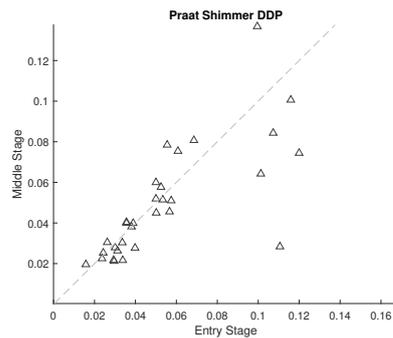

Figure 2. SET1 to SET3 Shimmer DDP relation - singer s34f

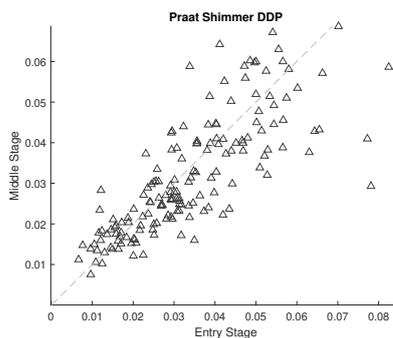

Figure 3. SET1 to SET3 Shimmer DDP relation – all females

One of the estimated parameters was the average absolute difference between consecutive differences between the amplitudes of consecutive periods (Shimmer DDP).

The shimmer DDP, similarly to other measures of this class, indicates the magnitude of changes in amplitudes of appropriate periods and can be identified with voice tremors based on small but high frequency changes in volume. This phenomenon adversely affects the quality of the voice produced. In order to check whether the SET3 presents the improvement of the DDP parameters in relation to the first set, the values from both sets were compared. In the presented figure 2, prepared for the example singer s34f, most of the Shimmer DDP values, shown in relation SET1 to SET3, are below the line determining the lack of differences/changes what can it mean, in that particular case, that the voice quality may be improved.

What is the situation for all female voices in the context of this particular parameter?

Also in the case of the Figure 3, there is a tendency to decrease values of irregularity parameters. Next, a simple statistic is presented, which consists of determining the number of 'improved' values for the analysed parameters. Table I contains the values obtained for all individuals taking part in the study.

It's shows that an improvement in quality may be observed. Particular attention should be paid to the SPR parameter, which is the ratio indicating ratio of two different formants in the Long Term Average Spectrum in the analysed signal

Table I

THE TABLE OF 'IMPROVEMENT' FOR ALL RECORDED SINGERS

	Better	Worse	Unchanged
Praat jitter (local)	666	369	16
Praat jitter (local absolute)	669	372	10
Praat jitter (rap)	579	452	20
Praat jitter (ppq5)	630	404	15
Praat Jitter DDP	579	452	20
Praat shimmer (local)	642	372	37
Praat shimmer (localdB)	654	357	40
Praat shimmer (apq3)	621	407	23
Praat shimmer (apq5)	637	371	40
Praat shimmer (apq11)	643	356	46
Praat Shimmer DDP	621	407	23
HNR35-mean	437	602	12
HNR35-std	588	439	24
SPR	627	389	26

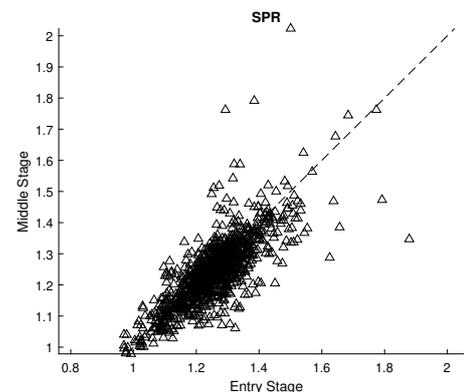

Figure 4. SPR for all singers

and is understood as an important quantitative measurement for evaluating singing voice quality for all voice types. It can be seen that this ratio improved in most of the cases. At the same time. Most of the jitter and shimmer values have been decreased, and what is more, values of the standard deviation for HNR35 have decreased. This should be considered as a simple indicator which shows that a stable part of the signal represents a signal which may have better vocal quality.

As the next, we present an 'improvement graph' for SPR values. Looking at the figure 4, it can be seen that in this case above 60% of the values has been improved. The above figures and tables show uncritical statistics and comparisons, estimated for all samples in the database. However, samples that were sung at the limit of a singers abilities should be excluded and statistics should be set again. It will also be interesting to identify changes in quality parameters only for the most comfortable samples (sung at the very centre of the vocal range).

#### A. Analysis for the comfort vocal range

An attempt was made to look at the data from which singing samples were excluded on the border of the possibilities of particular people. In the scope of sung samples, 3 samples were removed from the bottom of the range and 3 from the top of the range to analyse the range of comfortable sounds for

Table II  
IMPROVEMENT OF THE QUALITY PARAMETERS FOR THE COMFORT VOCAL RANGE

	Better	Worse	Unchanged
Praat jitter (local)	555	303	26
Praat jitter (local absolute)	537	276	71
Praat jitter (rap)	486	394	4

HNR35-std	496	370	18
SPR	525	331	22

Table III  
IMPROVEMENT OF THE QUALITY PARAMETERS FOR THE MIDDLE VOCAL RANGE

	Better	Worse	Unchanged
Praat jitter (local)	240	113	17
Praat jitter (local absolute)	234	106	30
Praat jitter (rap)	206	158	6
Praat jitter (ppq5)	222	141	7
Praat Jitter DDP	206	158	6
Praat shimmer (local)	235	113	22
Praat shimmer (localdB)	238	113	19
Praat shimmer (apq3)	232	131	7
Praat shimmer (apq5)	228	121	21
Praat shimmer (apq11)	233	123	14
Praat Shimmer DDP	232	131	7
HNR35-mean	162	204	4
HNR35-std	221	140	9
SPR	216	143	10

singers. The answer was to find out if the presence of samples in the recordings that are not comfortable for singers will have a significant effect on the overall picture of the results obtained.

The results presented in the table II show that the overall picture of the whole has not changed - all ratios have improved mostly. In order to determine the influence of border samples on the result correction, we determined the improvement factors for both situations as the ratio of corrected values to all samples (for all parameters) and compared with the results after discarding border samples. There has been a slight improvement here, which does not mean that it does not matter. In both cases a factor of over 60% was obtained, which indicates that the extreme samples do not affect the results. This may be due to the fact that the recordings paid attention to the comfort of singing and interrupted the session at the moment when singing a certain pitch of sound made it difficult.

#### B. Analysis for the middle of vocal range

In the next scenario, samples from the middle of the vocal range were selected for the study and shown in table III. In this scenario, the results increased on average by a few percentage points. Some parameters showed improved values in 70% of cases. This shows that while recording of the samples is worth to determine the most comfortable sounds to sing and choose for testing those from the centre of the vocal ranges.

#### C. Analysis for the corresponding frequencies

In the next scenario, samples from the middle of the vocal range were selected for the study and shown in table IV. The quality coefficients aggregated for selected frequencies finally confirm the hypothesis that the central part of the recording is more valuable for the analyses.

Among many qualitative parameters estimated for the recorded samples and aggregated for particular frequencies sung by the surveyed persons, for the presentation jitter (local, absolute) was chosen. As it was mentioned before, jitter is a measure of frequency instability. Differences of the values

of that parameter gives us information about differences of the quality of the signal. In the presented example, the jitter parameter (mean value) decreased in the case of the middle segment in the case for most of the investigated sung frequencies (additionally standard deviation of the parameter also decreased) so it should be considered as the final confirmation of the hypothesis that the central part of the sample, associated with the sustain phase, presents a signal with greater stability and thus better quality.

## V. CONCLUSION

The article in general concerns the subject of signal analysis and is focused on the analysis of the quality of the signal representing the voice, in particular the voice of the singers. In the process of analysing of the voice quality, as with any signal, it is important to have samples whose content faithfully reflects the examined features to the maximum. In the case of singing samples analysis, the specifics of generating this signal should be taken into account. The singing signal characteristics can be described in an approximate way using the ADSR model. It indicates that in the initial phase of voice production and in the final phase, physiological phenomena occurs (reflected in ADSR by the attack and decay phases), which may affect the analysed features. In the analysis the middle part of the stable phase should be taken into account. The problem starts when the samples are too short. Very often it happens that the people being recorded try to shorten the sung phrase. When the analysed recording is too short, the impact of the attack phase becomes noticeable, as documented in this article. All values of the analysed signals, for the most of the samples, indicated higher signal quality in the sustain phase. This is best seen in the case of the quality coefficients aggregated for frequencies. Additionally it was confirmed that samples from the middle of the vocal range are those the best reflecting the voice of the singer.

The results concerning voice quality analysis presented here may be useful for constructing a singing quality assessment system. A large number of the results obtained for this study

requires further, deeper analysis and may lead to subsequent applications.

#### ACKNOWLEDGMENT

The authors would like to thank the members of the Jan Szyrocki Memorial Choir from the West Pomeranian University of Technology who have devoted their time to recording voice samples. Thanks are also due to the experts in the field of voice emission, especially for Mr. Adam Kuliś from Study of Culture, for substantive consultations.

**Abstract**—In this paper we propose a novel system for automatic assessment of narrative answers using information retrieval algorithms. It is designed to help professors to evaluate the answers that they receive from their students. It is a Java application that communicates through a REST API. This REST API has at its core the Lucene library and exposes all the great functionalities that Lucene has. The application has one UI for the students and one UI for the professor. The student will select the professor, select the question, upload the answer and send it. The professor will evaluate the student answer using the algorithms that will be discussed in this paper. Also in this paper a series of experiments will be presented, and their result will give us a better understanding of the algorithms and have a taste of how they work.

## I. INTRODUCTION

IN our days e-learning is becoming more and more popular because of the benefits that it can offer. Because evaluating students on-line represent an important action, research in the domain has been focused on improving the on-line assessment systems, by integrating various methods for accomplishing this desire. The majority of online assessment systems have integrated numerous types of questions that can be evaluated and graded easily, based on direct matching: true/false, multiple choice, fill in the blank.

However, there is the general opinion that these types of objective tests are not enough. There are many topics, especially in the domain of human science, as well as technical domain, where the evaluation of a student cannot be complete without narrative answers. In this case, the student must formulate the answer to questions in the form of free text. Thus, it is desired for an online assessment system to integrate assessment of objective questions and narrative questions together for a complete evaluation of the students' capacity of assimilating information.

Nowadays, there is no viable method that can evaluate the answers given by the students. Having the computer understand our language and not only numbers will bring great benefit because they can process faster than us and come up with solutions in seconds rather than hours, days,

weeks or months. So we will give the computer a set of answers and compare it with the model answer which is the correct answer.

In our original work, the comparison between the student answer and the correct answer will be done by applying some information retrieval algorithms. Each algorithm will be taken one by one to investigate on how it works, how it compares to the other algorithms and what results it gives to the test data. The algorithms that will be used are Vector Space Model (VSM), Bigram and Language Analyser.

## II. RELATED WORK

In the last years, there has been research in the domain of automatic assessment of narrative answers. The results have been integrated in certain academic or commercial platforms [4], [5], [6], [7], [8], [9], [10].

A classification of these techniques can be found in [4]:

- Statistical methods
- Text Categorization Techniques (TCT)
- Information Retrieval algorithms.
- Full Natural Language Processing (NLP)
- Clustering
- Hybrid approaches that combine several techniques

Although the techniques may seem very different, the general idea that stands at the base of these systems is the same: to compare the student's answer (or candidate answer) with the teacher's ideal answer (or reference answer). The closer they are, the higher the student's score is.

There is a series of studies on the use of Information Retrieval Algorithms in automatic evaluation of free answers that indicates their efficiency in the domain. In [11] the author presents a comparative study of 5 algorithms. The model answers and student's answers are represented as vectors and then similarities between them computed by using cosine similarity. The obtained results are very satisfying. In [12] is also presented a comparison of 3 algorithms: Fingerprint, winnowing algorithms and the cosine similarity that are widely used to compare documents.

### III. SYSTEM OVERVIEW

The system has a modular architecture [2] presented in the figure 1. The user interacts with the system through the Java Application which has access to the database and to the REST API. The application modules communicate through Data Transfer Object (DTO).

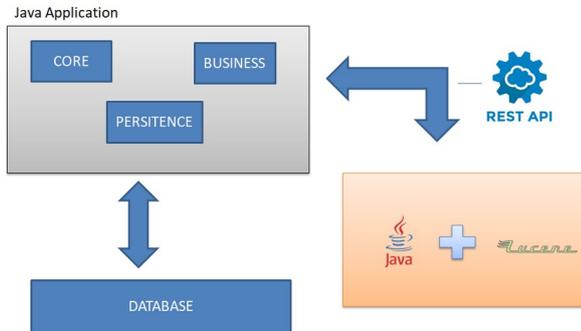

Fig. 1. Block Diagram of System Modules

A DTO is an object that carries data between processes. In other words, DTOs are simple objects that should not contain any business logic but may contain serialization and deserialization mechanisms for transferring data [3].

#### A. System Features

When the application is run the user will be prompted with a login screen and an option to register. The user will have to create a new account by selecting that option and fill up the register form.

In this system a user can have two roles. He can be a professor or a student. The application will provide to the student a combobox with the list of professors that are available. The student must select one of the professors. The selected professor will receive his answers. After this the student can choose whether to upload a file which contains the answer or insert the answer in the text area provided by the application. The student can edit his answer as long as the answer has not been send to the professor.

Once the answer is complete and the professor selected the student can now safely send the answer. The answer will be saved in the database and the professor that was selected will receive it for evaluation.

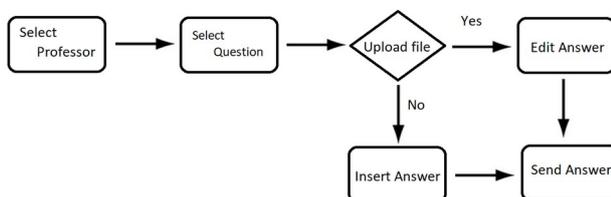

Fig. 2. Student activity diagram

The application will provide the professor with all the answers that the students submitted to him. The answers will come with the status of NOT\_PROCESSED. The professor will now choose a reference text to evaluate the answers that

were submitted. To evaluate the answers, the application will use different algorithms. But before the professor can evaluate, he must index all of the answers.

After the process of indexing is done the status for the answers will change from NOT\_PROCESSED to INDEXED and he will be able to apply all the algorithms. The evaluation is done using the three algorithms: VSM, Bigram and Language Analyser. For each algorithm there will be a separate score. The higher the score, the closer it is to the correct answer entered by the professor.

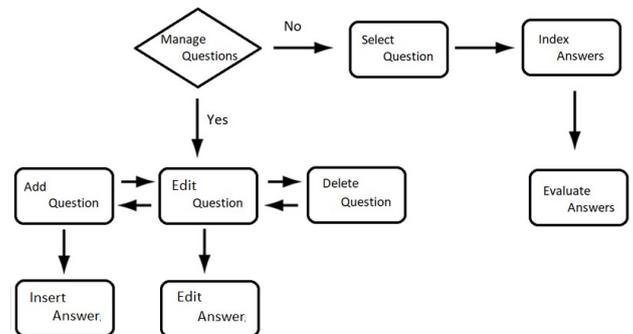

Fig. 3. Professor activity diagram

These are the high-level functionalities for the student and the professor, how they interact, what are the flows for them. Next we will take a closer look on how the index process works, how the algorithms work and all that is happening behind the scenes.

#### B. Inverted Index

Lucene uses a structure called an inverted index, which is designed to allow very fast full-text searches [13].

An inverted index consists of a list of all the unique words that appear in any document, and for each word, a list of the documents in which it appears.

To create an inverted index, we first split the content field of each document into separate words (which we call terms, or tokens), create a sorted list of all the unique terms, and then list in which document each term appears.

### IV. ALGORITHMS

The algorithms are the heart of the system. Let's have a closer look at those algorithms and see how they actually work.

#### A. Vector Space Model

Once we have a list of matching documents, they need to be ranked by relevance. Not all documents will contain all the terms, and some terms are more important than others. The relevance score of the whole document depends (in part) on the weight of each query term that appears in that document. The weight of a term is determined by three factors [1]: term frequency, inverse document frequency and field-length norm.

### B. Bigram

When words are used in conjunction with each other, they express an idea that is bigger or more meaningful than each word in isolation. The two clauses “I’m not happy I’m working” and “I’m happy I’m not working” contain the same words, in close proximity, but have quite different meanings [1]. If, instead of indexing each word independently, we were to index pairs of words, then we could retain more of the context in which the words were used. These word pairs (or bigrams) are known as shingles [1]. Of course, shingles are useful only if the user enters the query in the same order as in the original document. But this point is an important one: it is not enough to index just bigrams; we still need unigrams, but we can use matching bigrams as a signal to increase the relevance score [1].

Not only shingles are more flexible than phrase queries, but they perform better as well.

### C. Language Analyser

Full-text search is a battle between precision, returning as few irrelevant documents as possible, and recall, returning as many relevant documents as possible. While matching only the exact words that the user has queried would be precise, it is not enough. We would miss out on many documents that the user would consider to be relevant. Instead, we need to spread the net wider, to also search for words that are not exactly the same as the original but are related [1]. There are several lines of attack: rRemove diacritics like ‘, ^, and “ so that a search for rôle will also match role, and vice versa; remove the distinction between singular and plural; remove commonly used words or stop words to improve search performance; Including synonyms; check for misspellings or alternate spellings, or match on homophones—words that sound the same.

Lucene ships with a collection of language analyzers that provide good, basic, out-of-the-box support for many of the world’s most common languages [13].

## V. EXPERIMENTS AND RESULTS

We needed some datasets to test the algorithms, so for the first dataset we asked our friends to give 15 answers regarding any topic that they want. They chose “sadness”. The following text is the relevance answer: „Sadness is a normal feeling, an emotion we occasionally feel and should not be denied. Sadness is necessary; otherwise we could not appreciate the beautiful moments. It's normal not to feel good when you suffer a loss, when you're disappointed when something goes wrong.”

### A. Experiment 1

Answer: **Sadness is an emotion we sometime are feeling and should not deny it. Without those moments we will not be able to appreciate the value of the world. This pain feels like a push of the soul, it is like a hollow in the soul**

that does not let you hope for better. **It's normal to feel like this, to be disappointed when something goes wrong.**

Score: VSM(18.4), Bigram(29.3), Language Analyzer(31.6)

We see that the answer contains quite a few words compared to the relevance text. Bigram scores very high because of the two word pairing that appear in the relevance text as well as in the answer text („Sadness is”, „an emotion”, „it's normal”). Language Analyzer also gives us a high score because of the stemming function that it applies to the our texts, so words like “feeling”, “feels” are transformed to “feel”, “sadness” to “sad” and so on. Basically every word from the texts are stemmed to their root form, thus increasing the chances to find the same word multiple times.

### B. Experiment 2

Answer: **Sadness is an emotional pain we often try to hide from others. We experience beautiful moments when we are not sad. It's normal not to feel good when you suffer a loss, when you're disappointed when something goes wrong.**

Score: VSM(26.5), Bigram(52.8), Language Analyzer(47.1)

We see that this answer contains an entire phrase that also appears in the relevance text and every algorithm gave us high scores. Here we see bigram scoring very big. By having the words in the exact order as in the relevance text, bigram scores higher, informing us that this answer is very relevant.

We will not show the results for the entire dataset. We chose only the ones that are the most interesting. The other results are similar with the ones presented above, either they are very close or they are very far or they are somewhere in the middle.

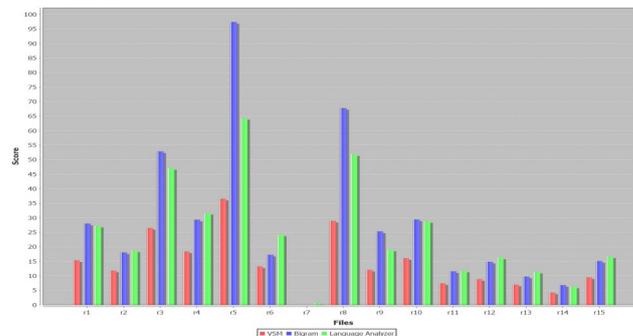

Fig. 4. Bar chart result for the first dataset

RED: VSM; BLUE: Bigram; GREEN: Language Analyser

As you can see in figure 4, for the first dataset, Bigram and the Language Analyser both perform better than VSM. This is because VSM takes into account only the words that are found in the answers, it does not perform any additional operations. Bigram searches through the answers not only with single word queries like VSM but also with pairs of 2 words, thus keeping some of the semantic for the respective

answer. Language Analyser besides using the single word queries also uses the stemming of the words, so any variation of that word will be taken into consideration. Bigram and Language Analyzer are the way to go. Each one has their strengths and weaknesses. So on our dataset, for some answers bigram scores the most and for other answers Language Analyzer scores the most.

We will now look at the physics dataset. We will present the bar chart and the relevance order that the answers have for each algorithm (figure 5).

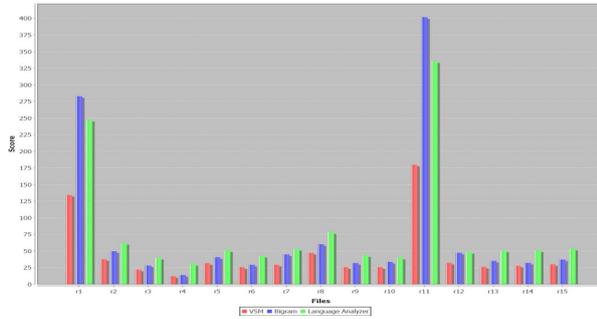

Fig. 5. Bar chart result for the second dataset

RED: VSM; BLUE: Bigram; GREEN: Language Analyser

First are VSM and Bigram. There is a big difference in the relevance order between them. By having a larger answer and a larger relevance text those results are normal for bigram, because bigram has more chances to find pairs of 2 words, thus making the answers more relevant.

Now let's look at Bigram and Language Analyzer. There are also differences in the relevance order between those two. Again this has to do with the fact that we have bigger answers and a bigger relevance text. So, the Language Analyzer is taking full advantage of its stemming operation, because a larger text means that the Language Analyzer will have more words that have the same root, thus a higher score.

The mean for each algorithm calculated from the data acquired in the 2 datasets appears in figure 6.

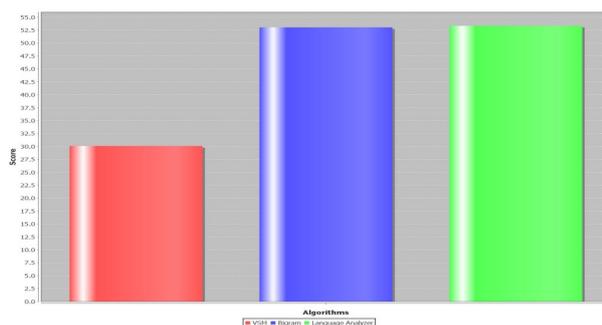

Fig. 6. Algorithms mean result

RED: VSM; BLUE: Bigram; GREEN: Language Analyser

We have the following results: VSM Mean: 30.1, Bigram Mean 53.05, Language Analyser Mean: 53.35.

As it can be seen the difference between Bigram and Language Analyser is very slim, advantage to Language

Analyser. Either one of the two can be used to automatically evaluate answers.

## VI. CONCLUSIONS

The paper presents our novel system that automatically evaluates narrative answers using information retrieval techniques. As seen in the experiments above, Bigram and Language Analyser were the algorithms that performed the best, with Language Analyser having a small advantage over Bigram. But nonetheless both of them are very good and have scored good results on our test datasets.

Even though the objective was achieved it is not yet complete. Of course we can give scores to our answers, but we want some kind of mechanism to interpret this score and give that answer a grade. Also we might look to improve the algorithms to perform even better, a solution might be to combine Bigram and Language analyzer concepts. The performed experiments have shown satisfying results. For the time being, the module is integrated in an e-learning platform, in order to further be used and evaluated by the professors.

The proposed DC Microgrid is connected to a 10-kW PV array through an unidirectional DC-DC boost average converter, capable of generating a regulated 300V DC Bus that supplies unidirectional and bidirectional DC-DC converters that control the charging and discharging of two storage power sources, Li-ion battery and Supercapacitor, and also a 2 HP 1750 rpm PMDCM - DC load.

### III. FUZZY LOGIC PID SPEED CONTROL DESIGN AND MATLAB SIMULATIONS

In this research paper the FLC is conceived as a multi-input single-output (MISO) subsystem with two inputs and one single output. The inputs of the fuzzy controller are two measured variables whose values are collected by a set of sensors integrated into a data acquisition system describing the speed error (“e”) and the rate of change of the speed error (“ce”),  $ce = \frac{\Delta e}{\Delta t}$ , from PMDCM, the choice suggested in

[5]-[6]. The both inputs are then "fuzzified" using membership functions provided by an expert operator to determine the degree of membership in each input class. The resulting "fuzzy inputs" are evaluated using a linguistic rule base and fuzzy logic operations (AND, OR, NOT) to yield an appropriate fuzzy output and an associated degree of membership [7]-[8]. The "fuzzy output" of FLC is then “defuzzified” using a “centroid” gravity method to give a crisp output response to control the input voltage of a controlled source voltage whose output provides the regulated voltage to the PMDCM armature [8].

The fuzzy logic controller (FLC) SIMULINK model it is shown in Fig. 2.

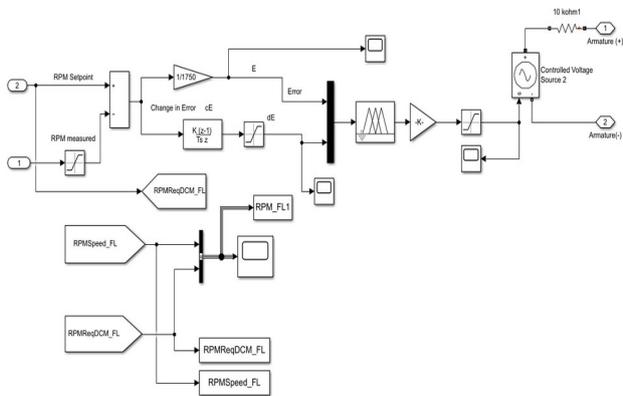

Fig.2 The Fuzzy Logic controller SIMULINK model

As it is shown in Fig.2, the inputs of the FLC, i.e. the RPM PMDCM speed error (E) and the rate of its change (cE), are converted into fuzzy linguistic variables. They are divided into a finer fuzzy partition with seven terms as it is suggested in [5]-[7], namely negative big (NB), negative medium (NM), negative small (NS), zero (ZO), positive small (PS), positive medium (PM) and positive big (PB). The range of the both inputs is [-1750 1750], and for output voltage is [-300 +300]. The universe of discourse of error,

rate of error and output is normalized to [-1, 1]. The Fuzzy Logic Designer block used to implement the SIMULINK FLC model specified in Fig. 2 it is shown in Fig. 3, where the membership functions for all two inputs and the output are represented with triangle-shaped function that it is shown in Fig. 4.

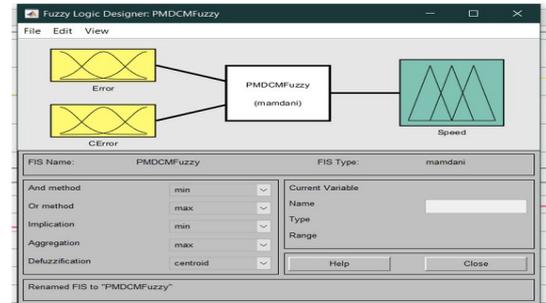

Fig.3 The Fuzzy Logic Designer block

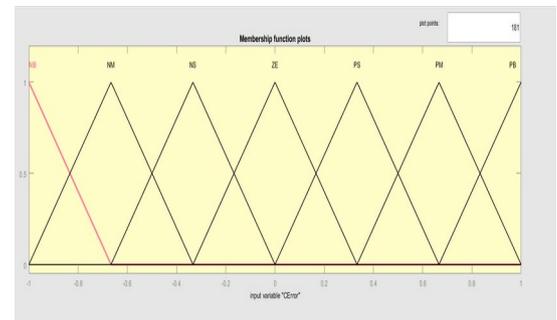

Fig.4 The membership function used for both inputs and the output of Fuzzy Logic controller

The optimal performance of the FLC design it is well depicted in 3-dimensional space of both FLC inputs and its output by a surface view shown in Fig. 5. The MATLAB simulation results of RPM FLC PMDCM speed control for a step response are shown in Fig. 6, and its robustness to changes in tracking setpoint and load torque it is shown in Fig.7.

In Fig.6 it is revealed a great performance for FLC RPM speed, a very short rising and settling time, and also a very good tracking accuracy.

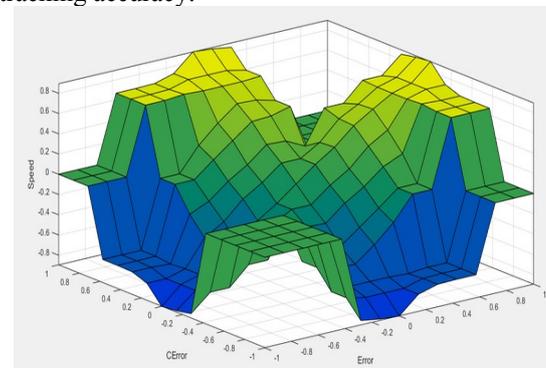

Fig.5 The surface view of the optimal performance of the Fuzzy Logic controller

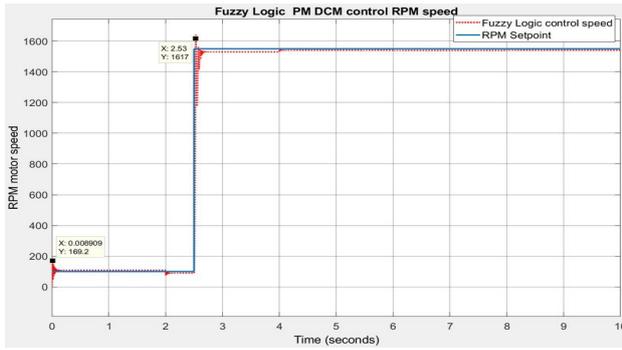

Fig.6 The FLC performance of RPM control speed versus PMDCM RPM tracking setpoint

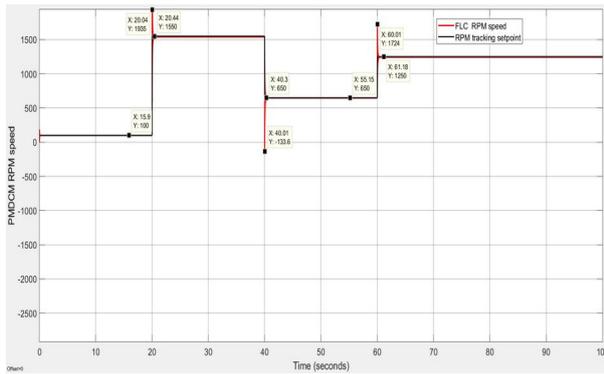

Fig.7 The FLC performance of RPM control speed versus the changes in PMDCM RPM tracking setpoint

In [9] it is suggested a combination of PID and FLC in a new structure FLPID, as it is shown in Fig.8.

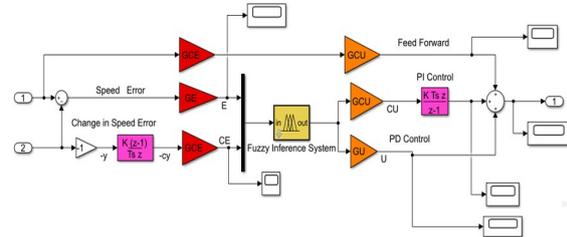

Fig.8 The Fuzzy Logic PID controller SIMULINK model (see [9])

As it is suggested in [9] the scaling factors of Fuzzy Logic PID that it is shown in Fig.8 are calculated based on PID tuned optimal values of control parameters,  $k_p, k_i, k_d$  using the advanced SIMULINK PID block option. Thus, the PID are set up for the following optimal values of parameters:

$$k_p = -2.047, k_i = -14.7, k_d = -0.0487, T_s = 0.1 \text{ that lead}$$

to the following values of the scaling factors [8]:

$$GE = 1750, GCE = GE * (k_p - \sqrt{k_p^2 - 4 * k_i * k_d}) / 2 / k_i = 190.4049$$

$$GCU = k_i / GE = -0.0084, GU = k_d / GCE = -2.5577e-04, K=1$$

The overall performance of the Fuzzy Logic PID controller it is shown in Fig. 9.

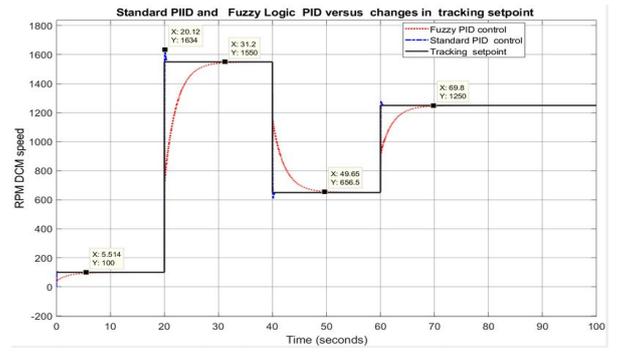

Fig.9 The Fuzzy Logic PID RPM control speed performance versus standard PID control

#### IV. PMDCM SPEED CONTROL STRATEGIES PERFORMANCE ANALYSIS

A comparison of MATLAB simulations results for the proposed PMDCM speed (RPM) control strategies, i.e. PID, FLC and their combination FLCPID, in terms of tracking accuracy, rise and settling time responses, as well as robustness to changes in tracking reference value and load torque are shown in Fig.10.

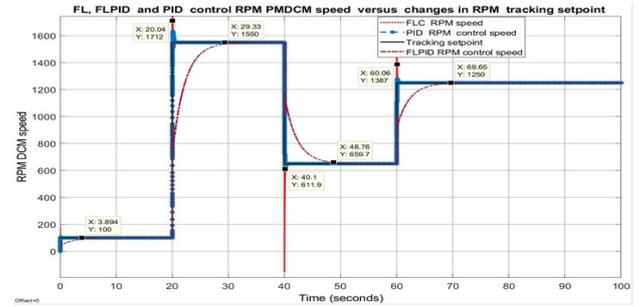

Fig.10 The PID and FLC performance of speed (RPM) control versus the changes in PMDCM RPM tracking setpoint

In the following figures Fig.11, Fig.12, and Fig. 13 there are shown the PMDCM armature current, armature voltage and the load torque profile for the combined speed (RPM) control Fuzzy Logic PID, more smooth compared to those obtained for PID and FLC separately. Also, a rigorous analysis of the performance in terms of tracking accuracy, rise time and settling time responses, and the robustness to changes in tracking setpoint and load torque indicates that PID and FLC control strategies perform slightly better compared to FLCPID, but the last one acts much smooth during the transient than first two control strategies, more useful for such of kind of applications.

#### V. CONCLUSION

In this research paper we developed a 10-kW Microgrid of 300V DC bus connected to a PV array that supplies power to a 2 HP 1750 rpm PMDCM, two storage power sources such as a Li-Ion battery and a Supercapacitor. The PV array is connected to DC Microgrid thru a DC-DC boost average

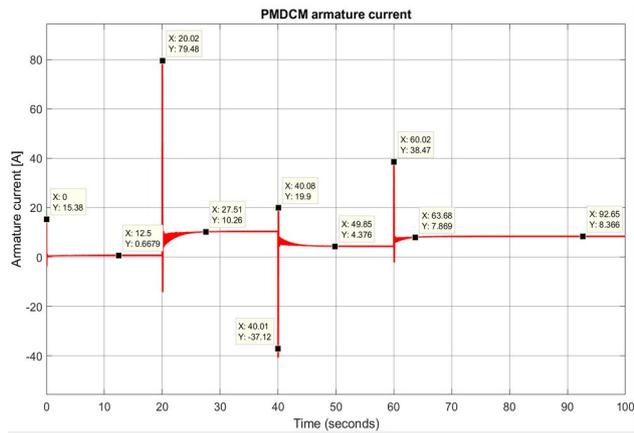

Fig.11 PMDCM armature current

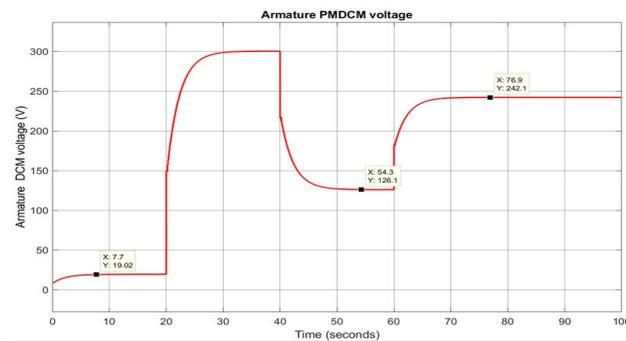

Fig.12 PMDCM armature voltage

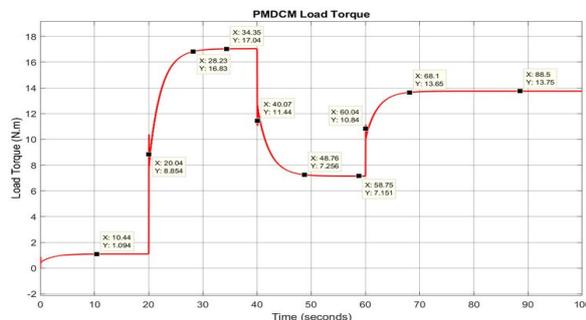

Fig.13 PMDCM load torque

converter controlled by an MPPT implemented by using the simplest PandO technique. The PMDCM is connected as a DC load thru a monodirectional DC-DC boost converter, and the both storage power sources thru two bidirectional DC-DC boost-buck converters. The investigation it was focused to develop for the proposed PMDCM a Fuzzy Logic speed control approach, and also a hybrid combination of the both control strategies, known as Fuzzy Logic PID controller.

