The next step in the development of a full Big Data stack was the MapReduce paradigm [5]. This paradigm was created as a means of unifying the disparate solutions that previously had to split their focus between the problems of pluralisation and the actual problem hence obscuring the latter. This new paradigm was a reaction to this unwanted, additional complexity and provided a simple abstraction layer allowing the programmers to specify their computations in the form of a chain of *map* and *reduce* steps, hence its name. The *map* function is responsible for processing the input key-value pair into intermediate results, also in the form of a key-value pair, whilst the *reduce* step is responsible for merging the intermediate values into the final result. This system, while capable of operating separately from the distributed file system, generally exists in symbiosis with the storage nodes of such a file system, thus resulting in the popular technique used to remove bottlenecks in the data processing, which generally referred to as "bringing processing to the data". The combined GFS and MapReduce provided the foundation for modern Big Data processing systems capable of satisfying all five V's, namely the aforementioned Volume and Velocity, and the previously unmentioned Veracity, Variety and Value.

Whilst the initial advancements in distributed file storage were proprietary and generally only available in the companies on the bleeding edge of Big Data technology, the Hadoop Distributed File System alongside with the rest of the Hadoop project were created by the Apache foundation, thus resulting in a significantly lowered barriers to entry into the Big Data industry [6]. The Open Source nature of this project also provided a good basis for the development of new data processing tools hence becoming an unofficial standard for big data storage and analysis systems.

One of the limitation of the early MapReduce systems was their inherent assumption that the data flow is acyclic, that is

that a computational task begins with data being read from the file system and ends with the resulting data being written back to said file system. This, combined with the fact that distributed file systems, such as the GFS and HDFS were optimised for high throughput and not low file access latency, meant that, while possible, the execution of tasks that reused the working set of data was inadvertently slowed down by the file systems access time. In order to facilitate the execution of such tasks, a new framework named Spark was proposed [7]. Spark's Resilient Distributed Datasets (RDDs) provided a way for the data to be cached in memory during the execution of the iterative task, hence avoiding the performance penalty resulting from repeated file system accesses. This novel approach allowed for a significant decrease in the execution time of iterative tasks such as linear regression or the alternating least squares computation, making Big Data based machine learning solutions viable.

With the proliferation of new data processing frameworks the tight coupling between the MapReduce programming model and the Hadoop file system became an impediment which had to be worked around by the developers of these solutions. A new incarnation of the Hadoop framework was created with the aim of alleviating the aforementioned limitations and clearly separating the resource management from the programming model. The framework was named Yet Another Resource Negotiator (YARN) [8]. In this framework, MapReduce was no longer the primary focus and thus became simply one of the possible tools that could be run. This new version of MapReduce is commonly referred to as MapReduceV2. A multitude of programming frameworks, that initially had to be built on top of MapReduce and thus were beholden to its limitations, were updated to use this new model even before YARN left the beta stage of its development, therefore validating the design decisions made by the YARN creators.

As a result of the aforementioned progress the Big Data ecosystem became not only a feature rich set of tools but also a stable and mature foundation for building new solutions and applications that deal with large volumes of data [9].

### B. Industrial applications

Modern industry tends to generate an enormous amount of data every day while in many cases lacking the technical capabilities required effectively process and derive long-term insights from it [10] [11]. In many cases the extent of use of this data boils down to being shown to the operator on-site so as to facilitate the monitoring of the industrial process. Such analysis is not only limited by the finite capabilities of both human mind and memory but also results in very low bus factor, making the expert an unexpedient component of the process. This situation however is slowly changing with new approaches and initiatives such as the industry 4.0.

The financial industry has devoted considerable research efforts into what could be considered proto-Big Data processing since as early as 1997 [12]. In this sector one of the most important computational tasks is fraud detection, which unlike most statistical data analysis, concerns itself with

data in motion, with real time emphasis. Some AI application require enormous collections of data to be stored, prepared and processed by machine learning such as the EEG annotation data [13], industrial emergency states detection [14] [15] or medical augmented reality future diagnosis [16].

### III. STATE OF TECHNOLOGY

As presented in II-B there exist numerous applications of big data in different domains. One of the interesting examples was reported by Skuza et al. [17], another example of the barely explored domain is the usage of big data for process tomography [18]. Process tomography is a set of techniques that are responsible for acquiring data from a given process, processing them and providing information about concentration distribution and flow.

Process tomography together with big data solves lots of different problems that emerge with traditional approach. Romanowski et al. started to join these two fields to propose a solution for detecting material plugs in pneumatic conveying measurement data [18] [19]. The authors used Hadoop (installed on three independent computers) together with Mahout machine learning library. The data consisted of five experiments performed on several different pipe diameters with different flow conditions. The tests were performed in two distinct locations at different times. Total data obtained during the data acquisition part was about 40 GB but it must be stated that the computational system is able to handle significantly larger amount of data. The authors present proof that the combination of big data tools and conventional algorithms can be used in automatic detection of material plugs in vertical or horizontal flows. This indicates that using big data tools such as Hadoop is an excellent alternative for traditional approach.

Process tomography uses lots of different techniques which include lots of different sensors from which the data is obtained. Numerous different sensors with numerous output format are a problem designed to be solved by big data. Rymarczyk et al. propose and discuss the system which is designed to optimize and automate given process by using numerous tomographic sensors [20]. The paper indicates the importance of using such systems for maintaining competitiveness. The design of the system includes multiple sensors like ECT (Electrical Capacitance Tomography), ERT (Electrical Resistivity Tomography), UST (UltraSound Tomography), together with temperature and pressure information. In the next step the authors perform the data acquisition during which the data is saved to a server for later processing. Next part uses image reconstruction together with cloud computing which later is employed to control industrial processes.

There are numerous steps needed to be performed in the system in order to obtain data required to control some process. There is also an increase in amount of data that needs to be processed. As a result the data processing part may take a longer amount of time. To lower that the parallelisation can be introduced. This approach was used by Chen et al. where he designed and tested solution that uses crowd-sourcing to help with understanding the particle-tracking problem [21]. The

authors addressed that at the time being there are no solutions that can accurately analyse flow in silos. This resulted in building a system that employed experts and non-experts to analyse tomographic images. The results from this system were compared to the results from the automatic approach. The paper clearly states that the crowd solution is significantly better in terms of scale, delivered result and economics in comparison to the automatic approach. What is more, the system can be applied in different domains which makes it generalisable.

The goal is to produce system that will be responsible for controlling industrial process in order not only to prevent undesirable behaviour from happening but also to obtain better understanding about the process along with the possibility of optimisation of the process. The newest approach proposed by Romanowski gives more insight on joining big data with process tomography by extending work presented by Chen and is an example of the desired system [4]. The author in his work designed a methodology that improves current state of knowledge, regarding recognition of specific bulk flow regimes (e.g. pipeline blockage threats). To obtain such improvement the author presented solution using Hadoop platform for distributed data processing on large quantities of data using cluster computing. For the classification part the Apache Spark with SVM as an algorithm was used as a supervised learning method. The system can also be employed to handle processes from different domains. The main advantage of this solution is the improvement in finding flow regimes that may be critical for the process and perform actions to prevent such flow. This work also describes how to jointly analyse incoherent data.

### IV. GOALS, VISION AND PROPOSED APPROACH

The aim of the work is to develop new algorithms for the collection, organisation, processing and analysis of large data sets obtained from industrial systems of non-invasive diagnostics and control, based on process tomography.

As part of the work, it is proposed to use a containerisation-based [22] implementation system that will allow for easy increase of available disk space and computing power, both using an external cloud infrastructure and generally available consumer computer equipment. Due to the particular requirements of the platform components, it may prove inadvisable for such an approach to cover the entire project. The use of containerisation has certain consequences and limitations that should be considered. Containers introduce another (though lightweight) layer "reflecting" a given element of the platform from the concept of the real-time system. Stations and diversified installation software have specific hardware requirements (eg. control interfaces) or visualisation (eg. the use of calculations directly from the GPU), which may potentially disqualify the software as a service subject to containerisation. In connection with the above, work on the implementation system based on the above approach has been focused on the computational cluster responsible for Big data analysis of historical data and eventually, real-time sensor readings. Fig. 2 presents the proposed model in which the

dependence of the control loop on the cloud is limited to "fine tuning" so as to avoid affecting the delay of regulation.

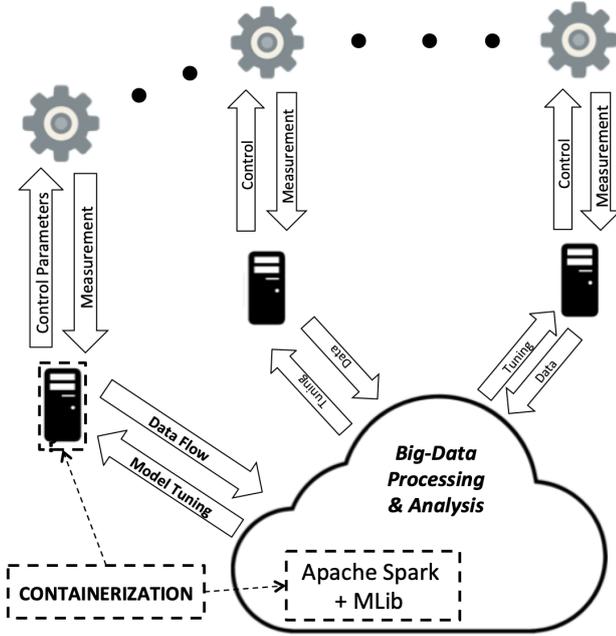

Fig. 2. Proposed model

Based on the aforementioned attempts, from section III, at creating data based systems for the purposes of analysis and control of tomographic processes, the planned focus of our research is twofold. Firstly, we plan to assess the benefit, defined as an increase in the computation speed of visualisation of the measured flow, of using a cluster consisting of consumer-grade hardware over the traditional approach of carrying out the computations on one high-end workstation. Secondly, we plan to assess the viability of using such cluster as a perpetually self-improving industrial controller. It is our belief that, provided enough training data, such a system could potentially operate with only minimal supervision from an operator, hence allowing a single expert to oversee a larger number of apparatus than it is currently possible. This concept will require an extensive amount of experimentation before it can be considered ready for industrial use, though at this early stage two criteria of viability can be defined:

- 1) capability of gradual auto-tuning of traditional controller
- 2) nearly real-time performance of the flow analysis

Should only one of these criteria be met the system would still be a valuable enhancement of a traditional system, either as an "auto-tuner" or as a real-time (or almost real-time), flow visualisation platform.

Should both of these criteria be met the future steps would include a "run-ahead", real-time simulation that could be used to predict potential faults and act accordingly to prevent them. An alternative approach for this purpose is also considered, namely instead of simulating the flow, an additional machine learning model could be used as a fault predictor. The architecture of the proposed cluster can be seen on figure 3.

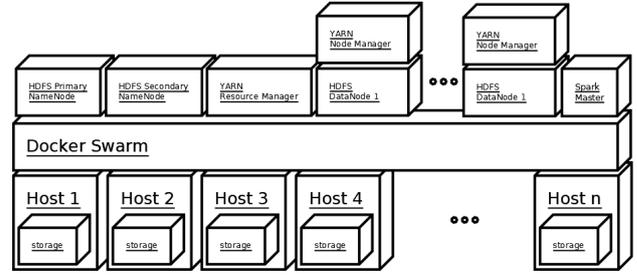

Fig. 3. Structure of the proposed cluster

## V. EVALUATION

The initial evaluation of the system generated promising results, as the even with as few as 5 low cost machines it was capable of outperforming the existing single-machine solution present in the Tom Dyakowski Process Tomography Laboratory in Lodz University of Technology, shown on figure 4. In the initial testing, which used a very limited number of machines with the exact same hardware, the increase in the speed of computations (measured as a decrease in computation time) was linear, whilst the latency did not exceed 2.3 seconds. Due to a very limited number of machines with the exact same specifications, subsequent tests had to involve a variety of configurations. Since the machines available did not have the

Fig. 4. Tom Dyakowski Process Tomography Laboratory: experimental silo (left) and data acquisition, processing and visualisation workstation (right)

exact same hardware specification, it is impossible to measure a precise number of machines at which the cluster becomes a more efficient computational environment, however this non-uniformity proves to be a notable advantage of our approach. Since the cluster was capable of working with machines with differing specifications, one could construct such a solution without incurring additional cost, by simply using the spare, possibly outdated, hardware already available on-site.

## VI. DISCUSSION AND FUTURE WORK

This paper presents the idea of a big data system based on tomographic solutions. The general structure of the cluster is shown in Figure 3. Particularly noteworthy here is the ease of expanding the system described, both in terms of

physical devices and additional services. An example of such an extension is the planned addition of more efficient nodes equipped with an increased amount of volatile memory and a high-end graphics card in order to facilitate parallel computing.

As part of further work, proprietary algorithms for automatic acquisition, analysis and interpretation of large data sets [23] will be developed, as well as intelligent decision algorithms supporting effective diagnostics and monitoring of flow processes [14]; including those to be the next step after crowdsourcing data labelling cases impossible to be automatically processed at once [24] [25]. The prepared algorithms will be verified both by simulation and by real experimental data from their own experiments carried out on the basis of unique, semi-industrial research installations. The results of research will enable computer systems to make quick decisions in the field of monitoring and control. Furthermore, the computational environment may be suited to personal-medical applications, such as the continuous glucose monitoring, resulting in better diagnosis, safety and hence better life comfort [26].

## VII. CONCLUSION

This work presents a pioneering concept for the Big Data system. The solution concerns the integration of data from sensors used in process tomography, which enables imaging and feedback associated with control in the field of process optimisation. The presented infrastructure can bring tangible benefits in various sectors of the industry due to its scalable nature, allowing for smooth expansion as the company or its requirements grow. The described approach is based on a Docker Swarm cluster which facilitates easy fail-over in case of hardware node failures.

## ACKNOWLEDGMENT

This work is partially financed by the Smart Growth Operational Programme 2014–2020 project no POIR.04.01.02-00-0089/17-00. The project is conducted in the Institute of Applied Computer Science at the Lodz University of Technology.

**Abstract**—Cloud availability is a major performance parameter in cloud Service Level Agreements (SLA). Its correct evaluation is essential to SLA enforcement and possible litigation issues. Current methods fail to correctly identify the fault location, since they include the network contribution. We propose a procedure to identify the failures actually due to the cloud itself and provide a correct cloud availability measure. The procedure employs tools that are freely available, i.e. traceroute and whois, and arrives at the availability measure by first identifying the boundaries of the cloud. We evaluate our procedure by testing it on three major cloud providers: Google Cloud, Amazon AWS, and Rackspace. The results show that the procedure arrives at a correct identification in 95% of cases. The cloud availability obtained in the test after correct identification lies between 3 and 4 nines for the three platforms under test.

### I. INTRODUCTION

Availability is a major Quality of Service descriptor in cloud services, and an essential component of Service Level Agreements [1]–[3].

Many efforts have been devoted to understanding and improving the availability of cloud systems. The relevance of the issue has been re-stated very recently by Varghese and Buyya, which list it among the top research directions, mentioning the 49-minute outage suffered by Amazon, which cost the company more than \$4 million in lost sales, as an indicator of the economic importance of achieving a high availability [4]. The same concept had been voiced in [5], where the authors even propose to consider a *Reliability as a Service*, where reliability is a parameter that users can specify and a service by itself, rather than the random state of a cloud-based service. Concerns for the legal implications that may arise due to a less-than-adequate cloud reliability have been recently expressed in [6].

An analysis of the main causes of cloud failures has been carried out in [7], where growth trends are also identified, and [8], where mechanisms are subsequently discussed to minimize the impact of outages. Some papers have focussed on the analysis of the cloud architecture to get a high availability by design [9]–[11]. A different approach has been taken in [12] and [13], where machine learning technique have been employed to predict cloud outages (and react accordingly).

If we switch from the perspective of a cloud designer to that of a cloud user, the main interest lies in understanding if the cloud is performing up to the expectations. Setting up, or employing the services of, a cloud monitoring platform is essential in this respect. Several architectures have been proposed for that purpose, e.g. in [14]–[16], and a recent review is contained in [17].

Unfortunately, very few attempts have been done to actually measure cloud availability from a third party vantage point. An early attempt based on users' reports has been reported in [18]. The shortcoming of that approach is that the starting time of the outage may not be reported correctly, since a time lag is always present between the time an outage occurs and the time a user first reports it. The ending time of the outage may be also reported wrongly, since most users do not take on themselves to report it, and we have to rely on the cloud provider announcing that the problem has been solved and the cloud is back to its fully operational state. Statistics of working periods and outages have been modelled in [19] with data coming from a small private cloud. Active measurement systems based on ICMP probing packets have been investigated in [20]–[22]. A major issue with all measurements campaigns conducted so far is that they do measure the quality of service experienced by the user, but in doing so they include the loss contribution provided by the network located between the cloud user and the cloud server. The availability that is measured in the end is an underestimation of the actual cloud availability.

In this paper, we propose a measurement method that allows to distinguish between the losses due to the network and those due to the cloud, returning the true cloud availability. After describing the intrusive network problem in Section II and recalling the definition of availability in Section III, our study provides the following original contributions:

- we propose a measurement procedure to measure true cloud availability (Section IV);
- we assess its success rate (Section V), showing that it outperforms previous methods usable for that purpose;
- we apply our procedure to three major cloud providers and contrast the results with concerns arisen in early measurement campaigns (Section V), showing that the

availability at IP level is close to four nines, and the the network contribution is so relatively large as to significantly alter the overall results in the absence of a correct failure attribution procedure.

## II. THE LONG ROAD TO THE CLOUD

Cloud availability measurements are a major tool in assessing a cloud provider's compliance with SLA targets and obligations. However, those measurements may lead to false conclusions if they are not carried out properly. In this section, we take a look at what is probably the most important reason for lack of accuracy.

Contents placed on a cloud are located among one or more data centers, whose location is, by definition, unknown to the user [23], [24]. Whatever the way by which we probe the cloud to measure availability, third-party measurements are conducted from outside the cloud, i.e. through the network. In probing the cloud, we can therefore mimic the experience of the user, traversing one or more Internet Service Providers (ISP) and several Autonomous Systems (AS), as shown in Fig. 1.

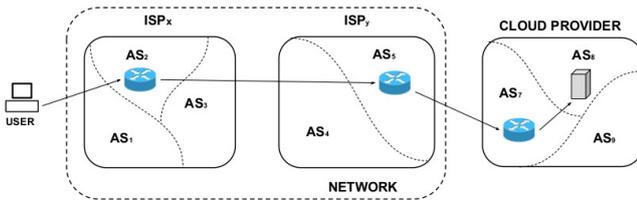

Fig. 1: The path from user to cloud provider.

It has been noted that false outages may be declared, since the lack of response to a user's request to a cloud may be due to packet losses in the network rather than the cloud itself [20]. This appears to be a major problem if we wish to get an accurate measurement of the actual outage rate for the cloud. When measurements are conducted through ICMP probing packets (pings), the Majority Voting rule to declare an outage has been analysed as an effective remedy in several contexts [21]. Under Majority Voting, an outage is declared if a majority of pings get no echoes. However, it cannot be considered as the definitive solution, since its accuracy depends on the specific combination of cloud and network performances.

We therefore need a more generally reliable approach to obtain an accurate measurement of cloud outage in the face of the losses of probing packets due to the network.

This is particularly relevant, since such measurements can be employed to enforce the contractual obligations contained in the SLA and the legal dispute that may arise, a danger that has been dreaded in [6]. Actually, the liability of the cloud provider in the case of obligations related to service malfunctioning has been mentioned as a major obstacle to the wide adoption of the cloud by banks [25]; the same has been reported for the semiconductor industry [26]. If we fail to recognize that service outages may be due to

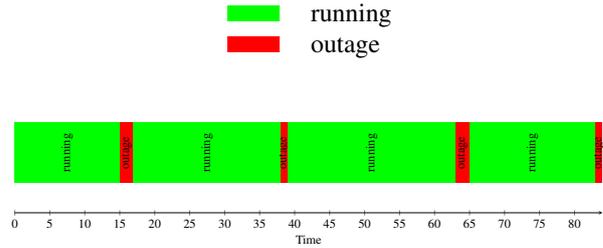

Fig. 2: Cloud state sequence

the network rather than the cloud, the cloud availability is actually underestimated, and the cloud provider may incur undue penalties. At any rate, the overall cost of data center outages is made of many components, which can build up to a very large amount, as reported in a study by the Ponemon Institute [27].

## III. AVAILABILITY OPERATIONAL DEFINITION

Before dealing with the contributions of the network and the cloud to the availability as seen from an external observer, we have to define how the observed availability is measured. In this section, we arrive at the operational definition of availability we have employed in this paper.

For our purposes, the state of the cloud is considered as a succession of working periods and outages, as shown in Fig. 2. If we describe the state of the service through the function  $a(t) : t \rightarrow \{0, 1\}$ , the availability over an observation period  $T$  is then

$$A = \frac{1}{T} \int_0^T a(t) dt. \quad (1)$$

Within this paper, we do not consider the case of graceful degradation, where the cloud service is still running, but with a significantly worsened quality of service. Even though a service may experience a graceful degradation, we imagine that we can always classify the service as either being available or not. For example, if we tolerate a latency lower than a prescribed value, the service may degrade down to that value, while still being considered as available, but will be considered as unavailable when the latency exceeds that threshold.

If we indicate by  $W$  the overall sum of the durations of working periods and by  $F$  the overall sum of the durations of outages, we have the usual definition of availability as the fraction of ON periods over the observation window  $T$

$$A = \frac{W}{W + F}. \quad (2)$$

However, the actual measurement process does not allow to recover the function  $a(t)$ , but rather its sampling version, obtained by probing the system at a discrete set of times. The discrete times are those at which discrete events take place, such as failed or successful service queries.

As a consequence, for cloud services, two general models have been defined in [28] to describe availability from discrete events:

- The dual state model;

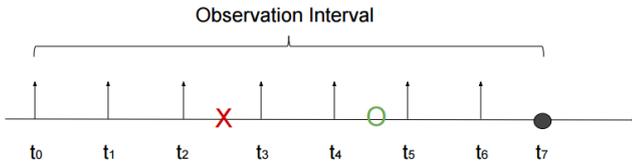

Fig. 3: Probing sequence example

- The success ratio model.

In the dual state model, the availability is computed as a function of the sum of the durations of all down states experienced during contracted service time. In the success ratio model, we refer instead to the event themselves, rather than their duration: the availability is computed as a function of the number of successful and failed resources requests during the contracted service period.

However, if we probe the cloud at periodic intervals (as opposed to random or irregular ones), the distinction between the two models blurs. Considering, e.g., the sequence of probing queries shown in Fig. 3, if we define the down duration as the time distance between the first failed probing query and the first subsequent successful probing query, the two models provide exactly the same availability output (5/7 in this case).

#### IV. CLOUD AVAILABILITY MEASUREMENT

The third-party measurements reported so far in the literature adopt a probing mechanism employing the ping command, which however does not allow to distinguish between outages due to the network and those due to the cloud. In this section, we propose a procedure that allows to obtain the availability of the cloud only. In Section IV-A, we first outline the problems affecting the measurement schemes employed so far, then provide an overview of our new procedure in Section IV-B, and finally describe its phases.

##### A. End-to-end availability

Current procedures to measure the availability of a cloud rely on the use of probing packets sent out from one or several vantage points mimicking the location of a real user. These packets are sent out periodically, as shown in Fig. 3. So far, the ping utility has been used for this purpose. Ping operates by sending Internet Control Message Protocol (ICMP) echo request packets to the target host and waiting for an ICMP echo reply, as shown in Fig. 4 (ping operations are described in Chapter 8.4 of [29]). Echoes from ping are counted as indicators of an operating cloud, while missed echoes are counted as indicators of a failing cloud. It is assumed that a cloud server returning the probing packets is also working correctly to provide services to its clients, i.e., we do not consider software problems related to service provisioning. The ratio of returned echoes to the overall number of sent probes gives us the availability of the cloud.

However, the use of this utility suffers from two main drawbacks:

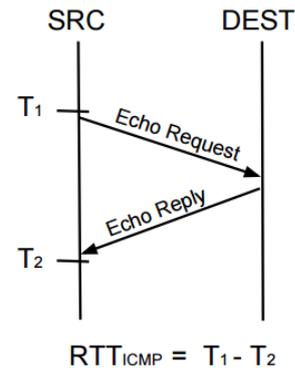

Fig. 4: Ping utility

- it returns an end-to-end measurement that incorporates all the failures taking place on the road to the cloud;
- it employs the ICMP protocol, which may be dealt with differently than TCP/UDP segments, and typically with a lower priority so that the reported availability may be lower than that actually experienced with the cloud-based service.

While the former problem cannot be solved by acting on the probing mechanism alone, the latter problem can be eliminated by employing nping probing packets instead. Nping is an open source tool for network packet generation, response analysis and response time measurement (see Chapter 18 of [30]); it can generate network packets for a wide range of protocols, allowing users full control over protocol headers. We can therefore employ it to generate TCP-like probing packets, which undergo the same priority treatment as the true packets we would employ when using the cloud service <sup>1</sup>.

##### B. Overall procedure

For the time being we consider the reliability at the IP level only, meaning that we are interested in assessing if IP packets transporting the payload involved in the cloud service actually make it through the cloud once they reach it. Our procedure to measure the availability of the cloud, and the cloud only, goes through the following steps:

- 1) Probing the whole sequence of hops along the path from the measurement vantage point to the cloud;
- 2) Associating an ISP to each hop along that path;
- 3) Identifying the first hop belonging to the cloud provider, i.e. the hop marking the entry into the cloud providers domain;
- 4) Counting missing echoes from that first cloud hop and computing the corresponding cloud availability.

In the following, we take care of step 1 in Section IV-C, steps 2 and 3 in Section IV-D, and step 4 in Section IV-E.

##### C. Tracing probing packets

As just recalled, ping (or nping for that purpose) is an end-to-end tool, which does not reveal anything about what

<sup>1</sup><https://nmap.org/nping/>

happens in between the probing source and the end host. We wish instead to get the sequence of IP addresses of routers that make the path from source (our probing vantage point) to destination (the cloud server).

In order to get a complete view of the path from source to destination, along which packets enter the cloud, we can employ the `traceroute` programme<sup>2</sup>. This programme uses limited Time-To-Live (TTL) ICMP probes to discover the IP addresses of IP router interfaces along the path from source to destination, using ICMP echo requests (see Fig. 5). Despite being the most used method to get information about Internet topology, `traceroute` suffers from the following major problems, which may lead to no return from the probed routers or to returned invalid IP addresses:

- ICMP packets may be filtered out by firewalls along the way.
- load-balancing routers may alter the path [31];
- successive TTL-limited packets do not necessarily follow the same forwarding path, so that we may get different chains of routers while we try to discover a single path to destination;
- some hops do not return ICMP replies;
- some routers may be anonymous, i.e., their existence is detected but their interface address is not returned [32];
- some routers may return the address of the interface from which the message came [33];
- some routers return a fixed IP address, regardless of the address of the actual interface on which the message has landed;
- some routers may return an IP address chosen randomly among those of the router's several interfaces;
- the connectivity between routers may be provided through chains of ATM (Asynchronous Transfer Mode) switches or MPLS (MultiProtocol Label Switching) tunnels (reported to account even for 30% of paths [34] [35]), which may make the path opaque to IP probes.

Though the original version of `traceroute` employs ICMP packets, other versions may employ UDP or TCP probing packets.

The UDP version employs limited TTL packets and large destination port numbers. When an intermediate router receives such a probing packet with a zero TTL, it returns an *ICMP time exceeded* message. The source can progressively increase the TTL discovering farther routers along the path, till it reaches the destination. However, the use of UDP messages to high ports shares the same problem with firewall as ICMP packets [36].

A version called `tcptraceroute` has been proposed<sup>3</sup>. The TCP version of `traceroute` bypasses firewalls by directing TCP packets to well-known ports (e.g. port 80), though some firewall may still block TCP packets when no host behind the firewall accepts the TCP connection.

<sup>2</sup><https://wiki.geant.org/display/public/EK/VanJacobsonTraceroute>

<sup>3</sup><https://www.freebsd.org/cgi/man.cgi?query=tcptraceroute&manpath=FreeBSD+9.3-RELEASE+and+Ports>

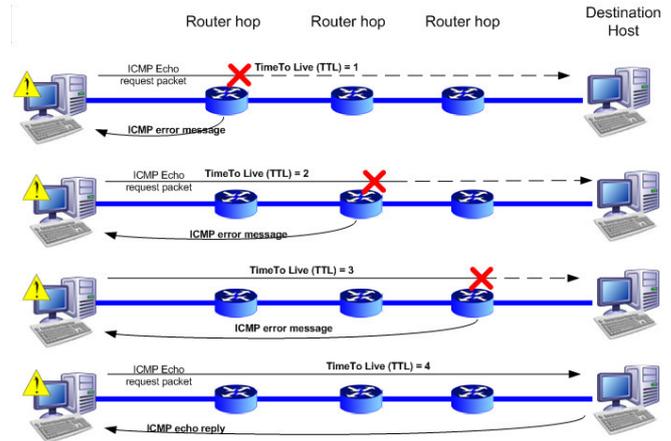

Fig. 5: Working of the `traceroute` programme

Despite the shortcomings of ICMP-based `traceroute`, it appears however to reach targets more successfully than its UDP and TCP counterparts [37]. In this paper, we therefore stick to the classical ICMP-based `traceroute`.

Other methods have been proposed to bypass the limitations of `traceroute`; a recent survey is contained in [38]. The most relevant category at the interface level (which is the one we adopt here) is based on the options of the IP packet header. However, in most cases, it relies either on the cooperation of intermediate routers or on the use of multiple vantage points, which excludes them from the horizon of third-party measurements. In addition, their use increases the chances of packets being discarded or triggering alarms on IDS (Intrusion Detection systems) [39].

#### D. Identifying cloud boundaries

After identifying the chain of routers that lead to the ultimate cloud destination, we wish to identify the AS (Autonomous System) to which each router belongs, and eventually the ISP administering that AS. This is essential to identify the router marking the cloud ingress. Our procedure will go through the following steps:

- 1) Get the ASN associated to each hop on the path to the cloud;
- 2) Get the ISP administering the AS along the path;
- 3) Extract the router marking the ingress into the cloud provider's domain.

Our procedure employs the following protocols and programs:

- `Traceroute`;
- `whois`;
- `RISwhois`.

While the first two are pretty standard programmes, the third one is actually a modified version of `whois`. While the standard version of that protocol queries the Internet Routing registries, the modified version `RISwhois` has been devised in the context

of the RIPE RIS (Routing Information System) project<sup>4</sup> and allows to get data directly from a network of BGP collectors, which collect data from the BGP tables of their peers. Such a use of BGP is envisaged and described in several papers concerned with the need to build the AS topology [38], [40]. Our aim in combining the response from the tools listed above is to arrive at a consensus about the correct ASN to attribute to each hop in the path to the cloud. Our procedure will return a positive result if we achieve either a 2/2 result or a 2/3 results, i.e. at least 2 of the tools agree.

It is to be noted that the `brdmap` programme is also available to identify domain borders, as described in [41], where it has been employed, however, through the use of 19 vantage points, whereas our procedure employs a single vantage point.

The first tool we employ to carry out the IP-to-AS attribution is `traceroute`. For each hop, the `-a` option allows to get the AS number. However, as pointed out in [40], the `traceroute` command alone does not give an accurate AS number in all cases, and it does not even return an AS number in roughly 10% of cases. We consider separately the case where `Traceroute` returns an ASN for each hop and that where it does not.

If `Traceroute` does not return an ASN number, we resort to `whois` and `RISwhois` in parallel. If they both return the same ASN, then we consider that to be the correct ASN; otherwise (i.e., if they either return different ASNs or do not return an ASN at all), the procedure is considered to fail.

If `Traceroute` does return an ASN, however, we do not stay content with that, since we strive for a higher reliability, aiming at least at two sources confirming the same ASN. Therefore, we first turn to `RISwhois`. If `RISwhois` gives us the very same ASN as `Traceroute`, we end the procedure and output that ASN as the correct one. If that's not the case we call the standard `whois`, which acts as the final referee. If it confirms one of the two ASNs previously obtained by `Traceroute` and `RISwhois`, then we obtain a 2/3 majority vote and declare that as the correct ASN. If, unfortunately, `whois` returns a third ASN, different from those obtained with `Traceroute` and `RISwhois`, the procedure is considered to fail. The whole procedure is reported as Algorithm 1.

At this point, we have the full list of ISPs administering the hops along the path to the end cloud server. We can then identify the hops belonging to the cloud provider through the algorithm described as Algorithm 2.

### E. Cloud availability estimation

Now, we have hopefully identified where the probing packets actually enter the cloud. We have all the data needed to measure the actual cloud availability.

If we indicate by  $N_{in}$  the number of probing packets entering the cloud, i.e. making it to the first cloud hop, and by  $N_{out}$  the number of echoes actually returned from the cloud end

                empty report if there's else break;

    return ASN, ISP;

---

server (i.e., the final hop in the sequence of hops obtained with `traceroute`), our measurement of the cloud availability is

$$A = \frac{N_{out}}{N_{in}}. \quad (3)$$

This approach allows not to factor in the losses due to the network on the way to the cloud, since they do not enter the  $N_{in}$  term. A remaining limitation of the approach is that echoes actually sent back by the cloud end server may get lost due to network problems on the return path.

**Algorithm 2: Identification of the first cloud hop**

---

**Input:** Cloud Provider, AS-traceroute to Cloud Provider  
**Output:** Position of the first Cloud hop in AS-traceroute report

$ISP \leftarrow \text{null}$ ;  
 $hopPosition \leftarrow 1$ ;  
 $cloudStart \leftarrow \text{null}$ ;  
 $currentEntryPosition \leftarrow 1$ ;  
 $Table \leftarrow \text{empty key-value table}$ ;

   $selectedHop \leftarrow \text{select hop in hopPosition}$ ;  
   $ISP \leftarrow \text{Identification of ASNs and ISPs (selectedHop)}$ ;  
   $newTableEntry \leftarrow \text{append entry (hopPosition, ISP)}$ ;  
   $hopPosition \leftarrow hopPosition + 1$ ;

**while** *there's table entry in currentEntryPosition* **do**  
   $currentISP \leftarrow \text{getValue (currentEntryPosition)}$ ;  
  **if** *currentISP is equal to Cloud Provider* **then**  
    **if** *cloudStart is equal to null* **then**  
       $cloudStart \leftarrow currentEntryPosition$  ;  
    **else**  
       $cloudStart \leftarrow \text{null}$ ;  
   $currentEntryPosition \leftarrow currentEntryPosition + 1$ ;

**return**  $cloudStart$ ;

---

## V. EXPERIMENTAL RESULTS

We have applied the procedure described in Section IV to three major cloud providers. In this section, we report the results.

Our aim is to assess two different things: the dependability of our procedure and the availability of cloud providers. The latter is of course meaningful if our procedure possesses the former feature.

For both purposes we considered three major cloud providers: Google Cloud, Amazon AWS, and Rackspace (all of them are included in the survey reported in [42]). We performed 50 tests for each of them, for a total of 150 tests. Each test consisted in sending probing packets over a period of 8 hours, going through the procedure described in Section IV, and assessing whether the cloud has responded (i.e., it is working) or not. The overall duration of test was therefore 400 hours for each provider.

The dependability issue is crucial. We have to be sure that the procedure works under real conditions and may be employed routinely. We stress the fact that our procedure requires neither the use of special software nor restricted information.

In Table I, we report the test results. Reporting an ASN as outcome means that we were able to get an ASN for all the hops along the path from source to destination, excluding from the count those hops that did not respond (for which we have of course no elements at all to infer their ASN). Overall, we get the ASN for the whole path roughly in 95% of cases; this result represents a good advance over the 90% declared in

Outcome	Frequency [%]
ASN (2/2 confidence level)	90.66
ASN (2/3 confidence level)	4.00
No ASN	5.34

TABLE I: Test results for procedure dependability assessment

the reference paper [40]. In the remaining 5% of cases there were some hops for which, though they did respond, we were not able to get a consensus over the ASN. For non-responding hops, a possible way to dispel the darkness is suggested again in [40]: if a non-responding hop is located along the path between two responding hops exhibiting the same ASN, then it is safe to assign that same ASN to the non-responding path. This solution would leave out just those non-responding hops located at the border between two ASes.

However, the final aim is to correctly assign outages, and we need to identify the first hop belonging to the cloud provider. In that case, non-responding hops may represent a problem, since they can actually be those belonging to the cloud provider. In our battery of tests, we were unable to identify the first cloud hop in 30% of cases, practically all due to Amazon (where the identification procedure failed in 45 out of 50 tests). Though this may appear as a disappointing performance, we must consider that a) it concerns a single provider; b) it is a matter of policy, which may be circumvented by arrangements between the cloud provider and the third-party organisation in charge of conducting the availability measurement (for example, if allowing for such measurements to be conducted on the basis of an agreement, Amazon could enable its routers to respond to probing packets sent by the authorised organisation, e.g. by recognising its IP addresses).

Once we have assessed that the procedure can be routinely carried out, we can employ it to assess the actual availability of the cloud. We consider the three major cloud providers that we have already mentioned: Google, Amazon, and Rackspace. We have carried out daily tests (lasting 8 hours) over 30 days, identifying the first hop belonging to the cloud provider and correctly assigning packet losses.

The results are shown in Table II, where we see that all three providers offer an availability better than 3 nines (actually quite close to 4 nines). There are two questions that naturally arise after these results:

- Is the contribution of the network relevant in availability assessment?
- Do these results confirm previous measurement campaigns?

The former question impacts the relevance of our measurement procedure. If the contribution of the network were negligible, there would be no interest in providing a measurement procedure capable of distinguishing between the failures taking place on the net and on the cloud. We see in Table II that in two out of three cases the network losses are at least twice as large as those due to the cloud. Even in the case of Rackspace they are all but negligible. In the absence of any loss attribution procedure the observed availability would

Measurement	Google Cloud	Amazon AWS	Rackspace
# probing packets	864 000	864 000	864 000
# packets reaching cloud	863 750	863 711	863 899
# lost packets (network)	250	289	101
# lost packets (cloud)	125	104	195
Availability	99.9855%	99.9879 %	99.9774%

TABLE II: Availability measurements

be 99.9566%, 99.9545%, and 99.9657% respectively. The difference between those values and those in Table II may look negligible, but we must not forget that we are talking about figures very close to 100% anyway and a difference as low as 0.01% is significant in this context (see an account of router availability issues in [43]). In the case of Google Cloud the actual difference appears to be 0.0289%, which would amount to 152 min (roughly 2 hours and a half) more downtime in a year, which is not negligible, given the quality-of-service expectations of customers. In addition, making a bundle of network and cloud losses would significantly alter the relative performances of the three cloud providers: Rackspace, ranking third in the correct measurement, would jump to the first place if we decided not to distinguish between the two sources of loss.

We can now turn to the latter question: how do these results compare with past measurement campaigns? We have reminded in the Introduction that there's not a host of measurement campaigns on cloud performance. However, a procedure like ours, which does not attribute to the cloud losses that are not its fault, naturally results in better performance figures for the cloud. Actually, though the results reported here are by no means exhaustive and conclusive, the availability look much better than was previously feared [18].

## VI. CONCLUSIONS

Our procedure allows us to assign the cloud the outages that are actually due to it and excluding those due to the network. It increases the accuracy of existing availability measurement procedures. The procedure can be conducted from any third-party vantage point and may be safely employed to assess the compliance of cloud providers with SLAs. The early results of its application show that the availability of cloud providers may be significantly underestimated.

Some limitations need to be addressed, though. A major limitation is that the non-response rate may be significant and must be reduced, since that prevents from obtaining a full view of the ISPs along the way. Though this can be achieved by way of agreements between measuring parties and cloud providers, it is too optimistic to hope for a 100% response rate. A second limitation is that network losses on the path back to the source may still cause the availability to be underestimated.

# Advances in Network Systems and Applications

**M**ODERN network systems encompass a wide range of solutions and technologies, including wireless and wired networks, network systems, services and applications. This results in numerous active research areas oriented towards various technical, scientific and social aspects of network systems and applications. The primary objective of track Network Systems and Applications conference track is to

group network-related technical sessions and promote synergy between different fields of network-related research.

The track currently consists of technical sessions:

- ANSA—Advances in Network Systems and Applications
- IoT-ECAW'19—3<sup>rd</sup> Workshop on Internet of Things—Enablers, Challenges and Applications

# Formalization of Software Risk Assessment Results in Legal Metrology Based on ISO/IEC 18045 Vulnerability Analysis

**Abstract**—The Measuring Instruments Directive sets down essential requirements for measuring instruments subject to legal control in the EU. It dictates that a risk assessment must be performed before such instruments are put on the market. Because of the increasing importance of software in measuring instruments, a specifically tailored software risk assessment method has been previously developed and published. Related research has been done on graphical representation of threats by attack probability trees. The final stage is to formalize the method to prove its reproducibility and resilience against the complexity of future instruments. To this end, an inter-institutional comparison of the method is currently being conducted across national metrology institutes, while the weighing equipment manufacturers’ association CECIP has provided a new measuring instrument concept, as a significant example of complex instruments. Based on the results of the comparison, a template to formalize the software risk assessment method is proposed here.

## I. INTRODUCTION

WHEN MEASURING results obtained from a measuring instrument are used to determine the price to pay for a certain good (such as water, heat, petrol, electricity) in the EU, said instrument is subject to the Measuring Instruments Directive (MID) 2014/32/EU [1]. The essential requirements of the MID include software requirements for protection against corruption, see L 96/173 in [1]. In addition, the MID defines conformity assessment procedures which an instrument has to pass before being made available on the common market. In the frame of most of these assessment procedures, manufacturers are required to conduct a risk assessment demonstrating that their product fulfils the essential requirements. To aid manufacturers with this task, PTB (Germany’s national metrology institute, one notified conformity assessment body for the MID) has developed a software risk assessment procedure [2]. This procedure, specifically tailored to the needs of legal metrology, i.e. the economic sector of measurements subject to legal control, is employed by PTB when performing conformity assessments. To harmonize conformity assessment practice across Europe, the European Cooperation

This work was conducted within the frame of work package 4 of the European Metrology Cloud Project.

in Legal Metrology (WELMEC) Working Group 7 “Software” is currently investigating this software risk assessment method in the frame of an inter-institutional comparison. The aim is to demonstrate the objectiveness of the procedure and the reproducibility of its results. If needed, it is intended to amend the procedure to achieve both goals. To ensure impartial results, generic abstract instruments are used for the comparison. Initial findings indicate that producing objective assessment results for today’s simple instruments should be feasible. However, future complex systems will pose a bigger challenge. Most importantly, the simple representation of the assessment result in the form of a single risk score simplifies the assessment process too much. Therefore, it is proposed to improve the investigated method by formalizing the recording of its results, by means of a risk assessment template. Since the procedure closely follows the vulnerability analysis of ISO/IEC 18045 [3], the outcome of this paper should be useful to all assessment procedures (such as ETSI TS 102 165-1 [4]) that are based on the same standard. The remainder of the paper is structured as follows. The basic principles of the risk assessment procedure are recapitulated in Section II. Section III details the inter-institutional comparison, the examined generic measuring instruments and describes challenges derived from the results of the comparison. The proposed solution by means of a formalized risk assessment template is detailed in Section IV. Section V summarizes the paper.

## II. BASIC PRINCIPLES OF THE RISK ASSESSMENT PROCEDURE

As mentioned in the introduction, manufacturers of measuring instruments shall perform and document a risk assessment of their instruments before submitting a prototype to a NB for conformity assessment, in accordance with Module B (type evaluation) of the MID. To aid manufacturers and NBs in this task, a procedure was developed and published in [2]. With the aim of providing an objective procedure to generate reproducible results, the method is based on the international standards ISO/IEC 27005 [5] and ISO/IEC 18045 [3]. ISO/IEC 27005 provides a principle description of the risk assessment process consisting of three phases:

TABLE I  
TOE RESISTANCE OF MEASURING INSTRUMENTS TO ATTACKS AND  
ASSOCIATED PROBABILITY SCORE [3].

Sum of points	TOE resistance	Probability score
0-9	No rating	5
10-13	Basic	4
14-19	Enhanced Basic	3
20-24	Moderate	2
$\geq 24$	High	1

### A. Risk Identification

During risk identification, unwanted events (so-called threats to assets) are defined based on "legal and regulatory requirements, and contractual obligations". Such assets can be derived from the essential requirements given in Annex I of the MID. For convenience reasons, only two such assets are examined here. One asset is the measurement result with the associated security property authenticity, since the MID prohibits the use of measurement results that do not originate from a certified measuring instrument. The other asset is the software critical for the measurement purpose, which shall not be modified or replaced. Therefore, such software can be assigned the security properties integrity and authenticity. A list of all assets applicable to legal metrology is given in [2].

### B. Risk Estimation

During risk estimation, threats are assigned a quantitative or qualitative risk measure. One possibility to calculate such a measure is given by ISO/IEC 27005 itself, where "risk is a combination of the consequences that would follow from the occurrence of an unwanted event and the likelihood of the occurrence of the event." If unwanted events (threats), have been defined properly, they can be assigned an impact score between 0 (no effect) and 1 (all measurement results affected), signifying the severity of the consequences. The method from [2] uses a score of  $\frac{1}{3}$  if only one result is affected by the threat. In addition, a measure for the probability of occurrence is needed. This can be estimated by evaluation of different actions (attack vectors) that an attacker needs to implement for the threat to be realized. The vulnerability analysis provided in Part 2 of ISO/IEC 18045 [3] constitutes one possibility to quantify the probability of occurrence for such attack vectors by means of point scores assigned in the following categories:

- Elapsed Time (0-19 points)
- Expertise (0-8 points)
- Knowledge of the Target of Evaluation (0-11 points)
- Window of Opportunity (0-10 points)
- Equipment (0-9 points)

An example for a fully evaluated attack vector with assigned scores is given in Table III. The calculated sum score can be mapped to a target of evaluation (TOE) resistance, see [3], and an equivalent probability score between 1 and 5, see Table I. The third column is not part of the original table presented in [3]. Afterwards, by multiplying impact and probability score a risk score can be obtained which will be in the range between 1 (very low risk) and 5 (very high risk).

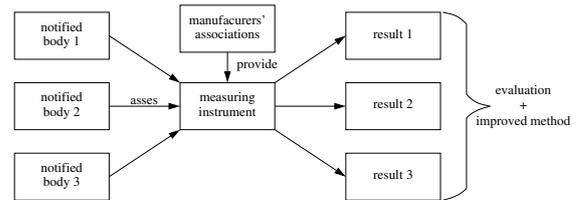

Fig. 1. Anticipated workflow of the risk assessment inter-institutional comparison and its projected outcome.

### C. Risk Evaluation

During risk evaluation, the calculated risk is put into the context of the field of application for the assessed instrument. Estimated risks are prioritized and a cut off point for the risk assessment is defined. In addition, an initial list of risks to be mitigated by order of importance is produced. As a rule of thumb, PTB will ask manufacturers who have obtained a risk score of 4 or 5 for their instrument to implement additional protective measures. Once these have been implemented, the phases of risk estimation and risk evaluation (including amendments, where necessary) are repeated until the risk score is reduced to 3 or lower. Since attack vectors for real-world measuring instruments might become very complex, they can be decomposed by means of Attack Probability Trees (AtPT), see [6]. These AtPTs can be used by an assessor to subdivide any given attack vector, evaluate the sub-goals and to find the attack probability score for the original complex attack vector.

## III. INTER-INSTITUTIONAL COMPARISON AND IDENTIFICATION OF CHALLENGES

Since conformity assessment bodies all across Europe are faced with the challenge of interpreting and evaluating the results of risk assessments, WELMEC Working Group 7 has decided to examine the procedure developed by PTB more closely by means of an inter-institutional comparison with five different NBs. To start the comparison, assessors from these NBs took part in a training exercise. The training covered both the basic procedure [2] as well as AtPTs [6]. Afterwards, see Subsection III-A, two generic measuring instruments were selected for all partners to assess. Subsection III-B describes the examined threats and initial findings. Figure 1 illustrates the workflow of the inter-institutional comparison.

### A. Description of Generic Reference Instruments

The first instrument assessed is a complex cloud-based measuring system proposed by CECIP, the European weighing instruments manufacturers' association. WELMEC Working Group 7 anticipates that such systems will be the norm in legal metrology in the near future. The system consists of a number of sensors subject to legal control that send data to a processing software running in the instrument manufacturer's own cloud, see Figure 2. The cloud offers data storage and a display server (DSP). The DSP sends measurement results to different display devices, e.g. smart phones or general-purpose printers. Communication between the components is

realized via Wi-Fi with WPA encryption. Additionally, all transferred data are protected by CRC-16 codes to ensure integrity of transmitted data. Three kinds of users are foreseen for the cloud: administrators with full privileges, maintenance personal with access to log files and backend users. In case data are lost during transmission, all sending devices have sufficiently large buffers for retransmission. Two categories of display devices are established, namely "full control" and "receive only", where the prior devices are only accessible to a trustworthy user group. A full system description will be published by CECIP in a future paper. Due to the complexity of the cloud-based instrument and the resulting increased probability for assessment errors, it was agreed to also use a second simpler generic instrument.

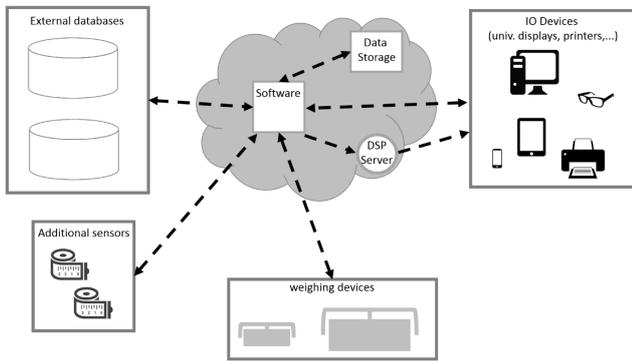

Fig. 2. General structure of the generic complex cloud-based system provided by CECIP, the European weighing instruments manufacturers' association.

The weighbridge depicted in Figure 3 is an automatic weighing instrument designed for weighing cargo transported on a truck. The measurement is started through the terminal's GUI consisting of an LCD and eight buttons. The measurement result is directly shown on the LCD. Two load cells measure the weight of front and rear axle of the truck. Two evaluator units interpret the output of the load cells. These units then communicate with the terminal where the final measurement result is computed. Evaluator units and terminal are based on microprocessors, data can be read from the terminal via RS485 or exported to a USB stick. The terminal checks the authenticity of all other units at startup by requesting a CRC-16 of their firmware based on a secret start vector. Legally relevant parameters and software are stored in the terminal unit on a hardware-protected flash memory. All software on the system is subject to legal control. All connections within the system are physically sealed.

*B. Experimental Results of the Inter-institutional comparison*

To narrow down the scope of the comparison, it was agreed to examine only two threats for both instruments, although in

Fig. 3. Components of the generic automatic weighing instrument.

TABLE II  
ASSESSMENT RESULTS PROVIDED BY DIFFERENT NBS.

Threat	NB	Impact	Probability score	Risk
complex cloud-based system				
T1	NB1	1	4	4
	NB2	1	1	1
	NB3	1	4	4
	NB4	1	4	4
	NB5	1	3	3
T2	NB1	1	2	2
	NB2	1	1	1
	NB3	1	5	5
	NB5	1	3	3

T1	NB1	1/3	2	1
	NB3	1	3	3
	NB4	1	3	3
	NB5	1	3	3
	T2	NB1	1	1
NB3		1	3	3
NB4		1	3	3
NB5		1	3	3

principle, all assets derived from the MID would need to be taken into account:

- T1: An attacker introduces false measurement results into the measuring instrument.
- T2: An attacker modifies or replaces the software critical for the measuring task.

All NBs were asked to identify at least one attack vector per threat per measuring instrument and to evaluate that attack vector as described in Section II. The outcome is a list of point scores for the five mentioned categories. The sum score results in a probability score, see Table I, which produces a risk score when multiplied with the identified impact. Table II summarizes the results provided the NBs for threats T1 and T2. Not all NBs assessed both threats for both instruments. The results from different NBs for threat T1 for the cloud-based system are visualized in Figure 4. For this threat, all NBs selected an attack vector with a permanent effect (impact score of 1). Despite varying sum scores (11 to 17), the probability and risk scores for NB1, NB3, NB4 and NB5 are very close to each other due to the range of sum scores allowed by Table I. The only exception is the attack vector selected by NB2, which appears to be more difficult to implement than the others. When comparing results from NB4 and NB5, another property of the ISO/IEC 18045 vulnerability analysis becomes apparent: A larger score for expertise might be compensated by a smaller score for time, since a layman may take longer to implement a certain attack than an expert. While the results for T1 might suggest that consistent results can be easily obtained by different assessors, the results for threat T2 prove otherwise, see Figure 5. All four NBs concluded that the chosen attack vector would have a permanent effect. For all other scores, the results vary widely. Consequentially, probability and risk scores also differ. One reason for this variability is the imprecisely formulated threat T2, which allows either a partial modification or a complete replacement

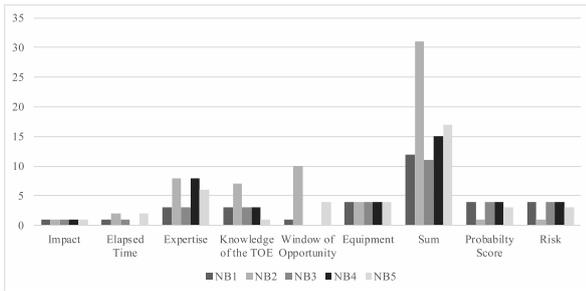

Fig. 4. Results for the complex cloud-based measuring system, evaluation of threat T1 (introduction of false measurement results).

of the software. While a small modification will require less expertise and time (attack examined by NB3), a full redevelopment will require more expertise, time etc. (attack examined by NB1). It is concluded, that properly documented attack vectors and precisely defined threats are key to comparing risk assessment results obtained by different parties. Moreover, assessment results for the cloud-based system do not depend on the perspective of the examiner alone, but also on the chosen attack vector. If an attacker aims to introduce false measurement results by providing them with a valid CRC-16 from a trustworthy source, this will be much less difficult than manipulating data within the WPA-protected Wi-Fi. To solve this disambiguity, all NBs were also asked to perform software risk assessments for the much simpler weighbridge instrument, detailed in Subsection III-A. The results obtained for threat T1 are depicted in Figure 6. NB3, NB4 and NB5 chose to examine attack vectors with a permanent effect, e.g. replacement of a sensor. Again, the point scores vary depending on the selected attacker profile (layman with restricted knowledge vs. expert with publicly available knowledge). Nevertheless, all three NBs arrive at similar sum and probability scores, resulting in identical risk scores. NB1 has examined an alternative attack vector requiring repetition for each measurement (reduced impact of  $\frac{1}{3}$ ). Since this attack also appears to be more complex (writing a specialized software vs. installing a sensor) the risk score obtained is much lower. In this regard, a set of evaluated reference attack vectors could reduce the assessor's required effort and harmonize the outcome of different assessments

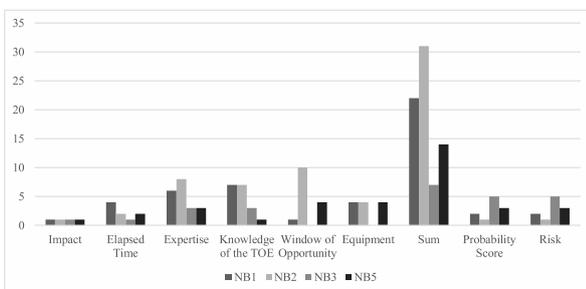

Fig. 5. Results for the complex cloud-based measuring system, evaluation of threat T2 (modification or replacement of software critical for the measurement).

performed for the same instrument. Concerning threat T2, the same effect can be observed, see Figure 7. While NB3 and NB5 focused on the simple modification of existing software, NB1 expected attackers to implement new software and then replace the original. The differences are due to the different focus of the attack vectors and an imprecisely formulated threat. This could be avoided by formulating individual threats per identified asset and requiring assessors to document chosen attack vectors and their effects for later comparison.

### C. Main Challenges

The justification - for rejecting certain assessed attack vectors as unlikely or for quantifying certain scores as wrong - was provided by a review session among the NBs involved. In practice, discussions between NBs about risk analyses provided by different manufacturers are unlikely to happen. Moreover, new examiners may not be familiar with these findings and will be facing the same challenges. As shown in Subsection III-B, an objective comparison of risk assessments is only possible if certain prerequisites are fulfilled:

- Instructions for new evaluators on how to assess risks according to the standard shall be readily available.
- Examples for evaluation of common attack vectors to reduce the workload for evaluators shall be supplied.
- Proper documentation of the complete attack vector and justification for the evaluation shall be required of all assessors for better comparability of assessment results.

Section IV addresses all three by providing a formalized framework, by means of a software risk assessment template.

### IV. FORMALIZATION OF RISK ASSESSMENT RESULTS

Instructions on how to perform a vulnerability analysis are provided by Part 2 clause B.4.2.2 ff of ISO/IEC 18045. Since the method discussed here is based on that standard, the same instructions may be used when performing software risk assessments in legal metrology. However, the standard's guidance is intended for all fields of IT security and is thus kept very general. In the template proposed, a shorter method description is included focused on the needs of legal metrology. Thereby, it is ensured that all assessors are aware of all steps to be performed. The workflow of the template is shown in Figure 8. The template includes a list of all assets

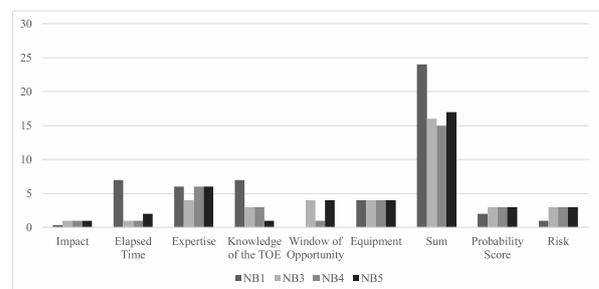

Fig. 6. Results for the simple weighbridge, evaluation of threat T1 (introduction of false measurement results).

TABLE III  
EXAMPLE FOR A FULLY EVALUATED ATTACK VECTOR.

Attack vector	Time	Expe- ri- se	Knowl- edge	Window of opport.	Equip- ment	Justification
Attacker constructs fake results from datasets protected by a CRC32 with a secret start vector.	0	3	3	0	0	Assumed attacker: customer. CRC is a linear operation on binary vectors, an XOR-connection of two datasets automatically produces a third dataset with correct CRC. This can be calculated with standard software by a proficient user. No window of opportunity needed. The CRC is described in the manual.

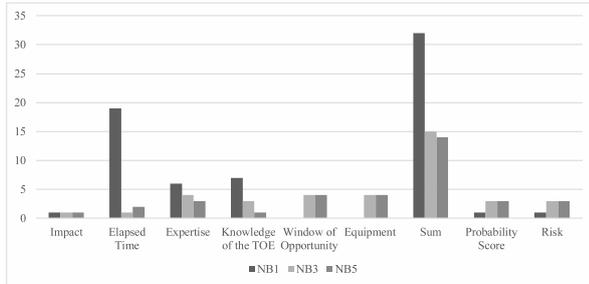

Fig. 7. Results for the simple weighbridge, evaluation of threat T2 (modification or replacement of software critical for the measurement).

and their security properties derived from the MID. These are accompanied by explanations of the assets and examples on how an attacker might invalidate their security properties. The assessor is required to select the applicable assets from the list and to formulate the relevant threats precisely. Even though the identification of attack vectors cannot be standardized, the template provides assessors with some assistance. A number of evaluated reference attack vectors are given, see Table III for an example. Also, assessors are offered the possibility to use AtPTs to decompose attack vectors to facilitate the evaluation. Most importantly, the template requires all assessors to provide justification for each point score alongside the evaluated attack vector. If sufficient details and justification are provided, discussion about assessment results will no longer be necessary, unless a different assessor takes issue with the point score assigned to a specific attribute. In this case, an AtPT can be used to decompose the

attack until no room for argument is left. The template will not guarantee uniform results, but if the guidance remarks are observed, there will be sufficient documentation to successfully argue in favor or against a certain assessment result. The template can be found under the following link: [https://www.ptb.de/cms/fileadmin/internet/fachabteilungen/abteilung\\_8/8.5\\_metrologische\\_informationstechnik/8.51/Risk\\_Assessment\\_Template\\_v11.docx](https://www.ptb.de/cms/fileadmin/internet/fachabteilungen/abteilung_8/8.5_metrologische_informationstechnik/8.51/Risk_Assessment_Template_v11.docx)

V. SUMMARY

As long as software risk assessment depends on human creativity and judgement, the resulting risk scores will always be biased. Nevertheless, detailed guidance on the assessment steps together with proper documentation of all steps of the assessment may serve as a basis to make software risk assessment results more easily comparable. The vulnerability analysis of ISO/IEC 18045 already provides general remarks on the workflow and on the point scores for specific attributes of assessed attack vectors. These were mapped to the needs of the legal metrology community and augmented by specific detailed examples to help assessors with repetitive tasks. The experimental findings from the inter-institutional comparison and the suggested risk assessment template, should be applicable to any group planning to implement ISO/IEC 18045 vulnerability analysis. To validate the template, WELMEC Working Group 7 is currently performing a second stage of risk assessments using the new template.

**Abstract**—With the advent of the Internet of Things (IoT), many domestic devices have been equipped with information technology. By connecting IoT devices with each other and with the Internet, Smart Home installations exist that allow the automation of complex household tasks. A popular example is Google Nest that controls cooling, heating and home security. However, Smart Home users are tempted to neglect that such IoT devices pose IT-Security risks. Examples like the Mirai malware have already shown that insecure IoT devices can be used for large-scale network attacks. Thus, it is important to adapt security approaches to Smart Home installations. In this paper, we introduce FANE, our concept for a Firewall Appliance for Smart Home installations. FANE makes a few realistic assumptions on the network segmentation and the communication profile of IoT devices. This allows FANE to learn firewall rules automatically. Our prototypical implementation indicates that FANE can secure a wide range of IoT devices without requiring network-security expertise from the Smart Home user.

## I. INTRODUCTION

IN THE last years, the proliferation of Smart Home installations has gained momentum. Today, the consumer market offers a huge number of different Internet-of-Things (IoT) devices.

Smart thermostats, cameras, speakers and even toothbrushes contain information technology that connects the IoT device over the Internet with cloud services or other IoT devices. For example, IoT devices from the Google Nest family [1] provide a straightforward, user-friendly way to control heating, cooling and home security. Smart speakers like Amazon Alexa [2] allow to control many daily activities via voice control. From the perspective of the manufacturers, the Smart Home concept allows new business models, e.g., to sell new product features as digital upgrades for IoT devices.

On the other hand, consumers might be tempted to overlook that the IoT devices pose an IT-Security risk. For example, the lifetime of a traditional security camera ends when the device is broken. In contrast, the lifetime of an IoT security camera that connects over the Internet should come to an end when its manufacturer discontinues security updates, even if the IoT security camera is still working. Otherwise, the IoT security camera might end up as, say, part of the Mirai bot network, which consisted of approx. 500,000 devices in 2016 [3].

From the perspective of a consumer without in-depth expertise of network security, it is next to impossible to find out if the IoT devices present in a Smart Home installation are subject to attacks over the Internet. In this paper, we

explore options to integrate a firewall into typical Smart Home installation that can detect and deter such attacks. This is challenging, since the firewall must be compliant with the typical modes of use of a Smart Home installation, and a consumer cannot be expected to evaluate firewall rules or identify false alarms. On the other hand, the IoT devices used differ from general-purpose devices such as smartphones and desktop computers. This might allow for pre-configuration to some extent.

In particular, we make the following contributions:

- 1) We systematically compare the lifecycle of a classical firewall with the lifecycle of IoT devices in a typical Smart Home installation.
- 2) We propose FANE, a Firewall Appliance on a Wi-Fi bridge in Smart Home installations.
- 3) We describe a proof-of-concept implementation of FANE based on a Raspberry Pi, and we evaluate it with three different IoT devices.

We show that it is possible to develop a generic IT-Security concept for IoT devices in a Smart Home installation by making few realistic assumptions, e.g., the IoT network segment is only used by single-purpose IoT devices, which do not fundamentally change their communication profiles. We have implemented this security concept in FANE. Our evaluation indicates that FANE can secure the IoT network segment without requiring the user to possess network-security expertise.

**Paper structure:** In Section II, we review related work. In Section III we provide a problem statement. We describe FANE in Section IV, followed by a proof-of-concept implementation in Section V and an experimental evaluation in Section VI. Section VII concludes.

## II. RELATED WORK

In this section we provide a brief definition of Internet of Things and Smart Home, and we introduce related work on firewalls, firewall management and approaches to generate firewall rules automatically.

### A. Internet of Things and Smart Homes

The "Internet of Things" (IoT) refers to physical appliances, which have been equipped with information technology in order to connect them with other devices directly or over the Internet [4]. IoT includes a wide range of appliances, from

connected cars over smart buildings to connected machinery in an Industry 4.0 setting. The concept "Smart Home" narrows down this range to devices that let end users to control, monitor or access everyday objects of the daily routine [5].

### B. Security Challenges

To assess the security properties of Smart Home installations, it is important consider the basic security challenges that occur in installations of IoT devices. One study [6] lists six major security issues:

**Identity and Authentication:** In IoT environments, numerous devices need to authenticate each other in order to provide trustable services. Thus, reliable techniques for identification and authentication are needed.

**Access Control:** To create new services it is necessary to aggregate data from different providers. This is challenging, because in typical IoT scenarios each provider has its own access control policy.

**Protocol and Network Security:** If IoT devices communicate with each other in a distributed network architecture, distributed schemes for key management are needed.

**Privacy:** The Smart Home concept means that numerous IoT devices monitor the actions of its users in order to devise meaningful responses. Thus, privacy very important from a user perspective.

**Trust and Governance:** In IoT architectures there are two dimensions of trust. The first dimension is between users and their IoT devices. The other dimension is between the IoT devices. Device A needs to trust the accuracy and integrity of the data produced by device B. Data governance goes in the same direction, in a sense of data and access governance.

**Fault Tolerance:** Mechanisms for fault tolerance need to be established to counteract faulty or tampered devices.

Other studies [7] list similar challenges.

### C. Firewalls State of the Art

Firewalls are able to control and log the network traffic based on rules set by an administrator or security expert. In literature different firewall generations are distinguished [8]. 1st generation firewalls are known as packet filters which operates on the transport layer. The filtering is based on source and destination IP addresses, ports and protocols. 2nd generation firewalls are also operating on the transport layer and they are known as stateful packet inspection. State tables are used to keep track of the network traffic and filtering is based on state and context of packets. 3rd generation firewalls are operating on the application level and require different proxies for each service. The proxy acts as a middleman between source and destination to reestablish a new session. Current firewall technologies are called next generation firewalls. These next generation firewalls are looking deep into packets and combine traditional firewall technologies with network filtering capabilities on the application level [9]. However, all these generations have in common that an expert is needed to define rules or check them for correctness which motivates our new approach.

### D. Firewall Lifecycle

Traditionally, a firewall must be part of the IT-Security process, as described by the ISO 270xx standards family [10], the German BSI Grundschutz Standard 200-2 [11] or the ITIL process for security Management [12]. The IT-Security process starts with a IT-Security policy that has been passed by the management. Based on this policy, business objectives, the assets to be protected and a risk classification can be identified. Subsequently, measures can be defined and implemented that restrict the IT-Security risks to acceptable levels. In the following, the effectiveness of these measures needs to be monitored. Based on this information, corrective actions can be planned and executed [13]. Note that all process steps require a person with IT-Security expertise, which cooperates with various IT experts from the operations department.

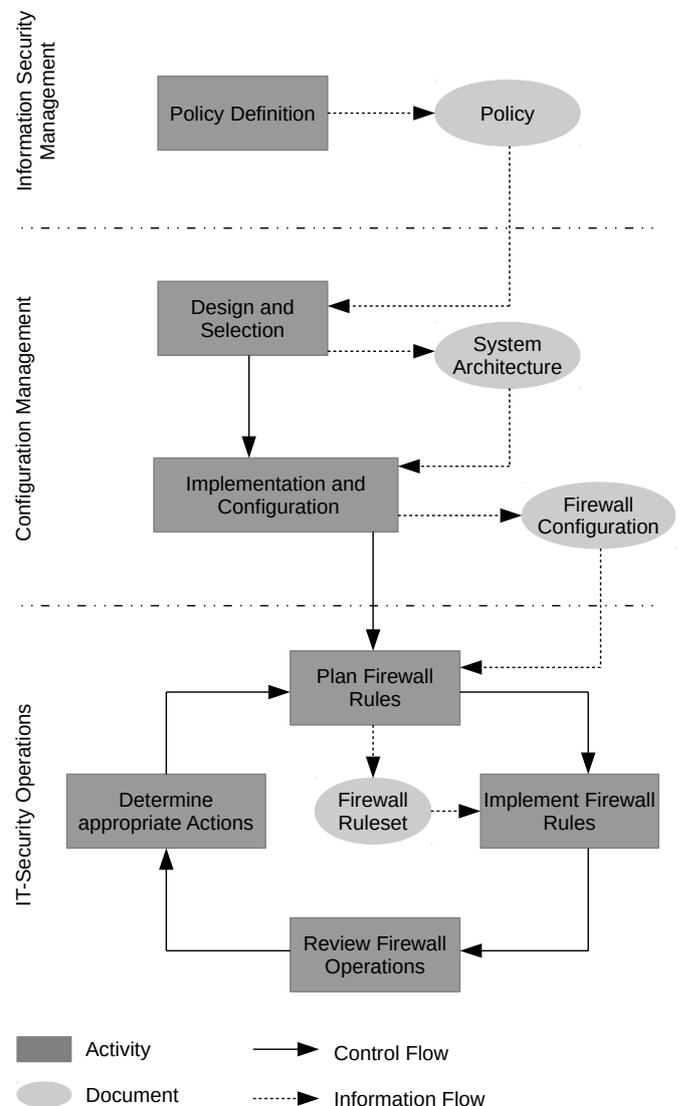

Fig. 1. Traditional Firewall-Lifecycle

A firewall fits into the IT-Security process [14] as shown in Figure 1. In the Information-Security Management phase, the management defines a security policy based on company-wide security objectives. This policy is independent from technical realities. Based on the security policy, an IT-Security expert designs the architecture of the firewall system and selects the firewall system components. In the implementation and configuration phase, the IT-Security expert adapts the firewall system to the system architecture with its network segments, hosts and applications. This includes a preliminary set of firewall rules that define which network packets are allowed to pass the firewall. In the next step, a plan-do-check-act cycle takes place where the firewall rules are designed, implemented, reviewed and improved in a repetitive way. Typically, this cycle is part of IT-Security operations. It allows to adjust the firewall rules to changes such as new business applications, hosts moving from one network segment to another one, or in case of detecting new attacks. Note that not only the management of firewall rules is a cyclic process, but also the IT-Security process. If the management observes that the security policy is ineffective, this policy can be changed as well, and it has an impact on all design decisions further down the IT-Security process chain.

#### E. Firewall Rules

It is a labor-intensive task for a domain expert to create a rule set for firewalls manually. One option to obtain firewall rules (semi-)automatically is to use data mining or machine learning on a training set consisting of network packets. This option is based on the assumption all user applications operate as intended while the training set is recorded. Respective approaches [15]–[17] have been proposed for Intrusion Detection systems, but might be adaptable to firewalls as well. By using k-Means, C4.5 decision tree algorithms, Naive Bayes classifier, Neural Networks or Support Vector Machines, it is possible to derive common characteristics of allowed network connections. Those characteristics could be translated into firewall rules. It is also possible to generate firewall rules by mining the firewall log [18] instead of a dump of network packets. However, all approaches require an IT-Security expert to decide which generated rules are relevant to meet the security requirements, and the quality of the generated rules still needs further research.

A different option to generate firewall rules is to deduce them from a formal specification of security requirements by using argumentation logic [19]. This approach allows to automatically obtain a detailed, comprehensive set of rules from a high-level specification. However, creating a specification of the security requirements for a certain system architecture still requires expert knowledge in IT-Security.

### III. PROBLEM STATEMENT

In this section, we explore the differences between traditional firewalls and firewalls needed for IoT devices in a Smart Home installation. In addition, we derive requirements for a Smart Home firewall.

#### A. Does a Firewall Fit into the Smart Home Concept?

To find out in which ways traditional firewall use cases differ from Smart Home use cases, we consider the modes of use, network architecture, application scenario, user roles and information technology used.

*a) Modes of Use:* A firewall is an access control mechanism that allows or blocks network traffic between two network segments that have different security properties [20], e.g., an internal network and the Internet that is open for anybody. The firewall enforces a set of firewall rules that allow or prohibit network packets to travel from one segment into the other one. The firewall rules depend on the use cases that are executed over both network segments. For example, a business workflow "Answer customer requests" might require that a set of machines in the internal network is allowed to send and receive email to/from the Internet. Thus, firewall rules must be defined by a network-security expert with domain knowledge. If the workflows, the applications or the segment boundaries are changed, the expert must adapt the firewall rules as well. Traditionally, firewalls are tailored for complex multi-purpose scenarios where the hosts execute numerous different applications that change over time.

Smart Home use cases are fundamentally different [21]: A typical IoT device is a physical object that has been extended with information technology to improve its usefulness. For example, a smart toothbrush [22] can tell its user if a tooth has gone unbrushed. Thus, IoT devices are constructed for a single purpose that does not change over time. It only makes sense to install a toothbrush control software on a smart toothbrush. As a result, IoT devices are single-purpose objects. If the device is not needed any more, it will be disposed.

*b) Network Architecture:* Firewalls depend on the network segmentation. With traditional use cases, a network installation might contain multiple segments protected by multiple firewalls. A prominent example is a perimeter network [20], which contains assets such as Web servers that must be accessible from an external network. Two sets of firewall rules protect the perimeter network against the external network and the internal network against the perimeter and the external network. However, the number and architecture of the network segments might be individually different for each network installation.

In contrast, a typical Smart Home installation with IoT devices produces three network segments with different security properties: (a) the untrusted Internet, (b) the home network with trusted devices such as the user's laptop and printer, and (c) an IoT network segment that contains all IoT devices. Since the IoT device and its software comes as an integrated package, the user has little options to influence the security of the IoT device, e.g., by disabling unused network protocols or by removing unused software functionality. Thus, the IoT network segment should be separated from the home network [23], which is used for sensible tasks such as online banking or online shopping. All devices in the IoT network segment can be expected to require an Internet connection, to

provide a service, to obtain updates and upgrades, to allow a remote control via smartphone app, etc.

c) *Application Scenario*: Firewalls follow the IT-Security lifecycle, as explained in Section II. Based on a general security policy that has been defined from a management perspective, a network-security expert defines the position of the firewall(s) in the network architecture and a set of firewall rules. By using a plan-do-check-act-cycle, the firewall rules as well as the firewall hard- and software must be constantly monitored, evaluated and adapted to changes in the IT infrastructure.

On the opposite side, one of the fundamental principles of the Smart Home concept is to let IoT devices use sensors to observe its environment, in order learn appropriate actions with a minimum of user interaction and without requiring the user to scrutinize the operations of the IoT device on a regular basis. For example, the nest thermostat observes the temperature preferences of its user and if he or she is at home, and controls the heating system accordingly. Furthermore, the duration of use of IoT devices is an one-dimensional process that starts with the deployment of a device and ends with its disposal, just like non-smart devices [24], i.e., it does not follow a periodic lifecycle where it is constantly monitored and improved. For example, a smart light switch never changes its function, and it cannot be adapted to different needs.

d) *User Roles*: Setting up a traditional firewall typically requires three distinct roles: The role "Information Security Management" defines a security policy by considering the assets and (business) objectives that are relevant for a certain part of the IT infrastructure. Based on the policy, the role "Configuration Management" designs a firewall system, selects appropriate firewall components, and provides an initial installation and configuration of the system. Finally, a role "IT-Security Operation" constantly monitors and improves the firewall system, both on the level of the firewall rules and of the firewall hard- and software.

In contrast, an IoT device for a Smart Home usually is pre-configured by the manufacturer for typical use cases. The end user can deploy and configure the IoT device with minimal efforts, does not need to monitor it later on and does not need expert knowledge.

e) *Information Technology*: IoT devices make use of network protocols which have been well established. They use Linux-based operating systems, Cloud resources and Open Source programming libraries. The network security of IoT devices is based on mechanisms for encryption, certification and signatures that have been in use for years. Thus, from a technical point of view, off-the-shelf firewalls can be directly used to control the network traffic of IoT devices.

### B. Problem Definition

From a technical perspective, it would be a simple exercise for a network security expert to set up a firewall that controls the network traffic of an IoT device. However, this procedure conflicts with the general understanding how IoT devices should operate in a Smart Home. Thus, a firewall for Smart

Homes must differ in the following properties from traditional firewalls:

- P1** The firewall must be usable without expert knowledge.
- P2** The firewall must fit to the durations of use of Smart Home components.
- P3** The firewall must operate in a way that is typical for IoT devices in the Smart Home.

**P1** implies not only that the configuration and installation of a firewall in a Smart Home must not require network security expertise. It also means that a user cannot be expected to tell false alarms from real alarms, or to decide if a certain firewall rule is applicable to the home network. From **P2** it follows that such a firewall must deal with IoT devices that are bought once for a certain purpose and never change its basic properties until disposal, and it must operate in the same way. Furthermore, the firewall must operate in the same way. **P3** means that a firewall in a Smart Home needs to operate without permanent care from the user, i.e., it must monitor the network traffic, deduce meaningful firewall rules and provide appropriate reactions to forbidden network packets.

We have ruled out a cloud-based approach [25], [26] that externalizes the firewall to a trusted third party on the Internet. Although such an approach might fulfil the properties described, it requires a permanent Internet connection. In addition, a cloud-based firewall would transfer security-relevant information into the cloud. Thus, both the Internet connection of the firewall and the trusted third party would be a valuable target for an attacker.

## IV. FANE: A FIREWALL APPLIANCE

In this section, we introduce FANE, a concept for a Firewall Appliance that is compatible with the Smart Home paradigm.

### A. Network Architecture

A firewall separates network segments with different security properties. Typical IoT devices do not allow its user to observe security properties, and to configure security-related aspects, such as disabling unused functions. Furthermore, an IoT device is designed to be used like a classical, non-smart device, i.e., its users are tempted to forget that the device might pose IT-Security risks. For this reason, IoT devices should be placed in network segments that are isolated from all other network segments of the Smart Home.

Thus, FANE operates as a Wi-Fi bridge that connects the IoT network segment to the Internet and includes a firewall, as shown in Figure 2. The IoT network segment only contains single-purpose IoT devices, and the Wi-Fi bridge is the only connection of the IoT segment to other network segments and the Internet. We observe that this allows us to specify the security concept in advance.

### B. Security Concept

From Section III it follows that a traditional firewall approach is complex, because the underlying network segmentation and the processes executed over the boundaries of these segments are complex, too, and might change from

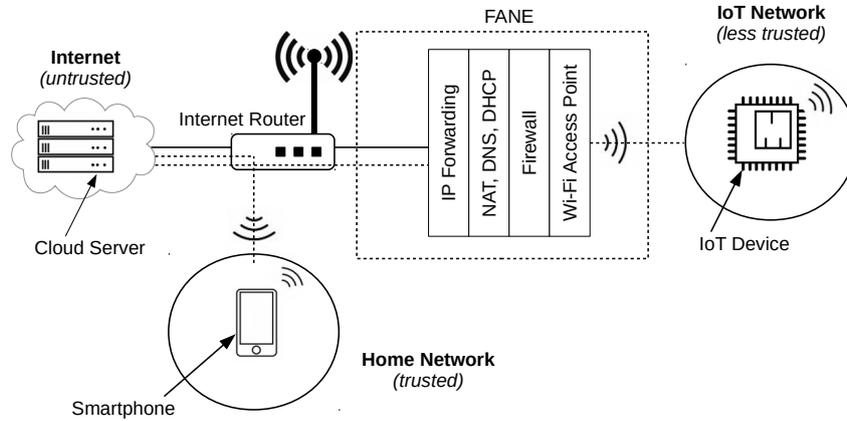

Fig. 2. System Architecture

time to time if a new software is installed on a device in the network. With our network architecture, we have reduced this complexity. We only need to consider three kinds of communication activities:

- An IoT device wants to communicate with a server on the Internet. For example, a smart thermostat wants to communicate with the user's smartphone, which is mediated over a cloud service.
- An IoT device wants to communicate with a device in another network segment. For example, the user installs a control application on a laptop to configure the smart thermostat.
- An IoT device wants to communicate with another IoT device in the same network segment. For example, our smart thermostat wants to directly communicate with the smart air condition.

Since FANE operates as a bridge to the Internet, only the first two kinds of communication have to be monitored, and the security properties of the endpoints of the communication can be specified at production-time of FANE: The open Internet is insecure by default, the IoT devices are less secure, and the devices in other network segments of the Smart Home are trustworthy. This allows to pre-configure the security concept of FANE in advance, i.e., it does not need a user with network-security expertise (Property **P1**):

- 1) No device on the Internet is allowed to open a network connection to the IoT network segment.
- 2) An IoT device is allowed to open a connection to the Internet, if this is part of its normal operation.

- 3) An IoT device is allowed to open a connection to devices in other (trusted) network segments of the Smart Home, if this is part of its normal operation.
- 4) A device from a trusted segment is allowed to open connections to the IoT network segment.
- 5) IoT devices are allowed to open connections to other devices in the IoT network segment.

### C. Smart Home Firewall Operations

FANE has to meet conflicting requirements: It must meet the expectations provided by Smart Home components (**P2**). In particular, this means that FANE must operate without constant supervision (**P3**). At the same time, as a security component it must not neglect the IT-Security process, including a plan-do-check-act cycle to refine firewall rules. However, this must be possible without requiring the user to possess expert knowledge (**P1**).

We circumvent these conflicts, as shown in Figure 3): We distinguish between pre-configuration management and Smart Home operations. Because we restrict FANE to the network architecture described in Subsection IV-A, the policy definition, the firewall design and a baseline configuration of firewall rules can be done at pre-configuration time. Thus, we shift the initial parts of the IT-Security process into the responsibility of the Smart Home firewall manufacturer who possess IT-Security expertise. Furthermore, we propose to automate the configuration and the plan-do-check-act cycle in a way that it's phases can be started without expert knowledge at operation time. Finally, we define a process step in a way that the user is informed when an IT-Security expert is needed.

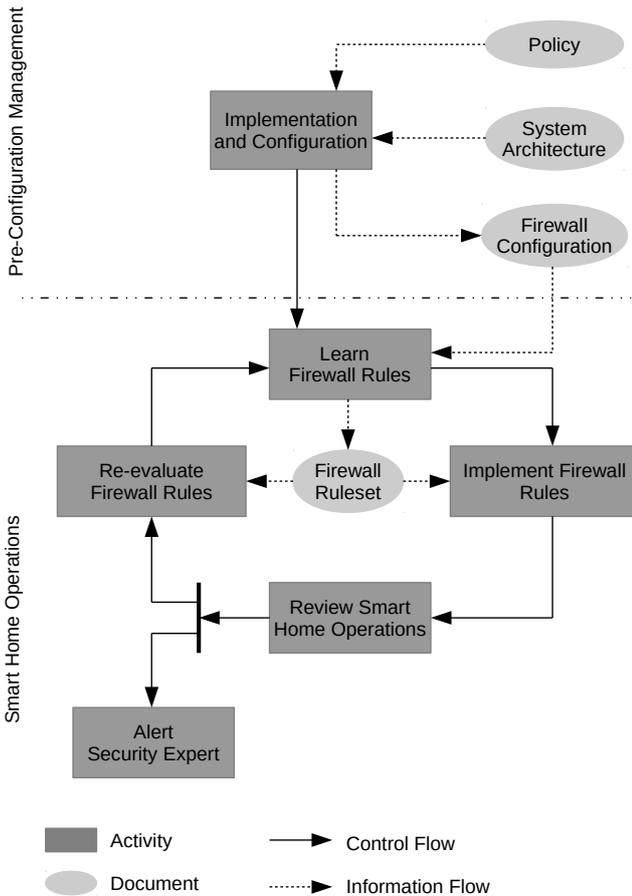

Fig. 3. FANE Operations

#### D. User Interaction

After having defined the operations of FANE, we can define the user interactions needed. Observe that no interaction requires expert knowledge (Property **P1**). FANE comes as an IoT device that runs out-of-the-box after being connected to a power outlet and the Internet.

When FANE is connected to the Smart Home installation for the first time or if new IoT devices are added, the user can tell FANE to **learn** new firewall rules by observing the network packets of the IoT devices. Assume an IoT device uses a functionality that has not been used during the learning stage, or the device has been updated and a new network connection is now blocked by FANE. In this case, the user has the option to let FANE **re-evaluate** the rule set. That is, FANE executes a learning stage on a certain device with the option to discard rules that have been learned before. The rules from the security concept (Subsection IV-B) cannot be discarded.

If FANE blocks a large number of network packets per time-interval, it generates an **alert**. The alert shows the user that immediate action needs to be taken, i.e., something happens

that cannot be handled automatically by FANE. For example, the IoT network segment might face a denial-of-service attack from the Internet, or an IoT device has been taken over and tries to connect to the attacker's command and control server on the Internet. In such cases, the user might decide to call the customer support of the IoT device, or ask an IT-Security expert for further investigations.

#### V. PROOF-OF-CONCEPT IMPLEMENTATION

In this section, we describe the software and hardware components of our FANE prototype, how FANE learns firewall rules and in which way it interacts with the user.

##### A. Our FANE prototype

We have realized FANE on the basis of a Raspberry Pi, which executes several linux shell scripts to configure and operate an iptables packet filter (see Subsection II-C). Figure 4 illustrates our hardware configuration and the main software packages used.

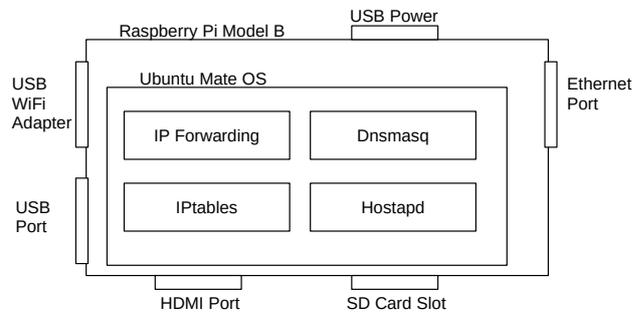

Fig. 4. Our FANE prototype

*a) Hardware:* From Section IV it follows that FANE must provide a Wi-Fi access point that creates a network segment for IoT devices. The IoT devices might want to communicate with other devices in the same segment, the home network segment and the Internet. Thus, FANE must be connected to the Internet, and its firewall must control all incoming and outgoing network packets of the IoT network segment.

We have implemented this approach on a third-generation Raspberry Pi model B. This is a credit-card sized single board computer containing a quad-core processor with 1.2GHz, 1 GB main memory and various network and connection interfaces. Because the on-board Wi-Fi chip cannot be configured as a Wi-Fi access point, we have connected an external Wi-Fi module via USB. We have used a 32 GB SD Card for permanent storage.

We would need only two switches to initiate the learning- and re-evaluation stage of the user interface, and one LED indicating an alert. The IT-Security expert, which might be needed to handle serious attacks on the IoT network segment, would be able to obtain firewall logs and other information by using an SSH connection. This way, our FANE prototype

costs less than 60 EUR. However, to ease development we have used an external USB keyboard and a LCD monitor.

b) *Software*: We have used the Ubuntu Mate Linux operating system as a basis of our software configuration. On top of a minimal OS installation, we need the following software packages and services:

- awk (script language to edit text files)
- cron (timed execution of processes)
- dnsmasq (DHCP client and DNS cache)
- hostapd (Wi-Fi access point)
- inotify-tools (monitor changes in files)
- iptables (network address translation and firewall)
- tcpdump (record network packets)

By configuring the Ethernet interface *eth0* as a DHCP client, our Raspberry Pi can be connected to any Internet router without further configuration. We have configured the *wlan0* interface with a static IP address and subnet mask, and we have configured it as a Wi-Fi access point by using *hostapd*. Our Smart Home firewall must act as a bridge between *eth0* (Internet) and *wlan0* (Wi-Fi segment for IoT devices). Thus, we have used *iptables* and *sysctl* to activate IP forwarding, including network-address translation and masquerading. With *dnsmasq*, we have realized a DHCP service.

### B. Learning Firewall Rules

For our FANE prototype, we have used a straightforward approach to learn firewall rules. For more elaborate approaches, see Section II. The learning stage consists of two phases, a *monitoring phase* and a *rule generation phase*. We assume that all network traffic recorded during the monitoring phase is allowed, i.e., we assume that no IoT device has been manipulated or attacked before the monitoring phase ends.

When FANE is connected to power and Internet for the first time, or if the user wants FANE to learn new rules, it enters the monitoring phase for a certain period of time. In this phase, FANE waits for new IoT devices connecting to the access point, and logs the network packets. We have implemented this phase as follows:

At boot time, a *cron* task with the time prefix *@reboot* starts a script that finds out if the set of firewall rules is the one that has been pre-configured from the security concept (Subsection IV-B). Alternatively, a user command starts the monitoring phase manually. In the monitoring phase, FANE uses the monitoring tool *inotify* to find out if the *dhcp leases* file changes. This indicates new devices using the access point. In this case, *inotify* executes a script that obtains the IP address of the device from *dhcp leases*. At the same time, FANE uses *tcpdump* to create a log file containing all network packets sent or received during the monitoring phase.

At the end of the monitoring phase, FANE stops *tcpdump* and enters the rule generation phase. In this phase, FANE parses the log file from *tcpdump* into firewall rules according to the IP addresses of the IoT devices that have used the access point in the monitoring phase. In particular, FANE uses a *sed* command to filter the log for incoming and outgoing IP addresses and ports. This set of addresses and ports is

reduced to unique entries in a second step. The odd lines in Figure 5 show, how the set of addresses and ports looks like after FANE has removed surplus information and duplicates from the log file. In a third step, a shell scripts parses the remaining addresses and ports into firewall rules that allow such packets for the *iptables* chain "FORWARD". The odd lines in Figure 5 illustrate this step. We have used the *iptables* policy "DROP", i.e., FANE drops all packets that are not allowed by the rules generated.

```

1 15:23:18 IP 10.200.65.101.1080 > 35.158.162.95.80:
2 iptables -A FORWARD -s 10.200.65.101 -sport
   1024:65535 -d 35.158.162.95 -dport 80
   -p tcp -j ACCEPT
3 15:23:22 IP 10.200.65.101.8553 > 35.157.158.75.1883:
4 iptables -A FORWARD -s 10.200.65.101 -sport
   1024:65535 -d 35.157.158.75 -dport 1024:65535
   -p tcp -j ACCEPT
5 15:24:36 IP 10.200.65.101.8653 > 35.156.40.103.1883:
6 iptables -A FORWARD -s 10.200.65.101 -sport
   1024:65535 -d 35.156.40.103 -dport 1024:65535
   -p tcp -j ACCEPT
7 15:25:07 IP 10.200.65.101.8554 > 35.157.255.122.80:
8 iptables -A FORWARD -s 10.200.65.101 -sport
   1024:65535 -d 35.157.255.122 -dport 80
   -p tcp -j ACCEPT

```

Fig. 5. Firewall rules learned from an adjusted packet log

Note that this procedure can be extended easily to extended firewall features, e.g., to include the *iptables* options for stateful inspection. At the end of the rule generation phase, FANE installs the rules and is ready for operation.

If an IoT device is not working properly, if a new IoT device is added to the IoT network segment or if an existing device is used in a way it has never been used before, the user can order FANE to re-evaluate the rule set. In this case, the user has the option to discard rules from preceding learning procedures, and to re-start the monitoring- and rule-generation phase.

## VI. EXPERIMENTAL EVALUATION

In this section, we explore the applicability of FANE with three different Smart Home appliances.

### A. Setup

Figure 6 shows our experimental setup. FANE is directly connected to the Internet router, and its integrated access point spans a Wi-Fi network segment for IoT devices. The Internet router creates a Wi-Fi home network that connects a smartphone to the Internet. Different cloud services connect the smartphone to the IoT devices. A cloud service might use a load balancer, i.e., the IP addresses the IoT devices connect to might change from time to time.

We have tested three different devices, which communicate differently with a control app on the user's smartphone:

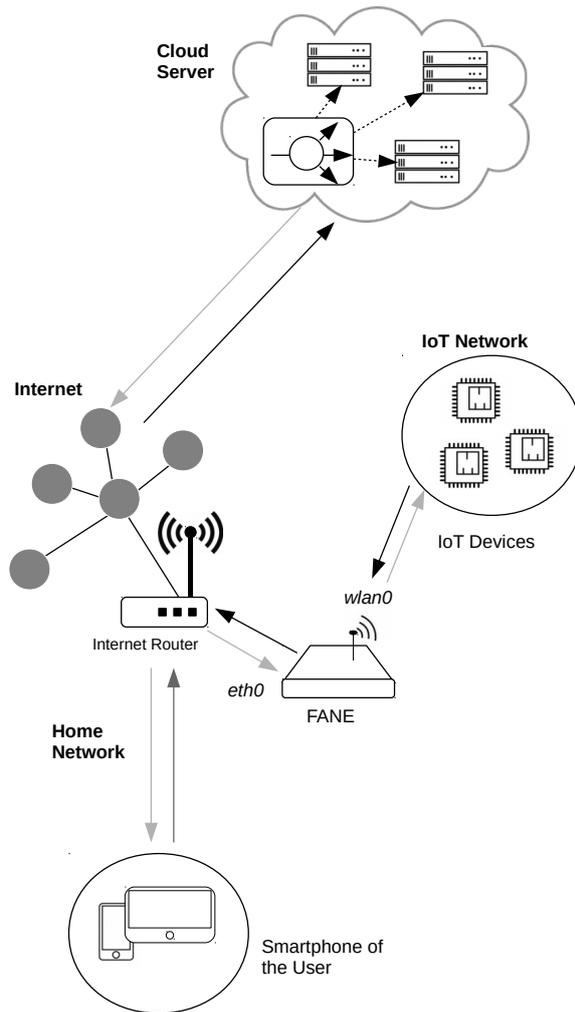

Fig. 6. Our experimental setup

- 1) An electrical IoT relay.
- 2) An IoT power outlet.
- 3) An IoT security camera.

The IoT devices do not communicate directly with each other, but with the user's smartphone and the Internet. Thus, for our experiments we do not need to preconfigure rule 5 from our security concept (see Subsection IV-B). We have configured each device for FANE's IoT network segment. We have used a monitoring phase of 40 minutes, and we have operated each device periodically during this phase. In the following, we briefly introduce each IoT device, and we describe what we have learned by using FANE as described.

### B. IoT Relay

Our first use case is an electrical relay "10A Wi-Fi smart switch", sold for less than 9 EUR, manufactured by Sonoff [27]. The IoT relay can be turned on or off via

smartphone app, which allows a technician to integrate non-smart electrical devices into a straightforward Smart Home installation. Sending commands from the app to the relay requires an Internet connection, i.e., there is no option to directly connect the smartphone app to the IoT device. After the relay is connected to the access point provided by FANE, and the user has installed the smartphone app, the relay is ready to use.

In our monitoring phase of 40 minutes, we have switched the relay on and off frequently via smartphone app for 10 minutes. After that, we have waited for a period of 20 minutes. Finally, we have operated the relay for further 10 minutes.

After completing the monitoring phase, FANE has written 1,800 lines in the packet log. All packets followed the TCP protocol and were sent/received to/from one singular IP address located at a dedicated server leased from Amazon. Thus, the rule generation phase has generated only one rule for in- and outgoing packets. The IoT relay was working properly after FANE has activated the firewall rule set generated. Figure 7 shows an example from the traffic log FANE has recorded from the IoT relay.

```

1 13:41:31.551813 IP 10.200.65.109.55147 >
   52.71.154.91.443: Flags [F.], ...
2 13:41:31.551870 IP 10.200.65.109.55145 >
   52.71.154.91.443: Flags [F.], ...
3 13:41:31.551914 IP 10.200.65.109.55161 >
   52.71.154.91.443: Flags [.], ...
4 13:41:31.668878 IP 52.71.154.91.443 >
   10.200.65.109.55161: Flags [.], ...
5 13:41:31.669239 IP 52.71.154.91.443 >
   10.200.65.109.55161: Flags [P.], ...

```

Fig. 7. Fragment of the packet log of the IoT relay

### C. IoT Power Outlet

Our second use case is an IoT power outlet "Smart Wi-Fi Socket Model SWA1", sold for 18 EUR, produced by Shenzhen Ligan Intelligent Technology [28]. Similarly to the IoT relay, the IoT power outlet can be turned on or off via smartphone app. In addition, it can be controlled with Amazon Alexa or Google Home, which allows to integrate non-smart electrical devices into an elaborate Smart Home concept without requiring a technician. Any command to the IoT power outlet is handled by a cloud service over the Internet.

In our monitoring phase, we have used the IoT power outlet via smartphone in the same way as the relay for 40 minutes. At the end of the monitoring phase, FANE has collected a packet log of approx. 2,600 lines, all of them TCP packets. The rule generation phase has generated rules that allow five

different IP addresses, all of them in the address range of the Amazon AWS cloud.

The IoT power outlet was fully operational after FANE has started to filter network connections. We have observed that only one of the five addresses in the firewall rule set was actually used to operate the outlet via smartphone app. We assume that some network connections are used only for analyzing customer behavior or similar purposes, i.e., blocking them would not reduce the functionality of the device.

#### D. IoT Security Camera

The most complex IoT device tested was a "720P HD IP Wireless security camera", sold for 37 EUR and manufactured by XinweiYa [29]. The IoT security camera sends a live video stream to the smartphone of the user. Furthermore, the smartphone app allows to restart the IoT security camera, and to rotate it around two axes. After connecting the IoT security camera to a power outlet, it can be configured with a smartphone app to use FANE's access point.

During our monitoring phase of 40 minutes, we have restarted the IoT security camera, we have let the IoT security camera sent a live video stream of 10 minutes to the smartphone, we have waited for 20 minutes, and we have restarted it again for another live stream of 10 minutes. After 40 minutes, FANE has collected 8 MB packet log of approx. 27,000 lines, most of them UDP packets.

The rule generation phase produces a rule set of 20 rules for this device. Those rules allow services like Network Time Protocol (NTP) or Domain Name System (DNS) as well as cloud services hosted on Amazon AWS, the Microsoft cloud and the Alibaba cloud.

We have observed that the IoT security camera was not working properly, after FANE started to filter network packets. Our investigations have shown that this due to a specific load balancer. The IP address of the load balancer was allowed by the firewall rule set generated. But the load balancer referred the IoT security camera frequently to IP addresses unknown to FANE. However, it would be possible to adapt the learning approach to cope with such a load balancer. For example, FANE could detect and accept IP addresses that are close by addresses that are already allowed by the rule set.

The packet log has also shown that the IoT security camera first tries to reach the smartphone app in the same network segment directly, via multicast. Thus, even if the IoT security camera makes use of the Internet connection, it might be able to provide its basic functionality without the Internet. From this observation we conclude that there might be options for FANE to distinguish between communication needed for the normal operation of an IoT device, and other communication needed for advertising purposes or usage analytics that can be blocked without undesired side-effects.

Finally, we have observed that the IoT security camera produces more network load by an order of magnitude than the other IoT devices tested. While this has slowed down the rule generation phase, it did not overstrain the IP forwarding capacity of our Raspberry Pi during normal operation.

#### E. Discussion

Our three use cases have provided evidence that a straightforward learning approach is applicable to many IoT devices used in Smart Home scenarios. Two of our three IoT devices remained fully operative after FANE has monitored the network activities of our devices for 40 minutes, and has subsequently generated and activated firewall rules. Furthermore, our observations have shown that it would be easily possible to extend our learning approach to consider load balancers. As there is no communication standard for IoT devices, it is problematic to generalize our findings to all IoT devices used in the Smart Home. However, using a cloud service seems to be typical for many use cases. Only network packets can pass FANE that are allowed by a specific rule. Thus, FANE increases the security of the Smart Home installation.

FANE operates without requiring the user to possess expert knowledge, by making three assumptions: First, the network segment created by FANE's access point contains IoT devices only. This allows to specify a security policy in advance, before FANE is delivered to the user. Second, the IoT devices operate as single-purpose appliances that do not fundamentally change their communication profiles. Due to this assumption, FANE can learn a rule set that remains stable over a long period of time, which makes it compatible with the Smart Home concept. Third, we assume that the IoT devices are working properly during the monitoring phase. This allows FANE to learn firewall rules unattended.

## VII. CONCLUSION

The last years have brought a plethora of Internet-of-Things (IoT) devices dedicated to Smart Home installations. While such IoT devices have numerous practical use cases, observations have shown that many of them come with IT-Security risks. For example, the Mirai botnet consisted of approx. 500,000 baby-phones, security cameras and other insecure IoT devices that were able to execute distributed denial-of-service attacks with 1 Tbit/s network bandwidth. However, typical Smart Home users do not possess the network-security knowledge needed to identify and deter attacks on IoT devices. Furthermore, the Smart Home concept encourages the users to leave IoT devices unattended for long periods of time.

In this paper, we have introduced FANE, our concept for a Firewall Appliance for Smart Home installations. FANE makes a few realistic assumptions on the network segmentation and the communication profile of IoT devices. This allows to pre-configure FANE with a generic security concept. It also enables FANE to learn firewall rules automatically by observing the network traffic of IoT devices.

Experiments with a prototypical implementation have provided evidence that FANE can secure ordinary IoT devices without requiring network-security expertise from the Smart Home user. Only one device was not working properly after FANE has activated its firewall rules due to a specific load balancer. However, this problem could be solved by accepting IP addresses close to addresses that FANE already knows.

## ACKNOWLEDGMENT

We would like to thank Eric Ilgunas for his exceptional work on realizing and evaluating the FANE prototype.

**Abstract**—Anomaly-based Intrusion Detection Systems (IDS) can be instrumental in detecting attacks on IT systems. For evaluation and training of IDS, data sets containing samples of common security-scenarios are essential. Existing data sets are not sufficient for training modern IDS. This work introduces a new methodology for recording data that is useful in the context of intrusion detection. The approach presented is comprised of a system architecture as well as a novel framework for simulating security-related scenarios.