The effectiveness of the proposed control strategies it was proved by intensive MATLAB simulations conducted on a MATLAB 2019a platform and SIMULINK. For future work we will be focused to extend the implementation of FLC and of the hybrid FLCPID control structure on a variable speed airflow fans used in a single zone or multi-zone VAV HVAC applications.

**Abstract**—Police and various security services use video analysis when investigating criminal activity. One typical scenario is the selection of object in image sequence and search for similar objects in other images. Algorithms supporting this scenario must reconcile several seemingly contradicting factors: training and detection speed, detection reliability and learning from sparse data. In the system that we propose a combined SVM/Cascade detector is used for both speed and detection reliability. In addition, object tracking and background-foreground separation algorithm together with sample synthesis is used to collect rich training data. Experiments show that the system is effective, useful and suitable for selected tasks of police surveillance.

## I. INTRODUCTION

**P**OLICE and various security services use video analysis when investigating criminal activity. Long surveillance videos are increasingly searched by dedicated image analysis software to detect criminal events, to store them and to initiate proper security actions (see e.g. the P-REACT project [1]). Solutions to automatic analysis of surveillance videos seem already to be mature enough, as the research community is recently also involved in major benchmark initiatives [2], [3]. The computer vision research focus is now shifted to the analysis of video data coming from handheld, body-worn and dashboard cameras and on the integration of such analysis results with police- and public-databases.

In typical object detection scenarios, there are much data to learn from and major objective is to use them in effective manner. In a security-oriented environment the user interaction should be kept as simple as possible and preferably limited only to marking single object in a selected image frame and initiating search to find occurrences of similar objects in other frames of the processed sequence or other sequences. This imposes several constraints on the Machine Vision solution that need to be addressed.

First of all the system should learn on-line or nearly on-line. Secondly - the system must perform per-frame detection quickly and provide approximate results in short time. And thirdly - to system must be able to learn from sparse data.

In this paper, an effective and time-efficient algorithm for instance search and detection in images from handheld video cameras is proposed. The system uses a discriminative approach to differentiate the object from its foreground. In order

This research was funded by NCBiR Agency, Warsaw, under BLOWIZ project, grant number DOB-BIO7/18/02/2015. The manuscript preparation was supported by statutory funds of the author's home institution (WUT).

to do so a combined Haar-Cascade detector and SVM classifier are used. We argue that this provides a very attractive trade-off between detection quality and training/detection times. Both the positive as well as negative samples are extracted only from training images.

Comparable detector solutions based on CNNs provide excellent detection performance [4]. Such solutions, however, rely on off-line training and training/detection speed is still a bottleneck for such systems. This effect is to some extent ameliorated by GPU utilization. Recent developments aim at reduction of detection times e.g. by cascading CNNs [5] or by detecting salient regions first using fuzzy logic [6] but significant reduction of training time is still an open area of research.

One contribution of the paper is the procedure of collecting as much realistic training data as possible providing limited user interaction. Ideally the system should be able to learn from a single ROI selection, all additional examples should be obtained automatically. Such least-user-effort approaches were already discussed e.g. for semi-automatic video annotation and detection systems, such as [7], [8]. In the cited approach, however, the user may be asked to annotated video several time (to decide about samples lying on decision boundary) which is not necessarily acceptable for all end users. An example of another successful detector that works on a single selection is given in [9]. The detector operates on sparse image representation (collection of SIFT descriptors) so it is very fast. Our initial experiments have shown that descriptor-based approaches works the best for highly textured and fairly complex objects.

The procedure of collecting training data given in this paper combines object tracking and background subtraction methods for semi-supervised collection of training windows together with foreground masks. The samples collected during tracking are further synthetically generalized (augmented) to enrich the training set. Scenarios, where tracking results are utilized for the collection of detector's training data, were already covered in literature, especially regarding tracking, with prominent examples [10], [11] or more recent CNN approaches [12], [13]. In such approaches the exact foreground-background separation (which is crucial for effective samples synthesis) is often neglected, since the algorithms typically have enough frames to collect rich training data.

The proposed methods were evaluated on a corpus of

surveillance videos and proved that its efficiency is good enough to be effective in supporting a user (police officer or security official) in their common working tasks.

The paper is organized as follows: in section II there is given a technical background and methodology used in our system, section III provides experimental results and IV contains conclusions. For reader's convenience Table I provides a short dictionary of abbreviations used in the paper.

## II. METHODS

### A. Detector overview

In the system described in this paper we utilize a classic detection framework, where a sliding window with varying sizes is moved over each frame and for each location the selected image part is evaluated against information gathered from training samples. A crucial part of the detector is formed by a SVM classifier which is responsible for evaluation of each selected image part. A pure SVM classifier when applied to hundred of thousands candidate areas would be too slow to learn and detect, so in our scenario so pre-classification step utilizing HAAR-like features-based cascade classifier is applied to limit the number of candidate windows to about several hundreds. We claim that this simple structure combines good detection rate together with acceptable detection speed (about 10 full-HD frames per second on modest Core i5 computer) as well as fine training speed in typical scenarios (up to few minutes).

In essence the two-stage detector architecture resembles some significant modern CNN approaches, where the detection is divided into region-proposal part and the region recognition part (see: e.g. [14]). In our approach region proposal is performed by cascade classifier, and final classification is done by SVM classifier. Both methods offer reasonable training and detection speeds required for this application.

In our scenario sources of data are naturally sparse. Depending on user decision the detector can be trained either on one or a short sequence of training images. Therefore a

critical part of our system are tools aiding user in an effortless collection of training examples from short image sequences as well as methods for artificial synthesis and generalization of training samples to provide the detector with the training data as rich as possible. These tools and methods are discussed in subsequent sections. The overall structure of the training procedure is given in Fig. 1.

### B. Collection of positive training samples

Although for some patterns (which include e.g. flat patterns) good detection results can be obtained using only one selected sample that is further generalized and synthesized into a set with larger variability, in most cases detection results highly depend on size and diversity of input training set. In the scenario discussed in this paper these properties of the training set can (at least partially) be achieved by collecting samples from a short sequence of input images. Our scenario is organized as follows: (1) a user select object of interest using rectangular area, (2) the application tracks the object in subsequent frames of the sequence (with optional manual reinitialization), (3) object foreground masks are established using motion information.

1) *Object tracking and foreground-background separation:* For tracking of rectangular area an optimized version of CSK tracker [15] that utilizes color-names features [16] is used.

As a result of the tracking procedure we obtain a sequence of rectangular areas that encompass the object of interest in subsequent frames. In most cases both object foreground as well as background will be present in the tracked rectangle. However, if the object is moving against moderately static background we can exploit motion information to effectively separate object foreground from background by background subtraction.

Let the tracking results be described by a sequence of rectangular areas  $\{R^1, \dots, R^T\}$  and let us denote coordinates of pixel  $i$  as  $p_i$ , color attributes for pixel  $i$  at time  $t$  as  $c_i^t$  and a mean of color attributes in the background as

$$\bar{c}_i = \frac{1}{n_i} \sum_{t: p_i \notin R^t} c_i^t \quad (1)$$

where averaging factor  $n_i$  is the number of frames where tracking window does not contain pixel  $i$  and can be computed as  $n_i = |\{t : p_i \notin R^t\}|$ .

Now we can specify a background training sequence for each pixel  $\{\hat{c}_i^t\}$

$$\hat{c}_i^t = \begin{cases} c_i^t & \text{if } p_i \notin R^t \\ \bar{c}_i & \text{if } p_i \in R^t \end{cases} \quad (2)$$

In accordance with the rule above, only pixels that at given time-step do not belong to the tracked area contribute to the background model computed for the image. Each pixel that always belong to tracked area is conservatively treated as foreground.

The background model adopted here follows algorithms from [17]. In this method scene color is represented independently for all pixels. The color for each pixel (both from

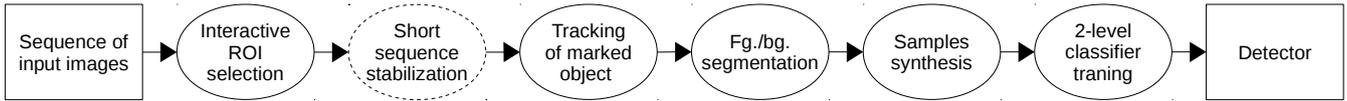

Fig. 1: Structure of the training procedure

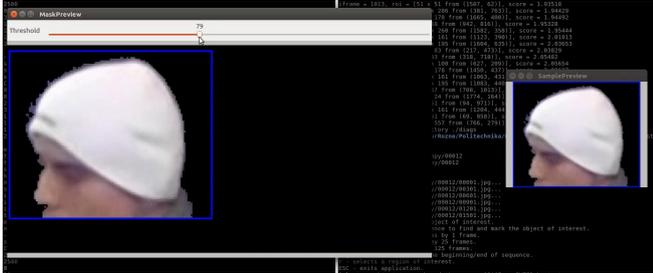

Fig. 2: Results of automatic foreground-background separation

Fig. 3: Division into a positive (P) and negative (N1-N4) examples

background and foreground  $BG + FG$ ) given the training sequence  $C_T$ , is modelled as:

$$p(c_i | C_T, BG + FG) = \sum_{m=1}^M \hat{\pi}_m \mathcal{N}(c_i; \hat{\mu}_m, \hat{\sigma}_m) \quad (3)$$

whereas the background model ( $BG$ ) is built from the selected number of largest clusters in the color mixture

$$p(c_i | C_T, BG) = \sum_{m=1}^B \hat{\pi}_m \mathcal{N}(c_i; \hat{\mu}_m, \hat{\sigma}_m) \quad (4)$$

where  $\hat{\mu}_m, \hat{\sigma}_m$  are estimated means and standard deviation of normal components in the mixture,  $\hat{\pi}_m$  are mixing coefficients  $M$  is the total number of mixtures and  $B$  is the selected number of foreground components. The pixel is decided to belong to the background when

$$p(c_i | BG) > c_{thr} \quad (5)$$

Threshold  $c_{thr}$  can be interactively adjusted by the user. Exact algorithms for updating mixture parameters are given in [17]. Sample result of background subtraction procedure is given in Fig. 2

2) *Image stabilization in a short sequence*: The foreground-background segmentation procedure works best when stable camera position is available or image sequence is stabilized before segmentation. The system proposed here uses a simple stabilization procedure basing on matching of SURF features [18] and computation of homography transformation between pairs of images. The stabilization works on short subsequences of the original sequence. First frame to stabilize is the frame used for marking the initial region of interest. The procedure then aligns all subsequent frames to the first frame by evaluating homographies relating two images. In order to do so, matching methods from [19] and the Least Median of Squares principle [20] is utilized. To increase stabilization efficiency GPU-accelerated procedures for keypoints/descriptors extraction and matching from OpenCV library are utilized [21].

### C. Collection of negative training samples

Negative samples that are used in detector training are extracted from the same sequence images that positive samples originated from. For each training image one fragment is used to extract positive sample, while the remaining part of the image is divided into at most four sources of negative samples as given in Fig. 3. Thus, an assumption is made that these remaining parts of the training sequence images do not contain positive samples. This assumption is not always valid, but may be strengthened by asking a user to mark **all** positive examples in the training sequence.

### D. Positive samples generalization and synthesis

1) *Geometric generalization*: In this step 3D rotations of patterns and their masks are applied to collected pattern images and their masks. It is assumed that patterns are planar, so this generalization method can be useful only to some extent for non-planar objects. The rotation effect is obtained by an applying a homography transformation, imitating application of three rotation matrices  $R_x(\alpha), R_y(\beta), R_z(\gamma)$  to a 3D object. The matrices correspond to rotations around  $x, y$  (in-plane rotations) and  $z$  (in-plane rotation) axes correspondingly. 3D rotation matrices are defined classically

$$\begin{aligned} R_x(\theta) &= \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos \theta & -\sin \theta \\ 0 & \sin \theta & \cos \theta \end{pmatrix} \\ R_y(\theta) &= \begin{pmatrix} \cos \theta & 0 & \sin \theta \\ 0 & 1 & 0 \\ -\sin \theta & 0 & \cos \theta \end{pmatrix} \\ R_z(\theta) &= \begin{pmatrix} \cos \theta & -\sin \theta & 0 \\ \sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{pmatrix} \end{aligned} \quad (6)$$

To compute the transformation, first a homography matrix is computed using formula

$$H = R - \frac{\mathbf{t}\mathbf{n}^T}{d} \quad (7)$$

where  $\mathbf{n}$  is a vector normal to the pattern plane (we set it to  $\mathbf{n} = (0, 0, 1)^T$ ),  $d$  is the distance from the virtual camera to the pattern (we set it arbitrarily to  $d = 1$ , since it only scales 'real-world' units of measurement) and  $R$  is the 3D rotation matrix and can be decomposed as

$$R = (R_x(\alpha) \cdot R_y(\beta) \cdot R_z(\gamma))^{-1} \quad (8)$$

In order for the image center (having world coordinates  $C = (0, 0, d)^T$ ) to remain intact during transformation we define 'correcting' translation vector as

$$\mathbf{t} = -RC + C \quad (9)$$

Then we can specify artificial camera matrices as  $K_1$  and  $K_2$

$$K_1 = \begin{pmatrix} f & 0 & c_{in}^x \\ 0 & f & c_{in}^y \\ 0 & 0 & 1 \end{pmatrix}, K_2 = \begin{pmatrix} f & 0 & c_{out}^x \\ 0 & f & c_{out}^y \\ 0 & 0 & 1 \end{pmatrix} \quad (10)$$

where  $(c_{in}^x, c_{in}^y)^T$  and  $(c_{out}^x, c_{out}^y)^T$  are pixel coordinates of input and output image correspondingly, while  $f$  is the artificial camera focal length given in pixels. In this application we set  $f$  to be  $f_{mul}$  times larger input image dimension. Multiplier  $f_{mul}$  decides about the virtual distance of our virtual camera to the object. Smaller values introduce larger perspective distortions of the transformation, larger values introduce smaller distortions. We arbitrarily set  $f_{mul}$  to 10 implying only slight perspective distortions.

The final homography transformation applied to the pixels of the input image is given by

$$P = K_2 H K_1^{-1} \quad (11)$$

Rotation angles  $\alpha$ ,  $\beta$  and  $\gamma$  are selected randomly from the uniform distribution (denoted here as  $\mathcal{U}$ ). The amount of rotation around axes  $y$  is twice times the amount of rotation around remaining axes to better reflect dominant rotations in human movement

$$\begin{aligned} \alpha &\sim \mathcal{U}(-1, 1) \cdot \delta_{max} \cdot 0.5, \\ \beta &\sim \mathcal{U}(-1, 1) \cdot \delta_{max}, \\ \gamma &\sim \mathcal{U}(-1, 1) \cdot \delta_{max} \cdot 0.5 \end{aligned}$$

and  $\delta_{max}$  is the parameters specifying the maximum extent of allowed rotation.

2) *Intensity and contrast synthesis*: In the proposed approach image intensity and contrast synthesis is applied in addition to geometric transformations. It is especially important for Haar-like features that lack intensity normalization. A simple linear formula is used here. For each pixel gray value  $I_{in}$  we have

$$I_{out} = a * I_{in} + b \quad (12)$$

where

$$a = 1 + c_{dev}, b = I_{dev} - \mu_I \cdot c_{dev} \quad (13)$$

where  $\mu_I$  is the average intensity of the sample and contrast deviation  $c_{dev}$  as well as intensity deviation  $I_{dev}$  are sampled from the uniform distribution  $c_{dev} \sim \mathcal{U}(-1, 1) \cdot c_{max}$  and  $I_{dev} \sim \mathcal{U}(-1, 1) \cdot I_{max}$ .  $c_{max}$  is a parameter denoting the maximum allowed contrast change and  $I_{max}$  is a parameter denoting the maximum allowed intensity change. Changes in contrast preserve mean intensity of an image. After application of the formula its results are appropriately saturated.

3) *Application of blur*: Training and test samples may differ in terms of quality of image details due to different factors such deficiencies of optics used or motion blur. In our case we apply a simple Gaussian filter in order to simulate natural blur effects

$$\sigma = \mathcal{U}(0, 1) \cdot \sigma_{max} \cdot \min(I_{width}, I_{height}) \quad (14)$$

where  $I_{width}$  and  $I_{height}$  are image sample sizes and  $\sigma_{max}$  controls the maximum size of the Gaussian kernel.

4) *Merging with the background*: Generalized training images are superimposed on background samples extracted from negative examples of size ranging from about 0.25 to 4 times the positive sample size. Gray-level masks are used for seamless incorporation of positive samples into background images.

### E. Detector training

Before training all training samples are resampled to a fixed size of 24x24 pixels. The detector training procedure is divided into two steps. In the first step the cascade classifier using HAAR-like features is trained. In our scenario for each cascade stage 300 positive samples and 100 negative samples are utilized. Minimum true positive rate for each cascade level is set to 0.995 and maximum false positive rate is set to 0.5. The classifier is trained for a maximum of 15 stages or until reaching  $\approx 0.00003$  FPR. The expected TPR is at least  $0.995^{15} \approx 0.93$ . By using these settings up to about 1000 detections are generated for each Full-HD test image.

During the second stage of training an SVM classifier is trained to handle samples that passed the first cascade classification. For most experiments the SVM classifier is trained on 300 positive and 300 negative samples. The SVM classifier uses Gaussian RBF kernel.

$$K(\mathbf{x}, \mathbf{y}) = \exp(-\gamma \|\mathbf{x} - \mathbf{y}\|^2) \quad (15)$$

The Gaussian kernel size  $\gamma$  and SVM regularization parameter  $C$  are adjusted using automatic cross-validation procedure performed on the training data. For SVM classification Histogram of Oriented Gradients features [22] are extracted. For each sample a 9-element histogram in 4x4 cells is created with 16x16 histogram normalization window overlapping by 8 pixels, thus giving  $4 * 16 * 9 = 576$  HOG features in total.

Negative samples are extracted from Cascade Classifier decision boundary (containing samples that were positively verified by CC but still negative) if possible. If not - image

fragments used as background images for positive samples or other randomly selected samples are used. In all experiments OpenCV 3.1 [21] Cascade Classifier and SVM implementation are utilized.

Given our test data, the number of resulting support vectors in the SVM classifier varies between 200 and 400. Let us review one specific configuration: 'hat' pattern trained on 55 images with masks and pattern generalization settings  $\sigma_{max} = c_{max} = 0$ ,  $\delta_{max} = 0.7$ ,  $I_{max} = 50$ . After SVM metaparameter optimization we obtain SVM regularization parameter  $C = 2.5$ , RBF kernel size  $\gamma = 0.5$  and the number of support vectors 233.

#### F. Detection and post-processing

During detection phase each test image is first processed by the cascade classifier typically returning several hundreds candidate areas. After this, each candidate area is examined by the SVM classifier and a score is assigned to each detection. The score is computed as the signed distance from the separating plane in support vector space with lowest negative scores treated as best matches and high positive scores as worst matches.

For each image only the best score area is considered for further processing. Frames from the test sequence are sampled and processed with increasing density (first, last and middle frame for start and then intermittent frames), to quickly produce some results for the user to review (non minima suppression is used to reduce clutter)

### III. EXPERIMENTS

#### A. Preliminary experiments

During the first stage of experiments there was selected a single test sequence '00012' with 1776 Full-HD frames. Using this sequence various parameter configurations were evaluated in order to assess basic properties of the solution proposed. Basing on these experiments some answers can be given regarding problems such as impact of utilization of two-layer detector on detection results and detection/training speed, impact of the method of selection of training samples on detection accuracy or impact of values of image synthesis parameters on overall quality. Above questions will be discussed in the following paragraphs. All experiments were performed on Intel Core i5 computer. During the first 3 experiments one sample pattern 'hat' was utilized, in the last experiment 3 other patterns 'logo', 'helmet' and 'shirt' were introduced. Examples of training samples are given in Fig. 4 and samples marked in full-frame image are given in Fig. 5. Filtered detection results for one test sequence presented in the form of a simple GUI are given in Fig. 6.

a) *Two-layer detector*: In the first experiment there was evaluated a trade-off between detection and training speed for different number of expected cascade stages  $k$  (Fig. 8). Identical parameters were used for all  $k$  except for the number of SVM training samples. For  $k < 15$  there were used 900 positive and negative samples to accommodate for weaker selectivity of the 1-st detection stage. For  $k \geq 15$  the default of

300 positive and negative samples were utilized as in all other experiments. The experiment shows that for low  $k$  training time is dominated by SVM training, for large  $k$  cascade training dominates. A good compromise for our data can be obtained for  $k = 15$ . Larger  $k$  obviously means also faster detection (Fig. 7), but also slightly worse detection results (Fig. 9) (likely due to utilization of more robust HOG features in the second stage).

b) *Collection of training samples*: In the next experiments there were compared detector performance for different training data collection methods. In the first place the data samples were collected using automatic tracking and foreground-background separation methods given in this paper. In the process 55 data samples from of 'hat' pattern were collected together with their automatically generated masks. The data consisted of images of a hat on top of a head, while the head was making full 180 degrees rotation around central axis. For comparison, a short sequence of training samples representing only 3 extreme head positions (*en-face* and two profiles) was utilized. For both sequences either appropriate foreground-background masks or no masks were used giving 4 different combinations of settings. The detection results are given in Fig. 10.

Not surprisingly the richest possible data source (55 frames with generated masks) gives the best results. It is valuable to note that for our data, application of both object tracking and automatic mask generation is substantial to get optimal results.

c) *Synthetic generalization of training data*: In these experiments different measures and intensities of samples synthesis were evaluated. The results are given in Fig. 11 and Fig. 12. The results show that moderate geometric as well as contrast and sharpness generalization provides best results. However, the selection of appropriate parameters is object and sequence-specific. E.g. it may be observed that near-flat surfaces e.g. 'logo' benefits from aggressive geometric distortions (i.e. larger rotation angles). In addition, the reduction of sharpness proved to work best for computer-graphics-generated samples.

d) *Detection of various patterns*: In the last of our preliminary experiments there was evaluated how the detector handles different types of patterns. Therefore, the pattern 'logo' was trained on a single training example with no mask, the pattern 'shirt' was trained on a sequence of 30 samples without a mask and the pattern 'helmet' was trained on 41 samples also without a mask. The result are given in Fig. 13.

It can be noted the relatively worse performance for the 'shirt' pattern, mainly due to numerous occlusions. Even in the case of the 'shirt' pattern we still have about 90% of successful hits for recall rates of 0.3. For best patterns such as 'helmet' we have 70% of positive examples with still 0 false positives!

In the course of experiments, it was observed that motion blur (inherent or originating from de-interlacing) is the most destructive type of noise regarding both training and detection phase. In addition, due to quite severe subsampling of the pattern (down to  $24 \times 24$ ), the detector may suffer from problems in distinguishing between patterns differing only in

Fig. 4: Example training samples of 'hat', 'logo', 'helmet' and 'shirt'

Fig. 5: Frame with marked 'hat', 'logo', 'helmet' and 'shirt' samples

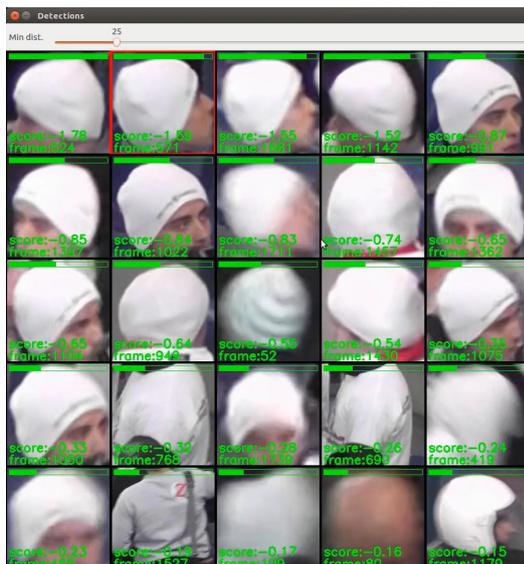

Fig. 6: Detection results filtered by minimum distance (25 frames) between hits

small details. On the other hand, due to this property, the detector should well handle also small patterns - only slightly bigger than the nominal  $24 \times 24$  pattern size.

### B. Large-scale experiments

Tests of the presented algorithm were conducted on a dataset containing 11 recordings, with nearly 30 thousand frames in total, with full HD resolution. Three patterns were created

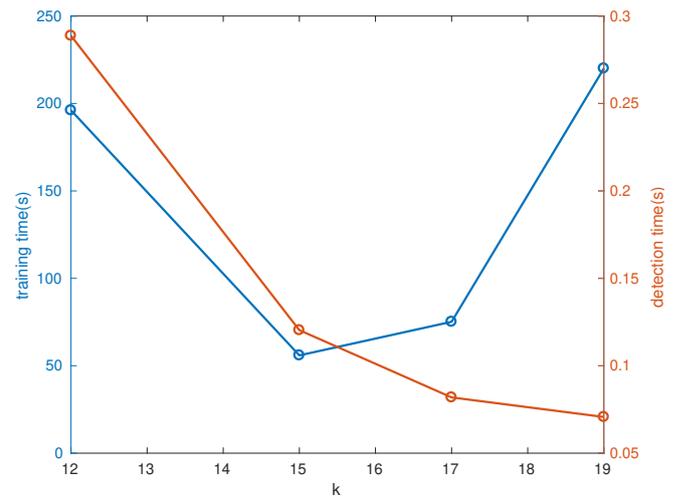

Fig. 7: Training/detection time vs. the number of cascades ( $k$ ).

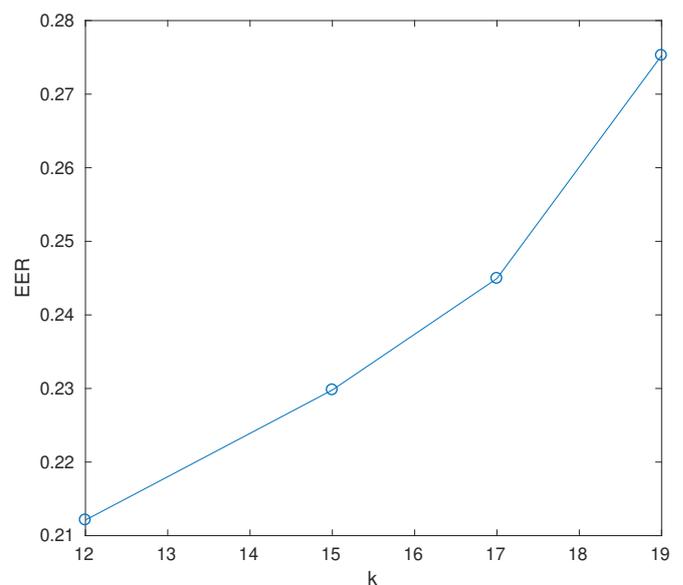

Fig. 8: 'hat' detection EER vs. the number of cascades ( $k$ )

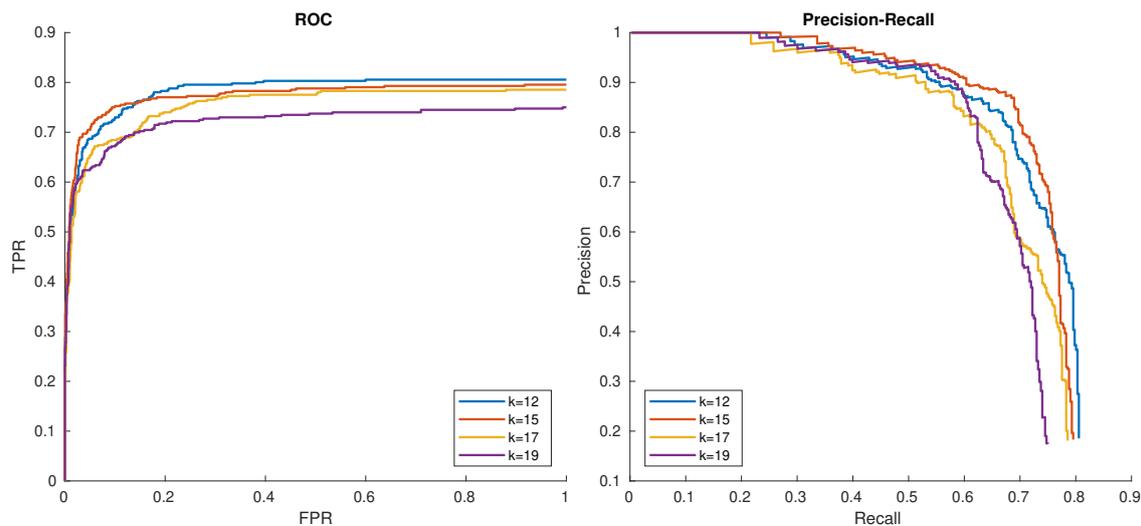

Fig. 9: 'hat' in '00012' detection results with respect to number of the requested cascade stages.

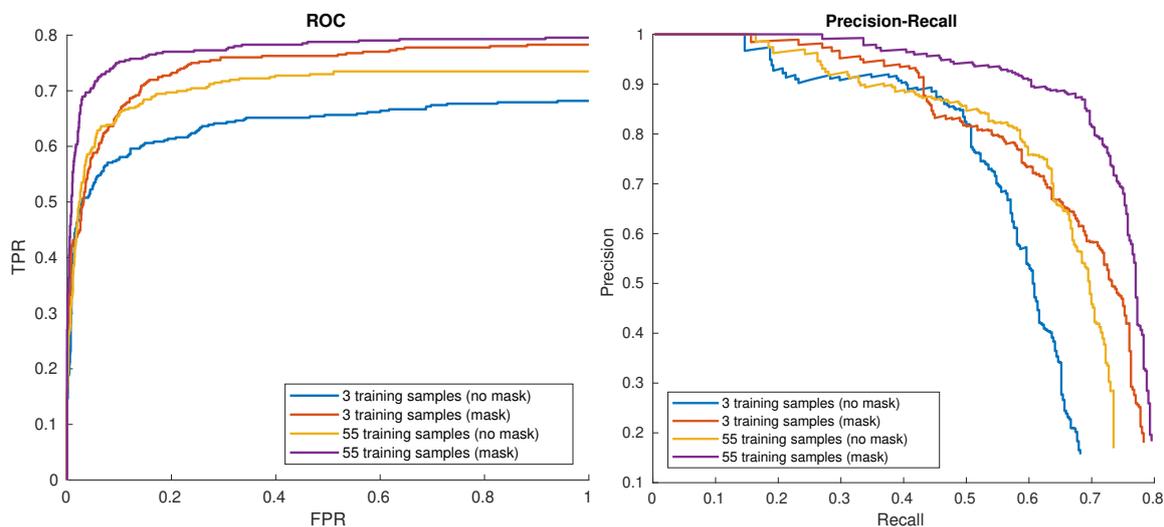

Fig. 10: 'hat' in '00012' detection results for different training data collection methods

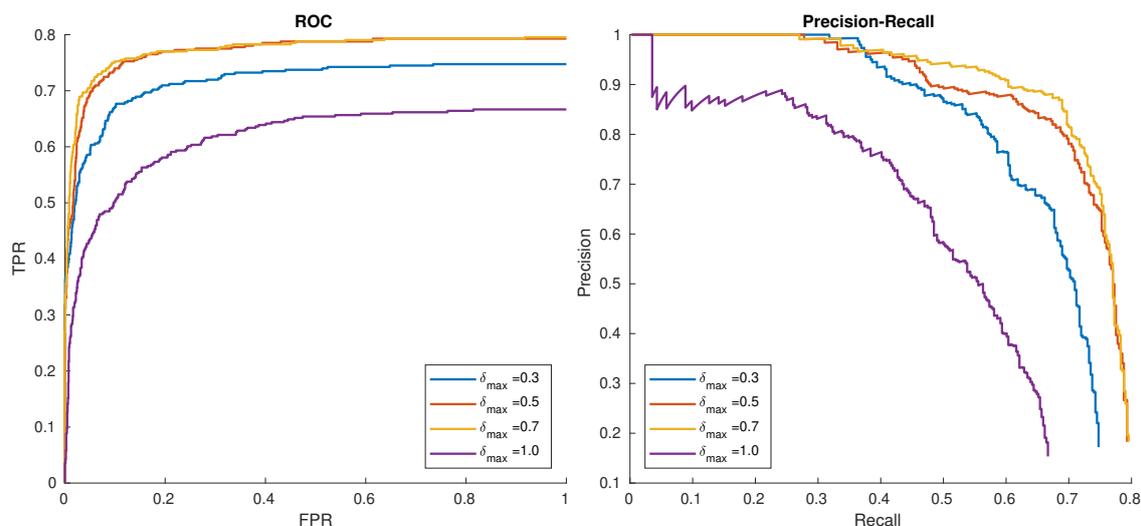

Fig. 11: 'hat' in '00012' detection results for different levels of geometric synthesis

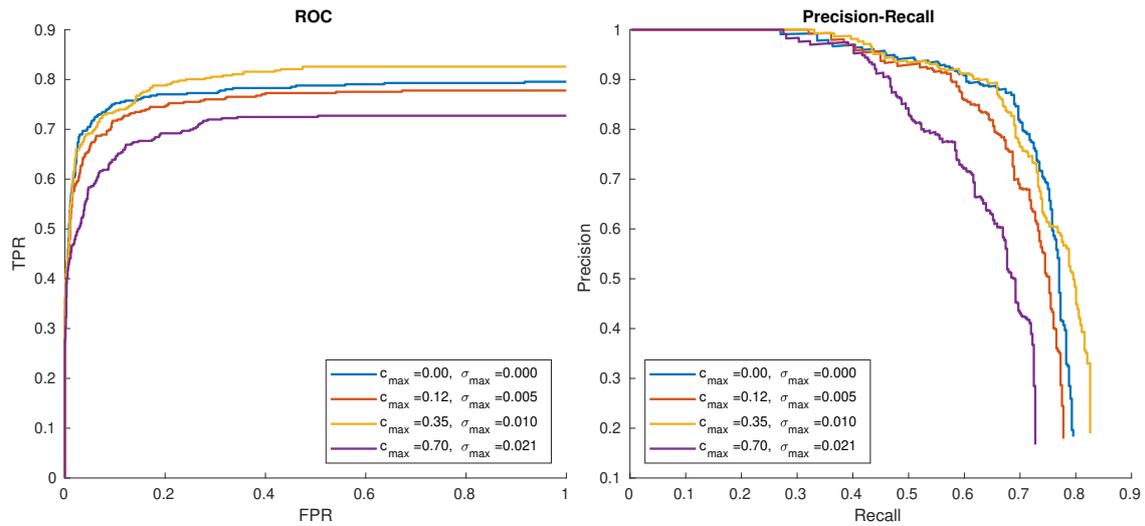

Fig. 12: 'hat' in '00012' detection results for different contrast and sharpness synthesis levels

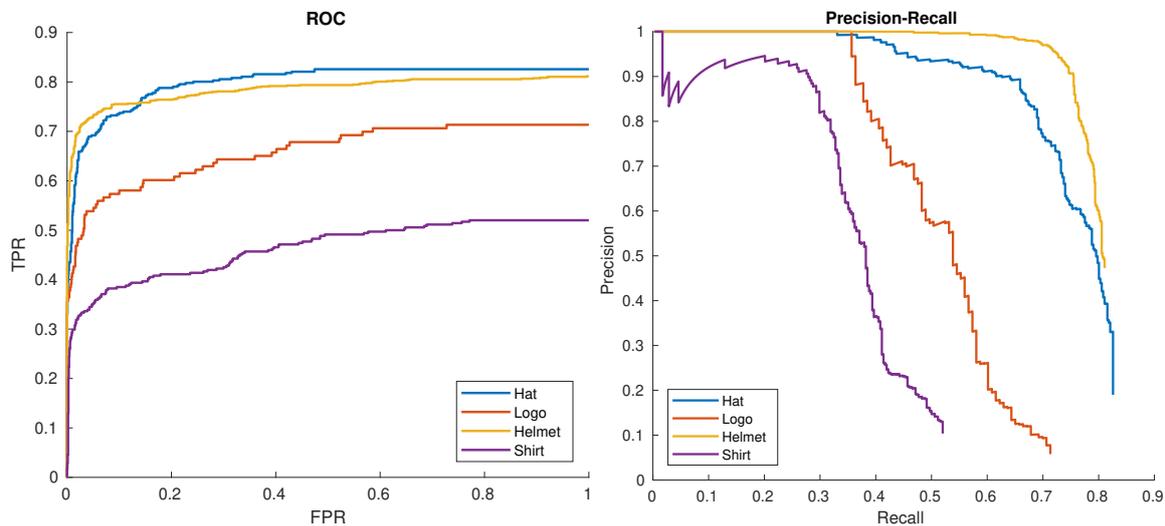

Fig. 13: ROC and PR curves of 'hat', 'logo', 'helmet' and 'shirt' detections in '00012' sequence

(Fig. 14), and all sequences were carefully labeled by hand to create ground-truth data. All patterns were created based on a single frame (one positive sample). As a training data, high quality still picture was used, with resolution scaled down to full HD.

Results of the experiments (ROC curve) for the selected pattern A is presented on Fig. 15a. EER is similar for all patterns A,B,C, and is equal to 25.3%, 28.3% and 28.0% for each pattern respectively. Accumulated EER equals to 27.4%. Obtained results resemble those from small dataset. Even though the training sample and query images were taken with different devices and had different quality, the algorithm gave satisfactory results.

Final addition to the testing scenario was the utilization of short sequences. For every short sequence, from all the results only the one with the best response was taken as a final detection and passed to further processing. Accumulated

results for the sequences of length 5 is presented on Fig. 15b (remaining charts are given in supplemental materials). EER for them are, respectively: 27.4%, 15.1% and 14.3%. It was observed that the longer the sequence the smaller is the quality gain.

More tests were also conducted using one of the widely used dataset – RGB-D Object Dataset [23]. It contains multiple everyday objects, along with masks, that can be used to create models and short sequences of scenes with multiple objects. Fig. 15c presents sample results obtained for the cereal\_1 object in desk\_3 sequence. Model was created using only 7 views of the object in this case.

#### IV. CONCLUSIONS

In this paper, we presented a solution that can support work of police officers in surveillance tasks. The system proved to positively address difficult task requirements concerning sparse

Fig. 14: Selected test patterns

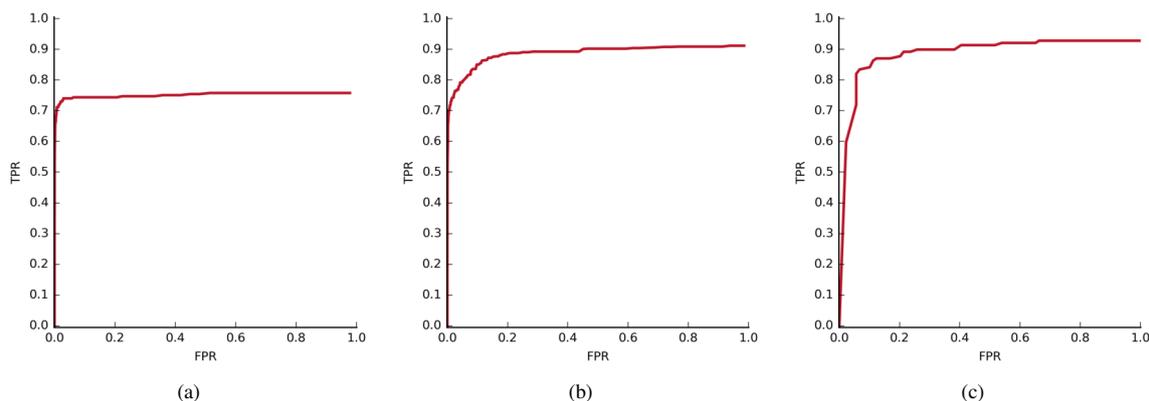

Fig. 15: (a) ROC curve for the pattern A. (b) Accumulated ROC curve for 5-elements sequence analysis. (c) ROC curve for cereal\_1 object in desk\_3 sequence

training data, quick learning and fast and reliable detection. An attractive training/detection speed and recognition rate trade-off was obtained by the application of 2-layer cascade/SVM classifier. The system proposed can learn from a single training sample, but also can collect samples from short image sequences with only small user supervision in order to obtain rich training data. Performance of the system vary depending on the type and quality of training/test data, but we argue that on average results are satisfactory and even not-the-best results provide sufficient information to be useful in practical surveillance scenario.

**Abstract**—Day for day it becomes easier to temper digital images. Thus, people are in need of various forgery image detection. In this paper, we present forgery image detection techniques for two of the most common image tampering techniques; copy-move and splicing. We use match points technique after feature extraction process using SIFT and SURF. For splicing detection, we extracted the edges of the integral images of  $Y$ ,  $C_b$ , and  $C_r$  image components. GLCM is applied for each edge integral image and the feature vector is formed. The feature vector is then fed to a SVM classifier. For the copy-move, the results show that SURF feature extraction can be more efficient than SIFT, where we achieved 80% accuracy of detecting tempered images. On the other hand, processing the image in  $YC_bC_r$  color model is found to give promising results in splicing image detection. We have achieved 99% true positive rate for detecting splicing images.

**Index Terms**—Image Forgery, Copy-Move Forgery Detection, Image Splicing, SIFT, SURF, Support Vector Machine (SVM), benchmark dataset, CASIA datasets, Gray Level Co-occurrence Matrix (GLCM)

## I. INTRODUCTION

IN today's world, digital images are widely used in various domains such as; newspapers, scientific journals, magazines, and many other fields [25]. Unfortunately, today's digital technology made it easy for digital images to be forged due to the availability of the low cost photo editing software [17]. For example, during the incident of Hurricane Harvey, fake images were posted of sharks inside New York as shown in Figure 1. Another example, in Figure 2 as the cutout of the newspaper showed a forged photographs of Bill Clinton, and Saddam Hussein at the White House [9].

Of course, this can cause chaos and panic among the viewers of such digital images. In addition, it can cause erosion in people's trust towards images [20]. Thus, in order to recover people's trust towards digital images, it is important to develop new trustworthy techniques for digital images forgery detection.

Image forgery detection is such a complicated job. Nowadays, it became very difficult to detect whether an image is fake or not. According to Huynh, et al. image forgery detection is one type of the passive techniques that use blind algorithms

for tampering detection in the suspected image without using any prior information. Accordingly, they divided passive techniques into two types: copy-move and splicing [11].

Figure 1. Hurricane Harvey fake reports that were published in BBC in 2017

The copy-move is defined by copying region of an image and pasting it in another place in the *same* image, generally to hide unwanted parts of the image. On the other hand, image splicing is the process of copying a region of an image and pasting it in another place in *another* image. Thus, detection of tampered regions is done through searching for very similar regions in copy-move images and completely odd regions in spliced images [12].

In this paper, we are extracting the image features and analyzing it to detect the forged images and also determine the type of the forgery whether it is copy-move or splicing.

Figure 2. Example of realistic looking forgery

Our work is test on multiple datasets. The rest if the paper is organized as follows; in Section II, we present the literature review for the copy-move and image splicing forgery detection. Section III, introduces our Methodology for both copy-move and splicing along with the datasets used. Experimental results for both techniques are elaborated in Section IV. In Section V we discuss the results and the limitation of the proposed algorithms. Finally, in Section VI we drive the conclusions.

## II. LITERATURE REVIEW

This section summarizes some of the work done in copy-move and splicing detection as follows.

### A. Copy-Move Forgery Detection

The copy-move attack is one type of tampering in which a region of the image is copied and pasted in another area in the same image to cover an important image feature. In [25] a technique for detecting copy-move forgery is presented based on SURF and KD-Tree for multidimensional data matching. Shivakumar et al. designed a system to identify the duplicated areas, then extracted key points in the forged areas and matched them among the SURF features, thus determined the possibility of forgery.

Alberry et al. introduced a fast technique optimizing SIFT and fuzzy c-means clustering for copy-move forgery detection. First, the algorithm detected and matched the key points in the image and clustered the points based on their descriptors using c-means algorithm. Their algorithm could successfully come over the computational complexity in the matching stage after using the clustering algorithm [5].

Pasquini et al. designed an empirical system to verify online news by analyzing images from news article. The system identified the set of meta-data visuals related to the same topic and presented some common visual elements. After that, the data set was compared with many websites with the same topic. Thus, the system the could differentiate between the images and output the fake one [20].

In [9] Fridrich et al. succeeded in detecting the forged parts even when the copied areas were skillfully enhanced and merged with the background and saved in the lossy JPEG format. They introduces a novel correlation between the original image segment and the pasted part to be used as a basis for a successful detection for the copy-move.

The paper [7] examined several block-based methods to detect the copy-move forgery. Bayram et al. showed their time complexity and robustness in the results. They discussed Discrete Cosine Transform (DCT), Fourier Mellin Transform (FMT) and Principal Component Analysis (PCA). The results were good on any JPEG image, but the algorithm is limited to non-rotated or scaled objects. However, they could improve the efficiency of copy-move forgery techniques by counting

bloom filters, especially when the image quality is high.

Ryu et al. [22] proposed a forensic technique to localize duplicated image regions based on Zernike moments of small image blocks. They utilized the characteristics of rotation in variance to reliably unveil duplicated areas after random rotations. By examining the image, they designed a new block matching operation centered on locality-sensitive hashing and decrease fake positives. Their experiments indicated high robustness for JPEG compression, blurring, additive white Gaussian noise, and moderate scaling.

The work done [15] by Kakar et al. proposed a novel technique based on transform-invariant features for copy-move detection. The results provided efficacy of this technique in detecting copy-move forgeries with translation, scaling, rotation, flipping, lossy compression, noise addition and blurring.

Lin et al. [18] introduced an image forgery detection using both copy-move and splicing forgeries detector. They first used a forgery picture identification strategy through periodicity assessment with the double mixing impact in the temporal and DCT domain. Then the function obtained by SURF descriptors is implemented to resist the variety of rotating and/or scaling of tampered objects in an image. Experimental results showed that their suggested methods were well conducted in the identification of forgery location. The suggested methods were prepared to identify the forged areas and acknowledge the non-original areas, especially for the copy-move forgery pictures.

Finally, We built our work of copy-move detection on [8]. Christlein et al. examined the 15 most prominent feature sets and created a challenging real-world copy-move dataset "Benchmark", that we used as part of our dataset. The paper showed many algorithms in detecting copy-move forgery using both key-point and block-based methods. The results showed that key-point methods have a clear advantage in terms of computational complexity, while the most accurate detection was achieved through the block-based method Zernike.

### B. Image Splicing Forgery Detection

The splicing attack is one type of tampering in which different regions of the same or separate sources are combined to create a new fake image. In [21], Riess et al. introduced a method for detecting image splicing through the change of illumination environment of the spliced object. They could overcome one of the biggest challenges which is computing the lighting environment from homogeneous materials. Their approach could successfully improve the mean error by almost 30%. Yet, hair, structurally unsmooth regions, and highly textured clothes were from the model limitations.

Ke et al. proposed forged image detection technique based on shadow consistency, assuming that the shadow and the main body were copied from one image and pasted to another. The algorithm worked as follows; the suspicious region including shadow and non-shadow were first selected and the texture features were then extracted. Next, the similarity of the two texture characteristics were measured using the correlation function. Finally, by comparing the similarity, the decision would be made whether the image was tampered or not [16].

Similarly, an algorithm for digital image forgery detection based on shadow detection of the spliced object was presented in [26] by Tuba et al. They based their algorithm on the fact that a shadow wouldn't change the surface texture, thus if two adjacent areas (with and without shadow) had different texture, then the image could very likely be forged. The algorithm used Local Binary Pattern (LBP) from shadow areas and adjacent non-shadow areas. The energy and entropy extracted from the features histograms proved to be the most discriminating.

On the other hand, Hakimi et al. used different approach for detecting image splicing based on LBP and Discrete Wavelet Transform (DWT). The images were first converted from RGB into  $YCbCr$  color channel. Next, the chrominance component were divided into non-overlapping blocks. After that, LBP operator was performed and the wavelet transform applied to all blocks. The output was then fed to the Support Vector Machine (SVM) classifier as features. Haar wavelet was used to reduce the image dimension. The results showed that the algorithm was effective in detecting spliced photos with acceptable accuracy [10].

Regarding LBP, and DCT, Bebis et al. [4] proposed a method to detect image splicing forgeries using these two techniques. They divided the chrominance component of the input image into overlapping blocks, then once used 2D DCT and once used the LBP for each block. Standard deviation is then estimated along with the DCT or LBP to extract the feature vectors from each block and fed it to SVM. Their experiments were on Benchmark dataset with detection accuracy of 97%.

In [13] Huynh-Kha et al. focused on developing a system to detect copy-move and the splicing forgeries together in one image. By applying one-level Discrete Wavelet Transform, the sharpened edges with high frequencies were detected from LH, HL and HH sub-bands. The suspicious region was extracted the feature using Run Difference Method (RDM).

Wang et al. [28] worked on splicing detection through using the GLCM and detecting edges from the integral image and then passing the resulted features to a SVM classifier. They used all images component  $YCbCr$  in extracting the feature vectors of an image. They used a certain algorithm to detect

the edges of the image horizontally, vertically and diagonally. We built our work in splicing detection on this paper, we used integral image in detecting the edges of the image.

### III. METHODOLOGY

This section is divided into two subsections; copy-move detection technique, and the splicing detection technique. We will explain how our algorithm in both techniques, the workflow, and our datasets are represented in the block diagram, Figure 3.

#### A. Proposed Method of Copy-Move Forgery Detection

1) *Working Plan*: In copy-move detection, based on [8]. Given an image, the detected regions are computed through the following steps:

- Step 1: Convert the image from RGB to gray-scale color model.
- Step 2: Divide the image into 4 equal blocks and calculate their integral features.
- Step 3: Divide each of the 4 blocks into another four blocks of same size and execute their features.
- Step 4: Extract key-points of all blocks using SIFT and SURF.
- Step 5: Calculate a feature vector for each key-point.
- Step 6: Match each feature vector by comparing each block's features executed with another block.
- Step 7: The forgery is then detected according to a certain threshold among all blocks.
- Step 8: The detected blocks are then displayed with the common object plotted.

2) *Datasets of Copy-Move Images*: We used multiple datasets for copy-move detection; **MICC-F8multi** consisting of 8 forged PNG images, **MICC-F220** consisting of 220 images, 210 original images and 10 fake images [14]. Images were either scaled or rotated or duplicated in different parts of the image. The last dataset was the **Benchmark** datasets that consisted of 4 datasets [8]. Examples of Benchmark datasets are shown in Figure 9.

3) *Pre-processing*: In the beginning, our system was designed using MATLAB, where it requests an RGB image of any format, then the system converts it into a gray-scale. Then the image now is ready for the blocking process. A simple two stages algorithm is then used to divide an image into blocks. In the first stage, the image is divided to 4 equal blocks of the same size and angle. Similarly in the second stage, the system divides each individual block into another 4 equal smaller blocks. This approach is called "*Multi Staged blocking*". We will result in having 20 blocks (4 large blocks + 4\*4 small blocks) as shown in Figure 6. The blocking technique eases the features extraction and matching processes that will be discussed later.

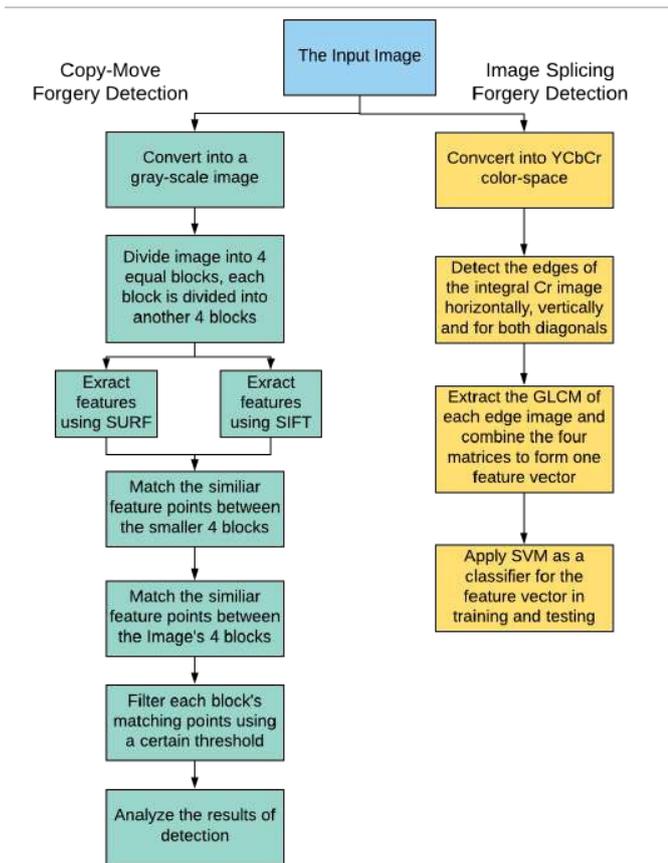

Figure 3. Image Detection Block Diagram

4) *Features Extraction*: For the features extraction, both key-point based methods were used; SIFT & SURF approaches for each block.

**SIFT Key-points based method**: SIFT (Scale-Invariant Feature Transform) is an algorithm to detect and describe local features in an image. The SIFT algorithm converts an image into a local feature vector called SIFT descriptors and these descriptors have powerful geometric transformations that are constant to scaling and rotation [5], [19].

In addition to extracting the features using SIFT, Harris features on the gray image is used to find the corner points. This process is applied to each block of the image. As a result, we obtain the valid points for the neighboring features.

**SURF Key-points based method**: similar to SIFT, SURF (Speed Up Robust Feature) is a descriptor used to recognize and locate objects. The values of Hessian determination for each pixel in the image are used to find the points of interest. Next, functions are constructed to be used to select extreme points [6].

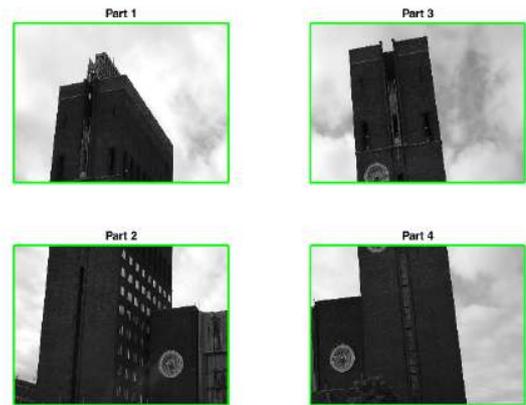

Figure 4. represents the first stage in multi-blocking

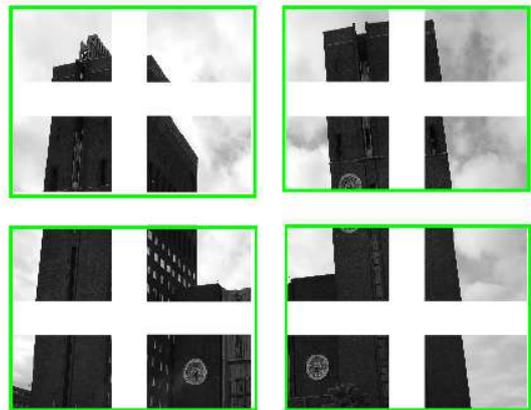

Figure 5. represents the second stage in multi-blocking

Figure 6. An example for the multi-stage blocking of a gray-scale image.

Alternatively, we replace the SIFT step with the SURF. Then, we find the corner points using the Harris detection on the gray image. This process is performed on each block of the image. Lastly, we obtain the valid points for the neighboring features.

5) *Matching Points*: After extracting the neighboring features of each block, the neighboring features are compared to features of another blocks as to find the matched features. Successfully, the locations of the corresponding points for each block will be determined. Ultimately, the system allows the user to view the corresponding points. The system shows the two suspicious blocks where they exceeded the threshold of detected matched points as shown in Figure 7.

6) *Filtering & Analyzing*: The blocks are filtered according to a threshold for the number of matching points detected between two blocks. The threshold is calculated from the

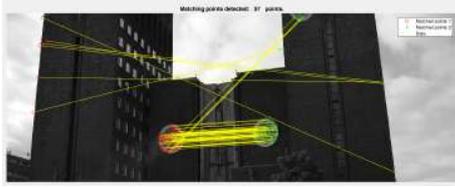

Figure 7. Some of the detected blocks of the image

average number of matched points detected in our datasets.

The system calculates a percentage of the forgery in the image based on the number of suspicious blocks. Accordingly, the percentage of forgery decides which key-point-based method works better on our datasets.

### B. Proposed Method of Image Splicing Forgery Detection

Regarding the image splicing forgery detection our algorithm is based on the Gray Level Co-occurrence Matrix (GLCM) for feature extraction similar to [28] and the Support Vector Machine (SVM) for classification [23].

1) *Working Plan*: Given an RGB image as an input, our system runs as follows:

- Step 1: Convert the RGB image to the  $YC_bC_r$  image component.
- Step 2: Extract each color channel.
- Step 3: Edge detection is performed on each individual color channel image resulting in edge images. The edges are detected horizontally, vertically and both combined.
- Step 3: Gray Level Co-occurrence Matrix (GLCM) is calculated for each edge, holding the features of the edge image.
- Step 4: These features are given to the Support Vector Machine (SVM) to decide whether a forgery is detected or not.

2) *Review on the System Algorithm*: Our algorithm assumes that the images are colored as colors encode relevant information and sensitive to lighting condition at the moment of image acquisition. Therefore, it is expected to have homogeneous color distribution in case of image splicing. Unlike the copy-move forgery detection, we use  $YC_bC_r$  color model instead of gray-scale images.  $Y$  is the component of luminance that contains most of the image content.  $C_b$  and  $C_r$  are the component of chroma blue-difference and red-difference [28].

Our algorithm for image splicing detection works as follows:

*Image Edge detection*: There are multiple edge detector techniques such as Sobel, LoG or Canny. In this paper we adopted similar technique to [27]. We used the edge detection on the equivalent integral image of the input image. We used four edge images which are: vertical, horizontal, diagonal

Figure 8. An example of spliced image and the Diagonal Edge detection of RGB,  $Y$ ,  $C_b$  and  $C_r$  images from top to down and from left to right respectively

and the opposite diagonal which we call the co-diagonal. After obtaining the  $C_r$ , we built Haar-like wavelet filters to find vertical and horizontal edges in the  $C_r$  image. Next, we calculated the integral image, and built a Haar-like wavelet filter, thus, we could construct the vertical and horizontal edges of the image. For the diagonal and the co-diagonal images, we applied the same method, however, a rotated version of the integral image was used instead of the original one.

*Gray Level Co-occurrence Matrix (GLCM)*: After constructing the  $C_r$  edge images, Gray Level Co-occurrence Matrix (GLCM) was applied for texture extraction for each horizontal, vertical, diagonal and co-diagonal edge image. Texture extraction is the equivalent process to the image extraction feature in the copy-move forgery detection. Thus, Texture features are needed to decide the forgery. The Gray Level Co-occurrence Matrix (GLCM) is calculated by creating 8x8 matrix that contains all the features needed for the four edge images. The combination of these matrices generates a feature vector of length 256. This vector will be fed to the classifier for the forgery detection.

3) *SVM Classifier*: Support Vector Machine (SVM) is an efficient and optimal classifier commonly used with machine learning systems, and neural networks [28], [2]. In our system we only have two classes original and fake. So, our model predicts the labels or the classes of our tested features.

4) *Datasets used*: We used CASIA datasets [1] for image splicing, which was divided into two versions; **CASIA I** that consists of 1,737 images (816 authenticated images and 921 spliced images). **CASIA II** consists of 12,625 images (7,492 authenticated images and 5,133 spliced images). We randomly

selected 500 authenticated images and 448 spliced images from both datasets to train and test model. We divided the chosen images into 2 classes; training class (790 images; 417 original images and 373 spliced images), and the testing class (158 images; 83 original images and 75 fake images). An examples for this dataset is shown in Figure 10. Finally, we were limited to colored images as our algorithm works on the  $YC_bC_r$  image components.

Figure 9. An example from Benchmark dataset. The original image is on the left and its fake copy is on the right

Figure 10. An example from CASIA dataset. The original image on the left and its spliced image on the right

#### IV. EXPERIMENTS & RESULTS

In this section, our results are presented for the copy-move and compared with [8], and the same for image splicing compared with [28]

##### A. Copy-Move Results

We examined two different versions of key-points based feature vectors; SIFT and SURF. methods in our system to extract the features from each block to detect identical features and thus, the type of forgery. We compared the SIFT with the SURF to find out which one is better for feature extraction. We ran our algorithm on 3 datasets MICC-F8multi, MICC-F220 [14], and Benchmark datasets [8] as shown in Tables I. From the table it appears that SURF produced more robust results as the number of matched feature points in all test datasets are relatively high when compared to that points matched and were extracted by SIFT.

Table I  
AVERAGE NUMBER OF MATCHING POINTS PER IMAGE

	Datasets		
	Average Matching Points		
	MICC-F8Multi	MICC-F220	Benchmark
SIFT	58	40	1774
SURF	113	120	2023

In Table II the confusion matrix is presented for the Benchmark datasets [8] and MICC datasets [14] with 163 tampered images and 110 original images as shown in Table II.

Table II  
CONFUSION MATRIX FOR COPY-MOVE DATASET

		Predicted	
		Original	Fake
Actual	Original	100	10
	Fake	10	153

Regarding the F-Measurements the achieved True-Positive (TP) rate is 56%, and the False-Negative(FN) rate is 3.8%. The other two metrics: the True-Negative (TN) rate is 36.6% and the False-Positive(FP) rate were 3.6%. The accuracy is 92.67%.

We compared our Benchmark dataset results with [8] as our work on is based on. The results showed that our execution time is less for each mentioned step leading to a decrease in the average execution time for image tampering detection.

According to [8] the average execution time for copy-move detection per image using SIFT is 610.96 seconds, while using SURF is 1052.12 seconds. For our proposed approach, the average execution time using SIFT is 150.8449648 seconds, and for SURF is 89.4841087 seconds. Our Results shows that "Multi-blocking" can enhance the execution time. In addition, it shows that SURF as a feature extractor is more reliable than using SIFT.

##### B. Image Splicing Results

We collected 158 images to test our system, 83 original images, and 75 spliced images. The system converts the input images to  $YC_bC_r$  to detect image splicing. In the following subsection, our results for each image component are presented including the accuracy and performance, beside highlighting the component that gave the best result.

1) *Y Image Component*: We created GLCM on the  $Y$  image component for all images in the dataset. Then we created a training model and added the test feature vectors for all 158 images in the  $Y$  image component. There was 40% fake images detected, which means 30 images out of the 75 fake images were correctly detected. On the other hand, 60% of fake images were falsely detected as original. Also, 80 images of 83 original images were correctly defined as original images. So, the percentage of original images falsely detected as fake images was 3%.

2)  *$C_b$  Image Component*: Again we developed the feature vector for  $C_b$  image component. The results were much better than the  $Y$  image component. The system showed 47% of fake images, which means that 35 images out of 75 spliced images were correctly found. While, the rest of the spliced images 53% were falsely considered as original images which is equivalent to 40 images of 74 spliced images. Regarding the original images 71 images were positively detected from 83 original images. However, there was 14% of original

images falsely detected as fake.

3)  $C_r$  Image Component: Our system gave the best result for  $C_r$  image component in image splicing detection. In Table III we present the confusion matrix of  $C_r$  image component based on 158 images from CASIA dataset [1]

Table III  
CONFUSION MATRIX FOR SPLICING DATASET

		Predicted	
		Original	Fake
Actual	Original	59	24
	Fake	1	74

The results of the  $C_r$  component show that we achieved True-Positive (TP) rate about 99%, and True-Negative (TN) rate greater than 71%. The False-Positive (FP) rate is 29%, and the False-Negative (FN) rate is just 1%. According to [28]  $C_r$  component showed accuracy up to 90.5% which is less than our result by 8.5%.

## V. DISCUSSION

In this section, the results will be discussed and compared to [8] for the copy-move, and [28] for the image splicing. Also, some limitations of the system are discussed.

Our algorithm showed that SURF in extracting features is more reliable than SIFT. According to our results, SURF managed to extract more reasonable matching points from the image blocks, which in return increased the accuracy of detecting the forgery in more than SIFT. Beside, SURF can detect the scaled and rotated forged objects.

In image splicing, we worked with the  $Y$ ,  $C_b$ , and  $C_r$  components individually.  $C_r$  proved its reliability in detecting the splicing higher than  $C_b$  and  $Y$  components.

There are some limitations in our system. First, There were few features extracted in the copy-move algorithm from some of the images in the dataset using our 2 feature extraction methods; SIFT and SURF. One proposed solution can be using another feature extraction as block-based methods such as DCT [24] or DWT [3]. Also, our algorithm depends on dividing the images into blocks in the copy-move detection, however some objects can be divided between multiple blocks which can cause negatively affects the matching point step that compares the features of the blocks to one another.

Concerning the splicing forgery detection, some of edges in integral images were not clear enough to be detected and added to the feature vector of the image. Thus, we propose using combined features instead. Also using a different kernel in the SVM model could be used instead Gaussian or Radial Basis Function (RBF) such as Linear, Polynomial or Sigmoid.

## VI. CONCLUSION

In this work, we presented a general framework for detecting two challenging forgery techniques, the copy-move and splicing. In particular, our system can detect the manipulated regions in the image. Our results show that a key-point based method based on the SURF features, can be more efficient for copy-move forgery detection than SIFT. Its main advantage is the remarkably low computational load, combined with good performance and detection of scaled or rotated objects. We also quantified the performance of splicing forgery detection using SVM model with RBF kernel, which give outstanding results when applied on the  $C_r$  component of the image. We hope our work can serve as an initial building block to improve the security of images on the web. We also believe that our insights would help the forensics professionals with a more concrete decisions.

**Abstract**—Although the unimodal biometric recognition (such as face and palmprint) has higher convenience, its security is also relatively weak. The recognition accuracy is easy affected by many factors such as ambient light and recognition distance etc. To address this issue, we present a weighted multimodal biometric recognition algorithm with face and palmprint based on histogram of contourlet oriented gradient (HCOG) feature description. We employ the nonsubsampling contour transform (NSCT) to decompose the face and palmprint images, and the HOG method is adopted to extract the feature, which is named as HCOG feature. Then the dimension reduction process is applied on the HCOG feature and a novel weight value computation method is proposed to accomplish the multimodal biometric fusion recognition. Extensive experiments illustrate that our proposed weighted fusion recognition can achieve excellent recognition accuracy rates and outmatches the unimodal biometric recognition methods.

## I. INTRODUCTION

WITH the continuous progress and development of the artificial intelligence technology, the conventional recognition technology is unable to meet people's advanced needs. In recent years, biometric identity recognition technology [1] has been widely studied to accomplish the user's identity recognition quickly and accurately.

Since the face biometric recognition technology has higher security and accuracy, it has attracted a large number of scholars to carry out research [2-3]. Many feature extraction methods have been proposed, such as the local binary pattern (LBP) [2], discrete wavelet transform (DWT) [3], nonsubsampling contour transform (NSCT) [4], Histogram of Oriented Gradient (HOG) [5] and Gabor transform [6] et al. These features have also been widely used in palmprint recognition and achieved good results [7-8]. However, when the biometric is affected by the environment factors, the recognition accuracy will decline. To address this issue, some scholars proposed the multimodal biometric recognition theory and carry out extensive research [9-10]. Since NSCT can capture the smoothness and continuities along the contour of the image, it possesses the properties of shift invariance and multi-scale and has been widely studied and employed to describe the features of the face and palmprint [11].

Inspired by this, we propose a novel weighted fusion algorithm based on NSCT and HOG to realize the multimodal biometric recognition with face and palmprint. Firstly, NSCT are utilized to decompose the face and palmprint images. Then, we propose a novel feature extraction method named as histogram of contourlet oriented gradient (HCOG). With full consideration of the intra-class similarity and the inter-class similarity of sample features, a weighted fusion strategy is proposed to realize multimodal biometric fusion recognition.

The main content structure of this paper is organized as follows. Section II discusses the proposed algorithm in detail. In section III, the proposed algorithm is verified by extensive experiments, and the experimental results are analyzed and discussed in depth. Finally, we summarize the conclusion in section IV.

## II. PROPOSED ALGORITHM

### A. Nonsubsampling Contourlet Transform

Contourlet transform [12] employs the Laplace pyramid (LP) transform to decompose the image, then combines the coefficient points with uniform direction into an image contour by using the dimensional filter bank (DFB). However, in the process of image decomposition and reconstruction, contourlet transform needs to adopt the down-sampling and up-sampling operations, which will give rise to frequency aliasing and cause image translation, larger distribution of decomposition coefficient, translation variability and some other problems. To address these issues, Cunha et al. [13] proposed the NSCT algorithm which adopted multi-resolution decomposition by nonsubsampling pyramid (NSP) and nonsubsampling directional filter bank (NSFB) decomposition. Figure 1 illustrates the principle of NSCT [13]. NSCT does not require down-sampling after filtering and up-sampling before band-pass filtering, it only up-sampling on the corresponding filter, and then using low-pass filter and band-pass filter to complete the low-frequency and a series of high-frequency sub-bands filtering.

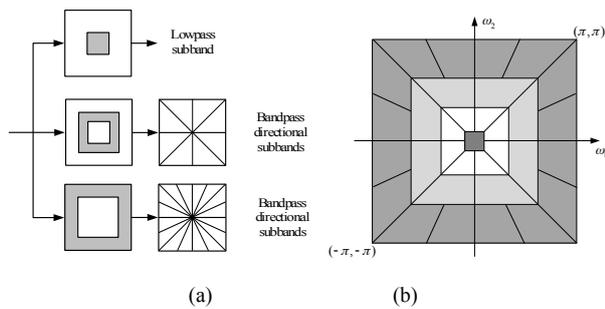

Fig. 1 Nonsampled contourlet transform. (a) NSFB structure that implements the NSCT. (b) Idealized frequency partitioning obtained with the proposed structure.

Since NSCT adopts the nonsampled operation, it has the stability with image shift, that is to say, it has the shift invariance.

### B. Histogram of Oriented Gradient

Histogram of oriented gradient [5] is a classical feature description algorithm, which can describe the edge and shape information of an image well. The specific steps of HOG feature extraction algorithm can be summarized as follows, and figure 2 shows the schematic diagram.

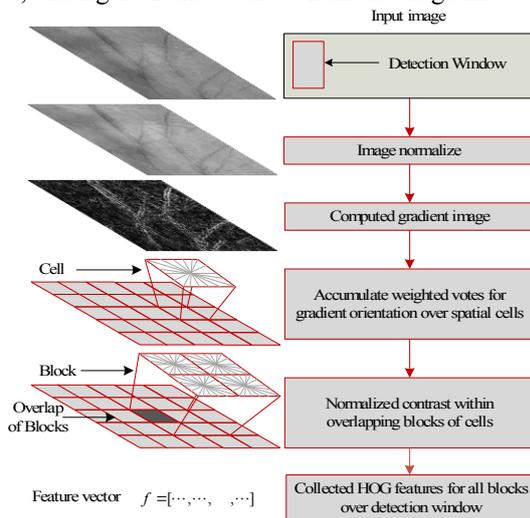

Fig. 2 Schematic diagram of HOG feature extraction.

(1) Normalize the image and calculate the gradient. (2) Divide the image into small cells with the same size and accumulate the weighted votes for gradient orientation with each cell to obtain the histogram of oriented gradient. (3) Group cells into large blocks and use the results to normalize all of the cells in the block. HOG descriptor is obtained by concatenating the normalized histogram vectors of all cells in each block. (4) Tile the detection window with a dense (overlapping is used) grid and cascade the feature descriptor of each block to generate HOG feature vector of the image.

The essence of HOG is the statistical information of image gradient, and the significant position of the gradient is mainly concentrated in the edge of the object. Therefore, it can achieve better recognition effect in the fields of pedestrian detection, and face recognition etc.

### C. Histogram of Contourlet Oriented Gradient (HCOG) Feature Description

Although HOG has achieved stable and good effects in recognition, it lacks multi-scale adaptability due to the restriction of hierarchical rules. To address this issue, Bosch et al. [14] proposed a spatial pyramid representation to encode the object shapes. Inspired by this, we propose a novel HCOG feature descriptor by combining NSCT and HOG to improve the multi-scale performance of the conventional HOG feature.