## I. INTRODUCTION

The current threat situation of the IT landscape makes it necessary to monitor systems and detect attacks at an early stage. Host-based Intrusion Detection Systems (HIDS) are important tools to inspect system calls and to analyze processes which are accessing systems. Especially anomaly-based HIDS are able to detect previously unknown attacks. These are trained in advance with normal behavior and detect deviant behavior in the event of an attack. The quality of an anomaly-based HIDS in relation to the detection and error rate is significantly linked to the quality of the training of these systems. In recent years, various data sets have been published to evaluate a HIDS. As it turns out all them have at least one serious problem [1]. In addition for comparability and evaluation, their metrics must be applied to a set of coherent standardized data sets. Thus, all existing data sets are not sufficiently applicable to design anomaly-based HIDS for the modern IT landscape. Especially when modern operating systems, multithreaded applications and concurrent communications are considered.

The methodology presented in this paper enables the simulation and comprehensive recording of normal and attack behavior with an high degree of detail. Further, we suggest plausible practices for implementing this approach. This includes a procedure to generate new data sets on current operating systems. The latter are suitable to develop and evaluate algorithms for today's state of the art anomaly-based HIDS.

This work was partly funded by the German Federal Ministry of Education and Research within the project “Explicit Privacy-Preserving Host Intrusion Detection System” (EXPLOIDS) (BMBF federation code 16KIS0522K) and “Competence Center for Scalable Data Services and Solutions” (ScADS) Dresden/Leipzig (BMBF federation code 01IS14014B).

## A. Relevance in practice and research

Our methodology can be used to record normal behavior from productive systems. This generates models based only on the data actually captured from live containers. This is the opposite to today's HIDS that often rely entirely on data captured from a staged lab environment. This way, a user can simulate a security violation by implementing a custom policy. This results in a transparent process, in which an IDS can be build and evaluated with an productive system in mind.

The procedure model serves research primarily with experimenting and evaluation of new IDS algorithms. In today's research, new algorithms are evaluated with outdated and incomplete data sets. Current data sets with extensive context enable new research and better evaluation of the algorithms.

## II. BACKGROUND AND RELATED WORK

Since 1998 data sets for training and comparison of HIDS have been published. The best known are: the DARPA Intrusion Detection Evaluation Data Set (KDD), from 1998 to 2000 [2] the data set of the University of New Mexico (UNM) from 1999, [3], [4], the data sets of the Australian Defence Force Academy, the ADFA-LD from 2013 [5], [6] and the NGIDS-DS from 2017 [7]. They share at least one of the problems described by Grimmer et al. [8] as shown in table I. These data sets consist of sequences of system calls. The ADFA-LD for example is relatively up-to-date, but it does not provide thread information, parameters and return values. In addition it contains system calls of a complete system with all its processes. In particular, it is therefore not possible to learn the normal behavior of a single program from it. Short examples for all four data sets can be seen in listing 1.

Unfortunately, the authors of the data sets omit many details about their implementation. There is little information about the general conditions under which the recordings have been made. This refers to information on the recording process, the tools and software versions used or the attack vectors engineered into the system. Moreover, the normal behavior and its origin are either not described at all or only insufficiently described. Pendleton and Xu describe in [1] an architecture

based on a syscall collector for data generation. For instrumentation the Intel tool "Pin" is used<sup>1</sup>. It allows applications to be extended with their own source code at runtime and to profile the application. This allows thread-based system call sequences and context information to be captured. The authors show this with the software example Firefox. Abed et al. describe in [9] a real-time IDS for passive monitoring of Linux containers using the tool strace. The evaluation takes place with the example of the database application MySQL in the normal and malicious behavior under consideration of the frequencies of system calls. The data set was not published. In [10] older and new algorithmic approaches were compared that evaluate sequences of system calls. It was observed that both the detection and the false alarm rates of the different approaches could not be improved beyond a certain value. The authors' thesis is that the quality of HIDS can be improved if the algorithms also take into account context information such as parameters and return values for system calls. To pursue this thesis, a new data set containing such information is needed.

### III. REQUIREMENTS

Based on the weaknesses of the previous data sets [8], the following requirements apply to the new data set and the method of producing it: Over time, the number, syntax and semantics of system calls of operating systems have changed. For this reason and to solve the lack of topicality, the system calls of today's systems and current software must be considered. To ensure that the generated data sets can be kept up-to-date in the future, the simulation process should be replicable. To fix the lack of thread information, the recorded system calls must contain process and thread information. This allows the data set to correctly represent normal and attack behavior in today's multithreaded environments. In addition, the recorded system calls must include metadata such as their time stamps, parameter and return values to solve the mentioned lack of meta information. The size of the data set, i.e. the number of contained sequences and their system calls can be selected as required in order to carry out procedures with large training requirements, such as the training of a neural network. This solves the lack of data volume. Normal and attack behavior shall be recorded

<sup>1</sup><https://software.intel.com/en-us/articles/pin-a-dynamic-binary-instrumentation-tool>

according to the same procedure. The basic conditions such as operating system/kernel, the software used and versions should be identical. The only difference between normal and attack procedures is the attack carried out during the simulation. The process must be customizable in order to be able to adapt the collected data to the respective application area by implementing own scenarios.

### IV. METHOD

Our method considers the previously established requirements to collect suitable data sets for training and evaluation of a HIDS. By using this method, scenarios can be defined and both normal behaviour and attack behavior can be simulated and recorded. Simulation in this matter means the staged execution of benign and attacker behavior on an actual machine. The method basically defines the following procedure pattern: (1) The acquisition of events at kernel level (system calls). (2) The use of a container-virtualized environment. (3) A framework for instrumentation and configuration of scenarios.

The procedure is based on a system model in which three actors *Victim Unit*, *Normal Behavior Unit* and *Control Unit* are related. The development of a system model represents an application scenario. The Leipzig Intrusion Detection Data Set (LID-DS) framework was developed and provided as a reference implementation.

With it, scenarios that include or exclude vulnerabilities can be defined, simulated and recorded. In recent years, Microservice architecture has become more and more established. With such an architecture, complex software is composed of many loosely coupled services. Due to this development, the whole process is adapted for use in container virtualized environments. Therefore, the resulting dataset no longer describes an entire complex system but a single component, e. g. a web server. This is referred as a scenario.

The result is a set of captured instructions executed by the system in the form of system calls related to single application. This shifts the scope towards attack vectors based on behaviour and network communication. However, many choices pointed out here only require a little adjustment to support other scenarios.

#### A. System model of an application scenario

Scenarios implemented in the LID-DS are based on software using the client-server model. However, also centralized alternatives like the mainframe architecture or peer-to-peer applications are within the scope of the recording framework. An example is the web server scenario, which consists of one web server as well as  $n$  units which request it. Figure 1 list the schematic model in normal and attack behavior. The *Victim Container* describes the *Server* in the network. This is monitored by a *Container Sensor* that extracts normal and attack behavior. The Sensor works introspectively and records the events on kernel level in the form of system calls with minimal influencing the behaviour. *Normal Behavior Unit(s)* resemble the clients in the network. In a web server scenario, they would execute requests to call a web page. As with reality,

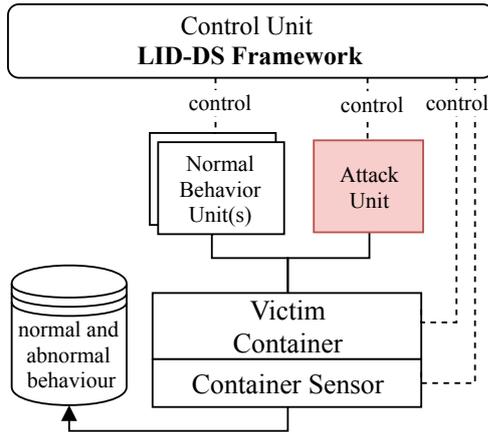

Fig. 1. system architecture to capture attack behavior

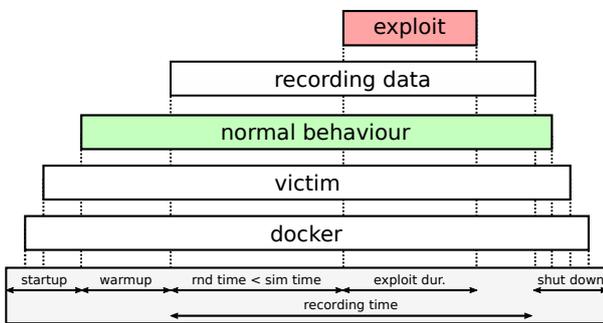

Fig. 2. Simulation procedure of LID-DS

several of these actors can exist to create a realistic normal behavior, including occasional load peaks. The *Attack Unit* also is a client in the network, which however executes an attack on the victim.

Normal behavior and attack behavior are caused by the influence of other entities like containers or processes. In a server-client application for example it is possible to map one or more webclients to a container. A separate *control unit* executes the LID-DS framework and implements the application scenario. LID-DS allows controlling the lifecycle of containers, which includes the initialization and configuration of the actors as well as the control and monitoring of the entire simulation process. Use cases are defined in the form of scenarios and executed by the process.

In this way, simple as well as more complex realistic scenarios, such as multi-step attacks, can be evaluated.

### B. Simulation procedure

The simulation process is shown in figure 2 and consists of the four consecutive phases *startup*, *warmup*, *simulation of normal program behavior*, *shutdown* and potentially the *exploit*. Basically, each implemented scenario is executed according to this procedure. At the beginning, the container is initialized and the Victim Container is configured and executed. At this point, benign user behavior is started to be executed with respect to the victim container. The subsequent

*warmup* phase includes a delay so that the system is in a steady (non-transient) state when recording starts. After the *warmup* delay has passed, the recording of the normal behavior begins. Granted, a malicious user pattern is supplied, the attack behavior gets executed at a randomly chosen time within the recording window. After the specified recording time has passed, the monitoring tool together with all containers gets shut down in reverse order that they started.

### C. Instructional System Call Tracer

Historically, *strace*<sup>2</sup> was used to monitor interactions between processes and the Linux kernel. *Strace* interrupts the traces process every time a system call is invoked, captures the system call, decodes it and then resumes the execution of the monitored process. It is obvious that while this behavior allows for easy recording and tampering of system instructions, for the purpose of recording system activity this is not very efficient. *Sysdig*<sup>3</sup> on the other hand, loads a small driver in the kernel that makes it possible to handle different events related to system calls. This event collection is, in contrast to *strace*, non-blocking. Furthermore, *Sysdig* pre-processes the data collected, combining information on system call executions with data from *tcpdump* or information on referenced files. Our approach settled on using *Sysdig* for recording system calls since it provides a pragmatical way of achieving the requirements identified here. This is best displayed by *Sysdig* providing export functionality, pre-processing of many file descriptors and rich filtering functionality, allowing for efficient prototyping. This choice, however, does not limit the approach's capabilities since *Strace* would allow for the extraction of data in a similar manner.

### D. Container Virtualization Engine

*Docker*<sup>4</sup> as a container virtualization engine (LXC) was chosen because it is a commonly used standard in practice. LXC is used to run multiple instances of the operating system isolated on a single host. In contrast to full virtual machine environments, guests share the kernel with each other. This level of virtualization allows a sufficient isolated environment to be created at the application level. To monitor one or more containers on the host, it is only necessary to inject the Sensor on the host level. This is resource-friendly and allows us to record application behavior with little impact to the system calls. It also gives us a high degree of flexibility in creating scenarios.

### E. LID-DS Framework

The LID-DS framework implements this procedure with minimal development effort. It covers all steps necessary for the simulation and recording of HIDS data. In detail, it takes care of the following steps: handling victim virtualization via *Docker*, System Call Tracing via *Sysdig* and communication between user behavior and victim via a bridge network. To

<sup>2</sup><https://linux.die.net/man/1/strace>

<sup>3</sup><https://github.com/draios/sysdig>

<sup>4</sup><https://www.docker.com>

schedule user actions the distribution introduced by Deng [11] has been chosen.

To record data of a scenario the following information must be defined: A Docker image, specifying the configuration of the victim environment, a set of benign user actions, an script exploiting a vulnerability of the victim and a metric to check for correct and finished initialization of the victim environment.

The LID-DS framework makes it possible to define several normal behaviors for a scenario and the associated victim. All of the passed behaviors are executed in parallel, each in its own thread. This makes it possible to simulate multiple parallel user sessions accessing the victim. This implementation opens up the possibility to mirror real-world network traffic instead of simulating staged user actions to the victim.

Within the scope of real world applications, many different scenarios can hopefully be defined by using a single user simulation definition. Furthermore, many malicious actions, especially actions of reconnaissance are indifferent to many victim configurations. For example, consider a TCP-SYN Scan using the nmap<sup>5</sup> tool.

## V. EVALUATION AND RESULTS

To evaluate how the proposed framework can be used to record host data consider CVE-2012-2122<sup>6</sup>, a tragically comedic security flaw in MariaDB/MySQL. A new data record is created by monitoring a vulnerable MySQL instance according to the procedure shown earlier. The setup consists of a Ubuntu Xenial in version 16.04 with the Docker version 18.09.6 and Sysdig in version 0.24.1. MySQL is used in version 5.5.23, which contains the vulnerability. The simulation time is 5 minutes, the time exploit is 120 seconds. As recording time we have chosen 5 minutes because Sysdig in its report<sup>7</sup> has surveyed an average running time of 5-10 minutes for containers. Two runs are performed. One run only generates normal behavior, a second run contains the attack on the vulnerability in addition to the normal behavior. As a result, the content and technical requirements from III are compared to this data set. The resulting data set is compared to the commonly used IDS data sets on basis of the categorized requirements (Table I).

### A. Comparison

The focus of this comparison is on the resulting artifact, the data set and the features it contains. Concerns related to efficiency during the recording phase are not considered in this paper. The central question is whether this procedure, measured against the result, can solve the criticism and problems of the previous data sets. The evaluation resulted in two data sets. Data set 1 contains normal behavior and includes 46839 system calls. Data set 2 contains normal and attack behavior and includes 128799 system calls. Listing 2 shows an excerpt

<sup>5</sup><https://nmap.org>

<sup>6</sup><https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2122>

<sup>7</sup><https://sysdig.com/blog/2018-docker-usage-report/>

TABLE I  
FEATURE COMPARISON LID-DS WITH OTHERS

feature	LID-DS	NGIDDS	ADFA-LD	UNM	KDD
topicality	+	+	+	-	-
thread info	+	+	-	+	+
metadata	+	-	-	-	+
data volume	+	+	-	-	+
reproduceability	+	-	-	-	-

of data set 2. For the interpretation of the results, the classified requirements are compared below.

1) *Lack of topicality*: The data was recorded on a modern Linux system, which has over 370 different system calls. The containerized environment and the LID-DS framework makes it easy to repeat such runs for different versions of operating systems. This makes sense because the number of system calls varies from operating system to operating system. The data set can be updated simply by adjusting the configuration and running it again.

2) *lack of thread information*: For each system call in the recording period the thread ID on which the process is running is recorded, as shown in listing 2. This ensures that the multithreading information that is important today is not lost. The most recent data set ADFA-LD lacks this information.

3) *lack of metadata*: For each system call, the data record contains extensive meta information such as high-precision time stamps, process name, transfer parameters and a section of the data buffer. The time stamps in the NGIDDS are only accurate to the second, which can lead to errors in the sequence.

4) *lack of volume*: Over 100 000 system calls were recorded during the survey period. For example, ADFA-LD, as well as the highly obsolete UNM data set, provides a smaller, fixed data set of system calls. The data collection period can be configured in LID-DS so that larger or smaller data records can be generated according to individual requirements.

5) *lack of reproduceability*: By using LXC, the entire simulation can be defined with the LID-DS framework and stored. Including software versions, parameters or configurations. The performed evaluation is stored in Github as *example*<sup>8</sup> and can be viewed and performed by anyone. The framework itself is published under the GNU General Public License. As we know, this is the first time that a process for generating HIDS datasets is available to the public in a fully reproducible form.

### B. Results

Overall, there is a significant superiority of the approach to generating modern HIDS data sets, as shown in table I. By using the LID-DS Framework, all technical and content requirements are fulfilled. The framework allows modern and operating system specific data sets to be generated, which is important to avoid training neural networks on the basis of outdated or incorrect system calls or nowadays uncommon

Sprockets info. leak	CVE-2018-3760
SQL injection with sqlmap	CWE-89

operating systems. The amount of data is also important for neural networks, which can be adapted by LID-DS. Multi-threaded information is valuable to view the behavior of a system down to the application and thread level. In this context, the metadata and parameters are also relevant. These can also contain application-specific information and support the correct interpretation of the application behavior. The overall approach provides the basis to effectively compare and evaluate HIDS in the future and to develop new classification features based on thread information, metadata and parameters in order to significantly increase the recognition rate and accuracy of HIDS.

## VI. CONCLUSION

The need for modern, uniform and metadata enhanced data sets can be satisfied by implementing this approach. This way, LID-DS is a significant contribution to future research, evaluation and comparability of Host-Based Intrusion Detection Systems. Additionally, this approach only needs slight adaptations to be functional in production environments. The major advantage of this approach is that it provides a high degree of flexibility in the form of scenarios that can be adapted to individual technical as well as policy requirements. For example, the evaluation MySQL example<sup>9</sup> from chapter V can easily be adapted using real network data. With this approach we have created a new data set. It was published as "Leipzig Intrusion Detection - Data Set (LID-DS)" in [8] which contains different use cases shown in table II. LID-DS framework and ready to use data sets are free to use and published on GitHub<sup>9</sup>. It is the first HIDS data set which contains normal and abnormal behavior, system calls and their timestamps, thread ids, process names,

<sup>9</sup><https://github.com/LID-DS/LID-DS>

arguments, return values and excerpts of their data buffers from traces of normal and attack behavior of several recent, multi-process, multi-threaded scenarios. Many of the included features cannot be extracted from previous data sets. With it, known algorithms can be enhanced or new algorithms, based on the various included features, can be explored. Additionally, staged scenarios based on internal expert knowledge can give a practical prediction on the performance of an algorithm. The approach outlined in this work focuses on giving every actor the possibility to build their own model from their own experienced traffic. Further information on the development of LID-DS and initial analyses can be found in the works of [12] and [13]. An extension of the procedure to include network sensors is planned. Furthermore, an updated version of the data set is scheduled to be released once a year. Every version should expand the data set by including recordings of the latest commonly used software systems as well as disclosed vulnerabilities. Additionally, recordings based on new versions of the Linux kernel and configurations according to new techniques used in development, hosting and pentesting will be the target of these extensions. We anticipate feedback to allow for the progressive development of a data set that finally allows for reproducible IDS research.

# 3<sup>rd</sup> Workshop on Internet of Things—Enablers, Challenges and Applications

**T**HE Internet of Things is a technology which is rapidly emerging the world. IoT applications include: smart city initiatives, wearable devices aimed to real-time health monitoring, smart homes and buildings, smart vehicles, environment monitoring, intelligent border protection, logistics support. The Internet of Things is a paradigm that assumes a pervasive presence in the environment of many smart things, including sensors, actuators, embedded systems and other similar devices. Widespread connectivity, getting cheaper smart devices and a great demand for data, testify to that the IoT will continue to grow by leaps and bounds. The business models of various industries are being redesigned on basis of the IoT paradigm. But the successful deployment of the IoT is conditioned by the progress in solving many problems. These issues are as the following:

- The integration of heterogeneous sensors and systems with different technologies taking account environmental constraints, and data confidentiality levels;
- Big challenges on information management for the applications of IoT in different fields (trustworthiness, provenance, privacy);
- Security challenges related to co-existence and interconnection of many IoT networks;
- Challenges related to reliability and dependability, especially when the IoT becomes the mission critical component;
- Zero-configuration or other convenient approaches to simplify the deployment and configuration of IoT and self-healing of IoT networks;
- Knowledge discovery, especially semantic and syntactical discovering of the information from data provided by IoT;

The IoT conference is seeking original, high quality research papers related to such topics. The conference will also solicit papers about current implementation efforts, research results, as well as position statements from industry and academia regarding applications of IoT. The focus areas will be, but not limited to, the challenges on networking and information management, security and ensuring privacy, logistics, situation awareness, and medical care.

## TOPICS

The IoT conference is seeking original, high quality research papers related to following topics:

- Future communication technologies (Future Internet; Wireless Sensor Networks; Web-services, 5G, 4G, LTE, LTE-Advanced; WLAN, WPAN; Small cell Networks...) for IoT,

- Intelligent Internet Communication,
- IoT Standards,
- Networking Technologies for IoT,
- Protocols and Algorithms for IoT,
- Self-Organization and Self-Healing of IoT Networks,
- Trust, Identity Management and Object Recognition,
- Object Naming, Security and Privacy in the IoT Environment,
- Security Issues of IoT,
- Integration of Heterogeneous Networks, Sensors and Systems,
- Context Modeling, Reasoning and Context-aware Computing,
- Fault-Tolerant Networking for Content Dissemination,
- Architecture Design, Interoperability and Technologies,
- Data or Power Management for IoT,
- Fog—Cloud Interactions and Enabling Protocols,
- Reliability and Dependability of mission critical IoT,
- Unmanned-Aerial-Vehicles (UAV) Platforms, Swarms and Networking,
- Data Analytics for IoT,
- Artificial Intelligence and IoT,
- Applications of IoT (Healthcare, Military, Logistics, Supply Chains, Agriculture, ...),
- E-commerce and IoT.

The conference will also solicit papers about current implementation efforts, research results, as well as position statements from industry and academia regarding applications of IoT. Focus areas will be, but not limited to above mentioned topics.

## EVENT CHAIRS

- **Cao, Ning**, College of Information Engineering, Qingdao Binhai University
- **Furtak, Janusz**, Military University of Technology, Poland
- **Hodoň, Michal**, University of Žilina, Slovakia
- **Zieliński, Zbigniew**, Military University of Technology, Poland

## PROGRAM COMMITTEE

- **Al-Anbuky, Adnan**, Auckland University of Technology, New Zealand
- **Antkiewicz, Ryszard**, Military University of Technology, Poland
- **Baranov, Alexander**, Russian State University of Aviation Technology, Russia

- **Brida, Peter**, University of Zilina, Slovakia

# Remote Programming and Reconfiguration System for Embedded Devices

Tomasz Michalec, Maksymilian Wojczuk, Robert Brzoza-Woch, Tomasz Szydło  
AGH University of Science and Technology,  
Department of Computer Science, Krakow, Poland.  
Email: robert.brzoza@agh.edu.pl

**Abstract**—This article presents a concept of a system which can be utilized as a remote management add-on for embedded devices. It can be applied to resource-constrained wireless sensors and IoT nodes based on a general purpose microcontroller unit or a field programmable gate array (FPGA) chip. The proposed solution facilitates remote firmware update, management, and operation monitoring. Thanks to the utilization of standard protocols and interfaces, the proposed system is very flexible and it can be easily customized for multiple modern microcontrollers or programmable logic chips. The presented system can be an efficient solution for fast prototyping and it can be an alternative to a time-consuming process of bootloader development for ad hoc devices. It can also be applied to remote laboratory access for educational purposes. A proof of concept prototype implementation has been successfully developed and evaluated. The implementation is available on a free license and utilizes a commonly available and inexpensive hardware platform.

## I. INTRODUCTION

INTERNET of Things (IoT) uses multiple nodes distributed among different physical locations. The nodes may require remote management and firmware upgrade mechanisms to be implemented. As the IoT systems are often utilized for monitoring and interaction with an environment, their operation has to be either well simulated or tested in a laboratory or in a target environment. If embedded or IoT software developers choose the approach that involves practical testing, the problem of the remote management of IoT nodes arises – it includes monitoring of a node operating condition, setting its operation parameters, and upgrading its firmware.

In production environments, a common approach of deploying a remotely manageable embedded device is to implement a bootloader. Unfortunately, the process of developing a bootloader software may be a very demanding and complex task – the software needs to be well tested because it is a crucial part of the system. In case of the bootloader malfunction, while the device's software development is at an early stage, the device becomes unusable until reprogrammed directly through a local interface. That requires physical access to the device's hardware – it can be very inconvenient in the domain of IoT and sensor nodes which may operate in remote locations.

In this paper, we present a concept and a sample implementation of a versatile add-on subsystem for remote management of embedded devices, IoT platforms, especially based on resource-constrained MCUs.

## II. RELATED RESEARCH AND AVAILABLE SOLUTIONS

A common scientific issue is designing a remote laboratory which is usually utilized to allow for remote access to laboratory infrastructure via the Internet [1], [2]. There are presented extensions of this concept, which allow designers to implement the remote laboratory on a single-board computer (SBC), but still it requires to run a full-featured operating system, e.g. Linux [3]. Such an operating system requires a large amount of hardware resources and energy.

A natural solution for firmware updates is to write a bootloader program. However, such a bootloader must be extremely reliable and it is more difficult to write a reliable bootloader which itself could be updated remotely using e.g. wireless connection [4]. Currently, one of the leading solutions in the field of remote management of the embedded devices is the utilization of the OMA Lightweight M2M (LWM2M) protocol [5], [6]. It is based on Constrained Application Protocol (CoAP) which is popular in the IoT domain [7] due to its relatively low resource requirements.

There are commercial solutions requiring additional hardware that could program flash memories of MCUs through the network, e.g. XDS220 USB/Ethernet JTAG Emulator or the Intel FPGA Ethernet Cable as used in [8]. However, those solutions are usually expensive, and their application is usually limited to a vendor-dependent subset of supported devices. Considering their application for a large number of managed nodes might not be economical.

A time-efficient approach for remote programming, software development and prototyping of embedded devices [9] may be more convenient if the remote reconfiguration is applied. The utilization of SBCs, such as Raspberry Pi, becomes more and more popular [10] even for high-end and military applications [11]. When equipped with proper software, such as the OpenOCD [12], [13], the Raspberry Pi SBCs can become remote management nodes as in e.g. [14].

## III. PROBLEM STATEMENT

After analyzing the available literature and solutions we decided to develop a concept of the remote development tool for MCU-based embedded systems with an option to expand its functionality to remote reconfiguration of FPGAs. The concept should allow designers to develop, customize, and deploy the versatile remote programmer-monitor tool for facilitating embedded software development.

The discussed problem concerns the development of multi-node systems based on embedded devices that require remote and batch firmware updates. The designed solution should meet the following crucial requirements: (1) the solution should be versatile or at least easy to adapt and extend for various MCU hardware platforms with an option for future FPGA configuration support; (2) the remote programming system should allow for easy interaction with remote embedded devices – mainly the firmware update; (3) it should detect the connected target board and adjust parameters automatically; (4) The remote reconfiguration tool should be able to operate on a commonly available and inexpensive hardware platform; (5) the interface for the user or a developer should be platform-independent.

#### IV. THE DESIGN CONCEPTS

In this section, we present suggested choices and concepts for implementing the remote reconfiguration system based on the requirements stated in Section III.

##### A. General architecture and communication

We propose the following architecture of the remote programming system. The system may consist of two separate main parts: (1) the hardware part called the Remote Programming Device (RPD) further in this article and (2) the management part which is a user application for interacting with one or more RPDs.

The *RPD* is able to remotely reprogram internal memories of microcontrollers with provided binary firmware files and optionally to reconfigure FPGA integrated circuits. Primarily is intended to work as a temporary add-on to an embedded device or an IoT node during final stages of software development. It can also be utilized for diagnostic and long-term monitoring purposes in prototype and experimental IoT systems. The embedded device, which is managed, reprogrammed, or reconfigured by the RPD, is in this paper referred to as the *target device*.

The *management part* is intended to run on a user's host computer. For the purposes of communication between the two parts of the system, we have chosen and recommend the LWM2M protocol due to its popularity, basic security, and ability to communicate not only within local networks but also globally over the Internet. As the management part, we decided to use the Eclipse Leshan<sup>1</sup> implementation of the LWM2M server. It provides a Web-based user interface (UI) which allows for interaction with connected RPDs. That interface does not need any additional specific software to be installed on the management computer.

To provide versatility, the RPD is recommended to communicate with the target device using a standard and popular interface, primarily Joint Test Action Group IEEE 1149.1 (JTAG) and, eventually, Serial Wire Debug (SWD). An MCU for RPD may be a typical inexpensive unit for embedded systems purposes. The Ethernet was chosen to implement a

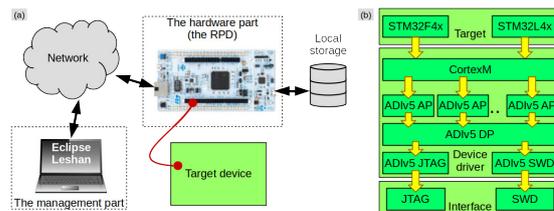

Fig. 1. RPD architecture and usage (a) and RPD abstraction layers diagram (b).

convenient physical layer for Internet Protocol (IP) communication. For the prototype implementation, we have chosen the Nucleo boards equipped with STM32F429ZI MCU with ARM Cortex-M4 microprocessor core. RPD uses a USB flash drive to store programming files and configuration locally.

The proposed remote programming architecture has been shown in Figure 1a.

#### V. SELECTED DETAILS OF SAMPLE IMPLEMENTATION

A sample software for the remote programming system has been successfully implemented. This section contains selected details which concern practical aspects of the remote programming system operation.

##### A. RPD general architecture

The RPD has been designed to be easily extendable. Its architecture is based on layers. Figure 1b shows the designed organization of the layers. The first layer, denoted as *Target*, is the only layer exposed to the external interface described further in Section V-B. The *Target* layer purpose is to represent all programmable devices in a unified way. The *Device driver* is an intermediate layer which can be partitioned into multiple sub-layers. The driver sub-layers are able to communicate with devices supporting ARM Debug Interface Access and Data Ports (ADiv5 AP and ADiv5 DP). Such an architecture allows similar devices to share common parts of software implementation. This layer is independent of hardware. The *Interface* is the lowest layer and it encapsulates logic needed to use a physical medium. It is tightly coupled with hardware used to realize the RPD.

As a proof of concept implementation, we provide support for programming two different MCUs. The users and developers can extend the range of the supported programmed chips by modifying the provided source code. Further details on the RPD are elaborated in Section V-C.

##### B. Communication part

We used a standard LWM2M protocol stack with the CoAP over User Datagram Protocol (UDP) implemented with the LwIP stack – a commonly used TCP/IP stack designed for embedded devices. We have used Eclipse Leshan as the LWM2M server to provide the user with a generic Web-based UI for managing the programmer resources.

The communication with the management part includes two parts: the management interface using the LWM2M and the file download part with the Hypertext Transfer Protocol (HTTP). The LWM2M implementation at the RPD side uses

<sup>1</sup><https://www.eclipse.org/leshan/>

the Wakaama code [5], [15]. The user can browse, read and update each connected device's properties through the UI. LWM2M server sends user's actions to particular devices and calls adequate procedures associated with resources. The firmware URL resource contains the URL of the current binary file. Once updated, the device downloads the newest firmware version from the HTTP server. A simplified process has been shown in Figure 2.

The whole communication between the user and the RPD is done through the LWM2M Server, excluding the binary download which is done using the HTTP. In order to ensure basic functionality for the sample implementation, we have defined an object representing the Remote Target – an embedded device to be programmed. The object contains properties necessary to monitor and control vital aspects of the remote target. The network configuration mechanism has been implemented and it can be dynamically changed without direct physical access to the device.

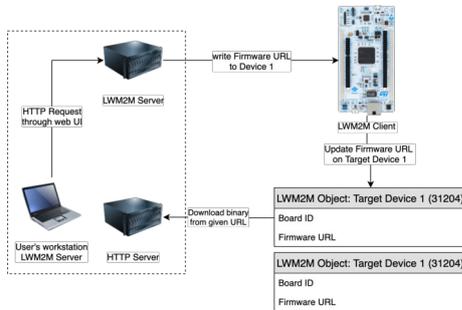

Fig. 2. Simplified communication flow (the LWM2M Server, the HTTP Servers, and the user's workstation may or may not be running on a single machine).

### C. Programming part

The sample implementation of the RPD is able to program flash memory of the following MCU families: STM32F4xx, STM32L4xx. Both of them are similar, but the STM32L4xx uses more energy-efficient technology and has updated hardware peripheral modules. JTAG has been selected as the hardware interface for the MCU programming in the prototype implementation. The JTAG's daisy-chaining feature is supported in the sample firmware. The RPD is also able to perform automatic discovery of connected devices by using their IDCODE registers. Discovered devices are exposed as independent targets to the management part.

## VI. PROTOTYPE EVALUATION

Further in this section, we present a quantitative evaluation of the sample implementation of the RPD and its analysis.

### A. Network communication

The system presented in this paper is intended to provide the possibility to transfer a new firmware binary file from the *management part* to a target embedded device programmed by an RPD. The main goal of the system is to allow for programming the target located in a distant physical location. To prove that functionality and usefulness of the created

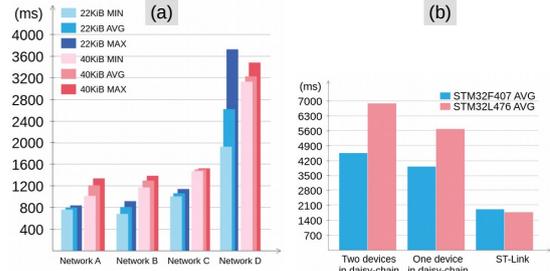

Fig. 3. Comparison of binary files download time (a) and programming time (b).

system we have tested time performance for different network environments. We conducted 5 practical tests for each of the following network conditions:

- **Network A:** The LWM2M server, the HTTP server, the user's computer, and the RPD with target boards are located in the same local network. The user's computer is connected with the router and switch through Wi-Fi interface.
- **Network B:** The LWM2M server, the user's computer, and the RPD are placed in the same local network, but the binary file is downloaded from an external HTTP server in another network but in the same city Kraków, Poland.
- **Network C:** The LWM2M server is running on the Amazon Elastic Compute Cloud (Amazon EC2) instance from Amazon Web Services in Frankfurt Datacenter and the binary files are placed also in Frankfurt, on the Amazon Simple Storage Service (the Amazon S3). User's computer, the RPD connected to target boards are located in Kraków, Poland, in the same local network.
- **Network D:** In this test set-up, the user's computer as a virtual machine, the LWM2M Server, and the HTTP Server on the EC2 Instance from Amazon Web Services were located in the United States Datacenter while the RPD was in the AGH University network in Kraków, Poland, Europe.

The results are shown in Figure 3a. The binary download time to the target is similar for the local network conditions and across neighbouring countries on one continent – in all of those cases the system has a similar level of its overall usefulness and the physical distance had only a limited impact on the overall system performance. The network overhead plays a greater role in large distances as in the *Network D* case. However, system can then still be considered useful because the binary download time does not exceed 4 s.

### B. The target device programming

This section discusses its overall performance in different scenarios with reference to the underlying dependencies of this process. The information can be useful in comparison with other available commercial solutions than mentioned in this section and also to provide more complete information for scientists and engineers who wish to contribute to the RPD development.

Time required for the programming process includes overhead for communication between the RPD and a target device,

erasing the target's flash memory, and the target's flash memory programming.

The JTAG clock signal (TCK) was set to 1 MHz. For erasing flash memory on STM32F4xx and STM32L4xx we utilized a mechanism to erase only those memory regions that were going to be programmed. For programming the STM32L4xx we used a binary file with size 40 KiB. STM32F4xx was programmed using a binary file with size of 22 KiB.

Tests in the following scenarios have been performed: (1) RPD with two devices in JTAG daisy-chain, (2) RPD with one device in JTAG chain, and (3) ST-Link programmer connected locally with USB. The latter scenario served as a reference for comparison with a commercial solution. All tests were repeated 5 times and the average time is presented in Figure 3b.

The process of programming a target device while another one is in JTAG daisy-chain takes longer than programming one target device only, because it was required to write the *BYPASS* instruction to all other devices in the chain. There is also additional code in the RPD that needs to be executed to handle multiple targets.

Even the STM32L4xx binary file is almost two times larger than the STM32F4xx program, time for flashing the STM32L4xx increased only 145%, because it also includes an overhead for programming operation.

The RPD firmware was compiled with the free GCC cross compiler, arm-none-eabi-gcc. With the compiler optimization level set to *Og*, the resulting firmware size is 149.2 KiB and the RPD program requires 135.4 KiB of static data memory.

The measured power consumption of the RPD is 1.1 W with fully operational Ethernet interface but without an external mass storage device. The total power consumption may vary depending on the utilized mass storage memory, usually a USB flash drive. In practice, the measured total power consumption with a flash drive connected is approx. 1.2 W.

## VII. CONCLUSION AND FUTURE WORK

In this article, we present a concept of the remote programming, configuration, and monitoring system for development and testing of embedded devices and IoT nodes.

The sample implementation of the reconfiguration system has been successful, the basic proof-of-concept functionality has been achieved, and the requirements stated in Section III are met which proves the overall correctness of the presented concept. The remote management interface is easy to use and can be run on many different operating systems thanks to the utilization of the Leshan LWM2M implementation with Web-based GUI. The created RPD software is ready for users to further develop the RPD functionality according to their own use cases, including new programmed devices, sensors, etc. The developed software is available on GitHub<sup>2</sup> on the free (MIT) license. The hardware price of the remote programming system presented in this paper is much lower than the commercial solutions presented in Section II. However, this implementation may require additional work needed for

customizing it for specific, not yet supported use cases. The additional labor cost can be less noticeable if the multiple RPDs with the same custom firmware are deployed.

Future improvements may include implementing a support for the SWD interface, optimizing storage management and flash memory writing, as well as remote management of the RPD firmware and health checks of the connected target devices using additional sensors.

## ACKNOWLEDGMENT

The research presented in this paper was partially supported by the National Centre for Research and Development (NCBiR) under Grant No. LIDER/15/0144/L-7/15/NCBR/2016.

# A Framework for Autonomous UAV Swarm Behavior Simulation

Piotr Cybulski

Military University of Technology  
ul. Kaliskiego 2,  
00-908 Warszawa, Poland  
Email: piotr.cybulski@wat.edu.pl

**Abstract**—In the last several years a large interest in the unmanned aerial vehicles (UAVs) has been seen. This is mostly due to an increase of computational power and decreasing cost of the UAVs itself. One of an intensively researched area is an application of a swarm behavior within team of such UAVs. Simulation tools are one of the means with which quality of solutions in this matter can be measured. In this paper such simulation framework is proposed. The proposed framework is capable of taking under consideration interferences between communicating UAVs, as well as interaction between UAV and surrounding environment. Mathematical models based on which simulation is performed were described, definition of simulation scenario and results of exemplary simulation were also presented.

## I. INTRODUCTION

THE unmanned aerial vehicles, commonly called as drones, are gaining more interest by both civilian and military organizations. From an academic perspective drones are specially interesting because of the swarm intelligence, that can be implemented into them. Combining the artificial intelligence (AI) with the UAV swarms can significantly change the way of providing services such as traffic monitoring, area patrolling or, in the military area of interests, creating a situational awareness. There are many propositions how to approach the swarm intelligence subject so that results will meet the requirements [1], but there is a lack of a common framework to compare results. One of the reasons is large variety of task types for the swarms. To name a few, search and attack on a target[2][3][4], area patrolling[5][6], disaster operations[7] or transportation services[8]. Currently, there are tools for simulating specific algorithms[9] or certain scenarios [7]. There is, however, lack of a general purpose tool for UAV swarm simulation. In this paper I presented the simulation framework to fill this gap.

## II. RELATED WORK

Due to large interest in the area of drone swarms, there have been developed few tools for simulating them. These are mainly for prototyping solutions and studying how does single UAV, or swarm of them, act in a particular scenario. Majority of them is designed to simulate a predetermined type of scenarios such as search and attack on target[4][9] or disaster operations[7]. Some of currently working simulators are based

on commercial software such as Matlab[10] or X-Plane[11]. Finally, there are programming languages, the Proto[12] for example, designed specifically for testing certain paradigms (amorphous computing in this case) application in the UAV swarms area.

## III. PRELIMINARIES AND BASIC DEFINITIONS

Using the definition from [1] let's define the UAV swarm as a team of an autonomous unmanned aerial vehicles, where behavior of a single UAV emerges from its inner state and from surrounding environment, including neighbor UAVs. Because of wide range of tasks for UAV swarms and scale of solutions for these tasks, the following assumptions were made regarding algorithms which are compatible with proposed framework:

- 1) The UAV swarm is controllable in decentralized manner;
- 2) No common knowledge database is being used. Each UAV has to either have necessary information, or it has to be able to obtain it during a mission;
- 3) An environment in which swarm is operating is continuous three dimensional space, or it must be convertible to such.

Each simulation object “inside” framework is treated in the same way in terms of controlling its behavior. It is possible to combine the fully autonomous object, such as swarm's members, with manually controlled units (e.g. proxies between an operator and the swarm). The later described framework is not restricted to any particular types of a mission. However, it is important to point out that mission objectives supported by the framework must be evaluable solely on the situation in the moment at which evaluation is performed. We will define mission objectives as a set of states simulation objects must be in. Formally a mission objective will be described in IV-C

## IV. THE BASIC SWARM MODEL

The main inspiration for basic swarm model was taken from “the asynchronous event-driven robotic network” presented in [13]. Following are main differences between basic swarm model and the one mentioned above:

- 1) A sender of a message is not known explicitly to a receiver, they can be inferred (if there is a need for it) from the message itself;

- 2) In each simulation moment there can be generated multiple messages by all objects.

#### A. The goal

The basic swarm model shall be capable of simulating communication between objects. Communication, if occurs, is not altered in any way between a sender and a receiver. In other words, interference is not taken under consideration.

#### B. The description of basic model's components

A core element of the model is a *simulation object*. Every entity modeled within simulation has to be considered as a simulation object. There are two types of simulation objects: passive and active. Passive simulation objects are aimed to represent entities such as:

- 1) On-the-ground beacons;
- 2) The GPS;
- 3) An environment.

These objects play important role in the behavior of the swarm (and not only that), but their key trait is that they are not changing its behavior due to an interaction with "outside world" (other simulation objects). Active simulation objects on the other hand are designed to represent real world's entities like:

- 1) Ground and aerial vehicles (drones for example);
- 2) Humans;
- 3) Anti-aircraft systems.

**Definition 1. The Simulation Object (SO)**, as the core element of the simulation, consists of following components:

- 1) A logical state;
- 2) A physical state;
- 3) An identifier.

A logical state shall contain all data required to control behavior of a simulation object. For example, a logical state can be composed of information about whether the simulation object is still alive, or what is its destination.

A physical state shall contain all data required to visualize simulation object in simulation's world, example of such data might be its position and rotations about each of axes.

A SO's identifier shall be unique name of this object during simulation. Each pair of identifiers shall be comparable (on whether they are equal or not), and for the set of all identifiers the relation of order shall be established on.

The main reason for distinguishing logical state from physical state is to emphasize that they may differ even if they represent the same phenomenon. As an example let us consider a position of an object. In this case the physical state would represent actual values, one may say the values that are correct. The logical state in this case could represent data received from devices such as the GPS or some on-the-ground localization systems. It may happen that these two states will be very different from one another, specially if simulation object will not be able to establish connection with positioning system.

**Definition 2. The Passive Simulation Object (PSO)** is an extension of the simulation object. It can send messages,

but it cannot receive any. Passive simulation object is the simplest element that can take part in the simulation. Each PSO contains, despite what it has inherited from SO, following elements :

- 1) A physical state update function; (PSUF)
- 2) A physical state control function; It produces an input for the PSUF; (PSCF)
- 3) A messages generation function; (MGF)
- 4) A messages generation function trigger; (MGFT)
- 5) A (logical) state transition function (STF) and its trigger (STFT);

**Definition 3. The Active Simulation Object (ASO)** is an extension of the passive simulation object. Its capabilities extends PSO in a way that it is can receive messages. Each ASO contains, above what it has inherited from PSO, message receiving function.

#### C. Formal definitions of the basic model's components

Let  $I^{SO}$  denote a set of all (passive) simulation objects' identifiers. By  $I^{ASO} \subset I^{SO}$  we denote set of active simulation objects' identifiers, this is a subset of the set of all the identifiers. Sets  $LS_i, i \in I^{SO}$  and  $PS_i, i \in I^{SO}$  denotes accordingly a set of all possible logical states of simulation object, and a set of all physical states of the same object.

For all simulation objects there is a common set of basic physical state attributes  $PS_0$  defined as follows:

$$\forall i \in I^{SO} : PS_i = X_i^{PS} \times PS_0$$

$X_i^{PS}$  - a set of secondary physical state attributes used by the  $i^{th}$  simulation object.

Using the above definitions we can define following behavior controlling functions.

#### Definition 4. The Physical State Update Function

$PSUF_i : PS_i \times U_i \rightarrow PS_i, i \in I^{SO}$  - a physical state update function used by the  $i^{th}$  object.

$U_i, i \in I^{SO}$  - a set of vectors to control the  $i^{th}$  physical state.

#### Definition 5. The Physical State Control Function

$PSCF_i : PS_i \times LS_i \rightarrow U_i, i \in I^{SO}$  - a physical state control function used by the  $i^{th}$  object.

#### Definition 6. The State Transition Function Trigger

$STFT_{i,j} : LS_i \times PS_i \rightarrow \{true, false\}, j \in I_i^{STF}, i \in I^{SO}$  - a trigger of the  $j^{th}$  state transition function used by the  $i^{th}$  object.

#### Definition 7. The State Transition Function

$STF_{i,j} : PS_i \times LS_i \rightarrow LS_i, j \in I_i^{STF}, i \in I^{SO}$  - the  $j^{th}$  state transition function used by the  $i^{th}$  simulation object.

#### Definition 8. The Messages Generation Function Trigger

$MGFT_i : PS_i \times LS_i \rightarrow \{true, false\}$  - a messages generation function trigger used by the  $i^{th}$  simulation object.

In order to define last two functions we need to define one additional set:

$M^\infty$  - set of all messages.

#### Definition 9. The Messages Generation Function

$MGF_i : PS_i \times LS_i \times I^{SO} \rightarrow 2^{M^\infty}, i \in I^{SO}$  - a message generation function used by the  $i^{th}$  object.

**Definition 10. The Communication Capability Function**

$E_{comm} : \prod_{i \in I^{SO}} PS_i \rightarrow 2^{I^{SO} \times I^{SO}}$  – a communication capability function.

Interpretation:  $\forall i, j \in I^{SO} : \langle i, j \rangle \in 2^{I^{SO} \times I^{SO}} \iff i^{th}$  and  $j^{th}$  simulation objects can communicate with each other (they can exchange messages with one another).

**Definition 11. The mission objective of UAV swarm**

Let  $I_i^T \subset \mathbb{N}, i \in I^{SO}$  denote a set of tasks for the  $i^{th}$  object identifier.

Additionally let

$$M_i = \{T_{i,j} : PS_i \times LS_i \times \mathbb{Z} \rightarrow \{true, false\}\}_{j \in I_i^T}$$

denote a set of tasks for the  $i^{th}$  object. Interpretation of the function  $T_{i,j}$  is as follows. If physical and logical state, at the moment of function execution, meet the criteria of  $j^{th}$  task then the function returns *true*, otherwise it returns *false*. Having defined tasks for the  $i^{th}$  simulation object, a mission objective is the set of all tasks for every object, that is:

$$M = \bigcup_{i \in I^{SO}} M_i$$

A mission objective is considered as completed if all tasks for every object are accomplished.

$$\forall i \in I^{SO} \forall j \in I_i^T : T_{i,j}(ps_i(t), ls_i(t), t)$$

where:

$ps_i(t) : \mathbb{Z}_+ \rightarrow PS_i$  – a function returning physical state of the  $i^{th}$  object for a given simulation moment.

$ls_i : \mathbb{Z}_+ \rightarrow LS_i$  – a function returning logical state of the  $i^{th}$  object for a given simulation moment.

$t \in \mathbb{Z}_+$  – the simulation moment at which task condition is being checked.

**D. The simulation**

In the following section we will use defined herein notation for description of simulation steps. Notation:

$$\forall x \in X : func_1(x), i = x; X \subset \mathbb{Z}$$

is equal, in C# programming language, to:

```
foreach (int x in X)
{
    func1(x);
    i=x;
}
```

Let's define the basic swarm model simulation as follows. For subsequent  $t \in \mathbb{Z}_+$ , where  $\mathbb{Z}_+$  is the set of positive integer numbers:

- 1)  $\forall i \in I^{SO}$  update physical state of the  $i^{th}$  object:
 
$$u_i(t) = PSCF_i(ps_i(t), ls_i(t))$$

$$ps_i(t) = PSUF(ps_i(t), u_i(t))$$
- 2)  $\forall i \in I^{SO}$  check if the  $i^{th}$  object generates messages:
 
$$d_i(t) = MGFT_i(ps_i(t), ls_i(t))$$
- 3) Based on previous check, generate messages:
 
$$\forall i \in I^{SO} : d_i(t) == true \Rightarrow$$

$$M_i^\infty(t) = MGF_i(ps_i(t), ls_i(t), i)$$

- 4) Generate communication graph:

$$c(t) = E_{comm}(\prod_{i \in I^{SO}} ps_i(t))$$

- 5) Each **active** simulation object receives all messages from all objects it can communicate with:

$$\forall i \in I^{ASO} \forall \langle i, j \rangle \in c(t) \forall m \in M_j^\infty(t) : ls_i(t) = MRF_i(ps_i(t), ls_i(t), m)$$

- 6) Every simulation object updates its logical state:

$$\forall i \in I^{SO} \forall j \in I_i^{STF} : v_{i,j} = STFT_{i,j}(ls_i(t), ps_i(t))$$

$$\forall i \in I^{SO} \forall j \in I_i^{STF} \forall v_{i,j} == true : ls_i(t) = STF_{i,j}(ls_i(t), ps_i(t))$$

- 7) The logical and physical state of all objects at the end of each iteration becomes their initial state in the next iteration:

$$ls_i(t+1) = ls(t)$$

$$ps_i(t+1) = ps_i(t)$$

**V. THE EXTENDED MODEL WITH STIMULI**

The basic model was extended by adding sets of stimuli. The main reason for this was to allow the simulation objects to interact with fragments of the environment rather than directly interact with each other. All definitions from the basic model remains unchanged.

**A. The goal**

Main goals of the extended model were:

- 1) To allow an interference in communication between the objects to occur;
- 2) To add an influence of observer's position on content of received message. For example we can consider a loudness of a sound, that will be perceived differently by objects located in different places.

**B. The description of extended model's components**

All the definitions from IV-C stays unchanged, below are listed only new elements of the model.

**Definition 12. The stimulus**

A stimulus is a carrier of messages. By analogy we can exemplify it as radio waves.

**Definition 13. The Passive Simulation Object using Stimuli (PSOuS)**

A passive simulation object using stimuli is an extension of the PSO, by allowing it to emit stimuli based on previously generated messages.

It keeps limitations from the PSO, so it cannot receive any messages. Due to the above mentioned reason, it cannot receive any stimuli as well.

Each PSOuS consist of (regardless of what it has inherited from the PSO):

- 1) Stimulus emitting functions;
- 2) Selector of stimulus emitting function.

**Definition 14. The Active Simulation Object using Stimuli (ASOuS)**

A ASOuS is an extension of both the PSOuS and the ASO. It can generate messages, emit stimuli, receive them and receive messages.

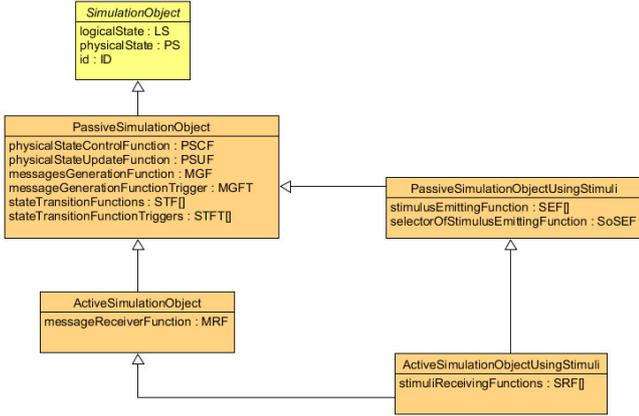

Fig. 1. Class diagram with the hierarchy of simulation object types.

Each ASOuS despite of what it has inherited from the PSOuS and the ASO, has stimuli receiving function.

A class diagram presenting the simulation object types hierarchy is presented on the figure 1.

### C. Formal definitions of the extended model's components

Let  $I^S$  denote a set of stimuli types identifiers, and by  $S_i, i \in I^S$  we denote a set of  $i^{th}$  type stimuli. Each set of stimuli must define following operations:

$+$ :  $S_i \times S_i \rightarrow S_i$  – the addition of the  $i^{th}$  type stimuli;  
 $P_i$ :  $PS_0 \times S_i \rightarrow S_i$  – the perception of the  $i^{th}$  type stimulus;  
 To clarify, each set of stimuli defines above operations only for its own type. Additionally, each set of stimuli must define a neutral element of itself.

$$\forall i \in I^S \exists ! e_i \in S_i \forall s \in S_i : +_i(s, e_i) = s$$

Finally, there must be a definition of perception operation on a subset of stimuli:

$$P_i^2 : PS_0 \times 2^{S_i} \rightarrow S_i, i \in I^S$$

### Definition 15. Stimulus Emitting Function

Let's denote a set of all stimulus emitting functions kept by  $i^{th}$  simulation object as  $SEM_i^\infty$ . Formal definition of the  $SEM_i^\infty$  set is as follows:

$\{SEM_{i,j,l} : PS_i \times LS_i \times M^\infty \rightarrow S_j\}_{l \in \mathbb{Z}_+, j \in I^S, i \in I^{SO}}$   
 $SEM_i^\infty$  – a set of all stimulus emitting functions kept by the  $i^{th}$  simulation object.

$SEM_{i,j,l}$  – a  $l^{th}$  stimulus emitting function being used by the  $i^{th}$  simulation object. The stimulus emitted by this function is of the  $j^{th}$  type.

### Definition 16. Selector of Stimulus Emitting Function

$SoSEM_i : PS_i \times LS_i \times M^\infty \times 2^{SEM_i^\infty} \rightarrow 2^{SEM_i^\infty}, i \in I^{SO}, j \in I^S$  – a selector of stimulus emitting function used by the  $i^{th}$  object.

### Definition 17. Stimuli receiving function

$SRF_i^\infty = \{SRF_{i,j,l} : PS_i \times LS_i \times 2^{S_j} \rightarrow M^\infty\}_{l \in \mathbb{Z}, i \in I^{SO}, j \in I^S}$

$SRF_i^\infty$  – a set of all stimuli receiving functions used by the

$i^{th}$  object.

$SRF_{i,j,l}$  – a  $l^{th}$  stimuli receiving function kept by the  $i^{th}$  object. This function accepts stimuli of the type  $j$ .

### Definition 18. Functional assigning corresponding stimuli type to emitters and receivers

$S^T : SRF_{i,j} \rightarrow I^S, i \in I^{SO}, j \in I^S$  – a functional assigning a stimulus type to a stimuli receiving function.  
 $S^T : SEM_{i,j} \rightarrow I^S, i \in I^{SO}, j \in I^S$  – a function assigning stimulus type to a stimulus emitting function.

### D. The simulation

All the definitions from IV-D remains unchanged. In order to describe the simulation process of the extended model, first we need to define the following function:

### Definition 19. The stimuli set at simulation moment function

$s_i : \mathbb{Z}_+ \rightarrow 2^{S_i}, i \in I^S$  – a function assigning each subsequent simulation moment its corresponding set of  $i^{th}$  type stimuli.

The simulation is performed according to the following steps.

For each subsequent  $t \in \mathbb{Z}_+$ :

- 1) See the step 1 of IV-D;
- 2) See the step 2 of IV-D;
- 3) See the step 3 of IV-D;
- 4) For every message generated by each simulation object select a set of emitters:  
 $\forall i \in I^{SO} \forall m \in M_i^\infty(t) : S_i^{SEL}(t) = S_i^{SEL}(t) \cup \{ \langle SoSEM_i(ls_i(t), ps_i(t), m, SEM_i^\infty), m \rangle \}$
- 5) Using each selection made in previous step generate messages:  
 $\forall i \in I^{SO} \forall \langle S^{SEM_s}, m \rangle \in S_i^{SEL}(t) \forall sem \in S^{SEM_s} : j = S^T(sem), s_j(t) = s_j(t) \cup \{ sem(ps_i(t), ls_i(t), m) \}$
- 6) With every stimuli receiver of each object perform perception operation on the appropriate set of stimuli:  
 $\forall j \in I^S \forall i \in I^{SO} \forall srf \in SRF_i^\infty : S^T(srf) == j \Rightarrow m_i^r(t) = m_i^r(t) \cup srf(ps_i(t), ls_i(t), s_j(t))$
- 7) Each simulation object receives all messages generated by its receivers in the previous step:  
 $\forall i \in I^{SO} \forall m \in m_i^r(t) : ls_i(t) = MRF_i(ps_i(t), ls_i(t), m)$
- 8) See the step 6 of IV-D;
- 9) See the step 7 of IV-D.

## VI. THE FRAMEWORK ARCHITECTURE

The framework architecture will be described according to [14]. The entire tool for the simulation of the UAV swarms can be divided into two web services and a client application. The client application is responsible for performing the simulation. Two web services provided by the framework, the first one to register every simulation moment, and the second one to visualize results of the simulation in 3D, are designed to reconstruct the course of the simulation later on (with vastly lower computational cost).

In the following architecture description we will primarily focus on the client application, because it is the only element that require implementation from a framework's user.

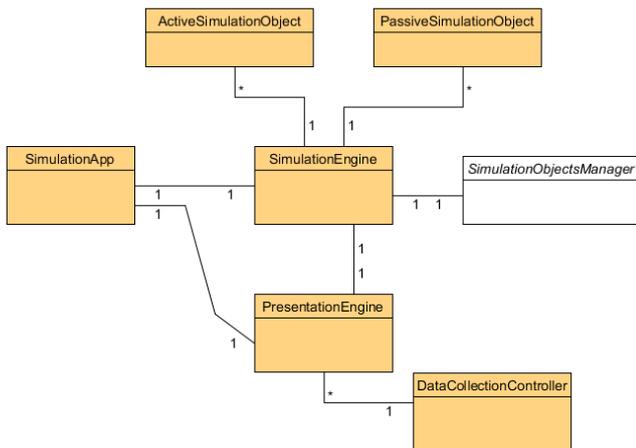

Fig. 2. The diagram of the main conceptual classes

### A. The logical view

The Figure 2 shows main conceptual classes that allows performing and saving simulation of the basic model results. The classes mentioned above are:

- **SimulationApp** – is the facade aimed to control the simulation. It is also responsible for management of the threads required to perform the simulation;
- **PresentationEngine** – is responsible for communication with the web service and saving simulation state on a server;
- **SimulationEngine** – supervises the course of the simulation and communicates with the presentation engine;
- **SimulationObjectsManager** – is the main element responsible for calculations needed by the simulation. It is also the element of which implementation quality impacts the performance of the simulation process the most;
- **DataCollectionController** – is the class responsible for registering the subsequent simulation moments;
- **ActiveSimulationObject** – is the class that represents the active simulation object. It contains all the elements depicted on the Figure 1
- **PassiveSimulationObject** – is the class that represents the passive simulation object. It contains all the elements depicted on the Figure 1.

The **ActiveSimulationObject** (usingStimuli) and **PassiveSimulationObject** (usingStimuli) classes are the only the components that requires further implementation.

### B. The process view

In the client module we can distinguish 2 main processes, as is depicted in Figure 3. The first process calculates subsequent states of the simulation, the second one communicates with the web services so the results from the first one can be saved.

It is worth mentioning that the above perspective is simplified, it doesn't involve any optimization (such as parallelization of calculation for every simulation object).

### C. The physical view

From the physical point of view, the client module instances can be located on the same device as the server is. Although, it is suggested to not share location of both modules.

Multiple client modules can be instantiated on one computer. It is also highly recommended for the computer that the database will be on to have sufficiently fast storage drive. It should be remembered that accessing the drive will occur much more often when reconstructing (visualizing) simulation, than when it is being performed (registered). The exemplary configuration is presented in the Figure 4.

### D. The developer view

The framework can be divided into 2 main modules, the client module that is doing the calculation, and the web module that registers the simulations, and it allows to access them later on.

The framework user needs to implement components such as functions to control physical state and messages generation/receiving function, they are all located in client module.

The client module consists of a set of dynamically loaded libraries (DLLs), while the web module is made of a WAR file that can be deployed on webservers like Payara[15] or Glassfish[16].

### E. The scenarios

The simplified scenario of the basic model's simulation was presented in the Figure 5. It is important to notice that steps 1-5 include, omitted on the picture, returning values needed for presentation layer from a manager.

Similarly the extended model's simulation scenario will only differ in number of steps it requires.

## VII. THE FRAMEWORK IMPLEMENTATION

The framework for the UAV swarms simulation was implemented in two technologies. The client module was implemented using C# (.NET Framework 4.7.2), and the web module was developed using JEE with frontend PrimeFaces framework in version 6.2. A 3D visualization of the simulation results is being performer with ThreeJS library.

The main reason why the client module was developed in the different language than the web module was the type erasure mechanism in the Java.

The following components are delivered as part of the framework:

- A basic implementation of physical state;
- A basic implementations of physical state control and update functions;
- A set of basic stimuli types;
- A tool for image-to-environment generation.

## VIII. AN EXEMPLARY SCENARIOS SIMULATION

The scenario of a UAV swarm mission consist of three elements:

- 1) Generating a map of a mission environment;
- 2) Configuring the simulation objects;

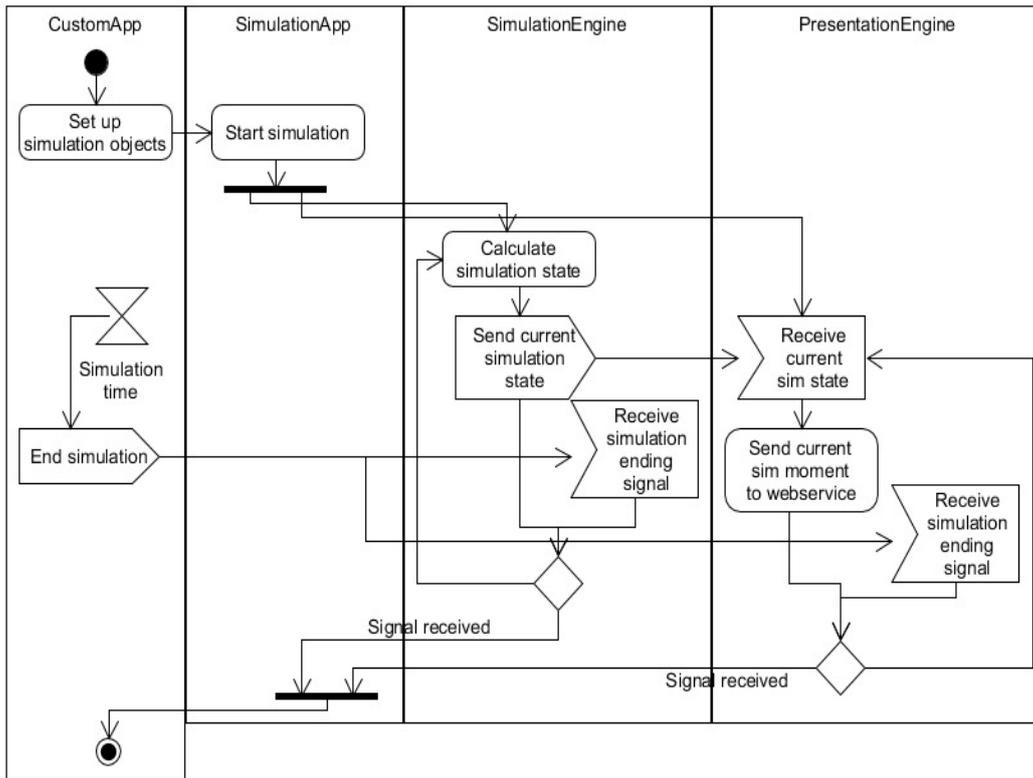

Fig. 3. The diagram of processes in the client module

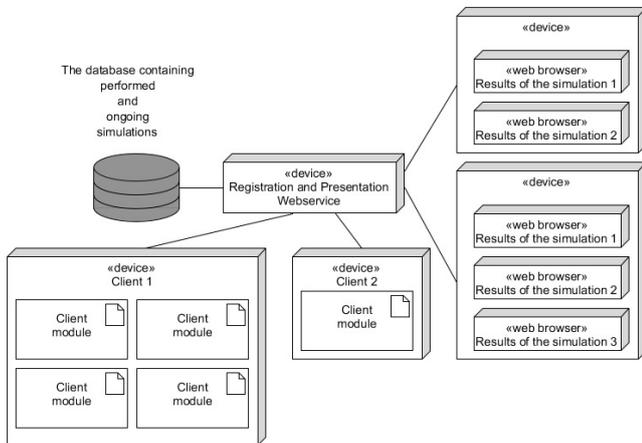

Fig. 4. The exemplary physical configuration

3) Setting up the mission objective for the simulation objects.

The mission environment map generation is a matter of two things. The first thing is to set parameters of the map, its width, depth, maximum heights etc. The second step is to select an image that represents the map. All these can be done with the provided tool (see Figure 7).

The simulation objects configuration is essentially about

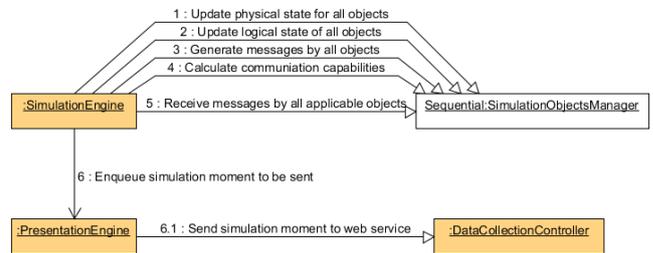

Fig. 5. The simulation of the basic model scenario

implementing functions described in IV or/and V.

The exemplary simulation scenario aimed to check whether a homogenous set of an unmanned aerial vehicles will be capable to reach a certain destination while avoiding environmental obstacles.

The environmental map was generated using bitmap depicted in the Figure 6.

Interpretation of the Figure 6 in the context of the map of environment is as follows:

- Height along the X axis will depend on the brightness of pixels along width of the picture;
- Height along the Z axis will depend on the brightness of pixels along height of the picture;

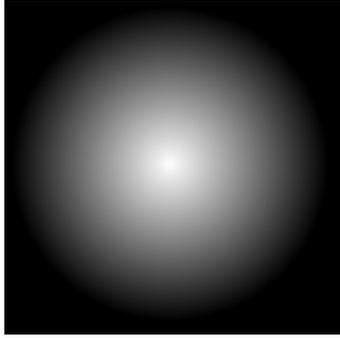

Fig. 6. The map of the mission environment used in the exemplary simulation scenario

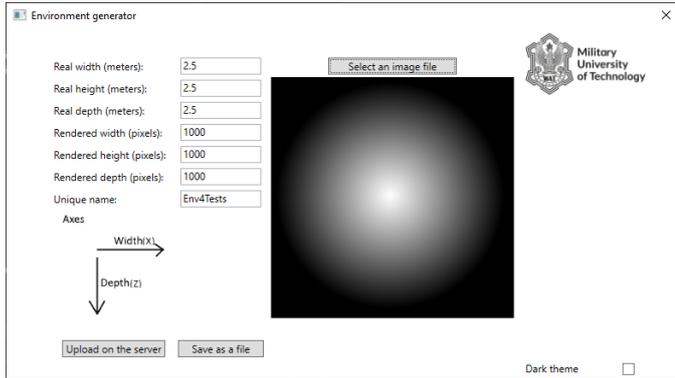

Fig. 7. The tool for mission environment generation

- The origin of the coordinate system (on the map) corresponds to the upper left corner in the picture.

The real world dimensions of the generated map were 2.5 meters by 2.5 meters. Maximum height (corresponding the white area in the Figure 6) was also set to 2.5 meters.

Four homogenous aerial vehicles have been placed on the map. Each of them had a goal to reach position (assuming xyz coordinate order) at point (2.5,0.1,2.3).

The simulation was performed using the extended model with one type of stimuli, let's call it collision type stimuli. A structure of the collision type stimulus is as follows:

$$S_1 = \{x : x \in R^3 \times \{true, false\}\}$$

The results confirmed possibility of performing the simulation with scenario described earlier. Three out of four objects reached their destination, the one that did not make it failed because of a flaw in an algorithm and not because of the framework. Below are listed figures showing particular simulation moments. The Figure 8 shows the beginning of the simulation, while Figure 9 shows middle of the simulation and the Figure 10 shows the simulation state at the end of the simulation process.

It is worth to mention that a map of the environment can be generated from any bitmap file. For example, more “advanced” map was generated using the file from Figure 11

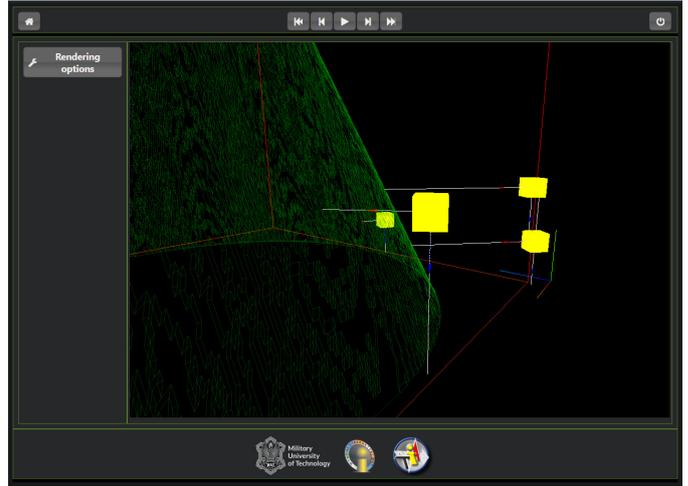

Fig. 8. The screenshot with results of a simulation in 14th simulation moment

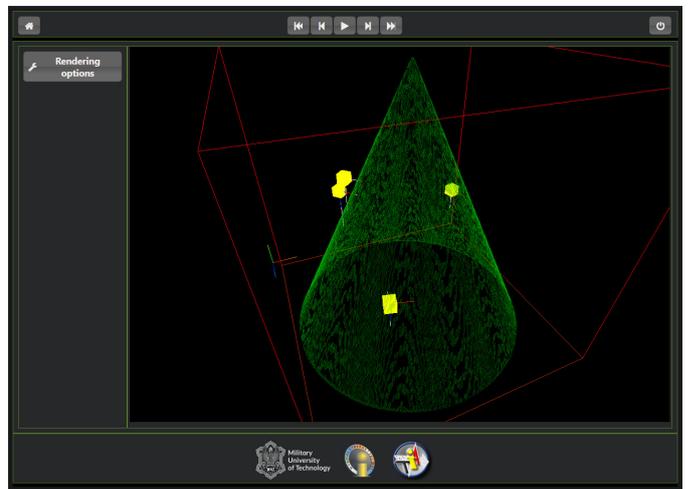

Fig. 9. The screenshot with results of a simulation in 109th simulation moment

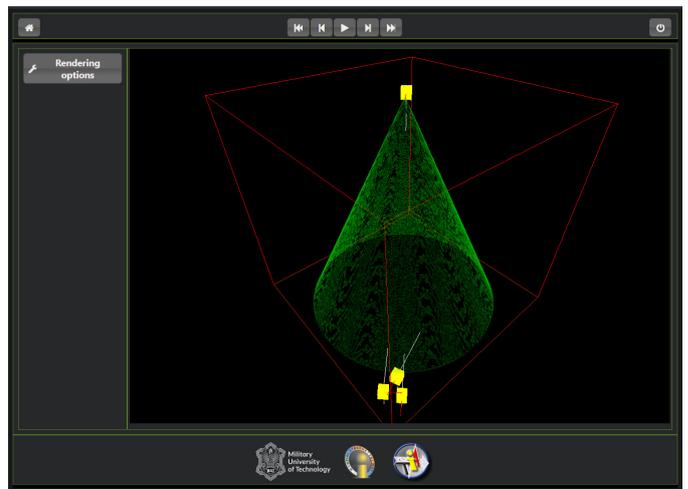

Fig. 10. The screenshot with results of a simulation in 431th simulation moment

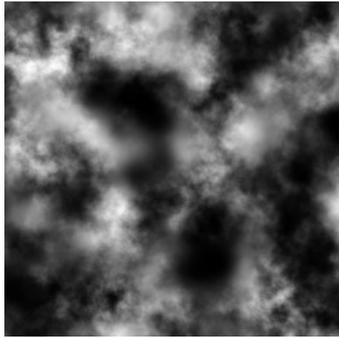

Fig. 11. An example of a mission area

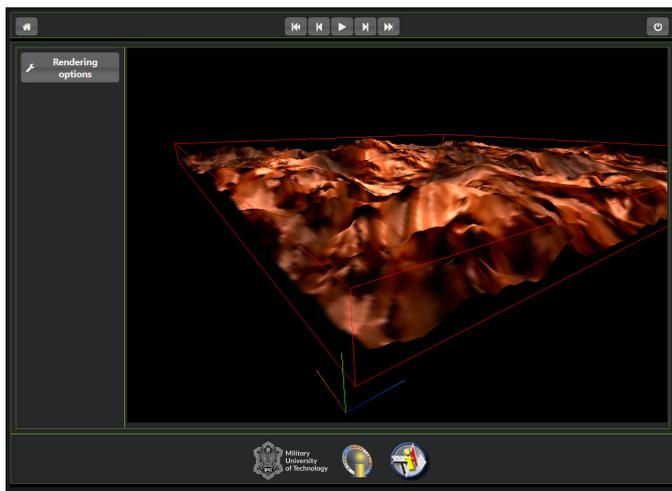

Fig. 12. A more advanced mission area – first view from the simulator

The mission environment generated from the Figure 11 was depicted on Figure 12 and Figure 13.

Each map can be rendered in two modes : solid and mesh. The map from Figure 12 shows the solid rendering mode, while Figure 13 depicts mesh rendering mode.

## IX. CONCLUSIONS

The goal of this work was to present the framework for the UAV swarm simulation with any scale and any type of tasks that may be set for it. Two simulation models, that are acceptable by the simulator, were presented, as well as their goals and limitations. The framework allows to perform simulation with user-defined map of environment, this is particularly useful when combined with the second model.

Results of an exemplary simulation scenarios were also presented.

There are two direction for future work on this framework. The first one is to design a script-like language so that a simulation objects configuration can be done without need of programmatic implementation. The second direction is to allow the simulation objects to be configured with languages other than C#, this would probably end up in designing a meta-framework for the tool presented here.

**Abstract**—To extend the lifetime of wireless sensor networks, recent works suggest the use of relay nodes. This paper surveys and examines representative approaches dealing with relay nodes deployment. It also discusses their shortcomings and presents a comparative study. Additionally, this paper provides a set of remarks and recommendations to improve the usage of relay nodes in wireless sensor networks and highlights open issues that need further investigation.

## I. INTRODUCTION

A WIRELESS Sensor Network (WSN) is composed of Sensor Nodes (SNs) and Collector Nodes (CNs), deployed in a well-defined geographical area, called Region of Interest (RoI), to monitor the occurrence and/or evolution of a target event [1]. Each SN is responsible for collecting data associated with this event, via its sensing unit, and communicating them, using its wireless communication interface, to one of the CNs, directly, if the latter is in its communication range, or through a multi-hop routing, with the contribution of other intermediate SNs [1].

The successful completion of the control/monitoring mission assigned to the WSN requires that the network should be deployed and managed in a rigorous manner, which guarantees the RoI coverage and the WSN connectivity throughout the assigned mission [1]. The coverage must be of a predetermined order  $k$  ( $k \geq 1$ ), where each point of the RoI is covered by at least  $k$  SNs. Likewise, the connectivity must be of a predetermined degree  $l$  ( $l \geq 1$ ), which means that each SN has  $l$  disjoint paths, connecting it to the CNs. Usually, a redundancy in coverage and connectivity is provided ( $k, l \geq 2$ ) to ensure fault-tolerance.

In the WSN, the SNs are responsible, on the one hand, for collecting data related to the target event, and on the other hand, for forwarding it to the CNs. These two energy-hungry activities limit the lifetime of SNs, and lead sometimes, to the loss of coverage and/or connectivity [1]. Moreover, SNs have limited communication range, which requires, in most cases, the use of multi-hop routing, where packets go through multiple SNs before reaching the CNs, which increases the overall delivery latency and data loss rate.

To overcome the aforementioned challenges, some recent WSNs architectures [2], [3] include, in addition to SNs and CNs, relay nodes (RNs) that benefit from extended energy

autonomy and a communication range greater than that of SNs. In WSNs, these RNs are intended, in particular, to preserve [4], [5] or to restore [6], [7] the network connectivity, by actively participating in the forwarding of the collected data from the SNs to the CNs. This allows to balance the load between the SNs and the RNs [8], [9], [10], and thus prolong the network lifetime.

Nevertheless, the realistic and efficient utilization of RNs in WSNs is a long process that is in its early stage, and it currently faces several challenges [11], [12], [13]. It is a process consisting of several phases. In the first place, the appropriate usage mode of RNs should be selected. After that, the next phase chooses the topology of the network, according to the context, the constraints, and the desired objectives, before starting the RNs deployment phase. This latter is an NP-Hard problem [11], [12], [13] that consists of determining the number and the positions of RNs in the RoI. Finally, to extend the lifetime of the deployed WSN, a last phase designed to optimally manage the built topology should be considered.

In this paper, we clearly define the contours of the problem of using RNs in WSNs, by surveying and discussing representative approaches dealing with RNs deployment. This survey, intended to help researchers to quickly understand existing works, is completed by a set of remarks and recommendations to improve the usage of RNs in WSNs.

The rest of this paper is organized as follows. Section II presents the operating modes that describe the possible situations of RNs usage that can occur in practice. Then, the objectives and constraints of the problem at hand are identified in Section III. Section IV is devoted to the description of the possible WSN topologies in the presence of RNs. Section V surveys existing RNs deployment methods, and discusses their underlying assumptions. Next, Section VI summarizes the reviewed approaches, discusses their shortcomings, presents a comparative study, and highlights open issues. Finally, Section VII concludes the paper.

## II. OPERATING MODES

Guaranteeing the WSN connectivity throughout the planned monitoring/control mission remains the main motivation for RNs usage, despite their relatively high cost compared to that of SNs [14], [15], because the loss of connectivity may lead

to the failure of the mission assigned to the network. Ensuring network connectivity is achieved through two modes of RNs usage: reactive mode and proactive mode.

#### A. Reactive Mode

This mode of usage occurs when the WSN, consisting of SNs and CNs, is already deployed in the RoI (Fig. 1(a)). As time goes by, the battery-powered SNs will gradually be energy-exhausted and begin to disappear from the network, thereby leaving in their places what is commonly called coverage voids [1]. The number and sizes of these latter will expand gradually, causing sometimes the partitioning of the WSN into completely disjointed subnetworks (Fig. 1(b)). In this situation, some still operational SNs cannot communicate their data to any CN. It is at this moment that RNs should be deployed at specific locations [16], [17], [18], to restore the network connectivity, ensuring that each SN is able again to transmit its data to at least one CN (Fig. 1(c)). Thus, the deployed RNs act as gateways that interconnect the pieces of the network.

#### B. Proactive Mode

Sometimes, the use of the RNs along with SNs and CNs is considered at the network setup [16], [17], [18]. This is a precautionary measure by which the network administrator aims to preserve the coverage and the connectivity, throughout the planned monitoring/control mission [6], [7]. In fact, the RNs participate, from the beginning, in the routing of the data from SNs to CNs. In this way, SNs are, partially or totally, unloaded from the routing activity, which allows to extend their lifetimes, and thus, preserve the coverage quality of the RoI. On the other hand, the participation of RNs in data routing has a much lesser impact on their lifetimes, compared to SNs, because RNs have extended energy, which allows preserving the WSN connectivity.

The proactive usage of RNs is better than its reactive counterpart, in the sense that it maintains both coverage and connectivity, through load balancing between SNs and RNs starting from the network setup. However, it is not meant for emergency situations, where the restoration of connectivity should be immediate.

In practice, the choice between these two RNs usage modes is dictated by the order of priority given to each targeted objective (coverage, connectivity, cost, etc.), the constraints specific to the control mission (budget, duration, urgency, etc.), the constraints imposed sometimes by the RoI (a single area or several geographically distant areas) and by the functional characteristics of the employed SNs and RNs (communication range, storage capacity, etc.). The next section identifies the objectives and constraints commonly considered in the literature.

### III. OBJECTIVES AND CONSTRAINTS

Connectivity is not the only reason behind the usage of RNs in WSNs. Some existing works not only seek to preserve simple connectivity (1-connectivity) but attempt to provide

fault-tolerance, by deploying a sufficient number of RNs, so that each SN will have  $l$  ( $l \geq 2$ ) disjoint paths to forward its data to CNs [4], [5], [9], [10], [14], [19], [20], [21]. In this way, it would be possible to substitute, in the opportunistic moment, a broken or overloaded path, by another more appropriate path.

In addition to connectivity and fault-tolerance, the usage of RNs has other objectives such as **(1)** the minimization of cost, through the minimization of the number of RNs to be deployed [4], [5], [11]; **(2)** the minimization of the packet delivery delay [8], [13], [22], [23], [24], by ensuring that the routing paths are as short as possible; **(3)** the maximization of the network lifetime, notably by preserving the energy of SNs [2], [4], [11], [25] and/or by using RNs powered by green energy (where they harvest large amounts of ambient energy) [5], [16], [26], [27], and **(4)** the maximization of the communications links quality [22], [27], [28], which allows to avoid or to minimize the packet re-transmission operations that have a negative impact on the energy consumption and on the packets delivery delay [1].

Sometimes, some of the above-mentioned objectives are taken into account in the form of constraints. These latter could be related to the budget allocated to the mission, and are usually implemented by limiting the number of RNs to be deployed [2], [3], [17], [27]. Considered constraints could also be associated with the real-time nature of the intended application, and are carried out by requiring that the packets delivery delay is always below a tolerable threshold [8], [13], [29]. Other types of constraints are imposed by the RoI, such as limiting the possible positions of RNs [3], [4], [5], [8], [12], [19]. This last constraint often occurs in real-life applications, because the RoI can include hostile or inappropriate places, where it would be difficult, or even impossible, to place the RNs. Also, the positions to be occupied by the RNs are always dependent on the placement of SNs and CNs in the RoI, as the main role of the RNs is to restore and/or maintain the WSN connectivity.

Of course, some objectives are contradictory, such as fault-tolerance and deployment cost, and some others are perfectly correlated, such as the quality of communication links and the energy consumption of SNs and RNs. The definition of an order of priority among these objectives, which takes into account the various constraints and the correct relationship between them, remains necessary for efficient usage of RNs. The next section provides an analysis of the different WSNs topologies considered in the literature to meet the desired objectives.

### IV. WSN TOPOLOGIES

The objectives, the constraints, as well as the RNs usage mode adopted to satisfy them, all must be considered when selecting, thereafter, the adequate topology of the WSN. This topology, which defines the communications among the various nodes and the role of SNs and RNs in the data routing operation, have three possible forms, namely, the 1-tier topology, the 2-tier topology, and the hybrid topology.

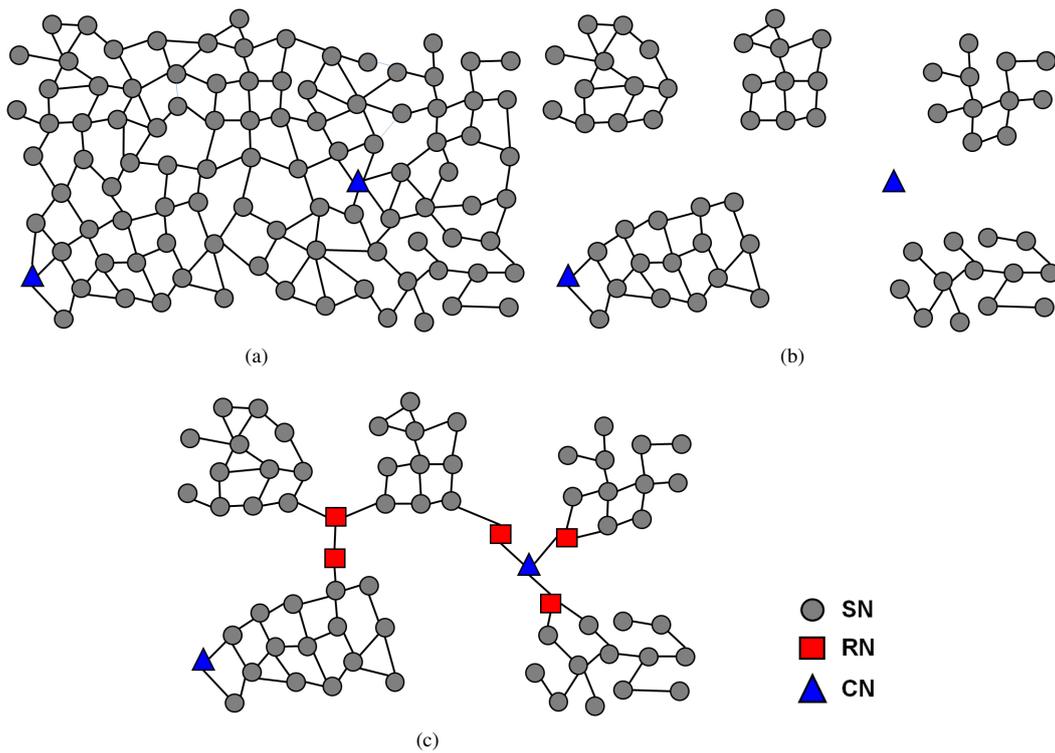

Fig. 1. Connectivity restoration by using RNs.

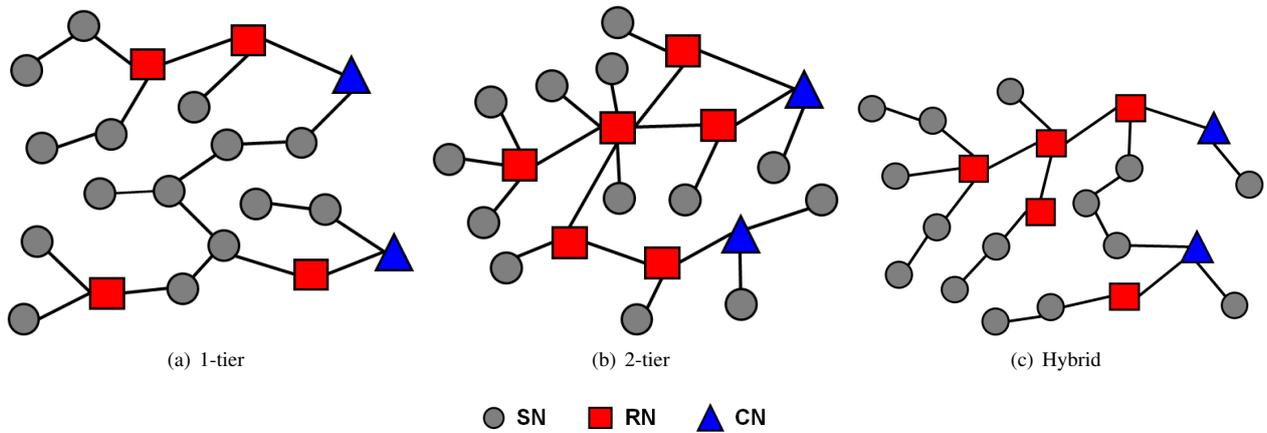

Fig. 2. WSN topologies composed of SNs, RNs, and CNs.

A. 1-tier topology

In this topology, shown in Fig. 2(a), SNs are involved, together with RNs, in the forwarding of data to CNs [6], [8], [11], [16], [17], [19], [28]. Thus, the intermediate nodes, forming the routing path connecting a SN to a CN, can be SNs and/or RNs. Typically, this 1-tier topology is selected when a reactive usage of RNs is assumed, more specifically, when RNs are merely used to restore the WSN connectivity. In this manner, RNs potential positions are limited and are located in the voids separating the pieces of the disconnected WSN [8],

[16], [18], [21].

B. 2-tier topology

In this topology, illustrated in Fig. 2(b), each SN deals only with the collection of data and transmits it to one of the CNs or, if necessary (no CN is within its communication range), to one of the RNs within its communication range. Subsequently, the RNs take care of routing this data to CNs [4], [5], [12], [13], [14]. Thus, the intermediate nodes, constituting the routing path connecting a SN to a CN, are necessarily RNs.

This 2-tier topology is seen as a clustering scheme of the WSN [4], [11], [14], [24], [30], where each cluster has a RN, acting as a cluster-head, and many SNs, acting as cluster members. This topology correlates much more with a proactive usage of RNs [5], [10], [27] because the positions to be occupied by the RNs should be well distributed over the entire RoI, so that each SN can communicate with at least one RN. In this way, it would be possible to build the necessary clusters based on RNs, such as all the cluster-heads are RNs [2], [4], [11], [14], [24], [30].

In comparison with the 1-tier topology, the 2-tier topology is more promising in terms of packets delivery delay and loss rate [8], [13], [22]. This is due to the fact that the routing paths, consisting only of RNs that have a communication range exceeding that of SNs, become shorter. Also, the 2-tier topology extends the lifespan of SNs [4], since these latter are totally unloaded from the routing task. In return, the 2-tier topology is costly, since its construction requires more RNs [4], [5], [19]. To address this gap, approaches adopting this 2-tier topology endeavor to minimize the number of used RNs.

### C. Hybrid topology

To take advantage of the aforementioned benefits of the 2-tier topology while minimizing the number of used RNs, some approaches [24], [25] adopt another topology, that we qualified it as *hybrid*. This hybrid topology resembles the 2-tier topology, except that the communication between a SN and its closest RN is performed, if necessary (RN is not in the communication range of the SN), via other intermediate SNs (see Fig. 2(c)). Thus, data collected by a SN can traverse a set of intermediate SNs, before reaching the first RN, which accomplish, together with some other RNs, the rest of the routing operation, similarly to the case when the 2-tier topology is used.

## V. RNS DEPLOYMENT APPROACHES

It should be noted that, unlike SNs that can be deployed randomly or deterministically [1], RNs are always deployed in a deterministic way, given the main following considerations: (i) RNs are responsible for forwarding data from SNs to CNs, whose positions must be computed according to the locations already occupied by SNs and CNs [31]; (ii) RNs are significantly more expensive than SNs. Thus, in comparison to a random deployment, a deterministic deployment allows to better optimize the total number of RNs.

The deterministic deployment of RNs consists in computing the number and the appropriate positions of the RNs in the RoI, which allow to reach the sought objectives and to respect the considered constraints while taking into account the assumed topology [4], [7], [28]. This problem has been shown to be computationally NP-hard [2], [3], [11], whose resolution involves two phases: a formulation phase and a resolution phase. The formulation phase describes, on the basis of the adopted assumptions, the relation between the different constraints and objectives, whereas the resolution phase, which is based on heuristics or meta-heuristics, selects from the

set of possible solutions, one solution that meets the desired objectives.

It should be noted that one of the most important assumptions that determine the soundness and practicability of a proposed deployment approach are those in relation with the adopted communication model. The latter describes, in a binary [2], [6], [11], [12], [17] or probabilistic manner [3], [16], [22], [26], [28], the quality of a communication link between two nodes, according to a set of parameters, which group in most of the proposed approaches, the distance between the communicating nodes [2], [3], [11], [12], [22], the transmission range (power) of nodes [2], [3], [11], [12], [22], the obstacles [32] as well as the medium of transmissions (radio, acoustic, etc.) [3].

In the related literature, there are different formulations of the deterministic deployment of RNs such as STP (Steiner Tree Problem) [4], [12], [17], [19], [22], CDS (Connected Dominating Set) [11], [25], SCP (Set Cover Problem) [8], [9], [13], [30], MST (Minimum Spanning Tree) [10] or ILP (Integer Linear Programming) [5], [7], [24], [26], [33]. Some other RNs deployment approaches [2], [14], [16], [28] come up with their proper formulation of the problem at hand. The formulated RNs deployment problem is solved through meta-heuristics such as the GA (Genetic Algorithms) [2], [20], the GSA (Gravitational Search Algorithm) [2], [18], [27], the DE (Differential Evolution) [27], the PSO (Particle Swarm Optimization) [18], the Column Generation (CG) algorithm [33] or other existing heuristics [34], [35], [36], [37], [38]. Some others RNs deployment approach [13], [14], [16], [26], [28] devise their proper heuristics to solve the problem at hand.

It should be remembered that the effectiveness of a RNs deployment approach depends on each of the above-mentioned phases, where the practicalness of an approach is strongly linked to the considered assumptions and constraints, as well as to the formulation phase describing their influence on the intended objectives. Moreover, the degree of satisfaction of the desired objectives, once they are correctly modeled in the formulation phase, depends on the efficiency of the adopted resolution method, which denotes its capacity to explore many possible solutions and to converge, quickly, towards a good-quality solution.

## VI. SYNTHESIS AND OPEN ISSUES

The introduction of RNs within WSNs in order to preserve or restore connectivity, in addition to other objectives, is a delicate task, which requires in the first place a clear definition of the objectives and an inventory of the various constraints, to determine the proper operating mode (reactive or proactive). Taking into account the latter, and without disregarding the constraints and the searched objectives, the appropriate topology could be selected. It is at this point that the real work of deployment begins, which consists of determining the number and positions of RNs, allowing the network to operate according to the chosen topology while respecting the objectives and constraints previously identified. This process

is illustrated in Fig. 3, which highlights the sequence and dependence among these phases.

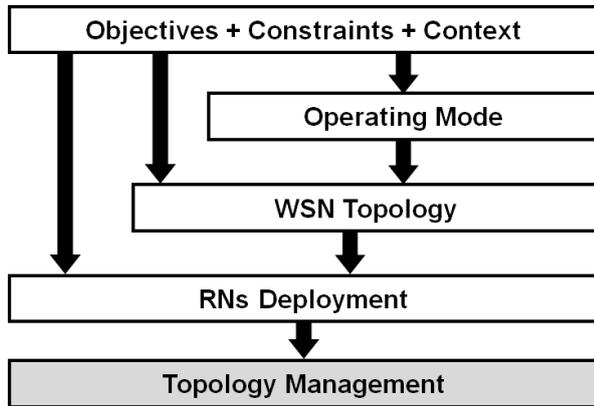

Fig. 3. Process of using RNs in WSNs.

Table I shows a comparative analysis of the most recent RNs deployment approaches. Although they start with well-defined objectives, some of these approaches have motivated the selection of the appropriate topology (1-tier, 2-tier, or hybrid) based only on the objectives. They overlooked the fact that this choice is tributary also to external constraints related to the envisaged application (budget and delay of deployment, allowed positions for RNs, urgency, etc.), which require to identify, in the first place, the appropriate operating mode (reactive or proactive) before thinking about the topology to be adopted. Due to the omission of this intermediate phase, the context of these approaches usage remains unclear.

In addition, these approaches suffer from a problem of practicalness, due to the omission of certain constraints having a quasi-permanent presence in real-life applications, or because of the adoption of unrealistic assumptions. For instance, excepting some works [3], [39], [30] that considered 3D or very specific RoI, all mentioned approaches are designed and/or evaluated under the assumption that the RoI is purely 2D, which makes them irrelevant for realistic 3D RoI, and limits their usage to very limited cases.

Furthermore, besides few works [32] that take into account, in a superficial way, the impact of obstacles, the wireless communications are modeled, in the others approaches, by very simple models that consider only the distance and the communication range of the nodes, omitting other important factors, such as obstacles, which can prevent the communications, or in the best cases, degrade their qualities. Also, some of these models are binary, forgetting the probabilistic nature of wireless communications, confirmed in several previous works.

Additionally, the constraint of RNs positions, which has a real and quasi-permanent presence, has been overlooked, or in the best cases, treated in a very superficial way, where all the allowed positions of RNs are chosen arbitrarily. However, in reality, the determination of these positions requires an analysis of the RoI. The impact of this gap will be more

significant in the case of purely 3D RoI, where the topography is the first factor that imposes this kind of constraints.

Finally, a serious problem should be mentioned and it concerns the basic idea behind the use of RNs in WSNs. Indeed, the intensive participation of RNs in data routing can exhaust, in a very fast manner, their limited residual energy, especially when the 2-tier topology is considered. This aspect has not been well dealt with and remains an open issue. To handle this situation, some approaches assume that a RN has an unlimited energy resource, which remains an unrealistic assumption (at least for now). Some other approaches have aimed to ensure  $k$ -connectivity to face the failure of RNs, but we believe that they need to be strengthened. More precisely, we believe that the process of exploiting RNs in WSNs should be fortified by a network topology management phase (see Fig. 3), designed in particular to optimize the RNs energy consumption, by using a load balancing strategy. To the best of our knowledge, no such complete solution has been proposed. Consequently, efficient topology management of a heterogeneous WSN, composed of SNs and RNs, remains an open issue.

## VII. CONCLUSION

Recent works suggest enhancing traditional WSNs architecture, consisting of SNs and CNs, by introducing RNs to provide reliable data transport from SNs to CNs. In this paper, we have presented and discussed the steps that constitute the process of exploiting RNs in WSNs. This process starts with the definition of the desired objectives and ends with the deployment phase, which consists in determining the number and the positions of RNs in the RoI. In the end, we have carried out a comparative study among the most recent RNs deployment strategies and pointed out the main shortcomings of existing works.

The identified shortcomings are related in particular to the practicalness of these works since most of them assumed that the RoI is 2D and adopted unrealistic communications models, omitting the undeniable impact of some factors on wireless communications, notably obstacles. Nevertheless, the most important remark is the absence of a topology management phase that should follow the deployment of the WSN, and which helps to optimize the resources of the WSN, especially the energy of RNs that are actively involved in data routing. This phase, which must further reinforce the measures taken by some recent works that have targeted fault-tolerance (by ensuring the  $k$ -connectivity of the network), should notably manage the load balancing among RNs. We believe that this phase is highly important and deserves immediate attention.

**Abstract**—Drivers' behavior in traffic is a determining factor for the rate of accidents on roads and highways. This paper presents the design of an intelligent IoT system capable of inferring and warning about road traffic risks and danger zones, based on data obtained from the vehicles and their drivers mobile phones, thus helping to avoid accidents and seeking to preserve the lives of the passengers. The proposed approach is to collect vehicle telemetry data and mobile phone sensors data through an IoT network and then to analyze the driver's behavior while driving, along with data from the environment. The results of the inference serve to alert drivers about incidents in their trajectory as well as to provide feedback on how they are driving. The proposal is validated using a developed prototype to test its data collection and inference features in a small scale experiment.

**Index Terms**—Internet of Things; Vehicular networks; Driving behavior; Inference; OBD-II; Android.

## I. INTRODUCTION

THE WAY drivers behave in traffic is a determining factor for high accident rates on roads and highways. In 2018, there were 69114 serious accidents on Brazilian highways [1]. In such context [2], by analyzing the driver's profile, it is possible to analyze the phenomenon and create mechanisms to positively influence driver behavior, thus making the routes safer and energy use more efficient.

Over time, technologies, such as smartphones, have become easily accessible to the population and have aided drivers. According to FGV-SP [3], the number of smartphones in Brazil already exceeds 230 million. Since most of these mobile phone models have sensors, such as GPS (Global Positioning System), accelerometer, gyroscope, 3-axis magnetometer (lateral, longitudinal and vertical or in coordinates  $x$ ,  $y$  and  $z$ ), we can use their data, as indicated by other studies, such as [4] or [5], to contribute to the driver behavior study.

Internet of Things (IoT) is a paradigm that combines aspects and technologies of different approaches: ubiquitous computing, communication protocols and technologies, sensors and actuators, composing a system in which the real world and the digital world interact symbiotically [6]. The IoT connected devices installed base comprised around 23.14 billion devices

in 2018 and it is projected to increase to 75.44 billion ones worldwide by 2025 [7].

The increasing number of internet-connected objects ranging from cell phones to air conditioners is a compelling force for a more comprehensive study of how such devices connect. The ease to share information among IoT devices open up a new environment for different uses, where objects with traditional use can turn into objects with a certain intelligence, as shown in [8].

The IoT concept is based on data sharing between several different devices, be they vehicles or, in their simplest form, smartphones. Thus, shared data can be treated in a way that generates different interpretations and providing significant indicators to, for example, influence users behavior [9]. Then, the device can be part of several IoT networks and with intelligence to infer actions.

For the proposed project development, firstly it was necessary to fully understand the IoT concept, which is used for new technology development and it is the assumption on which the Smart Drive project is based, developed and discussed in this article.

Like all new technologies, the IoT development also faces several challenges. One of main topics addressed in our IoT study is network security. The need for in-depth study of this topic is observed when analyzing the steps necessary for system operation, i.e. information sharing may be subject to malicious actions, which will compromise the network operation and even the user privacy. Some methods are employed to mitigate this problem, as explained in [10]. This topic was approached with its necessary applications in the project being registered in this paper.

The rest of this article is divided into four parts. Section II briefly highlights the main related works. Section III presents the Smart Drive project proposal as well as an overview of what was developed. Section IV encompasses the project development and implementation. Section V focuses on the main contribution of this paper regarding inferences of driver behavior. Finally, Section VI presents the conclusions about the validation of the proposal and comments on future work.

## II. RELATED WORKS

In order to start the proposed project, it was necessary to first investigate some related works, i.e. already published articles that had some ideas correlated with the objectives here exposed. Therefore, the following articles were analyzed:

- Driver Behavior Profiling Using Smartphones: A Low-Cost Platform for Driver Monitoring [11]: In this article, it is analyzed how smartphone sensors can be used to identify maneuvers. SenseFleet is proposed, a steering profile platform that is able to detect risky events direction; and
- Driver Profile Analysis: Event Detection through Smartphones and Machine Learning [2]: This article conducts an investigation with different sensors, present in an Android smartphone, and different classification algorithms, in order to evaluate which sensor set/method allows classification with greater accuracy. The results show that specific combinations of sensors and intelligent methods allow to improve rate performance.

It is important to note that other articles were also considered for the realization of the project and are cited hereafter.

## III. METHODOLOGY

For the project development, it was necessary to define what should be inferred and what should be returned to the user.

The project scope was based on the environment in which the car will be present, as well as its movement, given data sampling of several routes performed. So, it was possible to predict user behavior and to correlate data with streets that the car would go through. Thus, user's mobile phone can inform the best route as well as possible dangers in its trajectory.

The referred paper [12] is very useful regarding the functionality developed in the project, as well as the data to be inferred and corresponding interpretations. Also interesting is [2], which provides a good basis for the driver profile analysis.

### A. Objectives

Six specific objectives, that will provide a project progress vision, have been defined:

- 1) Collect telemetry data from vehicular computer. Such data will be captured from OBD-II (On-board diagnostics) device, as indicated in [5];
- 2) Collect data from user Android device sensors, as indicated in [13] and [14];
- 3) Develop mobile application gateway to receive collected data and transmit to server called Smart Driver;
- 4) Develop secure server, using Hypertext Transfer Protocol Secure protocol, with auto registration function to receive collected data and transmit it to application;
- 5) Execute inferences, both at application and server layers, using collected data, to identify driver behavior, as well as to send geographic information on the risk areas;
- 6) Develop application for users administration, access to collected data and inference results.

### B. Project phases

The architecture development has occurred in five phases, detailed as follows: in phase 1 data were collected from an OBD-II device, connected to the car, and the individual's smartphone; phase 2 consists of access to Smart Driver platform, from an application installed on smartphone; in phase 3 each user direction characteristics are verified by inference; Phase 4 consists of indications to the user about incidents generated from his driving and information about safety of certain routes; and phase 5 provides user administration interface, data and inferred information. Figure 1 shows, in an illustrative way, the phases related above.

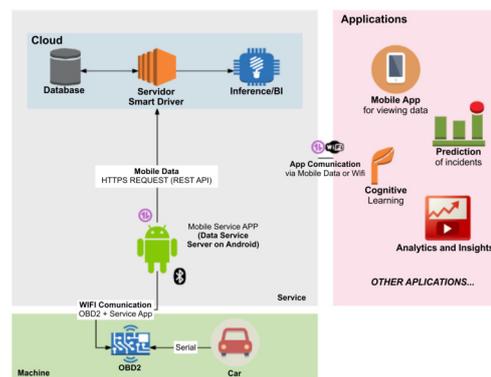

Figure 1. The project general architecture

### C. Sensors for an Android device

Some data have been set to be used from the user's Android device. These data are considered from the cell phone capability of acquiring them, for that, the work presented in [13] was useful. The data are quoted below:

- accelerometer - abrupt acceleration or deceleration can be inferred according to the acceleration vector provided by the sensor;
- GPS - provides the speed (m/s), making it possible to compare this value with the allowed track speed;
- orientation - according to the magnetometer and the gravity sensor, azimuth ( $-\pi$ ,  $\pi$ ) is obtained in radians. The change rate at the steering wheel is found by calculating the change after two subsequent samples, giving the idea of how sharp is the car turning.

The Android operating system was chosen as basis to this research because it is installed on almost seven times more devices than the iOS operating system in Brazil.

## IV. PROPOSED SOLUTION

This topic reports the development of proposed application for recording incidents and events while driving. The application module is responsible for receiving information generated by user and present it to the UIOT, a middleware responsible for data storage and sharing, developed and maintained by IoT research team, at the University of Brasilia. The tools used to develop the application module were Java, Android Studio IDE and Google Firebase.

### A. SmartDriver Platform

The SmartDriver platform development objective was to create a secure service for communication of stealthy data about user location, requiring that this service being scalable and highly available through the "Raise Middleware" use. Another important goal was the development of the user administration interface, the data and the plotting of the routes and cluster of incidents as heat zones on the map.

In Figure 2 is possible to visualize the reference region heat map, where heat points (red scales), present regions in which there were incidents, such as, abrupt acceleration and stops.

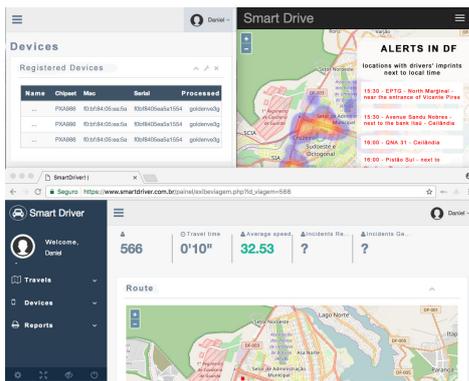

Figure 2. SmartDriver Platform

In this platform, in addition to presenting the risky areas on the roads, with their respective history of alerts, it is also possible to register new users. In order to do that, the Log in / Register window must be accessed to allow user will to set the requested email and password.

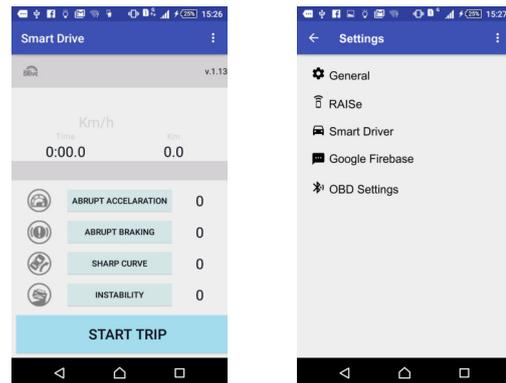

### B. Proposed mobile application

The application for capturing events has two main screens: Home and Settings.

The application starting screen is shown in Figure 3a. The user's trip will be initiated by clicking the Start Trip option. In this screen, the user's car speed will be displayed as well as the traveled time, the distance traveled and all events like abrupt acceleration, abrupt breaking, sharp curve and instability.

When starting the trip, in addition to tracking possible events while driving, user can report third-party events by clicking on event name buttons, as shown in Figure 3a.

Finally, the user will also have access to application settings, as shown in Figure 3b. In this menu, it is possible to access general application settings; connectivity function with Raise; connectivity settings with Smart Driver server; OBD-II device settings and the Firebase function that stores the updated Firebase token value, which identifies each device/user. This value will be used by the inference to send the results (data to be presented to the user) directly to device, which will be read by application and presented to user.

(a) Main screen

(b) Settings screen

Figure 3. Application screens

### C. Self-registration

The self-registration mechanism was developed as a way to facilitate the entry and management of devices in IOT networks, allowing sensors and actuators, aware of their context, to enter autonomously and securely in an environment capable of receiving massive volumes of data and control actuators safely. As explained in [15], the middleware responsible for receiving and processing data in cloud has two main components, the REST API Approach for IoT Services (RAISe) and the User Interface Management System (UIMS). RAISe is the web services interface responsible for responding to client requests, storing data provided by these clients. UIMS is the visual interface through which a user can consult data manipulated by the middleware.

The solution implements a complete self-registering architecture for the Smart Device from sending basic device data, such as serial number, MAC address and other identification data, thus forming a unique composite primary key for any device that enters into that network. After registration, the device can be associated with one or more users, keeping track of who handled the device during its life cycle. Thus, the sensor data recording is associated to user, promoting individual definition of their steering profile.

The entire information transit process between the device and the self-registering middleware is performed through a Secure Sockets Layer (SSL) connection. In addition, sender authenticity is verified based on a token generated randomly and periodically by the middleware and sent to the device after its registration process. Thus, in order to allow the call of service from a device, it must send an authentication token which must be within its validity.

Due to need for additional processing, the communication architecture between device and middleware is asynchronous. Thus, although the device makes repeated calls to the service to perform the data sending, the inference answer is performed only after processing data step, with message sending through an operating system API call. This solution was adopted because the constant data sending process from client requires a real-time response from the server.

## V. INFERENCE

The inference process is the base for the *insights* obtained from the collected raw data of the IoT devices. In the proposed model, part of the data processing and analysis is performed in the device itself, such as the identification of sharp braking and curves, and part is performed in a centralized way, mainly heuristics that depend on collective knowledge, that is, involving joint analysis of data coming from different devices.

Heuristics involving collective knowledge are precisely the main contribution of this project. The centralized analysis allows not only heuristics creation involving large volume of data, due to the difference of processing and storage capacities in relation to IoT devices, as it creates a bidirectional channel of communication, allowing the collectively generated *insights* to arrive at each of the individual devices. It is important to emphasize that, although several studies propose Vehicle-to-Vehicle communication models (V2V communication), the cloud-based communication strategy is more adequate at the present moment, since, while the mobile data communication technologies are more consolidated and provide good coverage and high speeds, V2V technologies are still in the early stages of deployment.

### A. Clustering and Alerts

From the collected data, the incident point clustering is performed to calculate the region hazard index and, thus, define the hazardous areas. The clustering groups points that they are at a distance of three meters from each other; this distance is necessary because it is very unlikely that two incidents will be marked exactly in the same geographic coordinate. Thus, the clustering process assists in the identification of areas where there is incident point concentration.

It was considered as an alternative the fact that, from the existing data sample, an inference was made to prove the proposed IoT architecture intelligence layer from the service layer, as well as to provide practical and efficient results regarding solution benefits. In this way, an automatic inference was developed, based on data from the Android device sensors, which analyzes if the speed sent to the Smartdrive server (middleware) is greater than track speed by 10%, if so, using Firebase, the server sends an "Over Speed" alert to the application and to the Android device's messaging system by means of a standard message class that logs all sent alerts as shown in Figure 4a.

Speed alerts are generated by regulatory speed capturing of route on which user is traveling. This is done through a geographic consult to the Openstreetmap geographic database, which was imported into the inference layer local database, a PostgreSQL DBMS with the postGIS extension.

User sends his geographical coordinate every 0.5 seconds; others sensor data are activated if the system identifies that the coordinate sent by user is within 50 meters of a hazardous area. Thus, a notification is sent to user informing that he is approaching a hazardous area as shown in Figure 4b.

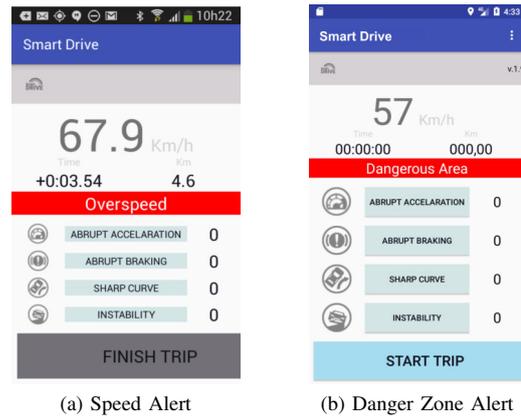

Figure 4. Alert screens

### B. Execution Layer Inference

Inferences executed only at service layer would not characterize an IoT solution. Given the application on smartphone could not be considered a smart object whether it did not have embedded intelligence, it was decided to make inferences about driver behavior directly in execution layer, so that its results can be sent to server in followed or simultaneously, depending on packet sending time configuration.

Again, to prove initial hypothesis in the work of the available data sample, we opted to identify two physical phenomena: abrupt acceleration and abrupt braking, from reading the three axes (x, y, and z) of the Android device's linear acceleration sensor.

Using simple logic without noise (Kalman), and as reference, the gravity acceleration (9.8 m/s) and threshold defined in [16] [17], the following equation has been set up to alert whether values exceed thresholds set for abrupt braking and acceleration (1): a is accelerometer X axis sensor measurement, b is Y axis measurement and c the measuring of Z axis.

$$0.4g < \sqrt{a^2 + b^2 + c^2} \quad (1)$$

Another inference implemented in execution layer is to use vehicular computer data through OBD-II protocol, in which, whenever vehicular sensor acceleration is greater than 1, both application and trip will start automatically. Besides that, the trip will be automatically interrupted when speed and engine rotation are both equal to ZERO.

## VI. CONCLUSION

With goal of validating the system and scaling a cloud solution capable of meeting the demand of a large number of users, we invited 50 volunteers to use our software for a period of 30 days, with an average usage of three hours per day and we obtained the following results:

- 1) 24 users (50% of the sample) did not have EML327 interface in their car;
- 2) 5 users (10% of the sample) had communication problems with the OBD-II adapter;

- 3) 3 users (6% of the sample) have managed to install the OBD-II adapter but did not use the application at suggested frequency; and
- 4) 18 users (36% of the sample) used the application with suggested daily frequency.

Analyzing the last group of 18 users, we have the following statistics:

- 1) smartphone sensors collected a mean of 160 Bytes/s;
- 2) OBD-II interface captured a mean volume of 80 Bytes/s.

Therefore, the average data rate generated by the solution was 250 Bytes per second. With these values, we can conclude that in a journey of one hour, each mobile phone will need to transmit to the middleware 900 MB of data collected.

After the data collection sent by the group of volunteers, we arrived at the following conclusions:

- 1) Some manufacturers have not yet fully adhered to the OBD-II protocol, either for reasons of industrial secrecy or for adhering to underlying standards as proposed by the European Union and some Asian countries.
- 2) The generated data volume by each mobile phone is very high. This fact is leading us to research solutions where the mobile phone does not send all the data to central middleware. Taking advantage of today's phones large processing capacity, we state as future work a pre-processing at the edge, sending to the middleware only alert information and summary statistical data.
- 3) The client side processing and data analysis to identify individual events, such as sharp braking and presence of curves, seems to be a good alternative to reduce the need for processing capacity in central server.
- 4) The proposal heuristics involving collective knowledge creates a bidirectional channel of communication, allowing the collectively generated insights to arrive at each of the individual devices.
- 5) At this moment, the cloud-based communication strategy seems to be more adequate to provide communication among vehicles, mainly because V2V technologies are still in the early stages of deployment.

The security aspects or GDPR were not addressed in depth in this work since the goal was to evaluate the proposed platform operational capability. A deeper analysis of these security and privacy issues and the conduction of new tests with a higher number of users are considered for future work.

**Abstract**—The irreversible process of demographic change, especially in Germany, leads to numerous challenges. According to this, research has to face the task to integrate the constantly ageing population into the urban and public space in such a way that there are as few barriers as possible. With the support of digitalization, so-called smart urban objects are being designed in order to do make integration, so that people and the available technology can be used most efficiently. A special ontology has been developed to meet this demand.

### I. INTRODUCTION

The demographic change of a permanently ageing population has become a globally visible phenomenon. Particularly in Germany, the population will be considerably older in the future than it is at present. According to [1], every third person will be older than 65 years of age by 2060. Corresponding with the tendency of a permanently ageing population goes the fact of changing needs and in daily life. In the era of the inevitable digitalization and in particular the *Internet of Things* (IoT), the challenge is to what extent digitalization can improve daily life for these ageing population. Accordingly, the concept of providing the urban space with so-called *smart urban objects* (SUOs) [2] is being pursued to increase the participation of elderly people by digitalization. These SUOs are elements of the urban environment, e.g. lights, information boards and benches, which are connected to a digital information space and allow for implicit or explicit interaction. The desired goal is to increase the feeling of security on urban environment by personalization of these objects. Some of these SUOs are described in detail in [2], [3], [4], [5] and [6]. The focus of this research is the intersection between the behavior of elderly people, currently referred to as *Ambient Assisted Living* (AAL), and *Smart City*. The final focus of this paper is to provide an ontology for classifying these SUOs so that both the technical aspects as well as the aspects of the AAL are considered.

### II. MOTIVATION AND RESEARCH QUESTION

The increase in barrier-free accessibility, especially for older persons, will be achieved with the support of SUOs. In order to enable a categorization of these objects, an ontology is required which takes both technical aspects and the view of public health and AAL into account. Based on this kind of ontology, designers of SUOs can consider all aspects mentioned to achieve maximum efficiency of these objects in the later context. In order to sufficiently answer this motivation, following research question is posed, which is the central issue of this article.

*How does a taxonomy for the design of SUOs have to be constructed in order to sufficiently consider aspects of Public Health and AAL as well as the technical perspective, so that a maximum increase of barrier-free accessibility is already addressed during the design process?*

### III. RELATED WORK

At this point, approaches and solutions are described and analyzed in terms of the way they answer the research question of this article. Basically, ontologies exist on the one hand in the field of Smart City and on the other hand in the field of so-called *Public Health*. At this point, both directions will be analyzed in depth and compared with each other, though the research question here characterizes exactly the intersection between these two directions.

In [7] an ontology in the area of Public Health is described, which characterizes in particular the direct situation in the hospital. Here so-called *medical classes* and *medical activations* exists. The former include specific diseases, symptoms, therapies, roles and departments in the hospital. The activations subsequently serve to bring these medical classes together in a meaningful relationship and thus describe the applications in the field of Public Health. An ontology-based approach in public health with the support of a *geographic information system* (GIS) is discussed in [8].

The ontology is used for the fusion of data from social and health related issues. Nevertheless, the GIS is the primary focus of the description, and ontology is only used as a tool. So therefore is no further discussion of it. In the contribution of [9] a set of different ontologies is presented, which should support designers in the development of so called AAL and those services. In detail, *actors*, *spaces* and *devices* are modeled and linked so that concrete AAL-elements can be described that have been used within the present study. Overall, this type of modeling is very complex and still has no generic character, meaning that any further use is crucial. A framework for managing the current state as well as the users profile information extracted from the internet and the mobile context is illustrated in [10]. This so called *Next Generation Network* (NGN) is an ontology for modeling typical users of AAL-services. But these services are only user centric and have no relation to technical issues. Also the platform in [11] offers assistance in communication and information acquisition by providing personalized and context-aware AAL-services. Therefore an ontology is used where users are the central aspect of the platform. Furthermore this ontology enables a historical view of the users changing characteristics and environment. In view of this explanation, only the user behavior is addressed without encompassing the technical factors. Also in [12] an ontology for structuring daily living activities of users is depicted, whereby a stronger focus is placed on the underlying aspect of AAL and thus on elderly persons. In contrast, the ontology in [13] discusses the technical aspects in terms of best practice for building automation devices and functions and how these underlying models are structured especially in the area of AAL. But in this case there is only a technical view without inclusion of users perspective.

In contrast to solutions of Public Health and AAL, there are some approaches from the Smart City context. These are presented in the following. This Smart City context is characterized by data collected from various distributed systems. Purposing these task in [14] the so called *Semantic Web* is used for designing a new Smart City ontology. The primary focus is to address the interoperability among the different systems and frameworks for describing Smart City objects. In [15] is an analysis about the impact of Smart City applications observed in the field of energy and transport. Besides [15] describes [16] an ontology to describe the entire Smart City domain. In [17] this description is extended for IoT-based applications. Nevertheless, [14], [15], [16] and [17] all have a strong technical focus and do not mind the user-centered perspective.

In addition to the number of ontologies mentioned so far, a so-called *Design Space* is described in [18] which enables the characterization and categorization of UI-based elements in the development of applications. This idea would require continuous expansion to include the sensors and applications of the IoT arising.

In summary, a wide spectrum of previous ontologies were presented. These addresses on the one hand the areas of

Public Health and AAL and on the other hand the topic of Smart City. The former ontologies have a strong user-centric focus and the latter are technically very pronounced. However, there is no solution among all approaches that represents a sufficient mix to satisfy the related research question of this article. In addition, the investigated solutions indicate that the aspect of interconnecting the underlying data structure is becoming increasingly important. As a result, this aspect would also have to be integrated more into the ontologies used in this context.

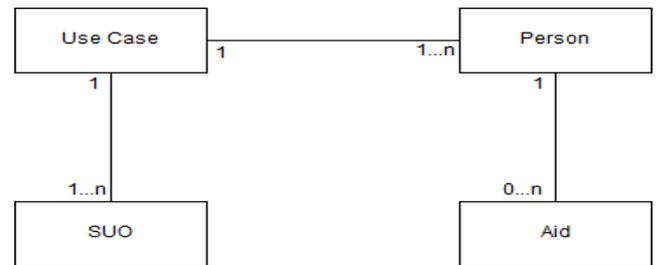

Fig 1. This picture illustrates the entity relationship diagram of the basic relation between smart urban objects (SUOs), the appropriate use case, involved persons and the personalized purpose (aid).

#### IV. DESCRIPTION OF SMART URBAN DESIGN SPACE

This chapter introduces the so-called *Smart Urban Design Space* (SUDS). Such a taxonomy meets the above-mentioned full range of criteria in terms of technical aspects, AAL and Public Health. A fundamental idea of this SUDS is the networking of the separate criteria. The basic context is represented graphically in Fig. 1, whereby each use case can be supported by at least one or more SUOs, which are used by at least one or more persons. In order for the SUOs to be used by the persons per use case, it may be necessary to provide additional assistance, which is continuously referred to as aid.

Against this background, a use case is the concrete scenario in which the elderly person(s) can use the digital support outdoors (outside buildings). Concrete examples in this context are an adaptive lighting system of the area to be walked in during a walkway, an adaptive park bench, which adapts to the individual sitting height of the respective person as well as intelligent information spotlights, which provide personalized information of the urban space to be visited. These examples are presented in detail in chapter 5.

Within the SUDS, the three criteria SUO, Aid, and Person exist for each use case, with their corresponding subordinate properties. In this regard, an overview of the entire taxonomy is shown in Fig. 2. A person has so-called competencies, which are continuously referred to as *skills*. These include *speaking*, *seeing*, *hearing*, *cognitive* skills such as easy logical thinking and *movement*, which in this case refers to walking without aids. The SUO contains the five criteria *actuator*, *sensor*, *parallelization*, *personalization* and *interaction sensor*. The *interaction sensor* describes which human

sense for an interaction of the SUO is required. It distinguishes between *seeing*, *hearing* and *haptic* handling such as using a touch pad. In addition to operating sensors, there is also the criterion of technical sensors, which is referred to merely as *sensors* within this taxonomy. There are *mechanical*, *piezoelectric*, *capacitive*, *inductive*, *optical*, *magnetic* and *signal-based* practices. The latter symbolize the provision of information by an external information source. Similar to technical sensor technology, the *actuator* also distinguishes between *mechanical*, *signal-based*, *optical*, *thermal* and *acoustic* variants. *Personalization* classifies the SUO according to whether each *individual* person is addressed individually, whether a group of people is addressed (*cluster*) or whether no individual personalization (*general*) is satisfied. In this context, there is also the criterion of *parallelization*, whether the SUO differentiates only *single-user* or *multi-user* in the respective use case. Similar to the SUO, the aid has a shortened set of criteria. The *interaction sensor*, *actuator* and *sensor* are used, with the latter describing the technical perspective. The characteristics of these criteria are analogous to those of the SUO.

V. CASE STUDY “URBANLIFE+”

In the research project *UrbanLife+*, the autonomy and participation of senior citizens in urban areas is explored in such a way that they can be increased. For this purpose, urban objects in Mönchengladbach are to be transformed into SUOs with the help of innovative human-technology interaction approaches, which provide senior citizens with technical support in line with their needs and enable them to move around the city safely [2] [5]. Three use cases are pre-

sented for these addressed solutions, which are then classified in the SUDS. These use cases are Adaptive Lighting, Adaptive Park Bench and the Information Radiators. In the following these are explained briefly and the classification in the SUDS is discussed individually. Overall it is represented in Fig. 2.

A. Adaptive Lighting System

The system of the Adaptive Lighting improves the feeling of safety on elderly people especially in dark areas at night by personalized and position-dependent variation of intensity and/or color of the light [1] [4].

B. Adaptive Park Bench

Adaptive Park benches are a kind of smart seats, that can adjust to individual anthropometric measures of people. Thereby the usability of the seats is enhance which in turn also enhances safe usage. Particularly older people face severe problems in sitting down and standing up at common seats. The reason is that, the gap between standover and the height of the seat surface imposes trouble when the older people have weakened leg muscles, impaired balance or general difficulties in bending their knees. For this reason the seat surface of the adaptive park bench can lift up to the standover of a pedestrian, which actively supports in sitting down and standing up. For ergonomic sitting the seat surface will be adjusted to the sitting person’s popliteal height. More technical details are described in [2] [19].

C. Information Radiators

Information Radiators are a class of devices capable of displaying dynamic information while installed at a static

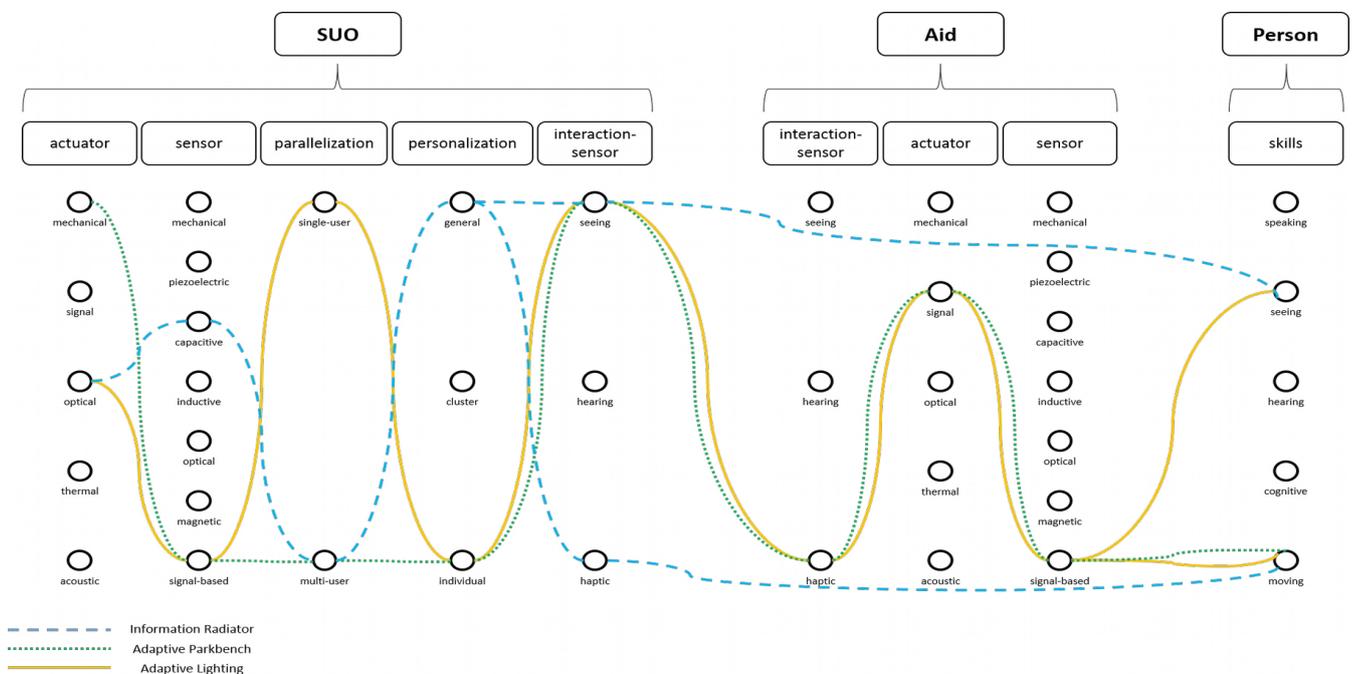

Fig 2. This figure is the representation of the so-called *Smart Urban Design Space* (SUDS). It shows the basic categories SUO, Aid and Person, with the available properties. By combining the properties of these categories addressed by the corresponding use case, a visualization similar to a dendrogram is generated. Furthermore in this figure, the three use cases are arranged in the SUDS. These use cases include the *Adaptive Lighting*, the *Adaptive Park Bench* and the *Information Radiator*, each of which is marked in the legend.

position in a public or semi-public environment. They can range from large interactive screens which can be used via touch, to small low-power devices equipped with low-resolution LED displays. The informational content they show is related to the local context. This includes, but is not limited to, offerings by commercial and noncommercial actors in the vicinity (such as stores, restaurants, cinemas, community centers, sports clubs, etc). The concept is discussed in more detail in [20].

## VI. DISCUSSION

As a result of the taxonomy of the SUDS developed in this paper, a rather interdisciplinary classification of the so-called SUOs has been successfully achieved, without getting stuck in technical details in this context, nor without too one-sided a view of social criteria affecting the user. In this context, the previous SUOs were specifically classified in the SUDS (see Figure 3). The SUOs classified so far include Adaptive Lighting, the Adaptive Park Bench and the Information Radiators. In addition to these existing SUOs, there is also the possibility of continuously classifying new ones in order to visualize the essential aspects of the local field of knowledge. The classification in this taxonomy (Figure 3) shows that more or less all SUOs have similar characteristics regarding their categories. For example, in relation to the interaction sensor, which is only haptically or optically pronounced in all previous objects. Consequently, an essential motivation for further SUOs would be to include acoustic signals in order to increase the intersection between the technical and personal skills.

## VII. CONCLUSION AND OUTLOOK

Concerning the research question within this article, a taxonomy called SUDS was constructed which merges the required aspects of AAL, Public Health and technical aspects and makes them usable for integrating so-called SUOs.

In the future, potentially beneficial SUOs could be determined and designed with the support of the SUDS, which do justice to the aspects of AAL and Public Health without violating the technical conditions.

## ACKNOWLEDGEMENT

This work was fully conducted in the scope of the research project *UrbanLife+* (16SV7442), funded by the German Ministry of Education and Research.

**Abstract**—Recently, IoT technology has been applied in various field. One of the possible fields of an application is logistics system. In current system, a delivery must go through the designated logistics hub, which doesn't provide shortest distance. Such system costs time and inefficient expenses. In this paper, we propose an enhanced parcel delivery system based on IoT technology for reducing total delivery distance and seeking for much economy. First, we designed a sort of IoT devices which can be attached to parcels. This device has various functionalities including the ability to figure out current delivery route. Second, we addressed some difficulties such as : (i) issues linking IoT device into its platform; (ii) issues for designing IoT devices functionalities. Third, we propose ways to improve the efficiency of IoT based parcel delivery system. From these considerations, our system may improve total economics of parcel delivery system.

## I. INTRODUCTION

Thanks to the 4th Industrial Revolution, Internet of Things (IoT) technology is expanding and prospering in many industrial sectors. Accordingly, a rising number of domestic and foreign corporate are rushing for their own IoT platform in order to launch new services. In current IoT platform, computing and saving process of data is mostly done in central cloud. However, the centralized IoT system is causing many issues. Centralized IoT system requires a giant central server which processes and saves data that are received from a number of devices. This demands big administrative expense. It is difficult to increase connection of IoT devices continuously, since central server has its limit. To resolve this problem, we should expand the central server, but expanding the central server is very inefficient and will not be recommended. In addition, IoT devices require efficient management of data and central server is very important due to its real time data processing. Therefore, if there is a problem with the central server, every IoT device belongs to the platform will become useless. It is predicted that distributed networking of IoT will take place in the future to solve these problems [1].

In this case, the central server's role will be reduced, and the portion of the work handled by the terminal device will increase. In the future era of IoT, firmware-based IoT devices, which only deal with simple tasks, will be raised to the

level of the RTOS (Real Time Operation System) to secure safety and connectivity. Amazon acquired FreeRTOS, the most commonly used RTOS in embedded systems in 2017 [2]. In the same year, Google announced Tensorflow-Lite, a deep learning framework for IoT devices, to compensate for problems with cloud-based AI devices [3]. Based on existing experimental IoT platform provide by SK Telecom (SKT) of Republic of Korea, our parcel delivery enhancement can be implemented. The name of IoT platform is ThingPlug which also provides LoRaWAN as dedicated global network for IoT.

In this paper, we propose a distributed networked IoT delivery system instead of a centralized IoT platform as described in section II. Section III introduces functionalities of delivery dedicated IoT devices. Section IV introduces a process that connects IoT devices to distributed network IoT platform. Section V discusses issues in the process of interworking commercial networks. Section VI describes dedicated IoT devices we implemented, and Section VII concludes and introduces direction of research.

## II. IOT PLATFORM

Various factors such as Network, Device, and Application Server are needed to implement in IoT service. IoT platform refers to a service that allows various components to meet and easily combine and helps increasing utility value by connecting each element. As a representative, Qualcomm's AllJoyn, Microsoft's Azure IoT Suite and SKT's ThingPlug provide centralized services [4][5]. In this paper, we use SKT's ThingPlug as an IoT platform. Designed terminal device collects sensor data according to purpose and sends it to ThingPlug network server through gateway. Application Server can import data stored in ThingPlug's Network server and send control commands to the terminal device. These sequences are well expressed in Fig. 1

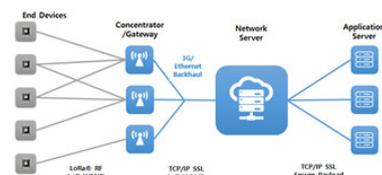

Fig. 1. IoT Platform

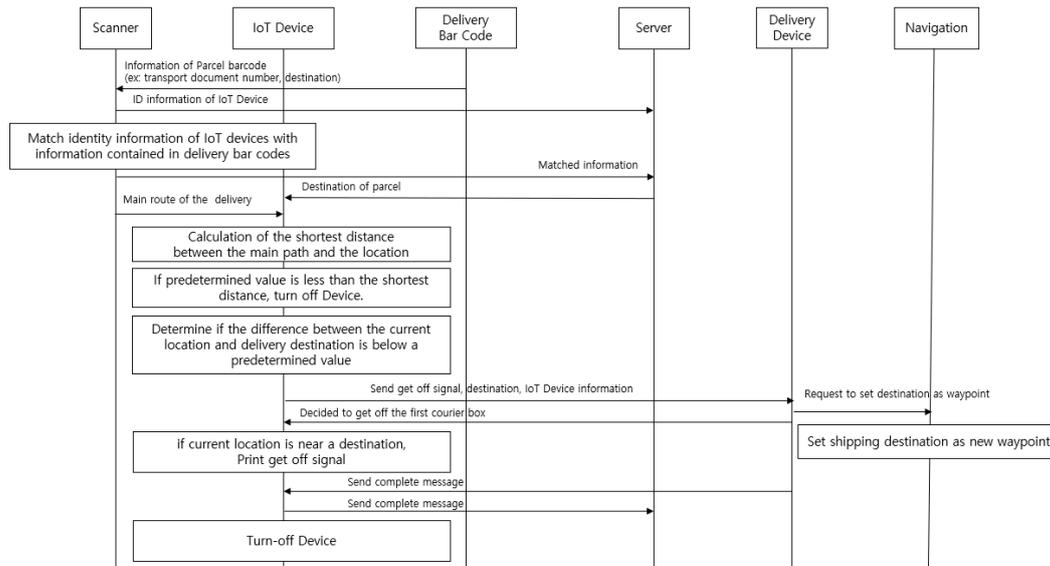

Fig. 2. Sequence Diagram of Improved Parcel Delivery

There are three ways to utilize ThingPlug Network Server. First case is to use one terminal device. In this case, we can communicate with ThingPlug Network Server using API provided or with ThingPlug via LoRa module. Second case is to use the terminal devices near the fixed gateway. In this case, we can connect the terminal device and the gateway in a wireless star topology method. Then the gateway collects the sensor from the terminal devices and send it to the ThingPlug server. At this time, the wireless communication between the terminal device and the Gateway can use LoRa RF, and the communication between the gateway and ThingPlug can use Ethernet. The third case is the terminal device that moves a wide range of areas. In this case, it is not possible for a single gateway to cover all the terminal devices, which is moving extensively. Therefore, we use Low Power Wide Area Network (LPWAN) that can communicate with ThingPlug server anywhere. LPWANs include LoRaWAN and Sigfox [6][7][8].

### III. IOT DEVICE FUNCTIONALITIES

Operation methods of IoT devices attached to delivery boxes were divided into several stages. There are four phases: the collection phase, GPS phase, the moving phase and the completion phase. We presented Sequence Diagram at Fig. 2

#### A. Parcel Collection Stage

ID information will be printed through the display module once pick-up of parcels starts with IoT device attached delivery box and IoT device is turned on. After a while LoRa will be connected with server. Then, the scanner will collect the data from the barcode attached on the delivery box. This data will be transmitted to the server and saved in a table form by matching the information, invoice number, and delivery destination of the IoT device. And IoT device get Collecting

path and calculate shortest path with collecting path and parcel destination. If that distance is less than threshold value, then start Parcel in move stage.

#### B. GPS Data Collection Stage

Once data are received from the geopositioning module of the IoT device, the data are stored for the current location of the IoT device. Usually, GPS is a representative one of geopositioning system. In case the data cannot be received from the GPS module, following steps are necessary. First, you need to get to nearby access point (AP) with Wi-Fi module. Then, obtain the current location information from the MAC address and API of the AP [9]. If Wi-Fi AP is not accessible, receive the current location information from Bluetooth module attached to the IoT device in the carrier's smartphone. If didn't get positioning data, you should be waiting for a certain delay and start from the beginning again.

#### C. Shortest Path Check Stage

In this stage, we need to know how to check the shortest path in order to add a new destination. At the destination, other parcels can just stop over and move on to next logistics hub. The process is as follows. Once data have been collected through stage B., then begin stage C. and use the data to check the distance between the current location and the destination. In case the distance is shorter than the threshold value, then send the parcel data to ThingPlug server via Lora and send ID info of IoT device to transmitter's smartphone via Bluetooth. Then, add new destination info from IoT device then update logistics path. Lastly, finish the moving step and move onto stage D. In case the distance is longer than the threshold value, loop will be started again after waiting for a certain delay of time.

#### D. Parcel Deliver Completion Stage

After the stage C. on every fixed time, then check the distance between current location and destination. In case the distance value is very small, IoT device will recognize that the parcel has arrived the destination. IoT device will emit signal by LED or display module. Then the courier can recognize that the box should be unloaded. Moreover, IoT device sends the completion signal to ThingPlug server and the signal will be updated. Then the server will send completion message to the IoT device. IoT device will emit return signal and will be turned off. Afterwards, the original shipper will collect IoT devices.

#### IV. IOT PLATFORM INTERLOCKING PROCESS

This paper adopted SK Telecom's IoT platform, ThingPlug, which utilizes LoRaWAN installed in South Korea, considering the size of the data and the size of the commercial network transmitted by IoT device. SK Telecom provides commercial network linkage through its officially certified LoRa module. In this paper, LoRa module of Wisol was used [10]. The LoRa module of the Wisol is connected to the Micro Controller Unit (MCU) and the Universal Asynchronous Receiver/Transmitter (UART) to send and receive messages through serial communication. The message sent from MCU to LoRa module follows the Command-Line Interface (CLI) command format defined in the user manual. ThingPlug's LoRa commercial network interworking is accomplished through Open Test Bed (OTB) certification and Quality Assurance (QA) testing.

Looking at the test items required by OTB certification, the first thing to do is to identify the debug message of the LoRa module from the MCU and design and implement it so that CLI command can be sent. During OTB authentication, all debug messages sent by LoRa module must be printed out because the debug message is verified through the customer's Host PC. Second, if you receive the Reset Downlink control command, we must reset the module after five seconds of delay. If IoT device that is on commercial network shows abnormal symptoms of operation, ThingPlug server sends an order to reset IoT device. MCU parses DEBUG message sent from LoRa module and performs Device Reset through CLI command. Since the reset command received from the server is a Confirmed message type, the reset must be performed after waiting about five seconds for LoRa module to receive the command and send the ACK. In addition, we should implement MCU command for perform the following actions: (1) Data Send 65 Bytes. (2)Data Send 66 Bytes. (3) Link Check Request. (4) Device Time Request.

For example, max payload is 65 bytes, so sending 65 bytes as shown in (1) can proceed without error but sending 66 bytes as shown in (2) must be able to check the ERROR debug message. Also, we need to check message type. There are two kind of message confirmed and unconfirmed. Confirmed message need to check packet was received. If the terminal device or Server sends a Confirmed message, they should send unconfirmed message with the ACK to make sure that message was processed. If there are no ACK, they send confirmed

message again. if retransmissions happened 8 times, return error and process will end. In addition, codes should be implemented that allow remote modification of the number of retransmissions. Because it is an additional remote-controlled IoT device, functions had to be implemented so that device can perform all tasks when variety of commands were issued from server. To do this, you need a code to verify that various functions work properly.

It was necessary to verify that Frame Count messages, which are larger than or smaller than the existing values, were received from the device in ThingPlug server by correctly parsing the corresponding messages, and that the frame Count was set to be larger than the existing values and then processed the message normally. It was also necessary to check if the message is handled normally when received from the terminal after setting up the Mgmt cmd. In addition, if the same message was received during processing after receiving the message, a code was required to confirm whether the message was dropped, and the uplink message was retransmitted and that the ACK was sent to the server.

There was a condition that the firmware of the LoRa module should be kept up to date to stabilize the IoT device, and that the PCB produced by itself should be used instead of the PCB provided with the IoT device. When communication with ThingPlug is required during the implementation of OTB certification items, open the device to the test network to conduct the experiment. The opening of the test network is completed by submitting the class with Device EUI to SK Telecom's ThingPlug manager and entering the information into LoRa module. You can register the device in your account in ThingPlug portal and send various downlink messages to the device through Open API Test. After OTB certification, SK Telecom is assigned a manager according to IoT service field and provided a test number for commercial network, which can be tested on commercial network in South Korea for three months after subscribing to CCBS. It also carries out commercialization and QA test through the manager's guide according to IoT service that it wants to provide. After passing QA test, connection of IoT device's commercial network will be completed.

#### V. ISSUES IN THE INTERWORKING PROCESS WITH COMMERCIAL NETWORK

In this paper, an esp32-based MCU board with built-in Wi-Fi function and Bluetooth function was designed and implemented. On top of this, GPS module and Wisol LoRa module for GPS tracking are connected by UART. However, there is only one pair of RX, TX pin for UART communication on pin diagrams. Therefore, the software serial replaces the deficient UART pins. Since esp32 does not officially provide the software serial, use the open source of third party. In addition, an additional hardware series is specified in the specification, which is not specified in the pin diagram. The esp32 offers up to three pairs of hardware serial ports.

During OTB test, the staff of the test shall be able to check all debug messages. Generally, the hardware serial buffer in

esp32 can be stored up to 256 bytes. If the LoRa module receives debug messages exceeding 256 bytes, the message is lost. Therefore, the size of the buffer should be increased to 1024 bytes through a member function of the Hardware Serial object to receive and output a complete debug message.

Since IoT devices are attached to delivery boxes, IoT devices must all be operational until delivery is completed after receiving delivery. To do so, battery management of IoT device is essential. For this purpose, the LoRa module OTB test-to-test Class A format was used. Class A format is not always on but is a very efficient method for battery management by storing data in the buffer when ACK comes from the server or when the value is entered from the sensor and performing operation every certain period of time. A typical method cannot store all data, but the same method of increasing the size of the hardware serial buffer in esp32 can store 1 kb of message, and the buffer of that capacity can store enough data, and the ACK of the server is sufficient. Energy management and performance are very important elements of IoT device, both aspects of IoT device performance and energy management can be grasped through this method.

## VI. IOT DEVICE

We implemented IoT Device for parcel delivery system as shown in Fig. 3. For basic control functions, MCU board with built-in esp32-based Wi-Fi and Bluetooth function, GPS module for GPS tracking function, and battery and battery charging are attached. The purpose of the design was to make the device as small as possible when manufacturing the device, and to prepare for the impact between delivery and delivery, the impact absorbing rubber was attached to the upper and lower parts of the IoT device, and acrylic plates and devices were firmly fixed using brass supports. To prevent impact damage to the acrylic or PCB plates, washers were added to each joint to enhance stability. In addition, the antenna was attached for desired Lora communication. The battery, which is at greater risk of short-circuit due to the weight during delivery, was fixed on acrylic plates. To secure GPS data, and the GPS Sensor was secured on acrylic plates to enable stable sensor reception. In order to manage the battery of the IoT device when not in use, the module can be switched on and off using the On - OFF switch. After checking whether the battery functions properly during delivery, we confirmed that 80 hours of continuous operation is practically possible. Although it has been suggested that the protruding part of the

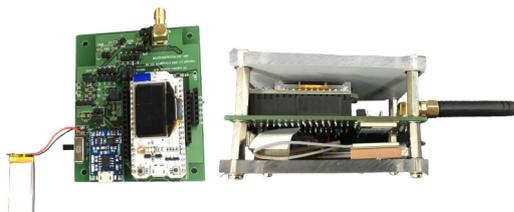

Fig. 3. Device Image

antenna will be a problem when using the IoT device seal, it is actually attached directly to the parcel when collecting data and can be used reliably when attaching it toward the sky when attached

## VII. CONCLUSION

In this paper, we proposed an enhanced parcel delivery system with IoT technology for reducing total delivery distance and for much economy. We showed the developing process and implementation to experimental IoT platform. Previously, central cloud did the most of control processing and computation. However, it is possible to divide up the processing to IoT device by using Bluetooth and Wi-Fi features. Then it became possible to process the data without going through server due to various functionalities of IoT device. In addition, the corresponding module can be deemed to be highly useful, such as by changing it to the delivery system or the tracking system. By using location information generated from these systems, it can be used as an active test data set in hub-related papers to prove the efficiency of the Hub and spoke method currently used and could check other additional logistics delivery methods [11][12]. Additionally, it would also devise and utilize a method for the security and integrity of the logistics system by combining blockchain with IoT platform and our IoT device functionality [13]. More functionalities can be considered; we can also add functions to identify the weight, type, size, and delivery area of the product entered before delivery and to show how to increase space efficiency and speed of delivery during loading parcels.

**Abstract**—The coverage of a Region of Interest (RoI), that must be satisfied when deploying a Wireless Sensor Network (WSN), depends on several factors related not only to the sensor nodes (SNs) capabilities but also to the RoI topography. This latter has been omitted by most previous deployment approaches, which assume that the RoI is 2D. However, some recent WSNs deployment approaches dropped this unrealistic assumption. This paper surveys the different models adopted by the state-of-the-art deployment approaches. The weaknesses that need to be addressed are identified and some proposals expected to enhance the practicality of these models are discussed.

## I. INTRODUCTION

THE WSN deployment on 3D RoI presents many difficulties evoked by the topography, which has a direct impact on the coverage quality. Indeed, the presence of obstacles can hinder the detection of the target event. Also, the use of mobile SNs to eliminate the coverage voids becomes increasingly difficult, and the random deployment generates a very low coverage quality for 3D terrains [1]. Thus, ensuring the coverage of a 3D RoI by a WSN requires a deterministic deployment of the SNs, which consists in precomputing their number and their positions [2]. The resolution of this NP-hard problem [3] goes through a formulation phase, which describes the impact of the different factors on the coverage quality, and provides in its end an expression measuring the coverage quality produced by a given deployment scheme.

Once formulated, the problem is solved using heuristics or meta-heuristics, to select an appropriate deployment scheme. The practicality of a selected solution depends on the formulation process, which has been accomplished differently in the literature, depending on the factors taken into account and the modeling of their impacts on the coverage quality. When deploying WSNs on 3D RoIs, the formulation phase needs to be enriched by adding the RoI topography factor. To do this, it is necessary as a first step to model the SNs sensing capability, taking into account the RoI impact. In the second step, this model is used to formulate the RoI coverage. In this paper, we survey existing formulations of the coverage of 3D RoIs by WSNs in order to identify their main shortcomings that must be eliminated and make them more realistic. The coverage models and the RoI coverage deduction are detailed in Sections II and III, respectively. Section IV discusses the reliability of these models and some open issues. Section V concludes the paper.

## II. COVERAGE MODELS

To estimate the coverage quality of the RoI, produced by the deployment of a WSN composed of  $\mathcal{N}$  SNs, it is necessary to check the coverage status of each point  $p_i$  of the RoI. This status is deduced from a basic information  $\mathcal{C}(p_i, s_j)$ , which is the state of coverage of  $p_i$  by each SN  $s_j$ . The factors considered in estimating  $\mathcal{C}(p_i, s_j)$ , and the formulation of their impacts on  $\mathcal{C}(p_i, s_j)$  represent the coverage model [4]. In the existing coverage models,  $\mathcal{C}(p_i, s_j)$  is formulated according to one or more of the following factors: (i) the sensing range of  $s_j$ ; (ii) the sensing angle of  $s_j$ ; (iii) the topography of the RoI; (iv) the weather permeability of the RoI, and (v) the permeability of the objects separating  $p_i$  and  $s_j$ . It should be noted that the first and second factors are part of the SNs characteristics, while the third, fourth, and fifth factors belong to the RoI characteristics. Consequently, the most general formula of  $\mathcal{C}(p_i, s_j)$  is given by Eq. 1, where  $\mu_d(p_i, s_j)$ ,  $\mu_\phi(p_i, s_j)$ ,  $\mu_v(p_i, s_j)$ ,  $\mu_w(p_i, s_j)$ , and  $\mu_o(p_i, s_j)$  are binary or probabilistic functions, modeling the impact of the first, second, third, fourth, and fifth factors, respectively. In the sequel, we discuss the different models proposed to consider the impact of these factors on  $\mathcal{C}(p_i, s_j)$ .

$$\mathcal{C}(p_i, s_j) = \mu_d(p_i, s_j) \times \mu_\phi(p_i, s_j) \times \mu_v(p_i, s_j) \times \mu_w(p_i, s_j) \times \mu_o(p_i, s_j) \quad (1)$$

### A. Impact of the SNs sensing range

The sensing range of  $s_j$  is a reference distance  $r_s$  from which we can pronounce on the coverage of  $p_i$  by  $s_j$  in function of their distance  $d(p_i, s_j)$  [5], [6], [7], [8]. The influence of this factor on  $\mathcal{C}(p_i, s_j)$ , modeled by the function  $\mu_d(p_i, s_j)$ , takes three forms: (i) *Deterministic impact* [5], [6], where  $\mathcal{C}(p_i, s_j)$  is constant with respect to  $d(p_i, s_j)$ , as long as  $p_i$  is in the sensing range of  $s_j$ . Otherwise,  $\mathcal{C}(p_i, s_j)$  is null; (ii) *Probabilistic impact* [9], [10], [7], where  $\mathcal{C}(p_i, s_j)$  degrades with respect to  $d(p_i, s_j)$ , and it becomes null when the point  $p_i$  is outside the sensing range of  $s_j$ ; (iii) *Hybrid impact* [11], [12], [13], by considering that  $s_j$  has two sensing ranges, the first is "with certitude", noted  $r_1$ , and the second is "without certitude", noted  $r_2$ , where  $r_2 > r_1$ . Thus,  $\mathcal{C}(p_i, s_j)$  is constant with respect to  $d(p_i, s_j)$ , as long as  $p_i$  is in the sensing range "with certitude" of  $s_j$ ; it is null when  $p_i$  is outside the sensing range "without certitude" of  $s_j$ , and it degrades with

respect to  $d(p_i, s_j)$ , in the remaining case. Fig. 1 shows 2D-graphical representations of these models.

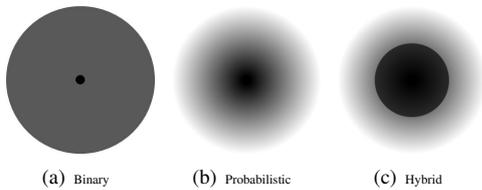

Fig. 1. Impact of the sensing range.

### B. Impact of the SNs sensing angle

Sometimes, the sensing capability of SNs is limited to an angle  $\phi$ . In this case, the coverage of  $p_i$  by  $s_j$  depends on the position of  $p_i$  with respect to the orientation of  $s_j$ , represented by the unit vector  $\vec{u}_s$ . Thus, the position of  $p_i$  with respect to the orientation of  $s_j$ , is measured by the angle  $(\vec{u}_s, \vec{s}_j \vec{p}_i)$ , whose impact on  $\mathcal{C}(p_i, s_j)$  takes three forms: (i) *Deterministic impact* [14], [6], [15], which means that  $\mathcal{C}(p_i, s_j)$  is constant with respect to  $(\vec{u}_s, \vec{s}_j \vec{p}_i)$ , as long as  $p_i$  is in the sensing angle of  $s_j$ . Otherwise,  $\mathcal{C}(p_i, s_j)$  is null; (ii) *Probabilistic impact* [9], [10], which means that  $\mathcal{C}(p_i, s_j)$  degrades in function of  $(\vec{u}_s, \vec{s}_j \vec{p}_i)$ , and it becomes null when  $p_i$  is outside the sensing angle of  $s_j$ ; (iii) *Hybrid impact* [16], [17], which means that  $s_j$  has two sensing angles, the first is “with certitude”, noted  $\phi_1$ , and the second is “without certitude”, noted  $\phi_2$ , where  $\phi_2 > \phi_1$ . Thus,  $\mathcal{C}(p_i, s_j)$  is constant with respect to  $(\vec{u}_s, \vec{s}_j \vec{p}_i)$ , as long as  $p_i$  is in the sensing angle “with certitude” of  $s_j$ ; it is null when  $p_i$  is not in the sensing angle “without certitude” of  $s_j$ ; and it degrades depending on  $(\vec{u}_s, \vec{s}_j \vec{p}_i)$ , in the remaining case. Fig. 2 shows 2D-graphical representations of these models.

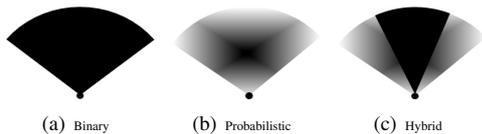

Fig. 2. Impact of the sensing angle.

### C. Impact of the RoI topography

To take into account the topography impact on  $\mathcal{C}(p_i, s_j)$ , most formulations proceed to verify the “visibility” between  $p_i$  and  $s_j$ , by using the Line of Sight (LoS) [15], [18], [19] method (Fig. 3). This latter selects  $N_v$  points  $q_i(x_i, y_i, z_i)_{1 \leq i \leq N_v}$ , located on the segment  $[p_i, s_j]$ , and compares the altitude  $z_i$  of each point  $q_i$  with the RoI height  $\mathcal{E}(x_i, y_i)$ , provided by a terrain model  $\mathcal{E}$ . Thus,  $p_i$  and  $s_j$  are considered inter-visible, if each point  $q_i$  is above the terrain. Once the visibility between  $p_i$  and  $s_j$  is verified, its impact on  $\mathcal{C}(p_i, s_j)$  takes two forms: (i) *Deterministic impact* [20], [15], [18], [19], by considering that  $p_i$  can be covered by  $s_j$ , only if  $p_i$  and  $s_j$  are inter-visible. In the opposite case,

$\mathcal{C}(p_i, s_j)$  is null. (ii) *Probabilistic impact* [14] by considering that  $\mathcal{C}(p_i, s_j)$  deteriorates (does not cancel out) according to the number of obstacles separating  $p_i$  and  $s_j$ . Some WSNs deployment approaches on 3D terrains do not consider the visibility factor when formulating the coverage. This choice is based on one of the following justifications. (i) Some events are detectable even if they occur in locations invisible to the SNs [21]; (ii) The terrain is assumed to be sufficiently convex, so that the visibility between a SN and any point within its sensing range is always possible [3], [1], [22]; (iii) The impact of the RoI topography, is already taken into account during the parameterization of  $\mathcal{C}(p_i, s_j)$  depending on  $d(p_i, s_j)$  [6], [7].

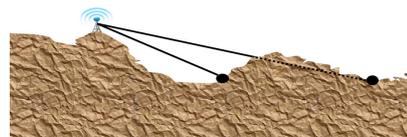

Fig. 3. LoS concept.

### D. Impact of the RoI weather and the RoI objects

In [23],  $\mathcal{C}(p_i, s_j)$  is considered dependent on the permeability of the objects and the weather of the RoI, where their impacts on  $\mathcal{C}(p_i, s_j)$  is formulated separately in a probabilistic way.

On Table I, we list the different coverage models, denoted  $C_1, C_2, \dots, C_{12}$ , adopted by the WSNs deployment approaches on 3D surfaces, where the difference between them lies in the factors taken into account and how their influences on  $\mathcal{C}(p_i, s_j)$  is modeled. The type of each model, which can be binary or probabilistic, is determined by the possible values of  $\mathcal{C}(p_i, s_j)$ . Indeed, a coverage model is binary if  $\mathcal{C}(p_i, s_j) \in \{0, 1\}$ , and it is considered probabilistic if  $\mathcal{C}(p_i, s_j) \in [0, 1]$ .

## III. ROI COVERAGE

The basic information  $\mathcal{C}(p_i, s_j)$  is used to formulate the coverage state  $Cov(p_i, \mathcal{N})$  of each point  $p_i$  with respect to the WSN composed of  $\mathcal{N}$  SNs. If the adopted coverage model is binary [6],  $p_i$  can be in two states with respect to the WSN: “ $p_i$  is covered”, if it is covered by at least one SN, and “ $p_i$  is not covered”, if it is not covered by any SN. Therefore,  $Cov(p_i, \mathcal{N}) = \max_{1 \leq j \leq \mathcal{N}} \mathcal{C}(p_i, s_j)$ . If the adopted coverage model is probabilistic, and  $\mathcal{C}(p_i, s_j)$  is interpreted as the probability of coverage of  $p_i$  by  $s_j$  [14],  $Cov(p_i, \mathcal{N})$  is given by  $Cov(p_i, \mathcal{N}) = 1 - \prod_{1 \leq j \leq \mathcal{N}} (1 - \mathcal{C}(p_i, s_j))$ . If the adopted coverage model is probabilistic and  $\mathcal{C}(p_i, s_j)$  is interpreted as the coverage quality of  $p_i$  by  $s_j$  [23], [11], [12],  $Cov(p_i, \mathcal{N})$  is equal to  $\max_{1 \leq j \leq \mathcal{N}} \mathcal{C}(p_i, s_j)$ , which means that the coverage of  $p_i$  is assigned to the SN that offers the best coverage quality for  $p_i$ . The last step in the formulating phase is to express the coverage quality  $Cov(\mathcal{A}, \mathcal{N})$  of the RoI  $\mathcal{A}$  by the WSN composed of  $\mathcal{N}$  SNs, using the state  $Cov(p_i, \mathcal{N})$  of each point  $p_i \in \mathcal{A}$ . This step is strongly related to the terrain model  $\mathcal{E}$  adopted to represent  $\mathcal{A}$  (Fig. 4), which may

be discontinuous, such as the matrix model or continuous, such as the mathematical and the TIN (Triangulated Irregular Network) models.

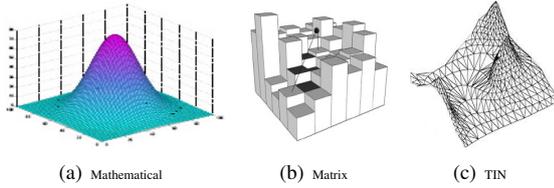

Fig. 4. Various terrain models used in the literature.

In the matrix model,  $Cov(\mathcal{A}, \mathcal{N})$  represents the rate of points of  $\mathcal{E}$  covered by the  $\mathcal{N}$  SNs [11], [12], [15], [18], considering that these points have the same level [11], [12], [13], [15], [18] or different levels [10] of importance. Thus,  $Cov(\mathcal{A}, \mathcal{N})$  is given by Eq. 2, where the weight  $w_i$  represents the importance assigned to a point  $p_i \in \mathcal{E}$ .

$$Cov(\mathcal{A}, \mathcal{N}) = \frac{\sum_{p_i \in \mathcal{E}} w_i \cdot Cov(p_i, \mathcal{N})}{\sum_{p_i \in \mathcal{E}} w_i} \quad (2)$$

Most approaches based on the mathematical model [5], [28] construct a matrix model  $\hat{\mathcal{E}}$  from the original model  $\mathcal{E}$ . Hence,  $Cov(\mathcal{A}, \mathcal{N})$  is computed according to Eq. 2, considering only the points of  $\hat{\mathcal{E}}$ . This transformation is avoided in some approaches [6]. The alternative idea is to estimate, using a geometric calculation, the surface  $\|\mathcal{A}_j\|$  of the portion  $\mathcal{A}_j \subset \mathcal{A}$  covered by each SN  $s_j$ . Thus,  $Cov(\mathcal{A}, \mathcal{N})$  is computed as the ratio of the surface covered by the SNs and the surface  $\|\mathcal{A}\|$  of  $\mathcal{A}$  (Eq. 3).

$$Cov(\mathcal{A}, \mathcal{N}) = \frac{\|\bigcup_{1 \leq j \leq \mathcal{N}} \mathcal{A}_j\|}{\|\mathcal{A}\|} \quad (3)$$

The approaches based on the TIN model formulate firstly the coverage quality  $Cov(t_i, \mathcal{N})$  of each triangle  $t_i \in \mathcal{E}$  [3], [1], [22], [23], which is calculated as the average of the coverage

quality of the important points of  $t_i$  (its center of gravity and its vertexes). After that,  $Cov(\mathcal{A}, \mathcal{N})$  is computed as the average of the coverage qualities of all the triangles  $t_i \in \mathcal{E}$ , assuming that these triangles have the same level of importance [4] or different levels [23]. The formula of  $Cov(\mathcal{A}, \mathcal{N})$  is given by Eq. 4, where  $w_i$  represent the importance affected to the triangle  $t_i \in \mathcal{E}$ .

$$Cov(\mathcal{A}, \mathcal{N}) = \frac{\sum_{t_i \in \mathcal{E}} w_i \cdot Cov(t_i, \mathcal{N})}{\sum_{t_i \in \mathcal{E}} w_i} \quad (4)$$

#### IV. DISCUSSIONS

The first important remark concerns the choice of the terrain model to represent the RoI. This choice is based, in most cases, on criteria other than reliability. For instance, the matrix model was used in [14], [9], although the TIN model is more appropriate. Additionally, the assumptions adopted in some formulations [3], [1] to justify the omission of the visibility factor are unfounded. Indeed, the assumption that the RoI is sufficiently smooth, where the visibility between a SN and all the points in its sensing range is guaranteed, is not realistic. Moreover, in the case where the visibility factor is considered [23], [14], its impact is formulated independently of the nature of the phenomenon being monitored and the type of SNs (laser, radio, etc.) used to detect it. In fact, these two parameters determine the manner (probabilistic or deterministic) and the degree of visibility impact on the coverage quality.

Moreover, some formulations adopt clearly unrealistic assumptions, such as the deterministic impact of the various factors on the coverage quality [3], [1], as well as the omnidirectional sensing capability of the SNs [22], [21]. Furthermore, most of the formulations [5], [6] do not consider the constraints imposed by the RoI, which limits the possible positions of the SNs. The existence of such constraints in complex 3D terrains is very likely. As a result, we believe that the design of a realistic coverage model remains an open issue. Its resolution requires to consider not only the type of SNs to be used but also the phenomenon to be monitored as well

as experimental tests, allowing the correct parameterization of their impacts and the deduction of the real relationship between them.

## V. CONCLUSION

Examining the several formulations of 3D terrain coverage by WSNs allowed us to confirm that this paramount process remains an open issue. We believe that carrying out experimental tests, to correctly assess and model both the influence of the above-discussed factors and the real relationship between them is the first step towards a practical and effective solution. As a future work, we plan to carry out an in-depth evaluation of existing resolution approaches related to the problem of 3D terrains coverage by WSNs. This will allow us to gain a better understanding in order to provide additional guidelines on the appropriate choice of the modeling/resolution approaches.

# Smart Urban Objects to Enhance Safe Participation in Major Events for the Elderly

Tobias Zimpel, Marvin Hubl  
University of Hohenheim  
Stuttgart, Germany

Email: {tobias.zimpel, marvin.hubl}@uni-hohenheim.de

**Abstract**—IoT increasingly permeates the public area, e.g., in traffic control and public transport. We propose to equip conventional urban objects with IoT technology to transform them into *Smart Urban Objects (SUO's)*. While there exists some research exploring the potentials, specific solutions to enhance safety for the elderly outdoors are still lacking. The elderly's safety is threatened due to declining physical conditions. As a consequence, the elderly may be excluded from outdoor activities such as participating in major events. Against this backdrop, we design SUOs for adaptive indications of urban hazards, barrier-free passages and for smart reservation of seats to enhance resting possibilities. We report on our solution using Bluetooth technology for remote sensing of older pedestrians serving as input for the objects' adaptive capacities. The SUOs have been installed for test purposes on a major event in a larger German city.

## I. INTRODUCTION

GROWING older is—sooner or later—inevitably accompanied by a deterioration of life skills, concerning motor skills, information processing skills and sensory capabilities [1]. This regularly intensifies the individual perception of threats to safety, particularly outside of the own home. Changes in body mechanics and impaired endurance pose a substantial risk for safe mobility [2], [3]. As a consequence, the elderly tend to avoid going outdoors without active assistance. This may lead to declining cultural and social participation up until the feeling of isolation. Empirical research has broadly studied and confirmed the positive influence of outdoor activities for the elderly's well-being [4], [5], [6] and we suggest that IT use of the elderly can have a positive impact on their participation in outdoor activities [7].

Demographic projections foresee a disparity between younger people who can provide care, and older people who will potentially be in need for care [8]. This anticipation virtually reinforces the requirement to find innovative means for assisting the elderly in their outdoor activities up until old age. The role of the built environment in this respect has long been acknowledged [9], [10]. As particular assistive means in the built environment we design so called Smart Urban Objects.

*Smart Urban Objects (SUO's)* are urban objects equipped with sensors, actuators and enabled to make potentially use of digital information processing. Examples of such SUOs are “smart” park benches, street lights, information panels or parking lots [11], [12], [13], [14]. By interconnecting them via internet technology they are *IoT objects*.

Unlike the example SUOs, we specifically aim at enhancing safety of older pedestrians for the participation in public outdoor major events. These events can be particularly exhaustive and hence hazardous for the elderly because of several reasons:

On major events use to be a relatively large crowd of people on a limited space. Additionally, the event area is usually characterized by temporary installations. These installations are furthermore rarely tailored for accessibility. All this may lead to increased confusion respectively to increased mental exhaustion and to increased physical exhaustion.

The arrangement of temporary objects also produces unexpected risks of tripping, as for example with cable bridges. Because of the temporary character, people often do not exactly know, where they need to go, if they search something particular. However, even if people know where they need to go, they are often unaware about accessible paths on the temporarily arranged area.

Older pedestrians may have increased need for seating rests. One reason is the aforementioned mental and physical exhaustion but can also be due to dizziness. Weather, especially heat, may be a factor, too. Older people often have impaired thermoregulation because of reduced fluid balance [15], [16]. This may stray the circulatory system even stronger, leading to seating rests for its relief and recovery.

Therefore, we design SUOs that adaptively warn for potential tripping hazards, indicate accessible paths and allow for reservation of seats from anywhere on the area. We have prototypically tested the SUOs on an outdoor public major event in a larger German city.

We make use of Leveson's conceptualization for *safety engineering* [17]. Safety is constituted as avoidance of accidents where the concept of accidents encompasses all situations that involve some unacceptable loss [17, p. 181]. In this respect, we focus on *conditions* potentially leading to accidents. Therefore, the concept of hazards is pivotal and is defined as “[a] system state or set of conditions that, together with a particular set of worst-case environmental conditions, will lead to an accident (loss)”. [17, p. 184]

On this basis, we make use of the implication that accidents occur only if an hazardous state coincides with some worst-case environmental conditions. Note, that hazards and environment constitute a dualism. That means whether a state is hazardous and whether an environmental condition is a worst-case one is mutually dependent. As our design object is the

urban *environment* through the means of SUOs, we define older pedestrians as the “systems” which can potentially be in a hazardous state.

We assume older pedestrians to be in a hazardous state if (a) they are only able to lift their legs comparatively little, (b) have impaired eyesight or (c) are in need for a rest. Corresponding worst-case conditions are (a) structural barriers, (b) “hidden” stumbling blocks and (c) missing seat opportunity. (a) Structural barriers, like curb stones or steps, may lead to an accident, if an older pedestrian cannot lift her legs high enough. (b) Stumbling blocks may lead to an accident if an older pedestrian cannot recognize it visually. (c) A need for a seat rest may lead to an accident, if there is no seat available.

In turn, (a) inability to lift the legs high is no problem if there are no steps or the like, (b) visual impairments do not lead to accidents if there is no hidden stumbling block on an older pedestrian’s path and (c) need for a seat rest is not critical if there is an available seat possibility. Conversely, if (a) a pedestrian can lift its legs high then steps are no effective barriers, if (b) stumbling blocks are visually recognized, they pose only little risks and if (c) a pedestrian has good endurance, missing seats are no safety problem.

This shows that principally two options are possible for enhancing safety: Avoiding hazardous states or avoiding worst-case environmental conditions. Since in our conception the hazardous states are inherent to the older pedestrians, we take them as given and seek to avoid the corresponding worst-case environmental conditions.

(a) The disability to lift the legs appropriately must be taken as is. However, the corresponding worst-case environmental condition can be avoided by guiding the pedestrians through passages without steps, curb stones and the like. Then, on the pedestrian’s individual path, there is no worst-case environmental condition. (b) Impaired vision must be taken as is. However, the corresponding worst-case environmental condition can be avoided by clearly indicating stumbling blocks, thus “unhide” them. There, we expect that an adaptive indicator is more salient than a static indicator. (c) Need for a rest, eventually, is taken as given. However, by reserving some seats and making them available adaptively to older pedestrians who announce a need for a rest, the worst-case condition that there is no available seat can be avoided.

Against this background we formulate our design-oriented research question:

*How to design Smart Urban Objects (SUO’s) for major events to adaptively avoid worst-case environmental conditions for older pedestrians being in a defined hazardous state?*

This paper proceeds as follows: In section II, we review the state of the art on IoT conceptualization as well as on pedestrian support with smart objects. In section III, we report on the design of our SUOs. In section IV, we evaluated our SUOs in terms of its principal functionality. In section V we discuss our SUOs and revised some conceptual issues,

like IoT. In section VI we conclude our work and provide an outlook.

## II. STATE OF THE ART

### A. *Internet of Things and Smart Objects*

Most basically “IoT is the network of things, with device identification, embedded intelligence, and sensing and acting capabilities, connecting people and things over the Internet.” [18, p. 4] As IoT objects are characterized by their situatedness in a physical real-world environment, sensors provide an input interfaces from the environment to the IoT object and actuators provide an output interface from the IoT object to the environment. Sensors convert physical signals from the real-world environment into digital data. Actuators convert digital data into actions that shall affect the environment.

In our conception, we allow that sensory input can be digitally pre-coded data, as for example when sensing radio signals, such as RFID or Bluetooth signals. While actuators are often considered to be physically moving parts [18, p.71], we include in our conception also non-moving parts that shall exert influence on the environment, like lights, audio-output, displays.

IoT can be seen from three perspective [19]: (a) The “Things”-oriented view contains technologies such as RFID, UID, wireless sensors and actuators as well as that the things shall be able to communicate with each other [19]. (b) The “Internet”-oriented view contains technologies such as IP for Smart Objects (IPSO) or Web of Things as well as middleware [19]. (c) Additionally a “Semantic”-oriented view can be taken, containing semantic technologies, e.g. for reasoning over data [19].

IoT conventionally has four layers [20]: (1) The sensor/actuator layer relates directly to the sensors, actuators as well as to the IoT objects themselves, hence to hardware [20]. (2) The network layer relates to the basic network technologies for data transfer [20]. (3) The interface layer provides methods for interactions with the IoT objects for other applications and users [20]. (4) Finally, the service provides services to satisfy user requirements [20]. This means, applications can be abstracted from the hardware-oriented sensor/actuator layer and be implemented on the service layer.

IoT objects are often referred to as smart objects. There are several differentiations for the “smartness” of the objects. One attempt is to differentiate the awareness capabilities [21]: (1) Activity-aware objects understand the environment as events that are directly linked with the object, such as touching the object [21]. (2) Policy-aware objects relate events to organizational policies. (3) Process-aware objects relate events to organisational processes [21]. Although this differentiation seems to focus on applications for business operations, it is conceptually applicable to other applications, e.g. if organizational policies are substituted by other norms.

An alternative typology of smart objects is given by their (I) capacity to store relevant data, including an identifier for themselves, (S) capabilities for sensory perceptions and (A) execution of actions with actuators, (D) decision-making

ability and finally (N) network connectivity [22]. Referring to the letters in brackets, an “I-N object” for example has an identity and data storage (where at least its identity is stored) and network connectivity. Note that not all combinations are considered to be realistic as for instance most object types without “I” [22]. Note also that objects need to implement a form of advanced information processing to exhibit decision-making abilities.

Smart objects are an important information technological basis for Smart City [23] as an application of IoT [24], [25]. Most conceptualization of Smart City contain or even accentuate inclusiveness as an aim. In this respect, we consider our IoT application to be a Smart City use case.

### B. Smart Urban Objects and Pedestrian Support

Poulsen et al. propose an urban light system that can respond adaptively to pedestrian’s occupancy patterns, wind velocity or that can be customized to individual color preferences via smart phone [12]. Albeit not in an outdoor setting, the potential effect of adaptive colors on the mood of seniors has been studied by Huldtgren et al. [26]. Cunha & Fuks propose to use light systems as a “host” for sensors to support continuous proactive care within a feedback loop [27].

Another type of objects are public interactive screens. These can be utilized as adaptive urban information panels. Cremonesi et al., Müller et al. as well as Vogel & Balakrishnan examine concepts for personalized interactions on such public screens [13], [28], [29]. The basic approach is to define virtual fences around the screen and for identified pedestrians in near proximity sections on the screen can be personalized.

As an interesting application that is more directly directed towards pedestrian support, Traunmueller & Schieck introduce a so called space recommender system [30]. There, routes can be recommended individually based on recommendations of other pedestrians concerning their walking experiences. While this system does not constitute a SUO in the narrower sense, it still can serve as a useful complement system, possibly running on public screens as recommendation input device.

Concerning public transport experience, Foell et al. propose an IoT based system for so called disadvantaged users [31]. “Disadvantaged” users are novice users, tourists, people with handicaps and older adults who have difficulties in orientating themselves properly in an unknown or uncomfortable environment. The system provides support in so-called micro-navigation, e.g. whether a person is in the correct bus or in how many minutes she needs to get off [31].

For supporting pedestrians with impaired vision Kumar et al. propose an assistance system that can run on a smart phone to detect obstacles and recognize the faces of acquaintances [32]. Although, this system shows similar problem solving structures as our system has, we rather focus to make the urban objects smart in the sense of interaction end devices.

## III. ARTIFACT DESIGN

To transform urban objects into SUOs we design a system against the following requirements: It must include

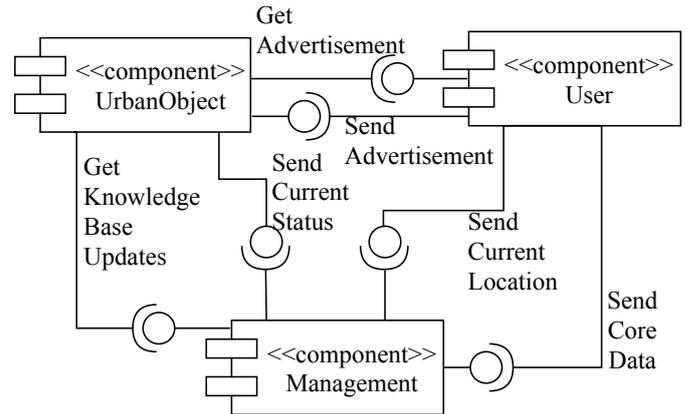

Fig. 1. Architectural Overview

- 1) the ability to book seats.
- 2) navigation information.
- 3) adaptive indications.

(1.) The ability to book seats is required to enable smart reservation of seats. (2.) Navigation information is required to guide older pedestrians via barrier-free passages. (3.) Adaptive indications are required to warn for urban hazards.

Fig. 1 shows the overall architecture of our whole system, including components for older pedestrians (*User* component) and SUOs (*UrbanObject* component). The SUO executes the *UrbanObject* component on small attached computers (e.g. “Raspberry Pi”), while mobile devices of older pedestrians (such as “Android” phones or “iPhones”) run the *User* component to allow booking requests and control Bluetooth signals. To coordinate SUOs in the overall system, we use a scalable central unit (*Management* component, see Fig. 2), based on service-oriented architecture. We use Secure Sockets Layer connections between each component and a protected database to provide basic security. Our *Management* component mainly consists of three sub-components—a seat management component (*Booking* component), urban object component (*SmartObject* component) and real time data processing component (*Live* component) for sensor data (e.g. current location of an older pedestrian or park bench temperature).

### A. Management Component

Each *User* or *UrbanObject* component manages only a subset of knowledge and cannot share knowledge with other *User* or *UrbanObject* components. Our *Management* component, therefore, provides services in distinct components to coordinate older pedestrians and SUOs and act as a global knowledge base. The following specialized components provide these services:

- *Booking*: Allocates a booking request to the best-suited seating accommodation with free seats.
- *SmartObject*: Provides knowledge and services for SUOs.
- *Live*: Integrates heterogeneous data from SUOs or devices of older pedestrians and updates the global knowledge base in real time.

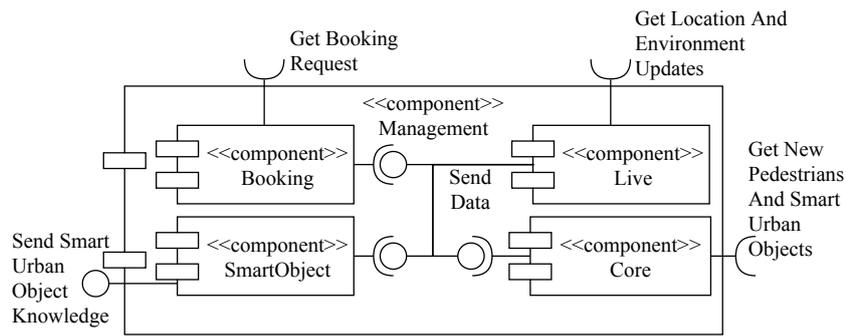

Fig. 2. The Management component

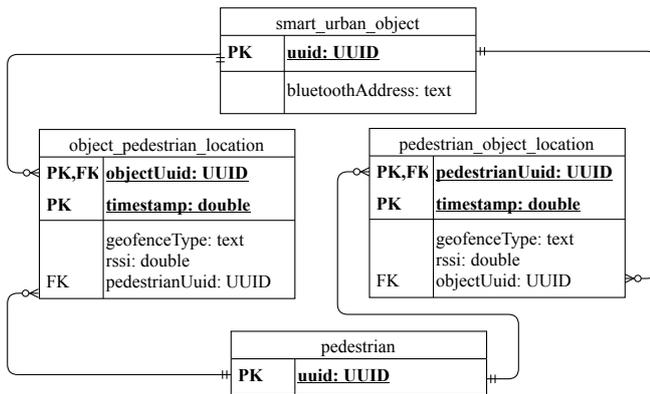

Fig. 3. Section with different primary keys

- *Core*: This component manages relatively static data such as identifiers for an older pedestrian or properties of SUOs (e.g. seat capacity).

Each of these specialized components provides REST-APIs for the *User* or *UrbanObject* component. Both components using HTTP requests to consume these REST-APIs. Hence, a network connection between components is necessary. Each component uses interchangeable data objects if they use the same data object. We're using an additional background service to manage load balance across multiple component instances and detect component failures. This background service registers all management component instances.

The interaction sequences take into account two different but simultaneous views. The first view considers the sequence from the perspective of the SUO, whereas the second considers the perspective of the older pedestrians.

### B. Interaction Sequences

The SUO sends its current status to the *UrbanObject* component and waits for the reply (see Fig. 4). Subsequently, the *SmartObject* component queries seat bookings and determines the most relevant information. This information consists either of the next seat booking on the SUO or of individual routing information for an older pedestrian. If the SUO has pending bookings, they will be transmitted, otherwise routing information for the nearest located older pedestrian. Then,

the SUO can interact with the older pedestrians, e.g. display information or adaptive indications. While older pedestrians moving through the major event area, their device uses Bluetooth Low Energy network technology to detect SUOs based on Bluetooth addresses (see Fig. 5). Subsequently, their device sends continuously RSSIs (Received Signal Strength Indicators) and Bluetooth addresses of detected SUOs to the *Live* component. Each SUO advertises Bluetooth Low Energy services with a static Bluetooth address. Based on the RSSI the *Live* component approximates the location of the older pedestrians, detects location zone changes (e.g. leaving a seat) and updates the global knowledge base. Simultaneously, the device of an older pedestrian advertise nonexistent Bluetooth Low Energy services at regular intervals (see Fig. 6). The device introduces a temporary service based on a new service identifier and a random Bluetooth address. This temporary service is not connectable for other Bluetooth devices. Meanwhile, SUOs listen to new Bluetooth Low Energy services and show adaptive light indications on urban hazards. The indication intensity depends on the highest service RSSI gathered from a listener for new service detection. When an older pedestrian approaches the SUO, visual indication on urban hazards increases. The advertisements and scans on the device of older pedestrians are independent of whether the *User* component is in the foreground or background.

### C. Live Component

SUOs and devices of older pedestrians transmit in an interval of one or two seconds, information about their environment or location. Each location consists of the recognized object and RSSI value, a timestamp and the corresponding older pedestrian. As a consequence, each location gets assigned to one SUO. The *Live* component aims to provide information to other components as quickly as possible. To avoid query join operations and time-expensive where conditions we store time-sensitive information of older pedestrians (e.g. their location or bookings) in redundant tables. Each time-sensitive information table has either the nearest SUO or an identifier for the older pedestrian as part of the primary key. Our primary key is complemented by a timestamp to read the newest insertion first, without additional sorting. Fig. 3 shows a section of our database schema providing these characteristics for

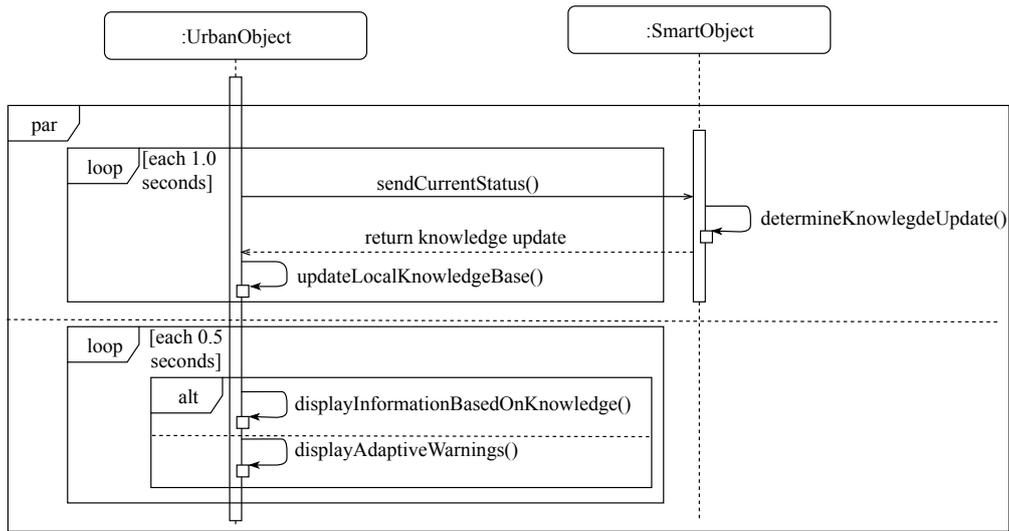

Fig. 4. Interaction between SUO and *UrbanObject* component

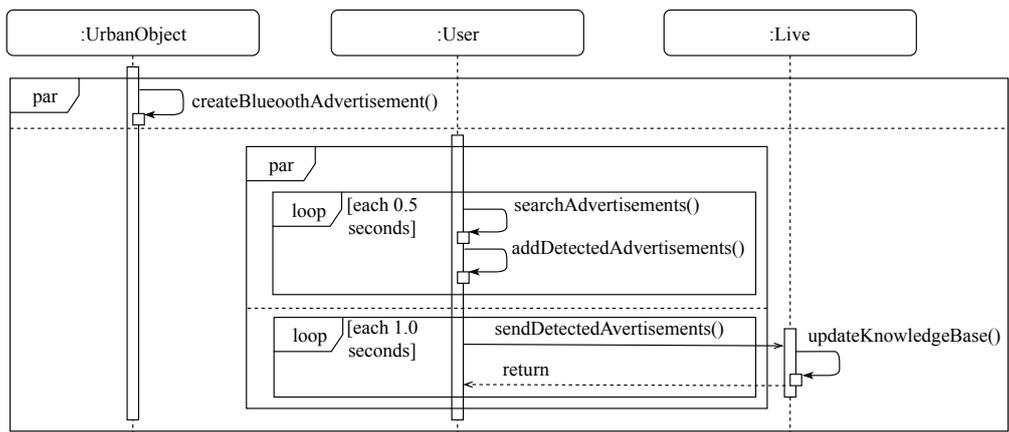

Fig. 5. Interaction between older pedestrian, SUO and real-time processing component

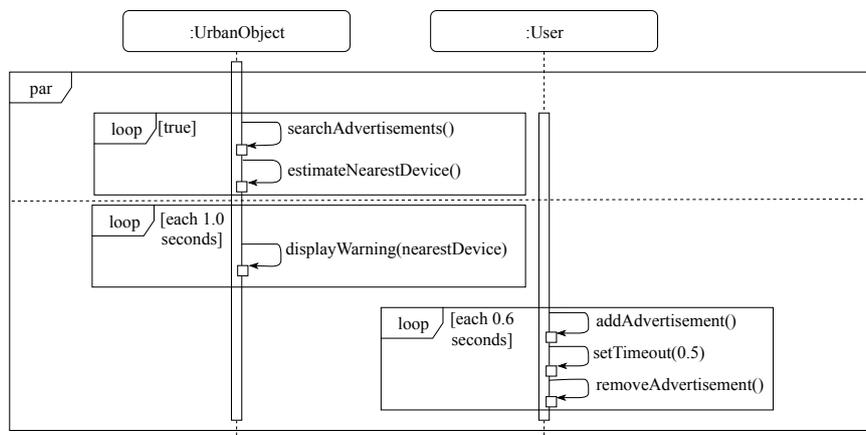

Fig. 6. Interaction between older pedestrian and SUO

locations. Due to the expected amount and frequency of data, we use a distributed database management system with two-dimensional key-value tables. Before providing information, we use gathered information to update possible dependent aspects, like the completion of bookings.

#### D. SmartObject Component

The *UrbanObject* component only receive required information for the estimated time between knowledge requests to limit resources (e.g hardware, web or computation). For this reason, the *SmartObject* component provides individual knowledge base updates for *UrbanObject* components. Its main goal is to select the most relevant information, composed of bookings on the own device or routes. We prefer information about bookings on the object to routes to other destinations for park-benches (see algorithm 1). The algorithm updates the new knowledge base with booking information of any nearby older pedestrian with a newer location update than the latest knowledge base update. If there is no older pedestrian with booking for the requesting object, our algorithm uses routing information to a booking for one older pedestrian with the latest position update as a knowledge update. To force the *UrbanObject* to show adaptive indications instead of booking or routing information, the *SmartObject* returns an empty knowledge update. In contrast to an empty knowledge update, we can force the *UrbanObject* to display independent pedestrian information by simulating bookings and locations.

   $p$   $\leftarrow$  Latest corresponding pedestrian location near to  $s_r$ 
   $p_{time}$   $\leftarrow$  Timestamp of  $p$ 
   $p_{geofence}$   $\leftarrow$  Estimate distance between  $s_r$  and  $p$ 
  if  $p_{geofence}$  is near then
    if  $p_{time}$  is newer than  $i_{new}$  then
       $i_{new}$   $\leftarrow$  Information about  $b$ 
    end if
  end if
end for
if  $i_{new} == NULL$  then
   $P$   $\leftarrow$  Pedestrian positions near  $s_r$ 
  for  $p \in P$  do
     $p_{time}$  Timestamp of  $p$ 
    if  $p_{time}$  is newer than  $i_{new}$  then
       $b$   $\leftarrow$  Next pending booking for pedestrian  $p$ 
       $b_{route}$   $\leftarrow$  Calculate barrier-free route
       $i_{new}$   $\leftarrow$  Information about  $b$ 
    end if
  end for
end if

```

---

We approximate the distance between an older pedestrian

and SUO with the obtained Bluetooth RSSI. Algorithm 2 converts the Bluetooth RSSI into an absolute number. Then, the algorithm divides the absolute number into geofences with weighting, whereby a lower geofence weight indicates a shorter distance. We use the geofence weight as distance lower bound between an older pedestrian and SUO. We use the SUO geolocation to determine pedestrians geolocation. Hence, the SUO geolocation corresponds to pedestrian geolocations if the approximated distance is close enough. Otherwise, we can't determine pedestrians geolocation.

       $s_{opt} \leftarrow s$ 
    end if
  end if
end for

```

---

The booking component is responsible for seat management and allocates seat preferences of older pedestrians to park benches. Its main goal is to achieve the best possible seat allocation for each older pedestrian based on their location. In order to achieve this goal, the system has to perform

two main tasks: monitoring of seats for occupancy detection and identification of the older pedestrian. It therefore uses the collected and processed data about detected SUOs by devices of older pedestrians (location of the older pedestrian), as well as information about the environment of seating accommodations. Algorithm 3 shows the allocation algorithm using environment and information of older pedestrians. The algorithm validates for each pending and active bookings of all seating accommodations if any seating accommodations have seats for the booking request. We calculate the number of free seats for one seating accommodations through subtraction of reserved bookings in the corresponding time slot from the individual total number of seats. This time slot starts five minutes and ends 30 minutes after the booking request. Thereby, this results in a 30-minute seat booking. We use the estimated distance between older pedestrians and seating accommodation as decision base and prefer a short distance. Therefore, our algorithm provides the nearest free seat accommodation. Subsequently, we transmit the allocated seat to our *Live* and *User* component to enable routing and provide visual feedback. If the older pedestrian arrives his booked park bench and her *User* component recognizes the seating accommodation at least two times, we mark the booking as active. We mark the seat as free if the older pedestrian leaves the seating accommodation or his booking end occurs. The older pedestrian leaves the seating accommodation if her latest obtained location is in an outer geofence zone for this seating accommodation.

#### F. Core Component

Before interacting with older pedestrians, the *User* and *UrbanObject* components need to register once and become known to other component instances. Hence, the *Core* component creates a unique random identifier for each new *User* or *UrbanObject* and informs the *Live* component. Another responsibility for this component is the attribute management for different kinds of SUOs. The *UrbanObject* component provides additional attributes to identify it in case of downtime, whereas the *User* component identifies itself (e.g. name or geographic coordinates). If any *User* component can not identify itself, we consider this *User* as new *User* component. Further attributes for components depend on the corresponding object type. This includes seat capacity for SUOs with type seating accommodation, whereas the type for urban hazards include different indication types.

#### G. UrbanObject Component

The *UrbanObject* component on the SUO control detection of an older pedestrian and provide visual feedback for the older pedestrian. Therefore, we connect the component with a color display and Bluetooth Low Energy Module. We overwrite obtained knowledge from *SmartObject* component and recognized older pedestrian if newer knowledge is available. If knowledge is available, the *UrbanObject* component can show this knowledge. Due to random Bluetooth address from mobile devices of older pedestrians, we aggregate recognized older

pedestrians. Then, we submit this aggregation as status to *Live* component. If the component shows an adaptive indication, we transform the highest Bluetooth RSSI within two seconds into a percentage value and use this value as indication intensity. In case of a difference greater ten between the last and current percentage value, we use the average as indication intensity for a smooth transition.

#### H. User component

Apart from a user interface to request a seat, the *User* component is responsible for the localization of an older pedestrian. Localization consists of scanning for *SmartObject* components and advertising of own services. This component compares detected Bluetooth devices against Bluetooth addresses in its knowledge base and filters *UrbanObject* components. Due to possible operating system restrictions from mobile devices of older pedestrians and changed settings, the *User* component has to monitor the outcome of localization operations. If the *User* component detects any deviation, it pauses the concerning operation, until the user solves it. We store the unique random identifier for an older pedestrian on their mobile device to keep the same identifier and allow component shutdowns and restarts. Thus, after a restart, it starts automatically scanning and advertising. If an older pedestrian rejects the localization, he enables an incognito mode, where his device advertises services for adaptive indication but do not scan for *UrbanObject* components. Consequently, no localization information will be transmitted. The mobile device has to support Bluetooth Low Energy to use the overall system.

## IV. FUNCTIONAL TESTING

To show the feasibility of our artifact, we conducted two scenarios, addressing different safety aspects. The first scenario, shown in figure 7, addresses the booking of resting possibilities to counteract against exhaustion. In contrast to the first scenario, scenario two (see fig. 8) focuses on the prevention of risks from urban hazards by adaptive indications. Scenario “seating accommodation” covers the need for seats based on exhaustion or physical restrictions of an older pedestrian if elderly recognize their need. Then, they announce their need for a seat, in this case, to our artifact. Our artifact will search for the best-suited seat, books this seat and informs sub-components. Subsequently, the older pedestrian receives her booking and goes to her seat. On the way, she sees routing information from *UrbanObject* components that allows her to find the barrier-free way to his seat. When arriving, the seat shows that the older pedestrian reached his destination.

The second scenario “adaptive indication” shows indications in different intensity based on the estimated distance between urban hazards and older pedestrians. On the other hand, if the older pedestrian walk away, the indication intensity decreases.

We suppose our artifact to be feasible if we provide technical functionality that is required to enable seat bookings for resting possibilities and adaptive indications on urban hazards.

Therefore, our artifact has to approximate the distance between the older pedestrian and urban hazards, estimate the

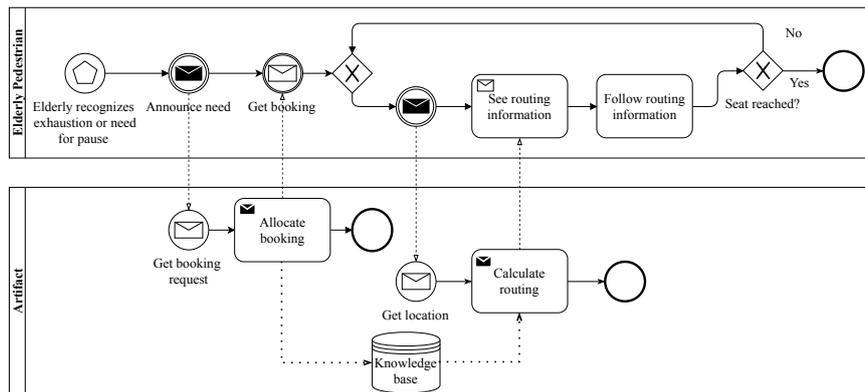

Fig. 7. Scenario “seating accommodation”

location of the older pedestrian and distribute knowledge. We validate the location detection and knowledge distribution in scenario “seating accommodation” and use scenario “adaptive indication” to prove the approach detection.

Our scenario-based testing takes primary place on the property of our institute. However, we have been able to reproduce the settings at the “Turmfest Rheydt 2019”, a major event in a larger German city. The settings include Raspberry Pi’s with LED matrices, Android phones, a laptop and a router. We have positioned Raspberry Pi’s at least five meters apart. Each Raspberry Pi runs the *UrbanObject* component with a preregistered SUO, while the laptop executes the *Management* component with sub-components. Android phones run the *User* component that includes a preregistered older pedestrian. Each device connects to a private wireless network, made available by a router, to consume REST-APIs. We implement the *UrbanObject* component in Python, whereas the *User* component is in Typescript and the *Management* component in Java. Our *Management* component uses Apache Cassandra as database system. In the study are other Bluetooth Low Energy devices, such that *UrbanObject* components started to run two minutes before starting each scenario.

In scenario “seating accommodation”, the Raspberry Pi’s represented seating accommodations. We requested seats via the *User* component, while we stayed outside the detection range of all Raspberry Pi’s. Then, we got a seat allocation and started to walk to a component, which was not our allocated seating accommodation. The *UrbanObject* component on this Raspberry Pi displayed an arrow towards our allocated virtual seating accommodation within five seconds. Meanwhile, we went further to our allocated seating accommodation, that displayed a symbol that represents a free seat when arrived in a zone of five meters. If entered a zone of a half meter and allocated seating accommodation, the component displays another different symbol within ten seconds. The scenario shows that our artifact can estimate locations of an older pedestrian and distribute knowledge across multiple SUOs. However, there can be a time gap of five to ten seconds between arriving and detection of arriving.

In contrast to the scenario “seating accommodation”, in

scenario “adaptive indication” our Raspberry Pi’s simulated urban hazards. Again, we started outside the detection range of all Raspberry Pi’s, so no indication was displayed. We went in walking pace straight towards a Raspberry Pi. The indication appeared during the movement and the warning intensity increased with decreasing distance. Finally, the indication disappeared. However, the indication intensity jumped at the same distance. We find the Bluetooth RSSI of the Android phone changed in a range of plus-minus six at the same distance. In fact, the scenario “adaptive indication” demonstrates our artifact provides approach detection. Nevertheless but we can not provide the exact mapping from Bluetooth RSSI to distance. Based on findings of scenario “seating accommodation” and scenario “adaptive indication” we suppose the feasibility of our artifact.

## V. DISCUSSION

We contribute a system to enable adaptive indications of urban hazards, barrier-free passages and smart reservation of seats. Thus, we transform urban objects into connected SUOs. We described two scenarios where SUOs support elderly to participate in major events. Our evaluation does not apply to adapted scenarios that include shielding elements or smaller distances between SUOs. In contrast, our evaluation applies to scenarios in urban areas or with an increased number of SUOs. We did not consider or compare the signal strengths of different small computers (inclusive accessories like displays) and mobile phones, including their operating system. Findings concerning the processing or handling of volatile Bluetooth RSSI shows white spots for further research. The artifact extension of localization with GPS-geographic coordinates may be future work. Due to our centralized approach, scalability limitations may occur. As a consequence, we can distribute our database about multiple machines or instantiate multiple component instances to counter.

Since our artifact does not require any special characteristics of the elderly and is not tied to any position or event type, our artifact can be used by all pedestrians and in all urban areas. The smart seat reservation including routing via barrier-free passages corresponds to routing from one location to another.

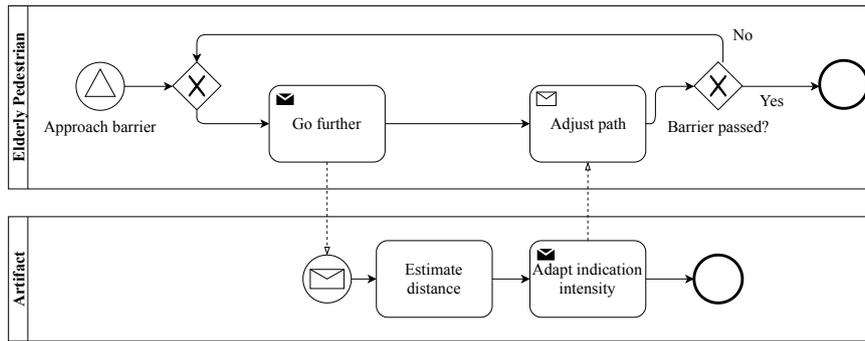

Fig. 8. Scenario “adaptive indication”

In particular, people with a handicap can benefit from our artifact, too. Included functions in our artifact are transferable to other use cases. For example, the smart reservation of rest possibilities can constitute a basis for individual routing to and reservation of toilets. Another application may be the smart reservation of parking slots (including routing) or the barrier-free finding of dining possibilities and dine pre-order for the elderly for major events. In addition, our artifact can support pedestrians in their everyday lives. The consideration of environment data (e.g. the number of people in a particular area) for routing calculation may be future work too.

Regarding our understanding of sensors and actuators explicated in section II, our SUOs can be classified as I-S-A-N objects according to the typology of López [22]. The SUOs have a unified identifier and some data storage (I), are able to sense the environment through Bluetooth signals (S), can affect the environment with visually outputs from the LED displays (A) and are connected in a network (N). For our purposes, this network can be a local area one. However, connecting the SUOs to the internet would be conceptually equal. Decision-making ability (D), that goes beyond simple stimulus-response, is delegated to the central management component, cf. figure 2. This management component implements the service layer in the sense of Xu et al. [20], as described in section II, too.

Revisiting our research question, table I summarizes how our SUOs can contribute to safety. The safety-engineering approach guided our pre-design phases with the conceptual separation of hazards and worst-case environmental condition. By “accepting” that we cannot alter some circumstances concerning the pedestrian state or the environmental conditions, we focused on means for avoiding that worst-case environmental condition *coincide* with an older pedestrian being in a defined hazardous state. Therefore it is of less importance whether the pedestrians are defined to be the system or the SUOs than to actually define respective states and conditions. These need to be defined in a way such that an engineer gets a “point of attack”. When a hazard is given, the engineer can try to find a way, how the environment can be adapted with feasible means. When an environmental condition is given, the engineer can try to find a way, how the system resp. pedestrian

state can be adapted, if possible. As adaption of the pedestrian state is seldom possible, a feasible way is then to find means that the pedestrian avoids sub-environments with worst-case conditions. Quite obviously, in our case we could also have referred to worst case environmental conditions as hazards in the environmental subsystem. We decided to define the pedestrians to be the system because our explicit approach is to make the *environment* adaptive to the pedestrians requirements.

## VI. CONCLUSIONS

We proposed Smart Urban Objects (SUOs) for (1.) adaptive indication of accessible passages, (2.) adaptive indication of stumbling blocks and for (3.) reservation of seat on public outdoor major events. Example scenarios are respectively:

- 1) An older pedestrian approaches a step but cannot lift her legs high enough to safely pass it. The step as an SUO detects the older pedestrian and points in the direction of an accessible passage with a lower step or no step at all.
- 2) An older pedestrian approaches a “hidden” stumbling block, like a small polder. The polder as an SUO detects the older pedestrian and warns her visually. Thereby we expect that an adaptive warning will be more salient and hence contributes more perceived safety of older pedestrians than a static one, which is always visible.
- 3) An older pedestrian needs a seat rest. She can reserve a seat from anywhere on the area. When she passes another SUO, the display of the SUO shows a pointer in the direction of the reserved seat. When the older pedestrian approaches the reserved seat, the seat’s visual reservation signal indicates that the pedestrian can sit down there.

With our SUOs we seek to enhance safety for older pedestrians who often have physical impairments and reduced resilience. The SUOs rely on detection of the older pedestrians via Bluetooth technology and provide output with LED-displays. The SUOs are implemented with Raspberry Pi.

We conducted scenario based functional testing to validate whether our SUOs are feasible with standard Bluetooth technology. The SUOs have been installed at a major event in a larger German city and have been positively tested with respect to its functionality in the target environment.

TABLE I  
CONTRIBUTION TO SAFETY WITH SUOS

Hazardous pedestrian state	Worst-case environmental condition	Contribution of SUO in avoiding the coincidence of hazardous pedestrian state and worst-case environmental condition
Inability to overcome structural barriers	Structural barrier on passage	SUO adaptively point in the direction of an accessible passage.
Pedestrian doesn't recognize obstacles	Stumbling block in pedestrian's proximity	SUO adaptively indicates the existence of a stumbling block.
Pedestrian needs a seat rest	No awareness on seat availability	Reservation of a seat from anywhere is possible. Adaptive signs guide the pedestrian to the reserved seat.