HCOG feature extraction method is summarized as follows. (1) Implement the multi-scale decomposition of images based on NSCT. Figure 3 illustrates the NSCT decomposition results of a palmprint image, where the decomposition scale is 2, the corresponding bandpass directional subbands numbers are 2 and 4 respectively. (2) Extract HOG feature with the obtained lowpass subband and bandpass directional subbands respectively. (3) Concatenate these HOG descriptors with different subbands and scales to obtain the final HCOG feature vector.

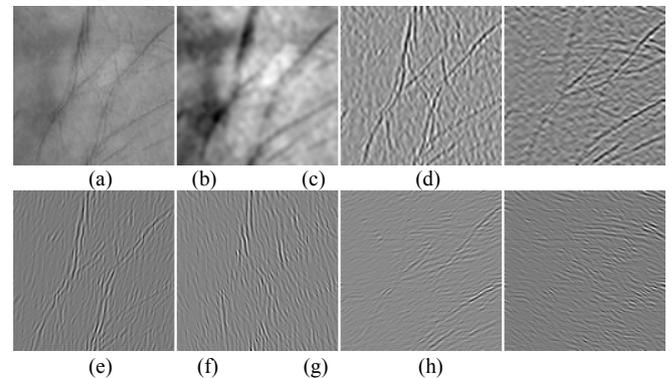

Fig. 3 The 2-level NSCT decomposition demonstration of a palmprint image. (a) Original image. (b) Lowpass subband. (c) and (d) are two different bandpass directional subbands of level 1. (e)-(h) are four different bandpass directional subbands of level 2.

### D. Weighted multimodal biometric recognition algorithm

Although the feature extraction methods of face and palmprint images are same, the feature descriptions of different biometrics are quite different. In order to avoid the mutual interference between different biometrics, we present a novel weighted fusion recognition algorithm with face and palmprint. The specific algorithm steps are as follows.

Step 1. Image preprocessing. Preprocess the training face and palmprint images, including image normalization and ROI extraction etc.

Step 2. NSCT decomposition. NSCT decomposition is performed on the preprocessed face and palmprint images.

Step 3. HCOG feature extraction. Extract HOG feature from subbands obtained by NSCT decomposition with face and palmprint images respectively. Concatenate the HOG descriptors of the NSCT decomposition subbands with each face and palmprint sample to obtain the HCOG feature vector respectively. Then the feature matrix can be obtained, denoted as  $H^f$  and  $H^p$  for face and palmprint respectively.

Step 4. Feature dimension reduction. Employ the linear discriminant analysis (LDA) or principle component analysis (PCA) to reduce the dimensionality of the feature

matrices. Denote the dimension reduced training sample matrices as  $Tr^f$  and  $Tr^p$  for face and palmprint respectively.

Step 5. Weight value calculation. Denote the training matrices as  $Tr^j = [Tr_1^j, Tr_2^j, \dots, Tr_C^j]$ ,  $j = \{f, p\}$ , where  $C$  is the class number, suppose there are  $n$  samples for each class, then the training sample number can be calculated by  $N = nC$ . Denote  $Tr_i^j = [tr_{(n-1)\times i+1}^j, \dots, tr_{n\times i}^j]$ ,  $j = \{f, p\}$  as the training subsets in the  $i$ th class. For each training sample  $x_k^f$  and  $x_k^p$ , calculate the similarity metric between different samples by using  $S_{kl}^j = S(x_k^j, x_l^j)$ ,  $j = \{f, p\}$ , ( $l = 1, \dots, k-1, k+1, \dots, N$ ). Then we calculate the intra-similarity as follows

$$\begin{aligned} \text{intra\_}S^j &= \frac{1}{C} \sum_{i=1}^C \text{intra\_}S_i^j \\ &= \frac{1}{n(n-1)C} \sum_{i=1}^C \sum_{k=(n-1)\times i+1}^{n\times i} \sum_{\substack{l=1 \\ l \neq k}}^{n\times i} S_{kl}^j, j = \{f, p\}. \end{aligned} \quad (1)$$

Calculate the inter-similarity as follows

$$\begin{aligned} \text{inter\_}S^j &= \frac{1}{C} \sum_{i=1}^C \text{inter\_}S_i^j \\ &= \frac{1}{C(C-1)n^2} \sum_{i=1}^C \sum_{k=(n-1)\times i+1}^{n\times i} \sum_{\substack{l=1 \\ l \notin I_i}}^N S_{kl}^j, j = \{f, p\}. \end{aligned} \quad (2)$$

where,  $I_i = \{(n-1)\times i+1, (n-1)\times i+2, \dots, n\times i\}$ ,  $i = 1, \dots, C$ .

Define the discriminant function as follows

$$d^j = \frac{|\text{intra\_}S^j - \text{inter\_}S^j|}{\text{intra\_}S^j + \text{inter\_}S^j}, j = \{f, p\}. \quad (3)$$

Then the weighted value is calculated by

$$\omega^j = \frac{d^j}{d^f + d^p}, j = \{f, p\}. \quad (4)$$

Step 6. Fused recognition. For any given test images of face and palmprint, denoted as  $y = [y^f, y^p]$ , we employ the step 1 to step 4 to obtain the feature vectors, and denote it as  $Tt = [tt^f, tt^p]$ . Calculate the similarity between the test sample and each sample in the training set by  $S_i^j = S(tt^j, tr_i^j)$ ,  $j = \{f, p\}$ , ( $i = 1, 2, \dots, N$ ). Then we use the weighted value calculated by formula (4) to complete the fusion process

$$S_i = \omega^f S_i^f + \omega^p S_i^p, (i = 1, 2, \dots, N). \quad (5)$$

Finally, the nearest neighbor (NN) method is used to implement the recognition task.

### III. EXPERIMENT AND ANALYSIS

In order to verify the effectiveness of the proposed algorithm, we carry out extensive simulation experiments on the multimodal database composed by the face and palmprint.

#### A. Experiment Database

Extended YaleB database contains 38 classes of face images, each class includes 64 different lighting conditions images. After manual cropping, the image size was adjusted to  $192 \times 168$ , and some face images are shown in figure 4.

Fig. 4 Face images of the Extend YaleB database.

Because the red blood cells in the human body has the characteristics of absorbing infrared light in specific bands. This can reduce the influence to the acquired palmprint images caused by palmprint desquamate, injury and sweating etc. We select the palmprint image acquired under near-infrared (NIR) illumination condition to fuse with the face biometric. The biometric research centre of Hong Kong polytechnic university (PolyU) has provided a multispectral palmprint database [1], which mainly includes four different spectral conditions (i.e. blue, red, green and NIR). It contains 500 different classes, and each class contains 12 palmprint images with four different spectral conditions. Figure 5 lists some palmprint images of this database.

Fig. 5 Some NIR palmprint images of the PolyU multispectral palmprint database.

#### B. Experiment Results and Analysis

Here we use the face and NIR palmprint images in Extend YaleB and PolyU database to constructed a multimodal database and conduct the fusion recognition experiment. According to the numbers of sample class and samples contained in each class, we construct a multimodal database with 38 classes and 12 samples for each class. We vary the training sample number from 2 to 7 from each class to demonstrate the experiments, the recognition rates of face and NIR palmprint are tested respectively to compare with the proposed fusion recognition algorithm. In this experiment, we used LDA method to conduct dimension reduction treatment. The specific experimental results are shown in table I.

TABLE I.  
RECOGNITION RATES FOR DIFFERENT BIOMETRICS WITH THE TRAINING SAMPLE VARIES FROM 2 TO 7.

Biometrics	Recognition rates (%)					
	2	3	4	5	6	7
Face	84.74	89.47	93.75	94.74	95.18	97.89
Palm	98.95	98.83	100	100	100	100
Fusion case	99.74	99.71	100	100	100	100

From the table I, it is easy to see that the proposed algorithm outperforms the unimodal biometric recognition cases. Especially, when the number of training samples is small, (such as 2 and 3), our fusion recognition algorithm is 15% and 10.24% higher than the face recognition, and 0.79% and 0.88% higher than NIR palmprint recognition, respectively.

In order to verify the efficiency of our proposed HCOG feature, we implement experiment with different feature extraction methods, such as DWT, LBP, HOG, NSCT and Gabor feature etc. In addition, we use LDA and PCA methods to implement the dimension reduction and compare them with the case by using the original feature. In this experiment, the number of training samples is 3, and the rest are treated as test samples. Specific experimental results are shown in table II.

TABLE II.  
RECOGNITION RATES WITH DIFFERENT FEATURE EXTRACTION METHODS

Feature extraction method	Recognition rates (%)		
	Original feature	LDA	PCA
DWT	97.66	98.54	97.08
LBP	97.95	98.54	97.37
HOG	92.40	91.81	94.74
NSCT	97.08	94.15	96.78
Gabor	98.25	98.54	99.12
Proposed method	99.74	99.74	99.71

From the data in table II, it is easy to see that the feature extraction algorithm proposed by us can effectively improve the recognition accuracy compared with the other feature extraction methods.

In order to verify the efficiency of the proposed algorithm, we draw the cumulative match characteristic (CMC) curve. As illustrated in the figure 6, the CMC curve takes Rank as the abscissa and the cumulative match score as the ordinate, which reflects the identity recognition ability of the biometric recognition system. It can be seen from the figure 6 that our proposed weighted fusion recognition algorithm can always achieve better fusion matching scores, which verifies that our recognition algorithm significantly outperforms the unimodal biometric recognition cases with face or NIR palmprint.

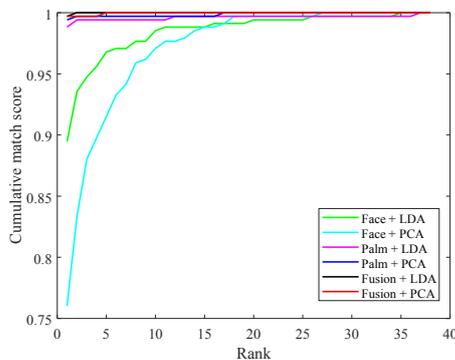

Fig. 6 Performance curves of our proposed weighted algorithms with the unimodal recognition in terms of Cumulative Match Characteristic.

#### IV. CONCLUSION

In this paper, a novel weighted fusion multimodal biometric recognition algorithm with face and palmprint is presented. By integrating the advantages of NSCT and HOG, a

novel HCOG feature descriptor is proposed. At the same time, a fusion weight calculation strategy based on the sample similarity is presented to realize the biometric fusion recognition. Experimental results show that the proposed HCOG feature description and weighted fusion strategy can effectively improve the fusion recognition accuracy.

# A GIS Data Realistic Road Generation Approach for Traffic Simulation

Yacine Amara, Abdenour Amamra, Yasmine Daheur, and Lamia Saichi  
Ecole Militaire Polytechnique, Bordj El-Bahri BP 17, Algiers, Algeria  
Email: amara.yacine@gmail.com

**Abstract**—Road networks exist in the form of polylines with attributes within the GIS databases. Such a representation renders the geographic data impracticable for 3D road traffic simulation. In this work, we propose a method to transform raw GIS data into a realistic, operational model for real-time road traffic simulation. For instance, the proposed raw to simulation-ready data transformation is achieved through several curvature estimation, interpolation/approximation, and clustering schemes. The obtained results show the performance of our approach and prove its adequacy to real traffic simulation scenario as can be seen in this video<sup>1</sup>.

**Index Terms**—Road interpolation, Road modeling, Traffic simulation, Vehicle virtual navigation.

## I. INTRODUCTION

In recent years, applications of road traffic simulation have become ubiquitous in everyday life: driving simulation or racing games are increasingly attracting the attention of developers. However, the results obtained are not always consistent with reality. When one wants to reproduce a realistic behavior, the developer must consider the real parameters of the road.

The realization of a real-life road simulation would make it possible to forecast the traffic generated in a given road network. This realism, modeled on a computer, would help managers to detect the problems present in the network, namely congestion, accidents, user stress, an insufficient number of channels, etc. Besides optimizing traffic on the roads without making urban changes, such as location of traffic lights, number, and width of lanes.

The shape of the road is complex, particularly at mountainous segments, severe turns, etc. Therefore, finding the best mathematical function that will fit the shape of these sections while taking into account compressing the number of data to be stored is challenging.

Geometric processing applications rely on the geometric properties of curves such as torsion, curvature, and tangents. In our study, we chose the curvature metric in the road's modeling surface, since the latter embeds the information on the shape of the road. The actual data is extracted from the Geographic Information System (GIS), the latter known for providing the ability to manipulate geographical information laid out on multiple layers. The metric being chosen; our approach is then organized as follows: extraction of the road layer as polylines in the GIS data; curvature estimation at the neighborhood of the points; a grouping of points in clusters according to

the sign of their curvature, and finally the approximation of clusters by continuous mathematical functions.

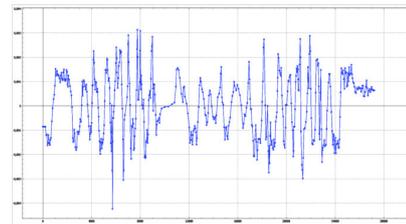

Fig. 1

## II. RELATED WORKS

Most of the work that has been proposed on road reconstruction is based on procedural modeling. Roads are generated by empirical rules often based on observation. We will classify the methods proposed in two categories: the methods taking the input of calculated roads (procedural approaches) and the models taking as input the data resulting from Geographic Information Systems (GIS).

### A. Procedural approaches

These approaches take as input roads derived or calculated by mathematical or optimization methods. Both, Parish et al. [1] and Jing et al. [2] generated models of cities in which road networks played a key role. Their roads were built from the central lines that are generated either by grammar rules named *L-Systems* [1], or model-based methods [2]. However, the defining laws or models to regenerate exactly the structure of urban roads are not available. Hence, their roads often drift from their real respective counterparts. In addition, their methods were not designed for highways and suburban roads.

Some of these limitations have been resolved by Chen et al. [3], where they used a tensor field from which a graph representing the road network was calculated. This can be modified to control locally the generated road profile. Their method permits creating large areas but does not allow the reconstruction of existing networks because of the problem of scale limitation. In addition, only urban roads were considered.

Another procedural model was proposed by Galin et al. [4, 5] based on a platform for generating mapped roads that contain many types of features such as trees, rivers, and lakes. Their roads resulted from a short path algorithm instead of the real data. As a result, we obtain fictitious roads that do not

<sup>1</sup><https://youtu.be/t8eyphcFYHc>

satisfy the constraints of civil engineering. The generated roads are erroneous and do not match the shape of the terrain. This lack of realism is because of the shortcomings of the proposed approaches. The major shortcoming of these works is not to have considered the actual data as input of the problem.

### B. GIS data approaches

To overcome the problems mentioned and to build more realistic roads, Bruneton and Neyret [6] proposed a method of generating large road surfaces from GIS data. They represented the roads with Bezier curves to join the sampled points and then mapped them on the ground. Although this model helps to perceive actual road coordinates, current roads are no longer built from Bezier curves. Again, these models are affected by the lack of realism. The details and constraints related to civil engineering discipline are not taken into account. Road networks must be defined by simple forms such as straight lines, arcs of circles, and clothoids. This drawback had been addressed by the following work:

1) *LSGA algorithm*: This work [7] introduces a new approach to construct smoothed curve pieces representing realistic roads. Given a GIS database of road networks, where the sampled points are organized as 3D polylines, this method creates horizontal and verticals curves, then it combines them to generate the roads. The major contribution of this work is a tree traversal algorithm that extends the sequences of the best fit primitives and a fusion process of these primitives. The latter must respect a certain grammar according to an automaton. This approach offers more realistic results than those that preceded it, and the errors are proportional to the noisiness of input data.

2) *Construction by clothoids*: In [6], the algorithm for adjusting a sequence of  $G_2$  polylines into clothoid segments takes place in two steps: first a piecewise linear approximation is applied, then a sequence of rigid 2D transformations is applied in order to align the in one consistent result. Although this method respects civil engineering constraints and models the transition between a circular arc and a straight line with a clothoid, its first pass through the linear segments loses the precision when estimating the radius of curvature.

3) *Automatic generation of 3D roads*: This method, presented in [8], is based on a set of civil engineering rules. It proposes a new approach for the automatic 3D generation of high-fidelity roads. It transforms GIS data that only contains 2D information from the central axis of the road into a 3D model of the road network. In the proposed approach, basic road elements such as road segments, road intersection are generated automatically to form sophisticated road networks. But in the modeling of the axe of the road, the segments were connected by Hermite curves, which satisfy only  $G_1$  continuity, hence the civil engineering constraints were not respected.

The proposed model must be realistic, that is to say, that it must meet the constraints of civil engineering and vehicle dynamics, for this reason, our study was based on an essential criterion which is *curvature*. Curvature, the inverse of the

radius of the circle tangent to the curve, is defined as the norm of the acceleration vector of a body traveling the curve at unit speed. It is the second derivative with respect to the curvilinear abscissa of the body position.

## III. CURVATURE ESTIMATION

### A. Definition

A parametric curve is a function  $r : I \subset \mathbb{R} \rightarrow \mathbb{R}^n$ , when  $n = 2$  it is called a *plane curve*. The curvilinear abscissa  $s$  from a point  $r(t_0)$ ,  $t_0 \in I$ , at a given point  $r(t_1)$ ,  $t_1 \in I$ , is defined by:

$$s(t_1) = \int_{t_0}^{t_1} \|r'(u)\| du \quad (1)$$

The vector  $T(s) = r'(s)$  is called the tangent vector. The normal vector  $N(s)$  is obtained by a rotation of  $90^\circ$  anticlockwise. The vectors  $T'(s)$  and  $N(s)$  are collinear. That is, there is a function  $k(s)$  such that:

$$T'(s) = k(s) \times N(s) \quad (2)$$

called the *curvature* of the curve at the point  $r(s)$ . The curvature also corresponds to the variation of the direction of the tangent vector respectively to the curvilinear abscissa:  $k(s) = \theta'(s)$ , such that :

$$\theta'(s) = \angle(\overrightarrow{T(s)}, \overrightarrow{(1, 0)}) \quad (3)$$

Since our initial data is in discrete form, we performed a local estimation using a sliding window. The latter is centered around a point allowing to approximate all its neighbors within the window by a second order polynomial. The interest of such an operation is to deduce the first and the second derivatives, to then calculate the curvature. Several approximation methods called *implicit parabola fitting* proposed in [9], which have a good performance and a fair simplicity of implementation.

### B. Second-order curve approximation

In the implicit parabola fitting method, proposed in [9], the curve is described by a function such that:  $y = f(x)$  or  $x = f(y)$ . The variation of  $x$  and  $y$  inside the window determines the parameterization to adopt, in fact if the variation of  $x$  is greater than that of  $y$ , the algorithm will select the case  $y = f(x)$  and vice versa. In order to simplify the notation, we will consider that  $p_0 = (0, 0)$ . The goal is to find  $f'_0$  and  $f''_0$ , which minimize:

$$E_x(f'_0, f''_0) = \sum_{i=-q}^q (y_i - f'_0 x_i - \frac{1}{2} f''_0 x_i^2)^2 \quad (4)$$

The solution of this problem of least squares gives:

$$f'_0 = \frac{cg - bh}{ac - b^2} \quad f''_0 = \frac{ah - bg}{ac - b^2} \quad (5)$$

such that :

$$\begin{aligned} a &= \sum_{i=-q}^q x_i^2 & g &= \sum_{i=-q}^q x_i y_i & b &= \frac{1}{2} \sum_{i=-q}^q x_i^3, \\ h &= \frac{1}{2} \sum_{i=-q}^q x_i^2 y_i & c &= \frac{1}{4} \sum_{i=-q}^q x_i^4 \end{aligned} \quad (6)$$

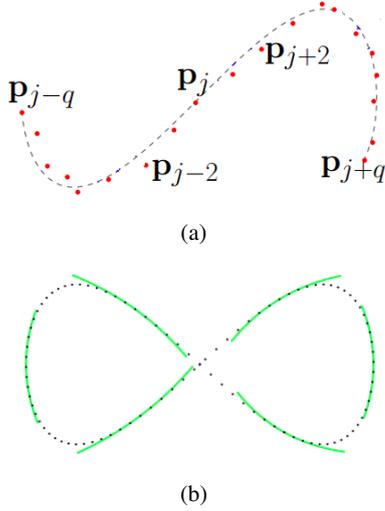

Fig. 2: (a) Points window, (b) Approximation by least squares

### C. Curvature computation

1) *Model and notation:* Consider a set of points  $p_i$  of a flat smooth curve  $r$ , in this study the curve is parameterized by the arc length, the estimate of the curvature for a plane curve requires an approximation of the first and second derivatives of  $r(s)$ . Let a point  $p_0$  be chosen. The derivation of  $r$  in  $p_0$  will be estimated from a window of size  $2q + 1$  around  $p_0 : p_{-q}, p_{-q+1}, \dots, p_q$  (see Fig 2a). We set  $p_0 = r(0)$  as the origin, the approximation of degree two can be written in the form:

$$r(s) = r'(0)s + \frac{1}{2} r''(0)s^2 \quad (7)$$

2) *The least squares approach:* The estimate of  $r'(0)$ ,  $r''(0)$  is obtained by the least squares approach (Fig 2b). The weighting  $w_i$  of the point  $p_i$  must be positive, relatively important for small values of  $|s_i|$  and relatively small for large values of  $|s_i|$ .

The arc length  $s_i$  can be estimated as follows:  $\Delta l_k$  is the arc length of the vector  $p_k p_{k+1}$ , where  $k$  varies from  $-q$  to  $q - 1$ . The arc length between  $p_0$  and  $p_i$  can be approximated by:

$$\begin{cases} l_i = \sum_{k=0}^{i-1} \Delta l_k, & i > 0 \\ l_i = -\sum_{k=0}^{-i-1} \Delta l_k, & i < 0 \end{cases} \quad (8)$$

### D. Curvature computation for a plane curve

For the case of plane curves, the idea of the Independent coordinates method [9] is to construct a parametric curve  $(x(s), y(s))$  that approaches the curve locally, by quadratic functions as a function of arc length.

$$\begin{cases} \hat{x}(s) = x_0 + x'_0 s + \frac{1}{2} x''_0 s^2 \\ \hat{y}(s) = y_0 + y'_0 s + \frac{1}{2} y''_0 s^2 \end{cases} \quad (9)$$

The derivatives  $x'_0$  and  $x''_0$  are estimated by minimizing:

$$E_x(x'_0, x''_0) = \sum_{i=-q}^q w_i (x_i - x'_0 l_i - \frac{1}{2} x''_0 l_i^2)^2 \quad (10)$$

The minimization of this equation can be written in the following matrix form

$$\begin{bmatrix} a_1 & a_2 \\ a_2 & a_3 \end{bmatrix} \begin{bmatrix} x'_0 \\ x''_0 \end{bmatrix} = \begin{bmatrix} b_{x,1} \\ b_{x,1} \end{bmatrix} \quad (11)$$

such that :

$$\begin{aligned} a_1 &= \sum_{i=-q}^q w_i l_i^2 & a_2 &= \frac{1}{2} \sum_{i=-q}^q w_i l_i^3 & a_3 &= \frac{1}{4} \sum_{i=-q}^q w_i l_i^4 \\ b_{x,1} &= \sum_{i=-q}^q x_i w_i l_i & b_{x,2} &= \frac{1}{2} \sum_{i=-q}^q w_i l_i^2 x_i \end{aligned} \quad (12)$$

---

#### Algorithm 1: Weighted least square variables setting

---

$I[] = a_1 = a_2 = a_3 = b_{x,1} = b_{x,2} = b_{y,1} = b_{y,2} = 0$

**for**  $i = -q; i \leq q; q++$  **do**

$I[i] \leftarrow I[i - 1] + \|p_i p_{i-1}\|$

**end**

$m = I[0]$

**for**  $i = -q; i \leq q; q++$  **do**

$I[i] \leftarrow I[i] - m$

$w \leftarrow \text{weight}(I[i])^2$

$a_1 \leftarrow a_1 + w(I[i])^2$

$a_2 \leftarrow a_2 + \frac{w}{2}(I[i])^3$

$a_3 \leftarrow a_3 + \frac{w}{4}(I[i])^4$

$b_{x,1} \leftarrow b_{x,1} + w(I[i])(x_i - x_0)$

$b_{y,1} \leftarrow b_{y,1} + w(I[i])(y_i - y_0)$

$b_{x,2} \leftarrow b_{x,1} + \frac{w}{2}(I[i])^2(x_i - x_0)$

$b_{y,2} \leftarrow b_{y,1} + \frac{w}{2}(I[i])^2(y_i - y_0)$

**end**

$d \leftarrow a_1 a_3 - a_2^2$

---

The same procedure is applied for the calculation of  $y'_0$  and  $y''_0$ . The tangent  $T$  is obtained by the normalization of the vector  $r'_0 = (x'_0, y'_0)$ , while the normal vector is obtained by a rotation of  $90^\circ$  of  $T$ .

## IV. CUTTING ACCORDING TO CURVATURE

This step will aim to cut the road into a set of primitives consisting of straight lines, left/right turns based on the value of curvature estimated at each point as explained in the previous step.

**Algorithm 2:** Coefficient computation

$$\begin{aligned}
x'_0 &\leftarrow (a_3b_{x,1} - a_2b_{x,2})/d \\
y'_0 &\leftarrow (a_3b_{y,1} - a_2b_{y,2})/d \\
x''_0 &\leftarrow (a_1b_{x,2} - a_2b_{x,1})/d \\
y''_0 &\leftarrow (a_1b_{y,2} - a_2b_{y,1})/d \\
\kappa &\leftarrow (x'_0y''_0 - y'_0x''_0) / \|(x'_0, y'_0)\|^3 \\
T &\leftarrow (x'_0, y'_0) / \|(x'_0, y'_0)\| \\
N &\leftarrow \text{sign}(\kappa)(-T_y, T_x)
\end{aligned}$$

For this, we will execute the following processes in the order indicated. We first start with a classification in two primitives only, that is to say left/right turn, we continue by extracting the sections which are straight lines independently of the primitives obtained previously and we thus finish by eliminating the isolated points, which are of the right type because a primitive of the right type must have a minimum number of two points. In what follows we will detail the procedure for filtering the curvature values according to the order of execution of the steps.

*A. Preprocessing*

In order to facilitate the different treatments, an initial marking of all the points of the curve has been carried out. For this, we assigned to each point whose curvature is positive the number +1, and -1 for those whose value of the curvature is negative, and we stored the result in a table named "ids" which will be subsequently updated by the results of the different processing.

*B. Left and right turns detection*

Our approach was based on a local estimate of the curvature sign near the point considered. A sliding window of size  $w$  has been used to estimate the global sign of the values inside the window by summing the values previously assigned, so the classification of the types of sections will be carried out as following :

- The sum is positive, so it is a right turn and the point is marked +1.
- The sum is negative, so it is a left turn and the point is marked -1.
- The zero sum is not a possible case because the size of the window around the point is odd.

This step is very important because it allows to assign a point to a given turn even if the sign of its curvature does not correspond, because it is the trend of the whole neighborhood is taken into consideration.

*C. Straight line detection*

Straight line detection is based on the value of the estimated curvature. Indeed, we know that a line is characterized by a null curvature. Since the values of the estimated curvature are not all accurate and contain noise, a threshold  $\delta$  has been set. If the curvature norm is below this threshold, the point will be assigned to a straight line primitive. Points satisfying the relationship  $|K(s)| < \delta$  will be assigned the number 0.

*D. Elimination of isolated right point*

Knowing that a marked point of a straight line can not be isolated, the solution is to go through all the points of the line and to modify those which are of marking different from their neighbors according to the signs of the curvature at this point, i.e. +1 marking if the curvature is positive, -1 otherwise.

**Algorithm 3:** Primitive assignment

```

while  $i < \text{ids.size}()$  do
  gpts gpt
  gpt.type  $\leftarrow \text{ids}[i]$ 
  gpt.id  $\leftarrow i$ 
  gpt.nbr  $\leftarrow 0$ 
  for  $i = 0; i < \text{ids.size}(); i++$  do
    if  $\text{gpt.type} \neq \text{ids}[i]$  then
      Break
    end
    gpt.nbr++
  end
end

```

## V. TURNS APPROXIMATION WITH SECOND ORDER POLYNOMIALS

*A. Preprocessing*

In order to interpolate curves with polynomials, a data structure has been created to facilitate processing on the one hand and to save the results obtained on the other hand. This data structure ("gpts") consists of an integer field named "type", which will contain the type of the primitive according to the marking carried out in the previous step. An integer field named "id", which will contain the identifier of the first point of the primitive. An integer field named "nbr", which will contain the number of points belonging to this primitive as well as two other fields "paramX" and "paramY", which will be used to store the coefficients of polynomials associated with turns. The structure being created, the fields were subsequently assigned according to algorithm 3.

For each left-handed or right-turn type primitive, we will proceed to the parameterization according to the length of the arc, so we will have two polynomials according to  $x$  and  $y$  such that:

$$\begin{cases} x(s) = a_0 + a_1s + a_2s^2 + a_3s^3 \\ y(s) = b_0 + b_1s + b_2s^2 + b_3s^3 \end{cases} \quad (13)$$

The polynomials in question will be of degree 3, this choice can be justified by the absence of inflection points since the primitives have been classified according to their (there is not a transition in the same road segment). They are convex or concave curves hence the choice of the polynomial regression that is a statistical analysis that describes the variation of an independent random variable, called here  $x$  or  $y$ , according to an independent random variable, called here  $s$ , being the length of the arc. We seek, by regression, to bind the variables by

a polynomial of degree 3. The calculation of the coefficients therefore amounts to solving a system of equations that can be expressed in the following matrix form:

$$\begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} 1 & s_1^1 & s_1^2 \cdots & s_1^m \\ 1 & s_2^1 & s_2^2 \cdots & s_2^m \\ \vdots & \vdots & \ddots & \vdots \\ 1 & s_n^1 & s_n^2 \cdots & s_n^m \end{pmatrix} \begin{pmatrix} a_0 \\ a_1 \\ \vdots \\ a_m \end{pmatrix} \quad (14)$$

The number  $m = 3$  corresponds, in our case, to the cubic polynomial regression. We will treat the case of the polynomial  $x(s)$  generated and it is the same for  $y(s)$ . The problem is therefore to find the vector  $\vec{a}$  in the equation:

$$\vec{x} = S\vec{a} \quad (15)$$

The solution is given by:

$$\vec{a} = (S^T S)^{-1} S^T \vec{x} \quad (16)$$

### B. Error criterion

Given the needs and requirements of the realism imposed on the generated road, we set ourselves the objective of approximating the GIS input data with lines and polynomials of third degrees such that the maximum deviation between the two curves does not exceed 2.0m, in this part we discuss the calculation of error as well as treatments to be undertaken in the case of exceeding this limit.

1) *Error computation*: The error  $d$  is estimated as the distance between the approximate point  $p = (x, y)$  and the entry point  $p = (x, y)$ , it is deduced according to the following formula:

$$d = \sqrt{(\hat{x}(s) - x(s))^2 + (\hat{y}(s) - y(s))^2} \quad (17)$$

The maximum value of this error must not exceed  $\delta$  for each of the points of the different right or polynomial primitives.

$$d_{max} < \delta \quad (18)$$

2) *Error processing*: Primitives whose error exceeds the required threshold must be modified, for this our approach is to generate from the initial primitive two primitives such that the number of points constituting each primitive is equal to half the number of points of the primitive. For a given primitive  $C_m$  one generates two primitives  $C_{m/2}$  and  $C'_{m/2}$ , and the same treatment will be executed on the two new primitives in a recursive way, this will assure us:

- Compliance with the error limit required for each final primitive obtained,
- The generation of a minimal number of primitives,

## VI. RESULTS

The results obtained when applying our method are summarized in Figure (3). The figures show the stages of our approach. Figure (3a) shows a sample of a road polyline. In Figure (3b), the curvatures were estimated by the least squares method. Note that this representation is more exploitable than that of Figure (1), and that there is less disturbance in the values of the curvatures due to windowing.

### A. Curvature estimation by the implicit parabola fitting method

In order to overcome the problems encountered when calculating the curvature by cubic splines, we opted for an estimation of the latter by the least squares. Compared with spline, the quality of curvature values improved significantly. Indeed, most points follow the trend of the turn where they belong as can be seen in Figure (3b). Nevertheless, in the case of more complex turns, outliers appear. Hence, we have proposed to neglect them, and to mark a window by a single sign of curvature relative to reality.

### B. Clustering

Figure (3c) shows that the points of the input road were grouped into three basic categories: left turn, right turn, and straight line. We note that the results are more refined, because this step corrects any possible residual error of the previous section. Moreover, it allows noise reduction, by defining the straight line segments from a given threshold, since the SIG data being noisy, we cannot obtain zero curvature values.

This step allowed us to have the same signs of curvature for a given type of cluster. Nevertheless, at this stage the clusters are not connected to each other, a major problem on which the approximation will be based in the following phases.

To overcome the problem of connection, we fix first the ends of the primitives, then we approximate the calculated model of the initial points. In this perspective, the Bezier curves with a least squares approximation prove to be an adequate choice. Indeed, the first and last control point are superimposed on their correspondents in the initial data, then the other points are calculated by minimizing the differences between the model and the initial data. The main disadvantage of this method is that it guaranties only  $C_0$  continuity between two clusters of successive points, which does not satisfy civil engineering constraints. Moreover, in some complex turns, it remains difficult to follow the shape of the cluster by a third degree polynomial.

Figure (3g, 3h) represents the constructed road. The initial data points circled and clustered. Note that the resulting model does not deviate from the input road polyline. The curves in magentas represent the edges of the road, the input data (polylines) are in red, and the model (at the central axis) is in blue. Figure (3h) illustrates the mapping of the road to the geo-referenced satellite image corresponding to the road section. As can be seen, the model provides a smooth representation of the road surface. We see that complex shapes such as turns are well approximated. In addition, our model meets the  $C_2$  continuity (imposed by road civil engineering), along the road without oscillations or other erratic behaviors that would compromise the visual comfort during the simulation.

## VII. CONCLUSION AND FUTURE WORKS

The objective of this work was the realistic modeling of the road surface by taking into account a number of civil engineering and vehicle dynamics constraints. We chose curvature

as a parameter describing the shape of the road in order to approach the profile of the latter as closely as possible.

We proceed through the estimation of curvature by a windowing approach because of the discrete nature of GIS data. In order to approach the reality, we grouped the points into clusters according to their neighborhood's curvature to obtain basic forms of the road namely left/right turns and straight lines.

This being done, the next step was to find the mathematical functions as well as the appropriate conditions and constraints to approach the initial data with functions that respect  $C_2$  continuity conditions.

The results obtained are satisfactory insofar as our road reconstruction approach takes into account the real constraints, moreover the model obtained is of  $C_2$  continuity, which reflects the smoothness of the position, speed and the acceleration of the simulated vehicle.

As perspective, we plan to improve and refine this work by considering road intersections, since the latter are frequently encountered in real-life situation.

# Crime Scene Reconstruction with RGB-D Sensors

Abdenour Amamra, Yacine Amara, Khalid Boumaza, and Aissa Benayad

Ecole Militaire Polytechnique, Bordj El-Bahri BP 17, Algiers, Algeria

Email: amamra.abdenour@gmail.com

**Abstract**—Photographic surveying, a fundamental procedure in crime investigation, is typically performed using 2D cameras. Although useful, such cameras remain limited due to the lack of depth information. In this work, we propose a 3D reconstruction solution that leverages the advantages of cheap RGB-D sensors to create a 3D model of the crime scene and to provide the investigator with an interactive crime scenario simulation environment. A structure from motion approach is proposed in order to align the captured point clouds on each other using 3D key points. An iterative refinement and a global optimization algorithm are later adapted for the optimization of the registered 3D model, which is then triangulated before the underlying surface is reconstructed. The resulting model is used for interactive crime investigation and object dynamics simulation. The obtained results show the effectiveness of our solution with a visually appealing rendering, an accurate simulation and a quantitative error of less than 18cm for the  $4m \times 4m$  indoor scene. An accompanying video is provided in order to illustrate the processing pipeline<sup>1</sup>.

**Index Terms**—Crime scene modeling, 3D registration, RGB-D sensors, Forensic computing, Interactive investigation.

## I. INTRODUCTION

In the world we live today, we hear frequently about crimes and the ways they are resolved. Freezing and preserving the crime scene is certainly one of the most important and delicate initial steps that the police perform upon the arrival to a crime scene. The idea is to conserve the spatial configuration of the objects surrounding the place where they think the crime took place for the purpose of avoiding any contamination.

In most current cases, the investigation is carried out in the simplest manner, that is, with paper, pencil and measurement ribbon, to sketch an illustration of the crime scene showing the position of the victim, as well as the other tools that could have served the criminal. For instance, a trivial improvement of the simple flat drawings can be a 3D representation of the scene allowing a better understanding of the series of events that conducted to the crime. For instance, several computer tools have been used by experts for the creation, the visualization, and sharing of electronic crime data among investigators. A first 3D reconstruction method based on this software is the design of a 3D model of the scene. Then taking pictures and pasting them on the 3D mesh. This method is simple and does not require much experience, however, it fails to preserve the 3D shape and dimensions of objects. Another method of 3D scene reconstruction is a faithful recreation of the scene. The latter requires the mastery of sophisticated 3D modeling tools and the measurements of all the important scene objects. Its advantage is that the resulting model is very close to reality.