# Advances in Information Systems and Technology

**I**ST is a FedCSIS conference track aiming at integrating and creating synergy between FedCSIS technical sessions that thematically subscribe to the disciplines of information technology and information systems. The track emphasizes the issues relevant to information technology and necessary for practical, everyday needs of business, other organizations and society at large. This track takes a sociotechnical view on information systems and relates also to ethical, social and political issues raised by information systems. Technical sessions that constitute IST are:

- AITM'19—16<sup>th</sup> Conference on Advanced Information Technologies for Management
- DSH'19—1<sup>st</sup> Special Session on Data Science in Health
- InC2Eco'19—1<sup>st</sup> Workshop on Data Analysis and Computation for Digital Ecosystems
- ISM'19—14<sup>th</sup> Conference on Information Systems Management
- KAM'19—25<sup>th</sup> Conference on Knowledge Acquisition and Management

# 17<sup>th</sup> Conference on Advanced Information Technologies for Management

**W**E are pleased to invite you to participate in the 17<sup>th</sup> edition of Conference on “Advanced Information Technologies for Management AITM’19”. The main purpose of the conference is to provide a forum for researchers and practitioners to present and discuss the current issues of IT in business applications. There will be also the opportunity to demonstrate by the software houses and firms their solutions as well as achievements in management information systems.

## TOPICS

- Concepts and methods of business informatics
- Business Process Management and Management Systems (BPM and BPMS)
- Management Information Systems (MIS)
- Enterprise information systems (ERP, CRM, SCM, etc.)
- Business Intelligence methods and tools
- Strategies and methodologies of IT implementation
- IT projects & IT projects management
- IT governance, efficiency and effectiveness
- Decision Support Systems and data mining
- Intelligence and mobile IT
- Cloud computing, SOA, Web services
- Agent-based systems
- Business-oriented ontologies, topic maps
- Knowledge-based and intelligent systems in management

## EVENT CHAIRS

- **Andres, Frederic**, National Institute of Informatics, Tokyo, Japan
- **Dudycz, Helena**, Wrocław University of Economics, Poland
- **Dyczkowski, Mirosław**, Wrocław University of Economics, Poland
- **Hunka, Frantisek**, University of Ostrava, Czech Republic
- **Korczak, Jerzy**, International University of Logistics and Transport, Wrocław, Poland

## PROGRAM COMMITTEE

- **Abramowicz, Witold**, Poznan University of Economics, Poland
- **Ahlemann, Frederik**, University of Duisburg-Essen, Germany
- **Atemezing, Ghislain**, Mondeca, Paris, France
- **Cortesi, Agostino**, Università Ca’ Foscari, Venezia, Italy
- **Czarnacka-Chrobot, Beata**, Warsaw School of Economics, Poland

- **De, Suparna**, University of Surrey, Guildford, United Kingdom
- **Dufourd, Jean-François**, University of Strasbourg, France
- **Franczyk, Bogdan**, University of Leipzig, Germany
- **Januszewski, Arkadiusz**, University of Science and Technology, Bydgoszcz, Poland
- **Kannan, Rajkumar**, Bishop Heber College (Autonomous), Tiruchirappalli, India
- **Kersten, Grzegorz**, Concordia University, Montreal, Canada
- **Kowalczyk, Ryszard**, Swinburne University of Technology, Melbourne, Australia
- **Kozak, Karol**, TUD, Germany
- **Krótkiewicz, Marek**, Wrocław University of Science and Technology, Poland
- **Leyh, Christian**, University of Technology, Dresden, Germany
- **Ligeza, Antoni**, AGH University of Science and Technology, Poland
- **Ludwig, André**, Kühne Logistics University, Germany
- **Magoni, Damien**, University of Bordeaux – LaBRI, France
- **Michalak, Krzysztof**, Wrocław University of Economics, Poland
- **Owoc, Mieczyslaw**, Wrocław University of Economics, Poland
- **Pankowska, Malgorzata**, University of Economics in Katowice, Poland
- **Pinto dos Santos, Jose Miguel**, AESE Business School Lisboa, Portugal
- **Proietti, Maurizio**, IASI-CNR (the Institute for Systems Analysis and Computer Science), Italy
- **Rot, Artur**, Wrocław University of Economics, Poland
- **Stanek, Stanislaw**, General Tadeusz Kosciuszko Military Academy of Land Forces in Wrocław, Poland
- **Surma, Jerzy**, Warsaw School of Economics, Poland and University of Massachusetts Lowell, United States
- **Tazi, El Bachir**, Moulay Ismail University, Meknes, Morocco
- **Teufel, Stephanie**, University of Fribourg, Switzerland
- **Tsang, Edward**, University of Essex, United Kingdom
- **Wątróbski, Jarosław**, University of Szczecin, Poland
- **Weichbroth, Paweł**, WSB University of Gdansk, Poland
- **Wendler, Tilo**, Hochschule für Technik und Wirtschaft Berlin

- **Wolski, Waldemar**, University of Szczecin, Poland
- **Zanni-Merk, Cecilia**, INSA de Rouen, France

- **Ziemia, Ewa**, University of Economics in Katowice, Poland

# Factors Influencing the Intended Adoption of Digital Transformation: A South African Case Study

**Abstract**—Organisations worldwide are facing a market pressures which are forcing them to undertake digital transformation projects or initiatives. This research study set out to explore this in more depth, asking questions about the intention of South African (SA) retail organisations to adopt digital transformation and probing into the understanding and perception of digital transformation itself, as well as future intended use cases for available digital technologies. A case study approach was deemed to be an appropriate strategy given the paucity of existing academic research on the topic. Participants in the study had a good understanding of digital transformation and digital technologies, but perceptions were mixed. The most prominent digital transformation initiatives in the SA retail industry were the adoption of cloud technologies and data analytics. The factors identified in this study, using the Technology, Organisational, and Environmental (TOE) framework, can assist retailers in their decision-making process concerning digital transformation adoption.

**Key Words:** Digital Transformation, Digital Technologies, Strategy, South African Retail Organisations, Technology Adoption, Perceptions, Understanding, TOE, Technology Drivers.

## I. INTRODUCTION

Many industries have been facing a market shift over the past few years driven by a better response to customer demand which forced enterprises to undertake digital transformation projects or be left behind the competition [1]. Digital transformation refers to a type of strategy that changes an enterprise business model which ultimately provides the customer with variants of tangible product by taking advantage of new or existing digital technologies [2]. The competitive landscape is changing in many industries due to business digitalization. Enterprises face threats of digital disruption from new market entrants while digitally savvy customers are demanding more from the enterprise [3]. Digital transformation affects every enterprise and sector as the market-changing potential of digital technologies is often wider than sales channels, supply chains, products and business processes [4].

One of the biggest challenges enterprises currently face is integrating and exploiting new digital technologies [4].

Digital technologies are tools that enterprises must make use of to get closer to their customers, transform their business processes and empower their employees [5]. Current new digital technologies include cloud computing, mobile, analytics, social media, robotics and Internet of Things (IoT) technologies [6]. These digital technologies can present the enterprise with game-changing opportunities if they are combined with accessibility of enterprise data to enrich their products, services and customer relationships [7].

There is a lack of information around digital transformation, its perceptions and use cases in the SA retail industry to aid its adoption. The main objective of this study was to understand and examine the current perceptions and status of digital transformation within a SA retail organisation. Furthermore, the study aimed to identify factors influencing the intended adoption of digital transformation within the SA retail organisation. This will provide the information and knowledge needed for the retail industry to make informed decisions about the potential future use of digital technologies and how to overcome adoption barriers.

The following propositions are posed to relate the research findings to existing theories and models identified in the literature review.

- PR1: There is a lack of understanding of digital transformation in the SA retail industry and perceptions of digital transformation are mixed.
- PR2: SA retail industry organisations have identified specific core technologies driving digital transformation.
- PR3: The intended adoption of digital transformation by SA retail organisations is affected by specific TOE (Technology, Organisational, & Environmental) factors.

It is important to study the factors influencing the intended adoption of digital transformation so that enterprises can understand the challenges and address them. Addressing these challenges will be beneficial to the enterprise as it will assist it to create a clear and coherent digital strategy, lead to retaining and attracting top talent, and create a company culture where employees could be innovative and creative. Ultimately, a digital transformed enterprise will be able to easily adapt taking advantage of new opportunities and have a competitive advantage over their competition.

## II. LITERATURE REVIEW

### A. Digital Transformation

Digital transformation refers to an enterprise business model that applies new or existing digital technologies and products or services into digital variants to offer a tangible product to their customers [2].

Digital transformation is not only about technology, but it also requires a new way of thinking and strategy by enterprise executives. *“Digital transformation is the profound transformation of business and organisational activities, processes, competencies and models to fully leverage the changes and opportunities of a mix of digital technologies and their accelerating impact across society in a strategic and prioritized way, with present and future shifts in mind”* [1]. Enterprise digital transformation strategies should include the application of digital technologies to enterprise processes, products and assets to enhance customer value, uncover new monetization opportunities, improve efficiencies and manage risk across the enterprise [8] [9].

### B. Digital Technologies

New digital technologies (social, mobile, analytics, cloud computing and Internet of Things [IoT] technologies) could present the enterprise with game-changing opportunities and existential threats. Leaders in digital transformation apply new digital technologies and related technologies in conjunction with the accessibility of enterprise data to enrich their products, services and customer relationships [7].

#### Social Media

The phenomenal and exponential growth of social media and mobile resulted in many organisations realizing that an online presence is required to reach out and connect with their digital savvy customers [10]. Capturing data from tools such as Facebook, LinkedIn and blogs are essential to integrate the information into the sales process [11]. Digital savvy customers follow brands on social media and expect to be able to view store inventory online to enable them to do “showroom” shopping before going into a physical store [10].

#### Mobility

Digital technologies have enabled enterprises to make use of mobility and ubiquitous connectivity features providing the enterprise with immediate interaction and access to a wide range of data and computing power and enabling enterprises to analyse their data and make decisions in real time [12]. Mobility resulted that tech-savvy customers across all facets of society completely changed their behaviours, expectations and the way they interact with enterprises [4].

Mobile penetration throughout Africa often thought of as the least digitally populated continent has reached 70% of its one billion inhabitants. Over 40% of the world’s population has an internet connection. Mobile technology advances allow for the capture of geographical and contextual data that was previously not possible [13]. Digitalization experienced a significant boost with the introduction of smart mobile devices and the applications that run on them [14].

Furthermore, the declining cost of mobile technologies has broadened their potential for worldwide use [13].

#### Analytics

Digital technologies provide enterprises with interpretation capabilities, enabling in-depth analysis and exploration of different kinds of data sets. Digital analytical tools coupled with computer-enabled techniques can yield insight to enterprise executives from massive multidimensional datasets enabling them to make use of analytics to make strategic enterprise decisions [13]. About 90% of the data available today has been produced in the last two years. This data explosion has been driven by new data sources such as digital transactions, mobile devices, embedded sensors and the growing use of social media by the global population. Enterprises could benefit from learning how to capture, absorb, store and analyse their data and turn their data into a valuable asset [14].

Data analytics should be incorporated into new digital products for personalisation reasons, but also to inform other enterprise departments like product development, sales and marketing [15]. Some enterprises are known for their analytical-based approach to ensure they personalise their service and marketing to the need of each of their individual customers by constantly innovating, improving their processes, launching new service based data-driven applications and capabilities [16].

#### Cloud Computing

Cloud computing has been defined as *“a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction”* [17]. Cloud computing technologies enable enterprises to outsource some elements of the IT value chain with benefits for enterprises such as reduced costs, scalability, flexibility, capacity utilisation, higher efficiencies and mobility [18].

#### Internet of Things (IoT)

The Internet of things (IoT) refers to a type of network that enables any device to connect to the internet based on stipulated protocols through information sensing equipment to conduct communication and information exchange. The IoT concept has become more practical in recent years due to the exponential growth of the use of smart mobile devices, the growth of data analytics and cloud computing. IoT enables things to be connected at anytime, anywhere, with anything and with anyone ideally using any network, path or service [19]. IoT will force enterprises to digitally transform and will bring fundamental changes to individuals’ and society’s expectation and perspectives on how technologies and applications work in the world [20].

C. Adoption Barriers

Digital Strategy

One of the biggest barriers to digital transformation and digital maturity is the lack of a clear and coherent digital strategy to drive transformation within the enterprise. Mature digital companies realise that digital technologies should be used to achieve strategic enterprise goals [9]. Digital strategy can be defined as “a business strategy, inspired by the capabilities of powerful, readily accessible digital technologies, intent on delivering unique, integrated business capabilities in ways that are responsive to constantly changing market conditions” [7]. Executives should use the enterprise digital strategy to create competitive advantage, value and customer satisfaction by combining existing technology with capabilities of other digital technologies [7].

Talent

Employing, retaining and developing talent within the enterprise is another challenge faced by digital maturing enterprises [9]. Talent was highlighted as one of the top three key influencing factors of successfully implementing digital transformation projects [21]. Having the right talent allows the enterprise to adapt to change and create new opportunities [9]. Digital leaders should embrace the fact that talented individuals are on the lookout for the best digital opportunities and want to work for digitally enabled enterprises [9].

Company Culture

Digital mature enterprises need to foster a culture where employees are encouraged to take risks, innovate, be creative and create a collaborative work environment [9]. Trying out a lot of things and learning quickly from errors can only be done if a culture of trial-and-error exists within the enterprise [15]. Changing the company culture is a real challenge during digital transformation. Traditional corporate cultures present executives with resistance to change and barriers that need to be overcome to ensure successful digital transformation [22].

Leadership

A lack of strong top-down leadership that steers digital transformation by setting direction, building momentum and ensuring the enterprise follows through is another barrier to becoming digitally transformed [5]. Enterprise executives are advised to focus on employees, culture, talent, skillset and leadership [12]. Enterprise executives must drive and coordinate digital transformation across the entire enterprise as it touches every functional area. The entire workforce must “digitalize” by fostering an enterprise culture of collaboration between departments whereby employees are enabled to exchange opinions and ideas across departments [15].

IT Function Transformation

Digital transformation has prompted enterprise IT departments to rethink the architecture platforms within the organisation to ensure new business demands originating from customers and suppliers who require more digital engagement are met [21]. Many IT departments are not set up to be flexible and agile to ensure quick and fast modifications to

applications on short notice when required by business departments. Flexibility, agility and the ability to service business requirements on short notice are all trademarks of a digitally transformed enterprise. The role of IT service provider needs to change to a role of consultant, enabler and innovator by applying “new IT concepts” like cross-functional digital teams, enterprise architecture (EA), co-location and IT innovation management [23].

Omni-channel (OC)

The customer retail experience has been profoundly transformed in the past 10 years by digital transformation projects which integrate digital technologies into the customer shopping experience [24]. Physical stores remain an important part of the customer shopping experience even though mobile device sales and online commerce are accelerating. But the distinction between traditional brick and mortar stores and online sales channels will disappear as the retail industry moves into a new phase, known as Omni-channel (OC) retailing [25]. OC retailing can be defined as the process whereby customers are influenced and move through multiple digital channels in their search and buying process [25].

D. Technology, Organisation, Environment framework (TOE)

The TOE framework was proposed by [26]. It “represents how different elements of an organisation (technology, organisation and environment) affect technological innovations and that the framework is suitable for research as it has the flexibility for variance of the factors or measures” [27].

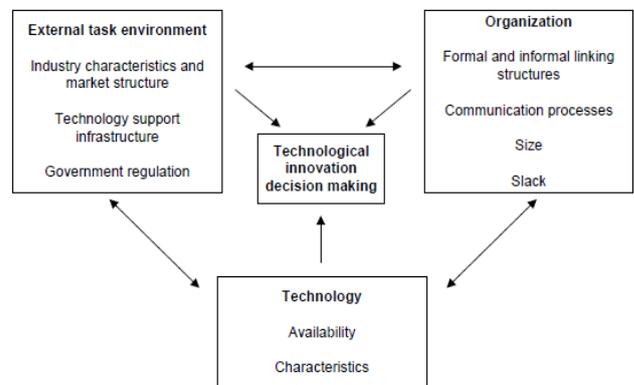

FIGURE I: THE TOE (TECHNOLOGY, ORGANISATION, AND ENVIRONMENT) FRAMEWORK [26]

The TOE technology aspect include all technologies that might be applicable to the enterprise including technologies currently being used by the enterprise, technologies that are available to the enterprise but are not being used and innovative technologies that might enable the enterprise to evolve and adapt [26] [27]. The organisational aspect of the TOE framework relates to all descriptive measures and resources of the enterprise (e.g. the number of employees and communication protocols) which effect may affect executive management decisions with regards to adoption and implementation [26]. Finally, the environmental aspect of the

TOE framework includes elements, such as the structure of the retail industry in SA, which might affect the adoption of technology within an enterprise [26].

### III. RESEARCH APPROACH AND DESIGN

The case study approach was chosen as an appropriate strategy to conduct this qualitative study. “A case study examines a phenomenon in its natural setting by employing multiple methods of data collection to gather information from one or a few entities (people, groups, or organisations)” [28]. The researchers actively solicited company documentation before and during interviews which were analysed to support the research.

The research was conducted within a leading African retailer which is part of a retail group with currently more than 4950 stores in 12 African countries. The retailer, used for the case study, currently has 2164 stores across Southern Africa and employs more than 15000 staff. The researchers chose the retailer’s head office, in the Western Cape region of SA, as the case site for this study. One of the researchers understands the company culture as he has been employed by the retail group for more than 7 years. Brands within the retail group are well-known household names in Southern Africa. The company has a strong customer focus and their core revenue comes from product sales through their stores to clientele.

The interviewees are listed in table I. All interviewees had degrees or diplomas. The gender split, 9 males and 3 females, is a fair reflection of the demographics found in the retail industry population. The sample population has vast IT retail experience (averaging 24 years) and had seen multiple IT strategies and technologies change over the past two decades.

TABLE I: RESEARCH POPULATION & SAMPLE

#	Position	Gender	Experience
P-1	Team Leader	Male	24 Years
P-2	Team Leader	Male	18 Years
P-3	Team Leader	Male	15 Years
P-4	Team Leader	Male	21 Years
P-5	DevOps	Male	10 Years
P-6	Enterprise Architect	Male	23 Years
P-7	Enterprise Architect	Female	25 Years
P-8	Director	Male	29 Years
P-9	Director	Female	26 Years
P-10	Director	Female	30 Years
P-11	Director	Male	32 Years
P-12	CIO	Male	35 Years

The interview protocol consisted of prepared structured (closed-ended) and unstructured (open-ended) questions. The researchers made notes during the interview of the interviewee’s comments, personal impressions and observations during the interview while audio recording each interview. The researchers used a thematic approach to analysing the documentation and qualitative data collected during the research using NVivo.

### IV. RESEARCH FINDINGS, ANALYSIS & DISCUSSION

The following three research questions drove the research:

- RQ1: What is the current understanding and perception of Digital Transformation within the SA retail industry?  
 RQ2: What digital technologies does the SA retail industry perceive are driving implemented to achieve Digital Transformation?  
 RQ3: What are the factors that influence the intended adoption of Digital Transformation within the organisation?

Twelve interviewees participated in the research strategy involving semi-structured interviews. Theme saturation point occurred from the ninth interview as no new themes emerged in the subsequent three interviews. Therefore, the researchers deemed the sample size sufficient (figure II).

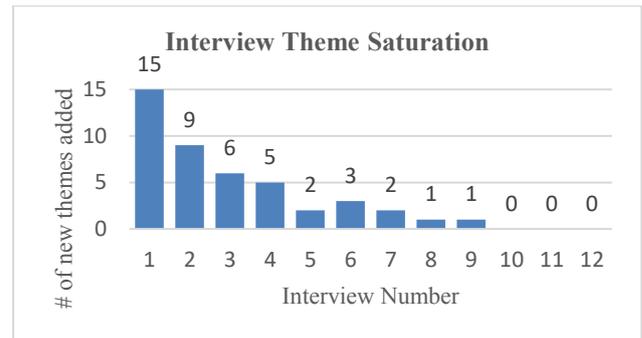

FIGURE II: INTERVIEW SATURATION PROGRESSION

#### A. Attitudes towards Digital Transformation

All interviewees demonstrated a positive attitude toward the adoption of digital transformation, highlighting common technologies that could assist the adoption of digital transformation within the enterprise. The majority of interviewees highlighted common factors that could influence the adoption of digital transformation and mentioned ways to overcome such factors. Furthermore, most interviewees indicated that implementing digital technologies will be beneficial for the enterprise leading to an increase in profit and reducing time to market, ultimately leading to an increase in market share.

#### B. Technology

A total of three factors were identified under the technology theme of which the two most significant were “perceived challenges” and “relative advantage”, refer to table 3 (the second column shows number of interviewees mentioning the theme). All participants perceived there to be both advantages and challenges by the adoption of digital transformation within the retail industry. The advantages and challenges could have a positive or negative effect on the adoption. The technology theme has been broken down into subthemes and will be discussed further in the next subsections.

TABLE II: TECHNOLOGY SUB-THEMES (NR OF MENTIONS)

Perceived Challenges	#
Infrastructure Impact	12
Security	10
Talent / Technical Skills	4
Relative Advantage	
Competitive Advantage	12
Reduced Cost	8

Time to Market	6
Customer Satisfaction	6
<b>Available Digital Technologies</b>	
G-Suite	12
Cloud	12
Artificial Intelligence	4
Machine Learning	2

*Perceived Challenges (+/-)*

A number of adoption barriers were highlighted in the literature review such as the lack of a clear and coherent digital strategy, talent, company culture, IT function transformation and Omni Channel retail capabilities. This was consistent with the responses from the participants with issues around security, workforce talent and resistance to change coming up the most.

It should be highlighted that despite digital strategy being highlighted during the literature review as one of the major challenges affecting the adoption of digital transformation, none of the participants mentioned this as a challenge.

**Infrastructure Impact (+)**

Several concerns were raised by participants around how the adoption of digital technologies, specifically cloud technology adoption, would impact their organisation’s infrastructure and thus would have a positive impact on digital transformation adoption. Most participants mentioned that the enterprise is currently busy with multiple projects to facilitate cloud adoption and that this will most certainly have a major impact on the existing infrastructure and data centres of the enterprise as P-3 stated “...we are in the process of digital transformation and part of it is moving from our own on premise infrastructure to hosted cloud-based infrastructure”. All participants were of the opinion that adopting cloud technologies will result in a saving for the enterprise as maintenance of the on-premise hardware will reduce significantly.

Another infrastructural concern that was raised was the need for high-speed low latency connectivity. P-6: “...with our cloud deployment as our need on high-speed low latency connectivity, for instance, is an infrastructure component that is important to improve on”.

**Security (-)**

Most participants highlighted that there is a security risk that must be considered with the adoption of cloud technologies as part of digital transformation: “You are moving outside the boundaries of your corporate network so that is a security risk.” (P-7)

P-7 is of the opinion that data is an organisation’s currency and the organisation should protect that intellectual property (IP) at all cost. P-8 also raised the concern for data protection by stating “...so by making us connected to everything at all times we have to make sure that we’ve got the bases in place to still protect a corporate organisation like we are”. P-2 further solidifies the security concern by stating “You’re ultimately putting everything into one place out there in the world, so security really needs to become a top priority”.

Further concerns were raised about SA’s Protection of Personal Information act (POPI) and payment card information (PCI) compliance. PP-2 states that “...the personal information act POPI requires information to be stored in a certain way with security applied. This actually becomes more important with cloud storage. Also, their payment card information also strict compliance rules that need to be adhered to...”. Although enterprises must take regulatory compliance into consideration it’s not necessarily a factor that would influence the choice of technology but rather the data generated by the technology as stated by P-11 “...I don’t think it necessarily influences the technologies that use but it certainly influences what you do with the data that that technology generates”.

**Talent - Technical Skills (+/-)**

As mentioned in the literature review, one of the most important critical success factors of digital transformation is to hire new digital talent to compliment or replace the existing workforce to ensure that the enterprise has the “right employees in the right place” [15].

Interviewees gave mixed responses when prompted to comment if the organisation possesses the necessary technical skills to implement digital technologies as part of their digital transformation strategy. Eight participants felt that technical skills within the organisation should not be an adoption barrier in today’s fast-changing IT environment: “...it’s not technical skills that will stand in our way” [P-8]. P-7 is of the opinion that the organisation could partner with an expert external third party to overcome any technology challenge by stating “We would have to partner with specialized partners in certain areas to take us on the journey. So if we partner with the right people I don’t think our technical skills will play such a big role”. However, P-2 felt that employees might fear new technologies and that new talent will be required to upskill existing employees by stating “Yes absolutely - the lack of technical skills as far as I can see brings about it a fear. New talent will be required for training of existing employees”.

*Relative Advantage (+)*

During the data analysis “Relative advantage” emerged as the second biggest factor under the technology major theme and having a positive impact on its adoption. Participants identified a number of perceived benefits (Table III), with customer satisfaction, competitive advantage and reduced cost being cited the most (second column = number of interviewees mentioning the theme).

TABLE III: PERCEIVED BENEFITS OF DIGITAL TRANSFORMATION

Customer Satisfaction	12
Competitive Advantage	9
Reduced Cost	7
Time to Market	6

All participants in the study highlighted that digital transformation would have a positive impact on customer satisfaction, ultimately providing the enterprise with a competitive advantage. Furthermore, by leveraging digital

technologies enterprises can collect data on customers and use data analysis techniques to offer customers specific goods and services as highlighted by P-12 “...*that if you start knowing your customer better you can offer him things that are very specific to him*”.

#### Available Digital Technologies (+)

Available digital technologies emerged as the third biggest factor under the under the technology major theme. An important factor pertaining to technology adoption is the availability of technological innovation [26]. It was important to identify the different digital technologies available as one of the objectives of this study was to identify potential use cases for digital transformation within the SA retail industry.

#### Google Suite (G Suite) (+)

G Suite is a set of Google applications that brings together essential services to help your business. This is a hosted service that lets businesses, schools, and institutions use a variety of Google products including Email, Google Docs, and Google Calendar. The adoption of Google Suite (G-Suite) technology, as a replacement of Microsoft Office, by the organisation was highlighted by multiple participants as an important step towards digital transformation. P-2 highlighted the benefit of multiple employees working on the same Google Doc from different locations while having a conference call by stating “*I mean it would it's nice to be able to sit and work on a document simultaneously with someone in Durban and Johannesburg while having a conference call*”.

#### Cloud (+)

The majority of participants stated that the use of cloud technologies plays a significant role towards the adoption of digital transformation. “*The cloud technology is one of the key technologies to enabled transformation. We are implementing Google cloud platform as our data lake option and we will leverage technologies such as AI in that platform*” [P-7]. The importance of providing the retailers and customers with close to real-time information on products and services were highlighted: “... *efficiently and close to real-time share information so that our feedback cycle from what we observe in our sales activity in the store can feedback all the way to our planning, manufacture, logistics and merchandising to close that loop so that that becomes more efficient*” [P-6].

#### Artificial Intelligence (AI) (+)

Artificial Intelligence (AI) refers to the ability of a digital computer, computer-controlled robot or systems to perform tasks commonly associated with intelligent beings like the ability to reason, discover meaning, generalize, or learn from past experience. The organisation will be leveraging their data in the cloud together with AI technologies to generate new valuable insights. P-7 states “*Put all of the data together in the cloud and then use the AI technologies to generate new insights for us. I think that there is a huge competitive advantage in machine learning and AI calls that technology will be able to derive insights way faster than a human will possibly be able to on volumes of data*”.

#### Machine Learning (MI) (+)

P-8 explained that the organisation already makes use of machine learning technologies to track if employee’s email has been infected by a virus. P-7’s personal view is that the organisation’s data in the cloud together with machine learning be of great benefit to the enterprise in the future.

#### C. Organisation

A total of nine factors were identified under the organisation theme during the semi-structured interviews. This made it the most populated major theme (Table IV).

TABLE IV: ORGANISATIONAL SUB-THEMES

Resistance to Change	12
Financial Resources	7
Big Data & Analytics	7
Digital Technology Readiness	6
Collaboration	5
Digital Strategy	4
Company Culture	4
Compatibility	3
Triability	3

The high number of factors identified by the participants suggested that organisational factors were dominant in their opinion when considering the adoption of digital transformation within the retail industry. The researchers will discuss these factors in the next subsections.

#### Resistance to Change (+/-)

The most cited factor under the organisation theme was resistance to change. Most participants highlighted that some employees have been working at the organisation for many years and is used to doing things a certain way: “...*we always has employees that are resistant to change so we might be leaving people behind if we don't put in a lot of effort to bring them on board and to take them with us on the journey. One of the factors is that people often say it's always been done in the same way that it's historically resistant to change*” [P-8]. P-6 highlighted the fact that before you can address resistance to change you must clearly define the scope of the project by stating “... *you need a clear definition of what your digital transformation is*”. Communication challenges can be addressed by a clear and well-defined scope which is clearly communicated to all employees. P-5 highlighted that as part of addressing the resistance to change within the organisation you may have to address issues with current processes. P-2 mentioned that change management is a very important factor in stating “...*change management is such a big thing. If you don't handle it correctly, they won't they won't adopt it, well not easily at least*”.

#### Digital Technology Readiness (+)

Some participants stated that the organisation needs to be prepared to adopt digital technologies. Preparing the organisation for digital technologies so that they are ready and willing to adopt new technologies will have a positive impact. P-7 stated that the organisation currently “...*rely heavily on the Gartner hype cycle, specifically the one for emerging technologies and retail technologies*” to ensure the

organisation is kept up to date with technology. Technologies that could present business value are proposed to the retailers to assess the retailer's appetite to adopt the technology. P-1 stated that each new technology is evaluated by a technical forum. The technology is assessed in a "sandbox" environment before testing it as a proof of concept (POC). Technologies are only approved for implementation after a rigorous evaluation process. P-5, who is part of the technical forum, states that each technology is assessed based on the organisation's requirement matrix and "...based on the requirements and our future requirements that we can think of we would select the technology that best fits our area and our vision".

#### *Financial Resources (-)*

Factors relating to financial resources in an organisation such as the cost of adopting new technologies or cost of changing existing technologies have a negative impact on whether an organisation will decide to proceed with implementing technology changes. Return on investment (ROI) plays a major part from the beginning when organisations decide on which technology projects will be implemented: "... if the return on investment is good enough then that's how I would motivate the use of new technology." [P-9]. ROI is very important in retail: "as low cost the retailer we are always striving to find more competitive ways to do things to be more cost-efficient" [P-9]. P-7 highlights the fact in some industries it is more difficult to secure funding for projects that in other by stating "...the retailers are very reluctant. In the banking sector and insurance sector money for major key investments is not such a big issue. In retail, you know the retailers are very reluctant to fork out the chequebook to buy these big investment items that are going to transform the companies".

#### *Big Data & Analytics (+)*

Data is being generated by a magnitude of sources within the organisation. The organisation harvests as much of the generated data as possible and store it in the cloud to use digital technology to generate new valuable insights for the business. P-7 stated that the organisation "...put[s] all of the data together in the cloud and then use[s] the AI technologies to generate new insights for us". The organisation benefited from the big data and analytics strategy in a number of ways. The organisation was "able to derive insights way faster than a human will possibly be able to on volumes of data" [P-7]. The sharing of information became easier: "...which then makes sharing information processes accessible to staff internally, external parties" [P-6]. Another benefit highlighted was that the adoption of cloud, analytics and the leveraging of big data gave the organisation the ability to better understand and know their customer. Marketing certain products to certain customers improved significantly as more information about the customer where collected, stored and analysed: "...if you can understand your customer you can better fulfil their needs and the only way to do that is with big data and data analysis" [P-2].

#### *Trialability (+)*

"Trialability is the degree to which an innovation may be experimented with on a limited basis..." [29]. A trial or test of the capabilities of digital technologies, in the form of a proof of concept (POC), is a way for an organisation to stifle any doubt or negative perceptions they may have about certain digital technologies and is a positive enabler of adoption. P-6 highlighted the fact that organisations don't always have to be the first to adopt new technologies, especially without proving that the adoption of new technologies will add value: "...you don't need to be the guinea pig and embark on new technology trends without proving that for yourself first. You don't want to go big bang on new stuff, you always want to take baby steps, always have POC's, test it out, monitor if you are achieving your goals and benefits you have set yourself and over time commit to more of that as you see that actually working within the organisation".

#### *Compatibility (+)*

"Compatibility is the degree of how consistent an innovation is perceived to be within an organisation and is affected by internal structures, strategy, values, experience and the needs of the business" [30]. P-7 confirmed that the retail organisation must investigate and demonstrate to the business that new digital technologies will add business value by stating that the organisation must "...determine what business value that is technologies will actually have for our retailers and also the appetite of the retailer to actually adopt that technology".

#### *Company Culture (+/-)*

Company culture can have a positive or negative effect on the adoption of digital transformation within the retail industry: "...if the culture is not ready or your culture is not very open to change, then that could be a barrier for you in terms of digital transformation" [P-7]. Experienced employees might see change as a risk to their careers. It is of utmost importance that the expectation of all employees are managed well, before, during and after embarking on a digital transformation journey as highlighted by P-6 "as people get a bit older, for them, it becomes a risk towards their career where the younger people are more eager to change. I think you need to balance that as well".

#### *Digital Strategy (+/-)*

The lack of a clear and coherent digital transformation strategy driven top-down by top management can be a negative factor adoption factor: "...you need a clear definition of what your digital transformation is. You do need to scope what you mean by that clearly. There is a risk that people might misunderstand what the context is and in terms of that there could be communication challenges" [P-6]. The need for a clear and coherent digital transformation strategy was emphasized by P-5: "...if traditional brick-and-mortar retailers want to survive they will need to transform and grow their e-commerce divisions." Their vision for digital transformation is clearly communicated to the entire organisation and is driven top-down by executives: "I think

the way the project is approached and communicated and the benefits explained to people will have a big impact on how positive the transformation will be accepted and how successful it will be” [P-9].

#### Collaboration (+)

Multiple participants highlighted that collaboration between employees within the organisation will have a positive impact on the adoption of digital transformation. P-8 stated that collaboration must be done between employees and clients to determine the scope for a project by saying “...collaborates with the clients at the highest level. Collaborate with what it is that they're trying to achieve”. The need to have communication tools available in an organisation with a distributed workforce was highlighted by P-2: “...we are a large group of people with the distributed management team across SA, there's definitely a need for communication tools that bring us together”.

#### D. Environment

Only three factors were identified under the environment theme (Table V). The retail customer was by far the most cited factor emphasizing its importance and customer-orientation.

TABLE V: ENVIRONMENTAL SUB-THEMES

Customer	12
Competition / Competitive Advantage	5
Time to Market	5
Connectivity	2

#### Customer (+)

The retailer customer was highlighted by most as one of the biggest driving factors of digital transformation within the SA retail industry, thus having a positive influence on adoption. The SA retail customer's behaviour when shopping and doing research before and during shopping is changing: “More and more customers are expecting digital transformation with buying online as well as doing online research and just the convenience of shopping anytime anywhere” [P-9]. Customers want to use their smart devices while shopping and expect information on products as and when needed: “...the customer has changed, the customer wants things and information at their fingertips, the customer wants to use new devices and in order to use their device of choice” [P-7].

Retail organisations must adapt and adopt digital technologies to ensure they cater for the needs of the changing customer by enriching the customer experience: [referring to the adoption of digital technologies to enrich the customer's shopping experience]: “...it needs to add customer value, it needs to improve the experience, it needs to reduce cost & risk, it needs to improve quality” [P-6].

#### a) Competition / Competitive Advantage (+)

Organisations have to change, adapt, transform and adopt digital technologies to stay competitive in the SA retail environment: “you will have to adapt and transform to stay competitive” [P-9]. A close eye is kept on what the competition is doing in the market, especially regarding digital technologies, to ensure sales and market share does not

decline: “...if our competitor is gaining market share or we are losing sales or whatever because of a competitor employing digital technologies it's definitely something that we will look at” [P-7]. Furthermore, the organisation is more reactive to externally visible digital technology innovations that could affect the customer's shopping behaviour: “When the customer's perception of innovation is positively affected by something, something that's clearly externally visible I do think that forces the organisation to adopt. You need to be more reactive in terms of an external visible technology influence than an internal one” [P-6].

#### Time to Market (+)

Time to market is a very important factor in a very competitive SA retail market. The perception arose during the semi-structured interview that digital technologies would improve time to market of products, thus having a positive impact on the adoption of digital transformation. Digital transformation coupled with improved business processes and activities will most definitely result in an reduced time to market and cost, increased market share and profit as mentioned by P-2 “...improve our processes and activities if we get this recipe right we will most definitely improve our time to market reduce our costs and increase our market share and hopefully this all leads to increase profits”.

#### Connectivity (-)

The retail group has a wide footprint of brick and mortar stores throughout Africa requiring an internet connection to trade and be operational. The lack of connectivity throughout Africa was raised as a factor that would negatively impact the adoption of digital transformation when P-3 stated “...I think connectivity is a massive issue given our big footprint and widespread brick-and-mortar stores connectivity is not consistently available everywhere”.

#### E. Technologies Driving Digital Transformation

The combined analysis from the literature review and semi-structured interviews revealed nine core technologies as driving the digital transformation within the SA retail industry. Table VI lists these, ordered by the combined number of participant responses per use case.

TABLE VI: TECHNOLOGIES DRIVING DIGITAL TRANSFORMATION

e-Commerce Solutions	12
Big Data & Analytics	9
Cloud	9
Artificial Intelligence	5
Bots	4
Machine Learning	3
Facial Recognition	3
Self-Checkout	2
RFID	2

The most cited technology across the board was to provide the retail group with an e-Commerce solution. All identified technologies were confirmed as relevant to the retail industry.

#### F. Summary of Findings

The findings can be used to answer the research questions.

### *Understanding and Perception of Digital Transformation*

The research study found that in terms of understanding digital transformation most participants had a general understanding of digital technologies that could be implemented as specific use cases to achieve digital transformation. However, none of the participants indicated that they are aware that digital transformation involves more than implementing certain digital technologies. The researchers found that there are a strong awareness and presence of digital technologies from participant responses received around the use of digital technologies within the SA retail industry which could have a positive or negative influence on adoption. Overall, perceptions from participants were mostly mixed to positive. The mixed perceptions were mostly due to date security concerns surrounding cloud adoption. Thus, the proposition is strongly supported.

### *Identified Technologies Driving Digital Transformation*

Participants identified nine technologies as driving digital transformation within the retail industry. Cloud technologies and data analytics were the most frequently cited and were the ones which the participants intended implementing. Specific benefits of these technologies included: satisfying changing customer needs, decreasing time to market, increasing customer value, which could be achieved by implementing digital transformation initiatives. Due to the agreement among and the specific technologies and benefits identified, this proposition is strongly supported.

### *Identified Adoption Barriers*

One of the goals of the study was to identify adoption factors, during the literature review and research strategy, and to provide the knowledge and information needed to the SA retail industry to ensure informed decision are made regarding potential future use. Several positive and negative different factors were identified across the Technology, Organisational and Environmental context.

Perceived challenges were highlighted as the biggest negative factor of the **Technological** theme, while relative advantage was highlighted as the biggest positive factor in the adoption of digital transformation. Data security when implementing cloud technologies was highlighted as a major concern / negative adoption factor while the adoption of cloud technologies and reduced onsite hardware was seen as a major benefit and stepping-stone to becoming digitally transformed.

The most adoption factors identified was under the **Organisational** major theme which indicated that participants thought about organisational factors. It became clear that resistance to change would be the biggest organisational barrier to overcome when undertaking digital transformation initiatives. Furthermore, it was highlighted that the cost of implementing digital technologies will play a big role and ultimately return on investment will be a deciding factor.

One of the most important findings that emerged from the **Environment** major theme was that the retail customer basically drives digital transformation. The changing customer, their needs and the change in how they shop was

highlighted by all participants. Thus customer-orientation rather than competitor analysis should drive the adoption of digital transformation in the SA retail sector.

## V. CONCLUSION, LIMITATIONS & FUTURE RESEARCH

The research study revealed that there was a good understanding of digital transformation from participants within the SA retail industry. However, this could be attributed to their level of training, years of retail experience, the position held within the organisation and the fact that the case site is currently busy with digital transformation projects. Therefore, this could not be generalized across the retail organisation or industry as a whole.

The core technologies perceived by participants as driving digital transformation in the retail industry with e-Commerce solutions, big data & analytics, and cloud adoption being mentioned the most. The findings from the study also affirmed that there is a consistent association between the adoption of new digital technologies and digital transformation. Finally, the findings identified 22 that affected the adoption of digital transformation within the SA retail sector grouped using the TOE model. **Technological** factors identified include the imperative to address technical challenges including securing a sound infrastructure (e.g. move some of the infrastructure into the cloud and secure a high-speed, low-latency connection ideally through a locally based cloud vendor); identified security risks include protection of IP as well as customer privacy and hire the correct technical skills. The relative advantages obtained include not only competitive advantage but also reduced costs, reduced time to market and improved customer satisfaction. Enterprises should make extensive use of digital technologies to create a customized personalized user experience through a comprehensive omni-channel approach. Digital technologies enable the enterprise to collect, analyze and interpret data which must be used to optimise their value chain, ultimately increasing profit.

The most prominent **organisational** issue identified was resistance to change, emphasizing the need for change management and a corporate culture embracing transformation and collaboration. Enterprises that add specialized digital change agents to their workforce to assist current employees through the digital transformation process will increase their success rate. Assessing the organisation's readiness, possibly through proof of concept sandbox testing is also important – these include aspects of the technology's trialability and organisational compatibility. Digitally mature enterprise must attract and recruit to ensure they don't have skill gaps. Reserving the appropriate financial resources is also important, as is ensuring that big data and effective data analytics are in place is also rated as a crucial step in digital transformation. A clear digital strategy which includes scope and objectives and is driven from the top down rounds off the organisational factors. The crucial **environmental** factor was, not unsurprisingly, a focussed customer-orientation for any technologies that are introduced i.e. does it help or add value for the customer as opposed to a knee-jerk competitor-driven

response. Many of these factors point towards the increased set of IT competencies that retail managers should master. Ultimately, enterprises must analyse the customer's behaviour through their entire shopping experience by making use of big data and analytics. An agile, creative, innovative workforce must elevate the customer's experience resulting in a competitive edge.

The extent to which these findings can be generalized to other countries depends on the structural and environmental similarity of the retail industry with the South African one which operates in a first world/third world context: infrastructure and scarce skills considerations may be more specific, but overall skills, readiness, corporate culture, change management, relative advantage and others are likely to be generalizable to many other country contexts.

Some limitations must be considered when interpreting the results of this study. The study provided a narrow focus on one large retail group, while the retail industry is made up of organisations of varying sizes. The seniority and the position that some of the interviewees fulfil in the case site enterprise resulted that they had limited time available for interviews. Also, the interviewee base was quite small but thematic saturation was reached after the ninth interview.

Future studies around the adoption of digital transformation in the retail sector could be conducted to identify new factors that might impact adoption. The research has identified the need for a study to be conducted across the SA retail industry in order to access a national view on digital transformation in different size retail organisations. In doing so the research will get a more in-depth view of positive and negative factors influencing the indented adoption of digital transformation and more potential use cases could be identified.

**Abstract**—The main aim of this article is to identify students' opinions concerning the place, role and influence of electronic marketing tools on making purchases on the Internet. The authors have applied the division of e-marketing into its traditional and electronic forms, on desktop computers and mobile devices, which was significant due to diversified opinions of clients concerning its use. The studies have been carried out with the application of a CAWI method examining a convenient, partially randomly selected sample of clients (students) who are the most active in the Internet. The studies were aimed at evaluating specific e-marketing media and techniques which, in the customers' view, influenced shopping on the Internet. In particular, the respondents commented on the advantages, disadvantages and benefits resulting from the application of e-marketing on mobile devices. The conclusions and recommendations from the study may contribute to better use of these factors in order to facilitate consumers' purchases, not only in the Internet.

## I. INTRODUCTION

THE PRIMARY objective of this paper is to present the impact and significance of electronic marketing (e-marketing) in the purchasing process, based on the opinions of a selected group of potential clients. It is a next study conducted as part of a series of research analysing a similar group of respondents in the situation where the opinions on e-marketing are largely diversified, and a dynamic development of mobile devices may be observed. Simultaneously, it should be noted that the study is of supplementary nature in relation to comprehensive studies undertaken by the authors examining the quality of websites and mobile applications.

Electronic marketing is understood in this paper as a combination of all components related to information technologies, especially the Internet, in order to increase the willingness of potential customers to make purchases [13]. It is associated with many tools which are mainly applied on the Internet [18] as well as new sales and payment techniques [3]. It encompasses a wide range of themes connected with, for example, the evaluation of the possibilities of new devices (smartphones, tablets), users' response to new marketing forms and tools, the development of new e-marketing tools, etc. Kaznowski [10] believes that it is a significant part of the marketing strategy of an organisation. On the other hand, it is the result of a combination of modern marketing theories, use of information technologies [16] as well as the product

of project management, in particular, change and risk management [7]. In order to create a marketing strategy related to the promotion of products and services via the Internet, it is necessary to carry out a project consisting in, among others, building an e-shopping website and devising marketing tools which would help to promote this website on the Internet. For a marketing strategy to be successful, we should collect and examine the opinions of potential clients regarding the media and marketing techniques. If we consider all the above comments, then electronic market will represent all the above-mentioned marketing activities aimed at meeting operational, tactical and strategic goals with the application of the Internet infrastructure [5]. At present, mobile marketing is an essential part of electronic marketing. Due to the fact that it is perceived as all (advertising and promotional) activities using the functionalities of mobile devices [2], [9], it is difficult to distinguish between advertising available in browsers and special, dedicated smartphone mobile applications [8]. According to AMMA (The American Mobile Marketing Association), mobile marketing is understood as any form of marketing, advertising or promotional activity addressed to clients and transmitted via the mobile channel [15]. This definition of the phenomenon is the one applied in the present article. In addition, m-marketing offers basically unlimited possibilities of adapting the forms of promotion and communication to the needs of an individual recipient [12].

Electronic marketing was the object of many studies, both in the Polish and foreign markets, also from the point of view of a client [14], [6], [17], [19], [11], and new works analysing this field continue to appear. It is true that the majority of significant studies were published before 2015, the period of the most intense development of modern smartphones and tablets along with their dedicated applications, nevertheless, especially in mass surveys, new development trends and new phenomena appearing on this market are constantly being analyzed [20].

The authors of this article aim to distinguish some of the basic tendencies related to these new phenomena as well as implications for the future development of electronic marketing, including mobile marketing. The present studies, which main aim is to analyse the use of e-marketing among the users

of all kinds of computer devices used to access the Internet. The findings presented in this article, discussion and resultant conclusions constitute a report of the research involving a selected sample of Internet users in Poland at the beginning of 2019.

## II. THE ASSUMPTIONS OF THE METHODOLOGY AND PRESENTATION OF A STUDY SAMPLE

Following the previously conducted research [5], [4], the authors adopted the verified research procedure which consists of the following stages: constructing the first version of the survey questionnaire; verifying the questionnaire analysing the respondents' comprehension of the questions contained in the survey and the significance of the queries for the research, with the participation of randomly selected groups of respondents engaged in the pilot study, random selection of the groups of students for the study; making the verified and improved survey questionnaire available for the selected student groups (with the application of a CAWI – Computer Associated Web Interview method); analysis and discussion of the obtained findings; conclusions and possible directions for e-marketing development, on the basis of literature references and the authors' own studies.

In its final form, after eliminating the least significant questions and introducing changes aimed at clearer presentation of the remaining queries, the survey questionnaire included twenty-three substantive questions, divided into five groups and five questions related to the so-called demographics of the study sample. The scope of questions for the specified parts of the survey was as follows: electronic marketing environment, the effectiveness of electronic marketing, evaluation of e-marketing as a source of information on products/services, evaluation of the distinguished e-marketing media and techniques: the evaluation of selected e-marketing media, respondent's approach towards marketing on mobile devices and some demographics features.

The presented study was carried out in mid-March 2019. The research sample was selected as a partially convenient and partially random sample among the students of the University of Warsaw. An invitation to complete a survey questionnaire was distributed electronically among 356 students, both full-time and part-time courses, as randomly selected students' groups. 294 students completed survey questionnaires, which constitutes nearly 83% of the sample. This indicates nearly a threefold increase in the number of respondents from the same environment compared to the study of 2016 [5], which suggests increased interest in topics related to the possibilities of using the Internet for marketing purposes, especially in its mobile form. The selection of the sample consisting of students brought about certain limitations with regard to the possibility to interpret the findings. As the studies by Batorski and Płoszaj [1] indicate, the age group among which the studies have been carried out is a population which is most active in the Internet, most focused on innovation, and the one which is also the fastest to purchase and apply the latest technical solutions. Therefore, it is difficult to generalise the

obtained results to be indicative of the entire society. On the other hand, it is a group which for the above-mentioned reasons is the most competent to evaluate the tools used in the internet and mobile marketing, because they spend the greatest amount of time in the Internet, not only to obtain information, but also to make purchases and communicate with the shops, using websites and mobile applications many times a day.

In the analysed sample, more than 95% of the respondents were representatives of this most active social group. The group included individuals who were 18-24 years old, with the average age of slightly over 21, where all survey participants had secondary education. Among the respondents, there were 57% of women and 43% of men, which reflects the present gender structure of UW students. At present, in the examined study sample there were 55% of working students and 45% of students who were not professionally active. More than 52% of the respondents came from cities with over 500,000 residents, further 11% from towns with 100-500,000 inhabitants, 24% from the towns with 10-100,000 residents, less than 5% from small towns up to 100 inhabitants, and only 9% were from villages. In the present study, the share of students coming from large cities increased, mainly at the expense of people coming from rural areas.

## III. ANALYSIS OF THE OBTAINED FINDINGS AND THEIR DISCUSSION

The survey questionnaire was made available on the servers of the University of Warsaw. The questions were divided into several groups, and the analysis of the responses with the discussion and comments are presented below.

The first group of questions was of introductory nature. Its goal was to identify the conditions of using electronic marketing. The queries concerned the frequency of using the Internet, the type of most frequently visited websites, devices used for this purpose as well as the place and frequency of doing online shopping. The response to the first question appears to confirm the other findings [1] – all students use the Internet a few times a day. Undoubtedly, this was due to the popularity of mobile devices and – as it seems, a specific environmental culture of using them everywhere and at any time. This conclusion also results from the response to the following question, where over 23% of the respondents stated that it is the main and the only device which they use to connect with the Internet. Given that almost 12% of respondents use only a laptop and desktop computer for this purpose, this still confirms a clear advantage of this device over others. The greatest share of the sample – 44%, however, uses a combination of a laptop and a smartphone to connect with the Internet. As indicated in the comments section, the smartphone is mainly used to listen to music, communicate, obtain information and carry out small financial operations. Financial decisions which require careful consideration and extensive works or communications are usually associated with working on a laptop. In comparison with the situation from three years ago, the use of the smartphone as the only device to connect with the Internet declined (by nearly 10%),

and the use of smartphone and laptop increased (by almost 11%). The most frequently visited websites are social media websites (25%). Websites providing information/news are also popular - 12%. Thus, it emerges that the main and widely appreciated functions of the Internet are those which are associated with providing information or communicating. The use of search engines is also of primary importance with regard to providing information which the respondents require (18%). However, searching for a particular item is not always associated with purchasing it on the Internet: it is frequently only connected with looking for data concerning a given product or service. Nevertheless, e-shopping websites are most frequently visited by 19% of the respondents, and financial services by 21%. Thus, the area where electronic marketing might be applied is wide. The growing popularity of the use of mobile devices is demonstrated by the indicated places of accessing the Internet – nearly 93% of the respondents stated that they use it everywhere, and 13 times fewer people (7%) responded that they use it at work, at home or the university.

The second part of the survey concerned the perception of the effectiveness of the application of electronic marketing by internet users: their subjective evaluation of the phenomenon of e-marketing, its comparison with traditional marketing and evaluation of the potential advantage of e-marketing over traditional marketing. The respondents assess internet marketing as good or very good in over 84%, and only over 15% perceive it as satisfactory or non-satisfactory. This is probably caused by the opinion that 24% of the respondents are convinced that internet and mobile marketing is better, and over 50% believe that the greatest effectiveness is achieved through a combination of electronic and traditional marketing. In turn, nearly 23% of survey participants think that the two types of marketing are difficult to compare because they are addressed to different target groups. In the case of almost a quarter of recipients, there exists a belief that the effectiveness of marketing depends on the age of the recipients and the most frequent use of media (smartphone versus laptop) associated with it. The respondents regard continuous availability (33%, 25% in 2016) via mobile and remote or desktop devices and the possibility of buying items after clicking on the advertising field (via link) (nearly 26% as compared to 19% in 2016) to be the greatest sources of advantage of marketing in the Internet over traditional marketing. Also, the previously emphasised possibility to obtain more information about a product or service (25%) is of considerable importance.

The third part of the survey concerned issues related to the use of sources of obtaining information on products and services on the Internet and outside the Internet as well as its subsequent application. Among the analysed sample, the Internet proved to be an a decisively dominant medium (86% individuals) to access information about products and services (as compared to previous score at the level of 33%). In combination with the information obtained from a circle of friends and colleagues, this comprises over 98% of the places of obtaining commercial information. The importance of such media as television, radio, press, leaflets or paper

information materials appears to be nearly non-existent, which points to little interest in this form of marketing among the representatives of this social group. Comparison engines turned out to be the most common tool (as it is believed by over 40% of the respondents) to search for information about products and services on the Internet. On the one hand, individuals are eager to use them, on the other hand, they do not perceive them as a tool which would be of crucial importance from the point of view of the effectiveness of e-marketing. The second place is taken by social media (nearly 31% share in the respondents' opinions). Even three years ago such an opinion would be encountered with disbelief; however, at present the influence of social media is becoming more and more important. This is also evidenced by the high, third place of blogs (15%). It is important to point out that even though a blog is in fact seen as a source of largely subjective information, it is still a medium which shapes consumers' tastes and views in certain sectors (e.g. fashion and cuisine). E-marketing offering different advertising forms contained on websites and carried out via emails is losing its importance (in total the score amounts to less than 9%). This form of advertising, which until recently was seen as dominant in this type of marketing, in a sense, is already regarded as a traditional form.

In the fourth part of the survey the respondents were asked to evaluate particular media and e-marketing techniques: the effectiveness of the applications of the media, approach towards selected e-marketing techniques, places in the ranking of products which induce consumers to make purchases, elements which respondents pay particular attention to and those which attract them the most as well as the evaluation of the respondent's approach to placing particular elements of e-marketing in marketing media and on various types of devices. The evaluation of the effectiveness of selected electronic marketing media was based on a four-point scale from: unsatisfactory, satisfactory, good and very good. The highest rated techniques were: presence in social media (26% of very good scores), clarity and attractiveness of a website (24% of very good scores) as well as the presence in mobile solutions (20%). The highest number of good scores were obtained by positioning (18%) and sponsored links (15%). In the latter case, the opinions were divided because slightly more people (18%) evaluated them only at a satisfactory level. Banners, links to other websites (19% and 18% respectively) and newsletters (21%) were evaluated at the border between satisfactory and unsatisfactory. The most unsatisfactory technique was related to advertising mailing messages (43% of unsatisfactory scores). This survey section was also aimed at creating a specific ranking of factors which motivate clients to make purchases. In this ranking, the first place among the responses was taken by the clarity and attractiveness of a website (33% of views). The second position was occupied by the presence in social media (22% of opinions). The subsequent places were taken by factors such as discounts after exceeding a specific value of the purchase (17% responses) and positioning (11%). The last positions in the assessment were taken by pop-up

windows (43% in the last position), e-mailing advertisements (20% in the penultimate position). According to respondents' opinions, clients pay the most attention to graphic elements (34%) as well as the innovativeness and attractiveness of the presentation (29%). They pay the least attention to technical elements of e-marketing such as: text (8% of the surveyed students believe it is the case) or the sound and music (14% of responses). So, what would attract them to visit the website? In the views of the study participants, at present, the most efficient in this regard are elements such as short videos (28%) and large graphic banners between a logo and the content (16%). The least effective are: buttons (5%) and pop-up windows (8%). The above ranking shows a specific transition of the existing clients to more modern technical elements of e-marketing and "fatigue" with the forms which are frequently encountered in the current practice of using the Internet. From the point of view of a client, the greatest acceptance for placing e-marketing in selected marketing media was recorded in the case of e-shopping websites (23% of responses), social media websites (20%) as well as company and news websites (15% and 16% respectively).

The last group of survey questions concerned the respondents' approach to the phenomenon of marketing on mobile devices, namely: advantages and disadvantages of m-marketing, benefits of m-marketing and the effectiveness of m-marketing techniques in relation to the client. Among the greatest advantages of m-marketing, the respondents mainly distinguished the fact that it is available at all times and everywhere (24%) and it can apply a personalised advertising message (21%). The last positions were taken by the high effectiveness of this medium (8%) as well as the fact that it can be treated as a determinant of modernity (10%). The advantages of m-marketing bring direct benefits for the client. Among the selected benefits, the most important factor (37% of the responses) was the use of NFC technique or QR codes (e.g. train tickets). According to the survey participants, the second significant benefit was geolocation and mobile navigation (31%). The subsequent positions were taken by the possibility to create mobile websites (13%) and SMS marketing (9%). The biggest disadvantage of m-marketing is the necessity of longer screen scrolling (34% of respondents believe it is the case) and increasing difficulty of getting rid of advertising messages (33%). Another negative factor is the fact that they take too much space on a screen which is already rather small (20%). The smallest number of people believe that advertising on mobile devices is too general and the graphic presentation is of lower quality (3-4%).

According to the survey participants, the greatest influence is indicated in the case of graphic advertising elements (66%). The next place is taken by the video advertising of the application (17%) and graphic advertising of the application (11%). The remaining kinds of mobile advertising are of limited importance, namely, they constitute only 5%. In the last six months, the aspects which had the greatest impact on respondents' purchases included: the use of mobile applications (44%), using geolocation and mobile navigation

(17%) as well as SMS marketing (14%). The remaining m-marketing techniques did not exert any significant influence on the purchases made by the respondents in the last six months.

#### IV. CONCLUSIONS

The conducted and presented studies lead to the following conclusions:

- the examined population is "immersed" in the Internet nearly all the time, using mainly mobile devices to search information, exchange communications, enjoy broadly defined entertainment (music, films, computer games), as well as make purchases or carry out financial transactions. This tendency has strengthened in the last three years,
- the opinion about electronic marketing and its impact on purchases is still very high. This is not reflected in the value of purchases; nevertheless, this results from appreciating the informative function of the Internet. Continuous availability and convenience of the use is not only or mainly associated with making purchases, but it also serves to obtain information about a product or service. The decisions concerning the purchase and the way this operation is being carried out (via the Internet or traditionally) are taken later,
- the attitude of the respondents towards comparison engines is unclear. On the one hand, nearly everyone uses them; on the other, clients do not perceive them as the most important tool which might be seen as a specific advantage of e-marketing over traditional marketing,
- the effectiveness of e-marketing media, in the respondents' opinion, depends mainly on the presence in the social media and characteristic features of the website (its clarity and attractiveness); in the ranking of the factors inducing consumers to make purchases, apart from the above aspects, the respondents list also discounts offered after exceeding a certain amount of money,
- pop-up windows and spam mailing are the two most disliked elements in e-marketing,
- the respondents mainly pay attention to such technical elements of e-marketing, like graphic elements, in particular, short videos, appearing mainly on social media websites,
- the irritation associated with excessive advertising in mailings is growing; while the degree of acceptance of e-marketing received via traditional and modern devices is rather high (28%). The studies concerning this very phenomenon in relation to websites [e.g.] show that this solution appears to be the most undesirable with regard to the evaluation of the website quality. The greatest level of acceptance for video marketing on mobile devices undoubtedly also plays an important role in this respect,
- we may also observe a phenomenon of a specific shift of the interaction with the Internet from traditional to mobile devices and more and more common blurring of the boundaries between mobile laptops and tablets due to the greater universal use of laptops. The dominating position of smartphones in everyday life also has more

and more influence on the evaluation of e-marketing in its mobile form,

- the advantages of m-marketing result from its continuous availability and a possibility to personalise the message; the disadvantages mainly consist in the fact that it occupies a large part of the screen and its related necessity of longer scrolling or the fact that such an advertisement is more and more difficult to remove from the screen.

The limitation of the study was the fact that it was carried out among a rather uniform sample of respondents coming from academic environment. As previously mentioned, this was the most active group with regard to new technologies, and the obtained findings tend to present a somewhat idealised view of the clients' relation towards both the technologies themselves as well as the operating media of electronic advertising. The study should be extended to include also other social groups which do not use the Internet to such an extent, both in their private life and economic activity. This would allow for a more comprehensive, holistic view of the possibilities of e-marketing applications. On the other hand, international and intercultural studies seem to be a very interesting direction for further studies, which would allow for specific universalisation of the obtained findings.

# Network Effects in Online Marketplaces: The Case of Kiva

Haim Mendelson and Yuanyuan Shen

*Abstract*—Advanced information technologies have enabled the development of online marketplaces that connect businesses and people on a global scale. Much of the analysis of the adoption, growth and engagement on these marketplaces in the extant literature is based on the premise that they are characterized by network effects—a premise that has major implications for their deployment, implementation and management. In this paper we test this premise using data from Kiva, the world’s largest online, peer-to-peer social lending marketplace. We find that while network effects are strong and significant during the early growth phase of the marketplace, they become weak or disappear once the marketplace stabilizes.

*Keywords*—Online marketplaces, network effects, peer-to-peer lending, online services.

## I. INTRODUCTION

ADVANCED information technologies are changing the structure of economic activity, with many traditional processes being transformed through the use of electronic marketplaces. Activities such as buying, selling and lending are moving from the established but labor-intensive and inefficient brick-and-mortar format to online marketplaces that increase efficiency, transparency and effectiveness and are already a major sector of the economy. The research questions addressed in this paper are: (i) are online marketplaces characterized by network effects? (ii) How does the answer depend on the growth phase of the marketplace? We address these questions using data from Kiva, the world’s largest social lending marketplace.

Network effects, also referred to as network externalities, reflect a positive relationship between the installed base of users on a platform and its value to users [1],[2],[3]. They are *direct* when there is a direct positive relationship between the size of the installed base and the value to users within that installed base. The classic example is the telephone network: adding a new user to the network increases the number of potential calls users can make, which increases the utility users derive from the network [4]. *Indirect* network effects arise when (i) the network is based on two complementary components, say  $A$  and  $B$ ; (ii) there is a positive relationship between the installed base of  $B$  and the value to users of  $A$ , and (iii) there is a corresponding positive relationship between the installed base of  $A$  and the value to users of  $B$  [1]. This results in a positive feedback loop between the installed bases of  $A$  and  $B$ : an increase in the installed base of  $A$  makes the

network more attractive to the  $B$ s, and as more  $B$ s join the network, it becomes more attractive to the  $A$ s. This means that more  $A$ s attract yet more  $A$ s indirectly through the  $B$ s—hence the term *indirect*. In this paper we test the existence of this positive feedback loop.

Network effects have a major impact on the way technology-based solutions are deployed and managed as they affect choices of efficiency, effectiveness and speed: in the presence of network effects, a highly-efficient and effective solution that does not achieve critical mass may fail regardless of its technical or economic merit. Further, if network effects are sustainable, a solution that manages to control a large user base may prevail even when it is inferior on a stand-alone basis [1]. Thus, network effects have a paramount impact on the deployment and management of platforms, and in particular—on online marketplaces.

In a peer-to-peer online lending marketplace, prospective borrowers post loan requests online either directly, on their own, or indirectly, through marketplace partners. Lenders browse the loan requests and decide which loans they would bid on. Lenders who wish to fund a loan submit conditional or unconditional funding commitments to the marketplace. The marketplace then matches loan requests to funding commitments, funds some of the loans, and services them until they are repaid (or until they default). It is commonly assumed that such lending marketplaces are characterized by indirect network effects between lenders and borrowers, as more lenders increase the probability of a loan request being funded, and more borrowers make the market more attractive to lenders, who can better diversify their loans and are more likely to find a match they are willing to fund. The latter consideration is important on Kiva, where lenders seek to support entrepreneurs with particular characteristics, and with more entrepreneurs and loan requests on the site, a lender is more likely to find one she is willing to support.

Network effects were found in a variety of industries ranging from telecommunications to Information Technology (cf. [5], [6], [7]). However, while the theoretical literature views network effects as an inherent feature of online marketplaces, we could not identify an empirical study that directly confirmed their existence in online peer-to-peer lending marketplaces. In this paper, we narrow this gap by investigating whether network effects actually exist on Kiva and how they depend on the growth phase of the marketplace.

The rest of the paper is organized as follows. Section II is a Kiva overview. Section III outlines our research hypotheses. Section IV describes our data and test methodology. Section V presents our results. We briefly conclude in Section VI.

H. Mendelson (haim@stanford.edu) is with the Graduate School of Business, Stanford University, Stanford, CA 94305, USA (see <https://www.gsb.stanford.edu/faculty-research/faculty/haim-mendelson>). Yuanyuan Shen (anashen@alumni.stanford.edu) is with the Graduate School of Business, Stanford University, Stanford, CA 94305, USA.

## II. KIVA

Founded in October 2005, Kiva operates a website where entrepreneurs from developing countries post loans through field partners—microfinance institutions, social businesses, schools, and other non-profit organizations. Loans come from individual lenders from across the globe, primarily from developed countries. Between October 2005 and June 2019, Kiva funded \$1.32 billion in loans extended to 3.3 million borrowers from 1.8 million lenders. These loans had an impressive repayment rate approaching 97%.

Each month, Kiva's field partners post on the Kiva website loan requests on behalf of the entrepreneurs they represent. Loan terms average 1.5 years. Lenders browse the loan requests and may contribute \$25 or more to fund the loans they select.

Loan requests remain posted on Kiva for up to 30 days. If a loan is not fully funded within that period, it expires and all lenders' commitments are refunded. If the loan is fully funded, Kiva's field partner sends the money to the entrepreneur. As of June 2016, about 95% of loan requests were fully funded. As the borrower repays the loan, the field partner returns the principal through Kiva to the lenders who funded it.

Kiva lenders are social investors who receive no interest and make no profit on their loans (however, Kiva's field partners may charge interest on the loans they make). Loans serve the needs of poor, under-served, or financially excluded (e.g., unbanked or underbanked) populations and aim to achieve a social or environmental impact.

We obtained our data from Kiva's data snapshot on build.kiva.org, augmented by querying Kiva's API. In addition to basic data on borrowers and prospective lenders, we have loan-specific information through June 2016. Our sample period is January 2007 to June 2016. In our sample, the majority (84.8%) of loan requests come from Asia, Africa and South America while most (89.4%) lenders come from developed countries in North America and Europe. As a macroeconomic control, our regressions use the effective yield on the ICE BofAML Emerging Markets Corporate Plus Index [8], which is available on a daily basis and is expected to influence loan funding in emerging markets (we also used the GDP growth rate and unemployment rate, which turned out insignificant).

## III. RESEARCH HYPOTHESES

In this paper, we formulate two key hypotheses on potential network effects and then test them using data from Kiva. As discussed above, the theory of network effects implies a positive feedback loop between the number of lenders and the amount of open loans (measured by their number or aggregate dollar amount): with more lenders, the platform should attract more loan requests, and with more loan requests, the platform should attract more lenders. This results in two key hypotheses:

*Hypothesis 1:* The dollar amount and number of open loans on Kiva should increase in the lagged number of active lenders.

*Hypothesis 2:* The number of active lenders on Kiva should increase in the lagged number and amount of open loan requests.

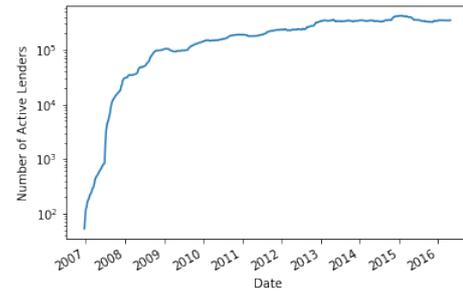

Fig. 1. Number of active lenders on Kiva

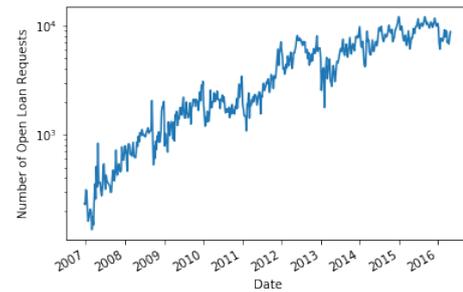

Fig. 2. Number of loan requests open on Kiva

Network effects and the associated feedback loop require *both* Hypotheses to hold.

## IV. DATA AND METHODOLOGY

We construct weekly time series for Kiva's performance over our sample period (2007 - 2016). We identify two phases in the development of the Kiva platform: a *growth* phase covering the first half of our sample period, and a more stable phase during the second half of our sample period. During the growth phase, both the amount of loans requested and the amount funded grow quickly. Then, the growth in both supply and demand flatten out. Further, during the second subperiod, the gap between the number of loans requested and the number of loans funded becomes larger.

Figure 1 shows the number of active lenders (i.e., those who have bid on at least one loan in the past six months) and Figure 2 shows the number of open loan requests on Kiva each week over our sample period, both on a logarithmic scale. The figures show how growth has abated between the earlier growth period and the latter stable period, when the number of active lenders flattens out and the growth in open loan requests deteriorates.

These patterns show distinct differences between the earlier growth period and the latter stability period. While the empirical network effects literature typically finds them at the early growth phases of new technologies, it does not recognize the stark differences between the early growth and stability periods. Madden and Dalzell [9] study the early growth of mobile telephony and attribute differences between high- and low-income countries to non-linear network effects.

We argue that network effects should be more prominent during the earlier growth period, when the growing installed

base is a key driver of adoption. Once the platform stabilizes, we expect other factors and tactical moves undertaken by the platform (e.g., field partner selection, budgeted loan amounts, etc.) to overtake the network effects as drivers of performance. Indeed, while peer-to-peer lending has been growing rapidly around the globe [10], Kiva has experienced a declining loan fulfillment rate, and during the 2011-12 period it started honing its business model, actively managing demand and supply down to the level of the types of loans made [11], [12]. In addition, Kiva was facing increased competition from new social microfunding sites (e.g., MyC4 in Europe, Wokai in China and MicroPlace in the U.S.), as well as from for-profit lending sites that catered to entrepreneurs (e.g, Zopa in Europe and CreditEase in China; these sites, which charge interest, competed with Kiva since many field partners charge interest to the entrepreneurs they serve). In addition, Feldman et al. show theoretically that the performance of peer-to-peer systems can degrade significantly as a result of user turnover [13]. We thus expect our network effects hypotheses 1 to 2 to hold during the early growth period and to become substantially weaker or altogether disappear during the latter stability period.

To test for these different behaviors, we divide our observations into two halves, (i) January 2007 to August 2011 and (ii) September 2011 to June 2016. Table I displays the correlation matrix among our key variables for the two sample subperiods.

TABLE I  
CORRELATIONS BETWEEN THE NUMBER OF ACTIVE LENDERS, THE DOLLAR AMOUNT AND THE NUMBER OF LOAN REQUESTS

Variable	Amount of Loan Requests	No. Loan Requests
Jan 2007 - Aug 2011		
No. Active Lenders	0.87	0.87
Amount of Loan Requests	-	0.99
Sept 2011 - June 2016		
No. Active Lenders	0.46	0.46
Amount of Loan Requests	-	0.95

In Table I, we observe a strong correlation between the number of active lenders and the number and dollar amount of loan requests during the first subperiod. These correlations substantially decline in the second subperiod. Due to the correlations among our key explanatory variables, we test each of our hypotheses separately. For Week  $t$ , we denote by  $n_t$  the number of active lenders (defined as those who placed at least one bid over the past six months), by  $a_t$  the dollar amount of open loan requests, and by  $l_t$  the number of open loan requests. We estimate (heteroskedasticity-corrected) OLS regressions using the specification below to test Hypothesis 1 that the dollar amount of loan requests increases in the number of active lenders:

$$\log(a_t + 1) = \alpha_0 + \alpha_1 \log(n_{t-1} + 1) + \vec{\alpha}_3 \vec{x}_{t-1} + \epsilon_t, \quad (1)$$

where the vector  $\vec{x}_{t-1}$  comprises the default rate on Kiva loans as of the end of Week  $t - 1$ , the effective yield on the ICE BofAML Emerging Markets Corporate Plus Index [8], dummy variables representing the year of  $t$ , and a trend variable.

An alternative test of Hypothesis 1 focuses on the relationship between the number of loan requests and the number of

active lenders:

$$\log(l_t + 1) = \beta_0 + \beta_1 \log(n_{t-1} + 1) + \vec{\beta}_3 \vec{x}_{t-1} + \zeta_t. \quad (2)$$

To test Hypothesis 2 that the number of active lenders increases in the dollar amount of loan requests, we estimate the regression:

$$\log(n_t + 1) = \gamma_0 + \gamma_1 \log(a_{t-1} + 1) + \vec{\gamma}_3 \vec{x}_{t-1} + \omega_t. \quad (3)$$

Likewise, we test whether the number of active lenders increases in the number of open loan requests by estimating the equation:

$$\log(n_t + 1) = \kappa_0 + \kappa_1 \log(l_{t-1} + 1) + \vec{\kappa}_3 \vec{x}_{t-1} + \psi_t. \quad (4)$$

In Equations (1) through (4),  $\epsilon_t, \zeta_t, \omega_t, \eta_t$  are random noise.

## V. RESULTS

Table II shows the results of our OLS estimations using White's method to account for heteroskedasticity [14].

As hypothesized, we observe positive and strongly-significant coefficients for our network effect variables during Kiva's growth period: a 1% increase in the number of active lenders results in a 0.31% increase in the dollar amount and a 0.46% increase in the number of open loan requests. A 1% increase in the dollar amount of open loan requests leads to a 0.17% increase in the number of active lenders, and a 1% increase in the number of loan requests leads to a 0.32% increase in the number of active lenders. These results are both economically meaningful and strongly statistically significant, confirming our hypotheses. Given that *both* hypotheses hold, we have the feedback loop confirming the existence of network effects during the growth period.

For the second subperiod (September 2011 through June 2016), the network effect coefficients become small and, for the most part, insignificant (the exception is the coefficient of the number of open loan requests in Eq. (4), which is significant at the 90% level). Based on equations (1)-(3), *both* hypotheses are rejected. Because a rejection of either one of our hypotheses leads to the rejection of network effects, we conclude that there are no meaningful network effects during the second subperiod. These results are consistent with our argument for the differences between the two subperiods (Section IV).

Equations (3)-(4) use the number of active lenders to estimate the dependent variable, which leads to autocorrelated residuals. To address this issue, we reestimated equations (3)-(4) by differencing the number of active lenders, using  $(n_t - n_{t-1})$  as our dependent variable. The results are shown in columns (3a) and (4a) of Table II. The main difference between the two specifications is that in equation (3a), the significance of the amount of loan requests declines in the first subperiod and increases in the second. Our conclusion remains intact: there are strong and significant network effects in the first subperiod whereas in the second subperiod, there are no network effects, as Hypothesis 1 fails to hold.

TABLE II  
RESULTS FOR HYPOTHESES 1 AND 2

Regressors	Jan 2007 - Aug 2011						Sept 2011 - June 2016

## VI. CONCLUSION

This paper studies network effects on Kiva by testing the existence of a positive feedback loop between the number of active lenders and the amount (in dollar value or number) of open loans. We identify strong and positive network effects during Kiva's initial stage of growth. The network effects essentially disappear in the latter period, when Kiva has reached greater stability. Our results suggest that network effects are particularly important during the initial growth phase of a marketplace platform. As growth abates and competition becomes fierce, the importance of network effects declines and other tactical, behavioral and competitive factors play an increasing role. This difference between the early growth and stability periods is largely ignored in the literature.

What are the implications for the way marketplaces such as Kiva are deployed and managed? Early on, network effects are all-important, customer acquisition and speed are key success factors, and the primary objective is to grow and achieve critical mass. However, the marketplace cannot rest on its laurels following its initial growth. Rather, the network effects weaken or even disappear, forcing the marketplace to engage in constant analysis, exploration and optimization. In the particular case of Kiva, social and behavioral factors such as the ones studied in [15] are key drivers of user behavior, and the marketplace has to dynamically optimize its features so as to keep attracting new users and increase the engagement of existing users.

Our analysis is preliminary as it has a number of limitations. First, one may use other variables to study the prevalence of network effects. Second, our results are based on a single research site, and it is worth examining to what extent they extend to other network settings and marketplaces. Further, more sophisticated econometric techniques may be used to study the drivers of marketplace adoption. These extensions provide fruitful avenues for future research.

**Abstract**—The approach to applications integration for World Data Center (WDC) interdisciplinary scientific investigations is developed in the article. The integration is based on mathematical logic and artificial intelligence. Key elements of the approach - a multilevel system architecture, formal logical system, implementation – are based on intelligent agents interaction. The formal logical system is proposed. The inference method and mechanism of solution tree recovery are elaborated. The implementation of application integration for interdisciplinary scientific research is based on a stack of modern protocols, enabling communication of business processes over the transport layer of the OSI model. Application integration is also based on coordinated models of business processes, for which an integrated set of business applications are designed and realized.

**Index Terms**—research, application integration, business processes, mathematical logic, formal logic, inference mechanisms, multi-agent systems, protocols, software agents

## I. INTRODUCTION: PARTICULARITIES OF WDC APPLICATION INTEGRATION

IN VIEW of the globalization of the economy and social life, National Science must integrate into the world and European organizations that promote the consolidation of research and consequently the development of scientific activity [2]. This is a very important process since there is an urgent need for interdisciplinary research, primarily for the assurance of sustainable development globally and regionally [3]. However, effective implementation of interdisciplinary research requires the creation of appropriate conditions for information exchange in the process of solving scientific problems. The scientific and technical progress that in its time facilitated the creation of information and communication technologies (ICT) nowadays benefits greatly from them. They are developing rapidly, covering new spheres of human activity and enhancing performance. Yet only field specialists can use ICT in a rational way, whereas the need for efficient information exchange within interdisciplinary research can only be met through rational ICT [19] application by specialists with deep knowledge in their areas of expertise [4].

The development of the information technologies (IT) domain that is experiencing qualitative changes related to ICT

Presented results of the research, which was carried out under the theme No. E-3/586/2018/DS, were funded by the subsidies on science granted by Polish Ministry of Science and Higher Education.

strengthening has created conditions for distributed computation and the efficient use of information and other resources. Consolidation of resources and the introduction of virtualization technologies are contributing to the process of substituting local solutions with distributed ones that allow the comprehensive use of all computing powers and data storage systems linked into a global network, thus granting access to accumulated information resources. The service approach formed on the basis of communication services has spread to the infrastructure, software development tools, and applications. The emergence of a wide range of new types of services, especially content-based ones, has led to the convergence of services and the formation of a generalized concept of information and communication services (ICS). The number of ICS providers has grown rapidly and convergent providers have emerged. The wide functionality, high quality, and moderate price of new services rendered by providers allow businesses to abandon the development of in-house or IT infrastructure and to use a wide variety of available ICS for component-based design of their information and telecommunication systems (ITS).

However, unified access to services is becoming a condition for the efficient use of the advantages of distributed systems and the possibilities of service-oriented technologies. At the same time, the formation of a new democratic IT environment, in which even small businesses can render services, has naturally been accompanied by the use of various tools and access technologies [5]. Therefore, historically the IT environment is heterogeneous, hence user access to its resources is to some extent complicated or at least inconvenient.

The same situation is characteristic of scientific activity in particular. For example, the World Data Centers (WDC) system created in 1956 under the aegis of the International Council for Science (ICSU) ensures collection, storage, circulation, and analysis of data obtained in various science areas [2]. During its existence, the WDC system has accumulated a lot of data and applications that may be used to solve the challenging problems of social development. They are one of the most powerful information resources used by hundreds of thousands of scientists, and the demand for it is increasing in proportion to the need for interdisciplinary research related to sustainable development, the solution of

urgent environmental protection issues, etc. However, problems related to the incompatibility of legacy applications caused by architecture differences, the variety of data presentation formats, and other factors prevent the effective use of such WDC resources.

Promising architectural solutions are being developed and gradually implemented in the ICT field, such as Next Generation Network (NGN) and Next Generation Service Overlay Network (NGSON) [6], that ensure the interaction of various transport layer technologies. Yet there is a need for a comprehensive integration of resources from various sources, and ICT developers' efforts should seek to enable scientists working in various domains to use the accumulated resources based on their areas of expertise, and not on the IT particularities. The sources, comprehensive access to which it is reasonable to ensure, include databases, websites and portals, various legacy file management systems, and data repositories structured according to various models.

Nowadays there exist more than 50 WDCs that for more than 50 years have created a system for data accumulation, analysis, processing, and international exchange. WDCs' powerful data storage systems retain huge volumes of astronomical, geophysical and other scientific data. WDCs' servers process this data using numerous and various applications powered by different technologies.

Certainly, from the point of view of scientists working on various resource-intensive problems, it is important to have access not to a large disordered system of possibilities, but to an integral complex of data and application sources intended to meet their specific needs, with a user-friendly interface that does not require any special IT knowledge. Nevertheless, the system for WDC data accumulation, analysis, processing, and international exchange does not provide such access. Furthermore, it was not designed for the growing level of scientific society's requirements and is not versatile enough to be used in interdisciplinary research. Therefore, a new interdisciplinary structure was created in 2008 — the World Data System (WDS) — to develop and implement a new coordinated global approach to scientific data, which guarantees omni-purpose equal access to quality data for research, education, and decision making. The new structure will have to solve the accumulated tasks, primarily the unification of formats and data transfer protocols, assurance of convenient access to data, and the organization of scientific data quality control [2].

Integrating formerly independent systems for the accumulation, storage, and processing of WDC data on a new advanced integration basis will allow a considerable enhancement of their overall efficiency. The creation of such a system will provide scientists with convenient centralized access to formerly separate resources, facilitating and quickening scientific and research activity around the world.

## II. RELATED WORK

An overview of existing integration solutions in all the mentioned aspects, starting with the integration technology aspect has been done. The existing solutions are powered by technologies for the creation, functioning, and development of distributed systems. Notwithstanding the differences of various technologies for the creation of distributed service-oriented systems, the overall principles and theoretical and methodological approaches are always similar. Independent services should be registered, described, and provided with the possibility to communicate transparently with clients and

with each other. Furthermore, networking interaction requires us to determine protocols for all levels of the OSI model. To do so, the corporate ITS standard structure with services intellectualization operations may be used, as suggested in [8], taking into account international, state, and branch standards, and corporate documents, first of all [9]. The structure consists of two parts, where the first covers the traditional four levels of standards of the TCP/IP protocols stack, and the second covers the user applications in accordance with the ITS class, destination, and services intellectualization operations. Figure 1 presents an example of the corporate standard structure.

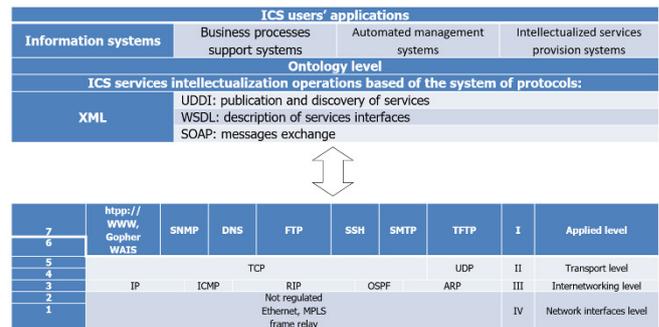

Fig. 1 Stack of services interaction protocols

For convenience, the figure presents the levels of the international standard for interaction of open OSI systems and their correlation with the corresponding levels of the TCP/IP protocols stack. The ITS classification used is proposed in [8]. It allows the systematization of various ICS by the level of users' requirements and queries, practical needs, and professional training, with no limitations imposed on the ITSs' functionality, attributes, or operations. The changes introduced apply to the first part of the structure and to the detailing of protocols that power the intellectualized interaction of applications in the course of solving users' more complex problems.

The services registry is maintained by the Universal Description, Discovery and Integration (UDDI) technology [10] that allows both people and client-programs to publish information on services and search for a required service.

The Web Service Description Language (WSDL) that, according to the W3C definition, constitutes an XML format for the description of networking services as a set of operations working with document- or procedure-oriented information through messages [11], is used for the unified description of services, which allows them to be used independently from the programming language. WSDL documents, by virtually creating a unified layer that allows the use of services created on the basis of various platforms, describes the service interface, URL, communication mechanisms 'understood' by the service, methods provided by it with corresponding parameters (type, name, location of the service Listener), and the service messages structure.

To implement the key part of the interaction—messages exchange—one of the widespread technologies may be used, and the selection should be determined by compliance with the requirements of the system for data accumulation, processing, and exchange:

**SOAP:** a user-friendly technology that is easy to use with the Business Process Execution Language (BPEL), which ensures interaction of distributed systems irrespective of the object model, operating system, or programming language. Data is transferred as special-format XML documents [12];

**CORBA:** a mechanism created to support the development and deployment of complex object-oriented applied systems, which is used for the integration of isolated systems, allowing programs that are developed in different programming languages and working in different network nodes to interact with the same ease as if they were in the address space of a single process. Such interaction is ensured through unified construction of their interfaces using a special-purpose declarative Interface Definition Language (IDL). At the same time, the interface and the description thereof do not depend on the operating systems or the processor architecture either [13];

**REST** (Representational State Transfer) is a style of software architecture for distributed systems, which is used to create web services. A global URL identifier unambiguously identifies each unit of information in an unvarying format. Data is transferred without any layers [14];

**WCF** (Windows Communication Foundation) is Microsoft's platform designed to create applications that exchange data through the network and are independent from style and protocol [15].

Although nowadays the most acceptable choice seems to be SOAP, based on which the interaction presented in Fig. 1 is performed, all the technologies allow the integration of services of various origin [16] – [17].

To take into consideration service-based, process-functional, and component-based approaches to the design and maintenance of users' solutions, the following well-known architectural means of organizing shared functionality are used:

Web Service Choreography is the approach that determines the protocols of web services' interaction to perform a single global task by performing parts thereof. The role assumed by the service determines its model of exchanging messages with other services. This method shows high efficiency for small tasks, but with increased complexity of tasks the number of services involved grows rapidly, solutions become too massive, and the efficiency drops quickly [18].

Based on the abovementioned technologies, a few solutions have been worked out, which may be used to create applied systems for the accumulation, processing, and exchange of scientific data in different areas. The best known among them are the ESIMO and GEOSS systems. They are quite widespread, although they have a number of drawbacks in terms of processing heterogeneous information.

One of the most crucial issues is that of developing mathematical models, methods, and means for the integration of various applications, both legacy ones based on traditional technologies and client-server and web-oriented technologies. The article proposes an approach to applications integration using the mathematical logic instrument and artificial intelligence theory for interdisciplinary research through the example of the WDC system functioning. The specificity of the applications integration for interdisciplinary research is

that the coordination of business processes models is not required because it is, in fact, substituted with schemes for performing users' tasks. In general, the applications integration is performed on the basis of coordinated business processes models, and the integrated complex of business applications is intended to support them.

### III. DEFINITION OF THE APPLICATION INTEGRATION PROBLEM FOR INTERDISCIPLINAR REASARCH

Mathematical models and methods as the basis for a holistic solution should be created to power data storage and processing centres, which will provide users with versatile possibilities at the level of information integration and servers availability. The mentioned models and methods should be devoid of the drawbacks characteristic of the algorithmic approach, related to the need to reprogram data processing algorithms upon the emergence of new data types and changes in the implemented algorithms or the emergence of new ones. At the data processing level, such a solution should ensure:

- computations distribution and the use of remote hardware resources;
- versatility and adaptation to the system load;
- system usage space;
- data supply by remote client or service;
- availability of intellectual data processing means directly to the end user with no special knowledge or skills;
- fast and simple integration of data and applications of various global information systems

### IV. THE APPLICATION INTEGRATION SYSTEM ARCHITECTURE

The principal tenet for the creation of a distributed system is the method of organizing services interaction. Of the two known main ways of services interaction - orchestration and choreography - the more efficient for the WDC systems is the former. Indeed, orchestration that aggregates basic services into hierarchically integrated systems, subordinating them to administrators – 'orchestrator' services - allows services to be unified by attributes that are convenient to WDC (science area, functionality, regional location, etc.), and to provide orchestrator services with powers in accordance with the international data exchange policies. Thus, it is possible to line up a simple and effective system, in which the search for the necessary services or the construction of their composition for the complex queries inherent in interdisciplinary research will not require a lot of time, as every Orchestrator Service has information on the functionality of inferior services, and in addition they can coordinate their possibilities in the process of the planning and execution of users' queries. Plugging new services into the system will not present a particular problem either, as doing so will only require the service description to be laid down, entered into the registry, and assigned to a certain orchestrator service.

Such an approach will work when users know exactly their information needs and have corresponding knowledge and skills to compile chains of queries to the known orchestrators. What is more important is that the approach will provide the opportunity to work with the system for users who cannot initiate services, by determining the sequence of their work and specifying execution and interaction parameters. Users only have to know how to formulate their needs in terms of a particular subject domain. In this case, the association of services and the organization of their cooperation require an intellectual constituent. For this purpose, intellectual agents are used, which constitute the system core, implementing its functioning logic, which promotes the formation of queries, plans their execution, and organizes basic services interaction. The introduction of intellectual agents as orchestrator services into the hierarchical structure forms a two-tier system; the bottom level consists of services performing basic tasks, the top level consists of intellectual agents that orchestrate basic services. By using the registries of subordinated basic services and their functionality and by interacting with each other, interconnected intellectual agents implement methods of logical inference. The inference result is the composition of basic agents' operations that allow user-defined tasks to be performed. This operations composition, or proof, is transferred to the lower level, where the operations necessary to solve the user's task are performed. At this point, control is handed over to the lower level agents that only return the final result to be sent to the user.

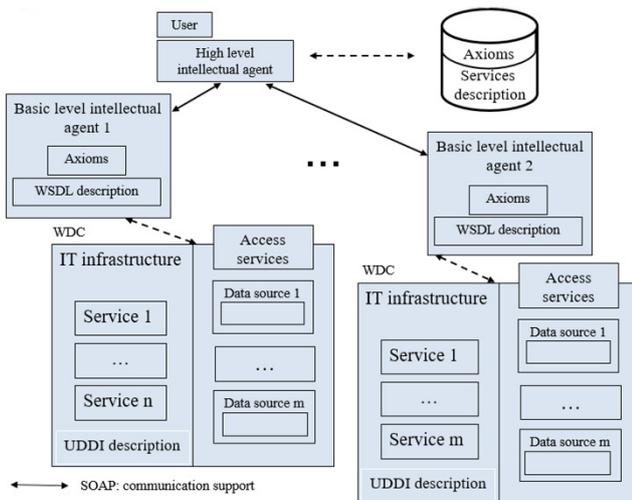

Fig. 2 System components interaction scheme

The user's query itself is performed upon formation of the proof containing references to one or several pointers to data sources and IDs of methods that the system services should apply to the data. Some queries do not require pre-processing of data, since the execution of services methods is sufficient upon receipt of information from the data source. Others require a certain sequence of prior data operations, and as a result, the execution of other services methods. The necessary connections are described in the axioms entered into the knowledge base upon registration of respective services in the system. These operations yield the final product of the system - data that are the solution to the user's problem. Since the system operation is determined by the user's query, the

system interface should help them make a query in familiar terms.

The proposed solution uses UDDI to create the service registries and WSDL for the unified description thereof. The key part—messaging—is implemented using SOAP, and services orchestration—using BPEL. Agents are described by means of JADE. The system components interaction scheme is presented in Fig. 2.

The description of the interface (WSDL) of every low-level service registered in the system and of related axioms is input into the system knowledge base and directly into the knowledge base of the Controller Agent to which the new service will be subordinated. The Controller Agent is selected in accordance with the policies adopted in the WDC system, for example, by the criteria of the geographical location of the deployed agent, in order to minimize data exchange.

At the agent level, the orchestrator agent (or several), having received the user's query, interrogates the agents in order to search for the necessary services and available resources. The user's query is processed taking into account the services of the system, their functionality (described by the axioms of the system), and the inference rules defined by logical formalism. The resulting proof is transferred to the lower level to be implemented.

At the services level, each agent invokes the required services from its set and sends processed data according to the action chains. This process is carried out in accordance with the task solution tree reconstructed by the solution tree reconstruction mechanism based on the proof.

To realize this interaction of services in the WDC system, the most appropriate is the logical approach, which allows both the level of the abovementioned requirements to be reached and the drawbacks of a traditional algorithmic approach to be eliminated. Indeed, it is only required to develop the inference method and the solution tree reconstruction mechanism that will implement the query formation processes, plan their execution, reconstruct and implement the task solution scheme. The logical approach is the most appropriate one to create and describe these constituents. The logical approach implementation requires one to:

- describe the existing applications and their functional capacities in the formal language;
- formulate the inference rules;
- determine the inference method;
- develop an algorithm of the user's query execution tree reconstruction based on the proof;
- implement these methods and mechanisms in the agents of the system.

## V. THE FORMAL LOGICAL SYSTEM

Let us describe the formalism upon which the program system that will ensure solution of the formulated problem will be built. We will take the first order clausal logic for a base and describe the formal system language in accordance with the structural elements determined in [3].

**Symbols: service:** ( ), [ ], { }, :, <, >, ;

**constant:**

- 1) *individual, of primary types* (int, real, char, bool) -  $a_1^1, a_2^1, \dots, a_1^2, a_2^2, \dots$  where each constant  $a_i^k$  pertains to type (primary type)  $k$ ; *structural type* (construct) -  $c_1, c_2, \dots$ ; *procedural type* (method) -  $d_1, d_2, \dots$ ; *objective type* (problem, entity, relation) —  $e_1, e_2, \dots$ ;
- 2) *functional i-place*, for individuals of type  $k$  -  $h_1^1, h_2^1, \dots, h_1^2, h_2^2, \dots$ ;
- 3) *predicate i-place*, for individuals of type  $k$  -  $A_1^1, A_2^1, \dots, A_1^2, A_2^2, \dots$  (this class includes taxonomic, relational and other predicates, as well as traditional relations, at least equality = and order  $\geq$ );

**variable:** for individuals of type  $k$  -  $x_1^1, x_2^1, \dots, x_1^2, x_2^2, \dots$ ,

where every variable  $x_i^k$  pertains to type  $k$ ;

**logical:**  $\neg, \wedge, \vee, \leftarrow, \exists, \forall, \leftrightarrow$

**Individual terms of type  $k$ :**

- 1) each individual constant  $a_i^k$  of type  $k$  is an individual term of type  $k$ ;
- 2) each free variable  $x_i^k$  for individuals of type  $k$  is an individual term of type  $k$ ;
- 3) if  $h_i^j$  is a certain functional constant for individuals of type  $k$  and  $\tau_1, \dots, \tau_j$  are terms for individuals of type  $k$ , then  $h_i^j(\tau_1, \dots, \tau_j)$  is an individual term of type  $k$ ;
- 4) there are no other individual terms of type  $k$ .

The terms obtained by applying construction rules 1 or 2 of the definition will be called primary, and all the others—complex.

**Formulas for individuals:**

- 1) if  $A_i^j$  is a predicate constant for individuals and  $\tau_1, \dots, \tau_j$  are terms for them, then  $A_i^j(\tau_1, \dots, \tau_j)$  is the atomic formula for individuals;
- 2) the atomic formula for individuals is the formula for them;
- 3) there are no other formulas for individuals.

Hereinafter we consider that the system contains an omni-purpose transformer of formulas into the traditional for the clausal form (we are talking about the Horn clauses) view with a single  $\rightarrow$  symbol, atomic formulas to its left and right, and an implicit quantifier  $\forall$ .

Specifiers, preconditions, post-conditions, specifiers of methods, specifiers of problems, clause, the system's knowledge and inference rules are presented in detail in [1].

## VI. THE INFERENCE METHOD

The method proposed in [2] based on analogy and types of assertions has been used. A detailed description of this method can be found in [1], [4], [7].

The inference mechanism work algorithm is presented in Fig. 3.

To improve the inference mechanism three known elements were integrated:

- 1) a multiset of literals (atomic formulas) (which will be called a multi clause (m-clause));
- 2) the ordered linear;
- 3) typification abstraction (to manage an ordered linear proof).

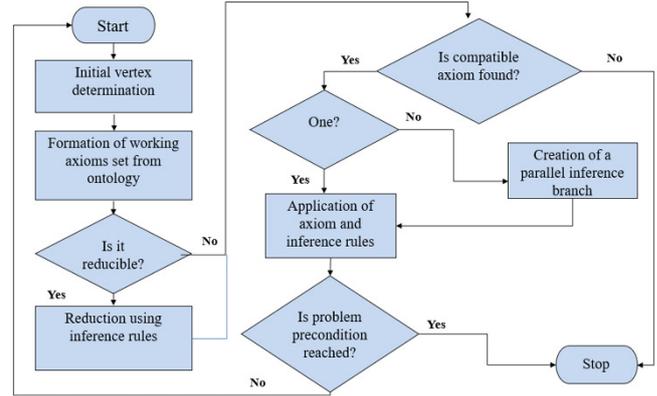

Fig. 3 Inference mechanism work algorithm

## VII. THE MECHANISM OF SOLUTION TREE RECONSTRUCTION

To obtain from the proof generated by the inference mechanism a functional sequence of actions to be used by our system, taking account of services features and nature, the solution scheme reconstruction mechanism should be initiated [1].

Condition: proof Result = $\langle V, T \rangle$ . To find: $G = \langle V, E, \Theta \rangle$	
Step	
1	Identification of the terminal triple—the triple that contains vertex $k$ that is neither the first nor the second component of any of the triples of set $T$ .
2	In the selected triple, the initial vertex is the post-condition vertex, the second is the method vertex, and the terminal is the precondition vertex. The method that turns the precondition into the post-condition is determined by the unambiguous correspondence to the vertex formulas of the post-condition and precondition of the method axiom. The vertices are connected with the edges: precondition to method and method to post-condition. If the precondition of the method axiom consists of a combination or intersection of several elements, a data vertex is inserted between the precondition and the method vertices, which groups the preconditions according to the relevant inference rule. If the terminal triple only contains two vertices, it means that the inference rule was used to convert the vertex clauses, and the place of the method vertex in this tree branch is occupied by the transformation data vertex that corresponds to the inference rule used, with the corresponding post-condition vertices.
3	The vertices, edges, and their correspondence are introduced into $G$ .
4	Having extracted the processed triple from the set of triple vertices $T$ , we repeat step 2. If the set is empty, the tree reconstruction is completed.

Fig. 4 Algorithm for vertex scheme reconstruction

The solution scheme constitutes a connected directed graph with no oriented cycles with parallel directed paths from the root to the vertices; it has three types of vertices, and is specified by triple  $G = \langle V, E, \Theta \rangle$ , where  $V = V_1 \cup V_2 \cup V_3$ ,  $V_1$  is a set of method vertices,  $V_2$  is a

set of precondition vertices and post-condition vertices,  $V_3$  is a set of data vertices in which data is merged or split;  $E$  is a set of edges;  $\Theta$  is a subset of Cartesian product  $E \times V \times V$ , which determines the correspondence of edges to pairs of vertices. The scheme determines the sequence and the correspondence according to the data of actions to be performed by the data processing system's executive mechanisms to obtain the result desired by the user [1].

Algorithm for vertex scheme reconstruction was presented on Fig. 4.

The reconstructed solution tree is fed to the actuator input. The implementation of a particular method specified in the solution tree is represented by a construct that describes the input data (entities, connections, relations between them), method preconditions, method post-conditions, and output data. The solution tree branches downstream of the data-splitting vertex can be executed in parallel until they reach the data-merging vertex, where, after completing all the parallel branches involved in merging, they continue to be executed consecutively. The work algorithm of the solution tree reconstruction mechanism is presented in Fig. 5.

## VIII. APPLICATION OF LOGICAL APPROACH TO PROBLEM SOLUTION

The approach efficiency on the real scientific task of calculating the component of life safety and indicating critical values of threat indicators for analyzing the sustainable development of the regions of Ukraine has been demonstrated.

The life safety component formula:  $Csl = \sqrt[3]{\sum_0^n Threat^3}$ , where the threat value is normalized by formulas (2) or (3). The purpose of indicating critical values of threat indicators is to determine the priority in consideration thereof in the decision-making process on the level of a single region and the entire country in order to mitigate the impact of threats on sustainable development.

Suppose that for every administrative unit  $i = \overline{1, n}$  there is a set of values  $\langle x_{i,1}, x_{i,2}, \dots, x_{i,m} \rangle$  of indicators  $X_j, j = \overline{1, m}$ , which characterize the negative impact of certain phenomena on the sustainable development processes in the economic, social, and ecological spheres. Such indicators, whose essence and

composition are determined by experts, will be called threat indicators.

Given the content of the critical values indication problem, the following characteristic function must be determined:

$$\Psi(x_{i,j}) = \begin{cases} 0, & \text{if value of } x \text{ is not critical} \\ 1, & \text{if otherwise} \end{cases} \quad (1)$$

where  $i = \overline{1, n}, j = \overline{1, m}$ .

It is clear that the determination of function  $\Psi(x_{i,j})$  must be based upon certain criteria that take into consideration exceeding by  $x_{i,j}$  a hazardous limit, the relative position of region  $i$  in the indicators rating  $X_j$  compiled for the comparison groups and for the entire country, and the degree of "hazard" of value  $x_{i,j}$  in comparison to values of other indicators for region  $i$ .

To account for the relative position of the region in the entire country's ratings, the following criterion is used:

$$R_{i,j} = \left( 1 + e^{\frac{a - x_{i,j}}{b}} \right)^{-1} \quad (2)$$

if higher values of indicator  $X_j$  correspond to a higher impact of the respective threat on the sustainable development, and:

$$R_{i,j} = 1 - \left( 1 + e^{\frac{a - x_{i,j}}{b}} \right)^{-1} \quad (3)$$

if lower values of indicator  $X_j$  correspond to a higher impact. In formulas (2)-(3), parameters  $a$  and  $b$  are calculated by the following formulas:

$$a = \overline{X_j} = \frac{1}{n} \sum_{i=1}^n x_{i,j}, \quad b = \sigma(X_j) = \sqrt{\frac{\sum_{i=1}^n (x_{i,j} - \overline{X_j})^2}{n}} \quad (4)$$

Criterion  $R_{i,j}$  is a dimensionless number that assumes values within  $[0, 1]$ . Values of around 0.5 correspond to average values of  $X_j$  in the selection, and values higher than 0.75 correspond to values that exceed the average ones by more than a standard deviation. In this case, the characteristic function (1) taking account of one criterion  $R_{i,j}$  may be expressed as follows:

$$\Psi_R(x_{i,j}) = \begin{cases} 0, & R_{i,j} < 0,75; \\ 1, & R_{i,j} \geq 0,75. \end{cases}$$

Criterion  $P_{i,j}$  that takes into account a region's relative position in the comparison group may be calculated by formulas (2)-(3) taking account of the fact that parameters  $a$

and  $b$  are calculated by formula (4) independently for each comparison group.

Criteria  $R_{i,j}$  and  $P_{i,j}$  are dimensionless numbers and are of similar nature and can therefore be aggregated through a weighted sum:

$K_{i,j} = w_R R_{i,j} + w_P P_{i,j}$ ;  $w_R + w_P = 1$ , where weighting factors  $w_R$  and  $w_P$  are determined by experts.

Thus, for region  $i = \overline{1, n}$  we have a set  $\langle K_{i,1}, K_{i,2}, \dots, K_{i,m} \rangle$  of values of the aggregated criterion that accounts for a region's relative position in ratings compiled for comparison groups and for the entire country. Now, among values  $K_{i,j}$ ,  $j = \overline{1, m}$ , the worst must be determined, which may also be performed by formula (2):

$$I_{i,j} = \left( 1 + e^{\frac{a - K_{i,j}}{b}} \right)^{-1}$$

where parameters  $a$  and  $b$  are calculated in selection  $K_{i,j}$ ,  $j = \overline{1, m}$ .

For values of criterion  $I_{i,j}$  the same remarks apply as for criterion  $R_{i,j}$ . Therefore, characteristic function (1) may be expressed as follows:

$$\Psi_I(x_{i,j}) = \begin{cases} 0, & I_{i,j} < 0,75; \\ 1, & I_{i,j} \geq 0,75. \end{cases}$$

Thus, values  $\Psi_I(x_{i,j}) = 1$  correspond to the highest priority of attention to be paid to the value of indicator  $X_j$  in the administrative decision-making process on the level of single region  $i$ .

## IX. CONCLUSIONS

Based on the analysis of existing data centres, their equipment and software, a high quality solution is offered that provides a simple and flexible way to integrate heterogeneous information systems and their services into the World Data System. One of the key features of the proposed solution is the automation of the algorithm construction of the actions sequence that executes users' queries. A logical formalism has been created to describe this solution, and on its basis an inference method and a solution tree reconstruction mechanism have been developed.

The analysis of available technologies used for the implementation of distributed systems allowed the use of such a set of software solutions for practical implementation of this solution: UDDI for creating a registry of services entered into the system; WSDL for a unified description of services; SOAP for exchanging notifications between services; BPEL for the overall coordination of services. Intellectual agents can be implemented using JADE.

The implementation of the proposed solution will provide an opportunity to use all the integrated computing capacities and data storage systems of the World Data System in a comprehensive manner. Thus, users will be able to easily gain access to all the necessary resources and services available to the system.

**Abstract**—One of the contemporary problems, and at the same time a challenge, with development and usage of supply chain Information Systems are the issues associated with privacy and cyber security, which emerged due to new requirements of legal regulations and directives. The human factor belongs to the biggest risks within these issues. Leak of information, phishing, unauthorized access are the main problems. Also vulnerability of the systems due to new information technologies is an important topic. In this paper we discuss development and usage of Information Systems with regard to the security aspects associated to the software development lifecycle. We present our approach on examples of a user authentication process in logistics.

## I. INTRODUCTION

THE information security and cyber security are strongly associated with the technological infrastructure of computer networks and computer systems processing information. A computer system is secure if the user can rely on its functionality and the installed application software is working consequently the specifications. Developing software applications with compliance to the user requirements is not sufficient, because the developed systems should additionally be secure and consistent with the current state of law regulations.

In this paper we will approach a problem of the exchange of a vast amounts of data in supply chains with respect to the data privacy and security issues. There is the European Union's General Data Protective Directive GDPR concerning the protection of natural person with regard to the processing of personal data [1]. On the background of this regulation and of the Payment Services Directive 2 PSD2 [2], which are concerning transaction systems on financial markets, and Fintech [3], the development of the secure software business applications turns out into a great challenge. In our paper we will suggest some improvements to the IS's development process, which result from the above stated system requirements and the further implications regarding privacy and data security aspects.

The supply chain defines the network that comprehends all the organizations and activities associated with the flow

and transformation of goods from the raw material stage, through to the end user, as well as the associated information flow [4]. In our paper we will concentrate on threats and possible solutions demanded for the secure supply chain activities and flow of information.

In the inter-organizational information systems, which link the companies to their suppliers, distributors and customers, a movement of information through electronic links takes place across organizational boundaries, between separately owned organizations. It requires not only the electronic linkage in form of basic electronic data interchange systems (as for purchase orders), but also the interactions in complex cash applications and information systems or an access to shared technical databases. Thus, the problems associated with the privacy and security are also very viable in supply chains contexts.

The credibility of information as also especially the trustworthiness of the participants in supply chains is required. In transportation and logistics, in order to eliminate a possibility of the documents frauds, non-existent suppliers or recipients, an essential element of the risk elimination in supply chains is the credibility ensured by an authentication.

We believe, that the enterprise information systems being a part in a logistic supply chains should be secured during all stages of their life-cycle, and will give some guidelines for development-time and run-time of the IS.

The security concerns become additionally significant with the regulations like General Data Protection Regulation (GDPR) in the European Union and other regulations to be expected coming soon. The problem is that they use terms like "reasonable security procedures" or "appropriate practices" and do not advice what type of technology is needed to protect the personal and enterprise data. They only state generally about the responsibility of the organizations to keep data secure [5].

Therefore, as stated previously, in our paper we will analyze how to integrate the needed privacy and (cyber) security aspects into the life cycle of Information systems to

ensure the above mentioned secure procedures and appropriate practices. For this aim the rest of the paper is organized as follows.

In Section 2 we will characterize the main threats and vulnerability aspects considering the information systems security due to the usage of new emerging IT solutions and the influence of EU regulations associated with privacy and security concerns. In Section 3 we will review some aspects of cyber security and then propose some solutions applicable for developing and using information systems. The aspects of information security due to the problems with user authentication and data access control are the main topics in Section 4. In Section 5 we give some examples for conducting user authentication and show how they can support an achievement of the required privacy needs for IS of enterprises according to the EU regulations. In the last Section we conclude our work.

## II. VULNERABILITY OF INFORMATION SYSTEMS SECURITY DUE TO NEW TECHNOLOGIES

The numerous cyber attacks associated with, i.e. a stealing of the identity, the leaks of vulnerable data, or the frauds in billion of dollars yearly raised new approaches in the risk taxing, as for instance shown by Global Economic Crime and Fraud Survey for 2018 in [6]. The rethinking of the ways and approaches for development and usage of software systems and considering the proper handling of modern technologies, and also the computer networks security problems are needed. In addition, the raising numbers of mobile technology users of Smartphones and tablets with the integrated Wi-Fi equipment, and the widening popularity of operation systems like Android and iOS, caused that the mobile systems are replacing gradually the traditional computer systems.

In [7] there is a diagram depicting the percentage of the mobile OS used on market based on the report showing the growing dominance of the mobile operating systems in the last two years. The mobile devices are currently used for the e-mail checking, news viewing, the communication in social networks, and also for the payments. Operating in such environments often requires a usage and sending of vulnerable private data, such as private contact data or/and the bank account information directly with the mobile devices. It could happen that a user do not have the sufficient consciousness and knowledge of the threats caused by the neglecting of the security features on the stage of software application development.

Considering the human factor, there could be also the security risks connected with the intended conscious handling of some enterprises or programmers developing software applications, which are acting in contradiction with the users aims and also the laws regulations with the aim of processing and stealing of vulnerable user data. Examples of such behavior are known, and widely described in the Internet and include the deeds such as notorious hacker

groups, the hybrid warfare [8, 9, 10], up to the cyber troops [10, 11].

We believe that activities aimed at eliminating of vulnerabilities related with the human factor could be the particularly the forecasting of the attacks, such as attack vector [12] (i.e. email attachments, pop-up windows, deception, chat rooms, viruses and instant messages) and also regarding them possibly early already on the stage of developing software and the by usage and maintenance of IS. Such actions will be needed not only for new systems (developed from scratch), but also in maintaining already existing relative new modern and legacy systems.

Moreover, considering the vulnerabilities enumerated by the Open Web Application Security Project OWASP Foundation [13], the counteractions, or possibly elimination of the some threats is also strongly desirable by defining constrains for systems, which are using new technologies like cloud computing [14] and/or blockchain [15].

By developing software systems there will be some additional basic considerations viable for aims of their future security. To begin with gathering of user requirements and enhancing them with the law regulations related to the user privacy and data security aspects. A proper choice of the software architecture of a software system, which will be supporting the required security needs, and also the secure procedures for user authentication and system access control are recommended. There are also some additional aspects in the development phase, as for instance the usage of libraries, which are resistant to the buffer overflow, eliminating of the redundancy by avoiding linkage to the external resources, and also eliminating redundancy in computer network communication between the hosts, etc. We will consider these requirements in the following Sections.

## III. CYBER SECURITY SOLUTIONS

While the ERP systems with the embedded automated financial settlements are the constituents of supply chains, their authentication process should accomplished at a proper security level. For this reason to stay in accordance with formal requirements, the systems in logistics and supply chains should meet the requirements of the dynamic authentication in order to eliminate a possibility of hijacking or the replay attack as in case of a spoofing attack.

The authentication and access control to digital resources are the crucial elements for ensuring security in a cyberspace. The EU Regulation 2015/1502 from 8<sup>th</sup> of September 2015 defines the minimal technical specifications and the procedures for the assurance levels of electronic identification and trust services for electronic transactions at the internal Europe Union market. The regulation defines tree assurance levels [16] as:

- Low,
- Substantial, and
- High.

They should be applied for electronic identification means issued under an electronic identification scheme. Additionally in the regulation the “dynamic authentication” is defined with the meaning of “an electronic process using cryptography or other techniques to provide a means of creating on demand an electronic proof that the subject is in control or in possession of the identification data and which changes with each authentication between the subject and the system verifying the subject’s identity”.

According to this regulation for the substantial and high assurance levels in authentication mechanism, the sending of person identification data should be preceded by a reliable verification method by the electronic identification means, and its validity assured by a dynamic authentication.

For this electronic proof it is also required to be modified (to alter) with each new user authentication, as well as to be resistant to the attempts of off-line analysis.

For meeting of the above requirements included in the EU regulation, concerning the dynamic authentication mechanisms, we believe that a promising solution may be the usage of cryptography with one-time passwords or one-time key, referred to as OTP [12]. A proof for semantic security of crypto-systems constructed with regard to the rule for one-time key in cryptography was given in year 1949 by C. Shannon in [17]. Nevertheless, the research efforts regarding secure cryptographic systems implementing the OTP rules are still ongoing.

We should emphasize the fact that the systems, which implement the OTP rule are potentially resistant to the cryptanalysis with the quantum computers. Cryptography considered as resistant to the attacks by usage of quantum computing is referred as post-quantum cryptography [18].

The transaction security is also required in Fintech services, such as e-banking, e-health, etc., where the keeping anonymity and also the user authentication should be in accordance with the high assurance level. At the same time the dynamic authentication on the middle and high assurance levels, as for data which is secret and with all right reserved, is defined by the Payment Service Directive (EU) PSD2.

It is to emphasize that the above mentioned GDPR and PSD2 have been indeed introduced as regulations, but until now, the applications implementing the dynamic authentication systems conforming to these requirements are lacking.

There are some known approaches to a deal with the above problem of a secure authentication, like a research on the one-time keys in user authentication method RUBLON [19]. In the RUBLON system based on a solution given in the patent [20] is applied, and it conforms to the OTP and semantic security requirements. What is more, on the base of the solution included in the patent [20] the enterprise DCD has applied this solution in the project CryptONE (unconditional secure crypto-processor [21]), where the decryption takes place with one-time passwords.

The concept of Industry 4.0 [22] has shown some digital trends, such as the process automation and usage of the artificial intelligence in the decision processes. Therefore, in the future the authentication not only of the persons and entities, but also of the devices and the processes will be needed.

Regarding the trust, privacy and security aspects in the life-cycle of information systems with respect to the threats and vulnerabilities discussed in Section 2, below we summarize and suggest some guidelines for development and system usage (run-time) in the IS lifecycle.

In the development and implementation stages of the lifecycle, beginning with the system analysis phase, the obtained user requirements should be complemented with the requirements resulting from the law regulations concerning privacy and security. It especially applies to of data to be exchanged by Information systems in Supply Chain Management SCM in cloud environments as presented in [23]. Thus, the new technologies like cloud computing are offering potentially more secure data storage based on duplication and distribution [24].

In the system development and implementation stages there are some additional important issues to be regarded as crucial for more reliable protection of privacy and security aspects of software systems, such as:

- A deliberate choice of a system architecture,
- A secure (user) authentication procedure and data access control,
- A choice of the appropriate libraries according to the security requirements,
- The strict rules for the usage of external sources,
- The following the network security rules and the usage of appropriate computer network protocols,
- The proper packet management in mobile devices.

The first issue is a decision for a choice of the system architecture, like centralized, (or decentralized) or Cloud Computing usage, and it is dependent on the kind of a developed application, i.e. the usage of further technologies such as blockchain. The expansion of the systems based on new cloud technologies and cloud computing [25] by using services as IaaS – Infrastructure as the System, PaaS - Platform as a service, SaaS – System as a service, as also the growing usage of mobile devices set additional requirements on implementing solutions for an access to the remote data resources. It is particularly important to regard whether the system is processing personal data, according to the EU GDPR rules, or it is a transaction system – in accordance with the PSD2 directive. In such cases the additional considerations to cyber security are desirable and needed.

In case of the Client/Server n-tier architectures the sensitive personal data should reside on a back-end data server without a direct Internet access.

The second issue – the process of authentication procedure and data access control should be conducted in accordance with the requirements of PSD2 Directive. Therefore, we suggest to consider the two-factor authentication 2FA, with the cryptographic strong second factor. We can also recommend a usage of an authentication method based on Challenge-Response, as proposed in OCRA specification [26]. Moreover, the usage of one-time keys OTP is recommended, as mentioned in the previous Section. This way of usage of OCRA and OTP is simple to implement and will increase the security of the (user) authentication process.

The third implementation issue is a deliberate choice of appropriate libraries according to the security requirements. The libraries resistant to buffer overflow and the adequate programming methods for strict control of data types are recommended, as described in [12].

The next issue is a deliberate usage of external sources. The rules for conscious usage of external sources, especially for mobile applications should include the possible restrictions of a necessary usage of the external resources and libraries [28].

The network security rules and usage of appropriate computer network protocols should be carried out according to the principles indicated by W. Stallings and L. Brown in [12].

The last issue, is a proper packet management for mobile devices. A developed software should prefer the usage of packages that are resident on the device, i.e. not dynamically loaded during their usage at the run-time.

At the running (operational) phase, we also emphasize one more time the crucial role of a secure user authentication and the usage of dynamically changing one-time keys. These issues will be considered in the next two Sections.

#### IV. AUTHENTICATION METHODS

From the perspective of the enterprises the problems with data protection in business processes can be seen from the different perspectives, as described in [23] and [24]. The one perspective is considering the security and privacy of sensitive business data which belongs to the enterprise or its partners in the supply chain. Another point of view is the protection of the privacy of individuals.

Regarding the reliability and quality of service QoS for e-Business, the critical role of the IS security is one of the major business management responsibility. According to [4], the security encompasses the policies, the organizational procedures and technical measures used to guarantee a proper functioning of IS and protecting the enterprise against the consequences of malfunctioning. A guaranteed level of service performance should be delivered in

accordance with Service Level Agreement SLA addressing the QoS of the source [4].

Regarding the trust in e-Business, where the contacts related to transactions occur by means of databases and computer networks, there are additional trade risks like: man-in-the-middle attack, spoofing, hacking, denial of service attacks, etc. The extent of this kind of attacks covers the manipulation of data, intentional use of a false identity or attacking the enterprise's portal. Therefore the security requirements imply the infrastructure availability, the network level protection and the message security.

Moreover, the transparency and audit-ability of the transactions, their non-repudiation and certification are the further needs. The message (information) security requirements demand a safeguarding of a user authentication. In addition, information integrity and confidentiality are also crucial. In this paper we concentrate on one chosen aspect of the message security – the user authentication which is a combination of claiming an identity and its verification proving that the identity is as claimed [4].

For user authentication as a one of the message security requirements, a broad spectrum of the guidelines, and approaches, are known and available [12]. For instance, the rules for a user authentication are defined in the Digital Authentication Guideline NIST SP [27]. In this publication the authentication of the user is defined as the process of assurance (assertion) of the identity of the users introduced to the system. Further, in Protecting Controlled Unclassified Information in NIST [26] there are lists with security requirements for identification and authorization services classified as two basic requirements, and eleven secondary, derived requirements. A common digital model for digital authentication as defined in [27] includes few key roles entities and some functions needed in the authentication procedure.

In the above model, if the requester addresses the registration authority RA to become a subscriber of the confidential service provider CSP, the registration authority RA is the trusted party, that ensures (states and credits) the identity of the user (requester). The credential is the data structure connecting the identity with additional verifiable attributes needed in the process of authentication of the claimant to the verifier. In the process of verification of user authentication there are four basic common way like: some information known to the person, some kind of things possessed by the person (referred to as a token), the aspects to the physical person (the static or/and dynamic biometrics). Generally the enumerated factors can be used in separation, or can be combined together. Nevertheless, there could be some problems with using of each method. Therefore the multifactor authentication is considered to be a proper solution. In the next Section we present our approach to the authentication problem.

V. EXAMPLES FOR USER AUTHENTICATION - PROPOSED SOLUTIONS

Regarding the GDPR Regulation and PSD2 directives, from which the requirements considering privacy and information security should be fulfilled by the information systems, in this Section we will give some subsequent examples of a possible user authentication processes by using the HTTP protocol [29] for authentication aims for Web-based applications. The HTTP protocol is commonly used by the implementation of the Web-applications; at present the recommendation for business is the usage the HTTP/2.0+ push protocol.

In Fig. 1 are depicted the three stages of the gradual development of this protocol - beginning with HTTP/1.1, then the following HTTP/2.0, to the HTTP/2.0+ push development stage. The development process of the subsequent stages has taken into account the aim of the minimization of the needed connections between the client and the server of a software application.

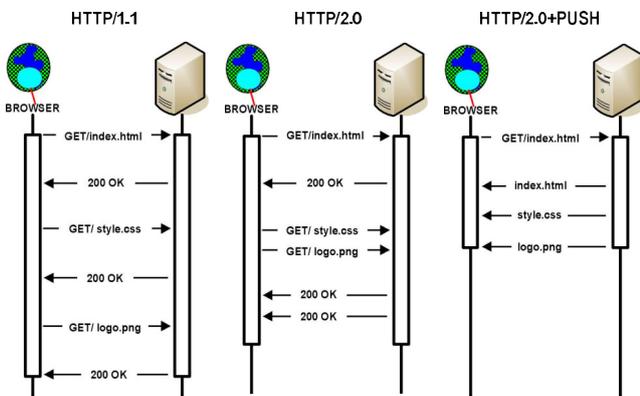

Fig. 1 Evaluation stages of HTTP protocol development

Using HTTP/1.1 protocol for opening of a Web page requires even three full transactions with the transmission of the elements containing the website descriptions. However, in the currently recommended version by W3C of the HTTP/2.0+ push protocol, the opening or refreshing of a website requires only one connection. The eliminating of unnecessary connections also significantly positive affects the security concerns, because it eliminates at the same time the possibility of seizing sessions and man-in-the-middle attacks to the necessary minimum, and this way reduces the risk of impersonating another users. It seems right, that good practices used in the development of HTTP, should also be utilized in systems applied for user authentication.

The second example is a simple authentication mechanism shown in Fig. 2, which uses only one single connection. This authentication method uses the asymmetric cryptography, also known as public key cryptography, which means, it uses public and private keys to encrypt and decrypt data. But in the process of the authentication the Client is using a secure

private key denoted as  $prK$  and a secret password  $P$  to compute a cryptogram:

$$\text{Cryptogram } S = \text{Crypt}(P, prK).$$

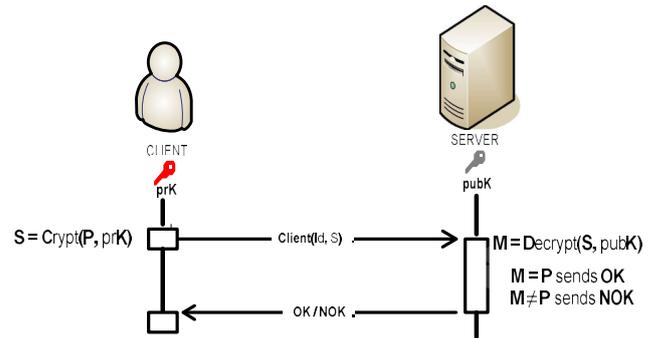

Fig. 2 Example of a simple authentication using asymmetric cryptosystems

The server, which knows the shared secret password  $P$ , performs the decryption by using the public key  $pubK$  in the method  $\text{Decrypt}(S, pubK)$  and verifies if the shared secret is known by the client; the cryptographic function  $\text{Crypt}()$  is a known cryptographic algorithm with a public key. As a cryptographic algorithm proposed for the analysis aims we recommend the usage of the RSA schema described in [30]. In this method, as shown in Fig. 2, the authentication mechanism uses only a single connection.

However, this simple authentication method can not be regarded as secure, and is vulnerable to the various attacks by unauthorized users. A simple attack is presented in Fig. 3, where the hacker has an option of intercepting the cipher text  $S$  and so impersonating another user by using the captured cipher text. This method is referred to as sniffing accomplished by the Web communications and spoofing by another user.

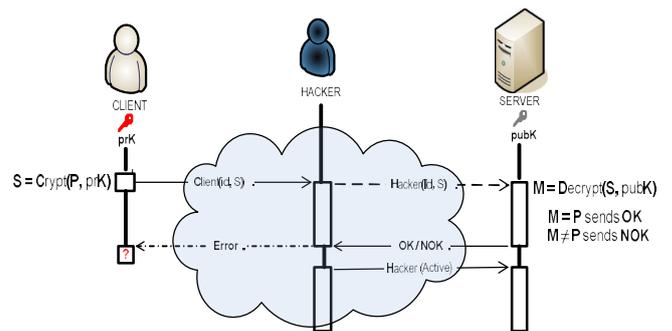

Fig. 3 The simple attack at authentication

The most secure authentication method is based on asymmetric cryptography and a cryptographic hash function named Hash [31]. This is a mathematical algorithm that maps data of an arbitrary size to a bit string of a fixed size (a hash) and is designed to be a one-way function, that is, a function, which is infeasible to be inverted [31]. The

proposed method uses the asymmetric cryptography and the cryptographic hash function - SHA2, in the authentication case shown in Fig. 4.

One must realize that removing parts of data will lead to results with lesser granularity, but this is a price, which must be paid to stay on the safe side and to stay compliant with the privacy rights.

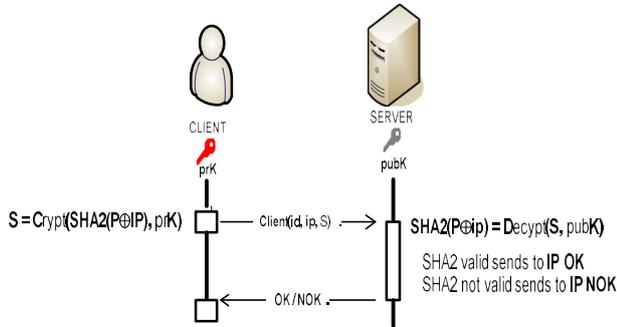

Fig. 4 Example authentication using asymmetric cryptosystems

In contrast to the known methods, which are using the hash function, in this solution the *IP* – the Internet protocol number was proposed as one of the input parameters for the hash function  $SHA2(P \oplus IP)$ . In this case the secret password *P* is aggregated with known *IP* and from this value a Client generates a cryptogram  $Crypt(SHA2(), prK)$ . The proposed method is eliminating the possibility of simple spoofing, because this way we authenticate only the user, which has the valid *IP* number. However, acting according to this scheme does not protect against cryptanalytic attacks known to asymmetric cryptographic systems such as RSA.

In the scheme depicted in Fig. 4 we use a fixed cryptographic key, and this way we allow the off-line analysis of the private cryptographic keys.

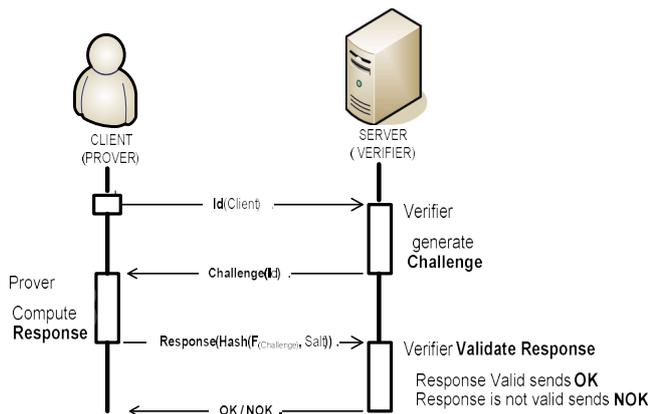

Fig. 5 Challenge-Response method in Client authentication method

In Fig. 5 there is a new situation depicted, where a Client uses another authentication method named the Challenge-Response protocol. In this method only the hash functions

are used; the method is used in OCRA. This method uses a constant function for a validation of the Response, and the Challenge can be regarded as variable value changing with each authentication.

In the last example (see Fig. 6) we give a proposal of Challenge-Response method based on the solution described in [20].

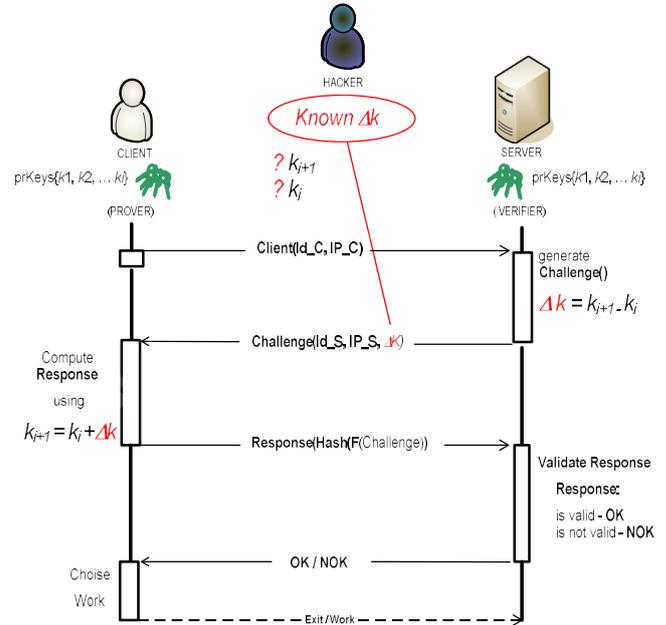

Fig. 6 Proposed Challenge-Response with OTP method in Client authentication

In Fig 6. a Challenge-Response authentication method is depicted, which is offering the perfect security of an authentication. In this solution, a high level of security is achieved through the authentication, which is using the advantages of OTP in asymmetric cryptography encryption and the hashing SHA2 method in the Challenge-Response mechanism. Additionally this proposal uses RSA, where the changeable shared value *prKeys* is a set of  $\{k_1, k_2, \dots, k_i\}$  and as a Challenge we are using the differential value  $\Delta k = k_{i+1} - k_i$ . In this case, even if someone is knowing the value  $\Delta k$ , it will be not possible to determine either the  $k_i$  or  $k_{i+1}$ .

The last shown method guarantees the semantic security, i.e. an adversary hacker can not gain even a partial information about an encrypted message (password) [32]. Therefore we recommend to undertake the user authentication in information systems collaborating in supply chains with usage of this method, as being the most appropriate for satisfying the requirements of cyber security, due to the EU regulations.

The last solution presented in this Section (depicted in Fig. 6) also conforms to the requirements of OTP and should be also resistant to the attacks with quantum computing, because, as stated above, the equation system given in the Fig 6 has no solution.

In this Section we gave some concrete examples for the authentication of the user (or processes) and also a proposal for an authentication of an information source, meeting the requirements ISO/IEC 2911, and also the European Directive from the 8th of September 2015 No. 1502 regarding the dynamically authentication.

## VI. CONCLUSION

Already Alvin Toffler, Future Shock and Third Wave author, has indicated that the next phase of the industrial development will be the information society, where the information will have a particular value [33].

In the context of a rapid development of modern information technologies and digitalization, there is a growing importance of new factors that could threaten the security of logistics processes. It may be due to the wrong decisions caused by false (unreliable, insufficient, or incorrect) information, or caused by non-compliance with the required procedures or wrong (false) documents.

A solution trying to tackle such vulnerability problems is for instance a proposal of the COBIT 5 Information Security Framework for reducing cyber attacks on SCM systems [34]. However the COBIT framework does not take into consideration the concerns associated with the security of the authentication, which are based on the norms ISO/IEC 29115, and the European directive 1502/2015, as nowadays required.

According to [35] there are seven security concerns, which are addressing the main problems in contemporary supply chains: the inventory theft, the mismanagement of cloud access, the smuggling, the increased piracy, the physical device tampering, trusting data to a third party vendor, and the IoT Sensor compromise.

The physical threats like the smuggling or the piracy are out of scope of the considerations of this paper. The inventory theft is in fact a physical threat, however the credibility of the stocks of the inventories still remains important. The physical device tampering can cause the corruption of the data or disruption of the devices (or chips). Furthermore, the IoT sensor data represents an another possible attack vector.

From the above concerns particularly the mismanagement of cloud access due to an improper authentication could lead to serious security risks for supply chains. Therefore credibility of data, and also of the data sources, and on the other hand the audit-ability of the vulnerabilities of enterprise system are becoming crucial to guarantee the security in SCM.

Another important aspect, due to the GDPR is the preventing of data privacy for enterprises offering their services in the EU. In [36] the authors propose an approach for deriving Workflow Privacy Patterns from legal texts; these patterns are meant to support the designing of privacy compliant workflows.

In our paper we have shown some solutions as a proposal for complementing the tools with the elements of a secure authentication, that are also applicable in the context of a usage of the blockchain technology.

The design of software applications with respect to the demanded security and privacy requirements remains one of the current challenge for development and usage of Information systems. The new EU Regulation GDPR and PSD2 concerning the technologies used to support the banking and financial services Fintech, draw attention to the enhancement of required assurance level in security for processing sensitive data. The increasing numbers of incidents with the data leaks and an unauthorized access to digital resources or the denial of service (DOS) and other attacks are the symptoms of the raising problems with proper dealing with cyber security of the systems.

As a one most weak constituent in the system security considerations is the human factor which can not be so easily eliminated. In this paper we suggest the usage of the proper mechanisms, methods, and technologies that could be involved into the life cycle of are the Information systems, (as the constituents of supply chains) with the aim to increase the security of data and the transactions. Accordingly we have highlighted the importance of the deliberate choice of a software architecture, following the security rules during data exchange via computer networks, and also recommend a usage of the technologies, which are viable for a secure user authentication i.e., those with one-time keys.

In the examples in the last Section we have shown some possibilities for reducing the number of the required connections during the user authorization process in order to reduce a possibility of the hacker attacks.

The improvement of information security for information systems, can be achieved especially by using carefully chosen user authentication methods with the aim of fulfillment of the requirements of the high assurance levels of EU regulations.

The aim of this paper was to present the authentication methods conforming to the all three assurance levels given in [16]. The proposed solution presented in Section 5, in the last sixth example is a unique new solution, which fulfills the substantial and high assurance level of this EU Directive. The proposed method guarantees the realization of a dynamic authentication needs, as defined in this regulation and required by GDPR and PSD2. Thus we suggest the usage of this method in association with the technologies like block chain and cloud computing.

In the future we will further investigate the security aspects of Information systems and especially consider the diverse methods for a secure user authentication.

Currently recommended is the usage of HTTPS and TLS protocols with elliptic curve sieve [37] with a small size of the encryption key. In the future we will consider the enhancement of this solution where the usage of RSA in the cryptography could be substituted by the application of the

elliptic curves or a lattice-based cryptography. Such solutions will be needed with the emerging quantum computing (post-quantum cryptography).

**Abstract**—The General Data Protection Regulation (GDPR) has strengthened the importance of data privacy and protection for enterprises offering their services in the EU. An important part of intensified efforts towards better privacy protection is enterprise workflow (re)design. In particular, the GDPR as strengthen the imperative to apply the *privacy by design* principle when (re)designing workflows. A conforming and promising approach is to model privacy relevant workflow fragments as Workflow Privacy Patterns (WPPs). Such WPPs allow to specify abstract templates for recurring data-privacy problems in workflows. Thus, WPPs are intended to support workflow engineers, auditors and privacy officers by providing pre-validated patterns that comply with existing data privacy regulations. However, it is unclear yet how to obtain WPPs systematically with an appropriate level of detail.

In this paper, we introduce our approach to derive WPPs from legal texts and similar normative regulations. We propose a structure of a WPP, which we derive from pattern approaches from other research areas. We also introduce a framework that allows to design WPPs which make legal regulations accessible for persons who do not possess in-depth legal expertise. We have applied our approach to different articles of the GDPR, and we have obtained evidence that we can transfer legal text into a structured WPP representation. If a workflow correctly implements a WPP that has been designed that way, the workflow automatically complies to the respective fragment of the underlying legal text.

## I. INTRODUCTION

**P**RIVACY and data protection are within the scope of interest of enterprises since years. Most current privacy related efforts in enterprises are driven by the General Data Protection Regulation (GDPR) [1] which came into action in May 2018 at the EU level. The regulation describes a set of imperatives enterprises have to consider in their workflows. A workflow is a business process automation, where information and tasks are transferred between participants according to business rules. Regarding GDPR, special attention should be paid to the Article 25 ('data protection by design and by default'). It obliges businesses to implement privacy-aware data management processes in all workflows that handle personal data. This is a complex and challenging task, because all respective workflows must be reconsidered from a privacy perspective. These requirements can originate from privacy norms written in national and international law texts. They also can result from a company's Binding Corporate Rules.

Workflow Privacy Patterns (WPPs) have been introduced by [2]. The idea of WPPs is to compile complex data privacy norms into a compact representation which support workflow

creators and analysts with designing and verifying workflows. WPP have to be pre-validated by data privacy experts and must be understandable for a wider audience. Workflow engineers without legal expertise shall be able to assess if the implementation of a particular WPP allows to create a privacy-compliant workflow. The implementation of a WPP shall not require legal expertise. Also, it shall be easier for a workflow analyst to find out if a workflow contains a WPP, than to conduct a privacy assessment unassisted. Thus, the WPP approach is promising. However, what is currently missing is a library of validated WPP designs. This is due to the fact that there is no approach to obtain WPPs from legal sources. In this paper, we introduce our approach to derive WPPs from complex legal texts containing data privacy norms.

Our research method is based on the design science [3] approach. We start with a problem statement, then we systematically compile a set of requirements for 'good' WPPs. Based on the structure of legal documents, we deduce which information must be represented in a WPP, and we provide a framework to extract this information from documents such as binding corporate rules, national and international law texts or compliance rules. We show applicability of our approach with two different use cases.

Our work indicates that it is possible to create WPPs in a structured way, resulting in WPPs with practical potential. This could foster companies in fulfilling privacy obligations which promote customer privacy protection.

**Paper structure:** The next section describes fundamentals and legal concepts related to our work and serves as a starting point for our research. In Section III we define a structure of a WPP, and in the Section IV we describe how to fill it with content derived from legal documents. This section also shows exemplarily how this framework can be applied to a fragment from the GDPR. Finally, Section V concludes.

## II. RELATED WORK

In this section we discuss legal and research foundation related to data privacy. We will also describe the concept of patterns which is in use in the computer science and other industry areas.

### A. Privacy concepts

The GDPR describes several requirements on privacy; most of them are well-proven concepts. The GDPR has an impact

on workflow designs on three different levels of abstraction:

On a global level, the GDPR obligates the enterprises to take care about data protection already *while planning and designing* their workflows. Specifically, Article 25 requires that the processing of personal data shall be planned and executed always in a way which supports privacy. This requirement is known also as privacy (or data protection) by design and by default [4]. It results from postulate of instant protection, and from the observation that effective data protection should not be realized only by reactive or retrospective actions [5]. To obtain privacy by design, other two levels must be taken care of. We describe them below.

The second level of the GDPR's impact on workflows is the *requirement for particular actions* in specific situations. Several Articles describe situations for which particular actions must be taken. For example, Article 15 ('right of access') calls for businesses that provide information about the amount of personal data, the purposes of the processing, its storage period, etc., as soon as a person files a request for information. Other articles describe further situations the enterprises must be prepared for. It can be changing or erasing personal data, if a person asks for it in line with the Article 16 ('right for rectification') or Article 17 ('right to be forgotten').

The third level is constituted by the *principles* relating to the processing of personal data. They do not describe specific actions or workflow fragments, but they still affect workflows. Some of these principles are described in the Article 5. For example 'purpose limitation' principle requires that the data collected to fulfill one particular business task should not be used for other purposes. The data minimization principle specifies that the amount of personal data which is collected or handled should be limited to the minimum required to finish the business task.

### B. Patterns

Design patterns are reusable solutions for recurring problems. Design patterns have been proposed in several fields. Already in 1977 Alexander [6] wrote "Each pattern describes a problem which occurs over and over again in our environment, and then describes the core of the solution of the problem, in such way that you can use this solution a million times over, without ever doing it the same way twice". The same kind of thinking was adapted in the fields of software engineering [7] and IT architecture [8].

In the field of workflow modeling, workflow patterns have been introduced [9]. Different perspectives of workflow models can be considered [10], depending on the intended use of the model. Well-known perspectives are 'control flow', 'data', 'resources', 'functional' and 'operational'. Most workflow patterns [11] focus on the first three perspectives. For example, [12] lists 43 different control-flow patterns ranging from the synchronization of parallel workflows to the explicit termination of workflows. Patterns regarding the data perspective [13] consider the visibility of data, data-driven interactions, the transfer of data and its transfer routes. Patterns such as 'Role-based allocation' [14] address the life cycle of work items

from the resources perspective. [15], [16] present exception handling patterns.

In the area of data privacy, collections of software design patterns have been already proposed [17], [18]. Such collections include options to collect, process and share personal data in a legal way, e.g., by using anonymization, onion routing or implied consent. However, a structured collection of design patterns for the data-privacy perspective in workflows does not exist so far.

### C. Representation of privacy requirements

In general, three approaches exist to integrate privacy requirements into workflows. They vary in the degree of abstraction and the degree of formalization.

Numerous 'best practice' *implementation guides* have been written by privacy authorities, privacy officers and law firms. Such guides contain textual descriptions of steps needed to handle legal obligations. For example, a guide could translate a GDPR Article into an intuitive description of steps which have to be performed. In many cases the guides are tailored to specific industry sectors. However, such guides are less structured than the legal articles. This induces some degree of freedom when implementing them into workflows. Thus, it is difficult to ensure that a workflow designed on basis of a guide is indeed compliant with the regulation.

*Checklists* allow to perform a target-actual comparison in a structured way. A checklist reduces the effort needed to incorporate legal requirements into workflows. A legal article is distilled to a list of capabilities which must be implemented. However, it is difficult to express some legal obligations only in form of one-dimensional checklists. For example, it would be confusing to represent the right of access as a checklist. This is because the right of access is interwoven with other articles of the GDPR, depending on aspects such as data transfers into third countries or conflicts with the rights of other persons.

Finally, industry-specific *reference models* provide optimized workflow models in a semi-formal language such as EPC [19] that handle typical privacy obligations. For example, a domain expert could define a reference model for handling incoming requests for access in a typical retailer scenario. Thus, the reference model contains best practices in a specific application domain. A workflow engineer could adapt this model to the workflows of his company. However, a reference model does not ensure that its implementation into the workflows of a company is correct regarding the privacy obligation. This has two reasons: Firstly, languages such as EPC or BPMN do not allow to model all obligations mentioned in privacy regulations, e.g., storage periods or data transfers to foreign countries with less developed privacy standards. Secondly, the workflow engineer has a high degree of freedom when adapting the reference model to his company.

## III. DERIVING WORKFLOW PRIVACY PATTERNS

Workflow models automate business processes that execute specific business tasks. To design a workflow model, a workflow engineer analyzes business objectives, company structure,

key performance indicators, etc. But also legal obligations must be met. This is where data privacy requirements come into play. They have an impact on workflow design and are involved in several aspects of workflows. For example, the order of activities (the sequence flow order) in a workflow is vital for privacy. A natural person must give consent *first*, before his data is stored or processed. The data flow within workflows is another important aspect. Authorization and authentication for gaining data access must be carefully planned. Also execution exceptions have the potential to violate data privacy regulations, say, if an activity on personal data cannot be completed without involving third parties.

Consider Text 1, which we will use as a running example in this paper. It shows a typical article from the GDPR.

*Text 1 (Fragment of GDPR's Article 15 - Right of access):*

1. *The data subject shall have the right to obtain from the controller confirmation as to whether or not personal data concerning him or her are being processed, and, where that is the case, access to the personal data and the following information:*
  - (a) *the purposes of the processing;*
  - (b) *the categories of personal data concerned;*
  - (c) *the recipients or categories of recipient to whom the personal data have been or will be disclosed, in particular recipients in third countries or international organisations;*
  - (d) *where possible, the envisaged period for which the personal data will be stored, or, if not possible, the criteria used to determine that period;*
  - (e) *the existence of the right to request from the controller rectification or erasure of personal data or restriction of processing of personal data concerning the data subject or to object to such processing;*
  - (f) *the right to lodge a complaint with a supervisory authority;*
  - (...)
2. *Where personal data are transferred to a third country or to an international organization, the data subject shall have the right to be informed of the appropriate safeguards pursuant to Article 46 relating to the transfer.*
3. *The controller shall provide a copy of the personal data undergoing processing. (...)*

Staying compliant with such legal regulations implies many consequences for a company's workflows. Enterprises must be prepared for the case when a customer places such access enquiry and they must be able to react accordingly.

#### A. Problem Statement

A WPP is a translation of one or more privacy obligations into a semi-formal specification, which can be integrated into a workflow model [2]. WPPs support enterprises to be compliant with data privacy regulations. In particular, WPPs shall foster

planning, implementing and auditing of workflows handling personal data. In order to find out how such a WPP must be structured and how it can be obtained in a systematic way, we need to consider the capabilities of the WPP users, and we need to define requirements that a WPP must fulfill in order to be applicable.

*a) User roles:* We have analyzed which different roles are involved in creation and use of WPPs. Our focus was on the functions the roles must fulfill, and which knowledge and which skills are needed in this regard. We have identified three distinct user roles:

**WPP creator** This role develops a WPP from a particular data privacy norm. This role has legal expertise needed to identify all information from various legal sources, that must be considered in order to implement privacy-compliant workflows. This skill is needed to be able to mirror the legal norm(s) semantically. The WPP creator needs background knowledge on workflow modeling to provide syntactically correct WPPs.

**Workflow engineer** This role models workflows with the help of WPPs. The workflow engineer implements WPPs into existing workflows or creates new workflows according to a WPP specification. This role needs domain knowledge on the workflow domain and workflow modeling skills, but it doesn't need to possess legal knowledge.

**Privacy officer** This role verifies and documents if workflows are compliant with data privacy norms. In this role can be a employee or an external auditor. A privacy officer has sufficient domain knowledge and legal expertise to find out, if existing workflow model meets certain privacy obligation.

*b) Requirements for WPPs:* From the intended use of the WPPs and the expertise of the user roles, we have derived three requirements for WPPs:

**R1** WPPs are a variant of design patterns. Thus, WPPs have to meet all *general requirements for design patterns*, e.g. completeness, understandability and reusability.

**R2** Because the workflow engineer may lack legal expertise, a WPP must contain *all information necessary* to model or validate a certain privacy obligation. For example, if a WPP is a specification for the implementation of the 'right of access' - as shown in Text 1 -, then it must be possible to create a privacy-compliant workflow on the basis of this WPP only, i.e., without having to consider additional legal texts.

**R3** WPPs must be modular to enable *linking of WPPs*. This is particularly important, as privacy obligations often are spread over several articles or multiple legal texts.

Given these requirements, we will now explore options to structure WPPs. We start by deriving an information model to express information from legal norms in a WPP. In the next section, we propose our framework to compile WPPs from legal texts.

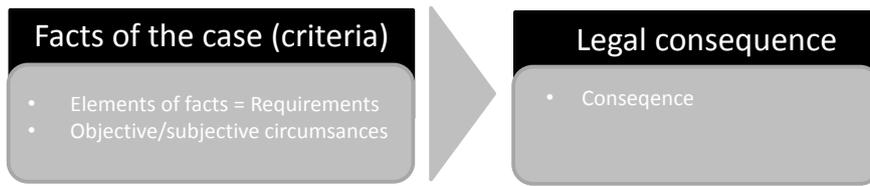

Fig. 1. Structure of legal texts

*B. Structures of legal texts and design patterns*

In this subsection we compare the structures of legal texts and design patterns. Obligations in legal texts typically follow a well-defined structure, as shown in Figure 1. A legal obligation is described by

- (1) **the facts of the case** and
- (2) **the legal consequences.**

The facts of the case specify

- (1a) the *general criteria* for the applicability of the norm and
- (1b) the *circumstances* under which a certain legal norm shall be applied.

The facts of the case result in an if-then form. Thus, the legal norm or corporate rule can be always interpreted as 'if all prerequisites are met, then the consequences apply'. The consequences in turn can be either

- (2a) a *course of action* that must be taken or
- (2b) a *yes/no-conclusion* in the sense 'if all prerequisites are met, then the regulated action is lawful'.

In a case of our running example, the general criteria for the applicability of the norm (1a) are described in Art. 2, 3 GDPR (Text 2, 3). The norm applies if the company handles personal data related to activities in the EU.

*Text 2 (Fragment of Article 2 GDPR): Material Scope*

1. This Regulation applies to the processing of personal data wholly or partly by automated means and to the processing other than by automated means of personal data which(...)

*Text 3 (Fragment of Article 3 GDPR): Territorial Scope*

1. This Regulation applies to the processing of personal data in the context of the activities of an establishment of a controller or a processor in the Union, (...)

The circumstances (1b) for a person claiming access rights are described in the first paragraph of Art. 15 GDPR (Text 1). It says that the company must actually possess information about this person. The legal consequence (2) is described in the subsequent paragraphs of Art. 15. The consequence requires the company to provide certain information (2a), according to further dependencies.

Design patterns consist of three components, as described in the previous subsection: (i) the *context* the pattern can be applied to, (ii) the *problem* description that allows the engineer to decide, if the pattern is useful for specific design problem, and (iii) a generic *solution* for the described problem [20]. Observe that the general structure of design patterns is similar to the structure of obligations in legal texts; this is shown in the Figure 2. Thus, it seems appropriate to define a WPP alike. To this end, we distinguish **activity patterns** where the consequence is a course of action (2a), and **check pattern** that result in a yes/no-conclusion (2b).

*C. Options to represent legal texts*

In order to obtain evidence on approaches to structure a WPP, we have conducted a series of preliminary experiments.

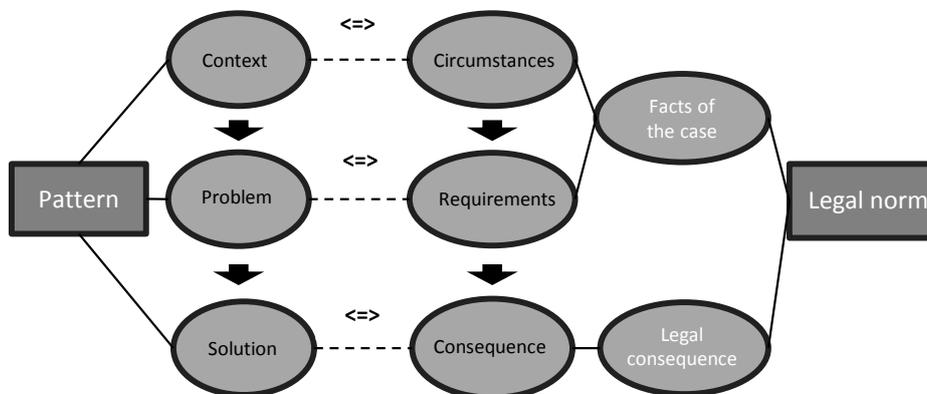

Fig. 2. Relation between legal texts and design patterns

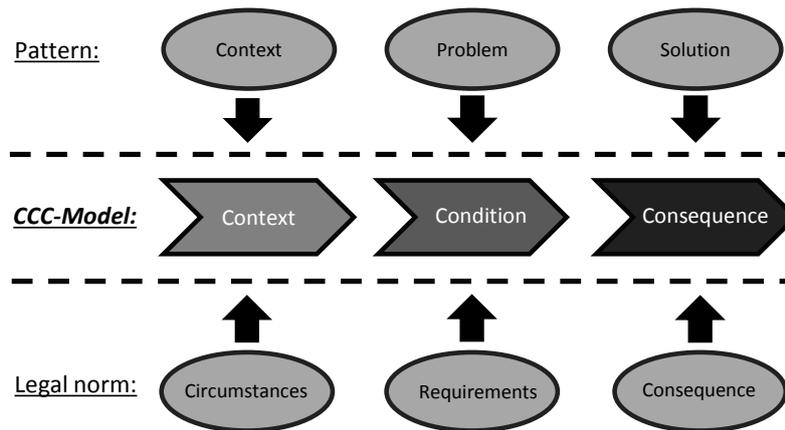

Fig. 3. CCC-Model

In particular, we have asked a class of master's students to model the facts of the case and the legal consequences of various articles of the GDPR. The students had a professional background on data privacy and security and attended an extra-occupational education class on workflow modeling.

The students have observed that the general criteria for the applicability of the norm (1a) refer to domain knowledge of the workflow that cannot be easily represented as a check list or a BPMN-style workflow model. We think that describing the criteria textually is the most appropriate option. Furthermore, our students have reported that the set of circumstances for the applicability of a specific article (1b) does not have an inherent order. Therefore it makes no sense to represent the circumstances as a workflow model fragment with a graphical language. A simple check list is sufficient and was preferred by the students. Our students also found out, that the legal consequence (2a) can be represented as workflow model. This model can be defined in a semi-formal language such as BPMN or EPC. If the consequence is a straightforward yes/no-conclusion (2b), this part can be cut down to a simple event 'Processing is lawful'. The final observation of the experiment was, that only such articles can be represented in a proposed way, which do not contain uncertain legal concepts. For example, consider Text 4. It requires legal expertise to decide for each workflow instance individually if the interests of the controller are overridden by the rights of a person.

*Text 4 (Frag. of Art. 6 GDPR): Lawfulness of processing*

1. Processing shall be lawful only if (...)
  - (f) processing is necessary for the purposes of the legitimate interests pursued by the controller or by a third party, except where such interests are overridden by the interests or fundamental rights and freedoms of the data subject (...)

#### IV. THE CCC MODEL

In this section, we introduce our CCC model. It structures fragments of legal texts into Context, Condition and Consequence. In the previous section, we have observed a similarity between the general structure of legal texts (the circumstances for applicability of an article, the legal requirements named in the article and the legal consequence) and three basic elements of a pattern (context, problem, solution). This similarity is outlined in Figure 3. Furthermore, we have obtained evidence how the different parts of legal texts can be represented. In this section, we first describe elements of a WPP structure, and then follow up with the CCC Model, which describes how to obtain systematically WPPs from legal texts.

##### A. WPP structure

We aimed for WPP structure elements that mirror and foster desirable characteristics of design patterns, such as completeness, understandability and reusability (Requirement R1). Furthermore, the structure of a WPP shall carry all legal obligations from the data privacy domain for a given scope (Requirement R2). It shall not result in oversized, inapplicable pattern forms, that violate the Requirement R1. The structure must allow modular stacking of WPPs (Requirement R3). Considering this, our WPP structure consists of *Header*, *Context*, *Condition* and *Consequence*:

a) *Header*: The header contains meta-information of the pattern. It describes essentials like name, type, legal focus of the WPP and relation to other WPPs. Further meta-information as an unique database ID, date or the name of the WPP creator, may be added.

**WPP Name** A distinct name of the pattern. It makes the pattern easily recognizable, and allows searching for it in a pattern catalog. The name of the WPP shall indicate the objective of the pattern.

**WPP Type** WPPs can be distinguished into check patterns and activity patterns, as observed in the last section.

**Legal Focus** Specifies all legal texts (articles, paragraphs, etc.) which were used to derive the pattern. It declares which legal obligation is covered (entirely or partly) with this WPP.

**Relation to other WPPs** WPPs can build upon each other. When implementing multiple WPPs into a workflow, sometimes the relation between WPPs needs to be specified. For example, a WPP creator might decide to split the legal obligation to delete data into multiple WPPs. One WPP keeps records of the data used, a second one ensures that the data is deleted at the specified time. WPPs might also exclude each other. For example, a WPP to execute a business task anonymously might exclude a WPP for the deletion of personal data. Since new WPPs might be created at any time, information on the relation to other WPPs may be incomplete.

b) *Context*: The context of a WPP contains an intuitive textual description of the situation and of the resulting problem, which is addressed by the WPP. The user must clearly understand when and for which objectives the WPP can be applied, and if the application of the WPP results in further legal obligations.

c) *Condition*: The condition provides all prerequisites mentioned in the legal texts that have been enumerated in the 'legal focus' field of the WPP header. Since the order of the prerequisites is insignificant, the condition is represented as a checklist. The prerequisites have to be defined as positive statements that do not leave room for misunderstanding. If all prerequisites in the checklist are met, the consequence applies.

d) *Consequence*: The consequence of a check pattern is a statement, which is true, if all prerequisites from the condition are fulfilled. In order to determine the consequence of the WPP, it is necessary to specify the type of the pattern first. This is, because the consequence component differs in its form depending on the type of the WPP. For a check pattern it is (a) a statement that the case described in the context field is lawful, according to the legal norms specified in the header. Alternatively - for an activity pattern - the consequence is (b) a chain of activities, specified with a workflow modeling notation like EPC (event-driven process chain) or BPMN (Business Process Model and Notation). This chain of activities has to be executed, if all the prerequisites described in condition component are met.

### B. The CCC Model

Typically, modeling a new WPP is triggered by a workflow engineer or a privacy officer, who has identified a recurring, challenging problem which has no corresponding pattern. Recall that the WPP creator must be familiar with legal texts (Requirement R2), but the workflow engineer does not necessarily possess such knowledge. Thus, a model for deriving WPPs must ensure, that all legal obligations are included in the resulting WPP.

We will now outline the six steps needed to derive a WPP. They constitute our CCC Model. For this we use the structure described in previous subsection. We use Text 1 to illustrate

these steps. Note that Text 1 refers to an activity pattern. An example for a check pattern can be found in the Appendix.

a) *Define the Scope*: At first, the WPP creator sets the outline of the new WPP. He decides which legal articles and paragraphs will be in the scope. By setting the scope, he must ensure that the resulting WPP meets the requirements of design patterns (R1). In particular, the WPP must be not too complex or too simple to be useful. He also has to ensure that the new WPP can be combined with already existing WPPs (R3). Furthermore, the WPP creator has to consider that the legal texts in the scope do not contain uncertain legal concepts that are unsuitable for a WPP, as shown in Text 4. Scoping of a WPP can be supported with four questions:

- Is the scope suitable to create a WPP that is non-trivial?
- Is the scope understandable for the workflow engineer?
- Does the scope overlap with a WPP that already exists?
- Does the scope include legal texts that need to be interpreted individually by a legal expert?

*Example 1: The scope of the WPP is the implementation of the 'right of access' according GDPR for customer data. The company doesn't collect data from and doesn't transfer data to third parties, but it uses automated means for data processing of customer data in the EU. Furthermore, the WPP addresses only requests that arrive electronically.*

b) *Define the Header*: In this step, the meta-data of the WPP is defined. The meta-data of the pattern is the *Name*, the *Type*, the *Legal focus* and the *Relations to other WPPs*. The WPP name should be intuitively understandable and reflect the WPP type. A name beginning with 'Processing' would indicate an activity pattern, while a name starting with 'Lawfulness of' would refer to a check pattern.

The articles and paragraphs specified in 'Legal Focus' mirror the scope of the WPP. 'Relations to other WPPs' contains information if the scope of this WPP depends on, overlaps with or contradicts with existing WPPs.

*Example 2:*

**WPP Name** *Processing the Right of Access from the Inventory of Processing Activities*

**WPP Type** *Activity Pattern*

**Legal Focus** *Art. 15 Par. 1a-d, Par. 3; Art. 2 Par. 1; Art. 3 Par. 1 GDPR*

**Relation to other WPPs** *dependency to WPP 'Update Inventory of Processing Activities'*

c) *Define the Context*: In the third step, the context must be specified. It shall describe the situation and the purpose of the pattern in a plain language that is clearly understandable without legal expertise. It must provide answers for the following questions:

- Which business activities are in concern of this WPP?
- When does the privacy pattern apply?
- Which activities can occur before or after the WPP?

*Example 3: A business unit has received a request from a customer. The customer asks if personal data concerning him is processed. If this is the case, the customer must be given access to his personal data.*

d) *Define the Condition:* The condition translates legal requirements into prerequisites for the applicability of a WPP. The prerequisites have to be defined as positive statements that do not leave room for misunderstanding for a person without legal expertise. Thus, we discourage citing or referring to legal texts. The following questions serve as a guideline to obtain a check list of conditions:

- Which legal texts are in the 'Legal Focus' of this WPP?
- Do those texts base on other legal definitions?
- Which different requirements exist in each sentence of the legal text?
- Is a certain requirement already excluded by 'Context'?

*Example 4:*

- The identity of the requester has been verified.*
- The requester asks for his or her own data.*
- The requester does not make use of this right more than three times a year.*

e) *Define the Consequence:* The Consequence depends on the WPP type. For a check pattern only a state must be defined, which comes into effect when all requirements set in the Condition are met. For an activity pattern, the consequence is a chain of activities which must be specified (e.g. in form of an EPC notation) in this step.

*Example 5: Figure 4 describes the activities to process the request for access from a customer as a business process model.*

f) *Review the WPP:* To ensure that the pattern is correct and useful, it must be reviewed according to the following questions:

- Does the WPP meet the general quality criteria of design patterns?
- Is the WPP understandable and applicable for persons without legal expertise?
- Do the components Context, Condition and Consequence represent all information specified in the 'Legal Focus'?

### C. Discussion

We have derived our WPP representation from the general structure of legal texts. Essentially, we can represent any legal article (or its fragment) as a WPP. However, it was not in the scope of this paper to find out if a WPP representation makes sense for a certain use case. For example, Article 21 GDPR contains "legitimate grounds for the processing which override the interests, rights and freedoms of the data subject". It needs a lawyer to find out if such grounds indeed override the rights of the subject. If a WPP contains such concepts, it might not

be useful for a workflow engineer, who does not possess legal expertise. But it might be possible to decide upon such aspects at the creation time of the WPP. Thus, we see potential for further research.

It remains an open issue to evaluate our approach systematically. This is challenging: we have to consider three distinct user roles, with specific expertise areas and domain knowledge. It is difficult to separately assess the WPP representation and the framework for generating this representation. It is also challenging to exclude the properties of the application domain, when testing the applicability of a WPP. For this reason, we plan to evaluate our approach with a broad, qualitative case study.

Finally, it needs to be investigated how the creation, usage or verification of WPPs can be supported within workflow modeling tools or even within workflow modeling notations. Furthermore, corresponding frameworks and (semi-)automatic approaches would help to express the full potential of the WPPs. They could support the verification if the workflow embeds a WPP correctly. They also could help confirming if the WPP is conclusive, that is, if all (or particular) aspects of a certain legal text are represented within the WPP.

### V. CONCLUSION

The GDPR and other privacy norms resulted in new requirements for workflows that handle personal data. It may be - for example - a requirement to ensure that a particular information is used only for the purpose explained to the customer. This information must be deleted when the original purpose for which it was gathered is no longer valid. Furthermore, individual rights such as the 'right of access' or the 'right to be forgotten' require for new workflow extensions which are not directly related to the original core business objectives of a company.

Implementing privacy norms into workflows is challenging. Auditors, workflow engineers and data privacy officers normally have different fields of expertise, but must cooperate in an interdisciplinary way to implement or verify legal requirements in domain-specific business tasks. A promising approach to tackle such challenges is the use of Workflow Privacy Patterns (WPPs). WPPs provide solutions to problems recurring in enterprise workflows. However, existing work on WPPs does not explain how such patterns can be obtained in a systematic way.

In this paper, we have investigated how to derive WPPs from legal texts such as the GDPR. We have defined three distinct user roles that are involved in the creation and use of WPPs. Furthermore, we have compared the characteristics of legal texts with the properties of design patterns. From this point we have developed a formal representation of WPPs that follows the structure of legal norms. Furthermore, we have developed a framework that compiles WPPs in six steps. With two different use cases we have provided evidence that our approach allows to map articles of the GDPR into a formal representation which supports process engineers in designing workflows, which meet legal requirements.

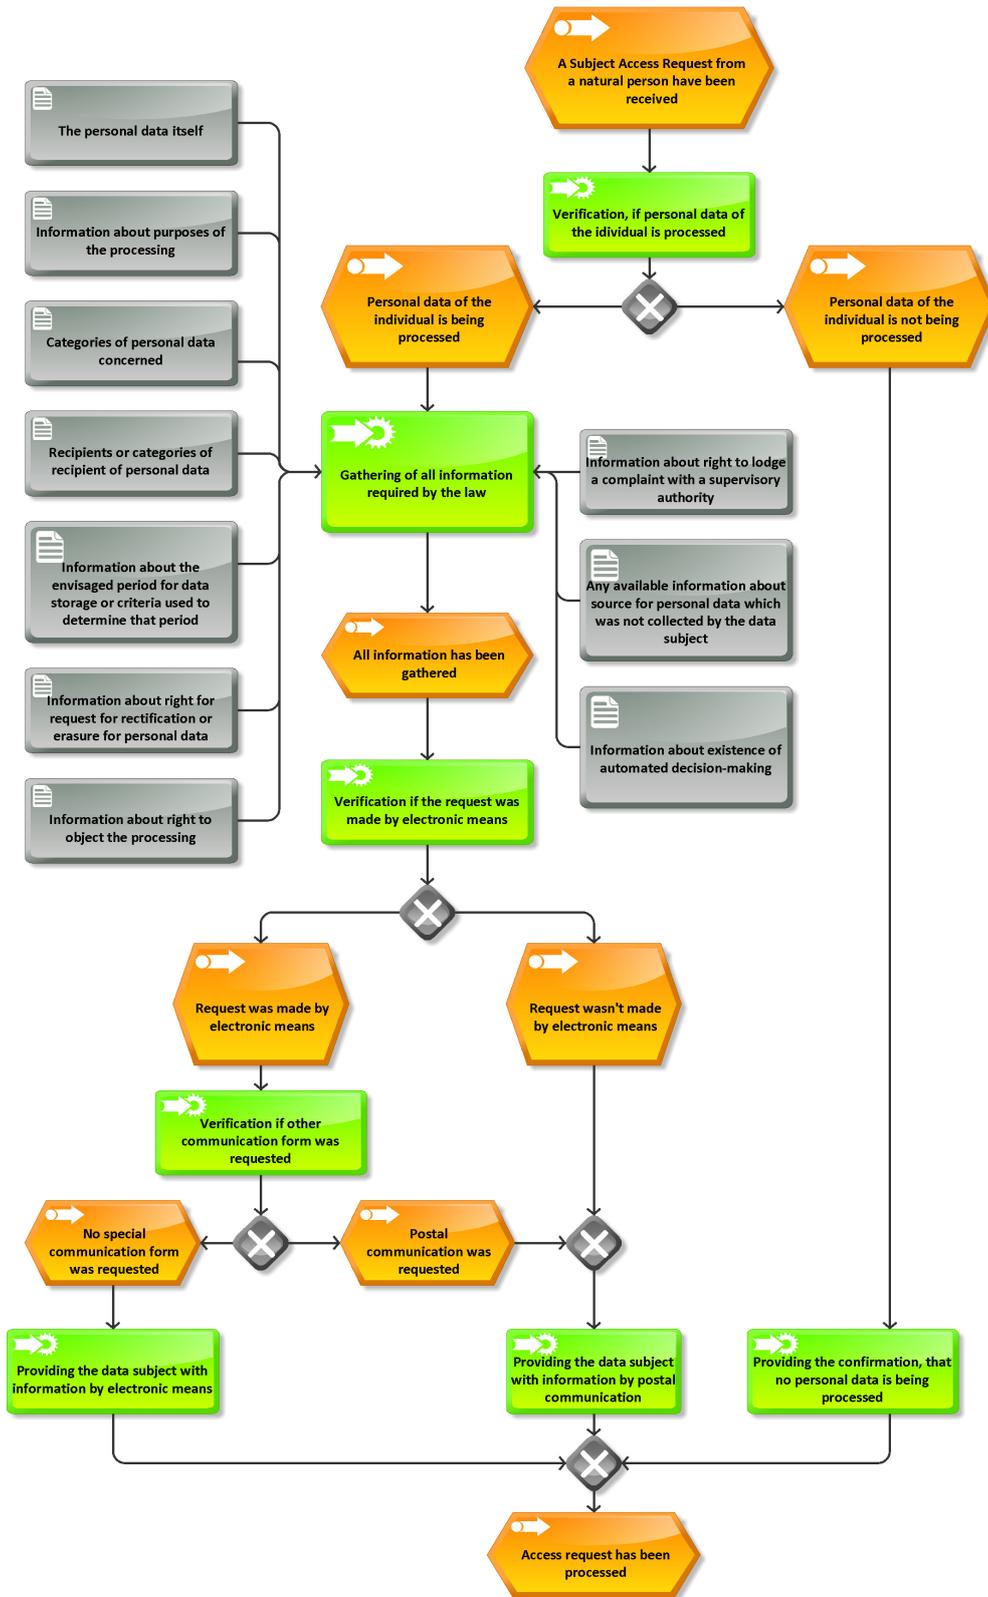

Fig. 4. Workflow to handle a request for access.

## ACKNOWLEDGMENT

We would like to thank Martin Bahr for his exceptional work on realizing the CCC Model.

APPENDIX  
EXAMPLE FOR A CHECK PATTERN

In this section, we illustrate a check pattern with the GDPR articles related to the consent for data processing. In particular, we have used our approach (cf. Section IV) to develop a WPP for the lawfulness of an electronic consent.

a) *Scope:*

Before an enterprise processes personal data, it must verify the lawfulness of processing. If there is no other legal basis, say, from other laws or a contract, the data subject must have been provided a consent to the processing of his or her data. The purpose of this WPP is to prove the lawfulness of an electronic consent from an adult according to the GDPR. The consent has been documented in a database.

b) *Header:*

**WPP Name** Lawfulness of an electronic consent  
**WPP Type** Check pattern  
**Legal Focus** The WPP considers the GDPR articles:

- Art. 4 ('definitions'), Par. 11 ('consent')
- Art. 6 ('lawfulness of processing'), Par. 1 (a)
- Art. 7 ('conditions for consent')

**Relation to other WPPs**

- 'Obtain Electronic Consent'
- 'Revoke Electronic Consent'

c) *Context:*

The purpose of this WPP is to prove the lawfulness of an electronic consent from an adult for the processing of personal data for a specific purpose.

d) *Condition:*

- There exists a record of a consent from the data subject in the database.
- The consent has been obtained in a lawful way. (cf. WPP 'Obtain Electronic Consent')
- The record documents that the data subject has been informed about processing activity, data to be processed, purpose of the processing, storage period, parties responsible for the processing and the receivers of the data.
- The record corresponds to the current processing.

- In the last 18 months, the consent has been given or there has been a processing activity related to this consent.
- There is an option to withdraw the consent that is easily accessible for the data subject. (cf. WPP 'Revoke Electronic Consent')
- The consent has not been withdrawn.

Note that the GDPR does not specify an expiration period for a consent. However, court decisions say that it is best practice not to rely on a consent that might have been forgotten already by the data subject.

e) *Consequence:*

If all conditions are fulfilled, a lawful consent for the processing exists.

**Abstract**—Most cloud providers use centralized servers to manage data. However, centralized servers still suffer the risks of single point of failure and data theft. We add a blockchain to the cloud service and propose a new architecture to manage data. Using blockchain as a connector to utilize the tamperproof, traceable, and data-sharing features of the blockchain to ensure that the transaction data are properly stored in each node. We use the stock simulation trading service to extend and divide the research design into two levels, namely, system and application services. First, we directly write the data into the blockchain. Second, we alternatively store the data in the cloud and then write it into the blockchain. Finally, the two versions are compared and analyzed to investigate their feasibility and performance. At the application service, we implement the smart contract for the existing stock transaction process to achieve real-time settlement.

## I. INTRODUCTION

WITH the cloud service, the cost of equipment maintenance within the company is converted into the cost of service operation [1]. And the maintenance of the system becomes simple and also increases flexibility.

However, while availing of the convenience of cloud services, enterprises' internal data or even highly sensitive data are stored in the data center of a third-party. If sufficient security measures are not taken, then security risks, such as data leakage and tampering, will occur. In recent years, well-known cloud service providers have frequently reported cloud vulnerability incidents [2].

In particular, many small- and medium-sized enterprises (SMEs) adopt centralized third-party cloud services. As the size of the enterprise increases, the vertical expansion of the cloud service database becomes prone to the risk of single point of failure [3]. In the case of a single point of failure or single-path disconnection, the cloud service provider will interrupt the network service and even the entire production line. This situation can cause considerable losses for companies [4].

The centralized environment of enterprises is increasingly unable to adapt to the needs. Thus, they are gradually moving from the original centralized database to the decentralized database. The blockchain is a large decentralized database. The

data structure of the blockchain ensures that the transactions in the network are traceable, immutable, and tamperproof. In this study, the information stored in the cloud is encrypted, and the user's digital assets and transaction records are distributed in different nodes in the network through the P2P network, thereby reducing the risk of being stored only in a single node. Based on the blockchain, the data stored in the cloud is encrypted and stored in the network's block. The user's file data will not be exposed to the risk of being leaked or stolen during cloud server failure [5]. Users can securely access data, and privacy is well protected.

The design of this study will be divided into two levels, namely, system and application services. We classify the level discussed in the previous paragraph as the system service level and analyze the problems that cloud storage may encounter. We hope to reduce the risks that cloud storage may encounter by using the blockchain. At the application service level, we design the blockchain smart contract for the existing stock transaction process. The traditional stock transaction employs the T+2 settlement cycle. However, through the blockchain, users can achieve real-time delivery of stocks and the trading become more secure.

## II. RESEARCH BACKGROUND

This study is based on the cloud service and stock market transaction implementation services proposed by Wang and Chang [6]. We use the concept and technology of the blockchain to extend and improve the establishment of the blockchain as a connector for cloud data services.

### A. Stock market simulation trading system architecture

We design a network-based stock market simulation trading system (hereinafter called SMSTS). Using ASP.NET web development including HTML, CSS, Bootstrap, C# and Python to design the SMSTS. The database is designed using the Microsoft SQL Server.

### B. Blockchain

Satoshi Nakamoto published a paper entitled "Bitcoin: A Peer-to-Peer Electronic Funds Transfer System" in 2008 [7], proposing the concept of bitcoin and its underlying technology.

This work was supported by the Ministry of Science and Technology, Taiwan, under contract number MOST-106-2221-E-005-053-MY3.

\*Corresponding author: eschang@dragon.nchu.edu.tw

The blockchain is a large global decentralized ledger database that records all transaction records [8]. Each node uses the proof-of-work hash function to determine who verifies these transactions. The node that obtains the verification right would broadcast the block to all of the nodes. Until the first successful node confirms the verification, the block quickly connects to the parent blockchain.

### C. Smart contract

The concept of a smart contract was first proposed by Nick Szabo in 1994 [9]. He advocated that the trading conditions could be automated by the program. When the conditions are met, the value can be transferred. All of these are performed automatically by the computer program, and no third party is involved.

### D. Ethereum

The concept of Ethereum was first proposed by Vitalik Buterin: A next-generation smart contract and decentralized application [10]. Ethereum is an application platform based on blockchain technology that allow many different applications to be built on the Ethereum platform.

### E. Stock settlement

Settlement is the end of a creditor–debt relationship. If it cannot be completed in time, then it may cause the next transaction to be unsuccessful, which will affect other business activities. The stock settlement cycle is T+2. Thus, if the settlement speed can be improved, then the efficiency of the capital market operation can be improved and the cost of verification by the settlement institution personnel can be reduced.

## III. ARCHITECTURE AND DESIGN

In recent years, cloud computing has become even more popular. However, when confidential information is in third-party cloud services, the risk of leakage increases. The blockchain database consists of several nodes and all participate in data management. Any data added to the blockchain database must be agreed upon by most nodes in the blockchain network to be successfully recorded in the block and cannot be controlled by a single entity. Such mechanism ensures that data are secure, transparent, and permanently recorded, thus making it difficult to tamper with the content.

This study divides the blockchain into two levels, namely, system and application service levels. In terms of system services, two versions are proposed for writing data into the blockchain database. The first version involves directly writing the data into the blockchain. The second version involves storing the data in the cloud, and the blockchain acts as a connector to encrypt and decrypt the location where the cloud stores data. In terms of application services, the details of the use of smart contract automation for SMSTS are described in the subsequent paragraphs.

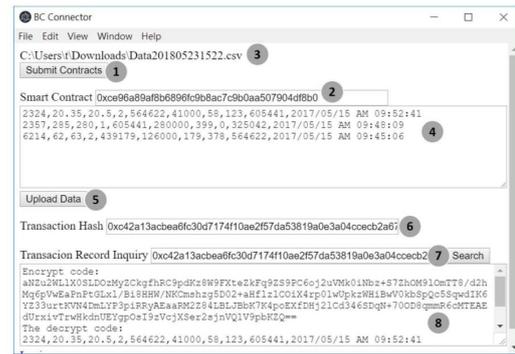

Fig. 1. User Interface of BC Connector

### A. Data directly stored in the blockchain

We use SMSTS that we have set up on the local server before, then set up the blockchain environment on the notebook. In this program, we designed the user interface to gradually write the data into the blockchain. Besides, we use symmetric key cryptography to encrypt the data.

1) *Blockchain environment setting*: We use the Ethereum platform to set up a private chain network and Solidity to write the smart contracts. Before the smart contract is submitted to the blockchain network, it needs to be compiled and deployed.

2) *Download the file*: We add the function button for downloading files in the SMSTS which enables users to download the transaction records from the SMSTS to their own computers and then write into the blockchain through the blockchain connector.

3) *Compile and deploy the smart contract*: To ensure easy operation by the user, this study designed a user interface that can be operated step by step, shown in Fig. 1. First, after pressing the (1) Submit Contracts button, it will generate an address in the (2) Smart Contract field, then click on File in the upper function bar and click on Open File, and then select the file to be written into the blockchain. After confirming the file, the file path will be displayed in (3). The file content will be displayed in the data column of (4). After pressing (5) Upload Data, the data will be written into the block. When the data are written into the blockchain, the encrypted Transaction Hash will be generated in (6). The user can also query the data of the blockchain through the (7) Transaction Record Inquiry, and the query data will be displayed in (8) Area. To ensure that the data are secure, we use the AES-128-CBC symmetric key encryption method to encrypt the data to be written into the blockchain. The Encrypt Code displayed in the query data bar is the encrypted garbled code. Even if the user obtains the Transaction Hash, the file content will still be invisible in the blockchain.

### B. Write the data address stored in the cloud into the blockchain

Most users use the centralized cloud server to store data, which is vulnerable to hackers; thus, the security of data is

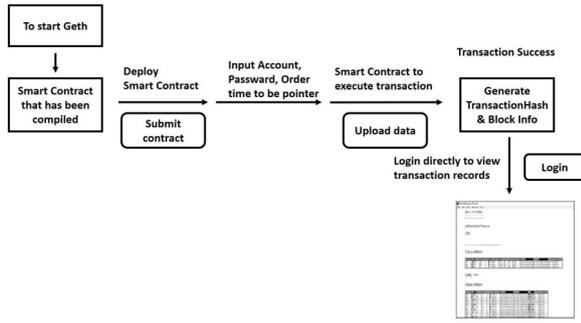

Fig. 2. Using the BC Connector to enter SMSTS query data

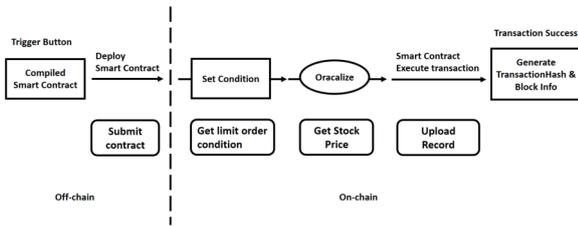

Fig. 3. Limit trading design flow

threatened. Therefore, this study integrates the web server, database, stock price program, and transaction processing program into the cloud system, allowing users to buy and sell stocks through the browser, thereby collecting data and using these data as the test data for writing the blockchain.

1) *Cloud erection*: We transfer the SMSTS to the Azure cloud platform and collect the data generated by the user through the simulation program for stock trading as the experimental basis.

2) *Using the blockchain as a connector*: We build a Electron, to design and develop our blockchain connector user interface. After launching Geth, another Git Bash window opens, with the electron command to execute our project. The account, password, and order time are used as pointers for the user on how to store the transaction data. After being encrypted and written into the blockchain, the user can directly log in to the transaction record page of the SMSTS to query the transaction data of the specified order date, as shown in Fig. 2.

C. Smart contract automation

Smart contract automation is applied to the stock limit trading service. Based on the design structure of the SMSTS, the system automatically generates the smart contract and deploys it to the P2P network environment. We have added a trigger button that allows users to link to their own blockchain wallet to perform limit trading services. The system design flow for this architecture is shown in Fig. 3

TABLE I  
APPLICATION LOAD TIME TEST RESULTS SET ON THE LOCAL AND CLOUD

Load time	SMSTS is set up on the local server (sec)	SMSTS is set up in Azure cloud server (sec)
1	2.07s	1.03s
2	2.54s	1.02s
3	2.05s	1.23s
4	2.01s	1.11s
5	2.52s	1.02s
6	2.40s	1.08s
7	2.31s	1.15s
8	2.23s	1.24s
9	1.99s	1.09s
10	2.36s	1.15s
Avg time	2.48s	1.12s

IV. EXPERIMENT AND EVALUATION

This study conducts a series of tests and analyses based on the architecture and design at the system service level described in the previous section, and the application service level will be compared with the existing platform.

A. Results from stock market simulation trading system test results

To test the performance, we use the Pingdom Website Speed Test, a free website tool that detects website speed and performance, to understand and evaluate the performance of the proposed service and to measure the load time of the website through experiments. We have designated San Jose(California,USA) as the test area.

The test results of the page load time and the time of writing data into the blockchain are shown in Table I. From the table, we can see that the cloud server is faster than the local server. This finding can be plausibly attributed to the fact that the cloud service providers focus more on optimization of the cloud storage service. This difference is also affected by the network speed, test location, and device capabilities between the cloud service provider and the research computer device.

B. Results from blockchain application system test results

We first compare the difference between (1)directly storing the accessing data in the cloud and (2)storing/accessing via cloud addresses recorded on blockchain. Table II shows that the time of transaction data generated by the SMSTS, which is directly stored in the cloud, is shorter and more average than that of other systems. Storing of the cloud data address to the blockchain increases the step of writing the blockchain; thus, it takes a long time. Compared with storing only the data in the cloud, writing into the blockchain is time consuming but more secure.

C. Discussion of cons and pros of the proposed blockchain system services

Traditional decentralized systems generally use a Replicated state machine [11] to implement a fault-tolerant mechanism. The blockchain uses similar approach, but it does not rely on a single entity to complete the service because there exists consensus agreement in the blockchain. When a transaction conflict occurs, only one transaction is approved to avoid double-spending. In order to solve the problem of Byzantine failure [12], we write the data encryption program in the smart

TABLE II  
COMPARISON OF DATA STORED IN THE CLOUD AND WRITE CLOUD DATA  
ADDRESS INTO THE BLOCKCHAIN

Load time	Data directly stored in the Azure cloud platform (sec)	Writes into the blockchain after the Azure output data address (sec)
1	21.14s	51.42s
2	20.31s	64.36s
3	15.92s	40.55s
4	14.54s	52.31s
5	24.64s	36.96s
6	18.51s	88.49s
7	16.61s	37.12s
8	19.92s	35.71s
9	23.16s	21.33s
10	17.18s	46.40s
Avg time	19.19s	47.45s

contract and enable it to be executed automatically, and then use the blockchain as a connector to achieve decentralized storage as the core of the cloud storage [13].

Through the solutions proposed in this study, the blockchain will be continuously extended, and the nodes can be connected to each other [14]. Once the data are written into the block, it cannot be tampered with, which helps the cloud provider in ensuring the security of the user data. Moreover, the nodes that are distributed in the network can reduce the cost of network transaction, authentication, and collaboration and can effectively solve the synchronization problem of the traditional distributed database. However, the current transaction speed of Ethereum is still very slow, only 10~20 transactions per second use sharding or plasma as a blockchain expansion solution.

#### D. Discussion of the benefit of blockchain application services

The proposed application is based on the limit trading service in the SMSTS developed in this research. Through the characteristics of the blockchain, real-time delivery of stocks can be achieved. The settlement cost can be reduced and the stock or payment time can be shortened [15].

#### V. CONCLUSION

This research is divided into three parts. First, we set up the web server and database system of the stock market simulation program in our Internet data center, collect transaction information from it, and store the data directly in our private blockchain. Moreover, the storage, verification, transmission, and communication of network data are performed through distributed nodes. Our private chain can record, sort, and encrypt every transaction. Participants use the verification code to link the transaction records and then use the characteristics of the blockchain to save records of all transactions and ensure the integrity of the data. Thus, the transaction history cannot be falsified.

Secondly, as more SMEs turn to cloud computing services, the blockchain can create secure, effective, tamperproof, and democratic computing networks. In this study, the location of each data block is recorded in the blockchain. When the file needs to be accessed, the system will verify the identity according to the private key of the user and assemble the file. We found that combining data in a blockchain with a decentralized cloud is safer than storing it in a centralized system. One device does not contain complete files, which

makes it almost impossible for hackers to steal data, thus improving security and reliability.

Third, the smart contract can automate of the stock limit trading service. The actual stock transactions do not need to wait for the T+2 settlement cycle. The blockchain increases the flexibility of trading strategy execution and reduces the labor cost of transaction clearance and settlement.

The blockchain can effectively reduce the cost of authentication, network transactions, and collaboration [16], can control the reading and modification of data through public and private keys by taking into account transparency and privacy security, and is reliable. This study conducts preliminary experiments in using the blockchain as a connector to store cloud data, and in the future, it can be applied to other applicable cloud services, even in different application scenarios.

**Abstract**—Sales forecasting is an essential element for implementing sustainable business strategies in the automotive industry. Accurate sales forecasts enhance the competitive edge of car manufacturers in the effort to optimize their production planning processes. We propose a forecasting technique that combines keyword-specific customer online search data with economic variables to predict monthly car sales. To isolate online search data related to pre-purchase information search, we follow a backward induction approach and identify those keywords that are frequently applied by search engine users. In a set of experiments using real-world sales data and Google Trends, we find that our keyword-specific forecasting technique reduces the out-of-sample error by 5% as compared to existing techniques without systematic keyword selection. We also find that our regression models outperform the benchmark model by an out-of-sample prediction accuracy of up to 27%.

## I. INTRODUCTION

IMPROVING the accuracy of sales forecasts is an important business challenge for optimizing production planning. As a decisive component of planning processes, sales forecasts form the basis of managerial decision-making. The automotive industry is characterized by a complex and uncertain business environment forcing car manufacturers to constantly improve their supply chain efficiency to stay competitive [1]. Hence, sales forecasts have become an integral component of supply chain processes. Because automotive manufacturers have implemented built-to-forecast vehicle production systems [2], accurate predictions are indispensable to ensure efficient production processes, optimize inventory levels, and improve the overall market performance [3]. Moreover, increasing product individualization places ever-higher demands on business information systems [4] and material requirements planning [5]. Inaccurate predictions can lead to inventory shortages, overstocking or unsatisfied customer demands [6].

Forecasting the future demand for durable consumer goods such as cars is challenging for three reasons. First, reliable forecasting models must integrate accurate representations of the customer buying behavior. Potential customers typically engage in online searches to determine what car to buy. Searching for pre-purchase information is regarded as an integral element of the consumer's buying behavior [7].

Extensive online research applies in particular to the purchasing process of cars. About 50% of the customers spend more than ten hours to identify the best matching vehicle for their requirements [8]. Ernst and Young report that customers devote more time for online research per-purchase of a car than for any other product [9]. Customers use different keywords and combinations of keywords to determine their choice. However, the extent to which these keyword-specific search results affect the sales performance of car manufacturers is still not known. Hence, understanding the online search behavior of customers is critical to improve forecast models. Second, fluctuating macroeconomic factors have a significant impact on automobile sales [10]. If lagged effects of economic factors are not considered in forecasting models, the forecast accuracy is further impaired. Third, in addition to the seasonal demand pattern for cars, external factors such as marketing campaigns further complicate the forecasting process.

Prior research on sales forecasting has focused on rather simple techniques that incorporate historic sales data and/or socioeconomic variables but pay little attention to information reflecting customer search behavior [10]–[12]. Subsequent approaches use customer online search data to predict car sales. Choi and Varian (2009) study a model that incorporates Google search data [13]. Their findings provide econometric evidence that using Google data can enhance the prediction accuracy of car sales. As a consequence, Google search data have become an important element of sales forecasting in this field of research [14]–[16]. Although these approaches predict car sales based on customer search data, they do not systematically select the most relevant keywords used by customers, which might lead to sales of new cars.

Against this backdrop, we propose a novel forecasting technique that combines keyword-specific customer search behavior from Google Trends with a set of economic variables for sales prediction in the automotive industry using a regression approach. To identify the most relevant keywords that customers use in Google prior to purchasing a new car, we use a backward induction approach. By using Google Ads, we identify the most relevant keywords that customers used

<sup>1</sup>This work has been partially supported by the Federal Ministry of Economic Affairs and Energy under grant ZF4541001ED8.

in Google search in the context of buying a new car. We include keywords related to new car purchases and exclude keywords associated to post-purchase and other queries unrelated with pre-purchase searches. Then, we obtain the Google Trends monthly time series of the most relevant keywords for new car sales. To validate our proposal, we use a unique dataset of car sales of a large car manufacturer from 2004 to 2019.

We find that our proposed forecasting technique improves the out-of-sample prediction accuracy by up to 5% as compared to models based on the same Google Trends search data without systematic keyword selection. Furthermore, we find that our forecasting models improve the out-of-sample accuracy by up to 27% compared to well-accepted autoregressive benchmark models.

The remainder of this paper is organized as follows. The next section discusses related literature on forecasting using online search data. In section 3, we present our proposed forecasting technique. In section 4, we report the experimental evaluation and discuss our findings. We provide our conclusion in section 5.

## II. RELATED WORK

Online search engines are frequently used as a starting point for the online research [17], [18]. With a market share of 88.5%, Google is by far the most frequently used online search service in the USA [19]. Due to the huge amount of daily search queries, Google represents a “Treasure House for web data mining” and previous research has focused on the predictive power of the search data [20]. Beside their popularity, search engines provide the benefit that the collected search data is less biased as compared to other user generated online data. In contrast to the use of social media platforms, online research is conducted in private and the personal activity is not revealed to others resulting in a less biased user behavior [21]. In recent years, several studies made use of Google data to improve forecasting as well as nowcasting accuracies. While forecasting is defined as the prediction of future events, nowcasting refers to the prediction of “the present, very near future and the very recent past” [22].

One of the first attempts to integrate search query data into a prediction model was made in the field of epidemiology [23]–[25]. Ginsberg et al. were able to predict the weekly influenza activity with a time lag of one day as they discovered a high correlation between influenza-related search queries and the percentage of daily physicians visits in which a patient had influenza-like symptoms. Further publications focus on the prediction of country-specific unemployment rates [13], [26]–[30], stock market movements and returns [31], [32], travel activities [33], and housing sales [13], [34]. During recent years, Google search data was employed in a wide range of different contexts, thus demonstrating the broad scope of possible application.

### A. Prediction of car sales

The use of Google search data for the prediction of car sales or car registrations has raised significant attention in the literature. Chamberlin (2010), Seebach et al. (2011), Du and Kamakura (2012), and Choi and Varian (2012) were the first who examined the predictive power of Google search data in the context of car sales [35], [14], [36], [33]. They conclude that Google data reflect changes in the volume of car sales and appears to be an appropriate data source for prediction models.

Carrière-Swallow and Labbé (2013) propose an online search data index to improve nowcasting models, predicting automotive sales in Chile [15]. Although they observe a relatively low Internet usage among the Chilean population, the integration of Google data improved both in-sample and out-of-sample nowcasts. In the former case, the whole data sample is used to fit the model and the forecasted observations are part of this sample (in-sample). As an attempt to mimic real data constraints, in the latter case, only a subset of the data sample is used to fit the model of which the forecasted observations are not part of (out-of-sample) [37].

Barreira et al. (2013) examine the eligibility of Google search data as a predictor for car sales in four European countries (i.e., France, Italy, Portugal, Spain) [30]. In contrast to previous work, they find only little evidence that Google data improves the accuracy of the prediction models for the included countries.

Taking cars as an example of high-involvement products, Geva et al. (2015) aim to improve the accuracy of an out-of-sample forecast by combining forum data in form of social media mentions/sentiments and search data [21]. They find a significant improvement of the prediction accuracy if both data sources are included in the model as compared to forum data only. Moreover, they observe a stronger improvement of the prediction accuracy for value than for premium brands.

Benthaus and Skodda (2015) pursue a similar approach by combining search data with Twitter sentiment data [16]. The results are in line with the findings by Geva et al. as a combination of the two data sources leads to an improved accuracy, both in-sample and out-of-sample.

The findings of Wijnhoven and Plant (2017), however, indicate that social media sentiments only have a minor predictive power as compared to Google search data or social mentions [38]. Consequently, Wijnhoven and Plant propose to only incorporate Google data and social mentions in a prediction model.

Fantazzini and Toktamysova (2015) investigate the out-of-sample accuracy of multivariate models using Google search data and economic variables to predict monthly sales of several car brands in Germany [3]. They find that Google data-based prediction models outperform competing models especially for forecast horizons longer than 12 months.

Nymand-Andersen and Pantelidis (2018) investigate the usefulness of Google search data with respect to nowcasting of car sales in the euro area [39]. They highlight the predictive

capabilities of online search data; however, they also underscore the need to further improve the data quality.

### B. Motivation of the search engine user

Although the use of online search data for forecasting purposes has grown considerably, the search motivation of customers has so far received little attention. The impact of the search motive on the predictive quality of a search query index can be highlighted by the following example. The search term “Honda” comprises multiple search purposes such as gathering product information before purchase, gathering product information after purchase, and gathering news about the brand or the product. To use the Google Trends data as a predictor for new car sales, the search query index should only reflect search queries related to a purchase intention (i.e., pre-purchase search). Extracting pre-purchase searches from aggregated data, however, remains a challenge. One approach is to use appropriate search categories (e.g., vehicle shopping) to exclude searches unrelated to a purchase. Graevenitz et al. (2016) argue that the underlying algorithms might be altered over time or the customer search behavior changes with regard to the keyword use [40]. Instead, they develop a model that links distinct search motives to the search and sales data to estimate the effect of pre-purchase queries on car sales. Hu et al. (2014) pursue another approach and try to isolate pre-purchase searches by excluding terms associated to post-purchase and other non-new-car-shopping-related searches (e.g., “parts”, “repair”) [41]. Most of the studies discussed above use rather simple keyword combinations, which only comprise the brand and/or the model name (e.g., “Honda + Civic”) depending on the level of aggregation.

## III. FORECASTING TECHNIQUE

Our proposed forecasting technique for new car sales using Google Trends search data for most relevant keywords is described as a five-step process depicted in Fig. 1. In a first step, relevant keywords and data are collected. To account for seasonality, the data is transformed to obtain deseasonalized time series. In a preliminary analysis, we detect the time lag of the Google Trends data and the economic variables with the car sales data. To identify the Google Trends data with the highest predictive power, we perform both an in-sample and an out-of-sample regression analysis. In the last step, we develop several multivariable regression models and determine the respective in-sample and out-of-sample performance.

### A. Google Trends tool

In 2006, Google launched the search analysis website Google Trends. The publicly available tool provides information about aggregated individual searches expressed in a search volume index. Hence, Google does not report the data in absolute numbers but provides the relative popularity of a search term. The index is calculated by dividing the data points of a query by the total volume of searches of the geography and time range considered [42]. The query shares

are normalized, such that 100 indicates the highest query share of the whole period. Since the search volume indices are proportionated to time and space, Google Trends allows to compare the relative popularity of a query across different geographic locations and time intervals.

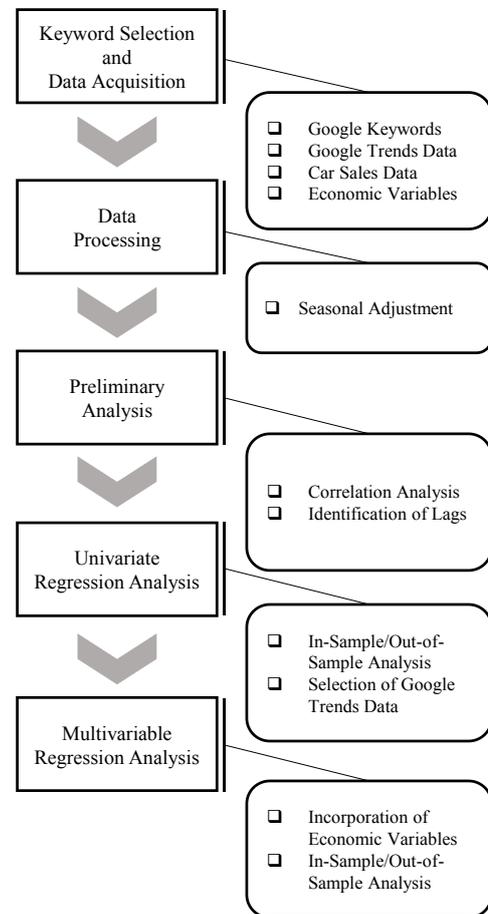

Fig. 1 Forecasting technique for car sales using most relevant search data

Moreover, Google introduced different categories and subcategories to refine the search for terms with multiple meanings. In the context of the automotive industry, the search results for “beetle” can be narrowed down by the choice of an appropriate category to exclude queries regarding the insect and only obtain results for the car offered by Volkswagen.

### B. Keyword selection

Selecting the most relevant keywords for Google Trends search is performed by using the online advertising platform Google Ads. Relevant keywords are identified following a backward induction approach [43]. The integrated Keyword planner tool suggests additional keywords based on keywords or groups of keywords entered by the user. The purpose of this process is to identify related keywords frequently employed by search engine users. We use the service to both identify top keywords that are commonly associated to new car purchase searches and keywords that relate to post-purchase or used car purchase searches.

### C. Data processing

Some data may exhibit a strong seasonality. To account for the systematic seasonal variation, we perform a decomposition operation. The time series is decomposed into a seasonally adjusted times series and the corresponding seasonal factors. This process is an implementation of the ratio-to-moving-average method (census method I). Due to the same reporting granularity the periodicity has not been adjusted.

### D. Preliminary analysis

This step encompasses a correlation analysis of the different Google Trends time series with the sales time series. As online information search is conducted in advance to new car shopping [44], we use cross-correlation to account for time lags. The incorporation of time lags is an essential prerequisite to obtain the optimal correlation between the data and to allow for forecasting the future instead of explaining the present. Cross-correlation has already been used to identify time lags in related previous work [14], [16]. The procedure is also applied to the selected economic variables. Moreover, the variables are checked for multicollinearity via bivariate Pearson correlation to prevent statistical and numerical issues in our subsequent regression analysis [45].

### E. Regression analysis

To determine the predictive power of Google Trends, search data (independent variable) and car sales (dependent variable) are used to estimate univariate linear regression models. We measure the in-sample and out-of-sample performance to identify the model with the best fit. Time lags detected during the preliminary analysis are taken into account for the model computation. We apply two performance criteria to evaluate the quality of the linear regression models. Both, Mean Absolute Error (MAE) and Root Mean Squared Error (RMSE) are frequently employed for model evaluations [14], [16].

MAE measures the average magnitude of errors in a set of data regardless of the direction of the errors. As a linear score, all the individual differences are weighted the same. As shown in formula (1), the absolute difference of actual sales at time  $t$  ( $y_t$ ) and the predicted sales at time  $t$  ( $\hat{y}_t$ ) is divided by the number of observations ( $n$ ).

$$MAE = \frac{1}{n} \sum_{t=1}^n |y_t - \hat{y}_t| \quad (1)$$

For the second regression metric, the error is also calculated as an average of the absolute differences between actual sales and predicted values, however, the individual deviations have been squared before. This leads to the fact that the RSME (see formula 2) is more sensitive to outliers.

$$RMSE = \sqrt{\frac{1}{n} \sum_{t=1}^n (y_t - \hat{y}_t)^2} \quad (2)$$

After identifying the Google Trends data with the best in-sample accuracy, we estimate additional multivariable linear regression models by including different combinations of economic variables.

As a benchmark, we use a seasonal autoregressive baseline model (see formula 3) previously applied in several studies [33], [39]. The model uses 12 months ( $S_{t-12}$ ) and 1-month ( $S_{t-1}$ ) lagged historic sales data and an error term  $\varepsilon_t$  to predict car sales  $S_t$ .

$$S_t = \beta_0 + \beta_1 S_{t-12} + \beta_2 S_{t-1} + \varepsilon_t \quad (3)$$

## IV. EVALUATION

This section reports an experimental evaluation of our forecasting technique for car sales based on most relevant Google Trends data. We describe the setup, report the results, and discuss the findings

### A. Experimental setup

We collected monthly search query indices for the respective car model and/or car brand in combination with the most relevant keywords selected via Google Ads. We focus on the car manufacturer Honda as a representative of a large seller in the US. To obtain Google Trends data for the brand Honda, we additionally include the model names of the four best-selling car models responsible for approximately 90% of the Honda car sales in the period considered. The intention is to achieve a high coverage of search queries for Honda cars by using the top sellers as a proxy. To exclude searches unrelated to the automotive industry the search query indices are generated within the category “Autos & Vehicles”. The result data are limited to searches originating from the US in the period from January 2004 to February 2019.

Our evaluation is based on a unique dataset containing the monthly US car sales from January 2004 to January 2016. We obtained additional data from February 2015 to February 2019 from the automotive industry analysis website CarSaleBase [46], which has been used as a source for automotive sales information in prior research [47]. To ensure the consistency of the two datasets, we check that the car sales data are congruent in 2015. We obtained 182 observations for each Honda car model.

The economic variables have been systematically selected on the basis of relevant literature [3], [48]–[50]. The variables either reflect changes in the price paid by automobile consumers, affect the automobile sales demand, or describe the state of the US economy [50]. Table I shows the selected variables and the respective descriptions.

TABLE I.  
ECONOMIC VARIABLES

Economic variable	Source	Description
Consumer confidence index (CCI)	OECD	The index provides a measure for the consumer confidence and indicates future developments regarding consumption and saving
Consumer price index for new vehicles (CPI)	BLS	The index reflects changes in the price level for new vehicles (base period 1982-1984=100)
Gasoline price	EIA	The monthly retail price of US regular all formulations gasoline price
Unemployment rate	BLS	US national unemployment rate
Standard & Poor's 500 Index (S&P 500)	Yahoo finance	US stock market benchmark

BLS: Bureau of Labor Statistics; EIA: Energy Information Administration; OECD: Organization for Economic Cooperation and Development

We used data from January 2004 to August 2017 to estimate the linear regression models. Consequently, this is also the period for the in-sample analysis. To evaluate the out-of-sample performance, we used the in-sample estimated models to predict car sales from September 2017 to February 2019.

As a linear relationship between the independent and the dependent variables is a fundamental prerequisite for a linear regression analysis, we verify linearity by using scatterplots. To ensure that the remaining assumptions are fulfilled, we analyzed the histogram of residuals and the P-P plot. To ensure homogeneity of variances, we examined a scatterplot of the predicted values and the residuals.

B. Results

We identified frequently employed keywords for searches relating to new car purchases and for searches not related to pre-purchase situations using the keyword planner tool of Google Ads. While pre-purchase keywords often relate to the procurement processes (e.g., search for car dealers), pre-purchase unrelated keywords predominantly cover attributes associated to used cars or car maintenance and repairs. Table II shows the different brand-related keyword sets, additional pre-purchase keywords, and the pre-purchase unrelated keywords that can be used for reducing search data results.