<sup>1</sup><https://youtu.be/IYnJSNV7QkI>

Unlike the methods mentioned above, our approach is based on the alignment of several 3D images of the same scene, with different points of view. This alignment is looking for spatial transformations that merge the views into a single globally consistent model. With such an approach, the reconstruction of scenes is not left to the skills and performance of a human actor; rather, it relies on real environmental measurements while taking into account the dynamics of objects. Interestingly, with a coherent 3D representation and a physics engine, physical laws can be simulated (e.g. simulation of a bullet's trajectory). Otherwise, it would be possible to test crime hypothesis without the need for deployment on the physical scene. For this purpose, the Kinect could serve as an affordable 3D scanner that has interesting performance in 3D shape capturing. Indeed, RGB-D cameras capture the color and the geometry of the scene and deliver colored 3D point clouds, but their data still needs a chain of preprocessing and 3D registration as well as surface inference in order to become a useful representation. In our case, these sensors were placed at the center of the crime scene and the forensic police will take care of swiveling it in order to scan the objects of interest.

In the remainder of the paper, we first discuss the literature of crime scene reconstruction and modeling in Section II. Then, we present our approach to 3D reconstruction and interaction in Section III. We validate our findings with several quantitative and qualitative assessments in Section IV. And we conclude with a summary of what we aimed for and what we really achieved, as well as some future perspectives that can enhance and extend the present work in Section V.

## II. RELATED WORKS

The attempt to reconstruct crime scenes with 3D reconstruction means finds its origins in [1]; where the authors used a mobile camera in a Structure-from-Motion (SFM) pipeline. Afterward, the authors in [2] presented a general comparison of 3D imaging sensors for criminal investigation. They took into account most of the 3D techniques available at that date. It should be noted, however, that Time of Flight (TOF) technology, the working principle of the Kinect v2, was not considered since the technology has not been widespread until the last decade. The authors in [3] used an alternative dense reconstruction approach directly on video sequences.

Initially used to solve the problem of ego-motion, Simultaneous Localization and Mapping (SLAM) techniques have been a hot topic in robotics for several years. Crime scene reconstruction works had followed through the light of SLAM technology; where the authors of [4] investigated the

utilization of a stereo camera rig in a SLAM based crime scene reconstruction pipeline. Nevertheless, it is worth noting that stereo mapping is a passive technique that reconstructs a cloud of 3D points by matching the corresponding key points found in both RGB images. Since it relies only on the feature points of the environment, RGB imaging techniques are subject to singularities when the images lack distinctive patterns (e.g. uniformly colored surfaces, which potentially characterize indoor scenes; thus, rendering stereo pairing difficult and resulting in a rough and distorted 3D content).

Another approach is to design a 3D model of the scene using 3D modeling software such as 3ds Max [5]. More recent approaches use laser scanners [6] to reconstruct the crime scene at a very high accuracy. An example of the laser scanners that were used for this purpose is FARO S-350 [7]. The latter is dedicated to fast and accurate 3D indoor and outdoor environments. Nonetheless, its high cost and lengthy reconstruction time are two famous shortcomings of such a technology.

In the light of the literature, and in the purpose of building upon the previous contributions, we investigate the utilization of RGB-D data, in an SFM pipeline with a loop closure mechanism and a 3D triangulation and surface reconstruction algorithm for the development of an interactive crime investigation solution.

### III. 3D CRIME SCENE RECONSTRUCTION

In what follows, we present our solution to 3D crime scene reconstruction and interactive investigation.

#### A. Solution Overview

Figure 1a illustrates the process followed to complete our work. As illustrates the diagram, our solution is essentially divided into three steps: a *data acquisition*, where the point clouds are delivered by the Kinect v2 RGB-D sensor. The second step is the *prepossessing* of the point clouds delivered by the sensor. The latter includes: down-sampling, filtering, and key points extraction and description. The last step, which is the most important, is the *3D alignment and reconstruction* that results in a coherent holistic 3D model for investigation purposes.

#### B. Data Acquisition

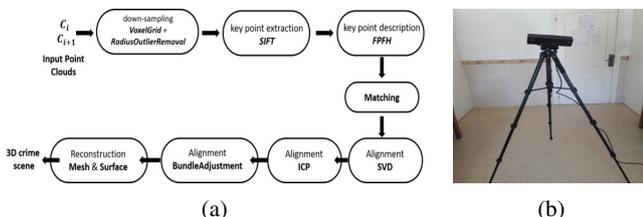

Fig. 1: Crime scene reconstruction setup. (a) Reconstruction pipeline, (b) RGB-D data acquisition setup

This phase involves collecting data from the scene with the Kinect, with the consideration that two successive images

overlap each other. To this end, and as the Kinect sees only the scene within its viewport, we place it at the center of the scene (see Figure 1b) and we have it rotated at small regular angles. We can, therefore, acquire images at multiple views during a complete turn for later reconstruction.

Despite the use of the rotating acquisition procedure, parts of the scene remain occluded in the captured views. In fact, these regions are not visible to the camera as shows Figure 2b. Such a phenomenon can be overcome by adapting the scans to cover the holes. At this level, we focus only on the acquisition of visible parts, because the missing parts can be treated separately after the reconstruction finishes.

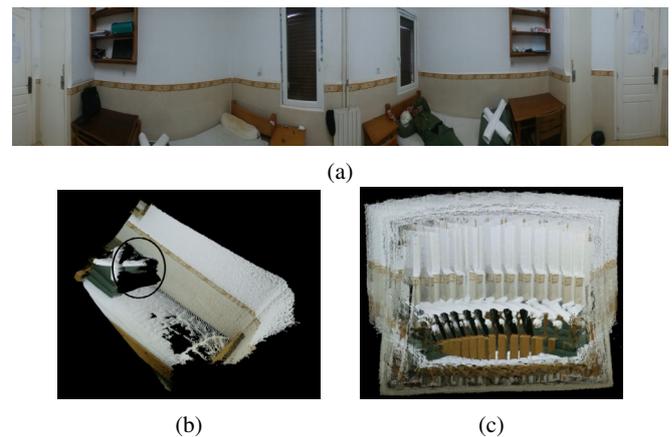

Fig. 2: RGB-D images captured from the experimental  $4m \times 4m$  crime scene. (a) Panoramic view of the crime scene, (b) Point cloud, with hidden regions, obtained from the captured view, (c) Projection of all the views in the same reference frame.

#### C. Filtering and down-sampling

In order to obtain a decent 3D model of the scene, and in the sake of faster 3D mesh creation, it is important to down-sample the raw point cloud. The down-sampling technique that we adapted is based on the Voxelgrid method [8]. After a consistent sampling, we obtain a less dense point cloud that preserves the underlying geometry without redundancy. The second preprocessing to be carried out is noise and outlier points elimination. For this purpose, we adapted the Radius Remove Outlier filter [9]. The latter smoothes the 3D points and removes isolated points.

#### D. Alignment and 3D reconstruction

This section is essential to our contribution, the objective here is the alignment of the different views in order to obtain a coherent 3D scene. Our approach to point cloud alignment is cumulative pairwise. In other words, we align a pair of point sets at a time, then we carry on with the following pair, and so on; until the last view (typically overlapping the first one, as we rotated the camera in order to scan the whole scene from the center).

Technically the alignment of the point sets results from the computation of a  $4 \times 4$  transformation matrix  $T$ . The latter embeds a  $3 \times 3$  rotation matrix and a  $3 \times 1$  translation vector. We add to this matrix the so-called homogeneous coordinates for the simplicity of computation to obtain the  $4 \times 4$  transformation matrix.

$$T = \begin{bmatrix} r_{00} & r_{01} & r_{02} & t_0 \\ r_{10} & r_{11} & r_{12} & t_1 \\ r_{20} & r_{21} & r_{22} & t_2 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

For example, in order to align three point clouds  $A_1, A_2, A_3$  together, one first aligns the second cloud  $A_2$  with the first  $A_1$ , where the result after minimization is the transformation  $T_{1,2}$ . We obtain a global intermediate result  $G_{1,2} = A_1 \cup T_{1,2} * A_2$ . Then, we align the third cloud  $A_3$  with the already obtained global result  $G_{1,2}$  to obtain the final result  $G_{1,2,3} = G_{1,2} \cup T_{1,2,3} * A_3$ .

In order to perform point cloud alignment, we propose the following scheme:

#### 1) Initial alignment

This phase aims to find the transformation between the different views respective to the acquired point clouds (see Figure 2c) after the matching of key points. The initial alignment of two point clouds (typically called source  $Sr$  and target  $Tr$ , where  $Sr_{aligned} = T * Sr$ ) begins with the extraction of characteristic points; then the computation of the descriptors respective to these points, followed by the estimation of correspondences. After the rejection of bad matches, we estimate the transformation that aligns the sets of points and we apply it on the source point set. In our work, we initially adopted the matrix Singular Value Decomposition (SVD) [10] in order to estimate an initial guess of the underlying transform. This preliminary result is prone to error since it is computed fast without any sophisticated refinement (see Figure 3a). Nevertheless, it serves as a desirable initialization for the subsequent Iterative Closest Point (ICP) [10] alignment algorithm which gets frequently trapped in local minima.

#### 2) Iterative refinement with ICP

In most cases, the initial alignment does not give sufficiently accurate transformation. Hence, our goal now is to refine as much as possible the already obtained transformation with the ICP algorithm. The latter finds first the closest points in both clouds of points (correspondence estimation); then it proceeds through the estimation of a transformation that best aligns the matched correspondences (alignment). These two steps (correspondence, alignment) are repeated until reaching a termination criterion (typically, an error threshold or a maximum number of iteration). Figure 3b shows the outcome of applying the ICP algorithm on the SVD result. Although accurate when aligning a few point sets, ICP inherently leads to cumulative small errors due to a large number of views (around 50 views for a small room).

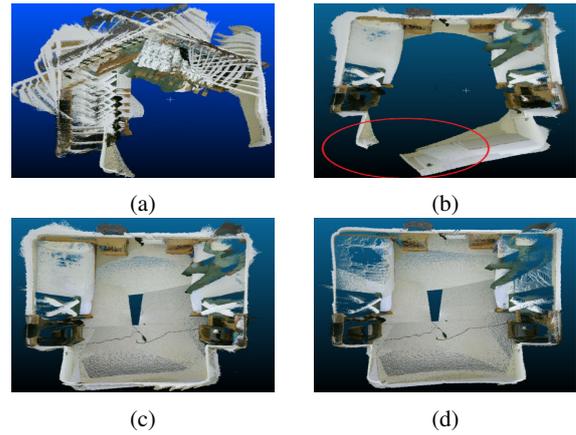

Fig. 3: Point cloud Alignment Results. (a) After initial alignment with SVD, (b) After refinement with ICP, (c) After loop closure, (d) After filtering and segmentation.

The global error between all the aligned 50 views after SVD is about 7m, which is huge for a  $4m \times 4m$  room. Indeed, ICP greatly minimizes this error to around 1m, but the accumulation of errors still impinges on the loop closure, due to a misalignment between the first and the last point set, that needs to be dealt with.

#### E. Loop Closure

As we mentioned earlier, point cloud alignment techniques introduce a non-negligible cumulative error, but the closure between the first and the last point clouds significantly reduced the error to its lowest levels. We noticed that this is not always the case, as when misalignment due to mis-correspondences is encountered, the overall reconstruction is no longer reliable. The reconstruction error increases with distance and misalignment is difficult to correct. Figure 4 illustrates the accumulation of misalignments after the application of SVD and ICP algorithms. This accumulation is more noticed at the corners of the room.

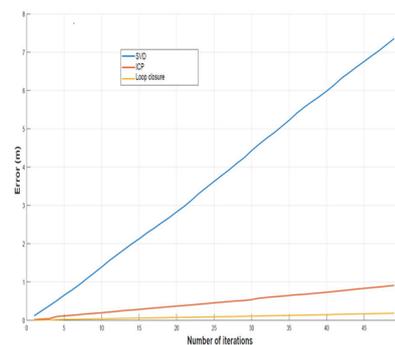

Fig. 4: The evolution of the cumulative error after SVD, ICP, and Loop Closure.

#### F. Filtering and segmentation

It is important that the point cloud after alignment bears little noise. For instance, the alignment algorithm filters some

**Input:**  $N$  point clouds  $C = \bigcup_{i=1}^N C_i$ .

**Output:** Optimal transformation ( $\hat{T}$ ) that minimizes the global misalignment ( $f$ ) between the  $C_i$ .

- 1) **Calculate the correspondences** between a given pair of clouds  $S, D$ ; such that  $(S, D) \in C \times C$  and  $S \neq D$ .
  - a) Initialize  $S' = \emptyset, D' = \emptyset$ .
  - b) For each point  $p \in S; \forall q \in D$ :
    - i) Calculate the distances between  $p$  and  $q$ .
    - ii) The point  $q$  of minimum distance corresponds to  $p$ .
    - iii) Remove  $p$  from  $S$ , and it to  $S'$ .
    - iv) Remove  $q$  from  $D$ , and it to  $D'$ .
  - c) Choose two subsets  $S''$  and  $D''$  of  $S'$  and  $D'$ , respectively, such that the elements of  $S''$  and  $D''$  are those of  $S'$  and  $D'$  with a distance below a given threshold.
- 2) **Estimate  $T$**  :

$$\hat{T} = \arg \min_T \left( \sum_{\forall S \neq D \in C} \|D - T * S\|^2 \right)$$

- 3) **Repeat 1 and 2** : until the following criterion is satisfied ( $f(\hat{T})$  is the global alignment error between all the  $N$  views after applying the transformation  $\hat{T}$ ) :

$$\|f(\hat{T})\|^2 \leq \epsilon$$

**Algorithm 1:** Loop closure Algorithm

of the noise but, if the cloud carries a lot of points not belonging to the model, the result of reconstruction may not be convincing to the investigator. After filtering our resulting point cloud with the Region Growing Segmentation filter [9] we obtained the result in Figure 3d.

### G. 3D triangulation and surface reconstruction

This step consists in creating facets from the point cloud by connecting the non-ordered points to each other in a triangular topology. To this end, we first apply Delaunay triangulation algorithm [9] for the creation of a smooth mesh. Figures 5a, 5b show our scene after surface reconstruction.

When we zoom in on the different parts of the scene (Figure 5b), we notice that surface reconstruction is generally of good quality except in some minor regions. These regions are typically characterized by a low density of 3D points resulting in a poor quality triangulation. To solve this problem, we captured 2D colored images during the acquisition phase, which will subsequently be used to fill the holes.

## IV. RESULTS AND DISCUSSION

In this section, we analyze the performance of our Loop Closure algorithm applied to improve the performance of 3D point cloud alignment. In order to demonstrate the intake of Loop Closure, we focus only on visual results and the variation of the cumulative error after the application of the three alignment algorithms. Figures 3c, 3d illustrate the final

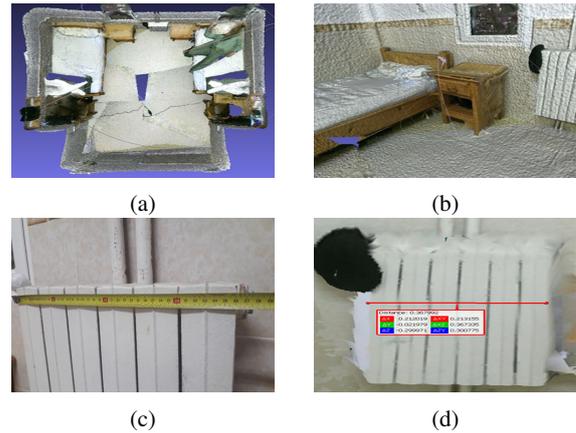

Fig. 5: Result After 3D Reconstruction. (a) Scene overview, (b) Zoom in the corner, (c) Real scene measurement, (d) 3D model measurement.

result of our scene after the alignment of all the views, we can see with the naked eye that the scene is closed, and the algorithm enhances the preceding result. We can also say that the alignment mean squared error has decreased considerably, it results in a misalignment of 18cm which is small given the 4m x 4m area of the room. The graph in Figure 4 illustrates this improvement.

### A. Implementation

The implementation of our proposed solution was achieved in C++ using the PCL library<sup>2</sup>, and Matlab 2017b on Windows 10 operating system. The different tests were carried out on a machine equipped with an Intel Core i5 processor of 2.30GHz and 6GB Ram.

In order to quantify the accuracy of our reconstruction, we compare the actual size and dimensions of scene objects to those obtained in the reconstructed model. This assessment is performed through cloud compare software<sup>3</sup>.

### B. Cloud Compare

This utility permits us the measurements of distances between 3D points. To make this comparison, we took real measurements of some objects in the crime scene, and we measured their respective reconstructed counterparts using Cloud Compare as shown in Figure 5c, 5d. Table I contains some measured dimensions of objects that were present in the crime scene. We notice clearly that our model gives enough accurate results, which were validated by investigators. These measurements mean that there is little overall difference between our model and the actual scene, where to 98% both measurements were similar. In addition, measurement error is more important in the larger objects due to the decreasing accuracy of the depth map delivered by the sensor.

Electric socket	39	39.2	0.2

TABLE I: Comparison between actual measurements and model measurements.

C. Crime scenario

A good 3D reconstruction of the scene helps the investigator in the investigation, we simulated a crime scene that can enrich our work. This scenario is intended to reproduce the hypothesis prior to the action of committing the crime. To this end, we used Unity software <sup>4</sup>, which is a multi-platform game engine. This software allows us to introduce virtual objects into our scene and then to make animations and to create scenarios. In our case, we used two virtual persons (victim and criminal) as shows Figure 6. We programmed these characters in order to obtain a scenario as close as possible to reality.

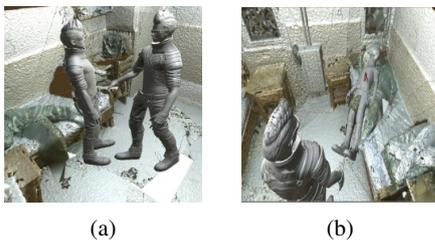

Fig. 6: Unity 3D simulated crime scenario: (a) Before, (b) After the crime.

D. Technical issues

We noticed during the deployment of our solution several technical problems. The first one concerns the stage of data acquisition, the Kinect sensor uses infrared rays to infer the depth of objects. Nevertheless, there are some hidden parts that could not be captured by the sensor. Another problem was encountered in the global alignment process, this problem is due to the accumulation of the errors. Correspondence estimation algorithms that are based on the feature descriptor are not optimized, which brings to bad matches, all of this leads to misalignment. The surface reconstruction stage generally gives good results, with the exception of the hidden or sparse regions. The last problem was noticed in Unity 3D during the simulation of crime scenarios, as the game engine accepts only three scene formats (.obj, .fbx, or .unity), we were obliged to

convert our model and to lose some scene’s color and geometry consistency.

V. CONCLUSION

We presented an RGB-D solution for accurate crime scene reconstruction and interactive scenario simulation. We leverage the potential of the cheap Kinect v2 TOF sensor in order to scan the crime space. Based on a set of key points we applied a preliminary alignment of the different views with SVD optimization. The latter is known for its speed but poor accuracy. However, it delivers a good guess for the subsequent iterative refinement algorithm (ICP). Afterward, we addressed the loop closure problem with a bundle adjustment algorithm.

Once all the views registered in the same reference frame, we proceeded through the triangulation and surface reconstruction. The resulting model is used for interactive crime investigation and object dynamics simulation. The obtained results show the effectiveness of our solution and its adequacy to the context being treated. We demonstrated the performance of our finding on a real scene. An accompanying video illustrates the whole chain of processing is available <sup>5</sup>.

As perspectives, we aim to extend the capabilities of the proposed solution to work outdoors. Regarding the external reconstruction performance of Kinect v2, we need to address the sensitivity to sunlight. Moreover, since our solution is better suited for offline processing, it would be interesting to investigate possible acceleration techniques for rapid on site reconstruction through the utilization of graphics processors and highly parallel techniques. Finally, the theory behind our work can be exploited for large scale reconstruction as well, after taking into account the required computational burden and the intervention of the different reconstruction elements.

# 7<sup>th</sup> Workshop on Advances in Programming Languages

**P**ROGRAMMING languages are programmers' most basic tools. With appropriate programming languages one can drastically reduce the cost of building new applications as well as maintaining existing ones. In the last decades there have been many advances in programming languages technology in traditional programming paradigms such as functional, logic, and object-oriented programming, as well as the development of new paradigms such as aspect-oriented programming. The main driving force was and will be to better express programmers' ideas. Therefore, research in programming languages is an endless activity and the core of computer science. New language features, new programming paradigms, and better compile-time and run-time mechanisms can be foreseen in the future.

The aims of this event is to provide a forum for exchange of ideas and experience in topics concerned with programming languages and systems. Original papers and implementation reports are invited in all areas of programming languages.

## TOPICS

Major topics of interest include but are not limited to the following:

- Automata theory and applications
- Compiling techniques
- Context-oriented programming languages to specify the behavior of software systems and dynamic adaptations
- Domain-specific languages
- Formal semantics and syntax
- Generative and generic programming
- Grammarware and grammar based systems
- Knowledge engineering languages, integration of knowledge engineering and software engineering
- Languages and tools for trustworthy computing
- Language theory and applications
- Language concepts, design and implementation
- Markup languages (XML)
- Metamodeling and modeling languages
- Model-driven engineering languages and systems
- Practical experiences with programming languages
- Program analysis, optimization and verification
- Programming paradigms (aspect-oriented, functional, logic, object-oriented, etc.)
- Proof theory for programs
- Type systems
- Virtual machines and just-in-time compilation

- Visual programming languages

# Composition of Languages Embedded in Scala

Seyed H. HAERI (Hossein)

Université catholique de Louvain, Belgium

hossein.haeri@ucl.ac.be

Paul Keir

University of the West of Scotland, UK

paul.keir@uws.ac.uk

**Abstract**—Composition is amongst the major challenges faced in language engineering. Erdweg et al. offered a taxonomy for language composition. Mernik catalogued the use of the Language Definitional Framework LISA for composition sorts in that taxonomy. We produce a similar catalogue for embedded language engineering in Scala.

We begin with techniques that are not specific to Scala. They are applicable in any host language with a module system and support for higher order functions. We, then, present two more techniques to examine Scala-specific language engineering. Interestingly enough, even though dealing with embedded languages, in terms of lines of code, our material is of comparable length to its LISA counterpart. Our work lends insight into Scala’s serviceability for composition, as a host for embedded language engineering.

## I. INTRODUCTION

*a) Language composition is a piece of reality!:* Everyday, there are new programming languages that are born by combining ideas from older languages. Inspiration aside, that is an act of composition in many cases. For example, roughly put, Scala adds functional programming and ML modules with mixin composition to Java; which, in return, is C++ without pointers; which, in return, is C with OOP.

The taxonomy of Erdweg et al. [1] suggests a terminology and notations for describing such compositions. According to them, one can formalise our Scala description as:

$$\text{Scala} \cong \text{C} \triangleleft \text{C++} \triangleright \text{Java} \triangleleft (\text{MLModule} \uplus \text{Mixin}) \quad (1)$$

*b) Observations from Chemistry:* Consider the reaction:

In Chemistry, two key ingredients for success in the study of such equations are: (CI<sub>1</sub>) the availability of substances as the *subjects of study*, and, (CI<sub>2</sub>) knowledge about *how* to perform a desirable composition. In reaction (2), for instance, both substances  $H_2SO_3$  and  $NaOH$  need to be available. One also needs to know how to double  $NaOH$  for the equation balance to be right. Also, how to add  $NaOH$  to  $H_2SO_3$  (like the rate of addition, proper temperature, etc.) needs to be known.

*c) Programmatic Availability & Composition:* The study of formulae like equation (1) determines the precise relative position of languages. Using the outcome, one would be able to add, for example, what is missing in equation (1) so that the “ $\cong$ ” can be replaced by an “ $=$ ”. One would also gather that the left-out “FP $\uplus$ ” is necessary right before MLModule for the balance to be right. Such manipulations are similar

to adjusting coefficients in reaction (2) to obtain a balance. Similar to Chemistry, two key ingredients become noticeable here: (PLI<sub>1</sub>) *programmatic* availability of programming languages themselves and their belongings as the subjects of study, and, (PLI<sub>2</sub>) knowledge about how to *programmatically* obtain desirable language compositions.

By the time of this writing, (mainstream) languages are next to inaccessible as programmatic entities. The study of programmatic language composition, nonetheless, can be conducted independently using, say, contrived languages. That is how this paper tries to gain (PLI<sub>2</sub>).

*d) Contributions:* We demonstrate three techniques for composing languages embedded in Scala. The first (Section II) is applicable in any host language with a module system and support for higher order functions. The second (Section III) is based on Lightweight Modular Staging (LMS) [2]. And, the third – which is also a new solution to the Expression Problem (EP) [3], [4], [5] – employs (possibly restricted) abstract types. The trick in our third technique is promoting the cases of Algebraic Data Types (ADTs) into their own ADT-parameterised standalone components. We showcase each technique using the example compositions of Mernik [6]. We, then, compare the three techniques for their success in addressing the EP concerns (Section V). A discussion about the related work also comes at Section VI.

*e) Coding Conventions:* This paper assumes familiarity with Scala. For each showcase, the syntax and semantics come in separate packings called `syntax` and `semantics`, respectively. Due to space restrictions, in our code, the name of the showcase is only appended as a comment to the end of the first line of the respective `syntax` or `semantics`. For the same reason, our code is also otherwise unusually compressed. Whilst the showcases are referred to in the prose in CamlCase, their respective Scala package (containing the showcase’s `syntax` and `semantics`) is named `like_this` or abbreviated as `lt`.

## II. SCALA-UNSPECIFIC

Erdweg et al. catalogue five different ways languages can be composed: language extension, language restriction, language unification, self-extension, and extension composition. Mernik offers simple DSLs to showcase those ways in LISA [7]. In this section, we employ Mernik’s simple DSLs for the same purpose, albeit in Scala.

### A. Language Extension

A base language  $B$  is said to be extended to a language  $E$  when the description of  $B$  is amended with a description fragment to get  $E$ . Erdweg et al. denote that by  $B \triangleleft E$ . Consider the language `Robot` below (packaged under the name `robot` in Scala) for a robot arm that takes commands for moving one unit to either of the four 2D directions. The semantics of `Robot` involves updating the arm's position (recorded in terms of the  $x$  and  $y$  coordinates) based on the commands (lines 11 to 16).

```

1 object syntax { //robot
2   class Command
3   case object Left extends Command
4   case object Right extends Command
5   case object Up extends Command
6   case object Down extends Command
7   case class Commands(s: Seq[Command])
8   object semantics { import syntax._ //robot
9     class Position(var x: Int, var y: Int)
10    object position extends Position(0, 0)
11    def locate: Command => Unit = {
12      case Left => position.x -= 1
13      case Right => position.x += 1
14      case Up => position.y += 1
15      case Down => position.y -= 1
16    }
17    def locate(cs: Commands) = cs.s.foreach(locate)
18  }

```

`Robot` is extended to `RobotTime` (the `robot_time` package) by adding to the semantics, i.e.,  $\text{Robot} \triangleleft \text{RobotTime}$ :

```

1 package robot_time
2 import robot._; import syntax._
3 def time(cs: Commands): Int = cs.s.length

```

Assuming that executing each command takes one time unit, the total time required for a set of commands is the size of the set. The method `time` in line 3 above adds that piece of semantics to `Robot` to get `RobotTime`. whereas `Commands(Right, Down, Down)` in `Robot` has only got the semantics  $x = 1, y = -2$ , it also has the semantics  $t = 3$  in `RobotTime`. (The coordinates are obtained by `locate` in line 16 of `robot` and the timing by line 3 of `robot_time`.)

Here is a difference between our implementation of `RobotTime` and that of Mernik: The latter is done in LISA: a Language Definitional Framework (LDF) that combines OOP with Attribute Grammars (AGs) [8], [9]. As such, LISA's counterpart for `time` has to visit all the grammatical rules in `Robot` to attribute the new piece of semantics to them. On the contrary, Scala gave us the joy of simply equating `time` by the number of the commands, regardless of the grammatical rules involved.

### B. Language Restriction

A base language  $B$  is said to be restricted to a language  $R$  when certain parts of the  $B$ 's features are removed upon transition to  $R$ . This is denoted by  $B \triangleright R$ . A typical usage of that is when a language is narrowed to a core of it. That is, certain parts of the base syntax are cancelled into combinations of other base syntactic parts that are deemed to be equivalent. For example, both `GPH` [10] and `Utrecht HASKELL` [11] are developed like that.

The language `RobotPositive` below (packaged under `robot_positive`) restricts `Robot` to only `Up` and `Right` commands. (Technically, the object `syntax` below is not required. Yet, we retain it for completeness.)

```

1 object syntax { //robot_positive
2   import robot.syntax.{Right, Up, Commands}
3   object semantics { //robot_positive
4     import robot.syntax.{Right, Up, Commands}
5     import robot.semantics.position
6     def locate(cs: Commands) {
7       for(c <- cs.s) c match {
8         case Right => position.x += 1
9         case Up => position.y += 1
10      }
11    }
12  }

```

Any attempt to use the expression in the previous section under `RobotPositive` will fail to compile for the availability of `Down` in it, which is absent in `RobotPositive`. On the other hand, `Commands(Right, Up, Up)` has the semantics  $x = 1, y = 2$  under `RobotPositive`.

### C. Language Unification

Erdweg et al. say two languages  $L_1$  and  $L_2$  are unified to  $L$  when both  $L_1$  and  $L_2$  make sense independently from one another and from  $L$  (as the composition's outcome). Furthermore, in  $L$ , neither  $L_1$  nor  $L_2$  should be dominated by the other so that a concept of equity prevails in the composition. The notation is  $L = L_1 \uplus_g L_2$ , where  $g$  is the so-called glue code required for the composition.

Having seen the language `Robot`, we now consider the language `ExprAdd` (packaged under `expr_add`): a simple ADT with two cases for natural numbers and addition.

```

1 object syntax { //expr_add
2   class Expr { //Expr ::= Expr + Term | ...
3     def + (t: Term): Expr = Add(this, t)
4   }
5   class Term extends Expr { //Expr ::= ... | Term
6     //Term ::= n
7     case class Num(n: Int) extends Term
8
9     case class Add(left: Expr,
10                    right: Term) extends Expr
11  }
12  object semantics { //expr_add
13    import syntax._
14
15    def value: Expr => Int = {
16      case Num(n) => n
17      case Add(e, t) => value(e) + value(t)
18    }
19  }

```

Using `value` in line 15 above, one obtains the semantics 5, 12, and 6 for the expressions `Num(5)`, `Num(10) + Num(2)`, and `Num(1) + Num(2) + Num(3)`, respectively.

The language `RobotUniExprAdd` below (packaged under `robot_uni_expr_add`) unifies `Robot` and `ExprAdd` by allowing the robot arm to take commands for moving as many units to either of the four directions as the corresponding `ExprAdd` argument evaluates to. As such, `Commands(Right(Num(5)), Up(Num(2) + Num(10)), Up(Num(2) + Num(2) + Num(2)), Down(Num(4)))` has the semantics  $x = 5, y = 14$ . Check `locate` in line 17 below.

```

1 object syntax { //robot_uni_expr_add

```

```

2 import robot.syntax.Command
3 import expr_add.syntax._
4
5 case class Left(e: Expr) extends Command
6 case class Right(e: Expr) extends Command
7 case class Up(e: Expr) extends Command
8 case class Down(e: Expr) extends Command
9
10 object semantics { //robot_uni_expr_add
11 import robot.syntax.Commands
12 import robot_uni_expr_add.syntax._
13
14 import robot.semantics.position
15 import expr_add.semantics._
16
17 def locate(cs: Commands) {
18   for(c <- cs.s) c match {
19     case Left(e) => position.x -= value(e)
20     case Right(e) => position.x += value(e)
21     case Up(e) => position.y += value(e)
22     case Down(e) => position.y -= value(e)
23   }
24 }
25 }

```

#### D. Self Extension

This is the situation when the description of a language  $L$  itself is used for extending it. Typically, embedded DSLs self-extend their host language. For example, all the languages we present in this paper self-extend Scala.

Like Mernik, we believe that demonstrating self extension takes much more than the volume of a single research paper. This is because bootstrapping a language  $L$  to the level where it can handle self extension is already more involved than that volume. Hence, we too drop demonstration of self extension.

#### E. Extension Composition

Extension composition is when (both or at least one of) the language descriptions that are to be composed are themselves compositions of other language descriptions. As such, extension composition can be regarded as higher order composition. Six combinations of extension and unification are possible (three distinguished by Mernik):

- 1) Double-Unification ( $\uplus$ ):  $L_1 \uplus_g (L_2 \uplus_h L_3)$ .
- 2) Double-Extension ( $\triangleleft$ ):  $B \triangleleft E_1 \triangleleft E_2$ .
- 3) Extension by a Unification ( $\triangleleft(\uplus)$ ):  $B \triangleleft (L_1 \uplus L_2)$ .
- 4) Extension of a Unification ( $(\uplus)\triangleleft$ ):  $(L_1 \uplus L_2) \triangleleft E$ .
- 5) Unification with an Extension ( $\{\uplus, \triangleleft\}$ ):  $L \uplus (B \triangleleft E)$  or  $(B \triangleleft E) \uplus L$ . Note the symmetry.

We now consider each combination.

1) *Double-Unification* ( $\uplus$ ): To that end, we begin by presenting Mernik's language Dec (packaged under dec) in Scala. Dec enables the programmer to bind a set of variables to integer constants.

```

1 object syntax { //dec
2 case class ConstDefList(ds: Map[String, Int]) }

```

Unsurprisingly, the (Scala-automatic) semantics of ConstDefList("a" -> 5, "b" -> 10) is then  $\{a \mapsto 5, b \mapsto 10\}$ .

With that, we illustrate the first class of Mernik's extension compositions using RobotUniExprAddUniDec (packaged under rueaud). As suggested by its name, this language is (Robot $\uplus$ ExprAdd) $\uplus$ Dec. The Robot $\uplus$ ExprAdd portion is already presented. See robot\_uni\_expr\_add in Section II-C. We now show how to obtain the remaining unification.

```

1 import expr_add.syntax.{Expr, Term}
2 object syntax { //rueaud
3 import robot.syntax.Commands; import dec.syntax._
4 implicit class CDLInCs(val cdl:ConstDefList) {
5   def in (s: Commands) = {
6     consts = cdl.ds; new EnvComm(cdl.ds, s)
7   }
8 }
9 class EnvComm(val ds: Map[String, Int],
10               val cs: Commands)
11 var consts: Map[String, Int] = Map()
12 case class Var(n: String) extends Term
13 object semantics { //rueaud
14 import syntax._; import robot_uni_expr_add.syntax._
15 import robot.semantics._
16 def value_ext: (Expr, Expr => Int) => Int = {
17   case (Var(n), c) => consts(n)
18   case (e, c) =>
19     expr_add.ext_semantics.value_ext(e, c)
20 def value(e: Expr): Int = value_ext(e, value)
21 def locate(r: EnvComm) {
22   r.cs.s.foreach {
23     case Left(e) => position.x -= value(e)
24     case Right(e) => position.x += value(e)
25     case Up(e) => position.y += value(e)
26     case Down(e) => position.y -= value(e)
27   }
28 }

```

rueaud.syntax aims at reusing the former language descriptions as they are. To that end, it takes a *pimp my library* approach [12] on trying to implicitly (lines 4 to 10 above) give instances of dec.ConstDefList the extra feature of being followed by commands possibly referring to the declarations. Such declarations followed by expressions are then instances of EnvComm. The variable consts (line 11) is where the processed declarations are stored. The new ADT case Var (line 12) is for looking up the value a name is bound to. rueaud legitimises commands for moving the robot arm as many units as a pertaining expression evaluates to (lines 23 to 26). Note that, because of Var, those expressions can refer to declarations as well. All that together gives ConstDefList ("a" -> 5, "b" -> 10) in Commands(Right(Var("a")), Up(Num(2)+ Var("b")), Down(Num(4))) the semantics  $x = 5, y = 8$  in RobotUniExprAddUniDec.