TABLE II.  
KEYWORDS USED FOR RETRIEVING GOOGLE TRENDS SEARCH DATA

	Brand-related keyword sets	Pre-purchase keywords	Pre-purchase unrelated keywords
1	honda	new + buy +	repair -tires -
2	civic + accord + crv + odyssey	dealers + dealerships + compare	mechanic - maintenance - inspection -old - used -owned - parts -lease
3	honda + civic + accord + crv + odyssey		

Table III shows the in-sample performance of the different regression models. We conducted an in-sample cross-correlation analysis to detect the optimal time lag between the Google Trends data and the sales data. For each Google Trends time series, the highest correlation was identified without any time lag. Our results indicate a positive relationship between Google Trends search data and car sales for all univariate linear regression models. The correlation coefficients ranged from 0.69 to 0.83 and were significant at  $p < 0.01$ . Search queries based on keywords for car models (set 2 in Table II) resulted in Google Trends data with the highest explanatory power in the in-sample analysis. The results also imply that specifying pre-purchase unrelated keywords to be excluded from search data further improves the model

TABLE III.  
IN-SAMPLE PERFORMANCE OF GOOGLE TRENDS BASED LINEAR REGRESSION MODELS

Keyword set (brand)	Keywords (pre-purchase)	Keywords (pre-purchase unrelated)	Correlation coefficient	Root mean squared error	Mean absolute error
1			0.70**	14845.5	11830.2
	●		0.69**	15133.2	11591.5
		●	0.72**	14603.9	11751.8
	●	●	0.69**	15150.8	11631.4
2			0.82**	11873.5	8864.5
	●		0.71**	14787.2	11687.4
		●	0.83**	11815.0	8856.0
3			0.71**	14819.7	11829.4
	●		0.69**	15228.5	11796.4
		●	0.79**	12952.9	10335.0

\*\* $p < 0.01$

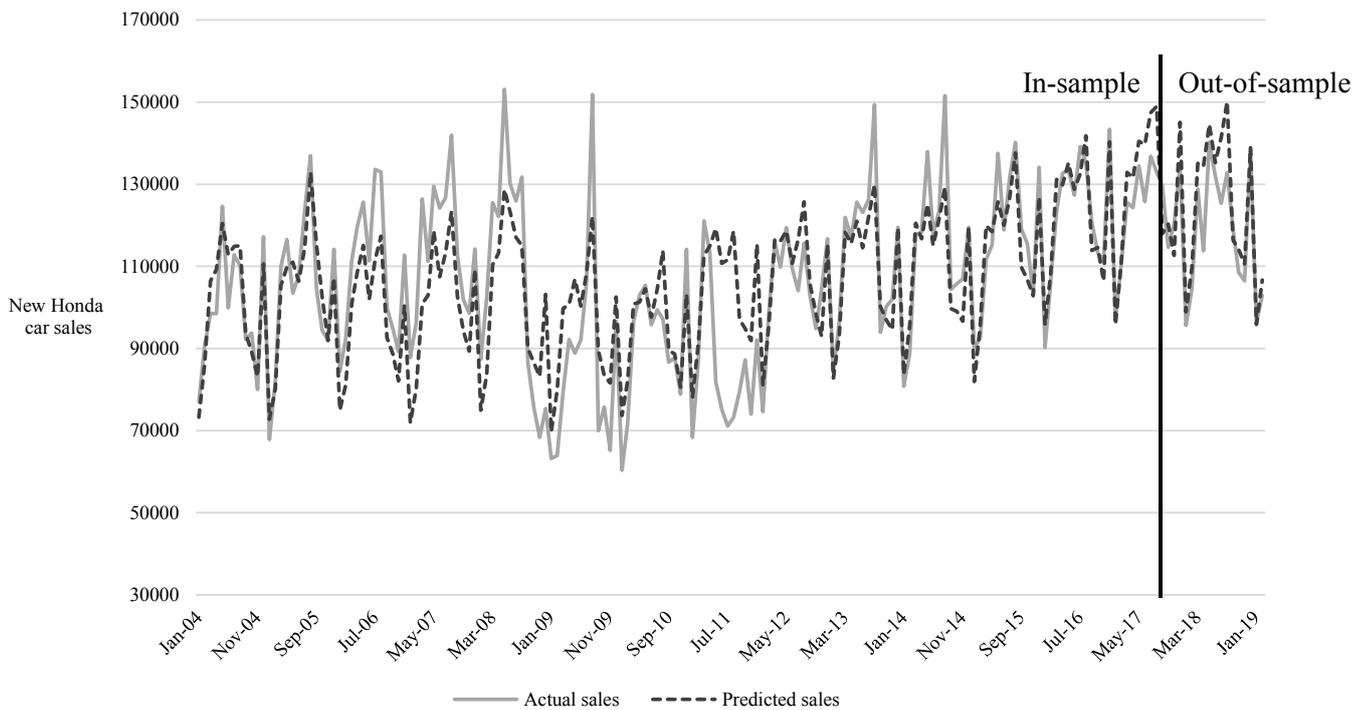

Fig. 2 Actual car sales and predicted sales based on most predictive Google Trends data

performance. That is, using car model keywords and specifying pre-purchase unrelated keywords for exclusion leads to lowest error measures among all regression models in the in-sample analysis (RMSE=11815; MAE=8856).

Excluding pre-purchase unrelated keywords from Google Trends data on car model keywords (set 2 in Table II) reduced the out-of-sample MAE by 5% from 7564.2 to 7183.8. Compared to Google Trends data on brand name (set 1 in Table II) without considering further keywords, the out-of-sample error (MAE=16796.8) is reduced by more than half. However, including keywords related to new car purchases do not reduce the prediction error. Fig. 2 illustrates actual sales and predicted sales using Google Trends data with the highest in-sample and out-of-sample accuracy. The figure demonstrates face validity of our approach.

After selecting the Google Trends data with the lowest prediction error, we conducted an out-of-sample analysis with a time horizon of 18 months. We included a set of economic variables to test for further reducing the prediction error. Since most of the economic variables are known to be leading or lagging indicators, we first identified the most predictive time lags via cross-correlation with the car sales data. Time lags were restricted to -12 to 0 months. If positive time lags for the variables were detected (i.e., economic variable from January 2016 has the highest correlation with car sales from December 2015), we incorporated no time lag. Table IV shows the chosen time lags for the economic variables and the corresponding correlation matrix.

TABLE IV.  
CORRELATIONS BETWEEN CAR SALES AND ECONOMIC VARIABLES

Variable	Optimal time lag in months	Sales	CPI	CCI	S&P 500	Unempl.
Sales						
CPI	-12	0.60**				
CCI	-10	0.57**	0.40**			
S&P 500	0	0.67**	0.91**	0.44**		
Unempl.	0	-0.63**	-0.38**	-0.89**	-0.50**	
Gasol. p.	0	0.04	0.69	-0.44**	0.04	0.39**

\*\*p<0.01; Unempl.: Unemployment; Gasol. p.: Gasoline price

All economic variables except the gasoline price showed a statistically significant correlation with car sales at  $p<0.01$ . The strongest correlation with car sales was observed for S&P 500 without time lag. Based on this preliminary analysis, we systematically generated univariate and multivariable linear regression models. The combination of predictors was restricted by the prevention of multicollinearity effects. Multicollinearity refers to a state of very high intercorrelation among the independent variables, which potentially impairs the unbiased estimation of the regression coefficients.

Because the gasoline price did not correlate with car sales in our analysis, the variable was not incorporated in any model. In addition to combinations of Google Trends data and 1-month lagged Google Trends data with each economic variable, we included all eligible combinations of economic variables.

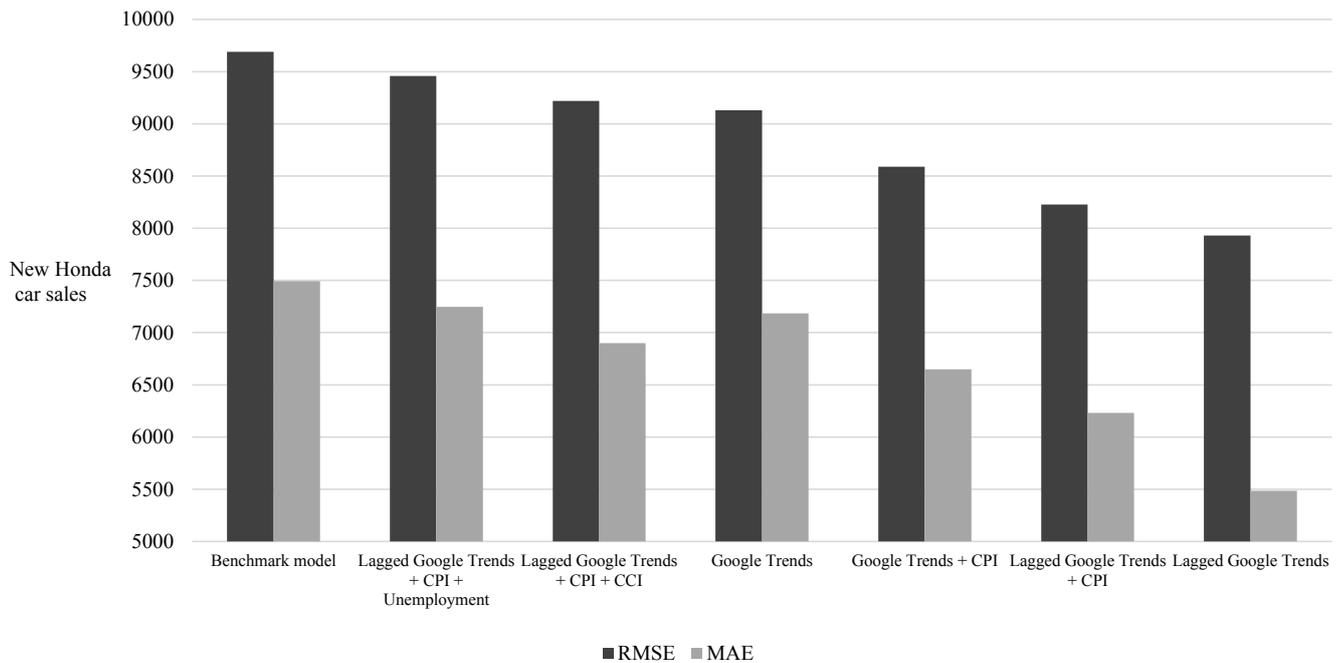

Fig. 3 Out-of-sample car sales prediction error of linear regression models with different predictive variables

Fig. 3 shows the results of the out-of-sample evaluation on a prediction horizon of 18 months. The figure only includes prediction models that outperformed the benchmark model. Both univariate Google Trends models achieved higher prediction accuracies compared to the benchmark model. A combination of Google Trends with economic variables did not necessarily improve the out-of-sample performance. A 12-months lagged CPI appeared to be the only predictor that decreases the forecasting error for unlagged Google Trends. All other multivariable regression models failed to improve the performance of the respective univariate Google Trends model. Although the in-sample error of Google Trends data with a time lag of one month (MAE=9536.5) is higher than that of Google Trends without time lag (MAE=8811.8), lagged Google Trends data achieved the smallest out-of-sample prediction error.

All (multiple) linear regressions met the criteria for linear regressions. For some of the linear regressions, we observed a slight bunching of the residuals, resulting in not perfectly identically distributed values. However, we considered the homoscedasticity assumption as fulfilled.

### C. Discussion

Our experiments demonstrate the effectiveness of carefully selected customer online search data from Google for accurately predicting automotive sales. Our findings provide evidence that our proposed forecasting technique benefits from the predictive power of Google Trends data. In the following paragraphs, we discuss the insights that can be obtained from our research.

Although most customers engage in online information search prior to the purchase of a new car, our results imply that Google Trends search data without any time lag yield the highest correlation with car sales. That is, Google Trends data

is most effective for predicting car sales of the current month. This finding is consistent with the results of prior research that identifies only few to no month(s) time lag [15], [16].

In the 18 months out-of-sample analysis, however, we find the highest performance using Google Trends data with a time lag of one month. Prior research suggests that, high in-sample prediction accuracy does not necessarily lead to high accuracy in an out-of-sample analysis and vice versa [14].

Our technique achieved the highest in-sample and out-of-sample accuracy for Google Trends data based on car model names combined with an exclusion of search queries containing keywords unrelated to pre-purchase situations. This finding becomes particularly evident in the out-of-sample analysis. Here, the prediction error was reduced by approximately 5% as compared to Google Trends data without keyword exclusion. Although adding pre-purchase associated keywords did not improve the model performance, systematic keyword use improved the predictive power of the Google Trends data in general.

While we find, with one exception, that incorporating the selected economic variables does not reduce the out-of-sample error, the in-sample performance was generally improved by adding the economic variables. While for the basic Google Trends data, combinations with both CCI and unemployment rate reduce the in-sample error, any two-variable combination of Google Trends data with a time lag of one month with one of the economic variables (CPI, CCI, S&P 500, unemployment rate) improves the in-sample performance. Moreover, any tested three-variable combination (Google Trends + economic variable 1 + economic variable 2) outperformed the respective univariate Google Trends regression model in the in-sample analysis. As depicted in Fig. 3, several multivariable regression models attained smaller prediction errors in the out-of-sample

analysis as compared to the benchmark model. A combination of Google Trends data with economic variables, however, did not always improve the accuracy of the corresponding univariate Google Trends model.

Future research might be pursued in at least two directions. First, while we focus on top keywords proposed by the keyword planner tool of Google Ads in this work, integrating additional keywords and keyword combinations could further improve the accuracy of the prediction. These additional keywords could be obtained by empirical studies that focus on customer search behavior. Second, although our experimental setup appears to be sufficient for our research purpose, more sophisticated methods for sales forecasting are available. Hence, our approach might be extended to machine learning methods such as Neural Networks.

## V. CONCLUSION

Our findings imply that predictions based on most relevant Google Trends search data that exclude pre-purchase unrelated searches improve the out-of-sample accuracy by up to 5% as compared to Google Trends data without systematic keyword selection. Moreover, we combine Google Trends data with relevant economic variables commonly employed for new car sales forecasting. In the performance evaluation of our linear regression models against a common seasonal autoregressive benchmark model, we find an improvement of the out-of-sample accuracy of up to 27%. Our findings help car manufacturers to obtain better forecasts and to make more informed decisions concerning their business strategies for production planning.

# Exploring Levels of ICT Adoption and Sustainable Development – The Case of Polish Enterprises

Ewa Ziemba

University of Economics in Katowice  
1 Maja 50, 40-287 Katowice, Poland  
ewa.ziemba@ue.katowice.pl

**Abstract**— This study is a part research on the effect of information and communication technologies (ICT) adoption on sustainable development in the enterprises' context [1]–[3]. Its main purpose is to identify parameters stimulating the progress of ICT adoption and sustainable development and assess the two constructs based on these parameters. The identified parameters of ICT adoption are grouped into four categories i.e., ICT outlay, information culture, ICT management, and ICT quality, whereas the parameters of sustainable development are classified into ecological, economic, socio-cultural, and political sustainability categories. This study employs a quantitative approach and descriptive statistics are employed to evaluate the levels of ICT adoption and sustainable development. The survey questionnaire was used and data collected from 394 enterprises were analyzed. The research findings reveal that digital and socio-cultural competences of employees and managers, financial capabilities ensuring ICT projects as well as law regulations associated with ICT adoption, and information security were at the highest level within enterprises. However, the lowest level was specific for BI and ERP system adoption as well as the adoption of latest management concepts and the exploitation of synergies between national ICT projects and own ones. Moreover, the improvement of efficiency and effectiveness of customer services, better and more efficient organization of work, the enhancement of customer satisfaction and loyalty and the acquirement of new customers and markets were at the highest level within enterprises. However, the lowest level was specific for enterprises' participation in the democratic public decision-making as well as energy savings and environmental protection. This study advances ongoing research on ICT adoption and sustainable development by exploring parameters which can be used to describe and assess the levels of ICT adoption and sustainable development in the context of enterprises. Moreover, these parameters help clarify areas that need further improvement and stimulate the progress of ICT adoption and sustainable development.

## I. INTRODUCTION

A new paradigm for economic growth, social equality and environmental protection was set in 1987 and introduced the concept of sustainable development to the international community [4]. Sustainable development is a development in which the needs of present generations are met without compromising the chances of future generations to meet their own needs [5]. According to Schauer [6], sustainable development has four dimensions which are ecological, social, economic and cultural sustainability. Ziemba [1] added a political dimension of sustainable development. Furthermore, it can occur at different levels

and within different contexts as many stakeholders on global, national, and community levels are involved in sustainable development [7]. Besides citizens and public administration, enterprises are one of these stakeholders that can contribute to sustainable development and benefit from it [8].

Bisk and Božić [9] highlighted that sustainable development today can best be attained by technological growth, whereas Grunwald [10] assessed the relation between technology and sustainable development as ambivalent. In particular, information and communication technologies (ICT) are a key enabler for sustainable development [11]–[13]. They make significant contributions to revolutionary changes in everyday life, business, and public administration, transforming society and fuelling economic growth. If society stakeholders are unable to acquire the capabilities to adopt ICT effectively, they will be increasingly disadvantaged or even excluded from the benefits afforded by ICT [8]. Some researchers have recognized ICT as one of the most important tools in developing sustainable business practices [14] and supporting the success of businesses [15]. It is contended that ICT enable businesses to improve productivity, foster innovation, cut down costs, increase the effectiveness of processes services, augment the efficiency of business decision-making, react to customer needs at a faster rate, and acquire new ones [16], [14]. Moreover, the ICT adoption by enterprises can gain benefits in environmental preservation by increasing energy efficiency and equipment utilization as well as it can increase information availability to all society stakeholders [6] and as a consequence influence social development [11].

After extensively searching the literature it can be noticed that ICT adoption and sustainable development require in-depth research, inter alia, research on assessing the levels of ICT adoption and sustainable development, and indicating areas that should to be improved. We need to have quantitative tools for describing and measuring the state of ICT adoption and sustainable development in the enterprises' context. These tools should allow to define the direction of desirable actions aimed at facilitating sustainable development as a result of ICT adoption.

There are some indicators and synthetic indexes for assessing ICT adoption, e.g. ICT Development Index (IDI) worked out by International Telecommunication Union [17] and Networked Readiness Index (NRI) of the authorship of

the World Economic Forum [18]. Sets of indicators for measuring sustainable development exist already prepared by Eurostat [19] and OECD [20]. Following an extensive review of the literature, it can be stated that it did not uncover any deep studies providing objective assessment parameters of ICT adoption within enterprises and sustainable development in the enterprises' context. Such parameters would help clarify areas that need further improvement and stimulate the progress of ICT adoption and sustainable development. This paper, therefore, focuses on exploring such parameters. Its aim is to propose parameters describing the progress of ICT adoption and sustainable development and assess the level of ICT adoption and sustainable development based on them.

This paper contributes to the literature in several ways. Section II reviews the current research on ICT adoption within enterprises, sustainable development in the enterprises' context and the assessment of these two constructs. Section III describes the unique research methodology and the data set used for the empirical work. Based on these data, Section IV presents the results, including an assessment of the levels of ICT adoption within enterprises and sustainable development in the enterprises' context. Section V provides the study's contributions, implications, and limitations as well as considerations for future investigative work.

## II. THEORETICAL BACKGROUND AND RESEARCH QUESTION

### A. Sustainable development

There are multiple definitions of the concept of "sustainable development". The most frequently quoted definition comes from the World Commission on Environment and Development, now known as the Brundtland Commission. According to it, the purpose of sustainable development is to meet "the needs of the present without compromising the ability of future generations to meet their own needs" [21, p. 43]. This definition clarifies the primary essence of the concept: the ability to self-sustain development that does not degrade the factors and mechanisms which constitute it.

Looking more closely into the term "sustainable", it is defined as something that is "able to be upheld or defended" [22]. The definition consists of two distinctive parts; the first one implies that sustainable development is the development that can be retained over time, while the second one indicates that sustainable development is the development that can be shielded from the consequences of negative events and processes. These two parts are closely linked, as it is not only events and processes that may affect development, but the means for development may also augment or create new events and fundamental processes that in turn make the task of maintaining development over time exacting [23]. For instance, our dependency of ICT has allowed for great developmental leaps of many societies since the industrial revolution, but is at the same time the

main cause of rising energy consumption and climate change that are now threatening the sole existence of all societies.

The core of the concept of sustainable development embraces two mutually exclusive ideas: the human need to preserve natural resources, and the need to improve the quality of life. Initially, it combined concerns about poverty and development with environmental issues. Then, interpretations of this definition were advanced, ranging from the "pure ecologist" position, through "moderate ecologist," "crash barrier," and "3D," to "4D" [6]. The first two interpretations are purely focused on the ecological dimension. In the "crash barrier" interpretation, the relationship with ecology is weaker, and it places equal weight on social and ecological issues. "3D" defines a further dimension of sustainability, encompassing ecological, social, and economic questions that have equal importance and have to respect each other. In the "4D" approach, cultural dimensions are introduced. Sustainable development is, however, a debatable concept due to its indefinite meaning, which is open to a variety of interpretations, depending upon the given situation [24].

A deeper understanding of the interconnected challenges the world faces allow to recognize that sustainable development has to embrace several sustainability pillars: from the three fundamental pillars related to environmental, economic and social aspects [6], [7] to pillars concerning cultural [25], [26] and political sustainability [25], [27].

This paper defines sustainable development in the enterprises' context as: a dynamic process which enables enterprises to realize their potential and improve their competences and business in ways that simultaneously protect and enhance ecological (Ecl), economic (Eco), socio-cultural (Soc), and political (Pol) sustainability.

Ecological sustainability is the ability of enterprises to retain rates of renewable resource acquisition, pollution creation, and non-renewable resource depletion by means of conservation and appropriate use of air, water, and land resources [28], [29]. Economic sustainability of enterprises means that enterprises can obtain competitive advantage, boost their market share, and increase shareholder value by adopting sustainable practices and models. Among the core drivers of a business case for sustainability are: cost and cost reduction, sales and profit margin, reputation and brand value, innovative capabilities [16], [30]. Socio-cultural sustainability is founded on the socio-cultural aspects that need to be sustained e.g., trust, common meaning, diversity as well as capacity for learning and capacity for self-organization [5]. It is perceived as dependent on social networks, making community contributions, creating a sense of place and offering community stability and security [27], [31]. Political sustainability must be built on the basic values of democracy and effective appropriation of all rights. It is connected with the engagement of enterprises in creating democratic society [27]. Based on the stream of research, Ziemba [1] indicated parameters that fully describe those pillars of sustainable development (Table I).

### B. ICT adoption for sustainable development

ICT represent significant opportunities for sustainable development [11], [12], [32]. The rapid evolution of ICT not only has radically changed of everyday life [33] but also businesses [34]. It has provided enterprises with new instruments to add value to various kinds of sustainability [16], [35].

ICT can be defined as any type of software and hardware used to create, capture, manipulate, communicate, exchange, present, and use information in its various forms” [36, p. 198]. Research on ICT adoption is mainly directed to the development of forecasting studies and the identification of barriers and drivers of technology adoption [37]. Reino et al. [37] indicated two main approaches that can be adopted for the study of ICT adoption phenomenon. These are intra-enterprise and inter-enterprise adoption. The former relates to the process by which ICT are fully adopted by an enterprise from their purchase to the full integration as part of the business strategy. The latter refers to the phenomena by which ICT adoption take place among an enterprise and its stakeholders as consumers, public administration and other enterprises [38]. It should therefore be acknowledged that ICT adoption takes place in stages and this implies that different levels of ICT adoption can be identified within enterprises.

Furthermore, many investigators, as well as developmental organizations recognize the significance of ICT for sustainable development [6], [11], [35], [39], [40]. ICT are accelerators, amplifiers, and augmenters of sustainable development. They make it feasible to enhance sustainable development more flexibly and dynamically. More pointedly, ICT presents opportunities to make trade-offs

between economic growth, the environment and social cohesion as well as culture and political issues [41]. Equally, there is the opportunity to maximize the social, ecological, economic and cultural opportunities of ICT and mitigate its adverse impacts.

In this study, ICT adoption has been explored in terms of intra-enterprise. Nevertheless, some issues of inter-enterprise adoption have been taken into consideration e.g., related to an enterprise’s collaboration with its customers. ICT adoption is understood as the whole spectrum of activities from the period when enterprises justify the need for adopting ICT until the period when enterprises experience the full potential of ICT and derive ecological, economic, socio-cultural and political sustainability from them [1]. The following four pillars of ICT adoption within enterprises are recognized: ICT outlay (Out), information culture (Cul), ICT management (Man), and ICT quality (Qua) [1], [2].

ICT outlay consists of the enterprises’ financial capabilities and expenditure on the ICT adoption, as well as funding acquired by enterprises from the European funds. The information culture component encompasses digital and socio-cultural competences of enterprises’ employees and managers, constant enhancement of these competences, personal mastery, and incentive systems fostering ICT adoption by employees. The ICT management component embraces the alignment between business and ICT, top management support for ICT projects in the entire ICT adoption lifecycle, implementation of law regulations associated with the ICT adoption, regulations on ICT and information security and protection. The ICT quality component comprises the quality and security of back- and front-office information systems, quality of hardware,

TABLE I.  
PARAMETERS OF ICT ADOPTION AND SUSTAINABLE DEVELOPMENT IN THE ENTERPRISES’ CONTEXT

Parameters of ICT adoption				Parameters of sustainable development	
<b>Out1</b>	Financial capabilities	<b>Man16</b>	ICT project team	<b>Ecl1</b>	Sustainability in ICT
<b>Out2</b>	Expenditure on ICT	<b>Man17</b>	Top management support	<b>Ecl2</b>	Sustainability by ICT

maturity of e-services, and adoption of ERP and BI systems. Table I describes each of the above ICT adoption pillars.

### C. Problem identification and research questions

ICT adoption for sustainable development is not a destination, but a dynamic process of adaptation, learning and action. It is about recognizing, understanding and acting on ICT adoption and sustainable development as well as on interconnections between them.

As mentioned above, in the previous study Ziemia [1] indicated parameters describing the constructs of ICT adoption and sustainable development in the enterprises' context, and then grouped them into appropriate pillars (Table I). ICT adoption embraces ICT outlay, information culture, ICT management and ICT quality, whereas sustainable development includes ecological, economic, socio-cultural and political sustainabilities. Then the quality of the two constructs was assessed by examining the construct reliability [42], convergent validity [43], [44], and discriminant validity [43], [45]. Overall, the results successfully established the reliability as well as convergent and discriminant validity of ICT adoption and sustainable development, and their pillars. Furthermore, the levels of ICT and sustainable development pillars were assessed (Table II) and the approach to the measurement of the two constructs ICT was proposed [3].

## III. RESEARCH METHODOLOGY

To address the main research problem and answer the research questions a quantitative research approach was adopted. Research methods included a critical review of the literature, logical deduction, a survey questionnaire, and statistical analysis. The research process has been described in the previous works [1], [2] but for the ease of this paper readability and sake of its completeness, it is also presented below.

### A. Research instrument

The Likert-type instrument (survey questionnaire) was developed. Closed-ended questions were specified to collect data regarding the evaluation of the parameters describing:

- The four pillars of ICT adoption i.e., ICT outlay (Out), information culture (Cul), ICT management (Man), and ICT quality (Qua) (Table I). The respondents answered the question: *Using a scale of 1 to 5, state to what extent do you agree that the following situations and phenomena result in the efficient and effective ICT adoption in your enterprise?* The scale's descriptions were: 5 – strongly agree, 4 – rather agree, 3 – neither agree nor disagree, 2 – rather disagree, 1 – strongly disagree; and
- The four pillars of sustainable development i.e., ecological (Ecl), economic (Eco), socio-cultural (Soc),

TABLE II.  
THE LEVELS OF ICT ADOPTION AND SUSTAINABLE DEVELOPMENT IN THE ENTERPRISES' CONTEXT (N=394)

Pillar	Mean	Q25	MDN	Q75	VAR	SD	CV in %	SK	CK

Source: [2]

The present study examines and evaluates particular parameters shaping each of ICT adoption and sustainable development pillars in the context of Polish enterprises. It focuses on addressing the following two research question:

RQ1: What is the level of ICT adoption in Polish enterprises?

RQ2: What is the level of sustainable development in the context of Polish enterprises?

and political sustainability (Pol) (Table I). The respondents answered the question: *Using a scale of 1 to 5, evaluate the following benefits for your enterprise resulting from the efficient and effective ICT adoption?* The scale's descriptions were: 5 – strongly large, 4 – rather large, 3 – neither large nor disagree, 2 – rather small, 1 – strongly small.

### B. Research subjects and procedure

In April 2016, the pilot study was conducted to verify the survey questionnaire. Ten experts participated in the study i.e., five researchers in business informatics and five managers from five enterprises – leaders in the ICT application. Finishing touches were put into the questionnaire, especially of a formal and technical nature. No substantive amendments were required.

The subjects in the study were enterprises from the Silesian Province in Poland. The choice of this region was driven by the fact of its continuous and creative transformations related to restructuring and reducing the role of heavy industry in the development of research and science, supporting innovation, using *know-how* and transferring new technologies, as well as increasing importance of services. In response to the changing socio-economic and technological environment intensive work on the development of the information society has been undertaken in the region for several years. In the next development strategies of the information society it was and is assumed that the potential of the region, especially in the design, provision and use of advanced information and communication technologies will be increased [46]. All this means that the results of this research can be reflected in innovative efforts to build a sustainable information society in the region and, at the same time, constitute *a modus operandi* for other regions throughout the country and other countries.

Selecting a sample is a fundamental element of a positivistic study [47]. The stratified sampling and snowball sampling were therefore used to obtain the sample that can be taken to be true for the whole population. The strata were identified based on enterprise's size (defined in terms of the number of employees), economy sector, and type of business activity (defined in terms of related to ICT and non-ICT activities).

The subjects were advised that their participation in completing the survey was voluntary. At the same time, they were assured anonymity and guaranteed that their responses would be kept confidential.

### C. Data collection

Having applied the Computer Assisted Web Interview and employed the SurveyMonkey platform, the survey questionnaire was uploaded to the website. The data were collected during a two-month period of intense work, between May 12, 2016 and July 12, 2016. After screening the responses and excluding outliers, there was a final sample of 394 usable, correct, and complete responses. The sample error for an infinite population was of about 5% for a confidence level 97% ( $p = q = 0.5$ ) which previous studies have suggested as acceptable [48], [49]. Additionally, it presented a successful representation of the different business types, economy sectors and size categories.

Table III provides details about enterprise's size, type of the business activities, and economy sector.

TABLE III.  
ANALYSIS OF ENTERPRISES PROFILES (N=394)

Characteristics	Frequency	Percentage
<b>Number of employees</b>		
250 and above (large)	78	19.80%
50–249 (medium)	83	21.07%
10–49 (small)	122	30.96%
less than 10 (micro)	111	28.17%
<b>Economy sector</b>		
I sector – producing raw material and basic foods	27	6.85%
II sector – manufacturing, processing, and construction	83	21.07%
III sector – providing services to the general population and to businesses	238	60.40%
IV sector – including intellectual activities	46	11.68%
<b>Business activities</b>		
ICT (manufacturing, trade, services)	136	34.52%
No ICT	258	65.48%

Source: own elaboration.

### D. Data analysis

The data were stored in Microsoft Excel format. Using Statistica package and Microsoft Excel, the data were analyzed. The descriptive statistical analysis was employed to describe the levels of ICT adoption and sustainable development parameters within enterprises. The following statistics were calculated: mean, median (MDN), first quartile (Q25), third quartile (Q75), mode, variance (VAR), standard deviation (SD), coefficient of variation (CV), skewness (SK), and coefficient of kurtosis (CK).

## IV. RESEARCH FINDINGS

### A. The level of ICT adoption within enterprises

In order to answer the research question *RQ1: What is the level of ICT adoption in Polish enterprises?*, a detailed descriptive analysis was conducted. The results are presented in Table IV.

It has been found that the average levels of ICT adoption parameters ranged from 3.24 to 4.22 (on a 5-point scale from 1.00 to 5.00). The median values were in the range between 3.00 and 5.00, whereas the mode values were 4 or 5. On average, the highest levels are specific for parameters related mainly to three ICT adoption pillars i.e., information culture, ICT management, and ICT outlay.

The highest ranked parameters of ICT adoption were (Table IV):

TABLE IV.  
THE LEVELS OF ICT ADOPTION PARAMETERS IN THE ENTERPRISES' CONTEXT (N=394)

Parameters	Mean	Q25	MDN	Q75	Mode	Sample volume for Mode	VAR	SD	CV in %

Man17	3.68	3	4	4	4	171	1.25	1.12	30.36
Man18	3.47	3	4	4	4	157	1.36	1.17	33.60
Man19	3.88	3	4	5	4	160	1.27	1.13	29.05
Man20	3.92	3	4	5	4	148	1.24	1.11	28.36
Man21	3.25	2	3	4	4	122	1.60	1.27	38.93
Man22	3.33	2	3	4	4	125	1.40	1.18	35.48
Qua23	3.66	3	4	5	4	151	1.49	1.22	33.34
Qua24	3.68	3	4	4	4	170	1.25	1.12	30.43
Qua25	3.71	3	4	5	4	161	1.25	1.12	30.10
Qua26	3.77	3	4	5	5	132	1.44	1.20	31.78
Qua27	3.75	3	4	5	4	142	1.50	1.22	32.67
Qua28	3.53	3	4	4	4	160	1.42	1.19	33.73
Qua29	3.44	2	4	4	4	130	1.57	1.25	36.52
Qua30	3.24	2	4	4	4	134	1.69	1.30	40.20

Note: mean, median (MDN), first quartile (Q25), third quartile (Q75), variance (VAR), standard deviation (SD), coefficient of variation (CV), skewness (SK), and coefficient of kurtosis (CK).

- Cul5 (mean = 4.22, MDN = 4, mode = 5) and Cul4 (mean = 4.20, MDN = 5, mode = 5). It means that digital competences of enterprises' employees and managers are relatively high. Managers and employees are able to operate a computer and the Internet, use a different kind of software and applications, search for information, use it and evaluate its usefulness, as well as creatively, efficiently and effectively use ICT so as to achieve a variety of business benefits;
- Cul10 (mean = 3.91, MDN = 4, mode = 5) and Cul9 (mean = 3.85, MDN = 4, mode = 4). It means that socio-cultural competences of enterprises' employees and managers are also relatively high. Managers and employees are open to change and novelties, can negotiate, integrate the team and build confidence, are able to manage a group as well as a multicultural team, know how to build varied relationships and networks, share knowledge and are able to manage knowledge;
- Out1 (mean = 3.98, MDN = 4, mode = 4). It means that enterprises' financial capabilities ensure the purchase and use of computer hardware, software, the Internet, telecommunications and improvement of digital literacy;
- Man20 (mean = 3.92, MDN = 4; mode = 4). It means that enterprises implement and apply the law regulations associated with ICT adoption, in particular related to electronic invoicing, electronic signatures, data protection, electronic services, protection of databases, distance contracts;
- Man19 (mean = 3.88, MDN = 4; mode = 4). It means that enterprises develop and apply regulations and tools

on information security and protection of personal data, also associated with ICT adoption in terms of intra-enterprise and inter-enterprise (e.g., in relations with customers and business partners).

Furthermore, the lowest levels of ICT adoption were mainly related to ICT quality and ICT management (Table IV):

- Qua30 (mean = 3.24, MDN = 4, mode = 4). It means that many enterprises did not implement any BI system and do not employ any business analyses e.g., sales, customers, financial, marketing, products analyses. In general, 25% of enterprises assessed BI adoption at a level not higher than 2.00 and 75% of enterprises – at a level not higher than 4.00. Coefficient of variation with the value above 40% shows substantial differences in BI adoption within enterprises.
- Qua29 (mean = 3.44, MDN = 4, mode = 4). It means that many enterprises did not implement any ERP system(or any integrated domain-specific systems) which provides a coherent, comprehensive and integrated support for business processes in the whole range of business activities, and supports the primary and secondary business processes, such as sales, purchasing, marketing, distribution, customer service, warehouse management, human resources and payroll, or finance and accounting;
- Man21 (mean = 3.25, MDN = 3, mode = 4) concerning the implementation and apply of ICT within enterprises arising from ICT public projects, coordinated and

implemented at national, regional and/or local level e.g., the construction of broadband networks, making electronic platforms of public services available etc.;

- Man18 (mean = 3.47, MDN = 4, mode = 4). It means that a lot of enterprises did not implement the latest management concepts, such as process approach, knowledge management, risk management, change management, quality management, customer relationship management, trust management, human resource management, networking approach.

In general, the level of ICT outlay was the highest within enterprises, followed by the level of information culture. The levels of ICT management and ICT quality were the lowest (Table II).

#### B. The level of sustainable development in the enterprises' context

In order to answer the research question *RQ2: What is the level of sustainable development in the context of Polish enterprises?*, a detailed descriptive analysis was conducted. The results are presented in Table V.

It has been found that the average levels of sustainable development parameters ranged from 3.25 to 3.96 (on a 5-point scale from 1.00 to 5.00). The median and mode values were 4.00 except for Pol15 with the MDN = 3.00. On average, the highest levels are mainly specific for parameters related to economic sustainability, whereas a parameter of political sustainability was ranked the lowest. The highest ranked parameters of sustainability were (Table V):

TABLE V.  
THE LEVELS OF SUSTAINABLE DEVELOPMENT PARAMETERS IN THE ENTERPRISES' CONTEXT (N=394)

Parameters	Mean	Q25	MDN	Q75	Mode	Sample volume for Mode	VAR	SD	CV in %
Ecl1	3.38	2	4	4	4	149	1.21	1.10	32.53
Ecl2	3.50	2	4	4	4	160	1.40	1.18	33.82
Eco3	3.48	3	4	4	4	166	1.24	1.11	31.99
Eco4	3.67	3	4	4	4	168	1.11	1.05	28.70
Eco5	3.54	3	4	4	4	163	1.36	1.17	32.95
Eco6	3.51	3	4	4	4	159	1.31	1.14	32.62
Eco7	3.96	4	4	5	4	180	1.01	1.00	25.35
Eco8	3.89	4	4	5	4	185	1.03	1.02	26.09
Eco9	3.68	3	4	5	4	150	1.27	1.13	30.64
Eco10	3.74	3	4	5	4	165	1.14	1.07	28.50
Soc11	3.76	3	4	4	4	181	1.01	1.00	26.74
Soc12	3.45	2	4	4	4	144	1.52	1.23	35.70
Soc13	3.47	2	4	4	4	150	1.50	1.23	35.29
Soc14	3.38	2	4	4	4	153	1.26	1.12	33.29
Pol15	3.25	2	3	4	4	148	1.32	1.15	35.40
Pol16	3.63	3	4	4	4	178	1.24	1.11	30.61

Note: mean, median (MDN), first quartile (Q25), third quartile (Q75), variance (VAR), standard deviation (SD), coefficient of variation (CV), skewness (SK), and coefficient of kurtosis (CK).

- Eco7 (mean = 3.96, MDN = 4, mode = 4). It means that the improvement of efficiency and effectiveness of customer services resulting of ICT adoption was evaluated relatively high by enterprises;
- Eco8 (mean = 3.96, MDN = 4, mode = 4). It means that thanks to ICT adoption the enterprise achieves better and more efficient organization of work resulting from improvements and automation of business processes, communication, collaboration and networking within the enterprise and in its relations with its stakeholders (customers, suppliers, partners), facilitating access to information;
- Eco10 (mean = 3.74, MDN = 4, mode = 4). It means that the improvement of customer satisfaction and loyalty from products and services offered to them by the enterprise as well as pre- and post-sales support resulting from ICT adoption was assessed relatively high by enterprises;
- Eco9 (mean = 3.68, MDN = 4, mode = 4). It means that the result of ICT adoption by enterprise is to acquire new customers and markets, including foreign ones e.g., through internet marketing, online sales, obtaining information on markets and customers;
- Soc11 (mean = 3.76, MDN = 4, mode = 4). It means that ICT adoption by enterprise allows to extend knowledge and skills already held by employees and acquire new ones (including digital knowledge and skills), as well as better align thinking and action in response to the changing reality, legal requirements and customer needs.

Furthermore, the lowest level of sustainability was related to political, ecological, and socio-cultural sustainability (table V):

- Pol15 (mean = 3.25, MDN = 4, mode = 4). It means that enterprises' participation in the public consultation and democratic public decision-making as well as development of cooperation, communication, partnerships and networks between enterprises and public administration were assessed relatively very low;
- Ec11 (mean = 3.38, MDN = 4, mode = 4). It means that a lot of enterprises did not achieve lower average annual energy consumption and increased protection of the environment through ICT consuming less energy and built with fewer materials (miniaturization), and more easily recyclable and disposable;
- Soc14 (mean = 3.38, MDN = 3, mode = 4). It means that reducing social exclusion due to age, education, place of residence or disability, by facilitating access to the enterprise, its products/services and jobs was ranked relatively very low.

On average, the level of economic sustainability was the highest, whereas the levels of ecological and political sustainability were the lowest (Table II).

## V. CONCLUSIONS

### A. Research contribution

Although the literature review suggested that the phenomenon of ICT adoption for sustainable development had been previously examined [6], [11], [12], [16], [32], [35], this study extended previous research on the contribution of ICT adoption by enterprises to sustainable development [1]–[3]. and indicated the levels of ICT adoption and sustainable development in-depth. It contributes to the existing research on sustainable information society, ICT adoption, and sustainable development, in particular in the enterprises' context by:

- indicating and assessing the level of ICT adoption, especially in terms of ICT outlay, information culture, ICT management, and ICT quality; and
- indicating and assessing the level of sustainable development, especially in terms of ecological, economic, socio-cultural, and political sustainability.

Firstly, this study indicated that ICT outlay was at the highest level followed by information culture, whereas the lowest and similar levels were specific to ICT management and ICT quality. Digital and socio-cultural competences of employees and managers, financial capabilities ensuring any ICT projects as well as law regulations associated with ICT adoption and information security were relatively highly ranked by enterprises. However, the lowest level was specific for BI and ERP system adoption as well as the adoption of latest management concepts and exploitation of synergies between national ICT projects and own ones. All these require to improve ICT adoption, mainly its quality and management pillars.

Secondly, the outcomes showed that economic sustainability was at the highest level, whereas the lowest and similar levels were specific to ecological and political sustainability. The improvement of efficiency and effectiveness of customer services, better and more efficient organization of work, the enhancement of customer satisfaction and loyalty as well as the increase of new customers and markets as a result of ICT adoption were evaluated relatively high by enterprises. However, the lowest level was specific for enterprises' participation in the democratic public decision-making as well as energy savings and environment protection were assess relatively very low. It means that enterprises reap more economic benefits than ecological and political ones from adopting ICT. It is, therefore, required to increase ecological and political sustainability through ICT adoption.

### B. Research implication for research and practice

While this research is exploratory, it should provide a valuable foundation for further work examining ICT adoption, sustainable development, and a synergy between them more widely.

Researchers may use the proposed methodology to do similar analyses with different sample groups in other countries, and many comparisons between different countries can be drawn. Moreover, the methodology constitutes a very comprehensive basis for identifying the levels of ICT adoption and sustainable development, as well as the correlations between the two constructs, but researchers may develop, verify and improve this methodology.

This study offers several implications for enterprises. They may find the results appealing and useful in enhancing ICT adoption, experiencing the full potential of ICT adoption, and deriving various benefits from ICT adoption. The results suggest various kinds of advantages like ecological, economic, socio-cultural, and political that can be gained thanks to ICT adoption. In addition, they propose some guidelines on how to effectively and efficiently adopt ICT in order to obtain those advantages. It is evident from the findings that Polish enterprises should devote utmost attention to the enhancement of ICT management and ICT quality. Most of all, this research can be genuinely useful for the transition economies in Central and Eastern Europe. This is because the countries are similar with regard to analogous geopolitical situation, their joint history, traditions, culture and values, the quality of ICT infrastructure, as well as developing democratic state structures and a free-market economy, and participating in the European integration process.

All in all, the research results might provide a partial explanation to the issue of how enterprises can participate in the creation of sustainable development.

### C. Research limitations and future works

However, as with many other studies, this research looking more than superficially into ICT adoption and sustainable development in the enterprises' context has been limited. First, the ICT adoption and sustainability constructs are new constructs that have yet to be further explored and exposed to repeated empirical validation. Second, the sample consisted of Polish enterprises only, especially from the Silesian Province. The study sample excludes statistical generalization of the results from Silesian enterprises to Polish enterprises. However, previous research into the success factors for and the level of adopting ICT in Poland [50] indicated that there is no difference between enterprises in the Silesia Province and in Poland. Therefore, these research findings cannot be confined only to the Silesian enterprises and can be extended to Polish enterprises. After all, caution should be taken when generalizing the findings to other regions and countries. Finally, the research subjects were limited to enterprises and it is therefore only the standpoint of enterprises toward ICT adoption for achieving sustainable development. Caution should be taken when generalizing the findings to sustainable development in general.

Additional research must be performed to better understand ICT adoption and sustainable development. First, further validation of the levels of ICT adoption and sustainable development should be carried out for a larger sample comprising enterprises from different Polish provinces as well as from other countries. Second, research on the measurement of ICT adoption and sustainability in households and government units should be conducted because they are, besides enterprises, the main stakeholders of SIS.

# 1<sup>st</sup> Special Session on Data Science in Health

**T**HE Special Session on Data Science in Health is a forum on all forms of data analysis, health economics, information systems and data based health service research, focusing mainly on the interaction of those four fields. Here, data-driven solutions can be generated by understanding complex real-world health related problems, critical thinking and analytics to derive knowledge from (big) data. The past years have shown a forthcoming interest on innovative data technology. Already now we can see how immense amounts of data and rapidly increasing, inexpensive computing power will lead the world to base its decisions more and more on data. We therefore have to work together. We need the knowledge of researchers from different fields applying diverse perspectives and using different methodological directions to find a way to grasp and fully understand the power and opportunities of big data in health.

This special session is a joint track by WIG2, the Scientific Institute for health economics and health service research, and the Information Systems Institute of Leipzig University.

## TOPICS

We embrace a rich array of issues on data science in health and offer a platform for research from diverse methodological directions, including quantitative empirical research as well as qualitative contributions. We welcome research from a medical, technological, economic, political and societal perspective.

The topics of interest therefore include but are not limited to:

- Data analysis in health
- Health Data management
- Health economics
- Data based health service research

- Integrating data in integrated care
- AI in integrated care
- Spatial health economics
- Structural equation modelling in medical research
- Risk adjustment and Predictive modelling

## EVENT CHAIRS

- **Franczyk, Bogdan**, University of Leipzig, Germany
- **Häckl, Dennis**, WIG2 Institute for health economics and health service research, Leipzig, Germany

## PROGRAM COMMITTEE

- **Alpkoçak, Adil**, Dokuz Eylul University
- **Dey, Nilanjan**, Techno India College of Technology, India
- **Kossack, Nils**, Head Mathematics and Statistics, WIG2 Institute for Health Economics and Health Service Research
- **Kozak, Karol**, Fraunhofer and Uniklinikum Dresden, Germany
- **Militzer-Horstmann, Carsta**, WIG2 Institute for Health Economics and Health Service Research, Information Systems Institute of the University of Leipzig, Germany
- **Popowski, Piotr**, Medical University of Gdańsk, Poland
- **Sachdeva, Shelly**, National Institute of Technology Delhi
- **Wasielewska-Michniewska, Katarzyna**, Systems Research Institute of the Polish Academy of Sciences, Poland
- **Wende, Danny**, WIG2 Institute for Health Economics and Health Service Research And Technical University Dresden

# Medical data exploration based on the heterogeneous data sources aggregation system

**Abstract**—The paper presents the implementation and use of the IT system implemented in the Department of Pulmonology of The University Hospital in Cracow. The system integrates data from heterogeneous sources of therapy, diagnosis and medical test results of patients with Obstructive Sleep Apnea (OSA). The article presents the main architectural assumptions of the system, as well as an example of data mining analyzes based on the data served by the system. The example of the research aims to present the possibilities offered by the integration of clinical data in telemedicine and the diagnosis of patients with sleep disordered breathing that may lead to certain comorbidities and premature death.

## I. INTRODUCTION

**O**BSTRUCTIVE Sleep Apnea (OSA) is a widespread sleep disorder. It is estimated that the syndrome is present in approximately 5% of the general human population [1]. It is characterized by obstruction of the upper airway despite ongoing breathing efforts that lead to intermittent hypoxia and awakenings. The typical symptoms of OSA are loud snoring with pauses in breathing and daytime sleepiness. If untreated, OSA can lead to a number of severe medical conditions, mainly cardiovascular complications [2].

Polysomnography is the gold standard in the diagnosis of OSA [1]. Continuous positive airway pressure (CPAP) is the gold standard in OSA treatment [14], [9], [20]. Diagnostic process as well as the therapy requires access to information from many sources. Both patient history and clinical examination as well as polysomnography (PSG) results are considered. Obtained data has a very diverse form and is generated from many sources and by various devices (physician, PSG result, therapy devices etc.). So far, the data was collected in various places — paper documentation, patient registration system, PSG service system and SD cards of CPAP devices. In the present paper we demonstrate unique solution among another polysomnography software, assembling various data in the one system.

The work was realized as a part of fundamental research financed by the Ministry of Science and Higher Education, grant no. 16.16.110.663. The research was co-financed with National Scientific Leading Center project funds.  
This research was supported in part by PLGrid Infrastructure

The implemented system allows for detail research and data analysis leading to improvement of diagnostic quality and shortening its time by gathering all required data in one system [15]. Clinical data in connection with PSG results and CPAP recordings are input to the analysis of multidimensional and multicriteria links between individual indicators and other tests (i.e. blood lipids, arterial blood gases, glucose, creatinine etc.). It is expected that the development of research based on these indicators will enable the creation of a metamodel of mechanisms operating in this area in the future. At the moment, the aim of the research was to identify in which situations the basic diagnostic criteria (individual indicators mentioned above) fail.

For the initial cardiovascular risk assessment, the SCORE cardiovascular risk algorithm (Systematic COonary Risk Evaluation) is frequently used. The main risk factors for cardiovascular complications in the studied OSA cohort collected in the database include: (1) BMI (body mass index), (2) blood cholesterol, (3) systolic blood pressure, (4) package years — a factor calculated as a combination of years of smoking of cigarettes and the number of pieces smoked per day, (5) gender, (6) age.

Selected PSG parameters include: (1) AHI (Apnea Hypopnea Index) — number of apneas and hyponeas per hour of sleep), the most important OSA indicator used to determine its severity, (2) ODI (Oxygen Desaturation Index) — number of hemoglobin oxygen saturation falls per hour of sleep) demonstrate the level of sleep hypoxia.

AHI is the basic and the most common objectively used index to stage OSA severity. Judging the severity of disease we should take into account other tools including subjective doctor's opinion. This personal impression may have important value and can be measured by Clinical Global Impression Severity Scale (CGISS).

The above list shows a certain space of possible inaccuracies. Based on the medical history and physical examination, physician evaluating patient using this subjective scale decides of the urgency for PSG examination.

## II. RELATED WORKS

While the problem of the diagnosis and treatment of diseases related to OSA is a well known subject, the number of IT solutions supporting doctors in this field is relatively small. One of the works in this field mentioned in the literature is the system described by Passali et al. [16], which concerns the database of OSA patients undergoing upper airway surgery. Anthropometric data, results of scales diagnosing OSA occurrence, data from PSG tests, laryngological tests and laboratory tests were stored in the database. The collected data concerned the condition of patients before and after surgery, allowing their use as a source for methods supporting the automatic diagnosis of patients.

A separate extensive system that collects data on patients with OSA is the ESADA database [5], which integrates data from 22 medical units from all over Europe. The system stores data regarding the treatment of patients from the moment of diagnosis through the entire treatment process. Such a diverse range of patient groups allowed for a series of studies related to the detection of previously unknown dependencies, the causes of disease, including environmental and epidemiological conditions [19]. Based on data collected in the ESADA system, the relationship between OSA and problems related to hypertension [21], [22], kidney diseases [12] and diabetes [10] were also determined. These data also allowed to indicate the relationship between the use of different scales of diagnosis of OSA on the effectiveness and accuracy of the diagnosis process itself [2]. Due to the large number of data stored in the ESADA system, we can expect in the near future further publications of research results, developed on their basis.

When it comes to OSA data integration systems in individual countries, two such solutions have emerged in recent years. One of them was the Turkish TURKAPNE system (The Turkish Sleep Apnea Database), which began operation in 2017 and is to collect information about patients treated with OSA within the next 10 years. Another is the Danish NDOSA patients database [7], [8], which is assumed to collect data on the treatment of OSA-related conditions, in order to improve the quality of treatment in this field. Based on the publications data available in the literature, systems supporting treatment in the OSA field begin to appear in the medical market to facilitate and improve the process of diagnosis and treatment of patients. However, these are mostly databases themselves, without advanced diagnostic algorithms based on more extensive methods of data analysis

## III. SOLUTION CONCEPT AND SYSTEM ARCHITECTURE

In order to integrate all heterogeneous data sources, and ensure their consistency and security, an IT system was developed. It's main elements are presented in Fig. 1 and it consists of:

- A virtual central server maintained in the infrastructure of ACK Cyfronet ;

<http://www.cyfronet.krakow.pl/en/4421,main.html>

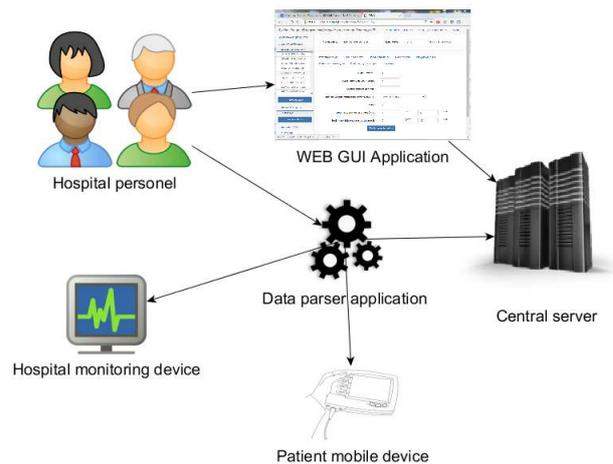

Fig. 1. Main system components

- A graphical user interface that provides access to the system for the hospital's medical staff (for entering data in non electronic format — diagnoses, lab results, etc.);
- Application that allows data to be exported to the system from two types of devices that monitor patients' sleep:
  - PSG device — advanced monitoring of patient's sleep during hospital stay;
  - CPAP devices — mobile patient devices that monitor patient's sleep during therapy outside the hospital.

The main application operating on the central server is based on the MVC (model-view-controller) architectural model developed with PlayFramework programming environment. The graphical user interface (GUI) of the application, which allows hospital staff to enter data and manage the system is presented in Fig. 2.

Datasets stored in the system are based on following:

- Clinical data — interview, physical examination, diagnosis, drugs;
- Diagnostic tests — PSG, CPAP, laboratory tests, spirometry;
- Medical recommendation — previous and planned treatment.

At the model layer, data is stored in a relational MySQL database, the structure of which is presented in Fig. 3. The business logic of the application is implemented in JAVA language on a virtualized CentOS operating system. The presentation layer is based on script templates in SCALA with HTML output code.

Based on the graphical user interface, hospital personnel provide the data in the system during the patient's visit to the hospital. In addition to standard questionnaires and medical diagnosis, data on further treatment as well as laboratory tests and lung tests — stored so far in external IT systems — are also provided.

Another key element of the system is the application that allows to extract data from devices that monitor the patient's

sleep. The current version of the system supports two types of devices. The first of these is the PSG device, which monitors the patient's sleep during his several-day visit to the hospital. The Sleepware3D application from Phillips Respironics is used to operate this device, and the data obtained from it is saved in RTF format. The second type of devices that monitors the patient's sleep during his stay outside the hospital are mobile versions of devices — CPAP, which generate reports in PDF format. In order to import selected reports from CPAP and PSG devices into the system, hospital staff run manually a dedicated application. The application developed within the system allows (using dedicated parsers algorithms) to extract data from device reports and export them to a central server that integrates them with other data related to a specific patient. PDFParser and RTFEditoKit JAVA libraries were used to extract data from documents in PDF and RTF formats as well as dedicated templates for extracting relevant data from these documents. Due to the fact that data import is performed for an individual patient, there is no problem of overloading the system during the import process.

Such integrated data, acquired from many heterogeneous sources, previously stored within various information systems and in paper form, are integrated into one universal data model (Fig. 3) within the presented system and made available for processing for advanced data processing and analysis methods.

#### IV. DATA EXPLORATION RESULTS

In the Introduction section, a research problem was initially drawn up. Data analysis presented in this research was performed to show the huge potential for integrated data collection in the IT system for their use in clinical practice. All computations was carried out on an integrated patient database, with the use of STATISTICA software. At first, the relationships between some patients' clinical data and their characteristics were investigated. The analysis showed that some dependencies exist. It should be stated here that particular variables could have different scales. Some of them

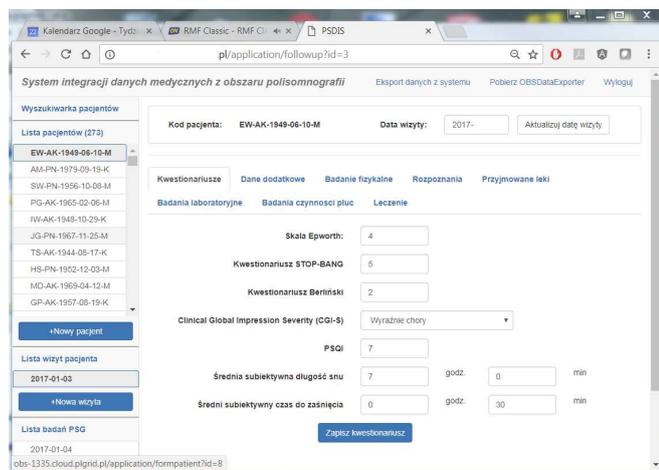

Fig. 2. WEB interface for system management

were qualitative (e.g. sex), other ordinal (e.g. measuring scales) and other quantitative (e.g. index of disorders). A series of tests on the dependence of parameters was performed — correlation test (Pearson's coefficient), t tests as well as chi square tests. Some of the dependencies can be presented in the charts Fig. 4.

From the charts of means in groups (Fig. 4) we can find the relationship between gender and the number of package-years and AHI. The AHI variable includes three classes that express the severity of the disease, where AHI = 3 means a severe OSA. We can observe a pattern that men with severe OSA smoke more. The question is that AHI depends on the amount of cigarettes smoked. The third graph shows that smoking correlates with AHI. While it cannot be demonstrated that smoking causes OSA, it can be assumed that perhaps smoking aggravates the severity of the disease. Such conclusions could be drawn from the tested sample it is certainly a pattern that is worth further research. Does severe OSA predispose to heavy nicotine dependence?

We can study the effect of risk factors on various OSA indices to find differences in their diagnostic strength. (Fig. 5). It can be seen that while age and BMI clearly affect the SCORE value, their impact on AHI and ODI (direct OSA indices) is small. This may negatively affect SCORE diagnostic capabilities, as evidenced by subsequent analyzes.

##### A. False Negatives Recognition

Looking for naturally occurring data structures, groups of patients with similar indicators and clinical characteristics, the method of clustering — unsupervised learning — k-means was used. Clustering is the most extensive group of machine learning methods called "unsupervised". Among the many known algorithms (EM algorithm, fuzzy c-means, Kohonen's Neural Networks, etc.) one of the oldest and most popular tools for the development of other tools is the k-means algorithm [11]. Clustering deals with searching for a structure in a set of unidentified data. It is the process of organizing objects into groups whose elements are in some way similar to each other [4]. In terms of computations, the algorithm is reduced to two-criteria optimization, where the distance between cluster objects is minimized, and the distance between clusters is maximized [6], [18].

The results are presented in Table I. The tests were successful, we managed to determine the concentration of patients with similar characteristics with a small error of validation. The distance between clusters was calculated by the Euclidian metrics, while the means and the most frequent values for descriptive variables are presented in Table I.

The analysis shows that 5 clusters can be distinguished from the patients (the number of clusters was set with cross-validation method): cluster 1, 3 and 4 these are cases of elevated AHI — which means that they group patients suffering from severe OSA. In contrast to clusters 2 and 5, which focus patients with mild form of the disease. It can be demonstrated using Table I that cluster 1 and 4 are: women with severe OSA and men with severe OSA — their CGIS (subjective

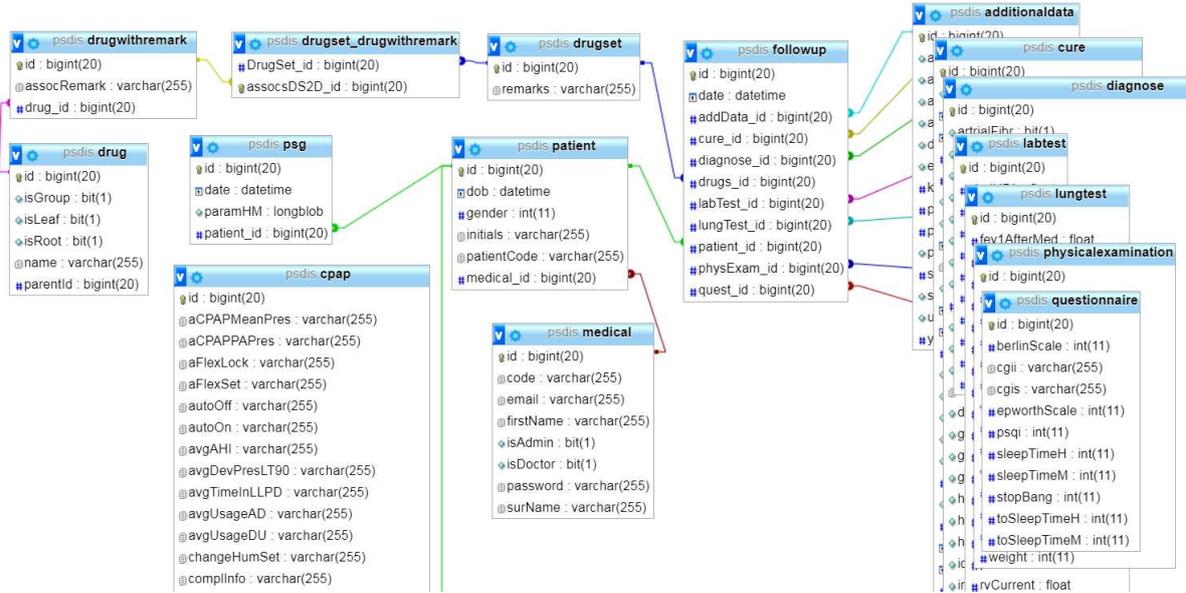

Fig. 3. Database structure

assessment of the doctor) and SCORE are high. Similarly, cluster 2 and 5 are the men and women with the lowest AHI — there CGIS and SCORE are low.

However, the analysis has identified yet another cluster — number 3. It is characteristic due to the high class of AHI (this class means that in the PSG examination the patient had the Apnea-Hypopnea Index >30), and at the same time low SCORE and CGIS. This means that they are possibly false negatives cases — patients with risk of having undiagnosed OSA (if the decision on referral for PSG examination should be made on the basis of machine learning methods).

Statisticians call this situation False Negatives. In statistical hypothesis testing false negatives are type II errors, where a negative result corresponds to not rejecting the null hypothesis. We can call it an underdiagnoses error. The conducted research

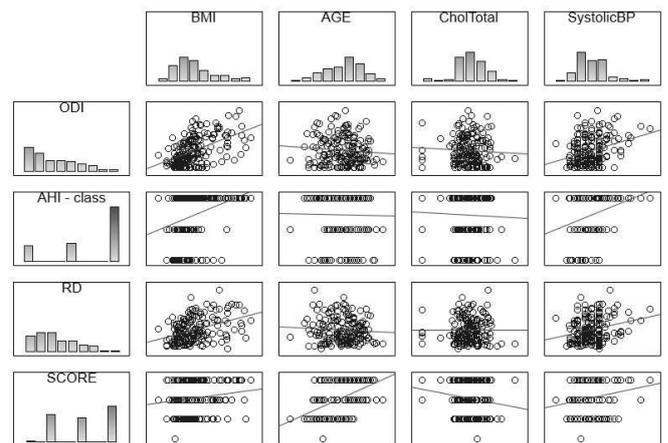

Fig. 5. The impact of risk factors on various OSA indicators

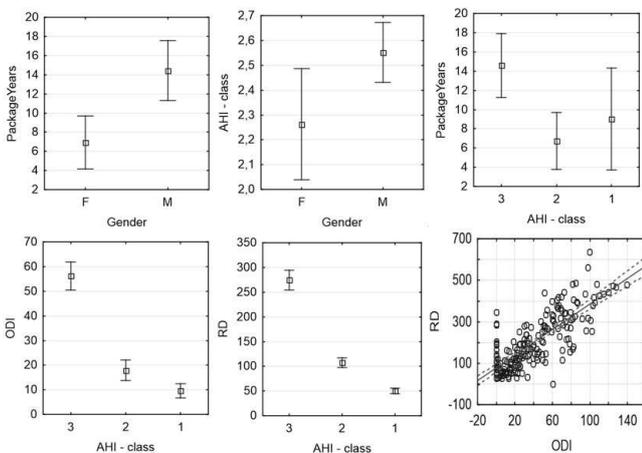

Fig. 4. Selected relationships between patients' characteristics

has shown that it is possible to select risk groups — patients whose diagnosis may be subject to the error false negatives, especially if the diagnosis would be carried out without PSG examination.

Is it possible to use this knowledge in future diagnoses? How machines can predict that a patient may belong to the FalseNegatives group and protect him against a mistaken underdiagnoses?

Cluster 3 is men who smoke less than other patients, who is also the youngest group among the respondents. They have high BMI, elevated blood pressure and cholesterol at the same time.

### B. False Negatives Prediction

In order to create a classification model, the algorithm for creating CART classification trees was used. Decision trees

TABLE I  
K-MEANS CLUSTER CHARACTERISTICS

Cluster	Gender	Age	CGIS	Package Years	BMI	Systolic BP	SCORE	Chol Total	AHI dominant	No of cases	(%)
1	F	58,4	3,6	8,5	40,0	140,5	3,15	4,29	3	32	17,0
2	F	59,3	3,0	4,2	30,1	132,2	2,80	5,27	1	25	13,2
3	M	43,1	3,0	9,2	34,3	141,9	2,20	4,90	3	29	15,4
4	M	62,8	3,7	19,5	34,8	142,4	3,78	4,41	3	64	34,0
5	M	56,7	2,8	10,3	28,4	133,2	2,71	4,46	1	38	20,2

are very popular among data mining tools [3]. Repeatedly described in the literature, they have found countless examples of applications [17], [21]. Their usefulness has been determined by the following characteristics: (1) easy to interpret by a human; (2) simple representation of complex relationships occurring in data sets; (3) no assumptions on the variability of input and output parameters, and (4) no assumptions on the probability distribution of variables; (5) the ability to operate on incomplete and noisy sets [13].

The algorithm evaluates the discriminative power of variables and chooses for division successively those that provide better separation of objects between classes. Then the split point is selected. The lowest Gini Index is chosen as the best dividing point. This process is repeated until a satisfactory tree is obtained (based on the leaf size or total classification error).

Fig. 6 presents the matrix of errors for the inducted CART classification tree. Using the tree we can predict that the patient belongs to the group of patients at risk of underdiagnoses mistake in 82.7% of cases. We reduce the risk of misdiagnosis by as much as a percentage if we consider the indications from the analysis.

Because false negatives cases mainly concern men, in graph in Fig. 7 only a fragment of the tree about men is presented.

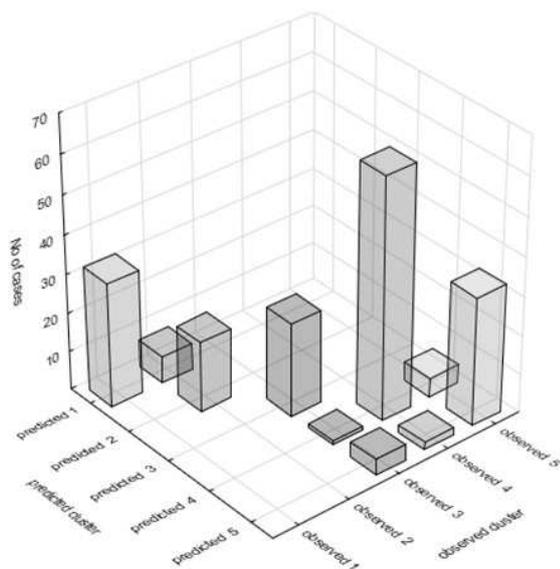

Fig. 6. The misclassification matrix for the False Negatives classification tree

Only in this area it is possible to predict the cluster 3.

Reading the rules induced by the tree we can notice: If someone is a man under 54 years of age, with a SCORE index below 3, it belongs to cluster 3 (FN) with 65% of certainty. If we additionally take into account the results of spirometry, including Tiffeneau index after bronchodilator below 86, the probability increases to 73.6%. Taking into account laboratory tests, it is worth paying attention to the content of C-reactive protein. If it is above 2 we are sure that it is FN (cluster 3), otherwise we check if the patient is younger than 43 years, then it certainly belongs to cluster 3. The remaining patients belong to cluster 5 — means true positives — patients with mild OSA.

When interpreting the results, it should be taken into account that the obtained results are susceptible to an error resulting from a small number of data stored so far in the system, and thus a relatively small number of variables that can be used in the analyzes. In the future, successive algorithms (decision trees and clustering) should operate on disjoint sets of attributes to avoid problem of endogeneity.

V. SUMMARY

This paper presents the design, implementation and preliminary results of a prototype system that enables to improve the diagnosis and possible decision-making about treatment of patients with sleep disorders. The main advantages of the system are aggregation of data from various sources (diagnostics, lab-tests, medical history) and its integration with devices for OSA diagnosis (PSG) and treatment (CPAP). It can significantly improve the work of the hospital staff and facilitate their access to previously distributed patient data.

Besides, the examples of data analyzes that allow searching for dependencies between clinical tests and diagnosis have been shown. Data mining analyzes allowed to find the characteristics of a group of patients for whom the risk of underdiagnoses was the highest. However, from a medical point of view, all presented results and obtained dependencies should be treated with extreme caution, because a small number of randomly selected parameters does not necessarily reflect reality. At this stage, the paper has only statistical and IT value, and its purpose was to show the huge potential for integrated data collection in the IT system for their use in clinical practice. The intention of the presented system is to improve the quality of diagnosis and treatment of patients affected by OSA and it seems that this goal is achieved after implementation of the system into daily clinical practice.

**Abstract**—Online registers contain a large amount of data about healthcare providers in the Czech Republic. Information is available to all citizens and can be useful to patients, governmental organisations or employers. Based on these data, we are able to create a high-quality snapshot of the current state of healthcare providers. Interconnecting data from more data sources together is an interesting task, and accomplishing it enables us to ask more complex questions. This paper focuses on answering several questions about dentists in our country. A dataset from one online database was created, using automated data mining methods and a subsequent analysis. Results are presented via an online tool, which was provided to owners of the data. They reviewed our results and decided to use our findings for the presentation to the Czech government and subsequent negotiation processes. Our paper describes used methods, shows some results and outlines possibilities for further work.

## I. INTRODUCTION

Dental care coordinated by the Czech Dental Chamber is an integral part of the healthcare system in the Czech Republic. Various dental services are provided by more than 8,000 dentists working at university clinics or municipal health centres as well as by private dentists and dental laboratories<sup>1</sup>. More than half of these dental practices are based in big cities, including the Capital of Prague. Universities provide dental study programmes fully in accordance with standards of the European Union. Dentistry curricula are completely separated and independent from general medicine study programmes. In general, dentistry programmes cover all basic requirements to practice dentistry in terms of prevention, diagnosis, treatment, medical opinion and monitoring. Students achieve knowledge and skills of all the activities and interventions as regards prevention, diagnosis and treatment of anomalies and diseases of the teeth, gums, jaws, and surrounding tissues<sup>2</sup>. From the government and higher education perspective, many online data sources describing the field of dentistry on both national

<sup>1</sup> <https://www.dent.cz/>

and regional levels are available. This information can provide interesting inputs for further analyses which explore new relations and patterns between graduates and practices.

### A. Portals presenting national dental care professionals

The network of healthcare providers in the Czech Republic is complex and well-described. The Ministry of Health of the Czech Republic and its departments provide searchable databases of all registered providers. These databases, which are available to all citizens, were included in a complex national review [1] of publicly available web portals together with others mainstream websites providing information from healthcare and medicine. The major online databases of individual healthcare providers and organisations are listed in Table I.

Table I  
Major Czech databases of healthcare providers

Name of the portal	Reference
Czech Medical Chamber	<a href="http://www.lkcr.cz">www.lkcr.cz</a>
Czech Dental Chamber	<a href="http://www.dent.cz">www.dent.cz</a>
National Register of Healthcare Providers	<a href="http://nrpzs.uzis.cz">nrpzs.uzis.cz</a>

ZnamyLekar	<a href="http://www.znamylekar.cz">www.znamylekar.cz</a>

In this paper, we focus on the second of the above-mentioned databases, which is guaranteed by the Czech

<sup>2</sup> <https://www.muni.cz/en>

Dental Chamber. These data fit most conveniently to our further investigation because they contain information only about dentists, not about other health professionals. The obtained dataset from the publicly available database is therefore as relevant as it can be for further examination.

### *B. Motivation and exploratory questions*

On the one hand, a lot of data describing dental care in the Czech Republic are freely available. In theory, there are no limitations and borders to mine and to process those data. On the other hand, a huge amount of records on individual dental care providers make a global overview and orientation in the particular domain of dentistry on the national level quite complicated and unclear. Moreover, the manual process of data extraction and local database construction is very time-consuming.

This paper aims to find an effective way of extracting data automatically from freely accessible online sources using a machine-based – instead of a human-based – approach. With respect to our other research activities [2]–[4], we decided to explore the domain of dental care from two different perspectives: (i) Czech higher education institutions, which guarantee various dental medicine study programmes, (ii) real distribution of dental professionals in everyday clinical practice. The process of mapping of dental care in the Czech Republic in terms of graduates' distribution across the country was a challenge from the very beginning. A student project devoted to this particular topic was solved at the Faculty of Science of the Masaryk University. Based on data from the Czech Dental Chamber portal, a pilot automated mapping between graduates and dental professionals was done. Finally, a web-based application presenting the achieved results in the form of an interactive visualisation has been designed, developed and implemented.

## II. METHODS

The preparation of a final output (i.e. the online visualisation tool in this case) had several stages: obtaining the dataset, data preparation for further analysis, development of multiple interactive views and a final evaluation. All activities were carried out by a team of three students under the supervision of mentors from the Web Design Department<sup>3</sup> of the Institute of Biostatistics and Analyses at the Faculty of Medicine of the Masaryk University (IBA FM MU). During the process of data mining, we followed the standardised and proven methodology called the cross-industry standard process for data mining (CRISP-DM). It helped us to avoid the common mistakes and to work efficiently as a team [5]. We have distributed our activities in this case study, too. The next sections describe our steps in the context of CRISP-DM.

### *A. Business and data understanding*

The web portal [dent.cz](http://dent.cz) provides information for members of the Czech Dental Chamber (CDC) as well as for the general public.

The portal consists of the following sections:

- list of dentists,
- education – a calendar of events, recommended literature and other study materials,
- LKS journal – information about their periodical,
- news – current events and news in the dentistry,
- about us – general information about CDC,
- for members – accessible only to CDC members,
- contacts – contact to the CDC office.

In particular, we were interested in the very first item, i.e. the list of dentists, for further investigation.

Records on particular dentists are available through records on individual healthcare facilities, and each dentist can be registered at none, one or more of these facilities. All records have a clearly defined common structure consisting of the dentist's name, information about his/her workplace, education and regional dental chamber. The section about healthcare facility where the dentist works is the key part of the record. It consists of the name of the healthcare facility, its address and contact. Three ways of filling this section are distinguished. In the first case, the dentist works only in one facility. In the second case, the dentist works in more than one facility. Finally, no healthcare facility is mentioned. Information about the dentist's workplace(s) is supplemented by a map.

The education section was another important part of this study. As was the case of healthcare facilities, it was filled in three different ways (one university, more than one university, no university mentioned).

### *B. Data preparation*

Data preparation consisted of two main steps. The first one involved web mining methods and the insertion of gathered pieces of information about dentists in a structured form into the database. The subsequent phase focused on data cleaning, which meant extracting useful analytical information by regular expressions from HTML codes into a new table in the database. All steps in this section were created in the Python programming environment using libraries that are described in Section 2.2.1. In the following text, more detailed information about the algorithm we have designed will be provided.

Web mining is generally called crawling [6] because the algorithm goes gradually through the web portal hierarchy. The crawling algorithm has two functionally different parts. The first part consists of many functions which work with URL links. The function for extracting all URLs from a specific web page is the most important segment of the code, in which several key conditions are defined. For instance, we had to select only unique URLs from the list of all URLs on the page, and we needed to ensure the algorithm would be terminated when the 'offset' was detected in the crawled URL. After we obtained the final list of URLs, we

<sup>3</sup> <http://www.iba.muni.cz/index-en.php?pg=contract-research--web-design>

created the function for scraping a specific URL. This is represented by extracting the HTML code, which includes all the information about dentists in the free-form text, from the web page.

In the second part of the proposed crawling algorithm, the obtained information was inserted into a newly created database. Firstly, the connection to a SQLite Database Server was created, then a table for crawled URLs was created and the first record was added to the database. Secondly, all URLs from the first web page were inserted into the database table and the table was updated with the HTML code of this page. This process was iterative until the HTML codes of all records in the table were filled.

The proposed methods of the extraction algorithm mentioned in the introduction of this section have two parts as well. In the first one, functions for extraction of information about dentists were created, using various regular expressions from the HTML codes. In this part of the code, names of schools had to be unified because there was an enormous inconsistency in foreign school names. Firstly, a new table for the extraction was created, then only the records about dentists (not about healthcare facilities) were selected from the primary table. Secondly, all extracted attributes were inserted into the database table at the same time. In this key step, the issue with more healthcare facilities per dentist was resolved by a uniform distribution of the Full-time equivalent (FTE) among the workplaces. For example, if a dentist worked in three workplaces, then the weight of each record about this dentist was 0.33. For further interactive data analyses and visualisations, it was crucial to extract the names of healthcare facilities as well, since each healthcare facility was defined with respect to its geographical location as a unique combination of the name of the relevant facility, its latitude and longitude. Subsequently, it was necessary to obtain further information about a given region and a district workplace using the postal code of that workplace, using data from the web portal <http://www.psc.cz>. This information was automatically extracted from the HTML code of this web portal using the above-mentioned method. The postal code of each workplace was primarily used to assign both the region and the district to each healthcare facility.

Using this procedure, however, we were not able to assign all regions and districts, so we subsequently decided to use the municipality where a given healthcare facility was located for search on the <http://www.psc.cz> portal. In this manner, the number of healthcare facilities with unknown regions and districts was significantly reduced. The proposed extraction algorithm was conducted with a SQL update of the table and thus the final version of the dataset for further data analysis was obtained.

### C. Modeling and Evaluation

Extracted and cleaned data saved in the SQLite Database Server was connected with the R programming language. Afterwards, SQL queries were executed over the database

using the R programming environment. These data aggregations were used for the creation of R Shiny application, especially for descriptive statistics and visualisations that were represented for example by textual descriptions donut charts or cartograms.

The application was independently evaluated twice in the work team: within the students' team and then in the mentors' team. The final output was also presented to other teams of the subject and their mentors. The whole auditorium had an opportunity to participate in the discussion. Subsequently, the application was presented to representatives of the CDC. They commented on factual accuracy and usability of the presented outputs. Finally, all remarks collected during the review process were incorporated into the application.

### D. Technological background and deployment

Various technologies, tools and packages were used during the deployment process. We are able to divide the technologies we used into two categories by their purpose within the whole project: (i) data retrieval group – tools and libraries which were used to obtain data from the web portal of the Czech Dental Chamber, (ii) data visualisation group – tools used in the final presented application for computing and rendering the user views with graphs and text information.

#### Data retrieval group

The technological group of data retrieval consisted of scraping [7], database operations, data cleaning and data parsing. Each of the related procedures and methods were performed using the Python 3 language. Packages like urllib, requests, BeautifulSoup and sqlite3. SQLite was used as the application's database layer.

#### Data visualisation group

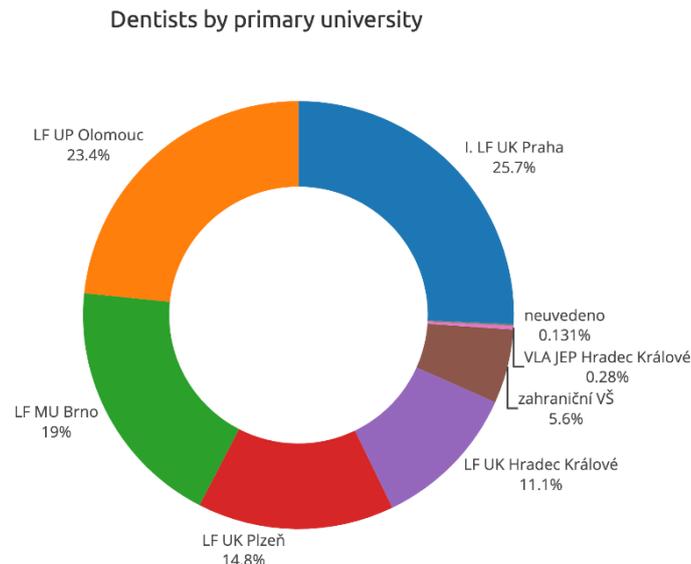

The technological group of data visualisation consisted of data aggregation, charts plotting and app deployment. Each of the related procedures and methods were performed in the R software environment. The RSQLite package was used for communication with the SQLite database engine in order to aggregate data effectively. Packages plotly and networkD3 were used to create interactive pie charts and a map of the Czech Republic. The whole application was built as an interactive R application using the packages Shiny and shinythemes. Furthermore, it was deployed on our Open CPU server. Therefore, our R Shiny applications allow real-time user interaction and data filtering in a simple online environment.

## III. RESULTS

We have created a publicly available tool which shows the state of distribution of dental care graduates all over the Czech Republic. The dataset was collected on 22 October 2018. The tool is available on a public URL<sup>4</sup> with the user interface translated to English.

<sup>4</sup> <https://vis.iba.muni.cz/apps/dent-en/>

## Number of dentists: 10726

Note: The chart does not include dentists who have studied multiple schools. Specifically, there are 20 cases.

Fig. 1 Percentage of dentists by universities at which they studied primarily

### A. Basic description and overview of studies

The application was created as an output of a student project. On the initial tab of the web application, the objective and basic information are mentioned.

The second tab deals with the education of dentists, precisely with their primary school in relation to their dental practice. Six faculties of medicine in the Czech Republic were distinguished:

- First Faculty of Medicine of the Charles University in Prague,
- Faculty of Medicine and Dentistry of the Palacký University in Olomouc,
- Faculty of Medicine of the Masaryk University in Brno,
- Faculty of Medicine in Plzeň of the Charles University,
- Faculty of Medicine in Hradec Králové of the Charles University,
- Jan Evangelista Purkyně Military Medical Academy in Hradec Králové.

All foreign universities were united into one category and another category was created by merging dentists with missing information on university at which they studied.

The total number of dentists registered on the website of the Czech Dental Chamber was 10,726. Twenty of them mentioned two different universities at which they had studied. It was not possible to identify which of these universities was the one at which they had studied primarily, therefore these dentists were not included in further analyses.

Fig. 1 shows the percentage of dental practitioners by universities at which they studied primarily. Most dentists

graduated from the First Faculty of Medicine of the Charles University in Prague (25.70%), the Faculty of Medicine and Dentistry of the Palacký University in Olomouc was the second most frequently mentioned one (23.40%), and the Faculty of Medicine of the Masaryk University in Brno was the third one (19.00%). The proportion of dentists who studied abroad was 5.60%. In fourteen cases, the dentist's education was unknown (0.13%).

### B. Dental offices in the Czech Republic

Dental offices in the Czech Republic are displayed on two tabs (the third one and the fourth one). The first of them describes only dental offices regardless of information on university graduates. About a fifth (21.00%) of dentists did not mention the healthcare facility in which they worked. More than two thirds (70.10%) of dentists worked in just one office and 8.90% of them worked in several offices. Therefore, a new variable was created – work time. Connection of work time to the FTE is described in more detail in chapter Data preparation. The third tab also displays maps containing information about numbers of healthcare facilities (6,579 in total) and work time of dentists by region. The cartogram allows user interactivity in the form of radio buttons. The user can choose from two options: the first of them shows the numbers of work times, whereas the second option displays the numbers of healthcare facilities by region. The first option can be seen in Fig. 2. This image clearly shows that the majority of dentists work in the capital (Prague) and its vicinity (Central Bohemian Region), followed by the South Moravian Region and the Moravian-Silesian Region. It is also obvious that the Karlovy Vary Region, has the lowest work time in the Czech Republic.

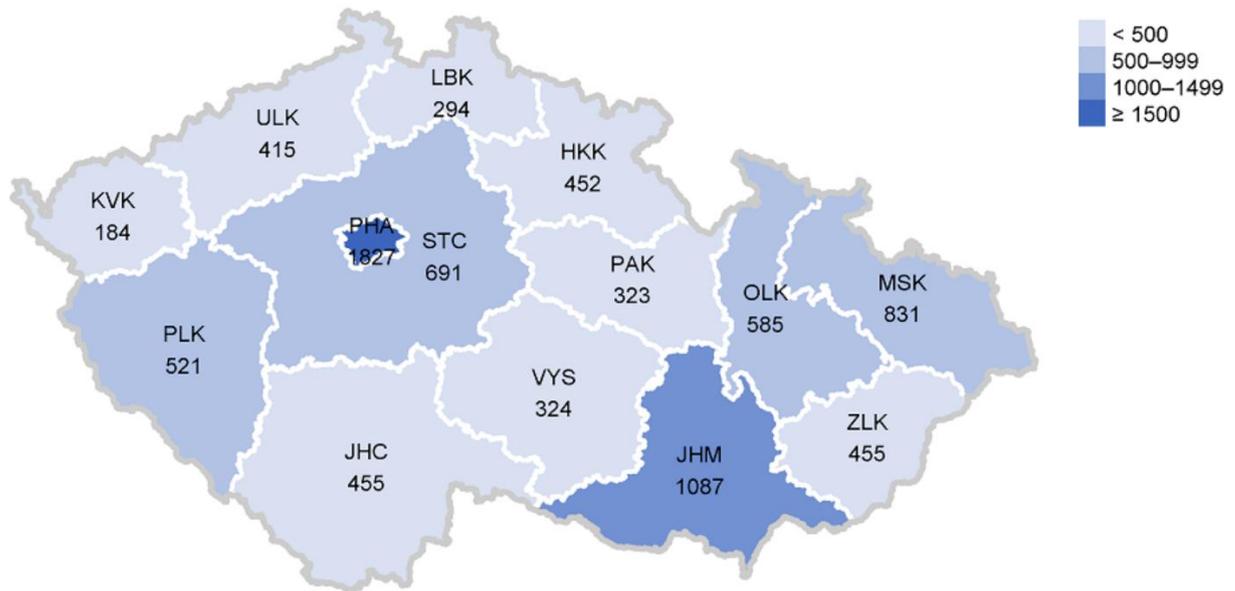

Fig. 2 Numbers of work time by region.

#### IV. DISCUSSION

This paper represents a student project solved under the supervision of senior mentors, where a proof of concept in online data crawling and scraping was carried out. Real data from a guaranteed online source on dental care were automatically mined and processed by a set of Python algorithms and stored in a relational database running on our own servers. The challenging task of complex mapping between data describing the distribution of dental professionals in practice was successfully solved. The final application is one from a group of similar projects [8], [9] being solved at the Institute of Biostatistics and Analyses at the Faculty of Medicine of the Masaryk University. It provides an original overview of data stored in the portal of the Czech Dental Chamber because it reveals hidden relations between graduates' and dental professionals' distribution across the Czech Republic.

The public R Shiny application and its outputs were subsequently consulted with representatives of the Czech Dental Chamber. Conclusions of the review were considered and implemented in the application. We believe that information obtained in this way will serve to increase the transparency of healthcare in the Czech Republic and will be an interesting source of knowledge for the entire community associated with the Czech Dental Chamber.

The proposed application is still open to changes and improvements. Updating the underlying dataset at different times would also be worth considering. It would then be possible to compare the evolution of migration over time and monitor the increment / decline of registered dentists across certain periods. In the future, it would be interesting to include demographic data from individual regions of the Czech

Republic in the analysis. It would then be possible to estimate the number of citizens in a certain region per one dental practitioner and whether a certain region is lacking this type of healthcare providers.

**Abstract**—The digitization of healthcare data has been consolidated in the last decade as a must to manage the vast amount of data generated by healthcare organizations. Carrying out this process effectively represents an enabling resource that will improve healthcare services provision, as well as on-the-edge related applications, ranging from clinical text mining to predictive modelling, survival analysis, patient similarity, genetic data analysis and many others. The application presented in this work concerns the digitization of medical prescriptions, both to provide authorization for healthcare services or to grant reimbursement for medical expenses. The proposed system first extract text from scanned medical prescription, then Natural Language Processing and machine learning techniques provide effective classification exploiting embedded terms and categories about patient/doctor personal data, symptoms, pathology, diagnosis and suggested treatments. A REST ful Web Service is introduced, together with results of prescription classification over a set of 800K+ of diagnostic statements.

## I. INTRODUCTION

In recent years, there has been an amplified focus on the use of Artificial Intelligence (AI) in E-health. There are numerous examples that include AI approaches to analyze unstructured data such as photos, videos, physician notes to enable clinical decision making; or the use of intelligent interfaces to enhance patient engagement and compliance with treatment and predictive modelling to manage patient flow and hospital capacity/resource allocation.

Two main information sources play a relevant role in healthcare field, i.e. images and natural language. The use of Natural Language Processing (NLP) found several applications related to medical ICT with the increasing adoption of Electronic Health Records (EHRs); in the last decade, a lot of application have been developed in order to extract information and knowledge from electronic EHRs [1] [2]. In fact, when structured data is stored in an EHR, it is desirable to support automated systems at the point of care, and to help physicians in diagnosis. These studies endorsed most NLP applications in the medical field; for instance, those concerning the use of Twitter data and sentiment analysis to study diseases dynamics [3], or [4], where the correlation among "stress", "insomnia", and "headache" is analysed. In the field of medical application, the image processing are very useful in EHR data manipulation [5] [6], where medical images play an important role in particular to help physicians to monitor the evolution of complex pathologies [7]. In this

work a combination of image processing and NLP techniques are exploited to extract information from a scanned image of a medical prescription and analyze the semantics of the embedded information with the final goal of assessing its correctness according to the "medical request service" related to the prescription being examined. The system performs a classification in order to automatically authorize or not the medical service required within the prescription. Indeed, in Italy there exist a public medical assistance that provide free "Medical services". These though have to comply with certain parameters to be freely provided. Currently, the assessment of compliance with these parameters is manually performed by a proper operator. The proposed application aims to provide a mechanism to help the operator, or even replace his/her intervention. The proposed solution provides an user-friendly application to help the operator with a pre-analysis to isolate the few medical prescriptions that require a human operator to decide about their correctness, trying to automatize as many prescriptions as possible.

In Section II an overall description of the system with some implementation details is provided. Section III and IV describe respectively image pre-processing operations and text extraction. Section V discusses about the solution used in spelling correction and section VI describes the information classification task. Results are presented in section VII, while section VIII highlights conclusive remarks also outlining some future works.

## II. SYSTEM ARCHITECTURE

In this section we illustrate the proposed system and the solutions used to achieve the goal described in the introduction. As shown in fig. 1, the system is accessible via a Web application that works according to the following steps. First, the input image is examined to establish the type and format of the medical prescription that image represents, then, text is collected and corrected to further isolate and extract all relevant strings and the information based on previously collected strings is classified. Finally, the prescription is eventually considered as valid for further approval or not, according to specific criteria based on the information and related classification; we named these two possibilities as *grantable* and *not-grantable* respectively The ASP.NET framework has been adopted to develop the whole application; in particular,

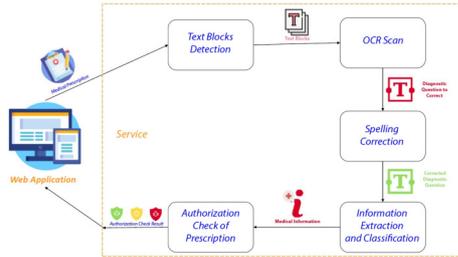

Fig. 1. Functional architecture of the proposed system

the ASP.NET Core version was considered, thanks to its support to open-source and multiplatform environments. In the paragraphs below, we discuss about each system module shown in fig. 1.

### III. MEDICAL PRESCRIPTION RECOGNITION

The first module of the proposed system aims to discriminate which type of medical prescription is being processed. The *type* is defined by the Italian national medical service ("Servizio Sanitario Nazionale", simply SSN in the following), indeed it includes:

- the prescription used to provide drugs, therapies, screenings or specialist examinations at the expense (entirely or partially) of the SSN; this prescription can be filled in by physicians that either works inside SSN structures (e.g., public hospitals) or they hold an agreement with SSN (being therefore a *partner* of SSN itself)
- the prescription where any medical care as those listed above are completely at the expense of the person that prescription was written for; in such cases, the physician is not required to hold any agreement with the SSN

The former type is also known as "ricetta rossa" (*red* prescription), and it is a specific prescription whose details also depend on local (region-based) rules, whereas the latter, known also as "ricetta bianca" (*white* prescription) has a general validity on the entire national territory, therefore in the rest of paper we just focus on this last type.

The system receives as input scanned images of prescriptions that must be classified as *white* ones or discarded. To accomplish this task, a supervised machine learning approach [8] is adopted. In particular, this well-known technique exploits a training set used to build a model that enables the classifier to perform the discrimination. Since we focus on white prescriptions only, the classifier is *binary*, i.e. it just establishes whether an image actually can be considered as a white prescription or not. To assess the effectiveness of the classifier, the widely adopted 75/25 approach has been considered as the training/validation set splitting. In addition, to prevent the overfitting problem, a data augmentation [9] has been performed on the dataset; note that due to its reduced dimension, we did not consider the cross-validation technique. The classifier we developed allows to detect white prescriptions with an effectiveness of about 93-95%. After that

Fig. 2. EAST architecture

a white prescription has been acquired by the system, pre-processing steps [10] are carried out on the image in order to facilitate the subsequent OCR phase; in particular, we perform smart crop, gamma correction and image rotation.

The first operation is required since images present into our system are often simple photos provided by individuals that use their smartphone during the upload of the request of a medical service. Since the image is rarely provided by physician or other specialists, the accuracy of the prescription should be therefore improved in most cases by cropping the image to discard its negligible parts. Gamma correction [11] is usually performed in the process of digital imaging to restore as much as possible the lighting condition of the original image. Finally, image rotation is performed since it has been often generated via smartphone camera by standard users (SSN customers) so alignment could be required; to accomplish this, we exploit the barcode stored in the medical prescription, whose high contrast of black and white pixels allows a simple yet successful image alignment.

### IV. TEXT EXTRACTION

After image pre-processing, text is extracted to build a string dictionary where each entry represents a field of the medical prescription. This OCR phase is carried out using EAST [12] text detector in conjunction with Tesseract [13] free OCR software. EAST is the acronym of Efficient and Accurate Scene Text Detector, based on a multi-channel fully convolutional neural network (FCN) with an efficient pipeline, whose purpose is to isolate blocks of text embedded into an image. It can be schematized as in fig. 2, where the FCN produces both information about words/phrases recognition and about the geometry of the area that contains them; both are evaluated using a threshold-based mechanism that finally provide us with text blocks to be further processed via Tesseract. Using directly Tesseract to recognize the text contained in the scanned medical prescription provided unsatisfactory results for the data set used as input, reasonably due to the low quality of canned images provided by end users. For this reason, we first used EAST, whose effectiveness in isolating text blocks was higher, then passing each block to the OCR software; this approach revealed to be slightly lower but successfully for extracting data from prescriptions. In fig. 3 is represented a scanned white medical prescription (left side), together with main text fields extracted using EAST and Tesseract (right side).

The medical prescription contains some field that are relevant for our goal, in the following briefly described:

- 'regione' stands for region (administrative area Italy is splitted into), in this case with value 'Sicily'

Fig. 3. Text extraction from a sample medical prescription

- 'assistito' is the name of end user (registered to the SSN) the medical prescription refers to
- 'indirizzo', 'cap', 'citta' and 'provincia' are different parts of the end user's address
- 'cod\_fiscale' is the fiscal code (i.e. social security number) used to identify the user
- 'prescrizioni' is the list of medical services (e.g. drugs, therapies, screenings or specialist examinations as specified in section III); in the example shown, three blood tests are reported
- 'quesito' is the medical diagnosis as reported by the physician, that motivates the previous list of medical services

The last field 'quesito' is the most relevant for our purposes, since specific medical cares (field 'prescrizioni') can be allowed - and freely provided - by SSN only for specific diagnosis, therefore the field pair is used to rate the prescription as *grantable* or not, as discussed in previous sections.

## V. SPELLING CORRECTION

Once text has been extracted, we proceed with a spelling correction, that is required as in most OCR softwares residual errors still occur, in particular in our scenario where the quality of scanned images is not always high (as said previously) and also the text that appears in medical prescription is usually with a reduced font size. Furthermore, the recognition of the diagnosis block ('quesito' in fig. 3) is not trivial since this field is actually a free text with variable length, hence also spelling errors due to an incorrect entry by the physician are still possible. For all these reasons, the spelling correction is applied specifically to the diagnosis block; it consists of the following tasks:

- *Non-word* error detection, that is the detection of words characterized by incorrect spelling;
- *Isolated-word* error correction, i.e. the correction of the word written incorrectly without taking into account the surrounding context;
- *Context-dependent* error correction, that is word correction characterized by spelling mistakes based on the context.

Since no specific context is provided in the medical prescription, the spelling correction algorithm we implemented focus on the first and second task listed above. To fulfill its specification, the algorithm uses a words dictionary. This

vocabulary is preliminarily obtained by extracting all the words constituting the various rules used by the system in the classification phase.

ApplySpellingCorrection method, for each word in the diagnosis block searches in the vocabulary for all words that begin with the same letter. Then the TryCorrect method is called, passing as a parameter the set of words extracted from the vocabulary. This method leverages on the Damerau-Levenshtein distance [14] to accomplish its task; such a distance is the minimum edit distance between two strings, i.e. the lowest number of character insertion, removal and/or replacement to transform the former string into the latter.

If such distance is zero the word is correct, otherwise it must be replaced with the correct word in the dictionary. In our experiments, a threshold for such distance is chosen to limit the subset of candidate words extracted from the dictionary. In the case of a null subset (for the given threshold), the word to replace is considered *unknown*, since no proper word in the dictionary has been found. The higher the threshold, the more (and possibly not suitable) words will form the subset of candidates, hence keeping as lowest as possible the value is recommended; we carried out successfully experiments using '1' as threshold.

The performance obtained from the Spelling Correction algorithms are quite satisfactory, this is due not only to the efficiency of the algorithm, but also to the use of the cache, in which all the rules are stored, the word vocabulary used for spelling correction and the different weights used to calculate the score of the different rules.

## VI. INFORMATION CLASSIFICATION

The goal of information classification is to assess whether a given prescription is grantable or not, as specified in previous sections; to do this, the text extracted (and eventually corrected) is properly classified exploiting both the *Syntactic rules* and the *Rule-based tagging* NLP technique [15]. Syntactic rules are used to model all valid grammar sequences, whereas Rule-based approaches use contextual information to assign tags to unknown or ambiguous words (often called *context frame rules*). Rule-based taggers generally require supervised training, but also other approaches are available [16].

The proposed solution exhibits simplicity and good performance as it only requires the use of syntactic rules for pattern matching information extraction, and the use of rules that use data belonging to the context frame, to extract new categories of information. In this first stage of development rules and patterns have been manually built, but this time-consuming and error-prone task is going to be removed by automatized rules generation in further development of this work. The well know schema for a syntactic rule contains three tags, i.e. Source, Target and Data (see eq. 1).

$$Source \Rightarrow Target \# Data \quad (1)$$

The *Source* attribute indicates a specific pattern that the system must detect within the text string being analyzed before

it can apply the rule itself. The pattern for this attribute can be either a simple string or a syntactic expression to specify that a regular expression must be matched to detect the pattern within the text. To discriminate the type of pattern the *Source* attribute is set, rules are classified in *Regex Rule* and *String Rule*.

In a *Regex Rule* the *Source* attribute contains a Placeholder whose structure is shown in 2 and 3, where *placeholder\_value\_1* and *placeholder\_value\_n* are correct pattern matching expressions.

$$\{\{placeholder\_type : *\}\} \quad (2)$$

$$\{\{placeholder\_type : placeholder\_value_1|placeholder\_value_n\}\} \quad (3)$$

The *Target* attribute indicates the Placeholder that must be used when applying the rule to replace the pattern indicated by the *Source* attribute detected in the analyzed text. This attribute can be set in two different ways. The former requires that it simply contains the string to be used to perform the replacement, whereas the latter requires that it contains the index indicating the position of the word contained within the *Source* attribute to be used as a Placeholder when the rule is applied. In order to distinguish the two set modes, the index is always preceded by the special character £(this solution was chosen to avoid redundancy in rule coding). The replacement of pattern matching present in the rule with the value contained in the *Target* field is a text tagging operation hence the related placeholder must be characterized by a tag structure. In particular, the system provides that the placeholder of each rule is enhanced by a string having the following structure:

*placeholder\_type : placeholder\_value*

Finally, the *Data* attribute in eq. 1 indicates all the information that can be extracted from the analyzed text when the rule is applied. In general, this attribute is enhanced by a string consisting of the representation of information in JSON format. The system also allows this string to contain parameters represented in two different ways, based on their semantics. In a first case the parameter is indicated by an integer preceded by the special character &, where the integer indicates the position within the *Source* attribute of the word to be used to evaluate the parameter; another option is to use the following syntax:

*index.attribute\_name*

where *index* indicates the position within the *Source* attribute i.e. the key that must be used to access the data structure maintained by the system containing all the information extracted through the application of the rules and *attribute\_name* instead indicates the category of information of interest.

The syntax used for the coding of rules does not require that the *Data* attribute must necessarily contain a string consisting of the representation of information in JSON format. In fact, it is possible to associate the *Data* attribute with a string having the following structure:  $index_0 + index_1 + \dots + index_n$

When the *Data* field receives such a value, information extracted when the rule is selected are collected from those having indexing keys equal to words from the *Source* field at position  $index_0, index_1, \dots, index_n$ .

The algorithm to classify information is implemented in C# and operates as follows. After rules are fetched from the configuration file, it rates each rule with a score depending on the number of words in the *Source* field, distinguishing placeholders from simple strings. In particular, the *placeholder\_type* of each placeholder in the *Source* lead to a different weight for its related placeholder; such weights can be manually specified within the configuration file. Rules rating allows to establish their application order (priority).

## VII. SYSTEM TESTING

In this section we describe the testing phase carried out to evaluate the performance of spelling correction and information classification algorithms, with the final purpose of establishing whether an input medical prescription can be classified as grantable or not, or eventually whether the system was not able to classify it at all.

To this purpose, a dataset with about 800.000 text rows coming from medical prescription has been used, while the rule set for the classification contains about 5000 mapping rules; note that in this test we did not consider strings extraction from medical prescription, since we focused on the assessment of performance classification. In order to efficiently perform the test, a C# script working in parallel for each row invoking an HTTP POST at the REST service was developed. During the test, several information are collected: number of traumas, number of diagnostic query, symptoms and areas present in it and, moreover, the number of spelling corrections (incorrect words and their correction and the Damerau-Levenshtein distance).