Instead of reusing expr\_add.semantics.value, the rueaud.semantics.value method uses the method expr\_add.ext\_semantics.value\_ext, which will be explained shortly. This is because the former is closed on the set of ADT cases it can handle. Hence, we resort to the following *extensible* semantics of ExprAdd:

```

1 object ext_semantics {
2 import syntax._
3 def value_ext: (Expr, Expr => Int) => Int = {
4   case (Num(n), c) => n
5   case (Add(e, t), c) => c(e) + c(t)
6 def value(e: Expr): Int = value_ext(e, value)
7 }

```

In the fashion of  $\gamma\Phi C_0$  [13], value\_ext above takes a continuation argument c (line 3), which caters postponing the closing time until the appropriately complete shape [14] of the ADT is known (line 6 above for expr\_add and line 20 for rueaud). As such, extending RobotUniExprAdd to RobotUniExprAddUniDec here involves manipulating the former. See Section V for more.

2) *Double-Extension* ( $\triangleleft$ ): The idea in RobotTimeSpeed below (packaged under robot\_time\_speed) is to enable

the user to instruct the robot arm with the speed for its subsequent moves, until further notice. It adds a pertaining command to RobotTime to obtain Robot  $\triangleleft$  RobotTime  $\triangleleft$  RobotTimeSpeed.

```

1 object syntax { //robot_time_speed
2   import robot.syntax.Command
3   case class Speed(i: Int) extends Command
4 }
5 object semantics { //robot_time_speed
6   import syntax._; import robot.syntax.{Command, Commands}
7   import robot.semantics.position
8   def locate: Command => Unit = {
9     case Speed(_) => {}
10    case c => robot.semantics.locate(c)
11  }
12  def locate(cs: Commands) = cs.s.foreach(locate)
13  var speed: Double = 1.0
14  def time(cs: Commands): Double = {
15    var sum: Double = 0.0
16    for(c <- cs.s) c match {
17      case Speed(i) => speed = i
18      case _ => sum += (1.0 / speed)
19    }
20    sum
21  }

```

The new command for altering speed is Speed in line 3 above. This new command has no impact on the arm's position, as manifested in line 9. It is in the time calculation where, once used, the related variable (i.e., speed in line 12) is updated accordingly (line 16) and taken into consideration for subsequent commands (line 17). Commands(Up, Speed (2), Right, Left) has the semantics  $x = 1, y = 0, t = 2$  in RobotTimeSpeed.

3) *Extension by a Unification* ( $\triangleleft$  ( $\oplus$ )): We now demonstrate RobotExtExprAddUniDec = Robot  $\triangleleft$  (ExprAdd $\oplus$ Dec). We begin by ExprAddUniDec (packaged under eaud):

```

1 import expr_add.syntax._
2 object syntax { //eaud
3   import dec.syntax._
4   class EnvExpr(val ds: Map[String, Int], val e: Expr)
5   implicit class CDL2CDLInE(val cdl: ConstDefList) {
6     def in (e: Expr) = {
7       consts = cdl.ds
8       new EnvExpr(cdl.ds, e)
9     }
10  }
11  var consts: Map[String, Int] = Map()
12  case class Var(n: String) extends Term
13 }
14 object semantics { //eaud
15   import syntax._
16   import dec.syntax._
17   def value_ext: (Expr, Expr => Int) => Int = {
18     case (Var(n), c) => consts(n)
19     case (e, c) => expr_add.ext_semantics.value_ext(e, c)
20  }
21  def value(e: Expr): Int = value_ext(e, value)
22  def value(ee: EnvExpr): Int = value(ee.e)
23 }

```

eaud is similar to rueaud in Section II-E1 and we drop further explanation. RobotExtExprAddUniDec below (packaged under reeaud) tries to make use of eaud.

```

1 object syntax { //reeaud
2   import dec.syntax._; import robot.syntax.Commands
3   class EnvComm(val ds: Map[String, Int],
4                 val cs: Commands)
5   implicit class CDL2CDLInC(val cdl: ConstDefList) {
6     def in (s: Commands) = {
7       consts = cdl.ds
8       new EnvComm(cdl.ds, s)
9     }

```

```

10  }
11  var consts = eaud.syntax.consts
12 }
13 object semantics { //reeaud
14   import robot.semantics.position
15   import robot.uni_expr_add.syntax._
16   import eaud.semantics.value; import syntax._
17   def locate(r: EnvComm) {
18     r.cs.s.foreach {
19       case Left(e) => position.x -= value(e)
20       case Right(e) => position.x += value(e)
21       case Up(e) => position.y += value(e)
22       case Down(e) => position.y -= value(e)
23     }
24  }
25 }

```

Here are the few idiosyncrasies of reeaud: Firstly, reeaud fails to reuse most of the syntactic facilities of eaud. This is because the former employs declarations followed by commands, whereas the latter employs declarations followed by expressions. In line 11, nevertheless, consts is reused. Secondly, even though RobotExtExprAddUniDec = Robot  $\triangleleft$  ..., in reeaud.semantics, we do not reuse robot.syntax. On the contrary, in line 15, it reuses the syntax of robot\_uni\_expr\_add (for RobotUniExprAdd). This is because, in Robot, it is only possible to move the arm one unit to either direction. The Scala syntax for those two pieces of (embedded) syntax cannot coexist side by side. See Section III-A2 for more.

reeaud.semantics.locate is similar to rueaud.semantics.locate. In RobotExtExprAddUniDec, ConstDefList("a" -> 5, "b" -> 10)in Commands(Right(Var("a")), Up(Num(2)+ Var("b")), Down(Num(4))) has semantics  $x = 5, y = 8$ .

As pointed out by Mernik, so long as functionality is the only concern, RobotUniExprAddUniDec  $\equiv$  RobotExtExprAddUniDec. The difference, both in LISA and Scala, is in the language descriptions, and the combinations by which they are obtained. Unlike its LISA counterpart, nonetheless, obtaining RobotExtExprAddUniDec in Scala involves intermediate material that is not reused in the final product.

4) *Extension of a Unification* ( $\oplus$   $\triangleleft$ ): RobotUniExprAddExtRobotTime below (packaged under rueaert) extends RobotUniExprAdd (Section II) by a timing facility. The time required for carrying out a command of moving in one direction equals what the pertaining expression evaluates to (lines 9 to 12). The method time below is a simple fold operation on the given sequence of commands, based on that explanation. RobotUniExprAddExtRobotTime = (Robot  $\oplus$  ExprAdd)  $\triangleleft$  RobotTime.

```

1 object syntax { //rueaert
2   import robot_uni_expr_add.syntax._
3 }
4 object semantics { //rueaert
5   import expr_add.semantics._
6   import robot.syntax.Commands
7   import robot_uni_expr_add.syntax._
8   def time(cs: Commands): Int = (0 /: cs.s){
9     case (s, Left(e)) => s + value(e)
10    case (s, Right(e)) => s + value(e)
11    case (s, Up(e)) => s + value(e)
12    case (s, Down(e)) => s + value(e)
13  }
14 }

```

Commands (Right (Num(5)), Up (Num(2) + Num(10)),  
Up (Num(2) + Num(2) + Num(2)), Down (Num(4))) has  
the semantics  $x = 5, y = 14, t = 27$  in rueaert.

5) *Unification with an Extension* ( $\{\uplus, \triangleleft\}$ ):  
Take RobotUniExprMul = Robot  $\uplus$  ExprMul, where  
ExprAdd  $\triangleleft$  ExprMul. The language ExprMul extends  
ExprAdd by a new ADT case for multiplication (Mul).  
What is unique about ExprMul amongst the visited extension  
combinations is that, upon extension, it changes the syntactic  
categories of the ADT cases it borrows from ExprAdd.  
(And, in fact, it also provides a new syntactic category, i.e.,  
Factor.) As presented in Section III-B, this can impose  
a great deal of complexity when language extension is  
implemented using inheritance. Here is ExprMul (packaged  
under expr\_mul).

```

1 import expr_add.syntax.{Expr, Term, Add}
2 object syntax { //expr_mul
3   //Term ::= Factor | ...
4   class Factor extends Term
5   implicit class TermTimesFactor (val t: Term) {
6     def * (f: Factor): Term = Mul(t, f)
7   } //Term ::= ... | Term * Factor
8   //Factor ::= n
9   case class Num(n: Int) extends Factor
10  case class Mul(left: Term,
11               right: Factor) extends Term
12 }
13 object semantics { //expr_mul
14   import syntax._
15   import expr_add.
16     ext_semantics.{value_ext => add_value}
17
18   def value_ext: (Expr, Expr => Int) => Int = {
19     case (Num(n), c) => n
20     case (Add(e, t), c) =>
21       add_value(Add(e, t), c)
22     case (Mul(t, f), c) => c(t) * c(f)
23   }
24   def value(e: Expr): Int = value_ext(e, value)
25 }

```

In line 1, ExprMul imports the syntactic entities it borrows  
from ExprAdd: the ADT case Add and the syntactic categories  
Expr and Term. It then introduces its new syntactic category  
Factor in line 4. Next, in lines 5 to 7, it provides the syntactic  
sugar for multiplication. Note how it, afterwards, declares  
numbers to now be of the category Factor – as opposed to  
Term in expr\_add.syntax. The rest of expr\_mul should  
be straightforward except for the Scala syntax of lines 15  
to 16. Those lines abbreviate expr\_add.ext\_semantics  
.value\_ext to add\_value in expr\_mul.semantics. In  
line 21, expr\_mul reuses add\_value for the solo ADT case  
that it borrows from expr\_add, i.e., Add.

```

1 object syntax { //robot_uni_expr_mul
2   import robot.syntax.Command
3   import expr_add.syntax.Expr
4   import expr_mul.syntax._
5
6   case class Left (e: Expr) extends Command
7   case class Right (e: Expr) extends Command
8   case class Up (e: Expr) extends Command
9   case class Down (e: Expr) extends Command
10 }
11 object semantics { //robot_uni_expr_mul
12   import robot.syntax.Commands
13   import syntax._
14
15   import robot.semantics.position
16   import expr_mul.semantics._

```

```

17 def locate(cs: Commands) = cs.s.foreach {
18   case Left(e) => position.x -= value(e)
19   case Right(e) => position.x += value(e)
20   case Up(e) => position.y += value(e)
21   case Down(e) => position.y -= value(e)
22 }
23 }
24 }

```

The above implementation of RobotUniExprMul (packaged  
under robot\_uni\_expr\_mul) takes tightly after RobotUni-  
ExprAdd (in Section II-C). We, therefore, do not provide  
a dedicated walk-through. Commands (Right (Num(5) \* Num  
(2)), Down (Num(4) + Num(2) \* Num(3))) has the seman-  
tics  $x = 10, y = -10$  in robot\_uni\_expr\_mul.

### F. Language Specific?

To investigate the extent to which Scala-specific language  
features impact upon our design, we intend also to com-  
pare against realisations in other languages. To this end, we  
have prepared a C++ implementation which adopts the Scala  
approach outlined so far. Respecting the dynamic polymor-  
phism of the Scala original, the C++ implementation utilises  
shared\_ptr smart pointer to manage the memory allocation  
and runtime typing of expressions; allowing the vector  
container member object of the Commands class to store  
different expression types. User-defined integral and string  
literals also allow a notably concise syntax for the Num and Var  
instantiations; e.g., Commands{Right{"a"\_s}, Up{2\_n +  
"b"\_s}, Down{4\_n}}. Future work will explore this further.

Note that we are keen in the solution of this section not  
to employ Scala’s built-in open recursion. Due to unrelated  
reasons, however, Scala compilers might still employ open  
recursion internally to compile our code. Nonetheless, our  
code does not require that Scala idiosyncrasy. Testimony to  
that lack of requirement is our C++ code. Note that whilst  
open recursion is automatic in Scala, in C++, one needs to  
explicitly use “this->” for the late-binding of open recursion.

## III. LMS-BASED

Rompf and Odersky [2] coin Lightweight Modular Staging  
(LMS) for Polymorphic Embedding [15] of DSLs in Scala.  
They employ a fruitful combination of the Scala features  
detailed in [16] that, as a side-product, offers a very simple  
yet effective solution to EP. In this paper, we use LMS for  
that EP solution. The essence of LMS is the use of Scala  
traits for extensibility and super calls for reuse. With their  
mixin nature, Scala traits can extend one another, enjoying the  
benefits of inheritance. In particular, an ADT can be inherited  
upon trait extension. But, the heir trait can also add its own  
new ADT cases. On top of that, super calls enable reusing  
methods on the cases of the original ADT. Whereas the new  
cases can be handled by the same method, albeit overridden  
by the heir trait.

In the package eaud below (for ExprAddUniDec), for  
implementing both the syntax and semantics, traits are used  
– as opposed to objects in Section II. Instead of importing  
members from other languages, it now extends those other  
languages to acquire the same members via inheritance. In

Scala terms, `eaud.syntax` is, for instance, said to be mixing in `expr_add.syntax` and `dec.syntax`, in line 1 below.

In line 4, then, `eaud.semantics` overrides `value`. In line 5, it handles the new ADT case `eaud.syntax` introduces. All those other ADT cases that `eaud` inherits are, in line 6, relayed to the upper levels of inheritance.

```
1 trait syntax extends expr_add.syntax with dec.syntax {
2   ... /* like eaud.syntax in Section II-E3 */ ...}
3 trait semantics extends syntax with expr_add.semantics {
4   override def value: Expr => Int = {
5     case Var(n) => consts(n)
6     case e => super.value(e) } ...}
```

This is how LMS facilitates both simplicity and extensibility. (Note that we needed not to resort to `value_ext`.)

LMS has been successfully employed for languages in a multitude of applications. For the benefits of LMS, the reader is invited to consult those works. Given that we did not come to observe new benefits, we will not get into that here. We rather dedicate this section to the difficulties we faced over employing LMS for embedded language composition.

### A. Minor Difficulties

The two categories of minor difficulties we faced relate to language restriction (Section III-A1) and clashes occurred between names upon composition (Section III-A2).

1) *Language Restriction*: Upon extension, the programmer is usually provided with no means for acting selectively on the members to be inherited. When mixing traits too, all the (public or protected) members get inherited automatically. Hence, with inheritance being the means for language composition, language restriction is not possible. That enforces `import` as the fallback. With the use of traits, the mechanics is, however, more involved than Section II. Because traits are abstract, one needs to materialise them first (line 2 below), and only then, they can be `imported` from (line 3).

```
1 trait syntax/* robot_positive */{
2   val robosyn = new robot.syntax {}
3   import robosyn.{Right, Up, Command, Commands}
4 }
```

Even though LISA also employs inheritance for language composition, this difficulty does not arise there. The reason is as follows: Being also an AG system, (subject) language semantics is specified in LISA by traversing the concrete syntax. On the other hand, leveraging its OOP, LISA allows the heir language to override the parent language's concrete syntax. As a result, language restriction is also possible in LISA via inheritance.

One final related comment: In our experience, enforced `imports` like those required for language restriction were not exclusive to that way of language composition. In fact, in a good number of other occasions, the languages do make selective use of one another. That, on its own, was not a knotty problem. It, however, requires increasingly more care when it comes to interplay with hierarchies of languages and the relevant Scala mixins.

Note that `imported` names (like those in line 3 above) do not get inherited but the respective materialised traits

(like `robosyn` in line 2 above) do. Such `imports` can be required on several occasions down the hierarchy. In the case of unification, however, where the multiple inheritance nature of mixins is employed, an extra `override` might also be enforced to disambiguate duplicated names across the meeting two hierarchies. See Section III-B for more.

2) *Name Clash*: Recall from Section II-E3 that `RobotExtExprAddUniDec = Robot < (ExprAdd ⊕ Dec)`. In an LMS-based implementation of `RobotExtExprAddUniDec`, therefore, one would naturally want to implement `rueaud.semantics` as follows:

```
1 trait semantics extends rueaud.syntax with
2   robot.semantics with eaud.semantics {//rueaud
3   ... /* locate like Section II-E1 */ ...}
```

That is, however, not possible. The error message is: “object `Left` is not a case class, nor does it have an `unapply` /`unapplySeq` member.” The problem is that, even though `Left` is inherited from `robot`, in `locate`, Scala would not be able to match it using the syntax `Left(e)`. The available constructor and extractor of `Left` take no arguments. Moreover, overloading that syntax is not possible. This is because Scala desugars both case classes and case objects to objects with `unapply` (or `unapplySeq`) methods. Objects, on the other hand, are final, banning any later manipulation. To proceed, one needs to use `robot_uni_expr_add.semantics` in return of `robot.semantics`.

The problem is harder to diagnose for `RobotUniExprAddExtRobotTime`. Recall from Section II-E4 that `RobotUniExprAddExtRobotTime = (Robot ⊕ ExprAdd) < RobotTime`. For the attempt

```
1 trait semantics extends rueaert.syntax with
2   robot_uni_expr_add.semantics with
3   robot_time.semantics {... /* rueaert */ ...}
```

even when one employs `robot_uni_expr_add.semantics` instead of `robot.semantics`, one gets an error – this time, regarding the composition itself: “overriding object `Left` in trait `syntax`; object `Left` in trait `syntax` cannot override final member.” The problem here is with `robot_time` being an extension to `robot`, bringing the case object `Left` into the mix with that of `robot_uni_expr_add` that takes an argument.

### B. Major Difficulties

The difficulties we spoke about in the previous subsection were not particularly acute in that not many circumvention attempts would fail for them. In this section, we will report a multi-staged combat with an acute difficulty we faced. In short, the combat was against the combination of Scala's path-dependant typing and intervention of concrete syntax.

The contents of this section might look too specific to Scala. They are not. Scala's path-dependant typing is just one way to foster family polymorphism [17] (as opposed to lightweight family polymorphism [18]). The familiar reader will figure out that the same problem is likely to emerge in every host language that embraces family polymorphism.

Given that `ExprMul` is a direct extension to `ExprAdd`, one's first guess would be:

```
1 trait expr_mul.syntax extends expr_add.syntax {...}
```

That is, however, not possible because, then, Num cannot be overridden. Recall from Section II-E5 that ExprMul changes the syntactic category of Num. But, even an attempt like those in Section III-A1 for the syntax

```
1 trait syntax {
2   val easyn = new expr_add.syntax {} //expr_mul
3   import easyn.{Expr, Term, Add} /* Num, Factor, etc. */
4 }
```

would still cause failure for the semantics.

```
1 trait expr_mul.semantics extends syntax with
2   expr_add.semantics {...}
```

Here is the error message: “overriding object Num in trait syntax; object Num in trait syntax cannot override final member.” This is because of the clash between the Num of such a `expr_mul.syntax` and `expr_add.semantics`. See Section III-A2 for an explanation on similar error messages.

Now, let us suppose for the sake of argument that the semantics too selectively `imports` the ADT cases:

```
1 trait semantics { //expr_mul
2   val emsyn = new expr_mul.syntax {}
3   import emsyn.{Num, Mul, Factor}
4   val easyn = new expr_add.syntax {}
5   import easyn.{Expr, Add, Term}
6   ... /* value or value_ext here */ ...
7 }
```

Recall that ExprMul adds the ADT case Mul to ExprAdd. To reuse – à la LMS – the ExprAdd semantics whilst also handling the new ADT case, one may (mistakenly) try:

```
1 override def value: Expr => Int = {
2   case Mul(t, f) => value(t) * value(f) ...
3 }
```

But, that will not type-check because of path-dependant typing interference: Expr in value’s signature is different from Expr that Mul inherits from. Here is the error message for line 2 above: “constructor cannot be instantiated to expected type; found: semantics.this.emsyn.Mul required: semantics.this.Expr.” Even worse: An attempt for reusing the semantics of the only ADT case that remains intact over the move from ExprAdd to ExprMul using `value_ext`

```
1 trait semantics {... //expr_mul
2   import easem.{value_ext => add_value}
3   def value_ext: (Expr, Expr => Int) => Int = {
4     case (Num(n), c) => n
5     case (Add(e, t), c) => add_value(Add(e, t), c)
6     case (Mul(t, f), c) => c(t) * c(f) }
```

will again fail due to path-dependant typing. The error message for line 5 above is: “type mismatch; found: semantics.this.easyn.Add required: semantics.this.easem.Expr.”

Given that `expr_mul.semantics` is to reuse pattern matching of `expr_add.semantics`, the former is also bound to the types – here, ADT cases – of the latter. In order to prevent the path-dependant clashes, thus, the only way forward seems to be for **both** `expr_mul.syntax` and `expr_mul.semantics` to import types of `expr_add.semantics`. This is, of course, very unnatural for the former.

```
value: Expr => Int
expr_add{Num, Add}, eaud{Num, Add, Var},
      expr_mul{Num, Add, Mul}
locate: Command => Unit (without e)
robot{Right, Left, Up, Down},
      robot_positive{Right, Up}
locate (with (e))
in reeaud: EnvComm => Unit
in robot_uni_expr_add: Commands => Unit
in rueaud: EnvComm => Unit
in robot_uni_expr_mul: Commands => Unit
EnvComm
reeaud, rueaud
```

Fig. 1: Duplicate Entities in Sections II and III

```
1 trait syntax { //expr_mul
2   val easem = new expr_add.semantics {}
3   import easem.{Expr, Term, Add}; ...
4   trait semantics extends syntax { //expr_mul
5     import easem.{Expr, Add, value_ext => add_value}
6     ...
7     def value_ext: (Expr, Expr => Int) => Int = {
8       case (Num(n), c) => n
9       case (a: Add, c) => add_value(a, c)
10      ...
11    }
12    ...
13 }
```

Still, if not done craftily enough, path-dependant typing can be an impediment. Replacing the line 9 above with

```
case (a @ Add(_, _), c) => add_value(a, c)
```

will fail to type-check because `a` is considered to be of type `this.Add`; whereas, `add_value` accepts an `easem.Expr`. The unsightly circumvention would be:

```
case (a @ Add(_, _), c) => add_value(a,
asInstanceOf[easem.Expr], c.asInstanceOf[easem
.Expr => Int]).
```

We would like to remind that all the difficulties illustrated in this section were only experienced in the presence of manipulation in the syntactic categories upon extension. Syntactic categories are often used for dealing with concrete syntax. Semantics, on the other hand, inputs abstract syntax. The following section presents a solution that disassociates concrete syntax from abstract syntax. It applies the LMS at the abstract syntax level, and, hence, independently of the concrete syntax that varies across languages. That design sets the different languages free on engineering their syntactic categorisation whilst enjoying the benefits of LMS.

#### IV. REFACTORING

The previous two sections were developed as if the guest language implementer was not aware in advance of the next guest languages and the upcoming combinations. We also maintained a backward compatibility policy in that we did not touch the older languages as we proceeded. Refactoring, however, is common in everyday software development.

Refactoring can have a variety of meanings, depending on the target and the methods used [19]. Here, we do not plan extensive refactoring. We only focus on duplicate elimination in the fashion of the *extract superclass* method [19, §12.6]. Fig. 1 lists a number of duplicates in Sections II–III.

We notice that the method `value` is duplicate in `expr_add`, `eaud`, and `expr_mul`. More precisely, the ADT cases `Num` and `Add` – which are, basically, inherited from `expr_add` – are handled thrice in the codebase. As will be shown in this section, we gave `value` its own abstraction.

We also notice that the method `locate` is present in two sets of language descriptions: in (i) `robot` and `robot_positive` (when the four direction commands do not take arguments); and, in (ii) `reeaud`, `robot_uni_expr_add`, `rueaud`, and `robot_uni_expr_mul` (when the four direction commands do take arguments). Each of those sets constitutes a candidate for refactoring. Finally, `EnvComm` is common between `reeaud` and `rueaert` – constituting yet another refactoring candidate. Although we have indeed refactored the candidates of this paragraph as well, we will not include their demonstration in this paper. The interested reader can look them up in our online codebase.

Let us now focus on refactoring the first row of Fig. 1. (Refactoring the other rows of Fig. 1 is done similarly.) Here is a succinct summary of actions to be taken: The idea is a combination of LMS and Component-Based Mechanisation [20], [21], [13]. We parameterise the ADT cases `Num`, `Add`, `Var`, and `Mul` by the language description and perform their semantics evaluation independently of the language description. We pack the two former cases – namely, `Num` and `Add` that are common between all the items in the first row of Fig. 1 – together in a trait. Then, we extend that trait for `Var` and later for `Mul`, both *à la* LMS. Finally, the concrete language descriptions only get to mix the respective abstract descriptions. The elaboration follows.

```

1 trait na_syntax {
2   type E
3   type N <: E //N for Num
4   type A <: E //A for Add
5
6   def n_extr(n: N): Option[Int]
7   def a_extr(a: A): Option[(E, E)]
8
9   object N {def unapply(n: N) = n_extr(n)}
10  object A {def unapply(a: A) = a_extr(a)}
11 }
12 trait na_semantics extends na_syntax {
13   def value: E => Int = {
14     case N(n) => n
15     case A(e1, e2) => value(e1) + value(e2)
16   }
17 }

```

In the trait `na_syntax` above, the abstract type `E` (in line 2) is a language-independent representation for the expression type of a guest language. Such a guest language can be an item in row 1 of Fig. 1 or any similar language with integer arithmetics that at least contains integral literals and addition. Given that ADTs are implemented in Scala using plain inheritance, two more language-independent abstract types have been employed that are announced to be extending `E`. Those are `N` for `Num` and `A` for `Add`, in lines 3 and 4.

Because `N` and `A` are supposed to later be instantiated to the respective cases of an ADT, they are expected to come with the Scala matching syntax, like those in lines 14 and 15. The Scala machinery for enforcing availability of the desirable matching syntax requires a discipline in coding that

is slightly tricky. The discipline involves, for each ADT case abstract type, inclusion of a same-named (singleton) object – called *companion* object – that ships, then, with an *extractor*, i.e., an *unapply* method of the right type signature. The actual duty of the extractor is relayed to an abstract method, to be enforced to every guest language that implements `na_syntax`. For `N`, for instance, that duty is on `n_extr` in line 6. The Scala signature of `n_extr` means that, if matching `N` succeeds, it would be initialising an argument of type `Int`. All that wiring enables the method `na_semantics.value` to handle the semantics of `Num` and `Add`.

```

1 trait nam_syntax extends na_syntax {
2   type M <: E
3   def m_extr(m: M): Option[(E, E)]
4   object M {def unapply(m: M) = m_extr(m)}
5 }
6 trait nam_semantics extends nam_syntax with na_semantics {
7   override def value: E => Int = {
8     case M(e1, e2) => value(e1) * value(e2)
9     case e => super.value(e)
10  }
11 }

```

The trait `nam_syntax` adds the abstract type `M` (in line 2 above), which corresponds to `Mul`. It also provides the Scala matching syntax in lines 3 and 4. The trait `nam_semantics` reuses (*à la* LMS) what is already implemented by `na_semantics` by performing a *super* call on the relevant ADT cases (line 9).

```

1 trait expr_add.syntax extends na_syntax {
2   /* ... like lines 2 to 10 of
3     expr_add.syntax in Section II ... */
4   type E = Expr //Fix the ADT type.
5   type N = Num //Fix the Num case.
6   type A = Add //Fix the Add case.
7   //And, fix the extractors.
8   def n_extr(n: Num) = Num.unapply(n)
9   def a_extr(a: Add) = Add.unapply(a)
10 }
11 trait expr_add.semantics extends
12   expr_add.syntax with na_semantics

```

In addition to working out the Section II concrete syntax, the trait `expr_add.syntax` above, now is required to provide evidence on it indeed having ADT cases for integral literals and addition. That, again involves some slightly tricky discipline consisting of two steps. First, in lines 4 to 6, the concrete counterparts for the abstract (ADT case) types in `na_syntax` are fixed. Second, in lines 8 and 9 the extractors promised to `na_syntax` are fixed.

Recall from `expr_add.syntax` of Section II that `Num` and `Add` are both case classes. Scala actually desugars case classes to normal classes in addition to companion objects with the right-typed *unapply* methods. That is why we can use `Num.unapply` and `Add.unapply` off-the-shelf.

Nothing more remains for `expr_add.semantics` to do except inheriting its (abstract and concrete) syntax from `expr_add.syntax` and its semantics from `na_semantics`.

```

1 trait expr_mul.syntax extends nam_syntax {
2   val easyn = new expr_add.syntax {}
3   import easyn.{Expr, Term, Add};...
4   //like lines 4 to 11 of expr_mul.syntax in Section II...
5   type E = Expr; type N = Num; type A = Add; type M = Mul
6   def n_extr(n: Num) = Num.unapply(n)
7   def a_extr(a: Add) = Add.unapply(a)
8   def m_extr(m: Mul) = Mul.unapply(m)

```

```

9 trait ExprMulSemantics extends
10   ExprMulSyntax with NamSemantics

```

Implementing `ExprMul`, in this fashion, is similar, as demonstrated above. It only is that, like in Section III, our use of traits instead of objects in favour of LMS imposes instantiation of the trait `ExprAddSyntax` (line 2) before `importing` the desirable concrete syntax items (line 3).

#### Remarks

`na_semantics` is similar to how one defines the semantics of `Num` and `Int` using Modular Structural Operational Semantics (MSOS) [22]. In MSOS, the semantics of a component is defined exclusively in terms of the relevant language elements – making it ignorant about all other language elements. `na_semantics` only concerns `Num` and `Int`, and, is ignorant about other language elements.  $\gamma\Phi C_0$  [13] describes that as: “client  $na\_semantics \langle F \triangleleft Int \oplus Num \rangle \{ \dots \}$ ,” where  $F$  is the *family parameter* of  $na\_semantics$ . In words, that reads: A family  $\Phi$  to be substituted for  $F$  needs at least to have components *Int* and *Num* (or their equivalents) in its mix.

From another language theoretical viewpoint, `na_syntax` and `na_semantics` are both type classes [23]. From that viewpoint, `ExprAddSyntax` is an instance of `na_syntax` and `ExprAddSemantics` is an instance of `na_semantics`. The evidence for the former is provided in lines 2 to 7 in `na_syntax`. Interestingly, however, our encoding of type classes in Scala is not the common one [24]. In particular, we do not prescribe the use of `implicit`s.

As also announced at the last paragraph of Section III, `na_syntax` and `na_semantics` (and also `nam_syntax` and `nam_semantics`) relate to the abstract syntax only. This is how they leverage LMS and yet do not suffer from the concrete syntactic anomalies discussed in Section III. Moreover, unlike Modular Reifiable Matching [25], the technique we presented in this section is not exclusively targeting two-level types [26]. The reason is that our technique in this section fully disassociates concrete syntax from the abstract syntax so there no longer is an issue of levels in the types. LMS itself comes with no such separation either – suggesting the name *abstract LMS* for our technique.

It is noteworthy that the disassociation of abstract and concrete syntax with the lack of the LMS anomalies discussed in Section III needs not specifically be *à la* LMS. The same impact can also be achieved using integration of a decentralised pattern matching [27]. In the latter technique, the syntax is defined in terms of abstract syntax components. The concrete syntax in the latter technique is then defined on top of those syntax components. The difference is that the abstract LMS composes components (that correspond to ADT cases) *additively* [28, §17.3], whilst the latter technique would be composing them *sequentially*.

The connection between this technique and Component-Based Software Engineering (CBSE) [28, §17],[29, §10] is also interesting. From a CBSE standpoint, `nam_syntax` is a component in that: Without binding to a particular implementation, it specifies its so-called ‘requires’ and ‘provides’

interfaces. The `nam_syntax` ‘requires’ interface is its lines 2 and 3 – imposing the following two requirements, respectively: The user of `nam_syntax` needs to provide a type `M`. And, there has to be a way to extract two expressions of type `E` from an instance of `M`. In return, the ‘provides’ interface of `M` is its line 4, where `M`’s Scala match syntax (used in line 8 of `nam_semantics`) is offered. As such, `nam_syntax` is promoting the ADT case `Mul` to its standalone component.<sup>1</sup> This is an important characteristic of the third technique that relates to the EP. Next section is dedicated to that relationship.

## V. EXPRESSION PROBLEM

EP is a recurrent problem in the field of Programming Languages, for which a wide range of solutions have thus far been proposed, e.g., [31], [32], [33]. Consider [34], [35], [36], [31], [32], [33], to name a few. Haeri [21] defines EP as the challenge of finding an implementation for an ADT – defined by its cases and the functions on it – that:

- E1. is *extensible in both dimensions*, i.e., both new cases and functions can be added.
- E2. provides *weak static type safety*, i.e., applying a function  $f$  on a statically<sup>2</sup> constructed ADT term  $t$  should fail to compile when  $f$  does not cover all the cases in  $t$ .
- E3. upon extension, forces *no manipulation or duplication* to the existing code.
- E4. accommodates *separate compilation*, i.e., compiling the extension imposes no requirement for repeating compilation or type checking of existing code. Such static checks should not be deferred to the link or run time.

In Sections II–IV, we presented three techniques for embedded language composition in Scala. All the three techniques satisfy E4. We now reflect on their E1–E3 competence: The first technique clearly satisfies E1. Section III-A2 outlines a scenario where LMS fails to satisfy E1. Whether the third technique satisfies E1 depends on whether it employs trait mixing for composition or not. Note that it needs not. The three techniques all relax E2, although they can be circumvented to work when defaults are available [35]. That is a consequence of Scala performing pattern matching at runtime. LMS too relaxes E2 and that has thus far been considered an acceptable setting. (For example, MVCs [37] and Torgersen’s second solution [34] both have the same issue.) The state of affairs for LMS might change in future though [38].

As witnessed by `RobotUniExprAddUniDec` in Section II-E1, the Scala-unspecific technique fails to satisfy E3 when new cases are to be added. As detailed in Section III-B, LMS has to fight path-dependant typing to satisfy E3 when syntactic categories are updated upon composition. Whether there always is a winning strategy for LMS in such a situation is not known. The third technique clearly satisfies E3.

<sup>1</sup>Two reasons for not promoting `Num` and `Add` to components: 1) that would complicate presentation. 2) the current design in which those two ADT cases are packed together in a single component (i.e., `na_syntax`) demonstrates how to address the Common Reuse Principle of Martin [30].

<sup>2</sup>If the guarantee was for dynamically constructed terms too, we would have called it strong static type safety.

We understand that the path-dependant typing difficulties of the LMS-based technique might indeed be a result of our peculiar design. In particular, our choice of giving the syntax and semantics of a language each a trait of their own might be picked as the root cause. We would like to defend that choice of ours, specifically, for the likelihood of engineering (or experimentation with) more than one semantics for the same syntax [15]. In such cases, separation of the syntax and semantics is inevitable.

Finally, one may wonder whether the third technique makes it to a new solution to EP. The answer is indeed yes. At least for EP in presence of defaults [35]. This is the third EP solution of its kind: It promotes ADT cases to their own ADT-parameterised components. See [20], [21] for the first and [27] for the second EP solution of this kind.

## VI. RELATED WORK

*a) LISA:* As stated earlier, this paper is highly inspired by Mernik [6]. We essentially took his examples for showing how to compose languages embedded in Scala. With LISA being an LDF, even though Scala is famous for its hospitality to embedded languages, we were surprised to end up having less lines-of-code (LoC) in all the three techniques.

Fig. 2 summarises the LoC comparison. In the LoC there, we have also included some syntactic cosmetics that we did not display in this paper. In our experience, the occasions where Scala outperforms LISA by far are those where the task was a ready cake for GPLs. Examples are RobotTime for all the techniques and RobotExtExprAddUniDec for the third technique. For the former, a simple container size query does the job. For the latter, simple trait mixing does.

The first technique generally performs better (in terms of LoC) than LISA. The second is even better usually with its utilisation of trait mixing (dismissing the obvious `imports` and `super` calls. At last, the third is the best with its a posteriori refactoring. The two occasions when LISA considerably outperforms Scala are RobotUniExprAdd for the first technique and RobotUniExprMul for the third. Those correspond to Sections III-A2 and III-B, respectively.

The factored out code in the third technique is not counted in Fig. 2. Once that too is added, the total LoC reaches 328 – which is 2 more than first technique’s LoC. We tend to think the reason is the simplicity in the semantics of Mernik’s examples. That caused the number of lines the refactoring saves to be less than the extra overhead the technique requires. For more realistic case studies, we expect the balance to be completely different. That would be well in favour of refactoring due to reasonably more involved semantics.

*b) Other Language Composition Catalogues:* Völter [39] proposes a taxonomy of language composition that he showcases in JetBrains MPS. His taxonomy is along axes, not all of which having a clear correspondent in the work of Erdweg et al. As explained by Mernik, the resulting ways for language composition that Völter prescribes, however, are subsumed by the latter taxonomy. Völter’s taxonomy gives (syntax-oriented) IDE development for languages a higher weight.

Barrett, Bolz, and Tratt [40] catalogue composition of six different Python and Prolog virtual machines. Their study has a particular focus on measuring performance of the resulting interpreters upon composition.

Zhang et al. [41] facilitate composition of languages that are embedded using Object Algebras [42]. This is achieved using their simple predesignated annotation. Their showcase focuses on hierarchies of language extension. Using linearised multiple language inheritance, they also simulate a single language unification. Zhang et al. do not consider higher order composition.

Melange [43] is an LDF that is specially equipped for language composition. Various syntactic facilities are available in Melange to instruct mix-and-match for many different aspects of a language – ranging from syntax, dynamic and static semantics, and name-binding to IDE features. Language composition under Melange is catalogued for a small set of showcases but with in-length discussions on customisability. The current documentation of Melange, however, makes it hard for us to compare its catalogue of language composition with similar works. Specifically, we fail to figure out which ways for language composition Melange supports in general (namely, for other scenarios than the ones already in their documentation) and how.

*c) Components for Language Specification:* PPlanCompS funcons are syntactic constructs that ship with their own fixed static and dynamic semantics (presented in MSOS). The PPlanCompS specification of a programming language is developed by merely assembling funcons [44]. Example assemblies are larger academic languages [45] and medium-scale ones [46]. Despite their merit, funcons do not constitute CBSE components. In particular, funcons do not ship with their ‘requires’ interfaces.

MVCs [37] are components for solving an extension to EP. Rather than components in their CBSE sense, however, MVCs are components in a Component-Oriented Programming [47] sense. (Cf. [21, §4.3].) MVCs rely on the implementation details of `how` a component realises its interfaces. CBSE components, in contrast, are identified by their ‘requires’ and ‘provides’ interfaces.

Haeri and Schupp [20], [27] take a CBSE approach for the implementation of embedded languages. Their approach employs type constraints and multiple inheritance. The third technique here employs (possibly constrained) abstract types instead of type parameters. Although essentially the same, the former can make code terser. In Scala, however, offering the match syntax is apparently not possible for type parameters.

Finally, Cazzola and Vacchi [48] too have taken a CBSE approach. Their components correspond to a DSL’s compiler passes. Accordingly, how their work relates to the common language specification formalisms is not clear. In contrast, components in our third technique are ADT cases – acting as the unit of study for formal semantics.

*d) Component-Based AGs:* AGs are a powerful means for language specification with many benefits that are well-studied. Attempts to modularise AGs go back to Saraiva and

	$L_1$	$L_2$	$L_3$	$L_4$	$L_5$	$L_6$	$L_7$	$L_8$	$L_9$	$L_{10}$	$L_{11}$	$L_{12}$	$L_{13}$	Sum

Fig. 2: Lines-of-Code Comparison between Mernik’s LISA and Our Three Techniques

Swierstra [49]. Saraiva’s Higher Order AGs (HOAGs) [50] were the initial steps towards using AGs in a component-based fashion. Viera and Swierstra [51] formally define several ways to combine HOAGs. However, those ways do not tightly correspond to the usual composition mechanics of general-purpose languages.

So long as EP is concerned, the correct behaviour of a HOAG w.r.t. E2 is not universally agreed upon. In terms of HOAGs, that amounts to the absence of an attribute expected from another component in the mix. In particular, should the code then fail statically or dynamically? Zipper functions [52], [53] act like HASKELL by statically reporting such errors so long as they can be caught iteratively [54].

Kiama [55] uses AGs embedded in Scala for language specification. It is possible to use Kiama in a component-based fashion – as done for embedding Oberon-0 [56] in Scala [57]. However, disassociation of the concrete and abstract syntax can become non-trivial in Kiama. We anticipate that would cause similar difficulties to those we faced over our second technique. For the Oberon-0 embedding, facing such difficulties were unlikely for the different pieces of syntax were all available in advance. On the contrary, whilst composing unrelated pieces of syntax, clash of concrete syntax is likely.

## VII. CONCLUSIONS AND FUTURE WORK

In this paper we present three different techniques for composing languages embedded in Scala. The first is Scala-unspecific and works in presence of common module systems and higher order functions (Section II). The second is LMS-based and requires mixin composition and `super` calls (Section III). The third works by promoting ADT cases to ADT-parameterised components (Section IV). We showcase the three techniques using the example compositions of Mernik, which, in return, were designed to exhibit LISA’s composition facilities for Erdweg et al.’s taxonomy of composition. We manifest the strengths and weaknesses of each technique. We compare them according to their performance as EP solutions (Section V) and LoC (Section VI-0a).

Systematic study of embedded language composition is a young topic. Numerous paths exist for future research. Examining our third technique against larger testcases is an immediate future work. A promising candidate is the LDTA’11 challenge of modular implementation of Oberon-0. The testcase can then be compared with the LDTA’11 contestants. We anticipate complications in dealing with a few

issues along the way: Firstly, the technique takes a design-by-contract approach on the names it chooses for abstract types, e.g., `A` and `N` in `na_syntax`. In large scale, these names are likely to clash upon composition. Avoiding that would imply a priori knowledge. That kind of knowledge is, however, rare in experimental language design. Secondly, outside lab settings, usual software engineering techniques may become inevitable. We took the lab liberty of not being concerned with that here. For example, `position` and `consts` lack proper scoping and are common intact amongst all the descendants of `Robot` and `Dec`, respectively.

Type classes are more widely practised in HASKELL. It would be interesting to see our third technique in HASKELL with its type classes instead of Scala’s mixins and inheritance. The comparison between the results of ours and those according to the following two HASKELL EP solutions would be particularly interesting: Data Types a la Carte [36] and Parametric Compositional Datatypes [32].

Object Algebras are gaining gravity as a powerful abstraction for embedded language development [31], [58], [59], [41]. The current technology for embedding Object Algebras, however, is heavyweight in both term creation [60] and algebra composition. It is easy to turn `na_syntax` and the like into Object Algebra Interfaces to lower those two weights. How useful the result would be in lowering those two weights in the current Object Algebras technology is another future work.

Finally, it is important to also produce catalogues like this paper in other host languages than Scala. Many languages have merits in hosting other languages. But, the limits of that and the key factors of it are not clear. Composition of the embedded languages is certainly amongst the important factors. A head-to-head comparison on hospitality of language composition is missing. We are currently working on that.

# Supporting Source Code Annotations with Metadata-Aware Development Environment

Ján Juhár

Email: jan.juhar@tuke.sk

**Abstract**—To augment source code with high-level metadata with the intent to facilitate program comprehension, a programmer can use annotations. There are several types of annotations: either those put directly in the code or external ones. Each type comes with a unique workflow and inherent limitations. In this paper, we present a tool providing uniform annotation process, which also adds custom metadata-awareness for an industrial IDE. We also report an experiment in which we sought whether the created annotating support helps programmers to annotate code with comments faster and more consistently. The experiment showed that with the tool the annotating consistency was significantly higher but also that the increase in annotating speed was not statistically significant.

## I. INTRODUCTION

THE MAIN hindrance programmers deal with when they need to comprehend source code is known as the *abstraction gap*. This gap exists between the problem domain and the solution domain of a given software system. Many high-level concerns from the problem domain are either lost or scattered as programmers transform them to code. As argued by LaToza *et al.* [1] and Vranić *et al.* [2], programmers often ask questions about the *intent* behind particular source code fragments. In this paper, we present and evaluate an approach for helping to preserve the high-level knowledge within source code annotations.

### A. Motivation

Two general approaches for retrieving information otherwise lost or scattered in source code are available:

- *recovery* of pieces of high-level information from the code by means of reverse engineering, and
- *preservation* of a programmer's thoughts and intentions in software artifacts.

Feature location tools from the recovering approach usually produce list of source code elements that are evaluated as relevant to the given feature [3]. Preserving approaches directly assign high-level information to source code elements with annotations [4], [5]. Although in both cases the retrievable data represent *source code metadata* (abbreviated: *metadata*), they are of different nature.

This work was supported by project VEGA No. 1/0762/19: "Interactive pattern-driven language development" and grant of FEEI TUKE no. FEI-2018-55: "Methods of code classification based on knowledge profiles".

Recovering approaches use *intrinsic metadata*, which either define source code elements themselves or can be derived from these elements. In contrast to them, preserving approaches focus on *extrinsic metadata*, which complement the intrinsic ones by adding custom, high-level details explicitly recorded by programmers. On one side, the more accurate preserved knowledge may help to bridge the abstraction gap better than the lower-level recovered one. On the other side, recording programmer's mental model of the code brings in an additional cost: the programmer must spend extra time to record it.

The immediate availability of intrinsic metadata makes them a great choice for code analysing tools in integrated development environments (IDEs) [6]. These can provide *structure-aware* visualizations (e.g., file structure browsers, semantic code highlighting, linting) and actions (e.g., contextual code completion, refactoring). However, intrinsic metadata also restrict these tools to lower-level domains.

It is thus a worthwhile question whether adding the metadata upfront will be too costly compared to any benefits they may bring later. Sulír *et al.* show in [4] how concern metadata in the form of Java annotations can enable rapid construction of reader's mental model of the implementation. Report of Ji *et al.* [7] shows that presence of feature-related metadata within source code comments was beneficial for software product line development. The authors presume that by employing a supporting tool the benefits can be further increased.

To tackle the tool support for such custom metadata in the source code we need to consider both the type of annotations that can be used and granularity of elements where they can be used. Ideally, a programmer would not have to consider all the different ways in which metadata can be bound to the code, but directly *express the intention* to bind metadata to specific source code elements and let a tool to perform the binding. This is the main motivational factor for the work presented in this paper, proposed through the idea of uniform annotation process in a metadata-aware development environment.

### B. Goal

The goal of this paper is twofold. First, we present the idea and prototype implementation of the uniform annotation process in an integrated development environment (IDE) extended by metadata-awareness. By IDE metadata-awareness we mean the ability to work with both custom code-bound metadata and

with annotations that bind them as with first-class source code elements. This goal is addressed in Section II.

Second, in sections III and IV we report an experiment we performed to evaluate the effect our prototype tool has on annotating speed and consistency of comment annotations created during code annotating task. An overarching research question for the experiment is “*Does metadata-aware IDE help programmers to annotate code with comment annotations?*”.

## II. ANNOTATION PROCESS IN A METADATA-AWARE DEVELOPMENT ENVIRONMENT

IDE tools are adapted to use intrinsic metadata derived from code elements. They can easily bind them to the originating elements and build dynamic code views or projections from them [6], [8]. Extrinsic metadata are available also but mostly limited to data from version control and bug tracking systems. As such, they are bound only to files, or lines of text. We can achieve more specific bindings with source code annotations.

In our work the term *source code annotation* (abbreviated: *annotation*) has a more general meaning than, e.g., *Java annotation*. As per Definition 1, we consider any binding of metadata to source code element as annotation.

**Definition 1.** *Annotations are in-place or addressing bindings of custom metadata to source code elements.*

A development environment able to utilize the metadata recorded by code authors may provide program comprehension support on a higher level of abstraction, closer to the problem domain of a software system. Our idea of such *metadata-aware development environment* (MADE) comprises of three following aspects:

- 1) Support for the annotation process, during which a programmer binds metadata to code elements.
- 2) Preservation of annotations and metadata as code changes.
- 3) Utilization of the metadata in various IDE tools to facilitate program comprehension.

In the work presented in this paper, we focus on the first aspect: on supporting the *annotation process*, which we define in Definition 2.

**Definition 2.** *Annotation process, or annotating, is a process in which metadata are being bound to code elements.*

### A. Types of Source Code Annotations

When faced with a task to annotate code, a programmer has three following types of annotations to chose from:

- Internal annotations contained within the source code files, further classifiable into two distinct types:
  - *Language-level annotations* (LLAs), which use native programming language constructs for metadata.
  - *Structured comment annotations* (SCAs), which give the “metadata” status to code comments.
- *External annotations* (EAs), which are created with a supporting tool and bound to the source code by addressing the annotated elements.

Each of these annotation types has a different set of inherent limitations, which we discuss in the following.

1) *Language-level Annotations*: LLAs are formally defined in language’s grammar and all standard language tools can work with them. On the other side, they can be used only if the language itself does support them, and only on elements where it supports them. An example of applying custom metadata with LLAs in *Java* language is given in Listing 1.

Listing 1. *Java* annotations as high-level metadata

```
@NoteChange @TagManagement
public void addTag(String tag) { /* ... */ }
```

2) *Structured Comment Annotations*: SCAs reuse general code comments, which can contain arbitrary text. For that reason we need to define a specific syntax for them that would allow us to parse the metadata. Listing 2 shows an example of such syntax. Such annotations can be used in almost any language, considering that a comment can be put at the desired place in the code. But they require supporting tool that can recognize the metadata and bind them to specific code elements.

Listing 2. High-level metadata in structured comment annotation

```
// [# note change ] [# tag management ]
public void addTag(String tag) { /* ... */ }
```

3) *External Annotations*: EAs are superimposed over the code by means of an addressing mechanism that locates annotated elements. The mechanism can use simple addresses like element’s starting and ending offsets within a file, or more robust descriptors of code elements [9]. Annotations are usually visualized in the code editor (see Fig. 1).

The most significant advantage of EAs is that arbitrary code fragments can be annotated, even inside files the programmer cannot (or does not want to) modify. On the other side, their addresses need to be kept in sync with changes made to the code and they are completely dependent on a supporting tool.

### B. Supporting the Annotation Process

Our focus on custom extrinsic metadata allows us to assume that annotating is going to be performed “manually” by programmers. Their goal may be to capture their mental model of the code in a form that can be used by tools and can help future maintainers of the code. In the design of a tool

Fig. 1. Metadata bound to code fragment through external annotations displayed in the editor’s gutter

supporting such annotation process, we should strive to remove unnecessary distractions from programmers' primary goal of annotating. For us, it primarily means that regardless of which type of annotation is used the workflow should be the same.

However, annotation of a given type differs from other types in how exactly it is applied to the code and what conditions must be met before it can be applied. The most important differences are the following.

- *Definition*: LLAs are represented by language elements, which may need to be defined before they can be applied (e.g., like *Java*'s annotation types). Similarly, EAs may require definition through a tool [10]. SCAs have no single definition of the source metadata and the programmer needs to maintain them individually in each comment.
- *Application*: Internal annotations must be typed<sup>1</sup> into the code at the appropriate place. EAs are applied through environment's UI and their application may be preceded by code selection.
- *Binding*: LLAs are bound to specific elements in-place according to language's grammar. EAs use addressing bindings, which may be text-level or element-level. And comments, as free-standing statements, have no bindings to the surrounding code elements.

To deal with these differences, we designed an *abstracted annotation process*, which by itself does not require any changes to the annotated code and imitates annotating the code with EAs. In this process, operations required to annotate code fragments<sup>2</sup> should be performed through IDE actions. The actions cover selecting code fragment for annotation and selecting annotation representing required metadata. When these are selected, the annotation should be applied automatically with the configured annotation type.

We implemented a prototype tool called *Connotator*<sup>3</sup>, which supports the abstracted annotation process and its configuration per project. The tool is implemented as a plug-in for *JetBrains IntelliJ* platform-based IDEs. The current implementation supports all three annotation types for the *Java* language, and SCAs and EAs for languages *Kotlin* and *Python*. It also provides *source code editor augmentations* [11] related to code annotations. In the following, we describe the annotation process and its realization in *Connotator* in more detail.

1) *Defining metadata annotations*: All annotations representing custom metadata are in *Connotator* managed through the main tool window (see Fig. 2). Annotations defined there may be applied to the code. The metadata model is currently rather simple: annotations are defined only by their names and optionally they can have a parent annotation. The tool supports annotation name refactoring, which appropriately updates all their existing instances in the code.

2) *Selecting annotatable code fragment*: Only valid code selections—those matching some AST elements—are mean-

<sup>1</sup>LLAs may take advantage of already existing IDE support like code completion, but some typing is still involved.

<sup>2</sup>We use the term code fragment in a sense of one or more consecutive elements selected for annotation.

<sup>3</sup>*Connotator* is available at <https://git.kpi.fe.i.tuke.sk/jan.juhar/connotator>.

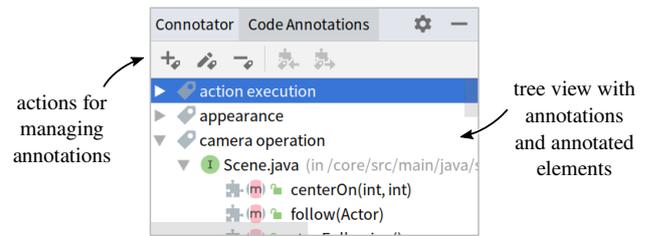

Fig. 2. Annotations tool window.

ingful targets for metadata. In general, fine-grained element selection (like statements and expressions) should be possible, but the specific set of annotatable elements should be configurable per-project. These requirements are in *Connotator* met through code fragment selection facility using tree patterns matched against the PSI tree<sup>4</sup> of code elements. A user can specify these patterns as *XPath*-like expressions built from a set of basic element types. For example, the following expression can be used to match *Java* statements without block bodies:

```
codeBlock/statement[not child::blockStatement]
```

To select elements for annotation, the user uses fragment-selecting action (with keyboard shortcut or from menus). The action resolves annotatable elements from current text selection or caret position in the code editor, as can be seen in Fig. 3(a).

3) *Applying annotations*: Existing metadata annotation can be applied on selected code fragment with dedicated action that allows the user to specify the annotation. Its usage is shown in Fig. 3(b). Once the annotation is selected, *Connotator* finishes code annotation automatically. It selects the annotation type to use from the tool's configuration (it can be specified separately for each type of annotatable elements) or selects one automatically based on their availability and predefined priority (LLA > SCA > EA). Fig. 3(c) shows the result of applying an annotation on class fields when *Java* LLAs are configured for their element type. Note that the tool also generates required *Java* annotation types if they do not exist yet.

The same annotation process is applicable for any annotation type; the only difference is in the final alteration of the code. As an example, Fig. 4 shows a `for` statement annotated with SCA. All the source code editor augmentations, like gutter icon and annotation highlighting, remain the same. An EA would differ only by no visible annotation inserted into the code.

### C. Binding Comments to Code Elements

Going back to the differences among annotation types, the one we did not discuss so far is *binding*. As far as LLAs and EAs are concerned, the binding is defined either by the language's grammar or by specific addressing mechanism used by the tool supporting EAs<sup>5</sup>. On the other hand, SCAs do not have any grammar-based or other bindings to surrounding code

<sup>4</sup>PSI (Program Structure Interface) tree is a version of concrete syntax tree backing most structure-aware features of the *IntelliJ* platform [12].

<sup>5</sup>In *Connotator*, we currently use just a very basic offset-based addressing. A more robust solution is out of scope of here presented work.

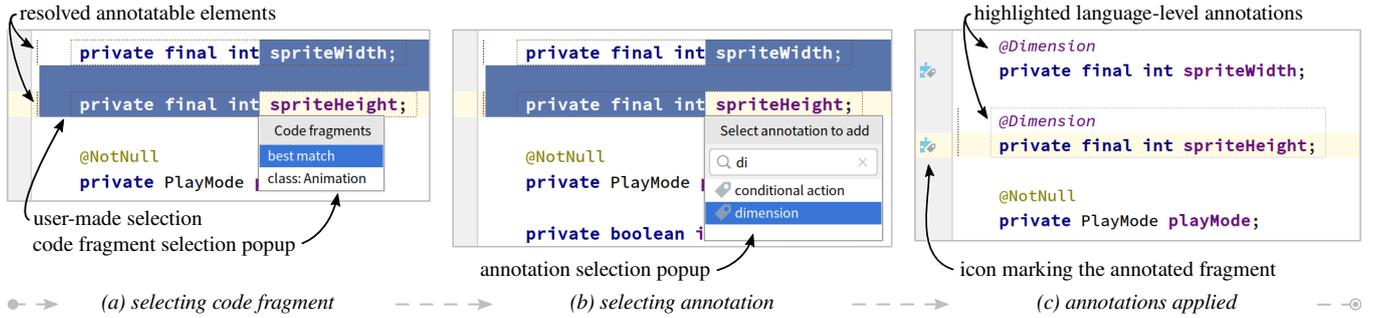

Fig. 3. Annotation process in *Connotator*. (a) The user selects code and uses action to resolve annotatable elements. (b) The user uses action to apply annotation to the selection and then selects desired annotation. (c) The tool applies *Java* LLAs because this type is configured for class fields in the project.

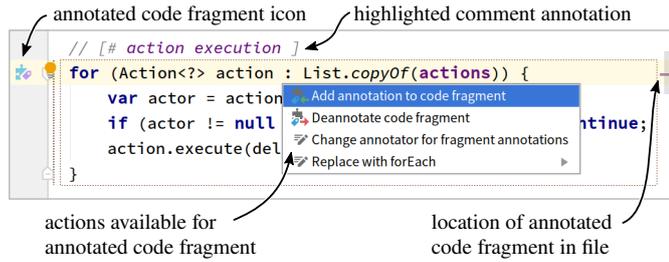

Fig. 4. IDE editor showing annotated block statement with associated actions and source code editor augmentations.

elements; in fact, compilers and interpreters for most languages ignore comments already in the lexing phase.

However, IDEs need to know about every concrete syntax tree token in order to be able to map each character from the file to the corresponding parsed node, and *vice versa*. For this reason they use custom lexers and parsers that preserve comments [12]. Nevertheless, only comment's parent can be determined from the tree (e.g., a comment inside a method), which is not enough to unambiguously assign comments to code elements. Does a comment standing alone on a first line within a method relate to the method (parent) or to a statement below? One possibility for dealing with such ambiguities is to deploy a set of conventions, or rules, to resolve them.

In the design of comment-to-element binding rules for a tool that needs to be able to find comments in the existing code, as well as to generate them when elements are annotated, we need to consider their following two properties:

- *Placement* of comments relative to elements they are bound to. There are many such relative placements that can be supported; see, e.g., the work of Sommerlad *et al.* [13] or our examples in Fig. 5.
- *Type* of comments that should be used. Particularly *end of line* and *block* comments are often supported by languages, sometimes complemented by conventional format of *documentary comment* (as *Java*'s *JavaDoc*).

Examples of possible relative comment-to-element placements and comment types are in Fig. 5. In the following, we describe how these placements and comment types are interpreted by *Connotator*, which supports their configuration

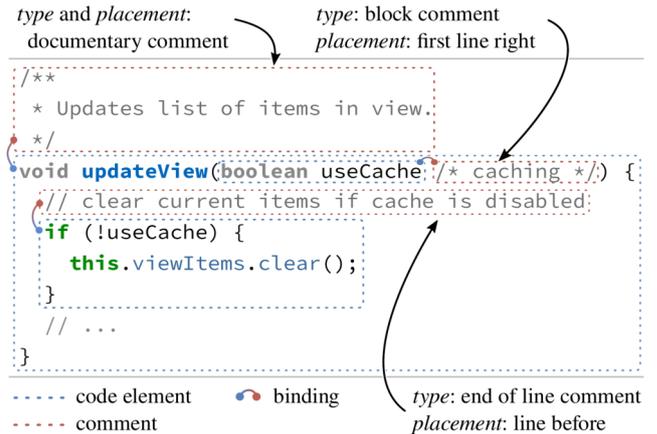

Fig. 5. Comment placements and types with bound code elements

for each annotatable element type.

- *End of line* comment is bound to the *if* statement on the next line through the *line before* relative placement.
- *Block comment* is bound to the method parameter *useCache* through the *first line right* relative placement. The *block* type of comment is required in this context because the bound element is followed by more tokens.
- *Documentary comment* is bound to the method *updateView* through the equally named *documentary comment* placement. This placement expresses the intention to bound the conventional documentary comment to the element it documents.

Because the user can manually insert a comment annotation at invalid position (such that does not bind it to any annotatable element), *Connotator* is able to issue warnings through in-editor highlighting when such comment is found.

### III. EXPERIMENT: ANNOTATING CODE WITH COMMENT ANNOTATIONS

Our main motivation behind the presented tool support for annotation process is in reducing overhead of annotating a source code. To evaluate any effects our prototype tool *Connotator* can have in this regard, we prepared a task in which a portion of a selected application's code base needs to be annotated with comments containing high-level concern

metadata. We specify what kinds of code elements can be annotated and where should the annotating comments be placed relatively to the annotatable elements: together, we will call this set of constraints the *annotation rules*.

In this section we present an experiment in which we compare two groups of students-programmers performing the described task. The first group uses *IntelliJ IDEA* with *Connotator* installed and the second, control group, uses *IntelliJ IDEA* in its default setup. We formulate the following two research questions for the experiment.

**RQ 1.** *Do programmers annotate source code with comments more consistently with defined annotation rules if they are guided by a metadata-aware tool that adheres to these rules?*

**RQ 2.** *Do programmers annotate source code with comments more quickly if the development environment is aware of the comment annotations?*

### A. Hypotheses

In the experiment we focus on two aspects of the annotation process: comment annotations *placement consistency* and *annotating speed*. In the following, we formulate related hypotheses. The goal of the experiment is to statistically test those hypotheses with a confidence level of 95% ( $\alpha = 5\%$ ).

1) *Comment Annotations Placement Consistency*: In *Connotator*, comment annotations placement rules are used to bind SCAs to specific code elements. We hypothesize that *Connotator* will help to *increase* comment annotations *placement consistency* in comparison to manual annotating. We define placement consistency (*PC*) of comment annotations as

$$PC = \frac{N_C}{N_A} \times 100\%$$

where  $N_C$  is the number of correctly (according to the annotation rules) placed comment annotations, and  $N_A$  is the number of all comment annotations placed during the annotating task. We formulate the following null and alternative hypotheses for RQ 1:

H1<sub>null</sub>: The **placement consistency** of comment annotations created during code annotation task with *Connotator* **is equal** (=) to the placement consistency of comment annotations created during the same annotation task with the standard *IntelliJ IDEA* setup.

H1<sub>alt</sub>: The **placement consistency** of comment annotations created during code annotation task with *Connotator* **is higher** (>) than the placement consistency of comment annotations created during the same annotation task with the standard *IntelliJ IDEA* setup.

2) *Annotating Speed*: *Connotator* abstracts the annotation process for different annotation types into a set of IDE actions. We hypothesize that these actions, when combined with the annotation rules for annotatable elements, will *increase* *annotating speed* of programmers performing code annotation task. We define annotating speed (*AS*) as

$$AS = \frac{N_A}{t}$$

where  $N_A$  is the number of all comment annotations placed in the code during the annotating task and  $t$  is the total time needed to complete the task. We formulate the following null and alternative hypotheses for RQ 2:

H2<sub>null</sub>: The **annotating speed** during code annotation task with *Connotator* **is equal** (=) to the annotating speed during the same annotation task with the standard *IntelliJ IDEA* setup.

H2<sub>alt</sub>: The **annotating speed** during code annotation task with *Connotator* **is higher** (>) than the annotating speed during the same annotation task with the standard *IntelliJ IDEA* setup.

### B. Setup

1) *Participants*: Participants of the experiment were 36 bachelor's degree Computer Science students from our department. They were in their fourth semester with programming courses and were familiar at least with languages *C* and *Java*. These students formed two study groups (not equally sized) of the Component Programming course, in which the *Java* language is used. One group of students was chosen as the experimental group where *Connotator* was used: we will call it the *Connotator* group. The other group of students was used as the control group working with standard *IntelliJ IDEA* IDE setup: the *manual* group. The *Connotator* group contained 20 participants and the *manual* group 16.

2) *Code for Annotation*: As a target for the annotating task we used source code of application for managing notes for bibliographic entries called *EasyNotes*.<sup>6</sup> It is a small-scale (about 2700 lines of code) project written in *Java*. An advantage of its code base is the presence of high-level concern annotations in a form of *Java* annotations, which were added by its author for the purpose of the study performed by Sulír *et al.* [4]. This provided us a very good starting point for preparing our own annotating task. From 25 available concern annotation types, we selected 10 that covered a large portion of the application's domain logic, its data model and persistence. We left out all the code directly related to the graphical user interface because it contained more complicated code generated by a UI designing application.

However, high-level concerns may be difficult to recognize in an unfamiliar code base. This difficulty of program comprehension represents the main confounding factor for our experiment because it can negatively affect the annotation speed (our dependent variable) and correctness of *contextual* placement of annotations (which we do not evaluate). Our attempt to minimize the influence of this factor was to try and bring the annotating close to a mechanical process, not unlike one performed by a programmer who is already familiar with the code. For this purpose, we renamed several identifiers to names that included some form of the relevant concern name.

3) *Format of Comment Annotations*: The two groups of participants did not use exactly the same comment structure

<sup>6</sup>Source code of the application *EasyNotes* is available at <https://github.com/MilanNosal/easy-notes>.

for annotations. As shown in Fig. 4, *Connotator* uses specific comment annotation format where the annotation name needs to be placed between prefix [ # and suffix ] within the text of a comment. These additional symbols are, however, meaningless without the tool and they would pose unnecessary hindrance for participants working without *Connotator*. For this reason, participants in the control group did use only simple prefix # before annotation name in comments to clearly designate that the following text is meant to be an annotation.

4) *Additional Materials*: We prepared two documents for study participants: annotation rules they need to follow during the task and a user guide for *Connotator*. We kept these documents short so they would fit each on one sheet of paper.

The document with annotation rules was designed to guide participants through the task of annotating EasyNotes' code. It described the form of comment annotations, their possible relative placements, and paired each type of annotatable element with required comment placement (for the last see Table I). The document was concluded with a table of actual annotations the participants should use. For each of the 10 annotations it specified words related to high-level concerns that could be found in element identifiers. It also explained the high-level meaning of each annotation. For example, for concern *citing* the table listed "*citing of publications*" as its explanation and "*cite, citation, publication*" as related words in identifiers.

In addition to the annotation rules, we provided participants in the *Connotator* group with a brief user guide of the tool. This guide explained the role of the annotations panel and the available workflows to select, annotate and deannotate code fragments. The guide also presented the *Connotator*'s ways of signalling through code highlighting whether a specific comment annotation is considered to be valid or invalid according to the configuration.

5) *Environment*: The experiment took place in our department's software laboratory room containing 20 computers with widescreen full HD displays and *IntelliJ IDEA 2017.3.5* installed on Windows 10 OS. We also set up a screen recording application to record the participants' annotating sessions for extracting the task completion times and for later analysis of their performance. We informed participants that their session was going to be recorded.

### C. Procedure

We carried out the experiment in two separate sessions, each for one group of participants and lasting 90 minutes (the

duration of a lab lesson). Each session proceeded as follows.

When the participants came for the experiment into the laboratory room, they already had their environment prepared: *IntelliJ IDEA* was running with the EasyNotes project opened and the screen recording was started. The *Connotator* group had the tool configured in accordance with the annotation rules.

First, the experimenter—the author of this paper—introduced the concept of annotating source code with high-level concerns. Then he presented the EasyNotes application, explaining its purpose and demoing its functionality.

In the next step, the experimenter handed over printouts of prepared materials, each labeled with a unique participant number. Then he walked the participants through its individual sections: form of comment annotations, possible comment placements, the comment annotation placements rules and the annotations themselves. For the *Connotator* group, the experimenter then covered the *Connotator* user guide complemented by presentation of its usage.

Next, the participants were asked to proceed with the task. They were also asked to minimize the IDE window and notify the experimenter when they finish. When each participant finished their task, he or she was asked to fill out a prepared questionnaire. At the end, the experimenter collected annotated projects and videos of annotating sessions.

### D. Evaluation

The first phase of evaluation consisted of analyses of captured videos, in which we needed to determine the actual duration of each participant's annotating task. Next, we proceeded with analysing annotated projects. The projects were analysed by counting created comment annotations. In every project annotated by an experiment participant we counted:

- Total number of annotations in comments.
- Number of invalid annotations, which were further categorized as comment annotation with:
  - *invalid placement*: annotations occurrences in comments that, given their placement in the code, did not annotate any element according to the annotation rules,
  - *invalid syntax*: comment annotations that did not use required syntax,
  - *invalid context*: comment annotations that annotated elements not related to the concerns expressed by these annotations.

### E. Results

Our data samples were unpaired, as each participant was either in *Connotator* or in *manual* group. There was one independent variable—availability of the *Connotator* tool—with nominal values "available" and "unavailable". Our dependent variables were comment annotations placement consistency and annotating speed, none of which looked normally distributed. We used the *Mann-Whitney U test* as a statistical test for our hypotheses. We report the results in the following.

TABLE I  
ANNOTATION RULES FOR THE ANNOTATING TASK

Annotatable code fragment type	Comment annotation placement
Class	
Method	Documentation comment
Class field	
Simple statement	
Method parameter	First line right
Block statement	Line before

1) *Comment Annotations Placement Consistency*: The placement consistency was higher in the *Connotator* group. The mean value in this group was 99.59%, compared with the mean of 83.55% in the *manual* group. Only 3 comment annotations were placed incorrectly for the *Connotator* group (participants typed them manually and ignored the tool’s warnings). On the other hand, *manual* group had 2 extreme outliers, who reached PC of only 46.43% and even 0.0%, respectively. If we exclude these two participants, the mean for the *manual* group rises to 92.17%. Statistical results are summarized as box plots in Fig. 6.

With or without the two extreme cases in the *manual* group, the computed  $p$  value is well below 0.001 ( $6.42 \times 10^{-7}$  and  $1.74 \times 10^{-6}$  respectively), which is also below our significance level (0.05). Thus, we reject  $H_{1null}$  and accept  $H_{1alt}$ . The conclusion is that comment annotations placement consistency was higher in the *Connotator* group and the result is statistically significant.

2) *Annotating Speed*: The annotating speed was also higher in the *Connotator* group, with the mean of 2.07 annotations per minute. The *manual* group reached the mean of 1.48 annotations per minute. See Fig. 7(a) for the box plot.

The computed  $p$  value for annotating speed is 0.11, which is above our significance level (0.05). Thus, we fail to reject  $H_{2null}$ . The conclusion is that while annotating speed was higher in the *Connotator* group, the result is **not** statistically significant.

It is, however, interesting to note that when we consider just the duration of the annotating sessions (box plot shown in Fig. 7(b)), the difference between groups is more prominent: participants from the *Connotator* group finished their task in 42.64 minutes in average, while for *manual* group the average is 52.76 minutes. The computed  $p$  value for session durations is  $< 0.001$ . We discuss the possible reasons for this

discrepancy between annotating speed and annotating session duration (among other observations) in Section IV.

### F. Threats to Validity

In the following, we discuss threats to the validity of the experiment and relevant control actions taken.

a) *Internal validity*: Assignment of participants into groups was not strictly random: we used existing groups of students, in which randomness is not guaranteed. The alternative was to randomly assign half of each study group to the experimental group and the other half to the control group. However, in such arrangement, the experimenter would need to present the annotating tool in front of participants assigned to the control group (they would be in the same room), which could also have an effect on the result.

Pilot-testing was limited to one participant who performed the annotating task with *Connotator*. At that time, 13 high-level annotations were selected. As we considered the time needed to reasonably complete the task too long, we decided to lower the count of annotations to 10.

b) *External validity*: Participants of our experiment were students, not professional programmers. According to the findings of Salman *et al.* [14], it might not have great effects on the results, because the tested approach—the *Connotator* tool—is new for both students and professionals. Nevertheless, we would need code authors or maintainers (who would know the project in detail) to eliminate the effect of program comprehension on the result. We attempted to eliminate this effect by making the task more mechanical, as described in Section III-B2.

Within the broader approach of using extrinsic metadata for program comprehension, we tested only its part—the annotation process. Without further integration of bound metadata into the IDE, their presence in annotations is not well utilized. However, the annotation process is the most time-consuming part of the approach, and we strive for a better supporting tool.

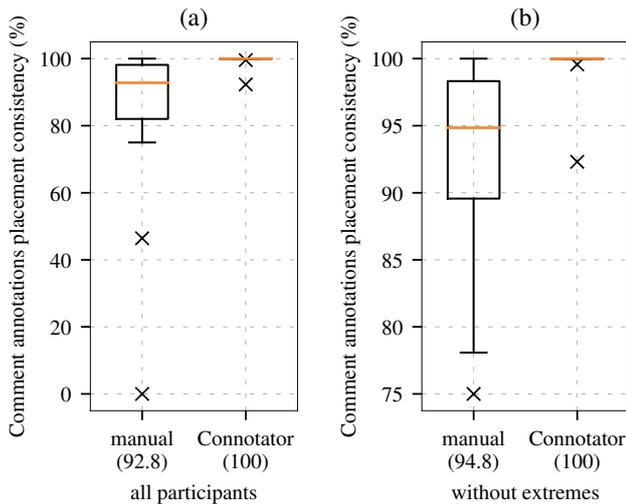

Fig. 6. The results of statistical evaluation of differences between groups of participants regarding their comment annotations placement consistency: (a) with all participants, (b) with the two outliers (0% and 46.4% PC) from the *manual* group removed. Median values are included below group names.