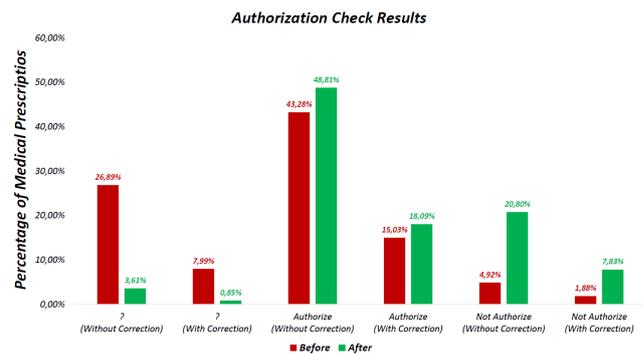

Fig. 4. Test Result

In figure 4 are shown the test results, where 'Authorize' and 'Not Authorize' indicate the grantable property, and '?' label collects those prescriptions that the system was not able to classify (named *unclassifiable* in previous sections. For each case, the two assessment (when spelling corrections are applied or not) are indicated separately.

The red line shows that approximately 30% of prescriptions are unclassifiable, a relevant (and then unacceptable) percentage in particular for the case when spelling corrections were not required. To tackle this situation, a first step was to map a lot of terms by writing a rule for each one of them, but this operation did not lead to a significant performance improvement, so we decide to include two additional information categories:

- *\_si*: featuring all those words whose combination, if present within the diagnosis text block, make the prescription grantable.
- *\_no*: where all those words that do not affect the classification of the medical prescription at all are stored.

The green line in figure 4 shows the result of the classification for this improved solution; in this case the classification improves significantly since only the 5% of medical prescriptions are considered unclassifiable.

### VIII. CONCLUSIONS

The main goal of the proposed system is to develop a service for the analysis and authorization of medical prescriptions. Results shown that in most cases the system allows automatic classification (as grantable or not) and only 5% were not automatically classified; from tests carried out on 800,000 recipes only around 4000 therefore required manual operator intervention. The classification phase is the most relevant part of the proposed system and its quality strictly depends on the number of rules used. Their writing is a time-consuming and error-prone task, especially if manually built, therefore a planned further work is to exploit machine learning techniques to automatically manage the set of rules.

### ACKNOWLEDGMENT

This work has been developed in cooperation with Pre-  
vimedical s.p.a. and Previnet s.p.a

# 1<sup>st</sup> Workshop on Data Analysis and Computation for Digital Ecosystems

**T**HE progress in Information and Communication Technologies (ICT) builds a strong basis to realize cross-domain data computation approaches. However, the data flow, coming from local sensors up to satellite remote sensing, business processes, enquiries, social networks and other manifold sources is extremely complex and dynamic. Therefore, sufficient data conditioning as well as analysis methods and corresponding ICT infrastructures are crucial for the extraction and handling of the information embedded in the data. Especially the development and implementation of efficient workflows for the integration of heterogeneous data types across various stakeholders presents a big challenge in the development of data-driven smart services. New paradigms are needed for empowering science, society and business to understand and design the interaction of systems and processes on different spatial and temporal scales. The idea of the workshop enables an interdisciplinary discussion of challenges and potential solutions in the new world of cross-domain data integration and information extraction (e.g. energy, health, environment, economy). We invite contributions presenting challenges, solutions, cases studies, and best practices dealing with ecosystem management, big data and workflow modeling. Competencies from the field of information systems, data science, environmental science, computer science, mathematics, medicine, energy and business are required to develop new promising ideas that contribute to the investigation and extraction of information from cross-domain data.

This special session is a joint event of WIG2, the Scientific Institute for Health Economics and Health Services Research, the Institute for Information Systems of the University of Leipzig and the Helmholtz Center for Environmental Research—UFZ.

## TOPICS

The topics of interest therefore include but are not limited to:

- Ecosystem design and management for cross-domain data exploitation
- Cross-domain maturity in businesses of different sizes and industry sector

- Case studies investigating challenges and potentials of cross domain analytical
- Efficient data management approaches along the chain of information
- Fusion of data, methods and results
- Data quality assurance
- IT-infrastructures and -architectures
- From data to variable and from variable to indicator workflows for smart services
- Best practices to improve interoperability
- Dealing with privacy and data ownership

## EVENT CHAIRS

- **Bumberger, Jan**, Helmholtz-Centre for Environmental Research – UFZ, Germany
- **Alt, Rainer**, University of Leipzig / Social CRM Research Center, Germany
- **Dietrich, Peter**, Helmholtz-Centre for Environmental Research – UFZ, Germany
- **Franczyk, Bogdan**, University of Leipzig, Germany
- **Reinhold, Olaf**, University of Leipzig / Social CRM Research Center, Germany

## PROGRAM COMMITTEE

- **Bosch, Jan**, Chalmers University of Technology, Sweden
- **Cirqueira, Douglas**, Dublin City University
- **Fileto, Renato**, Federal University of Santa Catarina, Brazil
- **Kabisch, Nadja**, Humboldt-Universität zu Berlin, Germany
- **Kirn, Stefan**, University of Hohenheim, Germany
- **Kirsten, Toralf**, Mittweida University of Applied Sciences, Germany
- **Lobato, Fábio**, Federal University of Western Pará, Brazil
- **Rot, Artur**, Wroclaw University of Economics, Poland
- **Suomi, Reima**, University of Turku, Finland
- **Veijalainen, Jari**
- **Viana, Julio**, Social CRM Research Center

## Location Intelligence in Cogenerated Heating Potential Data Analysis

**Abstract**—Different methodologies are used to assess the potential for using high efficiency cogeneration for cooling and heating. They are mostly adapted to the availability of data and tools for their analytical processing. This paper presents the approach applying location intelligence as a tool that allows using geospatial analysis algorithms and geovisualization of its results. Due to the extremely large amount of data and the dependence of the results on their accuracy and the level of aggregation, the initial methodology of the analytical process implied two steps: wide scale mapping by the "top down" method, and local mapping by "bottom up" method. However, in order to overcome the problem of regional disparities of quality and the existence of spatial data, certain adaptations of the initial methodology have been made considering the need for a single analytical approach for the entire area of interest. Randomized control of the obtained results indicate that applied geospatial algorithms satisfy the required level of accuracy and reliability of the final methodology.

### I. INTRODUCTION

IN 2004, the European Parliament and the Council of the European Union adopted the Directive 2004/8 EC whose purpose is to increase energy efficiency and develop high efficiency cogeneration of heat and power. The Annex III of the Directive defines the "High Efficiency Cogeneration" as the cogeneration production from cogeneration units that provides primary energy savings (PES) at least 10% compared with the references for separate production of heat and electricity (small scale cogeneration units, installed capacity below 1 MWe, and micro cogeneration units, installed capacity below 50 kWe, must provide primary energy savings, that is  $PES > 0$ ). Bosnia and Herzegovina (BiH) signed the Treaty establishing the Energy Community calling for the adoption and implementation of Acquis Communautaire on energy, environment, competition and renewables. The Acquis' essential directives pre-stipulate the area of energy end-use efficiency and energy services, energy performance of buildings and labelling. Bosnia and Herzegovina also signed to fulfill the obligations under the latest EED directive 2012/27EU [1] including the need to adopt policies incorporating local and regional potentials for using efficient heating and cooling systems, in particular

those using high-efficiency cogeneration and the potential for developing local and regional heat markets. According to the directive each country shall carry out a comprehensive assessment of the potential for the application of high-efficiency cogeneration and efficient district heating and cooling. The assessment covers entire territory of the country taking into account its specificities like present situation with central heating and cogeneration systems, climate conditions, economic feasibility and technical suitability on potentials for the application of high-efficiency cogeneration and efficient district heating and cooling. The analysis used in the assessment facilitate the identification of the most resource-and cost-efficient solutions to meeting heating and cooling needs [2]. This type of analysis has already been to some extent implemented within the European Union through, for example, the Multi-level Actions for enhanced Heating & Cooling Plans (STRATEGO) projects funded through the Intelligent Energy Europe [3] and Heat Roadmap Europe (HRE) [4].

Within the technical assistance provided by GIZ BiH (Deutsche Gesellschaft für Internationale Zusammenarbeit), it was carried out the study by a consultant group which, as part of the assessment, resulted in a mapping approach using geoinformation system (GIS) tools for presentation demands and potentials of using thermal energy.

This paper describes the methodology and the approach applying location intelligence (LI) as a tool that allows using geospatial analysis algorithms and geovisualization of consumption of thermal energy and the potential for the application of high-efficiency cogeneration and efficient district heating and cooling.

### II. THE METHODOLOGY AND THE MAPPING APPROACH

In order to properly assess the potential for the utilization of highly efficient heating and cooling technologies, primarily district systems and renewables, the spatial distribution of the demand and potential supply must be analyzed. Such an assessment demands a great deal of data which is often not available or at least not public or in a usable format. To work around most of these issues a two-

step approach is suggested here. In the initial step, the annual heat demand gathered on a national, regional or municipal level will be distributed spatially according to parameters such as population or building density. This will be used to perform a rough estimate to determine which areas are deserving of a more detailed analysis based on heat demand density and/or availability of local renewable resources. The second step will focus on the areas which have demonstrated a high potential for the utilization of highly efficient heating and cooling technologies either because of a high demand density or due to the abundance of renewable energy sources [5].

#### *A. Step one – top down analysis*

As it has been mentioned above, the initial mapping step will be conducted with a top down approach. Annual heating and cooling demand data will be gathered on national, regional and municipal levels (the availability and quality of data will determine the aggregation level). The collected data will be spatially distributed according to parameters such as population densities and land coverage. These data can be found in georeferenced forms in population and building censuses, cadasters and public databases such as the CORINE land use map [6]. The resolutions of these data are varied from very precise such as individual buildings or raster of 100 by 100 meters to less precise ones such as municipal or county level. The end result of this step will be a heating and cooling demand GIS map with a resolution of at least 1 by 1 km. Additionally to the demand, potential supply sources will also be analysed here. Potential heat sources such as excess industry heat, solar and geothermal energy as well as waste will be evaluated and presented in a GIS form. This analysis will provide the possibility to perform an initial evaluation of areas suitable for the exploitation of highly efficient heating and cooling technologies. Areas deemed worthy of further, more detailed, evaluation will be processed in the second step. This will include mostly larger cities and areas close to industrial parks and sources of renewable heat [5].

#### *B. Step two – bottom up analysis*

Areas identified as worthy of further evaluation will be analysed in more details in the second step. Here, a bottom up analysis will be implemented where the scale of the analysis will be individual buildings. For this purpose, cadaster data will be utilized to identify the locations of buildings and other vital data, where available, such as area, volume, age, use, level and time of refurbishment and so on. Representative buildings will be used or modelled to calculate the specific heating and cooling demands for certain building types based on parameters such as use, age and level of refurbishment. This will result in demands per area which will then be used to calculate the heating and cooling demand of all observed buildings. Where digital cadaster data is not available the CORINE land use map will be used and the process will result in a 100 by 100 meter

map of the area. Additionally, existing district heating infrastructure will be mapped. This will include production facilities and distribution grids. The resulting map will include the heating and cooling demands, existing infrastructure and potential sources of local renewable and excess heat [5].

Heating and cooling demands represent value (heat) energy required by population for heating and cooling buildings and spaces inhabited.

#### *C. The mapping approach*

The analysis of this type requires an extremely large amount of data, and the results depend on their accuracy and aggregation level. The methodology described above consists of two steps: state mapping by the "top down" method, and local mapping by "bottom up" method.

The first step of this process allows the development of a coherent map of demand for heating and cooling and potential sources of waste heat for the entire observed area of Bosnia and Herzegovina, its entities of the Federation of Bosnia and Herzegovina (FBiH), Republika Srpska (RS), and Brcko District (DB). The results obtained should serve to determine the priority areas for further analysis in the second step, which is based on a detailed analysis of demand at the level of individual facilities. This would provide detailed maps for areas of potential interest for the exploitation of district heating and cooling systems and high efficiency cogeneration which represented an important source of data for all further analyzes.

This approach would first result in a state map in resolution of 1x1 km, and as a final result, it would be obtained a set of maps with priority areas in 100x100 meter resolution.

Generally, this concept implies the approach applying location intelligence as a tool that allows using geospatial analysis algorithms and geovisualization of its results. In order to realize it may require the application of various tools, spatial data integration procedures [7], types of analysis such as geometric, topological, set oriented, grid and graph analytic methods [8][9].

### III. GEOSPATIAL ANALYSIS OF COGENERATED HEATING POTENTIAL DATA

In many instances the process of spatial analysis follows a number of well-defined (often iterative) stages: problem formulation; planning; data gathering; exploratory analysis; hypothesis formulation; modeling and testing; consultation and review; and ultimately final reporting and/or implementation of the findings. GIS and related software tools that perform analytical functions only address the middle sections of this process [10].

In this study, the first two stages related to problem formulation and planning are defined by a project assignment, so that the issues of the available data, the

analytical process itself, and the testing of the applied model, ie control of the results are outlined below. The quality and completeness of the data can have a dramatic impact and can cause implications for the results and the process of spatial data analysis itself [11]. During the geospatial analysis it was concluded that the sets of available data were not enough to carry out the analysis according to the initial methodology, and its adaptation was proposed. Also, a brief overview of the results of the analysis has been described, showing how well adapted the methodology is acceptable for further application.

### A. Available data

The major challenge for the design of the heating potential assessment study was the availability and quality of input data in various formats and for various purposes. For the purpose of providing data for calculating the needs for heating and cooling, various data sources have been used: land cadaster, population census, weather statistics, geodetic surveys, administrative statistical spatial boundaries, address register, map data (climate, rainfall, soil, forest cover), land use and land cover data CORINE 2012, official orthophotos, DEM, LiDAR, and public information on the Internet, such as studies on construction types, remote heating, energy efficiency, climate change and other sources related to the BH area. Useful sources were also typologies of residential and public buildings in BiH [12][13], as well as cogenerate sources and waste material co-incineration data [14].

Among the most important available data sets are the census data related to housing units, the way of heating and energy consumption. Some of the attributes associated with these sets were: the area of the apartment, the type of heating, the type of building, the year of construction, the number of floors, the building material, the building structure and the state of the object. Also, data for all existing district heating systems in BiH are collected.

Further, various data was collected for the needs of determining the specific annual heat energy required for heating and the annual cooling energy required per sector, which includes: altitude for municipalities, external temperature for building design, degree of development of municipalities, number of inhabitants per municipality, number of employees per sector, number households by municipalities, average household size per municipality, and total average residential area (usable area) per capita. Table I lists some of the spatial data sets used for the analysis.

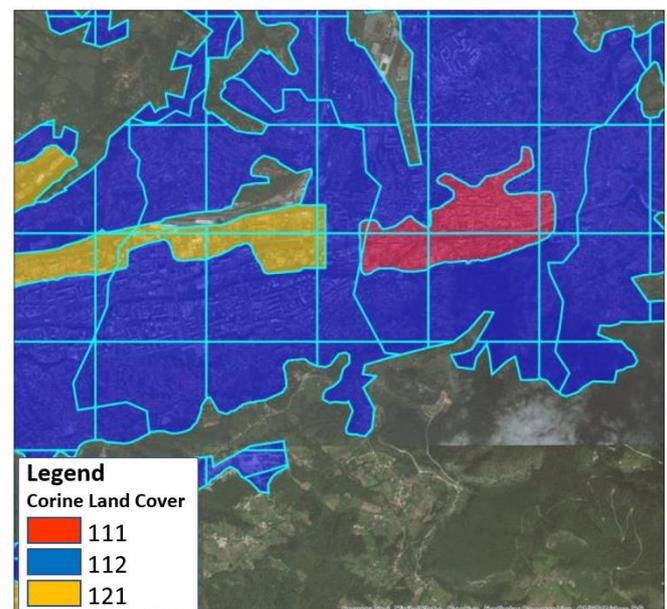

Figure 1. Intersection network, municipality boundaries and CLC data sets

### B. Geospatial analysis of heating potential data and adaptation of the methodology

In order to fully apply the described methodology, in addition the aforementioned sets, many more data were needed, but some were not available in useful form. Particular problems were the lack of geometric data on residential and industrial buildings in some parts of the country, as well as topological defects related to polygons of statistical units, which are used for the intersection with the network of squares for the presentation of the heating demands. Also, the lack of comprehensive and consistent data for the non-residential sector in BiH was particularly evident.

In order to overcome all the problems of regional disparities of quality and the existence of spatial data, certain adaptations of the initial methodology have been made considering the need for a single analytical approach for the entire area of interest.

#### 1) Country level mapping by the "top down" method

One of the aspects of this analysis was the determination of heating and cooling needs at the national and local level. In the first phase (top down) is made calculation of energy needs on state level for the following sectors: housing, public and service sector, and industry (Figure 2).

The procedure is based on determining the total area of housing, the public and service sectors, and the industry sector (in km<sup>2</sup>). This activity was carried out using the CORINE database, that is CORINE Land Cover (CLC), where are filtered only the categories of land cover which exclusively belonging to the one of the following classes:

- Continuous urban fabric (CLC code 1.1.1),
- Discontinuous urban fabric (CLC code 1.1.2.),
- Industrial or commercial units (CLC code 1.2.1).

The processing continued to provide information on how

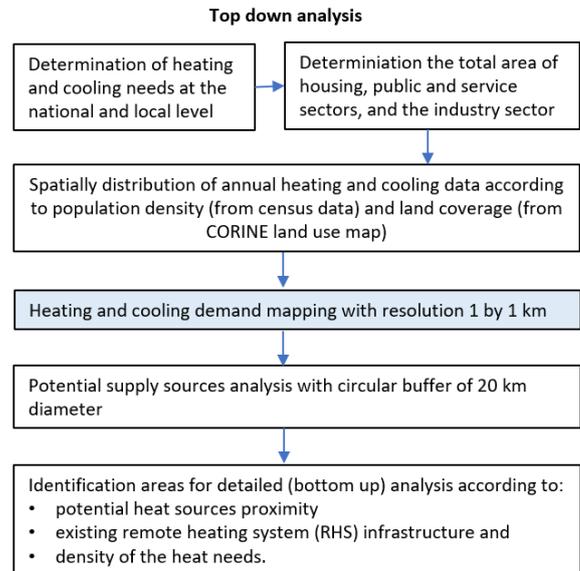

Figure 2. Steps of top down analysis

many municipalities have certain categories of land (in km<sup>2</sup>). Further, the same information is displayed spatially by a 1x1 km resolution raster. By addressing these data with data on energy needs calculation, final data was obtained at the municipal level and at the level of each square (1x1 km).

For this purpose, it was necessary to perform several operations in the GIS to enable the correct spatial distribution of the energy demand data. The first step involved intersecting three sets of data:

- Corina Land Cover (CLC) with
- 1x1 km network; and
- the boundaries of the municipalities.

Figure 1 gives the example of the data intersection. In this way, they are determined the area of each particle obtained, its belonging to the certain municipality and square of the

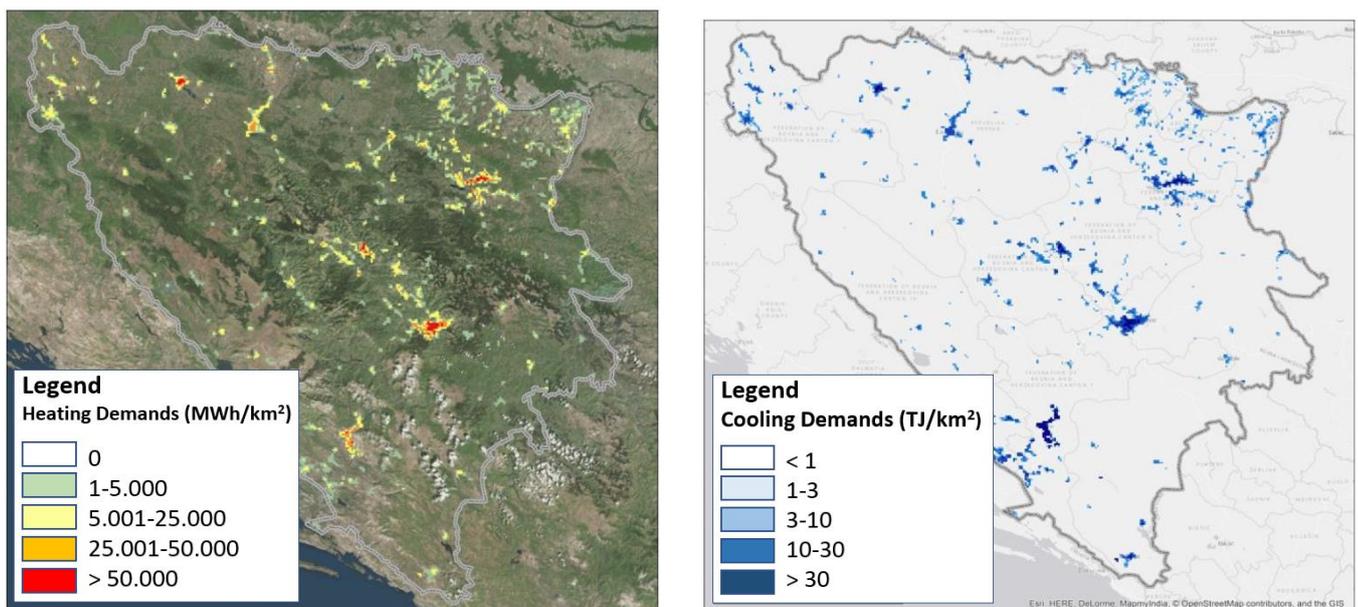

Figure 3. Maps of heating (left side) and cooling demands (right side) in Bosnia and Herzegovina with values in MWh/km<sup>2</sup> and TJ / km<sup>2</sup> units per year

network, and then heating and cooling demand are allocated to each particle.

Also, percentage share (%) of each particle in total area of a given municipality is determined for each purpose. The required annual heating energy for residential, public and service sector ( $RED_{pR/PS}$ ) is calculated using the formula (1):

$$RED_{pR/PS} = \frac{A_{pi}}{A_{in}} \times RED_{nR/PS} \tag{1}$$

where are:

- $A_{pi}$  area of the particle „p“ with purpose „i“;
- $A_{in}$  total area of land belonging to CLC class for purpose „i“ in certain municipality „n“;
- $RED_{nR/PS}$  required heating energy in municipality „n“ for residential, public and service sector.

In this way, the required heating energy for the industry sector is also determined ( $RED_{pl}$ ).

The total required heating energy at the level of each square should correspond to the sum of the individual needs of each respective particle for the different purposes of the CLC class land.

The same principle was used to determine the required cooling energy.

The applied methodology resulted in distribution of heating and cooling requirements at the level of the network square (1 km<sup>2</sup>) for the country. Due to a clearer view, two types of maps were created (Figure 2). with different measuring units (in MWh / km<sup>2</sup> and in TJ / km<sup>2</sup> yearly).

Figure 3 Maps of heating (left side) and cooling demands (right side) in Bosnia and Herzegovina with values in MWh/km<sup>2</sup> and TJ / km<sup>2</sup> units per year

For the purpose of allocating potential sources of waste heat, 21 sources, which are mainly large industrial and energy facilities (Figure 4), are identified and mapped. Currently, much of the surplus energy from these plants,

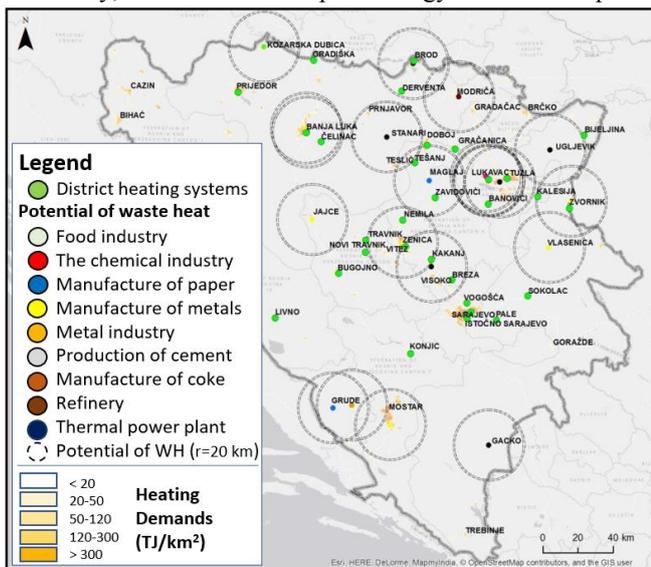

Figure 4. An overview of heating needs (TJ / km<sup>2</sup>) and waste heat potential

which can be used for heating and cooling purposes, remains unused, although these plants are mostly situated near densely populated settlements. The heat surplus from these plants can be theoretically estimated based on primary energy consumption or CO<sub>2</sub> emissions. A detailed description of the methodology for calculating the waste heat from CO<sub>2</sub> emissions can be found in the STRATEGO [15] report and research works [16].

For the purposes of assessing the potentials of high efficiency cogeneration in BiH, it is made the selection of areas which have relatively high density of heating needs, and these are mostly urban parts of municipalities and cities.

2) Local level mapping by the "bottom up" method

The second step relates to the mapping of heating and cooling demands at the local level for every selected area (municipality or city). Similarly, to the first step of the mapping (top down), the calculation for energy needs at the level of individual municipalities has been implemented separately for housing, public and services sector and for industry sector (Figure 5).

For selection of municipalities and cities, the following criteria were applied:

- existing remote heating system (RHS) infrastructure,
- proximity of the waste heat potential and
- the density of the heat needs.

The illustration of these data is shown in Figure 4.

According to the first and key criterion it is needed to select the urban environment with existing remote heating. The second criterion is the potential for exploitation of waste heat from industrial plants, as waste heat is the most convenient source for remote heating. A radius of 20 km has been set for areas with potential for waste heat utilization. The third criterion is the density of energy needs that goes to

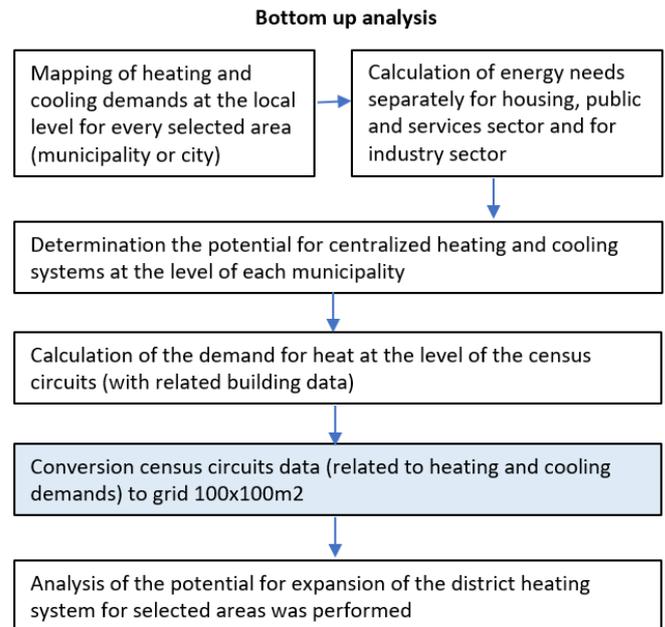

Figure 5. Steps of bottom up analysis

favor of those urban environments that do not have existing district heating and are not close to an industrial plant with waste heat but can justify investment because of high demands.

Taking into account the aforementioned criteria, a total of 39 cities and municipalities have been selected for further analysis, representing over 60% of total heating needs and 55% of cooling demand in Bosnia and Herzegovina.

According to the adopted methodology, heat energy needs for selected areas are determined for the residential and non-residential sector separately, and the results are presented on maps by network in resolution 100 x 100 m (Figure 6a).

In the final part of the study, it was determined the potential for centralized heating and cooling systems at the level of each municipality. Also, the analysis of the potential for expansion of the district heating system for selected areas was performed (Figure 6b). In discussion section of this paper, the deficiencies related to the application of the methodology are explained.

### C. Control of results

By visual detection, it is obvious that heating and cooling demands are distributed in terms of expectations and according to the areas where the largest number of inhabitants is concentrated (population per km<sup>2</sup>) and depending of geographic and climatic characteristics. In order to validate the data, it is conducted a detailed analysis of the municipalities of the City of Sarajevo (Figure 7) as well as several other municipalities, using information and experience gained through work on previous similar projects.

Based on the data presented in Figure 7, it can be concluded that the data spatial distribution satisfies, and the data are geocoded in accordance with the expectations and the real situation. The figures in the quadrants indicate heating demands in MWh / km<sup>2</sup>. The areas of the Novi Grad municipality (Figure 6a), namely the settlements Alipasino Polje, Hrasno and Cengic Vila indicate the high demand in this case as in the reality. On the other hand, the values

related to the peripheral parts of the city in Figure 6b, due to the smaller population density and the construction of individual residential buildings, indicate less heating needs. It can be concluded that the data is logically distributed in the space. For the purpose of final validation, a detailed analysis of the values based on their random selection was performed in accordance with the statistics norms.

For validation purposes, these results are also compared to other available data. For example, in the UK value of the largest demand quadrant is over 200,000 MWh, while in BiH it is close to 90.00 MWh. Considering the urbanization and population density (e.g. population density in the urban area of London is 1.65 times higher than in the urban area of Sarajevo), the data obtained can be considered as credible. Analyzing the available data from other countries in Europe (Spain, Czech Republic, Poland, Luxembourg), the results satisfy the expected framework (by the benchmark analysis).

## IV. DISCUSSION

Location intelligence (LI) implies an insight into the geospatial relationships between the phenomena that are studied to solve the problem important for spatial decision making [17]–[21]. This allows a layered spatial display of data sets processed using GIS tools for their transformation, analysis, and visualization.

In this study, LI had a twofold role:

- to prepare the cartographic basis for complex spatial analysis
- to visualize the spatial distribution of demands and potentials for the use of heat energy from cogeneration.

During the processing of geometric and attribute data in GIS special challenge was the heterogeneity of data (both syntax and semantic) [22] [23]. Namely, part of the accessible data represented attribute dwelling data referenced by census numbers and geometric data (polygons) of census circles that came from different sources. Due to its consistency and the unique model, it has been suggested to

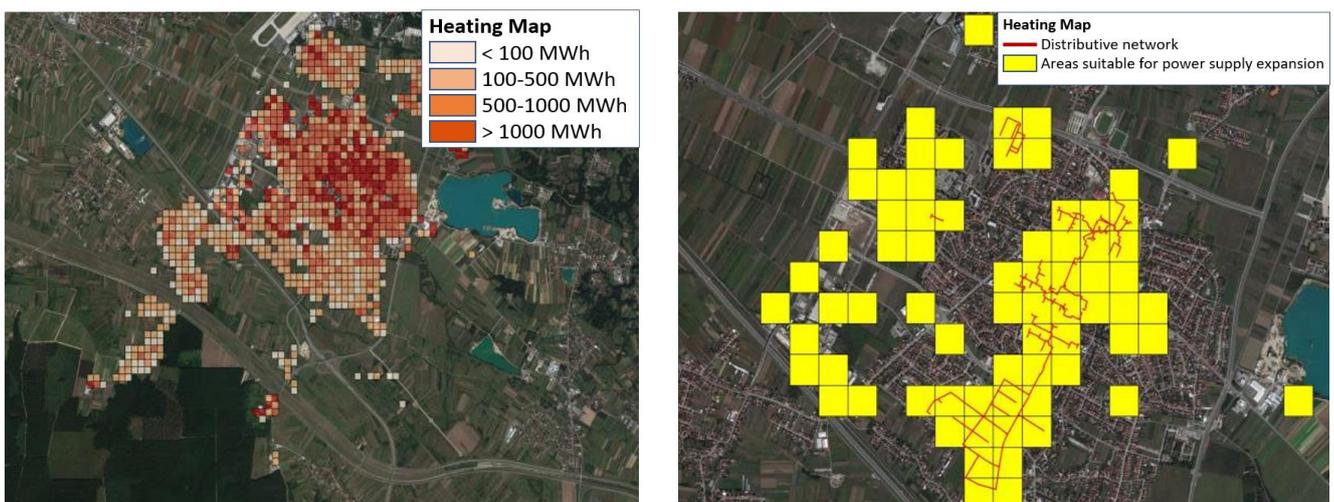

Figure 6. Examples of maps: a) heating demands presented by network 100 x 100 m (left side) and b) potential for expansion of remote heating system (right side)

Figure 7. Heating demands in MWh/km2 at 100 x 100 m network level in the City of Sarajevo, municipalities of Centar and Stari Grad

apply these data for the whole BiH area. Thus, they were used as a basis for the overall analysis, including the calculation of the demand for heat at the level of the census circuits.

Certain geometric data sets (for example, Brcko District) did not meet the topological conditions, so their further processing was done, including topology control, polygonization, and redrawing.

Further, the data on spatial content objects intended for commercial and other non-residential needs were not available for the whole area of interest, so that the following situations were evident for certain municipalities:

- partial or complete lack of data on buildings
- different formats and ways of layer presentation
- incompleteness of the data, including census numbers, inability to connect geometry with attribute data and other problems.

Also, no data on the district heating distribution network was available for a number of municipalities.

Because of these reasons different approaches have been used to compensate these shortcomings. For most of the municipality, data on buildings is downloaded from the Internet (Open Source Maps) and data are formatted to a unique format for applying a uniform GIS processing model. For some municipalities, it was not possible to determine the demands of the non-residential sector due to lack of data on buildings. Most of the data is taken from the cadaster databases resulting in the lack of many buildings and the unreliability of their areas due to timeliness.

After determining the key indicators of the situation with the energy needs, it is followed their geovisualization and creating of intelligent maps with different thematic levels (by point symbols, by municipalities, by grids 1x1 km and 100x100 m resolution). This implied the creation of several maps of heating demands (Figure 8), cooling demands (Figure 9), the potential of waste heat, the potential of renewable energy sources including solar energy, biomass, geothermal energy, and finally maps of existing district heating systems and the potential of their expansion. For the

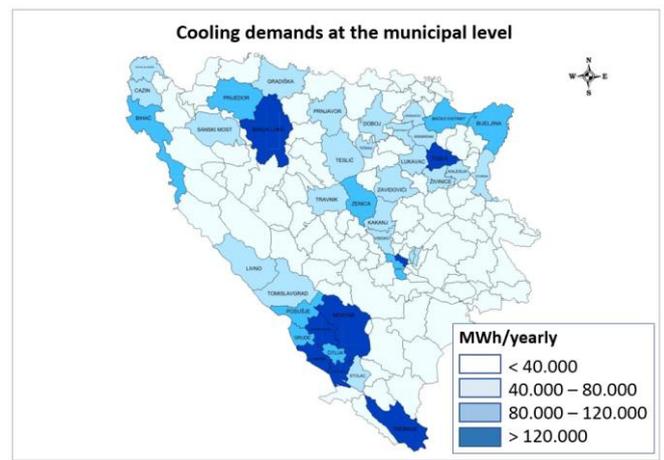

Figure 8. Map of cooling demands distribution by municipalities purposes of map creation, the appropriate models and designing procedures for each type of map were prepared followed by an appropriate set of data from the database.

For the purposes of mapping "top down", ie the determination of priority areas for further analysis, statistical data was collected at the level of individual municipalities. These data included the population, the total areas of all types of building and the climatic zones. Using these data and calculating the specific demand for heating and cooling for particular types of objects, demand for heating and cooling of each municipality was determined. These data were then distributed spatially by the CORINE map. Sources of waste heat and the potential amounts of energy they can deliver to the system are determined through collected data on greenhouse gas emissions according to the proposed methodology. The "top down" methodology used in this case was fully applied and no significant deviations were noted.

However, due to the lack of some key data needed to conduct „bottom-up“ analysis, the initial methodology had to be partially adapted. As cadastral data was not available for all the observed municipalities, and for some missing significant amounts of data, the application of Open Source Maps data was suggested, but this source was again insufficiently detailed. Data on the altitudes and the building purpose were also not available in a large part of the

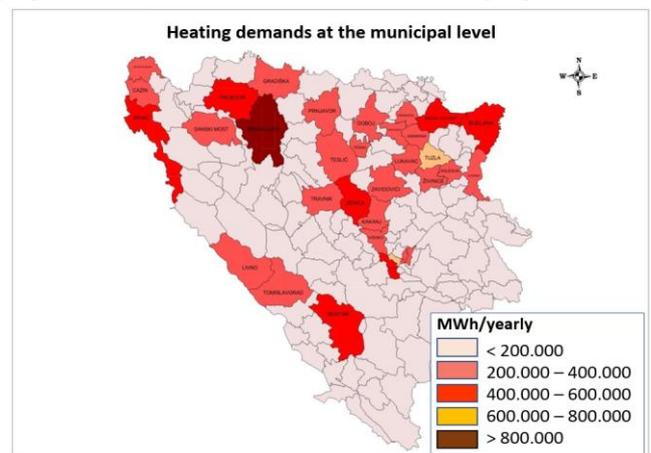

Figure 9. Map of heating demands distribution by municipalities

municipalities because they were either not public or not at all. Analyzing literature, it looks that are all common problems of similar projects. [24] [25]

In order to achieve the required goals, data at the level of census circles (which areas are mainly below 100X100 m) is applied, which gave results of comparable quality.

The proposed methodology could not be fully realized in this case due to the lack of key data, but the proposed alternatives are acceptable and have achieved satisfactory quality and level of detail.

#### V. CONCLUSION

In order to ensure the successful implementation of a comprehensive assessment of the potential for high efficiency cogeneration and efficient centralized heating and cooling, it is necessary to know the spatial distribution of their demand as well as potential sources of waste heat. Since the process of such mapping is highly dependent on the availability of data, it is initially proposed two step approach including methods of state mapping by the "top to bottom" and local mapping by "bottom up". The purpose of such an approach is, on the one hand, to create a coherent map with distributions of demand for heating and cooling and potential sources of waste heat for the whole observed area with a grid in resolution 1x1 km. On other hand, local mapping of selected areas gives a more detailed view of the state by applying a grid in resolution 100x100 meters [5].

For the final procedure applied for the assessment of the potential for the application of high-efficiency cogeneration and efficient district heating and cooling, they are suggested alternatives which were proved as acceptable. The main reason for the deviation from the initial methodology is the lack of data on which the methodology depends. This applies in particular to the data required in the "bottom up" mapping, ie to the current cadastral data on buildings. In order to conduct the process with an adequate level of detail, it is used census circuit data which generally have a resolution of less than 100X100 meters and are therefore applicable for the described procedure. The obtained results are in line with what the default methodology prescribes.

Randomized control of the obtained results indicate that applied data sets and appropriate geospatial algorithms satisfy the required level of accuracy and reliability implied by this methodology.

**Abstract**—New kinds of data collection like GPS-tracking, wearable sensors and mobile apps impose both technical and privacy challenges for medical research. In the MOPS study (*Machbarkeitsstudie für Ortsbezogene Parameter und Sensordaten* – feasibility study for geocoded parameters and sensor data) we provided 10 participants with a newly developed app and sensors for various physical and environmental parameters. We want to explore the feasibility of the recently established Medical Research Platform (MRP) of the Medical Faculty of the University of Leipzig and similar platforms for this kind of data collection and processing.

After briefly describing the Medical Research Platform we report on the technical set-up of the MOPS project in this setting and first practical experiences.

## I. INTRODUCTION

**T**ECHNICAL advances in the last decade – especially the ubiquity of smartphones – have made new kinds of data collection feasible for research. Sensors for many physical parameters are now comfortably wearable. Public facilities and initiatives for Open Data make more and more datasets publicly available, and it has become easy to – for example – link individual GPS data to public land use or noise maps. Software to work with this data is also freely available.

Medical research in particular is rooted in a tradition with strong focus on ethical and privacy consideration[2], and on long-term reproducibility on the results from raw data. That may sound trivial at first, but in practice it means getting explicit approval from an ethics board for each specific data collection, and storing all your raw data and analysis scripts for at least 10 years according to Good Clinical Practice.

### A. Privacy Issues

The collection of vast amounts of data about an individual raises serious questions about privacy. Long gone are the days that just using a pseudonym for each participant was viewed as a sufficient protection against re-identification. GPS data reveals your home and work address, answers to questionnaires might be matched against social media profiles and high-resolution sensor data from physical parameters contain highly specific individual patterns. Ever-present timestamps can be used to identify events and may themselves contain sensitive information.

An innocent looking data point like `{lat: 51.30175, long: 12.3775013, timestamp: "2019-05-20`

`17:32:12"}` could already be proof that the person this record refers to is an alcoholic (it's the time and place of an AA meeting).

For research, German law requires the “separate storage” of identifying data and research parameters (§27(3) BDSG). While this already means you should be using pseudonyms and store the names and contact information of study participants in a different database (or at least a different database table), it has been interpreted in the past as a requirement to also store research parameters with higher risk of re-identification like MRI data or genetic data separated *from each other* using different pseudonyms and a separate system (ideally managed by a trusted third party) to store the connection between these pseudonyms[6]. As discussed, tracking data from sensors certainly falls into the same category and should be treated accordingly.

### B. Reproducibility

In a setting where research datasets are basically CSV files with one row per participant and one column per variable, and the – previously committed to – analysis plan consists of a few well-understood statistical tests, reproducibility can be achieved by archiving a few data files in a text-based format. The description in the publication is often sufficient to redo the calculations.

Nowadays, however, data is often requested on the fly from various data sources, and sophisticated software packages (with many dependencies on other packages) are used to process the data.

Reproducing results – especially many years later – requires archiving not only data in various formats, but also scripts to automatically obtain the published results from the data. For this, archiving the exact software environment used for analysis is often necessary due to changes in packages, incompatibility of new versions or deprecation of features. This is also in line with more recent general requirements for scientific data management like the FAIR data principles[5]. It is however at odds with workflows that rely on online services (which might become unavailable or return different results), specific versions of proprietary software (whose licence key might expire) and in general complex systems of interacting parts.

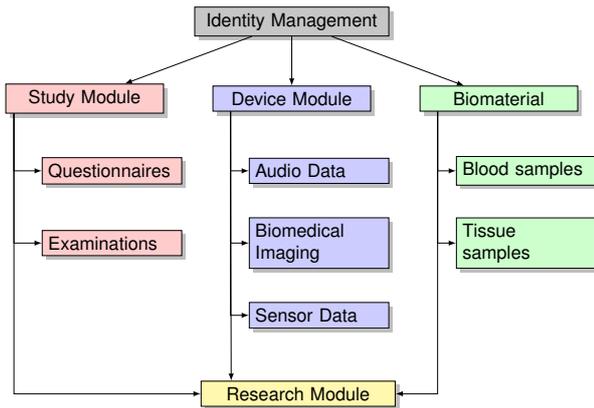

Fig. 1. Main Modules of the Medical Research Platform

### C. Scope of the MOPS study

With the MOPS study, we build on previous considerations on combining sensor data and publicly available data with classical approaches from epidemiological research laid out by Kirsten et. al. [1].

We use a small sample set ( $n=10$ ) to test the feasibility of the recently established Medical Research Platform (MRP) of the Medical Faculty of the University of Leipzig for this kind of study.

## II. THE MEDICAL RESEARCH PLATFORM

### A. Overview of the Modules

The study management software REDCap[3] has been used extensively at the Medical Faculty of the University of Leipzig since 2013 to conduct studies, especially those that are not part of a drug approval process. Electronic case report forms (eCRF's) are easy to set up and the system provides excellent support for various data management tasks.

In light of the new General Data Protection Regulation (GDPR) the use of REDCap was re-evaluated in 2018 and confirmed as a platform for future research projects – but it was amended by a separate ID- and Consent-management system to store identifying information and connection between pseudonyms separate from each other and from the REDCap system. Additionally, nextcloud-based file archives have been set up to separately store data from devices and to archive research datasets, and the LabCollector LIMS has been installed to track biomaterial samples.

A data protection concept was drafted to define the various modules of the Medical Research Platform (see Figure 1 – the Biomaterial module is not used in the MOPS study) and to describe what data (under which pseudonyms) is stored in each module, what the interfaces between the modules are and especially how and when the re-pseudonymisation is performed and how access rights are granted.

### B. ID Management

The ID Management solution LEIM was developed in coordination with the Data Integration Center of the Uni-

Fig. 2. The main screen of the MOPS app

versity of Leipzig Medical Center to serve as a flexible model implementation for a *Patient Identifier Cross-reference Manager*, a *Consent Management System* (accessible only via API) and a separate Web application for Contact Management. It's main focus is the smooth integration with the other components of the Medical Research Platform and an ongoing adaptation to the concepts and interfaces established by the Data Integration Center as part of the German Medical Informatics Initiative (SMITH). Currently LEIM does not use a so-called *PID-Generator* like the *Mainzliste*[4], but instead the pseudonymisation service generates a random Contact ID (*KID*) for use in the contact management and links it internally to the (also randomly generated) *PID*.

## III. THE MOPS STUDY

### A. Overview

In the MOPS project we equip participants with an app for GPS and mood tracking (see Figure 2), a wristband (bodymonitor.de) to collect physiological parameters like skin conductivity and temperature, and a sensor for environmental parameters like air humidity and temperature (FreeTec, Model NC-7004-675). Participants are asked to wear these devices for at least 24 hours, preferably longer.

It is a feasibility study to establish technical and organisational processes and to investigate the usability of the Medical Research Platform for this kind of data collection and processing.

Data	Source	Nr of records
GPS location data	App	286 805
Stress & Movement	BodyMonitor	4416 083
Mood	App (manual)	270
Transportation	App (manual)	196
Temperature/Humidity	FreeTec Sensor	2 504
Questionnaires	Interview	20

TABLE I  
DATA COLLECTED IN THE MOPS STUDY

### B. Organisatorical preliminaries

In order to conduct the study we submitted a study protocol to the Ethics committee. The study protocol did not only include the precise description of collected data, the aim of the study, description of recruitment process but also a data protection impact assessment detailing the risks for the participants in case of data leaks.

### C. Collected data

We collected data from 10 participants with the wristband, MOPS-App and questionnaires. Two of the participant used an additional sensor for surrounding temperature and humidity. An overview of the collected data points can be seen in Table I.

After collecting the data, participants were interviewed for their experiences. Most people found the wristband and the notifications of the app annoying or slightly annoying, while 7 out of 10 participants used Google Services to improve the accuracy of the location information, thereby transferring all the location data collected in the MOPS study also to Google.

Data cleaning and matching the various time-related data is still ongoing, but the overall functioning of the data collection was verified during a piloting phase (see Figure 3).

## IV. PRACTICAL EXPERIENCES WITH THE MRP

### A. LEIM for ID and consent management

For contact management, ID management and consent management a solution called LEIM (*Leipziger Einwilligungs-und Identitätsmanagement* – Leipzig Consent and identity management) had been developed based on the experience with similar tools especially at the German Center for Neurodegenerative Diseases.

The process of setting up a new study, defining the Informed Consent form and the types of Pseudonyms used is done through a simple web-based interface. Pseudonym types are defined by a simple declaration of fixed parts (most often prefixes) and random parts. The pseudonymisation service makes sure that random parts are created by a cryptographically secure pseudorandom number generator and that pseudonyms are unique within a study.

We defined the following pseudonyms: a Study Identification Code (*SIC*), an ID for the MOPS-App, an ID for the wristband, an ID for the sensor, and a pseudonym for the research dataset (*PSN*). In addition, each participant gets assigned a leading person identifier *PID* in the pseudonymisation service

of the Identity Management and an contact identifier *KID* in the contact management part of the Identity Management.

After that, a study- and role-specific token was created which allows requests to the pseudonymisation service of LEIM from other modules in order to map pseudonyms and to request consent status. Access to identifying information (names, addresses) is not possible through these requests.

As a last step, the project ID in the REDCap system has to be entered to allow easy referrals from contact management to data entry forms in REDCap (which requires the appropriate role for the user in both systems).

### B. REDCap for study data

In the MOPS study we collect only basic sociodemographic data – age and gender – as well as body height and weight in the study module. The pseudonyms for the devices (which are entered in the app, and stored on the the wristband and attached to the sensor) are stored only in LEIM, not in REDCap. Data entry and data export workes flawlessly in REDCap, as expected.

### C. Nextcloud for device data and research data archive

Nextcloud is an open-source, self-hosted file share and collaboration platform. It stores the uploaded files on the host file system, but provides checksums and versioning for all files, fine grained access control, access through a web interface as well as mounting it as a network drive (through WebDAV) and even a client for local synchronisation (not currently used in the Medical Research Platform). Using nextcloud is absolutely straightforward for any computer user.

## V. PRACTICAL EXPERIENCES WITH TECHNOLOGIES USED IN MOPS

Apart from the technical platform already provided by the Medical Research Platform we also explored various tools specific to the collection of sensor data.

### A. Flutter for App development

While there is certainly no shortage of mobile apps, especially with respect to monitoring anything health/fitness related, we wanted to explore how difficult it is to create a simple app where we could completely control the data collection and data transfer process.

Having a background in web development and scripting languages, we evaluated mobile frameworks that provided a familiar development workflow, especially having no (re-)compile times, a simple dynamic language and an accessible set of simple cross-platform widgets. We chose Flutter (flutter.io) and were able to create an app with GPS tracking, uploading, notifications to regularly enter the current mood status and mode of transportation within 3 days of work, resulting in little more than 500 lines of code.

The only compromise we made was not using GPS tracking in the background (i.e. when the app is not running), as this is currently only available as a commercial plugin.

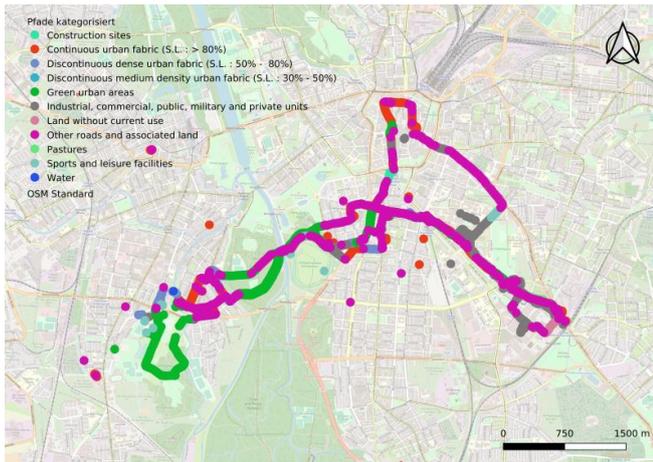

Fig. 3. A path recorded by the MOPS app, categorized by land use using the GeoEtiology PostGIS database

### B. PostGIS and QGIS for Geodata

As part of the long-term GeoEtiology project a PostgreSQL/PostGIS database was set up containing geocoded information about the Leipzig region from various sources. This includes noise maps, the road network, information about land use, places of interest (restaurants, schools), trees etc. Information about the social characterisation of a large number of addresses was purchased from the *SINUS Markt- und Sozialforschung GmbH*.

For the MOPS study, the database acted as an (rather large) part of the data processing pipeline in the device module. We loaded the data temporarily into the database, ran some queries involving the various spatial information stored there, and exported the aggregated results, see for example Figure 3 for a dataset from piloting where a path was categorized according to land use.

Although we repeatedly encountered queries that required some restructuring, additional indices and usage of materialized views to perform well, the overall experience with the GeoEtiology PostGIS database has been splendid.

### C. Guix for reproducible environments

The Medical Research Platform currently provides no special environment for scientific computing, instead, researchers are encouraged to ensure the reproducibility of their postprocessing and analysis scripts themselves by defining the required software environment alongside the scripts.

There are various lightweight approaches for different programming languages – virtualenv for Python, packrat for R, the Manifest file for Julia – but having whole virtual environments of all the software tools used has in the past been limited to container-based solutions like Docker.

We instead defined Guix environments[7] using the concept of channels, where specific versions of all used software (including R and Python packages, but also R and Python themselves) can be defined. All dependencies down to the operating system kernel are then tracked and set up. The channel definitions are simply checked into the version control

system alongside the scripts. Switching between environments is instantaneous, and reproducing environments on a different computer might require downloading packages but is otherwise guaranteed to reproduce the exact same results. While we used Guix environment for data processing scripts, we do currently not run the GeoEtiology database in such an environment.

## VI. CONCLUSION

Conducting the MOPS study on the Medical Research Platform is an interesting experience. The usage of different pseudonyms for different kinds of data and repseudonymisation for research datasets with the help of a separate ID management might seem cumbersome and overly cautious at first, but in practice it works well using the API of the LEIM pseudonymisation service. Generally, privacy concerns should be taken seriously and addressed at every step of the data processing.

Consequently working within Guix environments to ensure reproducibility seems doable in daily practice at least for the currently rather limited set of postprocessing and analysis scripts.

We hope to soon report on analysis results from the dataset collected in the MOPS study.

## ACKNOWLEDGMENT

The authors wish to thank Prof. Dr. Antje Körner, PI of the GeoEtiology project, for her support in using the GeoEtiology infrastructure. The activities were co-financed by the research project *Smart Sensor-based Digital Ecosystem Services* (S2DES, 2016-2020), funded by the European Social Fund (ESF; Grant Agreement No. 100269858)

# 14<sup>th</sup> Conference on Information Systems Management

**T**HIS event constitutes a forum for the exchange of ideas for practitioners and theorists working in the broad area of information systems management in organizations. The conference invites papers coming from two complimentary directions: management of information systems in an organization, and uses of information systems to empower managers. The conference is interested in all aspects of planning, organizing, resourcing, coordinating, controlling and leading the management function to ensure a smooth operation of information systems in an organization. Moreover, the papers that discuss the uses of information systems and information technology to automate or otherwise facilitate the management function are specifically welcome.

## TOPICS

- Management of Information Systems in an Organization:
  - Modern IT project management methods
  - User-oriented project management methods
  - Business Process Management in project management
  - Managing global systems
  - Influence of Enterprise Architecture on management
  - Effectiveness of information systems
  - Efficiency of information systems
  - Security of information systems
  - Privacy consideration of information systems
  - Mobile digital platforms for information systems management
  - Cloud computing for information systems management
- Uses of Information Systems to Empower Managers
  - Achieving alignment of business and information technology
  - Assessing business value of information systems
  - Risk factors in information systems projects
  - IT governance
  - Sourcing, selecting and delivering information systems
  - Planning and organizing information systems
  - Staffing information systems
  - Coordinating information systems
  - Controlling and monitoring information systems
  - Formation of business policies for information systems
  - Portfolio management,
  - CIO and information systems management roles
- Information Systems for Sustainability
  - Sustainable business models, financial sustainability, sustainable marketing
  - Qualitative and quantitative approaches to digital sustainability
  - Decision support methods for sustainable management

**Abstract**— The government of Saudi Arabia has adopted M-Government for the effective delivery of services. One advantage that it offers is unique opportunities for real-time and personalized access to government information and services. However, a low adoption rate of m-Government services by citizens is a common problem in Arab countries, including Saudi Arabia, despite the best efforts of the Saudi government. Therefore, this paper explores the determinants of citizens' intention to adopt and use m-Government services, in order to increase the adoption rate. This study was based on the Mobile Government Adoption and Utilization Model (MGAUM) that was developed for the purpose. Data was collected, and the final sample consisted of 1,286 valid responses. The descriptive analysis presented in this paper indicates that all the proposed factors in our MGAUM model were statistically significant in influencing citizens' intention to adopt and use m-Government services.

## I. INTRODUCTION

Governments from across the world have digitized their services to citizens through mobile technologies and the Internet, which has arguably improved communication between citizens and their governments, to provide better access to services and information, as well as improving government accountability, transparency and public governance [1], [2]. In this study, m-Government is defined as the use of mobile technology to deliver and improve e-Government services and information to citizens, commercial organisations and all government agencies. Previous studies have either regarded m-Government as separate to e-Government or as an extension or replacement of it [3], [4]. As it offers the public a valuable extra means to access services and information, it can be considered an advance in government service delivery [5]. Although e-Government and m-Government work on the same principle, the latter is distinguished by features that are particular to it: Citizens can access the network from anywhere and at any time [6]; and can instantly receive messages from government service providers on their mobiles [7]. The mobile phone has recently become the primary way people communicate and has thus arguably become a part of everyday life for many people [8]. Therefore, being able to access government services via mobile devices might be the

best route for citizens. Accessing government services and information on their phones means citizens neither have to visit the service provider in person nor go home to use their computer in order to do this [7], [9]. Access to the Internet may depend on economic factors, i.e. the extent of Internet access in a particular country, and how many citizens have access to computers providing mobile services can overcome these limitations [5].

An m-Government system provided by wireless technology, will give citizens opportunities for personalized access to government services and information in real time [10], [6]. This is especially beneficial for users in remote areas as m-Government services have the advantages of being affordable and easily and immediately accessible. Further, a relatively low level of digital literacy is required to operate them successfully [11], [6]. Given these features, the adoption of an m-Government system benefits both citizens and governments.

The Mobile Government Adoption and Utilization Model (MGAUM) has been developed as a framework from which to analyse factors affecting adoption and use of m-Government services [12]. This study aims to investigate and understand Saudi citizens' perceptions towards the adoption and utilization of m-government services in developing countries, particularly Saudi Arabia, in order to increase the adoption rate of m-government services.

## II. THE RESEARCH METHODOLOGY

The study was conducted in Saudi Arabia; and the questionnaire was distributed to adult Saudi citizens. The total valid responses constituted a sample of 1,286 Saudi citizens. SPSS was used to analyse the survey study data. The survey questionnaire was developed and modified from items used in previous research into both e-Government and m-Government. All items were measured with a 5-point Likert scale.

### A. Reliability and validity of the study

To be considered reliable, a research instrument needs to produce similar results if used in comparable conditions and be relatively free of errors [13]. As part of the pilot study for

this research, Cronbach's Alpha was chosen to assess the reliability of the questionnaire, and establish the internal consistency of the constructs used. Table 1 indicates the Cronbach's Alpha results for the complete research instrument, and demonstrates that the reliability of each of the constructs (independent and dependent variables) lies within the range of what is thought of as acceptable in academic research.

Face and content validity were chosen to be investigated rather than construct or criterion validity. The face validity of each item was ascertained in the pilot study to ensure that the model's factors measured what they were intended to measure; and items deemed to lack sufficient clarity, unambiguity or relevance were deleted or revised accordingly.

TABLE 1: INTERNAL CONSISTENCY OF THE STUDY SURVEY INSTRUMENT

Measured Variable	No of Items	Cronbach's Alpha
Perceived Usefulness (PU)	7	.898
Perceived Ease of Use (PEOU)	4	.862
Social Influence (SI)	3	.779
Perceived Compatibility (PCOM)	2	.868
Perceived Trust (PT)	7	.715
Culture (CULT)	5	.616
Awareness (AW)	4	.842
Perceived Mobility (PM)	3	.776
Citizens Service Quality (CSQ)	8	.920
System Quality (SQ)	7	.745
Intention to use (ITU)	4	.894

### III. RESEARCH FINDINGS AND DISCUSSION

This section provides an overview of respondents' demographic characteristics; and a descriptive analysis for each factor proposed in the MGAUM is given in order to explain their impact on citizens' intention to adopt and use m-Government services in Saudi Arabia.

#### A. Respondents' demographic data

In the final sample 813 participants were male (63.2%) and 473 were female (36.8%). The highest percentage of participants was in the 18–30 age group, the largest number held a bachelor's degree and over half the participants (46.7%) were government employees. All participants had Smartphone devices, with a large majority using mobiles and the Internet in daily life (96.4% and 93.3% respectively). Approximately three-quarters of the respondents (76.7%) have some knowledge about m-Government services in Saudi Arabia, whereas 22.9% had no knowledge. Moreover, the majority of participants (90.5%) already used m-Government services, but 9.5% had never used them. Participants who had already used m-Government services were asked to rate their general experience: 40.3% were very satisfied, 44.3% were satisfied to some extent, with only 5.9% not satisfied. Furthermore, 22.6% reported that the

requirements of the intended m-Government services were not clear and 26.6% reported that the system quality of m-Government services was not good.

#### B. The Measures of central tendency and Likert Scale

A central tendency sums up an entire set of differing values, so the mean, median or mode is used according to what is most appropriate for the specific conditions being described. The mean is the most common measure of central tendency and was used in this study [14].

A Likert scale, was chosen as the main instrument in this study's questionnaire, as the simplest and most practical way to measure strength of opinion; and a review of the literature shows that is most commonly and successfully employed in IS research [14,15].

Weighted averages were calculated for the Likert scales, from Strongly Agree=1 to Strongly Disagree=5, (see Table 2) so that the tendency of the composite scores could be ascertained. The numbers entered into SPSS represent 'weight' and the weighted averages for the scale needs to be calculated to understand means. The results can be interpreted to show how influential (or not) each factor is [16].

TABLE 2: WEIGHTED AVERAGES FOR 5-POINT LIKERT SCALES

Weighted average	Result	Result Interpretation
1 – 1.79	Strongly agree	Very influential
1.80 – 2.59	Agree	Influential
2.60 – 3.39	Neutral	Neutral or do not know
3.40 – 4.19	Disagree/	Uninfluential
4.20 – 5	Strongly disagree	Very uninfluential

#### C. Descriptive analysis of data

The data collected was analysed with reference to each of the constructs in the MGAUM [12]. Participants' attitudes, intentions and behaviour towards adopting and using Saudi m-government services were explored by means of responses to statements for which Likert scores could be calculated.

TABLE 3: RESULT FOR ALL FACTORS

Factor	Items	Mean	S.D.	Result interpretation
PU	7	1.3900	.49876	Very influential
PEOU	4	1.5733	.61942	Very influential
CULT	5	1.9997	.69224	Influential
PT	7	2.3586	.62882	Influential
SI	7	1.6516	.62692	Very influential
PCOM	2	1.5638	.66208	Very influential
AW	4	2.1763	.87356	Influential
CSQ	8	2.0852	.69808	Influential
SQ	7	1.8891	.54653	Influential
PM	3	1.5625	.57052	Very influential

Table 3 summarizes the results of the descriptive analysis with an interpretation of all results.

**Perceived Usefulness (PU):** It was important to determine what users' perceptions were about the usefulness of m-

Government, the advantages that they would gain from using m-Government services in terms of saving time, effort and money and how this influenced their behavioural intention.

Most (93.9%) agreed that using mobile government services would be useful. Participants believed that using them would enable government transactions to be effected more quickly as well as saving them time, money and effort (94.4%) and enable them to perform transactions from any location (96%); 89.6% believed that using m-Government services would make communication between a government agency and citizens easier through text message, applications and e-mail; and over 94.2% agreed that using mobile government services would remind them of important dates in order to conduct or receive government transactions in sufficient time or at the right time. Using features on mobile devices that are not found on the website, such as reminders, location and camera were thought to add value to services.

The factor was interpreted as significantly influential on citizens' intention to adopt and use m-Government services; and that use of m-Government services would increase when users perceive their benefits. This indicated that governments should take into consideration the requirements and needs of users to be met before implementing any services. The findings of this study are consistent with previous empirical investigations of factors that might affect the adoption of m-Government services in Egypt [17], and Taiwan [18].

**Perceived Ease of Use (PEOU):** The vast majority of participants (93.7%) agreed that learning to use mobile government services would be easy; and 92% believed that interactions with m-Government would be clear and understandable; 86.2% believed that using m-Government services required little skill and effort.

The total score for the PEOU factor was 1.5733 (see Table3), which indicated that PEOU is very influential on users' intention to adopt and use M-Government services. The result suggests that the user experience is the first step in adoption; and if a user finds m-Government services easy to use and that it saves time and effort, this impacts positively on behavioural intention to adopt and use them. If services are easy to use, and people do not have to rely on asking for help from another person to use the application, the number of users will increase. Thus, PU and PEOU are essential factors in the MGAUM, and any theoretical framework which seeks to analyse intention, adoption and use of m-government in the Saudi context or similar contexts in developing countries. The findings are with line with previous studies which found that PEOU is an important factor in determining intention to use [18], [19].

**Culture (CULT):** The concept of culture is complex and multi-dimensional, and contains many different aspects, for example, religion, social structure, language, political institutions, education and economics [20]. The behavioural intentions of Arab users are very much influenced by social values, interpersonal relationships and other issues related to religion [21]. CULT was measured by questions relating to

central cultural aspects including Image, Resistance to Change and Interpersonal social networks (*wasta* or social connection and nepotism).

With respect to the influence of Image, participants were asked if they felt that using m-Government services would enhance their social status and make them feel more sophisticated; and (82.2%) agreed that it would. Participants believed that using mobile government services would reduce the influence of interpersonal networks (*wasta*) (85.2%) and prevent any negative influence on their transaction by uncooperative employees (87.9%). Concerning Resistance to Change, only 27.2% of participants agreed that face-to-face dealings were better than using m-government, 17.4 % of them were neutral, and 55.4% disagreed entirely. Furthermore, 21.8% of participants agreed that visiting agencies to track transactions was preferable to online tracking, 64.4% disagreed and 13.8% were neutral. The composite of the CULT factor was 1.9997, a result that indicated that CULT is influential on users' intention to adopt and use of m-Government services. This corresponds with findings by other studies in the literature, that revealed that social and cultural aspects were significant influences on Saudis' intention to adopt and use e-Government systems from both citizens' and employee's perspectives [22]; and that the main barriers to Omanis adopting e-Government were cultural rather than technical issues [23].

**Perceived Trust (PT):** Different aspects of PT such as risks to privacy (sharing and storing personal information), security and trust were measured. Participants were asked if they felt that the Internet was not safe to be used for dealing with the government; and 41.0% believed that the Internet was safe, while 33.3 % believed it was safe, and 25.7% were neutral. This indicates some distrust in the Internet. By contrast, 73.9% of participants agreed that mobile government services were a safe and trustworthy environment in which to conduct government transactions, 20.8% were neutral and 5.3 % disagreed. This indicates that citizens' trust of m-Government services is high, and this might well have a positive influence on citizens' intention to use m-Government services. However, regarding whether providing personal information was safe 42.6% agreed, 19.8% were neutral and 37.6% disagreed; and 33% agreed their data could be misused when stored by m-Government systems, 24.3% were neutral and 42.8% disagreed. The total score for PT was 2.3586, indicating that PT is influential on intention to use m-Government in line with numerous studies that have noted that perceived trust was a significant factor [18], [24].

**Social Influence (SI):** This factor addresses users' perception of the effect of social influence and how this would encourage intention to adopt and use m-Government services. A large majority (80.5%) agreed that people important to them would think they should use mobile government services, 15.8% of them were neutral, and 3.7%

disagreed. 89.3% of participants said they would be encouraged to use m-Government services by their families and friends. The vast majority of participants (92.3%) intended to use m-Government services because it was the current trend. The composite of the SI factor was 1.6516, which indicates that SI is very influential on users' adoption and use; a result consistent with previous studies [24]. In a context like Saudi Arabia, where communities are very close, SI is a very important factor to include in the MGAUM, interestingly the desire to be seen by significant others as 'following the trend' was revealed as a powerful incentive in this context.

**Perceived Compatibility (PCOM):** This factor focuses on how users perceive the compatibility of m-Government services with their lifestyle and behaviour, and how this affects and encourages their intention to use m-Government services.

The vast majority (91.4%) of participants believed that using m-Government services would fit well with their lifestyles as well as being the way they liked to conduct government transactions (89.7%). The total score for PCOM was 1.5708 which indicates that this factor is very influential on intention to use; and that a high level of compatibility with the innovation would increase users' intention to adopt and use it. This finding is in line with other studies [24], [17]. Unlike previous research, this study included a high number of Saudi female participants. In a society where contact between sexes is sensitive for religious and cultural reasons, conducting government transactions on their phones arguably gives Saudi women both privacy and removes the need for face-to-face interactions with male government officials.

**Awareness (AW):** is the first stage where users experience a new service offered by the government. Participants were asked about which advertising methods could affect citizens' awareness of m-Government services and encourage their intention to adopt and use.

Many participants (76.7%) believed that they had a good level of knowledge about the benefits, features and services of m-Government, 14.9% were neutral, and 8.4% did not. Almost 68.6% of participants agreed it was easy to find out if a government agency offered its services via mobile devices, 17% of participants were neutral and 14.4% disagreed. Furthermore, 68.8% of participants agreed they had received enough information and guidance on how to use mobile government services, 14.9% disagreed and 16.3% were neutral. Also 66.6% were satisfied with the current awareness campaigns and advertising about m-Government services in Saudi Arabia, 16.4% were neutral and 17.0% were not satisfied. It is thus likely that AW positively influences citizens' intention to adopt and use m-Government services, in line with other findings [17], [25].

**Citizen Service Quality (CSQ):** Three main service quality dimensions were used to measure service quality in this study, i.e. reliability, responsiveness and empathy; and designed to measure customers' evaluation of the overall experience of services and explaining the difference between

users' perceptions and their expectations of the services offered by the government.

Participants were asked to what extent that they believed that m-Government service providers give 'a prompt service with a good response'; 75.6% agreed they did, 19.2% were neutral, and 5.2% disagreed. Similarly, most participants believed that m-Government service providers offered helpful assistance through SMS.

When asked whether they believed that information provided through m-Government services was accurate. 76.4% agreed it was, 19.9% were neutral and 3.7% disagreed. Furthermore, 69.4% of participants believed that m-Government service providers showed a sincere interest in solving citizens' problems, 24.8% were neutral, and 5.8% disagreed. The result echoes findings in Jordan [26] and Saudi Arabia [27] that the service quality dimension impacts significantly on citizen satisfaction and behavioural intention.

**System Quality (SQ):** This includes the technical aspects that are recognised by users, and which can affect their willingness and intention to adopt and use m-Government services. Regarding whether the speed of launching m-Government services applications or websites would affect participants' intention to use it, 79.1% agreed it would, 13.5% were neutral and 7.5% disagreed.

81.6% believed that m-Government was easy to navigate and that it provided good navigation functions; in contrast, 14.2% were neutral and only 4.2% disagreed. In respect of the existence of technical errors, such as applications crashing, links not working and unresponsiveness, (application/website), as well as the bad layout and unattractive interfaces of m-Government services 79.7% and 73.3% of participants respectively, agreed that these elements would reduce their willingness to use it. 86.2% of participants agreed that services should be compatible with mobile devices such as GPS and camera. Furthermore, 80.2% and 76.8% respectively believed that m-Government services provided fast responses to their enquiries as well as up-to-date information. The composite of the SQ factor was 1.8897, which indicated that SQ is influential on users' intention to adopt and use m-Government services. The results echo studies that indicated that when the system quality of m-Government services increases, citizens' intention to adopt and use them will also increase [26], [27].

**Perceived Mobility (PM):** The majority (89.8%) of participants expected to be able to use m-Government services anywhere and at any time; and found mobile government services were easily accessible, portable and easy-to-use on different models of Smartphone. 94.6% agreed it was important to get critical alert notifications on their mobiles from government agencies via text or email regarding passport renewal, traffic penalties and emergency cases whilst they were on the move. The composite of the PM factor was 1.5625 which indicates that PM is very influential on the intention to adopt and use m-Government services, and that citizens in Saudi Arabia value the ability to constantly access government services and information from

any location. The findings for this factor are consistent with previous studies in China [28].

The statistical analysis and discussion above allow us to estimate the most influential factors for increasing the intention to use m-Government services in Saudi Arabia.

#### IV. CONCLUSION

The researchers constructed the MGAUM model to identify factors revealed by the literature and personal professional experience to be likely to influence Saudi citizens' intention to adopt and use m-Government services.

The result of descriptive analysis presented in this paper indicates that all the proposed factors in MGAUM model (PU, PEOU, CULT, SI, PCOM, PT, AW, CSQ, SQ and PM) were statistically significant factors in influencing Saudi citizens' intention to adopt and use m-Government services and when properly addressed could increase the adoption rate of m-Government services.

We intend the results to provide a valuable insight into the main factors that influence citizen intention to adopt and use m-Government services in Saudi Arabia; which will be useful for researchers, the ICT industry and for policymakers who are keen to find strategies that result in quicker and more efficient take-up of such services.

This study added several contributions to theory and practice in the field of m-Government adoption and use. Firstly, this research developed the Mobile Government Adoption and Utilization Model (MGAUM) to analyse factors that affect users' adoption and use of m-government. MGAUM integrates the Technology Acceptance Model with a number of social, cultural and technological factors, taken from other recognized theoretical acceptance models that have been identified as key factors in the literature. Secondly, the MGAUM is empirically tested and validated by collecting and analysing primary data from the citizens' perspectives. Thirdly, this is one of the first few studies investigating the adoption and utilization of m-government in Saudi Arabia.

**Abstract**—Many governments worldwide are taking advantage of the latest developments in mobile technology to take the digital delivery of government information and services (e-government) to their citizens a stage further. Accessing government information and services via a mobile device is known as m-government, a system designed to serve citizens, companies and government agencies alike. M-government also has unique advantages over e-government, not least enabling users to access government services at any time and from any location. This paper presents a pilot study of the MGAUM model that was developed to analyze factors influencing the adoption rate of m-government services in Saudi Arabia. With the aim of validating a survey instrument with which to conduct the main study in Saudi Arabia, a pilot survey instrument was developed and modified by using previous instruments from research into both e-government and m-government. This pilot questionnaire was distributed to 71 Saudi citizens in the UK, and the final sample was 58 valid responses. The results of this pilot study reveal that all items in the survey instrument were reliable and valid within the range of acceptable academic research and suitable for use in the main study. The results of this pilot study were analyzed using SPSS.

## I. INTRODUCTION

The revolution in Information and Communication Technologies (ICT) has resulted in governments across world digitizing their services to citizens through tools such as mobile technologies and the Internet. Arguably, the implementation of e-government has resulted in better communication between citizens and their governments with enhanced access to services and information as well as improvements in government transparency, accountability and public governance[1], [2], [3]. Several governments have also implemented mobile government (m-government) by developing innovative service delivery channels that utilize wireless and mobile technologies [4], [5]. Accordingly, in this study, m-Government is defined as the use of mobile technology to deliver and improve e-government services and information to citizens, businesses and all government agencies. Previous studies have identified m-government as both separate to e-government or as an extension or replacement of it [5], [6]. Kushchu & Kuscu stress that it is an advance in government service delivery as it offers the public a valuable extra means to access services and information[4]. Although the same principles are common to

IEEE Catalog Number: CFP1985N-ART ©2019, PTI 633

e-government and m-government, the latter is distinguished by features that are particular to it:

- The main advantage for citizens of m-government is its mobility, giving citizens access to the network at any time and from anywhere[7].
- As mobile phones can be used easily, citizens can instantly receive messages from government service providers[8].
- In many countries, the mobile phone has recently become the primary way people communicate over distance; the mobile phone has thus arguably become a part of everyday life for many people[9], [10]. For this reason, being able to access government services via mobile devices might be the best route for citizens.
- More and more people are using their mobiles to access the web. For citizens, this means they neither have to visit the service provider in person nor go home to use their computer when they want to access government services and information[8], [10].
- Access to the Internet may depend on a country's economy in terms of the extent of Internet access and how many citizens have access to computers[6],[4]; these limitations can be overcome by providing mobile services.

Therefore, by using an m-government system provided by wireless technology, citizens will acquire opportunities for personalized, real-time access to government services and information[11], [7]. Users in remote areas will especially benefit from being able to access government services and information as m-services have the advantage of being affordable, easy and immediate to access and require a relatively low level of digital literacy to operate successfully [12], [7]. Given these characteristics, the adoption of an m-government system has benefits for citizens and government alike. Any government services that citizen can use via mobile devices, such as apps, mobile website (web platform), SMS or call centre, are considered as mobile government services. So, this research focuses on all government services are provided via mobile devices. Therefore, the government agencies should concentrate on

offering different channels for citizens to conduct government transactions at the same time to allow fast and easy access to these services fast. However, the main difference between the website and mobile devices is that features on the mobile web platform and Apps that add value to services, such as reminders, location and camera, are not found on the website. However, from the researcher's experience, people prefer to use native applications rather than a mobile responsive website.

The goals of this research are to investigate and understand Saudi citizens' perceptions towards the adoption and utilization of m-government services in developing countries, particularly Saudi Arabia, in order to increase the adoption rate of m-government services. This paper focused on validating the MGAUM model that has been developed by integrating the TAM model in conjunction with social, cultural and technological factors that the available literature has suggested are key to understanding technology acceptance within a specific context. The results of this pilot study reveal that all items in the survey instrument were reliable and valid within the range of acceptable academic research and suitable for use in the main study.

## II. BACKGROUND AND CONTEXT

Despite m-government systems being available for several years, citizens' adoption of e-government services in general and m-government services in particular still falls below expectations [1],[2],[13],[14]. Furthermore, in Saudi Arabia, like in most developing countries, m-government implementation is still in its infancy and there are many challenges related to implementation, adoption and use [1],[15],[16]. Factors such as the rate of mobile device and Internet penetration and their security, reliability and effectiveness, affect how successful a government will be at implementing m-government and user adoption and accounts for global variation [11]. However, there is a lack of research that allows a clear understanding of how factors such as these might impact the adoption and use of m-government services. This study rectifies this problem by providing a theoretical model purposely developed to carry out empirical research in this area. The results of this research will yield new insights about the key factors influencing the adoption of Saudi m-government, which will be invaluable to policy makers who require strategies that will result in faster and more efficient adoption of m-government services; as well as providing new information for researchers in the field and the ICT industry.

Research carried out in a number of different areas such as Malaysia and rural China [12], [17],[18] have made use of adaptations of the Technology Acceptance Model (TAM) and provided examples of how a number of social, cultural and technical factors can usefully be included in the TAM to

provide insights into the influences on citizens' intention to utilize m-government systems to access services and information. Cultural and technological factors like culture, trust and lack of necessary infrastructure have been demonstrated to be significant by comparative studies of m-government adoption in developing and developed countries [19],[20].

The adoption of m-government in Arab countries, however, still requires further research. Studies conducted in these areas [21],[22],[23],[20],[24] have revealed that factors such as trust, citizens' perceptions of the compatibility of m-government with their lifestyles, culture, awareness and the quality of the system are significant. Further, these studies show that there have been no empirical studies of m-government adoption in Saudi Arabia that includes factors like compatibility or culture. Similarly, there are no studies that take the quality of both technical and human factors into account or that investigate the issues from the viewpoint of the providers in addition to the intended users. There is clearly a need to carry out further research into Saudi m-government adoption.

In order to analyze factors that affect users' adoption and use of m-government, the researcher has developed a model called the Mobile Government Adoption and Utilization Model (MGAUM)[25]. The remainder of this paper consists of the following sections: Section 3 outlines the MGAUM, Section 4 covers the research methodology; Section 5 contains a descriptive and statistical analysis of the findings and Section 6 is the conclusion.

## III. THE PROPOSED RESEARCH MODEL (MGAUM)

In order to analyze factors that affect users' adoption and use of m-government, the researcher has developed a model called the Mobile Government Adoption and Utilization Model (MGAUM)[25]. MGAUM has been developed based on a critical analysis of the literature that relates to acceptance of technology, in conjunction with insights from several models and theories that are commonly used to analyze acceptance and usage of technologies. MGAUM integrates the Technology Acceptance Model [26], with a number of social, cultural and technological factors, taken from other recognized theoretical acceptance models that have been identified as key factors in the literature.

Further, MGAUM contains one dependent variable namely: Intention to use m-government (ITU), and three groups of independent variables namely: Practical Factors (PF), Human Factors (HF), and Technical Factors (TF). These independent variables comprise the key factors that critically influence the adoption and use of m-government.

This model uses the TAM as a starting point along with factors from other theories to analyze how users adopt m-

government services. Two factors were taken from the TAM: Perceived Ease of Use (PEOU) and Perceived Usefulness (PU). These two factors comprise the Practical Factors of MGAUM; the Human Factors are those that were revealed by the literature as important in further understanding the role played by the individual users' acceptance in this context and the Technical Factors are those identified as most likely to affect the adoption of m-government. The final design of MGAUM also used the researcher's experience of the local problems of accessing government services and information in Saudi Arabia to select those factors identified as key in the relevant literature. The main aim of MGAUM is to investigate the adoption of m-government services by citizens in developing countries, particularly Saudi Arabia, in order to increase the adoption rate of m-government services. The research model MGAUM is shown in Fig. 1.

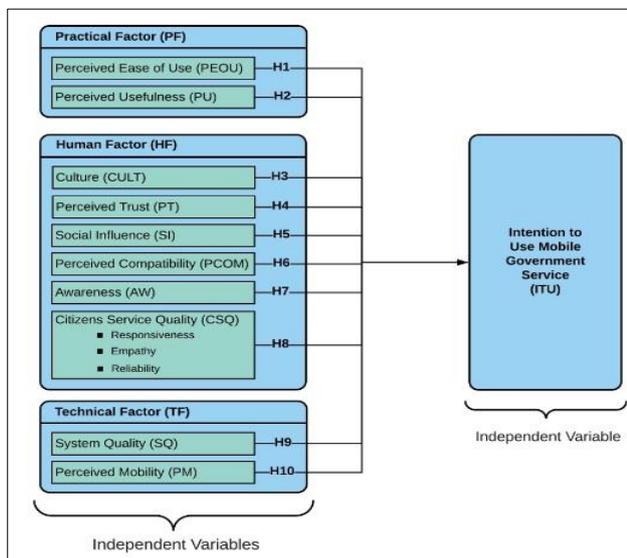

Fig. 1: The research model (MGAUM) [25].

The hypotheses of the study are as follows[25]:

H1: Perceived Ease of Use positively influences intention to use m-government services.

H2: Perceived Usefulness positively influences intention to use m-government services.

H3: Culture influences intention to use m-government services.

H4: Trust positively influences intention to use m-government services.

H5: Social Influence affects intention to use m-government services.

H6: Compatibility positively influences intention to use m-government services.

H7: Awareness positively influences intention to use m-government services.

H8: Citizen service quality factors (responsiveness, empathy and reliability) positively influence intention to use m-government services.

H9: System Quality positively influences intention to use m-government services.

H10: Perceived Mobility positively influences intention to use m-government services.

#### IV. THE RESEARCH METHODOLOGY

This pilot study was conducted in the United Kingdom. The questionnaire was distributed to Saudi citizens (public users) whether they had used mobile government services or not. Participants had to be 18 years or older to participate in this survey. Seventy-one participants took part in the questionnaire; but as all the questions had to be answered as they represented the research model, incomplete questionnaires were excluded from the survey. Therefore, the total valid responses constituted a sample of 58 Saudi citizens. The pilot study data were analysed by using the SPSS program.

The survey questionnaire contains 76 items and all the questions were developed and modified from instruments used in previous research into both E-government and M-government. All items were measured with a 5-point Likert scale from 'strongly agree' to 'strongly disagree'. In order to collect enough data to ensure a thorough analysis, the questionnaire had to be relatively lengthy. Manual distribution meant that the researcher could clarify points for the participants if necessary and contributed to obtaining a higher response rate.

##### A. Reliability and validity of the study

If a research instrument is to be reliable, it should produce similar results if used in comparable conditions [27]. Furthermore, an instrument's reliability depends on how free it is of error [28]. In order to assess the reliability of the questionnaire used in the pilot study, Cronbach's Alpha was chosen because the internal consistency of the constructs used in the questionnaire had to be established; in other words, we needed to measure the extent to which items in the questionnaire measured the same things when referring to a specific independent or dependent construct, and how these related to each other. Cronbach's Alpha is the most commonly used test to calculate and evaluate internal consistency, and thus reliability [29]. Cronbach's Alpha has a scale of 0 to 1, with 1 being the highest reliability, a value of independent and dependent variables 0.6 is considered to be acceptable [30]. Table 1 indicates the Cronbach's Alpha results for the complete pilot study instrument, which demonstrates that the reliability of each of the constructs (independent and dependent variables) lies within the range of what is considered acceptable in academic research.

A valid research instrument measures what the researcher intended [31], and the validity of an instrument is the extent to which it does this and provides the information required [32]. In order to establish the validity of our research instrument, the face validity and content validity methods

were selected rather than construct validity and criterion validity. This method is designed to establish the extent to which the purpose of the instrument is clear even to the lay person with only basic education [33], for example a 1st grader at school. There is a high level of face validity if the items in the questionnaire are clear and unambiguous, if the items are perceived as difficult to understand or confusing, then the face validity is low [33]. The pilot study allowed the face validity of each item to be tested by participants so as to ensure that the model's factors measured what they were intended to measure. Items without sufficient clarity, unambiguity or relevance were revised or deleted accordingly. Furthermore, six academics, all of whom had expertise in the field, were asked to review the items in the research instrument, this review and the pilot study demonstrated that all the items used therefore had a good degree of content validity.

TABLE 1: INTERNAL CONSISTENCY OF THE PILOT STUDY INSTRUMENT

Measured Variable	No. of Items	Cronbach's Alpha
Perceived Usefulness (PU)	7	.841
Perceived Ease of Use (PEOU)	4	.848
Social Influence(SI)	3	.753
Perceived Compatibility (PCOM)	2	.824
Perceived Trust (PT)	7	.618
Culture (CULT)	5	.606
Awareness (AW)	4	.816
Perceived Mobility (AW)	3	.819
Citizens Service Quality (CSQ)	8	.920
System Quality (SQ)	7	.755
Intention to use (ITU)	4	.879

## V. DESCRIPTIVE AND STATISTICAL ANALYSIS

### A. Respondents' demographic data

In this study, 58 participants answered the questionnaire, and that 38 participants were male (65.5 %) and 20 were female (34.5 %). The highest percentage of participants was in the 31–45 age group; the largest number held a Bachelor degree and over half the participants (51.7%) were government employees. All participants had smartphone devices, with a large majority of participants using mobiles and the Internet in daily life (93.1% and 94.8% respectively). Approximately three-quarter of the respondents (74.1 %) have some knowledge about m-government services in Saudi Arabia, whereas 25.9% had no knowledge. Moreover, the majority of participants (86.2%) already used M-government services, but 13.8% had never used it. Also, the survey asked the participants that already used m-government services to rate their general experience. The result showed that 44.4% were very satisfied with m-government services, 52% were satisfied to some extent, with only 4% not satisfied with m-government services. Furthermore, 27.6% of participants

reported that the requirements of the intended m-government services were not clear and 34.5% of them reported that the system quality of m-government services was not good.

When asked about what advertising methods could affect awareness of m-government services and encourage their use, participants rated them as follows: social media, emails and text messages (20.17%), advertisements in public areas (17.54%), TV and Radio channels (17.1 %), government agencies' websites (14.03 %) and finally, newspapers and magazines (14.03 %).

### B. The Correlation Analysis

A correlation coefficient analysis was run on this pilot study to discover the relationships between all constructs and to establish their significance. In 1988, Cohen proposed a guideline for correlation coefficient values as follows: Strong  $r = .50$  to  $1.0$ , Moderate  $r = .30$  to  $.49$  and Weak  $r = .10$  to  $.29$  [34]. The correlation coefficients can be seen in Table 2, which shows there is a positive relation between the intention to use m-government (Dependent variable ITU) construct and the rest of the constructs, with differences in the strength of this relationship from one construct to another. For instance, there is a strong correlation between Perceived Usefulness and Perceived Compatibility with Intention to use m-government services, with moderate correlation for Perceived Ease of Use, Social Influence and Culture whereas there was only a low correlation for Perceived Trust, Awareness, Perceived Mobility, Citizens Service Quality and System Quality.

TABLE 2 :THE CORRELATION BETWEEN THE VARIABLES

		Correlations										
		INT	PU	PEOU	SI	PCOM	PT	CULT	AW	PM	CSQ	SQ
INT	Pearson Correlation	1	.682**	.479**	.411**	.598**	.247	.323*	.089	.251	.074	.279*
	Sig. (2-tailed)		.000	.000	.001	.000	.062	.013	.506	.057	.581	.034
	N	58	58	58	58	58	58	58	58	58	58	58
**. Correlation is significant at the 0.01 level (2-tailed).												
*. Correlation is significant at the 0.05 level (2-tailed).												

The correlation results show that user experience is the first step in adoption; and if a user finds m-Government services easy to use and that it saves time, effort and is compatible with lifestyle and mobile devices, then this impacts positively on his/her behavioural intention to adopt and use them. If services are easy to use, and people do not have to rely on asking for help from another person to use m-government service, the number of users will increase. Thus, PU, PEOU and PCOM are essential factors in this study.

The result also indicated that government agencies should focus on the following factors (PT, CULT, AW, PM, CSQ, SI and SQ) to motivate and increase citizens' intention to adopt and use m-government services. Therefore, the government needs to raise awareness about the main goals of m-Government, the availability m-Government services and

the advantages and benefits gained from the use of m-Government services to conduct various transactions. Public awareness could be enhanced in various ways including interactive advertising and social media campaigns as well as traditional advertising methods such as brochures and advertisements on TV, public transport and in newspapers.

The pilot study has demonstrated that the initial design of the questionnaire will be suitable for the main study to be carried out in situ in Saudi Arabia. The result of the main study will be compared to the pilot study result for extra validation.

## VI. CONCLUSION

This pilot study focused on validating the MGAUM model that has been developed by integrating the TAM model in conjunction with social, cultural and technological factors that the available literature has suggested are key to understanding technology acceptance within a specific context. We intended in this study to provide a valuable insight into the main factors that influence adoption of m-government services in Saudi Arabia, which will be useful for researchers, the ICT industry and for policymakers who are keen to find strategies that result in quicker and more efficient take-up of such services. The reliability and validity of the pilot study have been established. The findings of this pilot study provided us with the basic information and will open the doors for future discussions. We plan to conduct this study in Saudi Arabia with a large number of Saudi citizens to explore what factors encourage them to use m-government services and what the barriers to acceptance are.

□ **Abstract**— This paper discusses data quality checking during business process execution by using runtime verification. While runtime verification verifies the correctness of business process execution, data quality checks assure that particular process did not negatively impact the stored data. Both, runtime verification and data quality checks run in parallel with the base processes affecting them insignificantly. The proposed idea allows verifying (a) if the process was ended correctly as well as (b) whether the results of the correct process did not negatively impact the stored data in result of its modification caused by the specific process. The desired result will be achieved by use of domain specific languages that would describe runtime verification and data quality checks at every stage of business process execution.

**Keywords**—data quality, runtime verification, business process, domain specific languages

### I. INTRODUCTION

NOWADAYS, the most part of processes is based on more than one information system or service. Moreover, the environment where processes are running usually is very heterogeneous. As a result, besides users, other information systems and changes made in them may affect execution of the initial process. One of the typical solutions for such situations is detection of incorrect execution by system monitoring or support staff, however, identification of affected business processes isn't possible in this case. As a result, the necessity for runtime verification of business processes appears to keep the process consistent at any time [1]. As it was discussed in [2], runtime verification of business processes allows (a) detection of incorrect execution that is possible in the case of system monitoring, but also (b) identification of business processes that may be affected by it. As a result, asynchronous runtime verification of business process was proposed focusing on timely and accurate problem identification.

□ The research leading to these results has received funding from the research project "Competence Centre of Information and Communication Technologies" of EU Structural funds, contract No. 1.2.1.1/18/A/003 signed between IT Competence Centre and Central Finance and Contracting Agency, Research No. 1.7 "The use of business process models for full functional testing of information systems".

However, runtime verification of business processes checks only the correctness of process execution based on the evaluation of process execution sequence, meanwhile this research proposes to extend it by involving data quality mechanism, that will assure the specific process did not negatively affect data stored in information systems that were affected by this process. It is achieved by applying data object-driven approach to data quality evaluation [3]. This approach is based on definition of data object which quality should be analysed, quality requirements definition that are applied to the parameters of the defined data object and measuring data quality. In scope of the proposed solution, data object is derived from data that were affected by running process. Data quality requirements are defined to check whether data are still correct and "external constraints" are still valid.

The paper deals with following issues: concepts used for data quality checks in the runtime verification (Section 2), idea and main concepts of the proposed solution (Section 3), analysis of the proposed solution (Section 4), conclusions and future work (Section 5).

### II. BASIC CONCEPTS

This chapter briefly discusses the concepts used in runtime verification and data quality research that are necessary for discussing the ideas and solutions proposed.

#### A. Runtime Verification

Runtime verification mechanism proposed in [2], doesn't intervene into execution of processes. It observes processes from the aside, collecting and verifying events confirming process step execution, in accordance with business process description. The main point is checking of the verification of business process execution in compliance with the process verification description. The description of the verification process must specify two aspects: (a) event confirming step completion, and (b) the time when each step in the process must be finished. Two main components of this mechanism are agents and controller.

The agent plays a role of event detector. It is software that checks the occurrence of a specific event. An example of such event can be record insertion. All events detected by

event agents are sent to the centralized controller for verification.

The controller analyses process verification descriptions, collecting event messages that were sent by agents and verifies flow compliance with the verification description.

Agents are developed for different components (databases, file systems, email servers etc.) and not implemented into software under verification. Thereby proposed mechanism allows verifying business processes executed by more than one system, running over several platforms, and even provided by more than one operator.

Runtime verification of business processes allows detection of incorrect execution and identification of business processes that may be affected by it. Both, detection of incorrect execution and identification of business processes that may be affected by it, take place immediately after changes were made by including appropriate checks in the runtime verification of business processes. In comparison with more traditional for such cases system monitoring, it allows to fix the occurrence of such problem as soon as possible for its timely solving to achieve as high result as possible. Moreover, identification of business processes that may be affected by it usually isn't considered at all. In other words, asynchronous runtime verification of business process focuses on timely and accurate problem identification.

Significant benefit of this approach is that it can be used when existing software does not respect any component addition. It is very useful in cases when the source code of some software is not available or there is not enough knowledge on all details of software implementation.

The idea of the proposed runtime verification is close enough to the formal class of runtime verification discussed in [5].

### B. Data Object-Driven Data Quality Model

Data object-driven data quality model consists of 3 main components: (1) data object that defines the data which quality must be analysed, (2) data quality specification that defines conditions which must be met to admit data as qualitative, and (3) quality evaluation process that defines the procedure that must be performed to evaluate data quality [6].

Every component of the quality model is represented by flowchart-based diagrams that are easy to read, create and edit. This approach is based on three domain specific languages (DSLs) created for every model's component.

As it follows from the listed components, used solution doesn't use the concept of "dimension". Instead, the wider concept of "data quality specification" is used. The main idea of this model is that all components are fully defined by user in correspondence with users' viewpoint on the specific dataset and quality.

Data object is defined in accordance with data needed to be analysed, the parameters that do not make sense for

particular users and use-cases are ignored. Data objects of the same structure form data object class where each individual data object may contain parameter values fully or partially [4]. Similarly, data quality specification is defined by user depending on the use-case. The nature of quality requirement or condition depends on the users' need. It can be compared with rule-based approaches used for relational database analysis. However, this approach reduces this limitation and can be applied to wider range of data structures. Currently, it can be applied to structured and semi-structured data. Data quality specification can be defined informally or in formal way, however at the last step all requirements are replaced by executable artefacts such as SQL statements or program code that further are executed.

Such approach is quite simple as it is very intuitive and close enough to "data" and "data quality" concepts nature. As a result, it is expected to be well-understood even by non-IT and non-data quality experts. It is one of the main benefits of this approach as usually approaches for data quality evaluation are suitable mostly for IT- and DQ- experts requiring deep knowledges in both areas [6]. However, data object-driven model can be used by wide audience without need to make in-depth analysis of the basics of the approach as it usually happens with other approaches where at least an exploration of the list of dimensions, their meanings and criteria under each of them, needs a lot of time for every particular solution as criteria differentiate from case to case [3], [6], [7]. At the same time, the proposed approach already demonstrated its effectiveness by applying it to real datasets [4], [6] – [8].

As a result, the given research uses data object-driven data quality model as the most appropriate option. In order to explain basics of the proposed solution, the next chapter summarizes the basic concepts involved in it. The required modifications are outlined to achieve desirable result.

## III. A PROPOSED SOLUTION

The main idea of the proposed solution is to allow check the quality of data while business process is executed after each data object update. In other words, when the process  $X_a$  step  $S_n$  is done, check data quality requirement  $DQS_1(X_a, S_n)$ . Data quality requirements in scope of this research are "external constraints" [9] defined for the particular process.

### A. Concept of Runtime Data Quality Control

Following runtime verification mechanisms proposed by [2], a business process description should be defined for process verification. Process description contains process states and events linking states (Fig. 1). From the data quality perspective each of processes may affect one or more data objects. Accordingly, data object class definition should be added to the process definition (described in the previous section). These objects are to be changed during business process execution and there could be different verification rules for each of process steps.

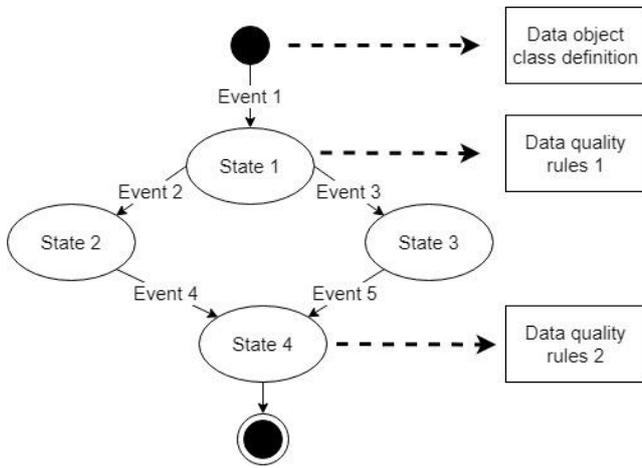

Fig. 1 Business process verification procedure

When process verification is running, new process verification instance is created by each business process start event. If necessary, corresponding data object is extracted verified according data quality definition. When next process execution event is detected, process verification instance is moved to the next state and next data object version is extracted, and its quality is verified. Thereby each process verification instance may have more than one data object instance and data quality of one data object may be verified not just at a fixed moment of time, but between its modifications accordingly (Fig. 1). This allows to identify (a) data quality loss exactly when it happens and (b) the incorrectly working process events.

According to [2] the business process verification involves two components: a *controller* and *agents*. Data quality verification adds *Data link* component to the solution (Fig. 2). Data link provides required connection to the database with business process objects and extracts data object copy when it is required by runtime verification controller. Therefore, not only data object class definition is required for data quality runtime verification, but also a definition of data object mapping to business process database: data link uses this definition for data object extraction from business process database.

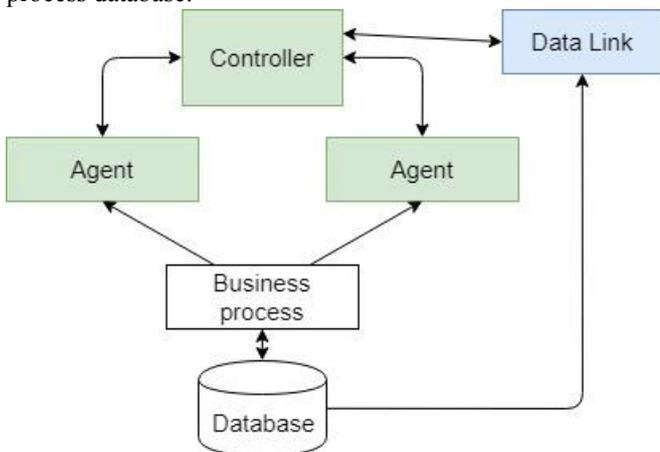

Fig. 2 Architecture of the proposed solution

**B. Data Object Definition**

DSL for defining of data objects is discussed in detail in [4] and [6]. As more and more customers are using electric scooter renting services, this will serve as an example to explain the proposed solution. One scooter rental case will be a data object sample. It contains data fields:

- rental ID;
- scooter code (*deviceCode*) – reference to the list of scooters available for the region;
- status (*status*) – rental status that may have one of three values: *riding*, *pause*, *finished*. When scooter is used, it always has status “*riding*”. If the customer decides to stop, leave scooter on the street, and lock it for further use after some minutes, scooter is in status “*pause*”. These “*pause*” minutes should be counted because another tariff may be applied for this period;
- start time (*startTime*) – time when the scooter’s rental is started;
- start location (*startLocation*) – location where the rental is started;
- finish time (*finishTime*) – time when the rental is finished;
- final location (*finishLocation*) – final location of the scooter;
- pause minutes (*pauseMinutes*) – minutes spent for pauses;
- total distance (*totalDistance*) – total ride distance.

**C. Data Quality Runtime Verification Process**

Data quality runtime verification requires a business process definition, including states of process, possible events, and a data quality definition. The definition of the verification process for an example of the scooter rental process is shown in Fig. 3.

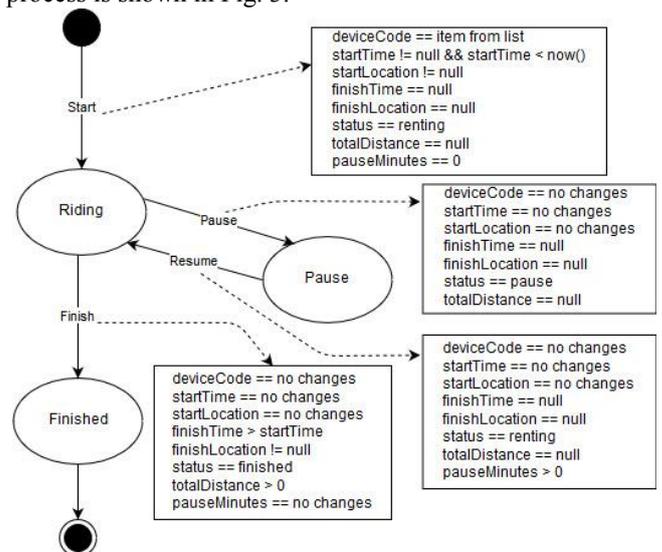

Fig. 3 Data quality verification of scooter rental process

When scooter rental starts, the initial data object should be extracted. According validation rules, the initial rental object contains information about rented device (reference to existing item from device list). *StartTime* should be different from null and less than *now()*, *startLocation* should be provided and the rental state should be “*renting*”.

After pause event is detected by runtime verification controller, a new data object version for verification should be extracted from database. New rules are applied to the object:

- *deviceCode*, *startTime* and *startLocation* remain unchanged (these values are set once when the object is created);
- *status* = “*pause*”;
- *pauseMinutes* should be unchanged comparing with the previous object version.

When riding activity is resumed (i.e., event “*resume*” is detected by the verification controller), the next copy of rental data object should be extracted, and a new set of rules should be applied:

- *deviceCode*, *startTime* and *startLocation* are unchanged;
- *status* = “*riding*”;
- *pauseMinutes* should be more than in the last version of object;
- *finishTime* and *finishLocation* are still null.

After ride finish event is executed and detected by runtime verification controller, the last version of rental data object is extracted from the business process database. The 4<sup>th</sup> set of data quality rules should be verified:

- *deviceCode*, *startTime* and *startLocation* are unchanged;
- *status* = “*finished*”;
- *pauseMinutes* are unchanged from the previous object version;
- *finishTime* and *finishLocation* are not null as the ride is finished and, moreover, *finishTime* > *startTime*.

As it can be noticed from the example, the runtime verification provides new possibilities for data quality verification:

- data quality may be applied and verified during business process execution and just for one object, not for the whole database;
- quality of data changes is verified by comparison of different versions of the same object;
- in the case of defect, the location of defect’s origin may be identified.