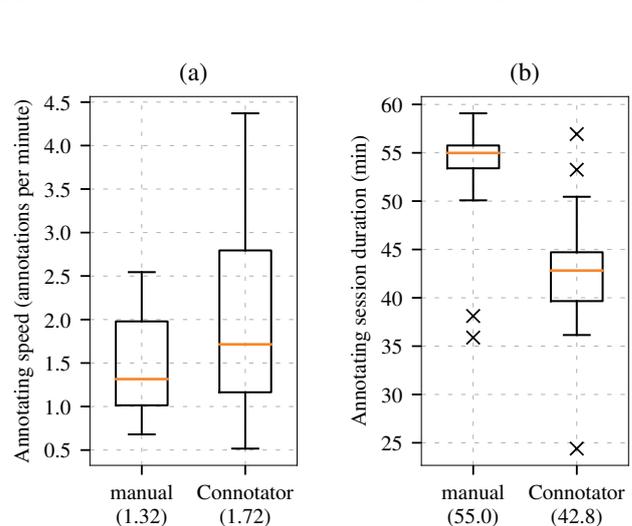

Fig. 7. The results of statistical evaluation of differences between groups of participants regarding (a) their annotating speed and (b) duration of their annotation sessions. Median values are included below group names.

c) *Conclusion validity.*: The most prominent threats to conclusion validity are the small number of subject participating in the experiment (36) and the confounding factor of needed comprehension of annotated source code.

#### IV. DISCUSSION OF THE EXPERIMENT

In this section, we present observations regarding the data we obtained by analysing source codes annotated in the experiment.

##### A. Differences in Number of Created Annotations

Based on our version of annotated EasyNotes' source code, which itself was based on annotations from its author and refined to finer granularities allowed by SCAs, we consider 70 to 90 comment annotations for an optimal result of annotating. Participants annotated code on the basis of the annotations table that we provided them. Ultimately, the specific code elements—and their count thereof—that participants chose to annotate depended on their understanding of both the annotations and of the code. In processed projects, we saw that the numbers of annotations created during the task varied significantly.

From the box plot in Fig. 8, we can see that the *manual* group performed better with regard to the number of annotations. The median (72.5 annotations) is closer to our optimal count than the median of *Connotator* group (61.5 annotations) and there are no very low (<30) nor very high (>200) values.

The most frequently and most inconsistently used was annotation *domain entity*. Some participants took this annotation too broadly and annotated a majority of variables named `note` or `notes`. Interestingly, the extreme cases of such very general understanding of this annotation (almost 100 occurrences in the project) were present only in the *Connotator* group.

Described differences in number of created annotations, especially the tendency towards lower count of annotations in the *Connotator* group, may be behind the discrepancy between annotating speed and session duration distributions (see Fig. 7). Also, 3 participants in the *Connotator* group annotated code in less than 40% of files they were asked to annotate, in comparison to only one such participant in the *manual* group.

We conclude that in order to more reliably assess the effect of our tool on annotating speed, the task should more precisely define both the elements to be annotated and the determining factor of when the task can be considered as completed. This may reduce the variability in annotations counts or at least allow us to exclude clearly incomplete tasks.

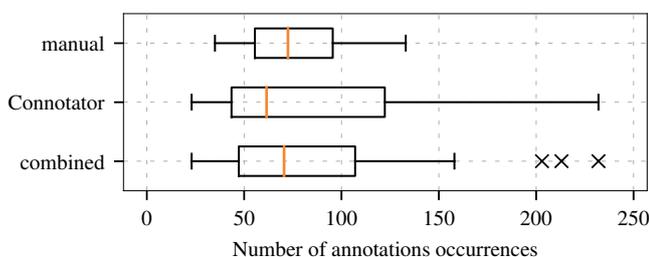

Fig. 8. Distributions of number of created comment annotations. Shows distributions for both groups and for all participants combined.

##### B. A Closer Look at Placement Consistency

Comment annotations placement consistency (*PC*) showed to be significantly higher in the *Connotator* group (see Section III-E1). This result may be not surprising as this group used tool that prevented *misplaced*<sup>7</sup> comment annotations. Our interest was, however, to find out how many misplaced annotations there would be in the *manual* group and whether the difference would be significant.

Fig. 9 shows absolute numbers of misplaced annotations in relation to all annotations created by individual participants. Only one participant in the *manual* group managed to make no placement mistakes, but he made totally only 35 annotations (the lowest number in the group).

##### C. Invalid Syntax or Context of Created Comment Annotations

There were 0 comments with invalid syntax in the *Connotator* group. *Manual* group made syntactic mistakes in 1.6% of comments in average, mainly by omitting the # prefix. Three participants in the *Connotator* group misspelled name of one annotation, which resulted in having them misspelled at every occurrence in the code. However, due to *Connotator*'s annotation renaming feature, such issue can easily be fixed. On the other hand, *manual* group had 2.6% of comments in average with misspelled annotation names. Without a supporting tool, such errors lead to inconsistencies that hinder the usage of such *comment tags* with common search tools [15].

As the tested annotation process does not influence program comprehension, we expected to find no difference in the numbers of contextually invalid annotations. This expectation was confirmed as these was only small and statistically insignificant difference: median values for percentages of contextually invalid annotations were 13.6% and 11.7% for *Connotator* and *manual* groups, respectively.

##### D. Observations from the Questionnaire

In the questionnaire we asked participants questions about how they would rate their understanding of annotations

<sup>7</sup>Misplaced comment annotation is an annotation within a comment that is not bound to any code element because its placement or comment type does not match annotation rules.

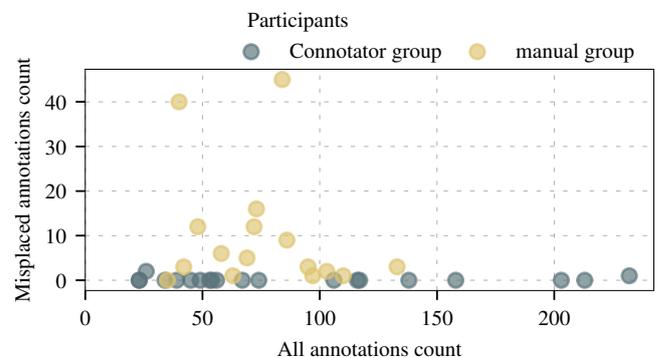

Fig. 9. Number of misplaced annotations of each participant.

meaning and of EasyNotes source code on a 5-point scale. Generally, participants expressed that they understood meanings of annotations and that they were able to comfortably navigate source code of EasyNotes. Differences between groups were minor, with marginally higher (i.e., better understanding) means in the *manual* group.

Next, we asked question regarding the annotation process, in which the participants answered as follows.

- 45% of participants from the *Connotator* group stated that annotating was simple and fast, compared with only 12.5% in the *manual* group.
- 43.8% of participants from the *manual* group considered annotating as laborious and 62.5% stated they copied existing comment annotations to create new ones.
- 90% of participants from the *Connotator* group considered the annotating tool as helpful.

We also asked how often they needed to check the document with annotation rules (on a 10-point scale from “in 1 out of 10 cases” to “in 10 out of 10 cases”). The responses are plotted in Fig. 10 and show that participants in the *Connotator* group reported less frequent usage of annotation rules (median of 3/10) than in the *manual* group (with median of 5.5/10). These responses indicate that participants working with our tool were less occupied by the details of the annotation process.

## V. RELATED WORK

In this section we look at other approaches and tools that share similarities with ours presented in this paper.

Mattis *et al.* present an approach named *Concept-Aware Programming Environment* [16]. They are interested in making programming environments aware of *concepts* that are present in the code through identifier names, with the goal to help programmers to build their mental model of the code. Another use-case is in detecting *architectural drift*: change in meanings and distributions of words used in names of identifiers during program evolution. Their method for finding concepts in the code is automated, but allows programmer’s intervention and correction. For sharing of corrected concepts in a distributed workspace, they suggest to embed them in comments, which would result in SCAs conceptually similar to our ones. Integration of their approach into development environments consists of tools for concept exploration, custom class diagrams, and concept-augmented IDE editor, debugger and VCS tools.

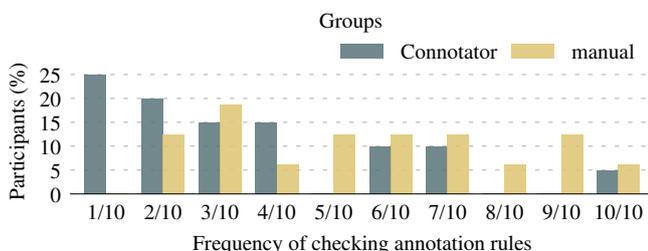

Fig. 10. The frequency of checking annotation rules by participants in  $n$  out of 10 cases of inserting an annotation into the code.

We presented a uniform annotation process that works for all annotation types and, considering their limitations, allows to choose the appropriate type per use case. Cazzola *et al.* extended LLAs for languages *C#* [17] and *Java* [18] to finer granularities through customized compilers, by which they extended the applicability of this single annotation type to code blocks and expressions. In comparison with our approach, the availability of annotations in the compiler and for processing through reflection at runtime is an advantage. However, a special tool (in this case a custom compiler) is still needed, and each such solution is restricted to a single language.

Current implementation of *Connotator* has only a simple metadata model, where annotations can represent high-level concerns through their names. A practical extension of this model would be to link external resources to the metadata. Similar thing was done by Baltes *et al.* who designed *SketchLink* tool [5] for linking sketches documenting high-level design to code elements through SCAs. Their design included a service for uploading and managing images of sketches from mobile devices and web browsers. IDE plug-in linked these images through unique identifier included in source code comments.

Our approach to select structurally valid annotatable code fragments uses AST patterns. Kästner *et al.* [19] and Behringer *et al.* [20] use AST rules to ensure structurally valid separation of features in feature-oriented development of software product lines. Kästner *et al.* call the annotation process *coloring* and Behringer *et al.* extend it with *snippet* code organization system for managing feature variability.

Cséri *et al.* [21] present their approach to assign source code comments to specific elements of the AST. They were interested in comment-to-element assignment for software maintenance tool, but had to work with legacy codebases, inside of which the assignment needed to happen. Their solution, similar to ours, consists of project-specific rules for defining relative comment placements, but the rules are more complex, supporting, e.g., assignment of a single comment node to multiple code elements. On the other hand, they do not differentiate types of comments, because they only process existing comments and do not need to generate new ones.

Rule-based comment assignment is also used in tool *TagSEA* by Storey *et al.* [22]. It uses a simple rule: comments are bound to the closest enclosing *Java* element. Such rule is sufficient if metadata granularity does not go below methods.

In contrast to our per-project configurable comment-to-element assignment, Sommerlad *et al.* [13] used fully-automatic assignment, distinguishing *leading*, *trailing* and *freestanding* comments. Their goal was to retain all comments and their positions while refactoring the code.

We used annotations for high-level metadata from the problem domain. Sulír and Porubán in their approach [23] used annotations to preserve low-level runtime information.

## VI. CONCLUSION AND FUTURE WORK

In this paper, we presented our work towards allowing programmers to more easily preserve their high-level knowledge of source code they create by annotating it.

We gave an overview of the concept of the metadata-aware development environment and focused on its first building block: the support for the annotation process. For annotating code with three different types of annotations, and making the annotating workflow uniform, we designed an abstraction of the process. First, a programmer chooses source code elements to annotate and annotation representing metadata that should be bind to these elements. Then, a specific annotation is applied automatically by a supporting tool. We also described our prototype of such a tool in the form of a plugin for *IntelliJ* platform-based IDEs, called *Connotator*.

Finally, we reported the experiment in which we evaluated *Connotator* regarding its effect on the annotation process. We confirmed the hypothesis that the tool could increase placement consistency of comment annotations with annotation rules. The group of participants using the tool achieved higher consistency and reported less distraction by the details of the annotating than the group without the tool. The hypothesis that the tool increases annotating speed was not confirmed, although the group using the tool tended to finish the task sooner.

The natural next progress is to explore in detail the remaining two aspects of MADE to better utilize the preserved metadata and facilitate program comprehension. An interesting direction may also be in merging intrinsic metadata already available in IDEs with the preserved, extrinsic ones, and providing a querying facility for the resulting model. The queries could be used to customize views of code provided by an IDE, similarly to the concept of *scriptable* IDE presented by Asenov *et al.* [24].

Although our approach supports multiple types of annotations, we used only one type in the presented experiment. We will focus on assessing the annotation process using a mixture of annotation types in future evaluations.

# 10<sup>th</sup> Workshop on Scalable Computing

**T**HE world of large-scale computing continuously evolves. The most recent addition to the mix comes from numerous data streams that materialize from exploding number of cheap sensors installed “everywhere”, on the one hand, and ability to capture and study events with systematically increasing granularity, on the other. To address the needs for scaling computational and storage infrastructures, concepts like: edge, fog and dew computing emerged.

Novel issues involved in “pushing computing away from the center” did not replace open questions that existed in the context of grid and cloud computing. Rather, they added new dimensions of complexity and resulted in the need of addressing scalability across more and more complex ecosystems consisting of individual sensors and micro-computers (e.g. Raspberry PI based systems) as well as supercomputers available within the Cloud (e.g. Cray computers facilitated within the MS Azure Cloud).

Addressing research questions that arise in individual “parts” as well as across the ecosystem viewed from a holistic perspective, with scalability as the main focus is the goal of the Workshop on Scalable Computing. In this context, the following topics are of special interest (however, this list is not exhaustive).

## TOPICS

- General issues in scalable computing
  - Algorithms and programming models for large-scale applications, simulations and systems
  - Large-scale symbolic, numeric, data-intensive, graph-oriented, distributed computations
  - Fault-tolerant and consensus techniques for large-scale computing
  - Resilient large-scale computing
  - Data models for large-scale applications, simulations and systems
  - Large-scale distributed databases
  - Load-balancing / intelligent resource management in large-scale applications, simulations and systems
  - Performance analysis, evaluation, optimization and prediction
  - Scientific workflow scheduling
  - Data visualization
  - On-demand computing
  - Virtualization supporting computations
  - Volunteer computing
  - Scaling applications from small-scale to exa-scale (and back)
  - Big data real-time computing / analytics

- Economic, business and ROI models for large-scale applications
- Emerging technologies for scalable computing
  - Cloud / Fog / Dew computing architectures, models, algorithms and applications
  - High performance computing in Cloud / Fog / Dew
  - Green computing in Cloud / Fog / Dew
  - Performance, capacity management and monitoring of Cloud / Fog / Dew configuration
  - Cloud / Fog / Dew application scalability and availability
  - Big Data cloud services
  - Architectures for large-scale computations (GPUs, accelerators, quantum systems, federated systems, etc.)
  - Self\* and autonomous computational / storage systems

## EVENT CHAIRS

- **Ganzha, Maria**, Warsaw University of Technology, Poland
- **Gusev, Marjan**, University Sts Cyril and Methodius, Macedonia
- **Paprzycki, Marcin**, Systems Research Institute Polish Academy of Sciences, Poland
- **Petcu, Dana**, West University of Timisoara, Romania
- **Ristov, Sashko**, University of Innsbruck, Austria

## PROGRAM COMMITTEE

- **Barbosa, Jorge**, University of Porto, Portugal
- **Camacho, David**, Universidad Autonoma de Madrid, Spain
- **Carretero, Jesus**
- **D’Ambra, Pasqua**, IAC-CNR, Italy
- **Durillo, Juan**, Leibniz Supercomputer of the Bavarian Academy of Sciences and Humanities, Germany
- **Garcia Valdez, Mario**
- **Gordon, Minor**, Software development consultant, United States
- **Gravvanis, George**, Democritus University of Thrace, Greece
- **Grosu, Daniel**, Wayne State University, United States
- **Holmes, Violeta**, The University of Huddersfield, United Kingdom
- **Kalinov, Alexey**, Cadence Design Systems, Russia
- **Kecskemeti, Gabor**, Liverpool John Moores University, United Kingdom
- **Kitowski, Jacek**, AGH University of Science and Technology, Department of Computer Science, Poland
- **Knepper, Richard**, Indiana University, United States

- **Lang, Tran Van**, Vietnam Academy of Science and Technology, Vietnam
- **Lastovetsky, Alexey**, University College Dublin, Ireland
- **Margaritis, Konstantinos G.**, University of Macedonia, Greece
- **Nosovic, Novica**, Faculty of Electrical Engineering, University of Sarajevo, Bosnia and Herzegovina
- **Pawłowski, Wiesław**, University of Gdańsk, Poland
- **Prodan, Radu**, University of Klagenfurt, Austria
- **Schikuta, Erich**, University of Vienna, Austria
- **Schreiner, Wolfgang**, Johannes Kepler University Linz, Austria
- **Shen, Hong**, University of Adelaide, Australia
- **Telegin, Pavel**, JSCC RAS, Russia
- **Tudruj, Marek**, Inst. of Comp. Science Polish Academy of Sciences/Polish-Japanese Institute of Information Technology, Poland
- **Vazhenin, Alexander**, University of Aizu, Japan
- **Wei, Wei**, School of Computer science and engineering, Xi'an University of Technology, China
- **Wyrzykowski, Roman**, Czestochowa University of Technology, Poland
- **Zavoral, Filip**, Charles University, Czech Republic

# Measure of Adequacy for the Supercomputer Job Management System Model

Anton Baranov, Dmitriy Lyakhovets, Gennady Savin, Boris Shabanov, Pavel Telegin  
Joint Supercomputer Center of the Russian Academy of Sciences

Email: {abaranov, ptelegin, shabanov}@jscc.ru, anetto@inbox.ru

**Abstract**—In this paper we investigate the problem of modelling modern supercomputer job management systems (JMS). When modelling the JMS, one of the main issues is the adequacy of the model used in experimental studies. The paper attempts to determine the measure of the JMS model adequacy by comparing the characteristics of two job streams, one of which was acquired from a real supercomputer and the other is obtained from the JMS model. We show that the normalized Euclidean distance between vectors of jobs residence times obtained from the job streams of the real system and the JMS model can serve as a measure of the adequacy of the JMS model. The paper also defines the reference value of the measure of adequacy corresponding to the JMS model with virtual nodes.

## I. INTRODUCTION

SUPERCOMPUTER centers are usually shared facilities for the users. The users share the supercomputer computational field, which consists of computational nodes (CN) integrated by a high-performance communication network. Typically, to perform calculations on a supercomputer, the user must create a so-called passport of computational job. The passport consists of a parallel program, input data and system requirements (number of cores or nodes, amount of RAM) and execution time limit.

Special software [1] like SLURM [2], PBS [3] or the Russian native job management system SUPPZ [4] manage jobs in supercomputers. The kernel of any job management system (JMS) is the scheduler. The scheduler generates a schedule for the jobs launches according to job passports. Information in the job passport includes required execution time of job, amount and types of resources. The JMS scheduler provides quite an accurate time prediction of the launch time for each queued job. Changes to this forecast are usually made when the schedule is renewed due to a new job submission, job removal from the queue, or premature completion of a running job.

A set of indicators is used to measure the quality of scheduler. These indicators include average load, average waiting time for a job in a queue, etc. [5]. These indicators are influenced by both the configuration parameters of the scheduler and the characteristics of the input job stream. At the same time, this influence is not always evident and cannot be esti-

mated or predicted, since modern JMS are rather complicated systems with many adjustable parameters. This is why JMS modelling is relevant for studying the way that the input stream characteristics and JMS configuration influence job scheduling quality indicators.

Functioning of the real system and its simulation will be somewhat different, this results two interrelated problems. First, it is necessary to find out how to measure the model reproduction accuracy of the simulated system, i.e. to determine the measure of accuracy (adequacy) of the model. This will make it possible to compare different models by their adequacy. Secondly, it is necessary to establish the maximum valid value (limit) of the measure of accuracy. The overrun of this limit means that the model is not adequate and cannot be used to analyse the real system behaviour. The main goal of the paper is search and selection of models adequacy measure, as well as definition of the adequacy limits for the JMS models.

## II. THE PROBLEM OF A SUPERCOMPUTER JOB MANAGEMENT SYSTEM MODELLING

A number of external and internal events occur during the operation of JMS. External events include job submission, premature job termination, deletion of job from a queue or job interruption by a user or an administrator, JMS start and stop, change in number of available computing nodes. The internal events include the next job launch at the appointed time according to the schedule. JMS logs the time stamp and type of each event.

We consider JMS simulation as the process of submitting the external events stream to the model input and logging the internal events stream. The model's resulting stream of the internal events should be similar to the same stream in the real system. These two streams are identical when the model is fully adequate.

Existing methods of JMS modelling can be categorized as follows:

1. Development of a JMS analytical model.
2. Experiment with a real supercomputer.
3. Study of the JMS with virtual nodes (VN) [6].
4. Development of a JMS simulation model.

This work was supported by RFBR grants no 18-29-03236 and 18-07-01325 and state assignment topic No. 0065-2019-0016

The analytical model allows investigating the impact of JMS changes on its interval indicators, but does not provide a way for predicting the launch time of individual jobs, which is necessary for forecasting. Due to the complexity of construction and orientation on interval indicators, the analytical model is not be considered in this paper.

### III. NATURAL EXPERIMENT AS THE WAY TO SIMULATE A JMS

By term “natural experiment”, we mean the reproduction of an input external event stream in a real supercomputer. Therefore, the JMS model in a natural experiment will be fully adequate. Nevertheless, a natural experiment cannot provide reproduction of simulation results with 100% accuracy. In fact, processing time of a job consists of three generally random variables:

- job launch time: the time spent by the JMS for the allocation of computational nodes and their configuration in accordance with the job requirements;
- job execution time on the selected nodes;
- job completion time: the time spent by the JMS to release the selected nodes, including control the completion of all job processes, deletion of temporary files and shared resources created by the job, reconfiguration of the nodes, etc.

Job launch and completion time will be referred to as overheads. The billing subsystems for the most of the JMS include overheads into job execution time. At the same time, the proportion of overheads is a random value and can depend on many factors, such as network delays, changes in the state of calculations in the operating system kernel, etc.

The main disadvantage of a natural experiment is difficulty of its reproduction, since expensive supercomputer resources in such an experiment will duplicate the calculations already performed. Practically, a natural experiment is performed by changing JMS studied parameters. In accordance with the change of the JMS quality indicators, the decision is made whether to save the changes or to return to the previous version of the JMS settings.

### IV. SIMULATION OF JMS WITH VIRTUAL NODES

Virtual nodes (VN) can be used to model the JMS. This is a software subsystem, which, instead of launching jobs on computational nodes of a computational field, makes a note that virtual nodes are engaged for the duration of the assignment. Real calculations are not performed in this case.

There are two ways to simulate a JMS with VN: in real time mode and in model time mode. In real-time VN is presented to the JMS as a computational field, the JMS actually operates in a natural experiment mode without launching jobs on a supercomputer. This allows us to speak about the accuracy of such modelling as comparable with the accuracy of a natural experiment. The disadvantage of this method is a long simulation time corresponding to the real time of the JMS operation.

The basis of JMS with virtual nodes in the model time is the idea of «advancing» system time in those moments when external or internal events do not occur. For example, if at some point of the experiment no new jobs are received, at the current moment, one job is being processed and it will be completed in an hour, then it is possible to move the system time one hour forward. Simulation in this case is significantly accelerated. To implement this method, it is necessary to develop a special software tool for advancing the system time with additional verification of the experimental results accuracy.

### V. JMS SIMULATION MODELLING

To build a JMS simulation model, specialized languages can be used, like AnyLogic, ExtendSIM, Simulink [7], GPSS World [8]. Modelling languages fully provide the modelling process – the model time advancing and the interaction of objects in the system, allowing the researcher to focus on the description of the essential properties and characteristics of the simulation model.

Beside specialized modelling languages, there are so-called JMS simulators: GridSim [9], CloudSim [10], WorkflowSim [11]. Simulators supply with a set of implemented job scheduling algorithms and provide the formation of interval indicators based on the processing of the input event stream. It is also necessary to mention JMS emulators, e.g. MicroGrid [12]. A distinctive feature of the emulator is the possibility of sharing the real system components and the emulated JMS parts in the experiment.

Existing simulation tools allow us to build a predictive JMS model and conduct experiments with it on any model input event stream. However, it is necessary to validate the experiments results for simulation models in order to determine the model adequacy. To do this, it is necessary to set a measure of adequacy, express this measure by some quantitative characteristic and determine the allowable limits of this characteristic values, within which the model will be considered adequate.

### VI. JMS EVENT STREAM MODEL

Let all events in the JMS occur at discrete points in time  $t_i$ . Consider the stream of independent submitted jobs  $J_1, J_2, \dots, J_k, \dots, J_N$ . Each job  $J_i$  in the queue has the following characteristics:

- the moment of the job submit  $r_i$ ;
- the required resources  $p_i$ ;
- ordered processing time  $e_i$ ;
- real processing time  $w_i$ ,  $0 \leq w_i \leq e_i$ , which consists of job launch time  $a_i$ , execution time  $b_i$ , completion time  $c_i$ .

Note that the actual execution time is not available for the job management system and cannot be used to build a schedule. As shown above,  $a_i$ ,  $b_i$  and  $c_i$  are random variables and can vary from launch to launch of the same job.

The scheduler determines the job launch moment  $s_i$ . Derived characteristics of the job are wait time for a job in the queue  $q_i = s_i - r_i$ ; job residence time (full time spent in the system from submit to job completion)  $f_i = q_i + w_i$ ; the moment of the job completion  $g_i = s_i + w_i$ .

An events stream with some characteristics is fed to the JMS model input. The result of the JMS model is an output model stream of events with a different characteristic set. Denote the characteristics of this stream in capital letters.

There are three well-established approaches to the formation of the input event stream [13]. The first approach is to use the real JMS event log. The approach allows reproducing the input event stream of a real supercomputer, taking into account all its features. The second approach is based on the SWF (Standard Workload Format) [14]. Event logs of some supercomputers, including university ones, published in SWF. The essential drawback is the incompleteness of the event flow: SWF represents only events related with jobs in the queue, and there is no information about changes in the nodes number, job deletions from the queue or interruptions in the job execution by the user. The third approach is to generate an input stream of events [15]. Each job parameter (submit time, ordered and real execution time, required computing resources) is a random variable with a certain distribution law. The law and distribution parameters are selected, as a rule, based on the analysis of the studied supercomputers event logs. This approach allows creating several different instances of input streams with the same distributions.

## VII. JMS MODEL ADEQUACY

The variant of determining the adequacy measure proposed by the authors is based on the proposed in [16] the model's reliability evaluation method — event validity, when comparing event streams of simulated and real systems. In the paper [16], no numerical indicators allowing comparing two event streams are provided.

Let us define the proximity measure of two event streams as follows. We formulate criteria for the unreliability of the predictive model. A model is defined as unreliable if the events number in the simulation did not coincide with the number of events in the real system. If any of the events were not reproduced in the simulation, or new events have arisen, then the model is unreliable. We also consider the model unreliable if the job submit time in the model and the real system do not match, if the job execution time or ordered computing resources do not coincide. Thus, the model is unreliable if  $n \neq N$ ,  $r_i \neq R_i$ ,  $p_i \neq P_i$ , or  $e_i \neq E_i$ .

The number, the order and the time of occurrence of all events are coincided in the experiment and in the real system for a completely reliable model. In practice, the construction of a fully reliable forecasting JMS model is practically impossible even for a natural experiment, as shown above.

Let us consider two model streams of events represented by jobs  $j = (j_1, j_2, \dots, j_n)$  and  $J = (J_1, J_2, \dots, J_N)$ . The job

characteristics  $j_i = r_i$  (submit time),  $p_i$  (resources required),  $e_i$  (required processing time),  $w_i$  (real processing time),  $s_i$  (job launch time). Similar characteristics has the job  $J_i = R_i, P_i, E_i, W_i, S_i$ . The difference measure will be not determined if in the streams do not consider either the number of jobs  $n \neq N$ , or the submit times of any job  $r_i \neq R_i$ , or the ordered resources and processing times for any job  $p_i \neq P_i$ ,  $e_i \neq E_i$ . In this regard, the characteristics can be rewritten as follows:  $J_i = r_i, p_i, e_i, W_i, S_i$ .

Let us construct two vectors of dimension  $n = N$ . For the stream  $j$  we define the vector of job residence times in the system  $v = (v_1, v_2, \dots, v_n)$ ,  $i \in (1, \dots, n)$ , where each component corresponds to the job number in the order in which it enters the system. The value of the component  $v_i = (s_i - r_i + w_i)$  is defined as the residence time of the job in the system, that is, the sum of the wait time and the processing time. For the stream  $J$  we similarly define the vector  $V = (V_1, V_2, \dots, V_n)$ ,  $V_i = (S_i - R_i + W_i)$ ,  $i \in (1, \dots, n)$ .

Thus, we obtained two vectors,  $v$  and  $V$ , the difference between the components of which actually determines the difference between the two JMS models. A natural measure of the proximity of two  $n$ -dimensional vectors is the Euclidean distance between them:

$$E = \sqrt{\sum_{i=1}^n (V_i - v_i)^2} \quad (1)$$

As shown by our experiments, the Euclidean distance increases with the number of processed jobs in the compared experiments. This dependence makes the Euclidean distance inapplicable as a measure of adequacy. We will normalize measure (1) and obtain the measure of the difference  $P$  of the streams  $j$  and  $J$ :

$$P = \sqrt{\frac{\sum_{i=1}^n (V_i - v_i)^2}{n}} \quad (2)$$

The measure of the difference  $P$  (2) does not depends with the number of jobs processed. This fact makes it possible to use the measure  $P$  as a measure of the model adequacy for experiments of any duration.

## VIII. THE REFERENCE VALUE OF THE MEASURE THE JMS MODEL ADEQUACY

The following method is proposed for determining the adequacy measure. The stream  $j$  is determined based on the statistics analysis of a real supercomputer work over a sufficiently long period, and so is the vector  $v$  on stream  $j$  basis. The events  $s_i$  related to the moments of launching jobs (internal scheduler events) are excluded from the stream  $j$ . The selected substream of external events is fed to the JMS model input, and as a simulation result, the stream  $J$  and the corresponding vector  $V$  are generated. The measure  $P$  of the difference between the streams is calculated. The smaller the value of  $P$ , the more adequate the JMS model.

When  $P = 0$ , the JMS model will be completely reliable. The question arises about the maximum permissible value of

the measure  $P_{\max}$ , such that a model with an adequacy measure  $P \leq P_{\max}$  will be considered adequate.

As was shown above, the repetition of a natural experiment does not give a precise reproduction of the result. At the same time, since the real JMS is adequate to itself, some measure  $P_{\text{ideal}}$  of the difference between the streams  $j$  and  $J$ , obtained during two repetitions of the same natural experiment, by definition will be less than the acceptable adequacy limit:  $P_{\text{ideal}} \leq P_{\max}$ .

Let us call  $P_{\text{ideal}}$  the reference value of the adequacy measure. Any model that has an adequacy measure less than or equal to the reference value does not differ in its behaviour from the real system.

Since, for the reasons listed above, carrying out two identical natural experiments in practice is very difficult, it is proposed to determine the adequacy measure reference value by comparing the results of JMS simulation with virtual nodes. We formed a model stream of 1000 jobs based on the statistics of the supercomputer MVS-10P OP installed in the JSCC RAS. This stream was used to model a Russian job management system SUPPZ with virtual nodes. The results are presented in Table 1. The column «number of jobs» corresponds to the number  $k$  of the first jobs of the stream  $j$  (the real SUPPZ) and the stream  $J$  (the SUPPZ with virtual nodes). The column «the number of different jobs» indicates the number of jobs for which the wait times were different in the streams  $j$  and  $J$ . From table 1 we can conclude that the reference value of the JMS model adequacy measure, calculated by the formula (2), is equal to 12.

### III. CONCLUSION

This paper attempts to determine the JMS model adequacy measure by comparing the characteristics of two job streams, one of which is derived from a real supercomputer and the other is derived from the JMS model. Each job in these streams is associated with a set of events – entering the queue, launching, completion. The authors reduced all the events of the job stream into a single vector, in which each component corresponds to a specific job and contains the time that job has spent in the system. The following pairs of vectors are explored in the article: the first vector was acquired from the job streams in the real system and the second one was the generated by JMS model.

TABLE I.  
MEASURES OF JOB STREAMS DIFFERENCE FOR THE SUPPZ WITH  
VIRTUAL NODES

Number of jobs (size of compared vectors)	Measure of stream difference	The number of different jobs
50	0	0
100	12.0	4
250	11.4	13
500	12.0	20
750	11.6	28
1000	11.2	35

It is shown that the normalized Euclidean distance between the vectors in the pair can be used as a JMS model adequacy measure. Besides that, the paper defines the adequacy measure reference value corresponding to the JMS model with virtual nodes.

**Abstract**—This paper presents an overview of what Big Data can bring to the modern industry. Through following the history of contemporary Big Data frameworks the authors observe that the tools available have reached sufficient maturity so as to be usable in an industrial setting. The authors propose the concept of a system for collecting, organising, processing and analysing experimental data obtained from measurements with process tomography. Process tomography is used for noninvasive flow monitoring and data acquisition. The measurement data is collected, stored and processed to identify process regimes and process threats. Further general examples of solutions that aim to take advantage of the existence of such tools are presented as proof of viability of such approach. As the first step in the process of creating the proposed system, a scalable, distributed, containerisation-based cluster has been constructed, with consumer-grade hardware.

**Index Terms**—Big Data, Process Tomography, data processing, data acquisition

## I. INTRODUCTION

MEASUREMENT technologies are a practical challenge for engineers who are increasingly improving them, with novel algorithms for solving optimisation problems being continuously developed.

With the advent of industry 4.0 [1], the volume of the measurement data generated by industrial process becomes too large for processing on a single workstation. Through the use of wireless sensor networks, measurements can be taken in places previously inaccessible for traditional, wired solutions, hence allowing for preventative repair of equipment before the actual failure occurs [2]. As such new, sensor-rich systems are created there exists an unprecedented opportunity to derive deeper insights regarding the nature of the whole process from the large volume of collected data.

An example of a system rich in sensors is process tomography. It is a rapidly developing non-invasive diagnostic technique, finding wider and wider applications in various fields of science. In recent years, process tomography applications have been developed in the petrochemical, pneumatic and gravitational transport of bulk materials, as well as in the pharmaceutical industry and biomedicine. Fig. 1 shows different types of process tomography systems.

In the issues of non-invasive diagnostics and monitoring, various types of tomographic sensors can be combined to provide multi-modality, versatility and adaptation to the dynamics

of the industrial process. The tomographic systems during computer diagnostics of the industrial process can also be supported by additional measurement sources, including ultra-fast video cameras, dedicated flow meters, scales, pressure and temperature sensors. In this way, additional information about the flow and its parameters is obtained. In addition, measurements from tomographic systems can be further used to reconstruct two- and three-dimensional images - both raster sequences and movie sequences. If this data comes from many sensors at the same time, is collected with high time resolution, and the industrial process is long-lasting, a large amount of data appears, which needs to be structured and categorised in appropriate database structures.

The diagnostic information collected using the process tomography measurement systems over a longer period of time can be characterised by the size of even a dozen terabytes, which predestines it for the term Big Data. In particular, such a term can be defined as long-term acquisitions of three-dimensional tomographic images with high temporal-spatial resolution, video recordings, sets of mathematical-physical models and descriptions of experiments. Therefore, this paper presents the concept of a system for collecting, organising, processing and analysing experimental data obtained from measurements using process tomography. The results of conducted research will enable computer systems of non-invasive industrial diagnostics to make quick and reliable decisions in the field of monitoring and control.

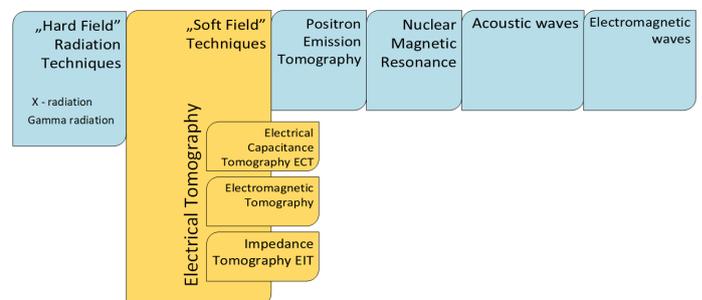

Fig. 1. Types of process tomography measurement modalities. Second from the left illustrates electrical tomography systems.

The contribution of this paper is the proposal for an ar-

chitecture based on containerised instances of Apache Spark and Hadoop which promises to offer soft real-time processing capabilities, whilst being trivially extendable to any number of distributed machines. Since all services in the proposed system are containerised, it is capable of being expanded or shrunk to fit the current needs through the simple process of either starting or shutting down a number of container instances.

## II. BIG DATA IN INDUSTRIAL APPLICATIONS

### A. Evolution of Big Data solutions

The Big Data technology as known today, begun with the creation of the Google File System which enabled large scale data storage while using low-cost commodity hardware [3]. While providing no distributed computational capability, it contributed fault tolerant, multi-access file storage which facilitated concurrent work on the same file, hence implementing distributed producer-consumer queues for large (Multi-GB) files. This architecture, albeit limited, provided the foundation for the systems capable of handling both high volume data at rest (static files) and in motion (dynamically appended files), thus inherently satisfying both the Volume and Velocity part of the five V's of Big Data [4].