#### IV. ANALYSIS OF THE PROPOSED SOLUTION

The presented idea allows not only to ensure the process was correct and any logical or “external” constraint weren’t complied, but also to identify the moment and activity that caused or led to incorrect or inconsistent result.

As an example, let us imagine we have a database which quality we use to check once a month. We have already checked the quality of data of this database a month ago and it was of an excellent quality without any data quality issues or even anomalies. Now, a month later, we check it once again and find data quality problems not only in new records but also in those which were of good quality a month ago. It is difficult to detect the moment, when the data was changed, i.e. the qualitative data was replaced by data of poor quality, especially, if we don’t have access to log files where all activities are fixed. Moreover, in some cases such log files don’t exist at all or they are not detailed enough. However, the proposed idea of runtime verification in combination with data quality checks would solve this problem, detecting the moment and activity that caused the problem. To sum up, the main advantages of the proposed idea:

- data quality is verified immediately after the data is created/ modified;
- it is possible to detect the process step where the data is damaged;
- data quality evaluation is performed for the entire data set, not only for a specific data object that was changed;
- evaluation of the total data quality is reliable all the time;
- data verification can be performed independently of the system being executed.

However, there are also some potential disadvantages:

- if the runtime verification is performed incorrectly, it can lead to a tangible overload of the process being verified;
- by performing data runtime verification in parallel with system execution, data errors can be obtained for correct data if the process performs faster than the verification process and the data changes do not correspond to the step which data modifications are checked.

The proposed approach differs significantly from the Object Constraint Language (OCL) approach, which is designed to protect the database against incorrect value input but does not detect errors in input data.

As for the proposed solution, the main scope of data quality checks is data object retrieval. Data for their further quality checking are retrieved from agents by using denormalization as it significantly speeds up data retrieval. The denormalization must be implemented dynamically without knowing the denormalized relational target structure in advance [10].

The quality checking analysis runs in accordance with the initial runtime verification mechanism. In scope of the one separate check for the business process to be analysed, it can be compared with the model checking and testing mechanism using pre- and post- conditions proposed in [11]. By precondition is meant the result of previous check that is used as an input, however postcondition checking is

performed when an execution of verification completes. It is obvious that preconditions should be correct to be suitable for usage in quality checks. In our case, all preconditions are considered as correct as they are analysed at the previous stages/ steps. However, another assumption is that the initial data at the initial state of a check (let call it  $q_0$ ), that also is a precondition, is also correct as any data modification was done previously, as it is assumed that statically stored data (that isn't involved in any process) is checked from time to time and as a result is correct.

The frequency and number of data quality checks as well as points when they should be done depend on the use-case and user's preferences. This idea corresponds with the data object-driven approach to data quality evaluation allowing users to take control over every step of data quality analysis process. As a result, the proposed solution respects quality checks: (a) after every step as well as (b) only when the user considers them as important, or (c) with periodical frequency after a particular step, for instance, once a day or every time after specific process is finished etc. The first option ensures in-depth and comprehensive quality analysis, when every step is checked. However, as there might be cases, when several steps are not of high importance at least for a particular user, or there is no necessity in continuous checks, for instance, in order to save resources and efficiency, the second and third options appear suitable. Moreover, in the future, the idea of prioritization mechanism would be evaluated to provide users the possibility to perform some checks with higher priority first. This mechanism would offer to users a higher level of control over the whole process.

The number of cases when the proposed solution can be useful is high, including the continuous assessment of the quality of information systems, e-government [12], etc. by data quality runtime verification. The proposed solution can lead to the improvement of quality of many services increasing government effectiveness and quality of public services [13] that nowadays become a topical issue.

## V. CONCLUSION

This paper deals with runtime verification for checking data quality during business process execution. The user defines data objects and requirements of his/ her interest using graphic DSLs and ensuring high quality of data object parameter values.

Unlike other data quality studies, the proposed solution provides an operational runtime verification of data quality requirements, allowing to detect deviations from quality requirements in the particular business process's execution step when incorrect data object parameters are recorded in the database. Verification of data quality requirements and the base process are parallel processes. Impact of verification on the base process performance is insignificant and acceptable if sufficient hardware capacity is available.

The proposed solution is an "external" solution that checks the data quality requirements without direct connection to the business process. Such approach allows enabling and disabling of runtime verification of data quality requirements operationally at various stages of information system usage. Graphical DSLs that is used to describe data objects and quality requirements is intuitively understood and suited for use by non-IT and data quality specialists.

In the future, the proposed approach might be applied to issues of the semantic web.

**Abstract**—Business Process Management (BPM) is an accepted discipline and its importance in increasing automation inside industrial environment is today recognized by all players. The complexity of modern management process will lead to chaos without a well-designed and effective BPM. Several BPM Suites were compared and BPM approach was applied to the case study of process management in a renewable energy power plant. Results both in process reduction and simplification and flow optimization obtained in the real case are discussed to state efficacy and efficiency of the adopted approach.

## I. INTRODUCTION

**I**N A competitive environment in which companies have to provide more and more effective and efficient services/products, asset management allows to obtain value from assets and achieve the company's business objective [1]. To accomplish both the goals to ensure good operational performance and long durability of the final products/services, it is necessary to define effective business processes, to monitor their performances and to provide corrective actions when necessary. In fact, the quality of the operational processes are more and more dependent on maintenance processes, thus they must be carefully engineered and effectively implemented. Maintenance management changed in the last decades thanks to ICT development, from a management perspective, Computerized Maintenance Management System (CMMS) has contributed to enhance the control of maintenance activities [2] and maintenance is considered a relevant business function, able to interact with all other strategic functions, such as operations, purchasing, suppliers (service providers), warehouses management, administration, therefore maintenance effectiveness and efficiency is crucial for business.

BPM frameworks provide tools that allow to *design* the business process using model, maps and rules, than it allows to implement them defining the architecture and adding rules. Moreover, framework executes and monitors the process (providing processes measurement) collects data, and, finally, it provides analysis and diagnosis that allows to improve the process itself [3].

Indeed, the process can be viewed from different perspectives thus producing multiple models and styles [4]: *control flow perspective*, *resource perspective* that means to focus on equipment, units, etc.; *data creation perspective*; *time perspective* that focuses on deadlines and *function perspective* that uses activities.

BPMN 2.0 is a logical description of business processes and how they operate that focuses on process implementation and Process simulation [5]. Usually, the business process simulation collects several data and provide a visual animation of the evolution of the process. The analysis of data permits the designer together with supervisor and manager to identify (potentially expensive) mistakes and, thanks to the Key Performance Indicators (KPIs), defined during the early designing of the process, increase the performance to getting and overall improvement of the process (e.g. removing bottlenecks).

In literature, the use of the BPM approach for maintenance management is not so common [6] (see references in [7], [8]). Most of them suggest that an Asset Management System Software can help organizations to achieve operational excellence, through a more effective cost control, a more efficient asset planning, a reducing in capital expenses, an optimization of operational costs, thus extending asset life-cycle and obtaining a higher Return On Asset.

This works briefly presents some of the criteria that were adopted by BaxEnergy© to develop a BPMS, starting from existing platform aiming at optimizing the maintenance of *renewable energy power plants* to be offered as a service to different companies. Renewable-energy Power Plant faces different challenges [9], [10], [11]. Finally, a case study is discussed highlighting the enhancement and discussing some details that lead to final implementation.

Section II introduces BPMS and some of the criteria used to compare the platforms, and provide the reader with a comparison among several platforms that was available at the moment of the study. Section III discussed the case study developed using the selected platform.

## II. BPMS COMMON FEATURES AND CRITERIA

BPMN can be useful both for planning complex business processes and to control and monitoring them once deployed. A business process can be defined as a set of connected activities that create value for customers; usually, they are classified into three groups: *strategic*, *operational* and *support*. A BPMN provides users and developers with tools that clearly denote the objective, who is in charge of any operation, starting and ending points, input and outputs, constraints and monitoring points. One of the most important aspect of BPMN is surely the graphical model that, usually, is formally

documented thanks to UML (Unified Modelling Language) class diagrams [5].

BPMN 2.0 is the current standard that adds the following characteristics: *human-readability*, that is a standard visual notation for modelling processes; *accessibility*, that means that all actors must understand what is represented; *machine-readability*, that implies the use of the XML notation for simulating and executing processes [12].

BPMN Graphical representations use several standard symbols that must be easily understood by both developers and users the most important are: *swim lane*, *pool*, *box*, *event*, *task*.

A fundamental element to make dynamic the process diagram is *gateway*: it allow the designer to choose where the flow of a diagram must follow a path or another by evaluating a condition. Two types are defined in the standard: *XOR* or *Exclusive*. Gateway is the task that drives the evolution of a process by evaluating a condition and selecting the next task, *OR* or *Parallel* Gateway split the evolution into two parallel branches that must be joined with the same element when the evolution of the process does not support parallel activities.

#### A. Evaluation Criteria

There is no doubt that some interesting features for a Software developer are meaningless by the point of view of a Business Process developer, and are meaningless for a standard employee, therefore the evaluation Criteria are grouped into two classes. The first group deals with the feature useful to software developers, the most important are as follows:

- *OpenSource*, software suite refers to open source model, that means that products are released under an open-source license, this feature allows to inspect the source and to add any additional features;
- *Community*, the community supporting the software suite should be as large as possible to share problems and their solutions. A large community implies Documentation and Tutorial are easy to find and this is useful both for software and model developers;
- *BPMN 2.0 supported*, this is a must for any new software, since today BPMN 2.0 standard is largely supported;
- *Additional modules and connectors*, they permits to extend the functionality of the Software and to write new custom connectors;
- *API provided*, this can be useful to easily add functionalities to the BPMS.
- *Innovation*, of course, it is important that software solution supports all recent technologies and methodologies but it must be also "mature" (according, for instance, with Gartner Magic Quadrant [7]). Some examples of innovative features are mobile device deployment without the need to develop a dedicated application, low-code Platforms, integration with Artificial Intelligence for performance analytics and so on;

Second group of features, that we could call *Functionality-based evaluation criteria*, belongs to Business Process Developers that focus on the processes themselves and, usually, have

no specific experience in software development. They need to model, describe and test production processes aiming at optimizing them according to some metrics (e.g. cost, duration, response time) often conflicting. The most important are listed below:

- *Web Modeler/Collaboration enabled*, it enables collaboration between developers;
- *Template Library*, the presence of a library of reusable models is a valuable add-on to any Suite;
- *Model and Process Versioning*, since processes run for long times, the ability to control the current version of Models and the ability to roll back to a previous version are very useful;
- *Powerful graphic interface*, the interface should support advanced interface functions as, for instance, Drag&Drop of models/processes, Form Editing that allows final users to create and edit data, to customize the colors of element in a diagram to make it more readable;
- *Process deployment*, the system should allows to make an instance of the modelled process to check errors and to locate performance indicators or failures;
- *Testing and Simulation*, the presence of an engine for simulating the process and/or validate the model is an essential feature;
- *Customizable Properties*, that means the ability to change the properties of the trial modelling tool.
- *Business rule engine and activity Monitoring*, possibility to integrate business rules for the process and to monitor the execution of a process;
- *Integration with Cloud*: since some BPMS are integrated with cloud service, it is important to support the integration between BPMS and Cloud.
- *Role Based Security*, that allows to manage of the security rules for each role.

#### B. A Brief Survey of BPMNs Platforms

The evaluation criteria used by throughout this work are based on Critical Capabilities such as Interaction Management, Monitoring and Business Alignment, Rules and Decision Management, Analytic and they are evaluated on the base of some Use Cases. Great importance is given to Continuous Process Improvement (referred as CPI) and to Citizen Developer Application Composition (that is the ability to leave aside from IT development staff) [5].

The BPM suites, that was evaluated, support highly intelligent applications which integrate more-advanced decision automation technologies (e.g. predictive analytic, artificial intelligence) and decision support for knowledge workers to automate business processes that require an adaptive behaviour [5]. It means that actually *iBPMS* is not a simple modelling software or a validation engine for BPMN, but it is both bound and integrated with other functionalities that keeps track of statistics and, sometimes, let even the user to define performance indicators.

The main characteristics of the tools were summarized and compared in tables I and II, the former deals with features

useful to developers and the latter to features useful to users, i.e. the provided functionalities.

TABLE I  
CRITERIA RELATED TO DEVELOPMENT

	OpenSorce	Community	Innovation	API
BPMN.IO	Y	-	Y	-
Cawemo	-	-	Y	-
Camunda	Y	Y	Y	Y
Bizagi	-	Y	Y	Y
Appian	-	Y	Y	Y
Activiti	Y	Y	Y	Y
IBM	-	Y	Y	Y
jBPM	Y	Y	Y	Y
KissFlow	-	Y	Y	Y
QuickFlow	-	-	-	-

TABLE II  
CRITERIA RELATED TO FUNCTIONALITY

	Web Functions	Versioning	Testing	Monitoring
BPMN.IO	P (Partial)	-	-	-
Cawemo	P	-	-	-
Camunda	Y	Y	P	Y
Bizagi	Y	Y	Y	Y
Appian	Y	Y	Y	Y
Activiti	Y	Y	-	Y
IBM	Y	Y	Y	Y
jBPM	Y	Y	Y	Y
KissFlow	Y	-	-	-
QuickFlow	Y	-	-	(SalesForce)

Since the use of opensource platform covering all the process, from development to monitoring, exposing a flexible ReST API to integrate easier with existing software are the most important requisites the selected platform was Camunda. The lack of processes Simulation is overcome thanks to the a great support of Javascript libraries that can be integrated with no effort.

### III. CASE STUDY

#### A. The Company

The case study was developed, during the research project WEAMS, in an Austrian company that is a BaxEnergy© client. The Company's core business is the construction and operations management of wind turbine power plants. The Company produces electrical energy through wind turbines, by itself or cooperating with other partners or investors. In the case study was considered that it actually deals with operations and maintenance processes of wind turbine farms.

After studying and analyzing their general organizational structure, we find 92 different relevant processes. These processes (e.g., tool provisioning, maintenance execution in harsh weather conditions, invoicing, checking financial guarantees, executing training, and so on) include several tasks with their relevant costs. In general we identified two main process categories related to wind turbines maintenance: *Core processes* (usually technical ones) and *Support processes* (usually organizational and financial ones).

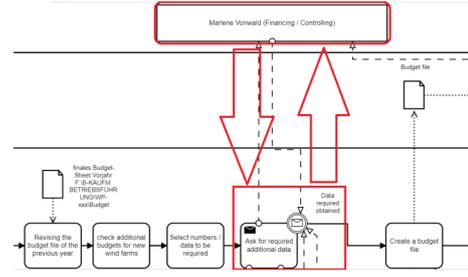

Fig. 1. Collaboration between actors of a process

#### B. Process Re-engineering

A subset of 39 processes out of the 92 relevant for the company were selected as they are the most frequently activated during a year and relevant also for other companies in the same business sector. Moreover, other ten maintenance core-processes, not previously engineered by the company were identified and implemented in order to guarantee better maintenance performance.

A first revision of the processes allowed to increase the general comprehension of process workflows, by the Company. In particular, to follow the correct logic of BPMN 2.0:

- The use of *send* and *receive* task was corrected;
- Some *End event* were added to complete some workflows;
- Some *Intermediate* events instead of useless tasks were introduced in order to simplify some process;
- Some *script tasks* were modified into *normal tasks* (because scripts will be added in a future phase);
- The use of *gateway* was corrected and useless ones were eliminated.

Furthermore, some specific processes were deleted as *stand-alone processes* and they were incorporated within other ones, by producing a unique layout representing the whole activity without missing any essential information and better visualizing interactions through inputs and outputs.

This *process synthesis* generated a total incorporation of 7 process into other ones, thus further reducing to 26 processes out of 39.

Let us note, the presence of a particular interaction between pools and collapsed pools inside the processes. Those interactions called *swim lanes* in the BPMN 2.0 standard are used mostly to enable the collaboration between core and supporting parts of the processes.

For example, in the process *Budgeting* a supervisor (financing/controlling) of the process needs to receive some additional information before going on with next task. In this case, the supervisor has to do two actions (see Figure 1): Before the re-engineering, the company used the above described interaction also to communications with the ticket system of WEAMS. Thanks to the BPM system, implemented in the WEAMS system, this use of send/receive tasks is no more necessary (see Figure 2) but it requires just a simple task in WEAMS system (see Figure 3). In this way, there is a

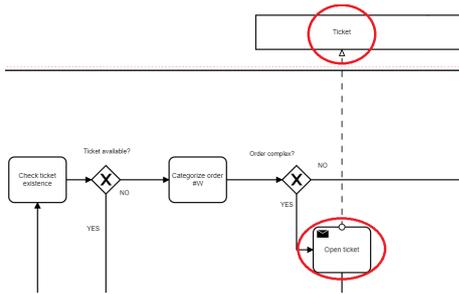

Fig. 2. Collaboration with the ticketing system of WEAMS

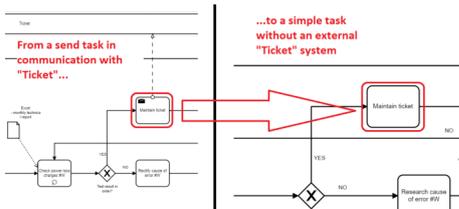

Fig. 3. From ticket system to a simple task

reduction of about 70 message flows due to ticket system implemented on the BPM system in WEAMS.

These relevant 26 processes were subjected to a deep revision in order to optimize elements and workflows and simplify them. Such a revision allowed to eliminate from the processes 26 phases and 106 transitions that was useless, obtaining more efficacy and efficiency in process workflow and improving the general performances of the maintenance processes.

In the second step of revision some of the 26 processes were splitted into two or more sub-processes in order to easily implement them into the WEAMS BPM system, thus generating 31 processes.

In the third step some maintenance processes were added to manage some aspects that are relevant for the Company business but that never were implemented by the Company, such as Planning ordinary maintenance's intervention, Human resources management, Warehouse management with spare parts and consumables, Personnel qualification management to meet normative requirements, Corrective maintenance management (ticket opening, see Figure 4), Predictive maintenance management (specifically inspections, see Figure 5), Asset status management, Service level management, Maintenance on the field and Logistics management.

### C. Key Performance Indicators

The section in which KPIs have the biggest role is the wind turbine maintenance and the most influencing factors are certainly economical, technical and organizational. Maintenance performance indicators reflect achievement and progresses in meeting a goal; clearly, the greater is the installed capacity the higher are Operational and Maintenance costs.

Leading indicators measure performance before the maintenance process results starts to follow a particular trend and

monitor if maintenance activities are producing good results in a long-term period. An example *Preventive Maintenance (PM) Completion Rate*: a low completion rate for PM would generate an increasing in asset maintenance work while a high completion rate means that asset preventive maintenance request is correctly being completed and, probably, future corrective maintenance requests will be reduced. Another example is the *Outage Schedule Compliance* an important metric to track future maintenance work because it allows to measure deferred asset maintenance, resulting in an increased risks and likelihood that asset performance will decrease at a future time, leading to lower capacity, increased downtime, and greater expenses.

Lagging indicators use historic data to obtain a measure to confirm coherence with long-term performance trends; they are used to determine how well a process performs.

In order to increase maintenance performance, both internal and external factors of a company should be considered as complex activities. Therefore, considering each influencing factor is essential to assess, control, measure and compare performances. The KPIs in technical standards (specifically UNI EN 15341: 2007) can be grouped into three categories: *economical* (E, 21 KPIs), *technical* (T, 21 KPIs) and *organizational* (O, 26 KPIs). A selection of them was considered to be linked to the maintenance related processes implemented as shown in Table III. These allow the Company to calculate performances of related processes.

## IV. CONCLUSIONS AND FUTURE WORK

Introducing BPMN 2.0 into an asset management model is an efficient way for controlling and sharing information between all actors involved in a process. Specifically, in maintenance management of wind turbines there are a lot of factors (e.g. weather conditions, personnel availability) and events such as logistics, administrative or technical ones (e.g. failure) that can change in an unpredictable way the process performances. The developed WEAMS BPM system allows the definition and execution of management processes within renewable energy power plant, simplifying relations among company functions, introducing standard activities for each process, assigning tasks to users, eliminating non added value phases thus providing an overall reduction of downtime of wind turbines, procurement optimisation due to higher efficiency in warehousing, human resources management, maintenance cost reduction.

# Identification of Heuristics for Assessing the Usability of Websites of Public Administration Units

Łukasz Krawiec, Helena Dudycz  
Wrocław University of Economics, Wrocław, Poland

Email: {lukasz.krawiec, helena.dudycz}@ue.wroc.pl

**Abstract**—A very important aspect of modern websites is their usability. Thanks to modern, and constantly developing technologies it is possible to create user-friendly services for each user. The usefulness of online services may be considered in terms of their functionality, clarity, and accessibility. It is particularly important that these criteria are met by public administration websites. The aim of this paper is to present the most common usability errors identified on the websites of public administration units as well as to indicate the links between particular types of problems and traditional heuristics of Jakob Nielsen. The survey was conducted by evaluating the websites of the Public Information Bulletin in Poland (BIP, which stands for “Biuletyn Informacji Publicznej”), which are supposed to provide universal access to public information by the citizens of the country. A heuristic method (based on J. Nielsen's heuristics) was used to evaluate 60 websites. The errors obtained were grouped into 14 categories. Each of the error groups was assessed by an expert in terms of its importance for the overall assessment of the website's usefulness. The analysis of relations between the identified categories of errors and heuristics of Jakob Nielsen indicates a need for specifying heuristics in the context of evaluating the usability and availability of public administration websites.

## I. INTRODUCTION

Regardless of the motives of designers or clients – the purpose of websites mainly comes down to the effective presentation of their content and efficient conveyance of information (usefulness) to the largest possible audience (accessibility). This means that it is important to ensure that both healthy and disabled people are able to effectively familiarise themselves with the information provided on the website and take advantage of its functionalities.

As far as creating useful and accessible websites of public administration units is concerned, it is necessary to conduct continuous research and usability tests, perceiving it as one of the basic activities in the process of developing such websites. The aim of such activities is to prevent dissatisfaction among users (i.e. citizens) and to provide a place where they can find the information they need quickly and efficiently.

The aim of this paper is to categorise the most common errors identified on the websites of public administration units as well as to indicate the links between particular types of problems and traditional heuristics of Jakob Nielsen. This

will help adjust the heuristic method to the needs of further usability studies of this kind of websites.

The structure of the paper is outlined below. The next section briefly explains the concept of usability in the context of websites. The section that follows focuses on the characteristics of the heuristic method for testing and evaluation of usefulness. Next, the Polish Public Information Bulletin is briefly described. The penultimate section presents the proposed procedure for the examination and the results obtained. Finally, a summary of the paper is provided.

## II. THE USEFULNESS OF A WEBSITE

In literature, usability is defined in a variety of ways. According to ISO 9241 [1], usability defines “the extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use”, while the standard ISO / IEC 9126-1 (for Standardization and Commission, 2001), related to Software Engineering and product quality, describes usability as the ability of the software product to be understood, its operation learned, to be operated, and to be attractive to the user. In the literature, usability is defined as the “capacity to be used” the device [2] and depends on what the user wants to do [3].

According to J. Nielsen, usability “is a quality attribute that assesses how easy user interfaces are to use” [4], comprising 5 components:

- Learnability: How easy is it for users to accomplish basic tasks the first time they encounter the design?
- Efficiency: Once users have learned the design, how quickly can they perform tasks?
- Memorability: When users return to the design after a period of not using it, how easily can they re-establish proficiency?
- Errors: How many errors do users make, how severe are these errors, and how easily can they recover from the errors?
- Satisfaction: How pleasant is it to use the design? [4].

The studies described in the literature [5] indicate that usability is the most important parameter affecting the quality of websites evaluated by their users. According to Paplauskaitė [6], the usability of the website determines its legibility, intuitiveness, and comfort of use. The concept

of web usability is connected with the concept of web accessibility. It means that people with disabilities have full access to the content of a given website, can understand it as well as benefiting from convenient navigation and interaction with the website [7]. It can, therefore, be concluded that the accessibility of websites is related to the human-computer interaction and is a feature of the user interface that allows all people to use it, regardless of their hardware, software or disability. Accessibility problems are most common among users with reduced mobility, hearing or vision, including those with cognitive disorders [8, p. 41; 9, p. 169]. Accessibility is now seen more broadly, i.e. the aim is to make the website accessible to as many people as possible, including the elderly, people with disabilities, people with low bandwidth internet access, and people using older devices, which are usually slower than modern ones [10].

P. Morville names usability and accessibility as two separate dimensions out of the six that make up User Experience, altogether creating a profit or value for the user, ensuring that they receive a product that meets their needs [11]. According to other authors, usability is a broader concept, a subset of which is accessibility, including issues such as interface handling problems experienced by people with disabilities [12, p. 7; 13].

### III. THE HEURISTIC METHOD APPLIED FOR EXAMINING WEBSITES

The literature discusses many ways to study the usefulness of websites [2; 14-18]. One of them is the heuristic method, which is one of the expert, inspection-based techniques of recognising usability problems. It consists in indicating the extent to which a given piece of software or a website complies with the developed rules and standards (called usability heuristics [2]) for the design of human-computer interactions. In this method, experts indicate what is correct and what is incorrect about the website being evaluated in terms of the heuristics applied [19].

The heuristic analysis of a website is a universal and easily applicable method. It is used for researching entire websites, as well as only one or two pages of a given website. It is a relatively inexpensive method as there is no need to involve users and the indicated number of experts is limited, i.e. three to eight experts are considered to be the optimal number [20]. An independent analysis performed by each of them supports the study's objectivity of and effectiveness. Thanks to this method, it is possible to detect many small as well as major errors related to the website's performance. Also, it allows one to identify the elements of the website that may adversely affect its usability.

The literature most often refers to heuristics developed by J. Nielsen, also referred to as traditional ones. These are [4]:

**H01. Visibility of system status** The purpose of the system is to inform the user about what is currently happening while

working with the system, e.g. by sending a message in situations where the system's response time is longer than usual or by placing very helpful progress bars while the user is performing a process consisting of several steps. Sounds or backlighting can be also applied to enhance feedback.

**H02. Correspondence between the system and the real world** The system should avoid technical terms and use only terms and expressions known to the user. In addition, the system should present only the information that is actually needed by the user. It is recommended that it be naturally and logically ordered.

**H03. User control and freedom** The result of the user's actions within the system should be reversible. It often happens that a person using a certain solution mistakenly chooses an option other than the desired one. In such a situation, the system is required to be able to revert activities without having to go through successive stages of the process with an incorrectly selected variant or repeat all the steps from scratch. A well-designed system should allow the user to pause their activities at any time and resume in the same place after the interruption.

**H04. Consistency and standards** The system should be consistent visually (the appearance of windows, colours, the layout of buttons, etc.), operationally (same way of starting operations, same keyboard shortcuts, etc.), and behaviourally (the system's expected reaction to the user's actions). The person using the product should have no doubt about whether similar phrases or actions always mean the same. It is recommended that the conventions applied to the whole platform be adhered to.

**H05. Prevention of errors** It is recommended that situations in which human error is likely should be detected and removed. As for uncertain situations, the system should ask the user if they are sure whether they want to execute the command. It is also worth using various forms of facilitation that will effectively eliminate common errors, for example, by checking spelling, grammar, or command line correctness.

**H06. Recognition and not remembering** The system should not require the user to remember information between successive stages of the dialogue. Access to information relating to the operation of the system should be possible from any location. In addition, it is important to ensure that all available options and actions are clearly visible.

**H07. Flexibility and efficiency of use** A desirable feature of a good system is that it allows operation using shortcuts. Activities often performed by the user should be flexible and adaptable to their needs. It is recommended that keyboard shortcuts, auto-supplements, lists of recently used commands, quick access bars, etc. be used. For tedious, multi-step processes, the system should allow the user to create macro commands.

**H08. Aesthetic and minimalist design** It is recommended to avoid placing unnecessary and distracting elements in the dialogue. They reduce the focus of the person using the solution on the proper content of the task. It should also

be remembered that simple designs, with a small number of elements, indicate the system's ease of use.

**H09. Help users recognise, diagnose, and recover from errors** Error messages sent by the system should be written in a language that is easy for the user to understand. They should carefully explain the cause of the error and suggest a way to repair it.

**H10. Help and documentation** It is recommended that every system have access to a user manual that should not be too extensive. The user, using this type of manual, should be able to easily find the information they need. Well-designed manuals describe the steps the user needs to take to restore their system back to normal.

In addition to the heuristics described above, the literature provides many other approaches to evaluating usefulness with this method, including the following:

- Cognitive Engineering Principles for Enhancing Human-Computer Performance [21],
- Weinschenk and Barker classification [22],
- The Eight Golden Rules of Interface Design [23],
- Usability Heuristics for Touchscreen-based Mobile Devices [24],
- First Principles of Interaction Design [25],
- 7 Usability Heuristics That All UI Designers Should Know [26].

Many of the above rules and guidelines are based on J. Nielsen's classic heuristics. The aim of many heuristics creators is to update and match them to the study of specific IT systems [27-28]. New heuristics proposals also result from a change in the way of looking at the interface usability issue. For example, the aforementioned Gerhardt-Powals [21] takes a more holistic approach to evaluation, including principles such as: automate unwanted workload, group data in consistently meaningful ways, practice judicious redundancy. A more detailed and fragmented approach is proposed by Susan Weinschenk and Dean Barker [22] on their list of twenty guidelines. These are among others: user control, accommodation, simplicity or predictability. Ben Shneiderman's goal was to create flexible principles that can be adapted to interfaces in different programming environments. For example: strive for consistency, seek universal usability, permit easy reversal of actions [23]. A similar point of view is represented by Bruce Tognazzini's guidelines, such as: aesthetic design, anticipation, autonomy, discoverability [25]. Most interface usability experts follow similar principles or build on existing proposals.

#### IV. THE PUBLIC INFORMATION BULLETIN AS AN EXAMPLE OF A PUBLIC ADMINISTRATION WEBSITE

From the perspective of the public interest, especially in the age of the information society, all public administration websites should offer features such as usability, or accessibility, which is inherent in it. The most important and widespread standard for this feature in the world is the WCAG (Web Content Accessibility Guidelines). Many countries are implementing additional

recommendations and legal requirements to ensure the quality of public websites containing information and content of particular interest to the general public. Among the examples thereof are the US Section 508 of the Workforce Rehabilitation Act [29], the German Barrierefreie-Informationstechnik-Verordnung [30], or the Italian Stanca Act [31], adjusting the law to the W3C WCAG 2.0 accessibility requirements.

In Poland, the Public Information Bulletin (BIP) is an example of a website of public administration units, constituting a unified system of Internet services ensuring free-of-charge and universal access to public information in Poland. Apart from the main website of the Public Information Bulletin (<https://bip.gov.pl>), the bulletin consists of services provided by entities obliged to maintain them, such as public authorities, economic and professional self-government bodies, entities representing state organisational units, political parties, and many others. Their task is to inform the public about their activity, i.e. to make public information available. Additionally, detailed requirements and recommendations for BIP administrators can be found on the website of the Ministry of Digitisation (<https://bip.gov.pl>). The straight majority of the above quality requirements come down to the concept of usability. BIP websites should, therefore, be exemplary in terms of this requirement in the context of heuristics adopted both as guidelines for the development of websites, as well as those used for research and evaluation of their usefulness using the heuristic method.

BIP websites are always marked with the appropriate logotype. Although a BIP website is linked to the authorities of a given city, it is a separate website and differs from the website of the city's administration unit. Given that, administrators of the respective types of websites (i.e. BIP and city administration, such as <https://www.wroclaw.pl> and <http://bip.um.wroc.pl>), often cooperate by providing hyperlinks to each other's websites or by distributing content according to its function. In some cases, both websites are placed next to each other, i.e. on the same server, but being two different and separate projects.

## V. RESEARCH METHODOLOGY

### A. Procedure

In order to identify heuristics relevant for the assessment of the usefulness of websites of public administration units, a study was conducted to assess the usefulness of selected 60 websites of the Public Information Bulletin. The examination was performed according to the following procedure:

1. Selecting the Public Information Bulletin websites for research purposes.
2. Researching the websites of the Public Information Bulletin using J. Nielsen's heuristics.
3. Identification of basic errors related to the usability of the Public Information Bulletin websites examined.
4. Categorisation of usability errors.

5. Evaluation of the importance and ranking of the different categories of errors.
6. Comparison of the proposed categories of errors with J. Nielsen's heuristics.

The results of the study are presented in the paragraphs below.

*B. Identification of basic errors related to the usability of the Public Information Bulletin websites examined*

The research began with an analysis of sixty websites of the Public Information Bulletin of large Polish cities. The research was conducted by 120 students aged 23-40, during classes in the subject of "usability of the human-computer interface". These people have been trained to do this task. Students worked in two-person groups, each researched one website. The test results were then verified by an expert. The website evaluation procedure was based on Nielsen's heuristics. After determining the general state of the usefulness of websites of this type, the research was narrowed down to twenty largest cities in terms of population (the most up-to-date data from the Central Statistical Office, i.e. from 31.12.2015 were used [32]). This time the analysis was more in-depth due to the fact that it included accessibility aspects. A number of errors and violations were thus identified, which had a material impact on the usability assessment. At a later stage, those had to be classified. A detailed analysis allowed us to identify the areas of the most frequently occurring errors and problems. Fourteen categories of errors were formulated:

**F01. Website ergonomics:** non-intuitive and unusual location of the website's key elements (e.g. main menu, search fields, accessibility functions, etc.) and too large and unstructured accumulation of elements on the main page, including many unnecessary ones.

**F02. Website consistency:** the selective appearance of key elements that should appear on each page within the website (e.g. main menu, footer, search field, etc.).

**F03. Content and its form:** errors in the text (spelling, punctuation, etc.), incorrect encoding of diacritical marks, illegible and inconsistent formatting and arrangement of the text (typefaces, colours, boldening, indentations, spaces, etc.), too few or too many graphic elements (including photographs) affecting the quality of the visitor's website experience, non-standard or user-unfriendly content presentation, and frequent replacement of content with external attachments (e.g. as PDF files).

**F04. Substantive content:** outdated or incomplete information, inconsistency of the information presented within pages belonging to a single category (e.g. selective contact details for individual departments of the city council - telephone and fax numbers provided for some of them and only an e-mail address provided for others), use of a specialist (legal or technical vocabulary) or convoluted (multiply compound sentences, etc.) language.

**F05. Navigation, menus, and grouping of web pages:** too many or too few options in the main or auxiliary menu (the

problem of a proper number of nests), non-intuitive arrangement and illegible presentation of options, lack of clear information about the possibility of rolling down submenus, recurring menu panels across one page, inconsistencies of individual instances of the website's main or auxiliary menu.

**F06. Navigation between web pages:** lack of or errors in breadcrumb navigation, poorly visible navigation panel, inconsistently performing links, lack of return to parent location button, lack of redirection to the homepage after pressing the logotype or title.

**F07. Navigation - website search engine:** performance errors, lack of results, unconventional format of results (e.g. official documents only), lack or a small number of advanced search options (filtering), lack of hints when entering text.

**F08. Navigation - links:** incorrectly described (alternative text) and outdated hyperlinks, references to non-existent locations, lack of description of error 404, lack of information about redirecting to an external website, lack of options for opening new pages in a new tab or in a new window.

**F09. Accessibility - mobile devices:** lack of website responsiveness, incorrectly executed mobile version of the website, problems with scaling individual elements (e.g. search fields).

**F10. Accessibility - colour set:** aesthetically unpleasant shades of colours and their saturation, too big or too small variety of colours, too big or too small contrasts.

**F11. Accessibility - functions:** illegible text, incorrect performance or lack of buttons related to accessibility (e.g. text scaling, changing contrast, etc.).

**F12. Accessibility - website map:** lack of or incorrectly designed, illegible website map.

**F13. Help:** hardly exhaustive or even non-existent help section, errors in the help section (problems which also concern the frequently asked questions), lack of hints and messages in problematic areas of the website.

**F14. Other errors and limitations:** the website loading time is too long or the loading process is completely stopped – often without any messages, access to all functionalities of the website is possible only after registration.

By means of expert analysis, each category of errors was rated in terms of its importance for the overall evaluated of the service's usefulness. The highest ranks were assigned to the categories that determine the possibility of using the website's functionalities, while the lowest ones reflect problems causing only users' moderate discomfort. The scale of the ranks is as follows:

- 1 – a problem of least significance;
- 2 – a minor problem;
- 3 – a problem of average significance;
- 4 – a major error;
- 5 – a critical error.

Each of the identified error areas was assigned one of five ranks. The results of this study are presented in table 1.

TABLE 1.  
RANKS OF ERROR CATEGORIES

No.	Error categories	Rank
F01	Website ergonomics	2
F02	Consistency across the website	2
F03	Content and the form of content presentation	3
F04	Content and the substantive matter	3
F05	Navigation, menu, and page grouping	5
F06	Navigation between web pages	5
F07	Navigation – website search engine	4
F08	Navigation – links	5
F09	Accessibility – mobile devices	4
F10	Accessibility – colour set	3
F11	Accessibility – functions	5
F12	Accessibility – website map	1
F13	Help	1
F14	Other error and hindrances	3

The most serious problems (rank 5 and 4) found across the BIP websites under examination are navigation difficulties (F05-F08) and availability limitations (F09 and F11). Violations such as F05-F08 i.e. ones related to website navigation can make it completely impossible to find the information needed by the user. During testing, in many cases, the unintuitive menu layout, containing an enormous number of mixed and unnecessary options, combined with an unoperational search engine, made it impossible to find the searched content.

The second type of serious error concerns availability. An increasing number of people are using smartphones and tablets, more and more often abandoning desktop computers. The lack of possibility to use a mobile device or limitations in this respect may effectively discourage many Internet users. Also the lack of accessibility-related functions (e.g. change of contrast) means a serious barrier for people with medical conditions, thus striking the basic principles and sense of BIP websites. The importance of colour choices (F10) has been rated as slightly lesser (average rank, i.e. 3) as it is solved by the contrast matching option mentioned above. Moreover, in none of the cases analysed did the colour scheme pose a considerable problem when reading the content. The same rank was assigned to F03 and F04. These are important aspects of a website, but rather than preventing its use they result in the user's impatience and irritation. The last area, F14, was also given an average rating, due to the diversity and occasionality of errors. The first two categories are less important for the perception of the website and are associated with bad user experience rather than serious impairment of usability, therefore they were assigned a lower rank of 2. The least important are areas F12 and F13, which should be only a supplement to a well-developed website.

### C. Comparison of the identified categories of errors with J. Nielsen's heuristics

The errors identified across the BIP websites, described in the previous section (i.e. F01-F14), were assigned to Jakob Nielsen's ten heuristics (specified in section 3). Table 2 presents a breakdown of the identified error areas and Nielsen's heuristics.

Every link between an error category and a heuristic is marked with an "X". One error area can be associated with several heuristics, while one heuristic can cover several of the specified problem categories. The last column and last row of the table summarise the number of links. For example, category F05 is thematically linked with almost all heuristics (from H01 to H08). Hence, the sum at the end of the line (last column) is 8. This category, therefore, affects many aspects of the site. The table can also be read from the perspective of heuristics. For example, H09 will only be affected in four error categories (F08, F11, F13, F14).

H03-H05 and H07 are the most frequently violated heuristics, i.e. those linked with the highest number of errors. These relate to the user's control over navigation, maintaining consistency and standards, error prevention, as well as errors that affect the effectiveness of use. These are therefore heuristics concerning the most serious usability violations. As for the error areas that concern the greatest number of heuristics, these are as follows: F05, F08, and F11, i.e. again navigation and availability and the less important element of B13 (help).

It turns out that the most serious errors are also the most common ones: F05-F08 (navigation, menu, control, search engine, and links) and F11 (accessibility functions). Individual usability violations covered by these areas appeared in at least half of the websites examined.

## VI. CONCLUSIONS AND FUTURE WORKS

This paper presents identified categories of errors occurring on public administration websites, which were associated with traditional heuristics of Jakob Nielsen. The proposed categories may be heuristics to be applied under the heuristic method for assessing the usefulness of websites. Compared to J. Nielsen's heuristics, in the identified categories of errors, many refer to website accessibility. Meeting the requirements for website accessibility is ensured by features such as the clarity and intuitiveness of the website, which translates into a good reception of the website by both healthy and disabled people. This means that the greater accessibility of the website improves usability as perceived by all users. Therefore, when testing the usability of a website, it is necessary to pay more attention to the verification of its availability.

Identification of the most frequent errors and usability violations on the websites of public administration units as well as determining their correlation with Jakob Nielsen's heuristics will be the basis for further research in this area. Its aim is to develop a comprehensive procedure for testing the usability and availability of public administration

services, with expert analysis being an element of key importance. Tests using this procedure will be conducted on the websites of the Public Information Bulletin. Further work may also result in the presentation of a modified

version of Nielsen's classic heuristics, tailored to the needs of testing public websites. The research is needed especially in view of those at risk of digital exclusion, as well as in view of the rapid growth of the Internet.

TABLE 2.  
HEURISTICS VIOLATIONS

Error categories	No.	Jakob Nielsen's ten heuristics										Number of heuristics linked to the error	
		Visibility of system status H01	Correspondence between the system and the real world H02	User control and freedom H03	Consistency and standards H04	Prevention of errors H05	Recognition and not remembering H06	Flexibility and efficiency of use H07	Aesthetic and minimalist design H08	Helping users recognise and diagnose errors, and enabling recovery from errors H09	Help and documentation H10		
Website ergonomics	F01	X		X	X			X	X				5

□

**Abstract** — The main aim of this research in progress is to develop an initial taxonomy of motivations underlying BPM (Business Process Management) adoption in organizations. This initial study is based on the analysis of 75 customer cases and success stories published on-line by BPM system vendors and BPM consulting companies. We used the mixed conceptual/empirical approach to taxonomy development basing the empirical analysis on descriptive data-coding canon. As the result of our research we present an initial taxonomy of the motivations for the adoption and use of BPM that consists of three dimensions: the organizational scope of a BPM initiative (enterprise-wide, process-focused or task oriented); presence (or not) of the information technology component; and, the importance of external versus internal drivers motivating a BPM initiative. Proposed initial taxonomy will be developed in further research and will serve to link the motivation to change with the expected benefits of BPM adoption.

## I. INTRODUCTION

Any organization making a decision about the adoption of Business Process Management (BPM) is guided by their specific motivations. These motivations are understood as the main reasons why organizations take BPM initiatives as a set of arguments used to support a decision concerning BPM implementation. The motivations behind the justification of organizational change are an indispensable element of every business case [1]. It is these motivations that most often reflect the benefits of BPM adoption [2]. In this study, the term “*motivation*” is related to its goals and expected benefits being the starting point for the decision to adopt BPM.

Although research generally confirms that individual motivations of employees are translated into the performance of the entire organization [3-5], studies on motivations for BPM adoption are virtually non-existent.

For the purpose of better understanding, analysis and use in future studies, motivations should be organized and classified by groups. In this study, we plan to develop an initial taxonomy of motivations which, according to the literature, can serve as a form of classification and as “*a fundamental mechanism for organizing knowledge*” [6, pp.

11-12]. Taxonomies help to arrange concepts, to perceive the relations between concepts and to draw conclusions from them. Taxonomies also reduce complexity, which is why they are useful and important for both research and management practice [6, 7].

In our study, we will use the methodology for taxonomy development proposed by Nickerson et al. [6] that is established in the field of Information Systems. However, it will be the first time applied in BPM research.

To develop an initial taxonomy of BPM motivations, we will use secondary data from BPM case studies and success stories published on-line. We believe that the identification and initial taxonomy of BPM motivational factors will bring a new and original contribution not only to BPM research but also to the practice of the planning of BPM adoptions.

This paper will be organized as follows: firstly, the research background will be presented, including theories underlying BPM as well as short discussions from the literature on the benefits of BPM. This theoretical background will be followed by the explanation of the research methodology used to create a taxonomy. The research results obtained will then be presented specifically as an initial taxonomy. Finally, the contribution and limitations of the study will be assessed and the direction of future research proposed.

## II. RESEARCH BACKGROUND

### *Theories underlying BPM motivations*

Theories and frameworks used for explaining BPM can help identify potential motivations and related goals to achieve through the use of BPM. Starting from the roots of process-based management concepts, we can point out two main perspectives in looking at BPM and the expected outcomes of its adoption: *the organizational perspective* and *the technological perspective*. For the organizational perspective, research and practice were focused on using process thinking during the design and improvement of an organization [8-10]. The technological perspective was

□ This work was supported by the Polish National Science Centre, Poland, Grant No. 2017/27/B/HS4/01734

addressed by using process-based concepts and tools to support the design and implementation of IT systems [11, 12].

An integrated and interdisciplinary BPM framework was proposed by [13, 14], who indicated *six core BPM elements* required for the holistic and sustainable use of process management. These include strategic alignment, governance, methods, information technology, people and culture. Further studies on BPM also began to emphasize the importance of the contextual and environmental factors for BPM adoption [15, 16]. As the BPM concept became more established, the list of potential expected benefits of BPM adoption expanded. Motivational factors could also be driven by customers, suppliers, competitors and legal pressures exerted on organizations [16, 17].

To explain BPM phenomena in an organization, the BPM literature indicates mostly theories, which we also present in this study as the main theories underlying BPM adoption and enhancing understanding of BPM motivations [18, 19].

The *technology-task fit theory* is mainly used in the field of Information Systems and explains the relationship between processes and technology. According to this theory, benefits from the implementation and use of IT systems in organizations can be gained if the information system fits the tasks that need to be performed [20]. This theory can explain motivational factors related to the use of technology. The *dynamic capabilities theory* refers to the purposeful adaptation of organizational resources and competencies in the continual improvement process to respond better to a changing environment [21]. The *contingency theory* points to the situational fit between the method of organizing and managing and the environment in which the organization operates [22, pp. 96-100]. Thus, the contingency theory explains the aspect of environmental motivations which are forced by the external environment.

To enhance the understanding of BPM phenomena the theories referred to above should be synthesized [19, 23]. This integrated approach can serve as a common platform for developing a comprehensive theory explaining BPM.

#### *Motivations as benefits drivers*

The adoption of any new approach or organizational change like BPM is an effort for an organization. This effort must be justified by the expected benefits that should result from the investment of its effort. Therefore, studying factors that motivate organizational change, including BPM adoption, should consider the analysis of the perceived organizational benefits of the implemented change [2, 24, 25].

We propose to discuss the connection between the set of motivations and goals and the set of outcomes and benefits. We understand the term "*benefit*" as the desirable and measurable outcome of BPM implementation, where outcomes are "*the goals a company realized*". We understand the goals as "*something a company desires to achieve*" [24], whereas motivations are primary reasons that inspire an organization to adopt BPM. The connecting elements between the two aforementioned sets are planned activities.

We can formulate the following chain of connections that explain why an organization's motivations should be studied: Motivations → Goals → Activities → Outcomes → Benefits

The study of Malinova et al. [24] explains an important relationship between the goals articulated for a BPM initiative and its actual outcomes and benefits. The vehicle that delivers outcomes inspired by the goals is a set of activities that a company undertakes within the scope of a BPM initiative.

The expectation of benefits may encourage decision makers to give support to a BPM initiative in their organization and would shape their expectations as to what can be achieved with it. On the basis of these expectations, combined with their assessment of current organizational needs, the goals of a BPM initiative are formulated. Depending on the general goal of a BPM initiative a different approach to its realization could be taken - a more centralized, top-down approach focused on managing few processes at the time, or, a decentralized approach with multiple distributed initiatives relying more on a dynamic organizational social system. We can, therefore, conclude that knowledge of the initial motivations of BPM will contribute to the success of the undertaking initiative.

### III. METHODOLOGY

#### *On-line cases collection and coding*

In order to collect data for our analysis we searched for published on-line BPM cases and success stories using the following search strings:

- Search string I ("Business Process Management" OR "BPM" AND "case study")
- Search string II ("Business Process Management" OR "BPM" AND "success story")

The collected cases were used as secondary data [26]. As this study is preliminary, we limited the number of stories by choosing recurring websites in both search strings and diversified them by choosing three websites of BPM suites vendors and three websites of BPM consulting companies. In total, 75 BPM case studies were used to propose an initial taxonomy. Due to the fact that proposed taxonomy can be further developed and we do not present the results of quantitative research, we believe that this sample is sufficient to present the study in progress.

In the first step of the analysis, in each case, we identified excerpts that offered reasons why the organization decided to adopt BPM. We identified 271 individual items of motivation which were subsequently coded based on descriptive data-coding canon [27]. We used NVivo software to support the coding process and analysis of qualitative data.

#### *Taxonomy development process*

We applied the methodology for taxonomy development by Nickerson et al. [6] and according to this study, we determined the meta-characteristic of motivations as the most comprehensive, based on theories underlying BPM adoption. We used three main characteristics as the basis: motivation

driven by an organization, by technology, and by the environment. The further development of taxonomy, therefore, be based on this conceptual pillar.

Due to the current lack of useful classifications of BPM motivation in the literature, we elected to use the mixed conceptual/empirical approach to taxonomy development [6]. We employed an empirical approach using coding canon to row data i.e., descriptions of motivations identified in each case. Subsequently, we coded and classified similar data under the same category using a deductive method of conceptualizing of data.

We made every effort to meet the qualitative conditions for taxonomy, which should be concise, robust, comprehensive, extendible, and explanatory [6]. However, the number of dimensions and the number of motivations can be extended in future research, so our preliminary taxonomy may be less than comprehensive.

#### IV. RESULTS

According to the used methodology [6], we identified three main dimensions to develop this initial taxonomy of BPM motivations. Based on BPM knowledge, we proposed characteristics for each dimension.

Analyzing the BPM literature on objectives, outcomes and the overall benefits of BPM, we noticed that they are formulated at different organizational levels. At the 'macro' level of the organization they refer to the overall effectiveness, strategy, organizational structures, methods of allocation and utilization of resources, etc. At the level of

processes, the goals and outcomes often refer to one or few more processes or the phases of the process life cycle, such as process design, analysis, redesign, implementation, monitoring and controlling [24]. Occasionally, the formulation of goals and expected benefits is focused on even more specific elements such as work positions and relate to tasks. A good example of such a situation may be the formulation of goals for the recently popular Robotic Process Automation applications where outcomes are expected at task or process levels [28]. Although it is obvious that all achieved results translate into the effectiveness of the entire organization [9], focusing the motivation either on the entire organization or process, or task will indicate the scope and complexity of planned organizational changes. For this reason, we decided to highlight the scope characteristics and three levels of impact within the 'Organization' dimension.

When planning the second dimension, 'Technology', we took into account the long-term relationship of the applied process approach with the implementation and use of information technology, which was also highlighted by us in the background of this study. We have, therefore, decided to examine to what extent the motivations for adopting BPM are inspired by technology.

In the third dimension, 'Environment', our intention was to check whether it is the internal or external environment that motivates decisions regarding BPM adoption more often. The internal environment is shaped mainly by the organization's owners, the board of directors, employees and organizational culture. However, BPM initiatives may also be triggered by

TABLE I.  
INITIAL TAXONOMY OF BPM MOTIVATIONS

<i>Examples of coded motivations</i>	Motivations related to the scope of the BPM initiative in an Organization			Motivations related to the use of Technology		Motivations driven by Environment	
	Motivations driven at the organizations level	Motivations driven at the process level	Motivations driven at the task level	Techno-logical motivations	Non techno-logical motivations	Internal environment driven motivations	External environment driven motivations
Clarify roles and responsibilities	x				x	x	
Improve governance mechanisms	x				x	x	
Comply with new regulatory requirements	x				x		x
Capture organizational knowledge	x				x	x	
Respond to customer requirements	x				x		x
Improve collaboration in an organization	x				x	x	
Eliminate process errors		x			x	x	
Reduce process costs		x			x	x	
Improve financial performance	x				x	x	
Improve process efficiency		x			x	x	
Reduce manual tasks			x	x		x	
Automate tasks			x	x		x	
Implement new IT system	x			x		x	
Improve data and information quality		x			x	x	

pressure from the external environment such as customers, suppliers or changes in regulations [23].

Table I presents the initial taxonomy of BPM adoption. In the first column we present the examples of encoded motivations from our study in order to show that, following the used methodology, at least one motivation is classified under every characteristic of every dimension. Such a taxonomy, according to qualitative attributes, is extensible and explanatory [6]. Therefore, can be extended in future studies.

#### V. CONCLUDING REMARKS, LIMITATIONS AND FUTURE RESEARCH

It seems obvious that organizations are motivated to adopt BPM by the desire to achieve expected benefits. However, the primary motivations for this adoption remained unexplored until the results of this study were presented. Our research is the first attempt to identify and categorize the initial reasons that grounded the decision on the adoption of BPM. Our research contributes to the theory by offering the first methodologically developed taxonomy of BPM motivation.

We believe that our research will contribute to inspiring organizations and dispelling their possible doubts about the benefits of adopting BPM.

We also acknowledge some limitations of our study. Firstly, it might be the case that success stories published on vendors' websites tend to describe cases with only positive effects of BPM application. Secondly, the investigated cases described the effects of various process initiatives without distinguishing between one-time improvement projects and initiatives that are a part of a systematic approach to BPM adoption that could enable ongoing process-based management of an organization. Motivations for these types of projects may have different dynamics.

In future studies, we plan to extend the sample of success stories. Based on classified motivations, we intend to develop motivation patterns that will include groups of motivating factors and organization characteristics. Finally, we plan to investigate how the various types of motivations impact the future success or failure of BPM initiatives.

**Abstract**—Spreading of information within social media and techniques related to viral marketing take more and more attention from companies focused on targeting audiences within electronic systems. Recent years resulted in extensive research centered around spreading models, selection of initial nodes within networks and identification of campaign characteristics affecting the assumed goals. While social networks are usually based on complex structures and high number of users, the ability to perform detailed analysis of mechanics behind the spreading processes is very limited. The presented study shows an approach for selection of campaign parameters with the use of network samples and theoretical models. Instead of processing simulations on large network, smaller samples and theoretical networks are used. Results showed that knowledge derived from relatively smaller structures is helpful for initialization of spreading processes within the target network of larger size. Apart from agent based modeling, multi-criteria methods were used for evaluation of results from the perspective of costs and performance.

## I. INTRODUCTION

Online platforms evolved from early stage technical systems to social media with integrated mechanics of social communication and interactions close to the real world [1]. Together with growing audiences, they attracted more attention of marketers. Apart from typical digital marketing channels based on display advertising and search engines new strategies focused on social media emerged. They include mechanism based on detailed targeting, consumer behavior analysis and commercial content dissemination with the use mechanisms of information spreading.

Results delivered from viral campaigns usually outperform traditional campaigns because of the utilized social influence and ability to induce high dynamics even with low budgets [2]. Social recommendations have high impact on customer decisions and, properly integrated with marketing communication [3], help to further increase performance [4].

The recent studies focused on viral marketing take into account data from real platforms as well as theoretical network models [5]. One of the goals is to increase campaign dynamics

and coverage with properly selected initial customers during the seeding process [6]. Apart from static networks, dynamic networks with varying structures are taken into account [7]. Other approaches take into account multi-layer structure of networks representing specifics of real social relations based on different networks, for example private and professional contacts [8].

Theoretical and simulation models are used for prediction of network coverage. They can be derived from analytic models used in epidemiology [9] or can be more focused on network structures and characteristics [10]. Other possibility is to use theories and models related to the diffusion of innovations [11].

While most of the research is focused on coverage and number of infected nodes within the network, from the practical point of view, marketing campaigns can have different goals and specifics. They are planned within assumed budget constraints and timing. A different strategy can be used to acquire high number of potential customers in a very short time than for a long term planning and organic growth of customer database. Campaign budget influences the number of initially infected nodes (seeds) and demographic characteristics. The quality of seeds and their number can be a key factor of campaign coverage and overall results. Additional budgets can be used to increase campaign dynamics or lifespan. To take into account various goals multi-criteria campaign evaluation can be used to select campaign parameters and goals according to preferences and priorities [12]. Earlier research has shown that in order to reduce computational complexity, campaigns can be planned with the use of simulations within smaller synthetic networks based on theoretical model. However, since the theoretical models might not always fit the real networks, the current study proposes the use of network samples for the initial simulations and detection of campaign parameters. Both approaches were compared with results obtained from the complete network and showed the ability to obtain approximate results with network samples.

The paper comprises of five main sections. After this introduction, in Section II literature review is presented. It is followed by the methodology presented within Section III and results in Section IV. Paper is concluded in Section V.

## II. LITERATURE REVIEW

Social platforms gather detailed information about user behavior and social relations with the main goal to better address commercial messages and properly target products and services [13]. The growing complexity and volumes of the collected data is a direct result of the growing number of users and that their activities moved to electronic systems [14], [15]. Social platforms are treated as tools to use social influence mechanisms to spread information between friends with the impact strengthened by social recommendations. Contacts within social networks are used to pass the information and it often induces information cascades as a main driver of viral marketing campaigns. Multidisciplinary nature of phenomena connected with information diffusion integrates efforts from scientists from various fields like sociology, computer science, physics and management with a different theoretical and practical goals [4] [9] [6].

For better understanding of the information spreading processes, theoretical models are used and they are often implemented within agent based environment or used for analytic studies [16]. Methodological background of studies is often based on models initially created for epidemic research like SIR or SIS with taken into account analytic view on processes and their dynamics [9]. Apart from them, more dedicated solutions were created to create models on microscopic level using information about network structures and relations between users. They are based on two key mechanisms represented by linear threshold models [11] and independent cascades [10]. Linear threshold model, with its later extensions, assumes the social influence induced by neighbors with the network and information flow when the number of neighbors exceeds assumed threshold. Cascading models use different mechanics with spreading based on propagation probabilities and communication with surrounding neighbors and passing content to them. These approaches can be treated as pull and push spreading models. Spreading models can be also used for analysis based on aggregated and macroscopic level [17].

Apart from the mechanics of the information spreading, the dynamics of processes are related to network models and their structures. For the simplest approaches, static networks of non-varying structures are used. More closer to reality are approaches focused on dynamic networks with a changing number of social connections or availability of nodes [18]. For better representation of real systems multi-layer networks are used with spreading dependent on connections between layers, their structures or similarities [8].

Many studies related to information spreading take into account the selection of initial customers, in a form of a seeding process, targeted with product samples or other marketing content with the main goal to motivate them to spread the information to friends within the network [6]. Proper

selection of seeds is crucial for successful campaigns, but the problem identified as influence maximization problem is NP-hard [10]. Greedy solutions deliver effective results, but with the high computational cost they are difficult to use within real networks [10]. More practical approaches base on heuristics and a selection of nodes with the use of the network metrics like degree or betweenness. Centrality measures can be used for selection of initial influencers with assumed characteristics [19] [20].

Apart from seeding only once at the beginning of the process, knowledge about the process performance can be gathered and used for additional actions to improve the process characteristics. Adaptive approaches can be used [21] to increase the reach and better utilize the available knowledge. Other possibility is to spread the seeds over the time and better utilize the natural spreading processes. It can be applied in a form of sequential seeding [22] or its extension with recomputed nodes' rankings at every simulation step [23]. Further improvement of seeding can be performed with the use of knowledge about community structures within the network [24], voting mechanics [25] or k-shell based approach dedicated for identification of nodes with high spreading potential [26].

Apart from single campaigns spreading, processes can interact or compete [27]. For such scenarios seeding can be planned to increase the chance of process to survive among competitors or reach audiences in a shortest time before other processes acquire them. Similar situation takes place in epidemic research where two or more pathogens are competing with each other or conditional infections are observed with activity of first virus required for next viruses. Competing scenarios are observed when awareness spreading is decreasing dynamics of epidemic [28]. It lead to extension of the single campaign models to multi-spreading processes for viral marketing studies[29].

Another studies take into account content specifics and network structures [30], proper ways to motivate users to forward the content [31], influence of emotions on content propagation processes [32] [33] and other structural or functional factors [34] [35].

The earlier studies focused mainly on influence maximization to increase coverage within the network. Campaign evaluation was also discussed as a multi-criteria problem [12]. Campaigns performed within agent based simulation environment were evaluated with the use of set of criteria related to budgets, campaign costs and the number of target nodes. Model output was delivering solutions with defined number of seeds or propagation probabilities. Study also showed the ability to perform simulations with theoretical models and apply selected strategies to real network. The current study extends the presented approach and uses network samples created with the use of snowball sampling [36].

## III. METHODOLOGY

Viral marketing campaigns can be based on various strategies. During the campaign planning, decisions are taken about

optimal number of initial seeds, methods used for their selection, motivation techniques used for users to increase their willingness to spread the content and type of incentives used to increase the propagation probabilities. Similar problems are related to campaign evaluation and selection of campaign metrics dependent on campaign goals. Other performance metrics can be used for campaigns focused on high network coverage than on highly targeted processes addressed only to specific customers.

While social networks store information about users, connections and network structures, it is possible to analyze information before campaign to optimize the strategy and maximize results. With the assumed campaign scenarios and goals it is possible to simulate and test different strategies for selection of campaign parameters. Due to high computational complexity it would be difficult for larger networks.

The approach proposed in this paper assumes the generation of synthetic networks based on theoretical models, generation of network samples based on real network, performing simulations focused on verification of different seeding strategies and campaign parameters and evaluation of results with the use of MCDA methods and, finally, launching the campaign within the real network (see Fig. 1)

Simulations can be performed within synthetic networks based on theoretical models like Barabasi-Albert model (BA) [37], Watts-Strogatz (WS) model [38] and Erdos-Renyi model (ER) [39]. The size of synthetic networks can be adjusted with reference to the size of real network and it can be a fraction of the real network e.g. 10%, 20%, 30% etc. It is also important to select proper network model with high similarity to real network. The presented approach uses Kullback-Leibler measure (KL) to compare network similarities [40]. Number of nodes and edges within synthetic network can be scaled for better performance and accuracy.

Since a real network not always must be similar to idealized theoretical models, another approach can be based on network samples generated as a fraction of the real network. Snowball sampling can be used to obtain smaller structures, which would allow to perform simulations easier, yet with assumed similarity to the full network structures. Samples can be scaled from lower to higher fraction of the complete network. It is assumed that accuracy of simulations in the bigger samples is more close to the real network but computational complexity is lower for the smaller samples.

The simulations for all samples and synthetic networks are performed with the use of various campaign parameters. The number of seeds represented by the seeding fraction (SF) and its effect on total coverage can be verified and is the representation of a campaign budget. Another decisions are related to seed selection strategy (SS). It can be based on different network metrics and it is also related to campaign costs. For example, targeting high degree nodes can be more expensive than low degree nodes.

From the other point of view, the selection of nodes with high closeness can be more expensive than the selection of nodes with high degree because of higher computational

complexity required to compute closeness metrics than degree. Another tested parameters are based on propagation probabilities (PP). For lower propagation probabilities, coverage within the network will be lower, but higher probabilities require higher motivation of users to forward the content. It may require incentives and is related to increased budgets.

To compare results from samples and synthetic networks, the proposed study performs analysis for all networks used. The MCDA module takes into account possible campaign success evaluation criteria like coverage, dynamics, campaign costs. In the subsequent step, the performance table obtained from the samples, as well as the criteria and preferences, are used to produce a ranking of possible advertising strategies with the selected MCDA method. After analyzing the ranking and performing robustness / sensitivity analysis, the analyst provides the campaign parameters recommendation for real network campaign.

In the prior research [12], the authors successfully used the PROMETHEE II method [41], [42] to evaluate viral marketing campaign strategies. However, in the proposed research the authors' wanted to emphasize the effect that the marketers' weights assigned to particular criteria have on the final strategies evaluation. Therefore, it was decided that full sensitivity analysis of the obtained solutions should be performed, which eliminated aspect of uncertainty of the decision maker's criteria preference. Moreover, since in the proposed approach the input data comes from simulations, data uncertainty can also be disregarded. However, the evaluation problem at hand still is characterized by weights and data expressed on a quantitative scale. Last, but not least, the obtained solution to the strategy evaluation problem should take the form of a complete ranking to allow the choice of the best strategy. Therefore, based on the analysis of 65 MCDA methods [43], [44] and the guidelines included in [45] and [46], the authors decided to found their approach on the TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution) method [47].

The TOPSIS method is a representative of the American MCDA school [48] which transforms all decision-making problem criteria into a single score value. In case of the TOPSIS method, based on the criterial performance of the evaluated criteria, a positive and negative ideal strategies are created, i.e. one which tops at each criterion and one that bottoms at all criteria. Subsequently, the score of each appraised strategy is computed as a relative distance between the strategy and both the positive and negative ideal solutions. Therefore, the best strategy would be the one which is closest to the positive ideal strategy, yet as far as possible from the negative ideal strategy in terms of criterial performance values.

#### IV. RESULTS AND DISCUSSION

##### A. Evaluation of viral marketing campaign strategies on a real network

The empirical study was based on a real network, a part of the topology of the Gnutella network as mapped in 2002 in the

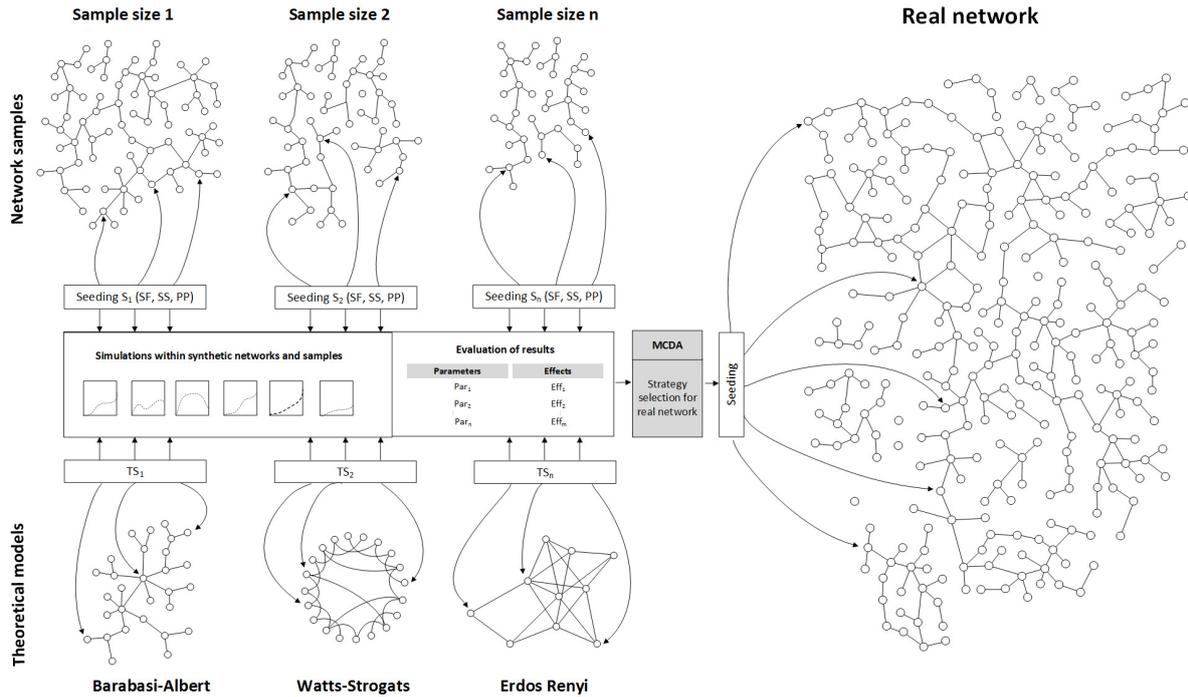

Fig. 1. Conceptual framework for real network strategy selection based on simulation results within network samples and theoretical models

[49] research. The mapped network comprises of 8846 nodes and 31839 edges. The nodes represent hosts in the Gnutella network topology and the edges represents connections between the Gnutella hosts in a single of the network snapshots collected in August 2002. The average values of the main network’s metrics are as follows:

- 1) total degree  $D = 7.1985$
- 2) closeness  $C = 1.587441e - 07$
- 3) Page Rank  $PR = 0.0001130454$
- 4) Eigen Vector  $EV = 0.01602488$
- 5) clustering coefficient  $CC = 0.0001130838$
- 6) betweenness  $B = 19104.87$

During the empirical study, the authors used the proposed framework to plan and simulate a viral marketing campaign. Ten simulation scenarios were generated to assure repeatability of the results regardless of the input parameters. Each scenario was composed of the weights drawn for each edge, ranging  $< 0; 1 >$ . These weights were later compared with the propagation probability of each node to determine whether or not the actual information propagation would occur.

As part of the simulations, a total of 400 sets of parameters were tested, built as a Cartesian product of the following simulation parameter values:

- 1) Par1 - 0.01, 0.02, ..., 0.09, 0.10;
- 2) Par2 - 0.01, 0.10, 0.20, ..., 0.90;
- 3) Par3 - degree (1), closeness (2), eigenvector centrality (3), betweenness (4) – the value is the rank of the method based on its computation speed.

Rank	Alt	CCi	SF	PP	Last Iter	Coverage Measure	
1	A11	0.7494	0.01	0.20	14.4	0.5174	1

Fig. 2. Visualization of the top 20 alternatives from the TOPSIS evaluation of the [49] real network.

Consequently, 4000 simulations were performed for the [49] network. The results of each simulation run were registered, including inter alia the iteration during which the last infection occurred as well as the total coverage achieved, which values were labelled for the further evaluations as Eff4 and Eff5.

After the simulations concluded, the TOPSIS method was

used to evaluate all 400 campaign scenarios. Initially, the weights of all criteria were set equal. The preference direction of the **Par1-Par3** criteria was minimum and of the **Eff4-Eff5** was maximum. Intuitively that would mean the decision maker would prefer low cost of the entrepreneurship, yet long duration and maximum coverage. The top 20 strategies are presented on Fig. 2. The best strategy, A11, obtained  $\phi_{net}$  score of 0.7494. This strategy is based on low values of SF and PP (0.01 and 0.20 respectively) and degree as the method of seeding nodes selection. The runner-up alternative, A10, is based on the same SF and PP values, but uses closeness as the method for selecting the seeding nodes. As a result, slightly broader coverage was achieved in minutely less iterations (0.02s difference). The third-best strategy, A7, maintains the degree measure and the SF of 0.01, however it reduces the PP by half, to 0.10. Such strategy would non-negligibly reduce the costs of the campaign (lower investment in incentives), and, since less nodes at each step would get infected, the procedure would take longer (16.8 iterations on average). However, the obtained coverage is significantly lower, equal to 0.1334 of the network, which is over three-fold worse than the winning A11 strategy.

For the purposes of comparison, the worst strategy, A400, was based on high SF (0.10), high (ignitable) PP (0.9) and eigenvector centrality as the measure. As a result, the contamination process averagely finished within 5.1 iterations, with the mean coverage of 0.9722. Although almost full network gets covered with that strategy, it is important to note that the incentive costs for such strategy would be very high to achieve 90% propagation probability. Also the duration of the campaign would be low, which is against the DM's preferences.

One of the benefits of the TOPSIS method is the fact it allows to build an ideal reference model for the given evaluation problem. In case of the problem at hand, the ideal strategy would be based on degree for selecting the nodes to seed information to and only 1% nodes would be seeded. Incentives would be in place to generate an average propagation probability of 0.01%. With such parameters of the network, the DM would like the outcomes of the marketing campaign to be 19.6 iterations resulting in 97.22% coverage. It is important to note, however, that although ideal, such strategy is only a reference model and does not exist.

The rank presented on Fig. 2 is based on an assumption that the weight of each criterion on the final outcome is equal. However, the DM often gives more significance to some criteria over the others. One of the tremendous benefits of the utilisation of MCDA in the evaluation of viral marketing campaign strategies is the possibility to perform a sensitivity analysis, to learn how even slight changes in preferences of each criterion would affect the final outcome. Therefore, in a subsequent part of the research, a sensitivity analysis was performed to show how the ranking relations between the top 20 alternatives would change if the weights of each criterion would change. The analysis was divided into five parts, one for each criterion. During each phase, the weight of a single

criterion was changed from 1 to 100, while the weights of the remaining criteria were set equally to 50.

The results of the sensitivity analysis are presented on Fig. 3. The top row of the figure (A-E) presents how the score of each strategy changed, resulting from each criterion's weight change, whereas the bottom row of the figure (F-J) presents how that change affected the strategies' positions in the ranking. The analysis of Fig. 3A,F shows that no matter how the weight of the criterion Par1 changed, strategy A11 remained the leading one. On the other hand, if the weight of this criterion dropped slightly below 40, strategy A7 would outrun strategy A10. Strategy A51 rank is not affected by the changes of weight of criterion Par1, whilst strategy A50 (ranked fifth) would be outrun by strategy A12 (ranked 7) if its weight was higher than 75. The analysis of the chart on Fig. 3A allows to observe, that while the score of alternatives A128, A131 and A132 is not significantly affected by the changes of Par1 weight, the remaining strategies gain more score as the weight of this criterion increases. A similar tendency can be observed on Fig. 3B, where the scores of all strategies increase along with the increase of significance of criterion Par2. When the weight of that criterion would exceed 90, the runner-up strategy A7 would outrun the strategy A11. An opposite tendency can be observed on Fig. 3E, where all alternatives lose score when the weight of Eff5 grows. Along with this criterion's weight growth, there are only little changes in the order of the three leading alternatives, however, if the weight of that criterion dropped close to 0, the leading strategy A11 would drop six positions to rank 7. This demonstrates the fact that strategy A11 is considerably supported by criterion Eff5. The observation of Fig. 3F-J shows that while for the criteria Par1 and Par2 the majority of rank changes occur when the weight of the criterion changes considerably, in case of criteria Par3 – Eff5, most of the rank changes occur with even minute changes of these criteria's weights.

### B. Selection of synthetic networks

As it was presented in section IV-A, the proposed MCDA framework allows to successfully evaluate various viral marketing campaign strategies performed over a real network. However, full networks are rarely available for the entities ordering campaigns. Often, only characteristics of a network are provided. Moreover, running comprehensive simulations on a real networks containing multitude of nodes is also time consuming. Therefore, it is beneficial to perform simulations on smaller synthetic networks before launching the actual campaign on a real network.

Consequently, in the empirical research, apart from evaluating campaign strategies based on full, real network, the authors also used the proposed framework to perform simulations on synthetic networks, similar to the real one, but of a reduced size. The strategies' rankings obtained for synthetic networks were then compared to the ranking obtained for the real network.

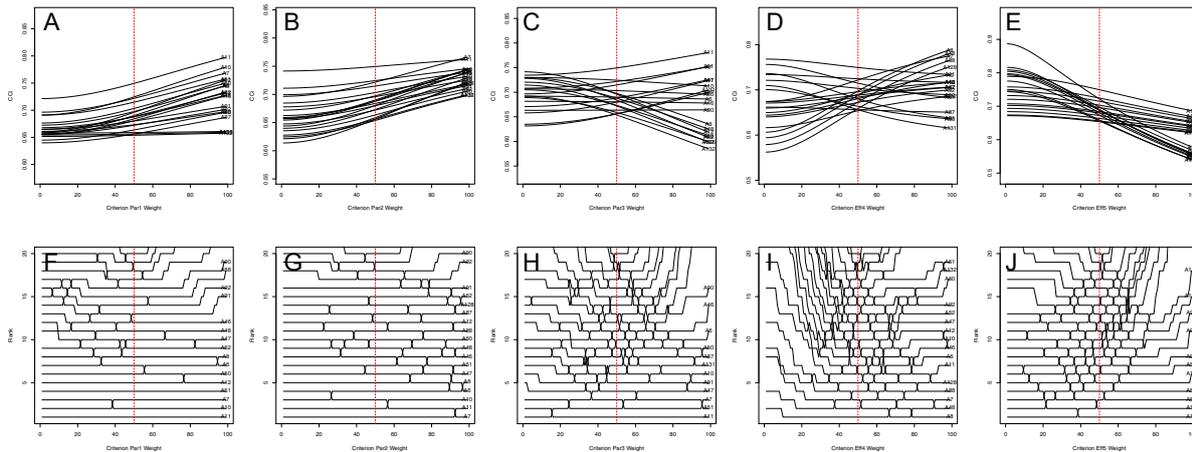

Fig. 3. Ranking sensitivity analysis for the top 20 alternatives from the TOPSIS evaluation of the [49] real network.

For the 10%, 30% and 50% size of the real network, BA, WS and ER networks were generated with the following parameters:

- 1) BA - number of nodes equal to 10%, 30% and 50% of the real network; number of edges  $m$  to add in each step equal to  $1, 2, \dots, 5$  – a total of 15 networks;
- 2) WS - number of nodes equal to 10%, 30% and 50% of the real network; the neighborhood within which the vertices of the lattice will be connected equal to  $1, 2, \dots, 5$  – a total of 15 networks;
- 3) ER - number of nodes equal to 10%, 30% and 50% of the real network; number of edges equal to the chosen number of nodes multiplied by  $1, 2, \dots, 5$  – a total of 15 networks.

As a result, a set of 45 networks was generated. In order to avoid arbitrary decisions which network to run the simulations on, the Kullback-Leibler divergence measure was used to compare the degree distribution of all generated networks to the real one. Based on the smallest value of the KLD measure, three networks were selected for further simulations. The selected networks are presented in Table IV-B.

### C. Viral marketing campaign strategies planning with synthetic networks

The results of the viral marketing campaign strategies planning with the use of the three aforementioned BA networks is presented in table on Fig. 4. The analysis of the table allows to notice that regardless of the selected network size, in all three cases the same strategy A11 was chosen as the superior one, similarly to the real network case. While in case of the real network this strategy lasted averagely for 14.4 iterations and resulted in 0.5174 coverage, in case of the synthetic networks, the process averagely lasted 10 – 11.2 iterations (slightly shorter) and resulted in 0.5783 – 0.7049 coverage (slightly higher). The second best strategy in all three synthetic networks was strategy A51, which above, in case of the real network, was ranked fourth. This strategy is based

on small values of SF and PP (0.02 and 0.20 respectively) and lasts averagely in 9.5 – 10.7 iterations resulting averagely in 0.5783 – 0.7049 coverage. The measure used here is also degree, as in the winning alternative.

The strategy A10, which for the real network evaluation was ranked second, in case of the synthetic networks reached place 3 for the 50% network and rank 4 for the remaining networks. More interesting is the case of strategy A7. On the real network it is ranked third, for the 30% network it remained at the same ranking position, however, for the 50% network it dropped to the fourth rank, whilst for the 10% network its ranking fell to 15th position. The strategy A7 is characterized by its very low SF and PP values (0.01 and 0.10 respectively) and degree as the measures which makes it one of the cheapest, with maximally extended information propagation process duration, on the cost of small final coverage. The duration of the process is very long for this strategy on the real network and the 30% and 50% networks (16.8, 12.8 and 13 iterations averagely, while the maximum average duration was 19.6, 12.9 and 13.7 iterations respectively). In case of the 10% synthetic network, the average duration is 9.7 iterations and the yielded coverage is lower, equal to 0.1784, which resulted in reduction of the A7's rank.

In case of the strategy A15 which for the 10% network is ranked third, it does not occur on the real network top-twenty list, and on the remaining synthetic networks it is below the first top-ten. This is an interesting difference, which can be further analyzed with the use of the sensitivity analysis (see Fig. 5). In case of the 10% network, the strategy is slightly supported by Par1 criterion. If the weight of criterion Par2 was increased, the strategy A15 would significantly drop in the ranking, down to rank 17. On the other hand, if the weight of the Par3 criterion became insignificant, strategy A15 would be ranked 10th. Regarding the efficiency rankings, Eff5 supports the strategy A15 (rank 11 to rank 1 increase when Eff5 weight increases from 1 to 100) and Eff4 is in conflict with A15 (rank 1 to rank 6 decrease when Eff4 weight increases from 1 to

TABLE I

100).

The sensitivity analysis can also provide information about the overall stability of the obtained solution. In case of the 10% network, the ranking is very stable and the A11 strategy either remains on the winning rank or drops to the second position if the weight of Par2 drops below 40%, Par3 drops below 10%, Eff4 drops below 25%. The only significant change occurs for the Eff5 criterion, where A11 would drop to rank 2 if the Eff5's weight increased to over 60% and even further if the weight increased to over 75%. If exclusively Eff5 was considered, the A11 strategy would be ranked 13th.

Similar stability for Par1-Par3 can be observed for the 30% network, however if the weight of Eff4 increased significantly or the weight of Eff5 increased significantly, A11 would be ranked 6th.

Last, but not least, in case of the 50% synthetic network, A11 would remain ranked 1st regardless of Par1 weight, would drop to 2nd position if Par2 had weight exceeding 90 or would drop to 3rd position if Par3 had negligible weight. In case of Eff4, the stability interval of the obtained solution is 0 – 80, whilst in case of Eff5 the stability interval is 35 – 100.

D. Viral marketing campaign strategies planning with network samples

As it was stated in the methodology section of this paper, although synthetic networks allow to minimize the computational efforts, their resemblance to the actual real network might be insufficient. Therefore in the subsequent step of the research, the original real network [49] was sampled, resulting in 3 networks containing 10%, 30% and 50% of the original

network. The sampling procedure was performed with the *snowball.sampling* R function from the *netdep* R library [50].

The results of the viral marketing campaign planning based on the real network [49] samples are presented in table on Fig. 6. Contrary to the synthetic networks' results, where the same strategy A11 was best in case of all three networks, in case of the samples of the real network, the rankings are more diversified.

When the 50% network is considered, the best-ranked strategy is the strategy A15, based on very low SF, higher PP (0.30), degree measure mediocre process length (14.1 iterations) and satisfying coverage (0.5075). Strategy A15 is followed by strategy A11, which uses smaller PP (0.20), which resulted in simulations in less dynamic process, leading to extending its duration to 17.9 iterations, but reducing the coverage almost by half, to 0.2685. The third position in the ranking belongs to strategy A55, which is based on 0.02 SF and 0.30 PP and results in efficiency results similar to the leading A15 strategy - 13.3 iterations and 0.5106 coverage respectively. However, the costs of such approach are higher due to the increase of the SF. When the 30% and 10% networks are considered, the A15 strategy is ranked second in the former and sixteenth in the latter, which, as mentioned earlier, is in contrast to the observations made for synthetic BA networks.

The equal-weights TOPSIS analysis was followed by a sensitivity analysis of the top 20 strategies for each of the sampled networks (see Fig. 7). An overall observation of the figures allow to see that the rankings for the 50% and 30% networks are much more stable than in case of the 10% network. To illustrate that fact, one can notice that

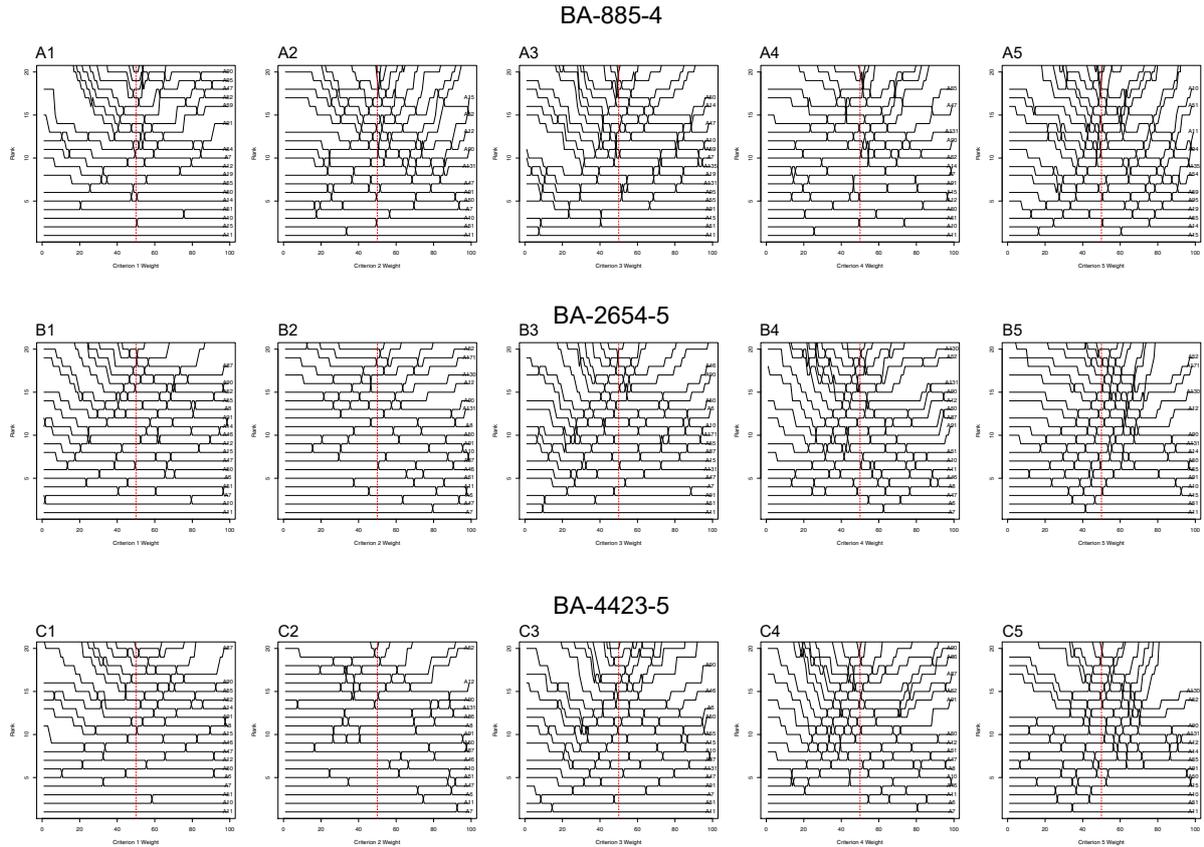

Fig. 5. Ranking sensitivity analysis for the top 20 alternatives from the TOPSIS evaluation of the synthetic networks. A1-A5 – 10% network, B1-B5 – 30% network, C1-C5 – 50% network.

in case of figures C1-C5 and B1-B5 only minute or none changes in the rank of the leading alternative can be observed when the weight of Par1-Eff5 criteria are modified. On the other hand, in case of the 10% network, if Par1 criterion weight was decreased significantly, the leading A23 strategy would drop to position 20 (see Fig. 7A1). Moreover, Fig. 7A2 and A5 demonstrate multiple leader changes in case of even slightest fluctuations of the Par2 and Eff5 criteria. When compared to the stability of the rankings obtained for the actual real network (see Fig. 3), this might suggest that a network obtained as a 10% sample of a real network is too small to maintain the stability of evaluation.

#### E. Comparison of rankings' evaluation accuracy

The research was concluded by a pairwise comparison of rankings based on equal weights for all analyzed networks. In the comparison, the scores and ranks of all strategies for each network were combined into a single table, ordered by the strategy name. This allowed to obtain correlation matrices for all the networks, presenting how correlated are the ranks (Table IV-E) and scores (Table IV-E) for each pair of networks.

The analysis of the correlation matrices allows to observe that the rankings for BA networks are highly correlated to the ranking for the real network with 0.9390 – 0.9799 correlation

coefficient for scores and 0.9631–0.9800 coefficient for ranks, which means that the relation between them is almost linear. In turn, for the sampled networks, only the ranking for the 50% network achieved high correlation coefficient with the real network, equal to 0.8797 for scores and 0.9222 for ranks. This shows, that the results of the evaluation for the real network and the 50% sampled network are very similar, yet the computational power required to perform the evaluation is significantly smaller. On the other hand, the correlation coefficient values for scores and ranks for the 30% network are much lower, i.e. 0.6043 and 0.6837 respectively, and for the 10% even lower, i.e. 0.4171 and 0.4629 respectively. Such positive yet low values of correlation coefficients indicate there is a positive relation between the rankings obtained for the real network and its 10% and 30% snowball samples. However, the margin of error there might be too high to base the actual campaign on the strategies obtained for such small network samples.

#### V. CONCLUSIONS

Nowadays, when over 45% of the world population are active social media users [51], information spreading in complex social networks begins to bring better results than traditional online advertising campaigns. Online marketers have begun

to invest greater effort into seeding information into social networks and providing incentives to increase the information propagation probability within the networks. These increased efforts have opened the research area for providing evaluation of various social network advertising campaign strategies as well as supporting the process of their planning.

The approach presented in this paper provides a framework for multi-criteria planning of viral marketing campaigns in social networks and their evaluation, in which various preferences and criteria of the marketer are taken into account. The example criteria provided in this paper allow to choose the satisfactory campaign strategy considering the costs related to the seeding of the information and providing incentives to

increase its propagation probability in relation to their effect on the process dynamics and obtained coverage.

The authors' contributions in this paper include:

- multi-criteria framework for evaluation of viral marketing campaigns in social networks;
- simulation engine and usage of synthetic network models and real network samples of limited size allowed to provide a viral marketing campaigns planning tool of reduced computational requirements;
- an example set of criteria was provided that allows to choose a satisfactory viral marketing campaign strategy based on multi-criteria consideration of its costs, dynamics and coverage;

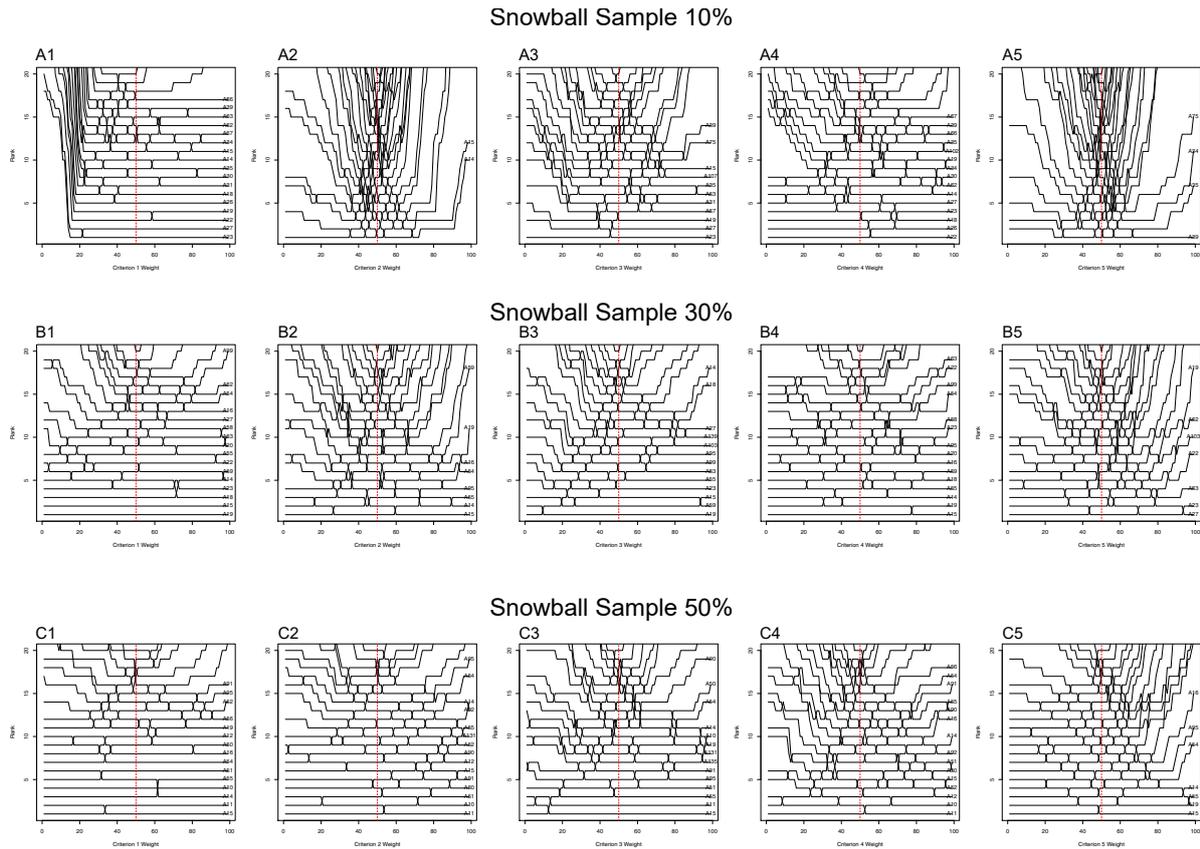

Fig. 7. Ranking sensitivity analysis for the top 20 alternatives from the TOPSIS evaluation of the real network [49] samples. A1-A5 – 10% network, B1-B5 – 30% network, C1-C5 – 50% network.

- the strategies' evaluation accuracy was compared between a full-size real network and a set of reduced-size synthetic and sample networks derived from the original network.

In practical terms, the empirical study has shown that while the synthetic networks, which were selected based on their Kullback-Leibler divergence, provided very similar results to the real network even when as little as 10% of nodes were used, in case of the sampled networks obtained with the snowball sampling approach provided satisfactory results only when the number of nodes was still relatively high. Also, while the rankings obtained from synthetic networks were stable, there was little stability of the rankings from the snowball sample networks.

All in all, the research has identified possible areas of improvement and future works. First of all, a more numerous set of sizes of sample network could be studied to verify how the network size affects its rankings' correlation to the real network's rankings. Secondly, only snowball sampling approach was used in the research. It would be beneficial to explore networks obtained with other sampling approaches. Last, but not least, the list of criteria could be expanded to allow more precise adjustment of the selected strategy to the marketer's needs.

□ *Abstract*—In the paper, a new multi-level hybrid method of community detection combining a density-based clustering with a label propagation method is proposed. Many algorithms have been applied to preprocess, visualize, cluster, and interpret the data describing customer behavior, among others DBSCAN, RFM, k-NN, UMAP, LPA. In the paper, two key algorithms have been detailed: DBSCAN and LPA. DBSCAN is a density-based clustering algorithm. However, managers usually find the clustering results too difficult to interpret and apply. To enhance the business value of clustering and create customer communities, the label propagation algorithm (LPA) has been proposed due to its quality and low computational complexity. The approach is validated on real life marketing database using advanced analytics platform Upsaily.

### I. INTRODUCTION

DETECTING communities is one of the usual and important problems in modern data analysis of decision support systems. Many approaches and algorithms of community discovery have been published in network literature [1]-[7]. A community can be considered as a densely connected group of nodes that is only loosely connected to the rest of the network [8]. An example of such a community in a large network is a set of customers in marketing information systems having similar profile or behavior [9].

In recent years, the efficient data mining of large volume and high dimensional data has become of utmost importance. Therefore, applying the most appropriate method of obtaining accurate and business-oriented partitions is crucial. In literature one can find many clustering algorithms, starting with classical k-means, through density-based, partitioning, self-organizing maps, graph-based, grid-based, to combinational and hybrid solutions. These algorithms are usually evaluated based on clustering measurements, showing that some clustering techniques are better for large datasets while others give good results finding clusters with arbitrary shapes. Nonetheless, there is no one algorithm that can achieve the

best performance on all measurements for any given dataset [4][10][11][13] and also obtain the best results.

Therefore, in marketing analysis, discovering accurate and business focused partitions using a single algorithm in isolation becomes highly complex. There are many reasons for these difficulties: sensitivity to initial values, unknown quantity of expected clusters, non-spherical datasets, sensitivity to noise and outliers, varying densities of clusters, or difficulties of business interpretation.

To strengthen the business outcomes and reduce weaknesses of the single algorithm approaches, a new hybrid multi-level method of community discovery will be proposed. It combines density-based clustering with business-oriented label propagation method. Five basic algorithms have been integrated into this method: DBSCAN, RFM, k-NN, UMAP and LPA. The DBSCAN, which has already been used in many applications [10]-[13], is taken as the density-based algorithms. DBSCAN identifies clusters by measuring density as the number of observations in a designated area. If the density is greater than the density of observations belonging to other clusters, then the defined area is identified as a cluster. Usually, in business application, DBSCAN creates a lot of difficult to interpret clusters. To improve cluster quality and interpretation, a second algorithm is proposed that enriches the results of DBSCAN and is able to form communities. After analysis of various community detection methods, the label propagation algorithm (LPA) was selected due to its simplicity and low computational complexity. The LPA was proposed by Raghavan et al. [14] for detecting communities in large networks. The idea of label propagation is as follows: before beginning computation, some nodes of the network possess assigned labels. During process execution, the labels are propagated iteratively throughout the network according to the formula below.

$$g_j = \arg \max_g \sum_j A_{ij} \delta(g_j g) \quad (1)$$

where  $A_{ij}$  is an element of the adjacency matrix of the network,  $\delta$  is equal to 1 when its arguments are the same, and 0 otherwise. There are many extensions of original label propagation algorithm [15], [8], [16]. In our approach, a weighted network is assumed, so formula (1) is rewritten as:

□ The project was partially financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19.

$$g_j = \arg \max_g \sum_j W_{ij} \delta(g_j, g) \quad (2)$$

where  $W_{ij}$  is the sum of weights on the edges between nodes  $i$  and  $j$  of the adjacency matrix of the network,  $\delta$  is equal to 1 when its arguments are the same, and 0 otherwise.

In other words, the nodes sequentially adopt the labels shared by most of their neighbors taking into consideration the weights of the edges. The propagation ends when the labels no longer change.

It is important to note that in our case study nodes are represented by clusters of customers created by DBSCAN. Neighborhoods of clusters are defined individually by the distance between the centers of clusters. The upper limit of neighboring is usually predefined by the manager or analysts, so the number of neighboring clusters is variable.

The business goal of the study is to obtain a higher quality of definition of customer communities from the marketing viewpoint. Therefore, in the approach the Recency Frequency Monetary value method has been integrated with graph clustering to give clusters of higher quality compared to the traditional mono-algorithm clustering. Various data sources, different quality measures, and business orientation provide more up-to-date and richer information for decision makers and marketing analysts.

The paper is structured as follows: in the next section, the basic characteristics of customers profiles and behavior are provided. The information is saved in the database and available using Upsaily platform. The third section describes a method of clustering of customers of the internet store and the measures to evaluate quality of the results. The fourth section details the label propagation algorithm and a method of discovery of customer communities. The results of the case study on real life database are presented and discussed in the last section. A general conclusion summarizes the outcomes of the proposed approach.

## II. ANALYSIS OF CUSTOMER BEHAVIOR AND PROPERTIES

The first studies of the subject of customer behavior were conducted more than 60 years ago [17], [18]. They focused on customer identification in offline stores, analysis of customer characteristics, and studies on buying-behavior patterns. It is quite common to find customer-behavior research based on questionnaires filled by researcher and a customer who would have accepted to take part in such a study [19]-[21]. Such research is time- and resource-consuming; however, but what is more important is the fact that customers behave differently when they are aware of participation in research.

Currently, analysis of customer behavior in e-commerce is much more convenient and more options can be applied. It is possible as today's e-commerce databases collect data about every single action the customer undertakes (visit, transaction, search, and many more) [17], [19]. Such systems concentrate on a delivery of the best fitting proposal for a customer in a perspective of the selected customer

segment, desired product, and conditions under which the product is offered. Those issues were examined by the authors in [12] using customer clustering based on the RFM method, considering customer recency, frequency of purchases, and monetary value of orders. RFM method has been shown to be very useful in determining the proper point in time to provide customer with an offer.

This paper concentrates on another set of characteristics describing customer behavior. The proposed segmentation was inspired by direct interviews with e-commerce managers who independently observed two principals in terms of profit generation, but also contrary segments of customers. One of the segments brings together fashion-driven customers (they focus on new and fashionable items). Second one is "bargain hunters" – discount-driven customers who are ready to purchase products present on a market for a longer period of time. This segmentation is called "fashion vs. discount".

Being aware of such an observation, the authors extracted data from transactional database of the structure presented in Fig. 1. Due to a large number of tables and attributes in the source database, only tables and fields used in the experiment are presented. The data used in the experiment come from a fashion store (clothes and related items).

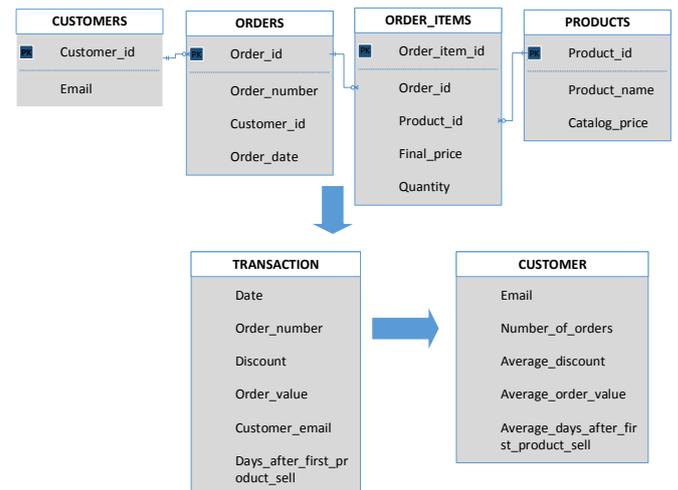

Fig. 1. Structure of source database and result tables

Having such a source database, the following measures characterizing transactions are computed (TRANSACTION table in Fig. 1):

- Value – as a quantity of items multiplied by price.
- Discount – as a percentage the difference between the highest transactional price of a specific item and its price in the current transaction.
- Days after first item sell – as the number of days from the first transaction of a given item and the current transaction.

In order to build customer profile (CUSTOMER table in Fig. 1): the above measures have been aggregated to define:

- Loyalty – expressed in the number of orders. Such an attribute differentiates the one-off buyer customer from the loyal customers.

- Average discount – high percentage discounts are typical for bargain hunters.
- Average number of days after first product sell – determines whether the customer is interested in new (fashionable) items or accepts purchasing items launched in previous seasons.
- Average order value – determines the amount of money the customer is able to spend for a single purchase.

Sample data being the input to the experiment is presented in Fig. 2. Whole data set included 264127 rows (customers).

Fig. 2 Sample input data

The Upsaily platform, directed to retail companies working in both B2C and B2B models, is geared towards current customers of the online internet shops. The experiment presented in this paper is based on database originating from B2C store. In the database, not only all customer transactions are stored (which is presented in Fig. 1), but also the basic data about their demographic and behavioral profile. Functionally, the solution can be classified as a Customer Intelligence system, i.e. one whose primary interest is current customers. The aim is not to help in acquiring new customers, but to increase customer satisfaction that translates into increasing turnover. It can be achieved by customers making follow-up purchases, increasing the value of individual orders (cross-selling) or more valuable products (up-selling). The Customer Intelligence approach is related to conducting analytical activities leading to creation of a clear image of the customer so that one can find the most valuable customers and send them a personalized marketing message. The system is equipped with several analyses including customer segmentation. The main screen of the platform where a manager can search for desired analysis is presented in Fig. 3.

The multi-level approach to discover customer communities will be described in the following steps:

1. Customers clustering using HDBSCAN algorithm.
2. Dimensions reduction using Uniform Manifold Approximation and Projection (UMAP) method in order to base next steps on two dimensions.
3. Centroid calculation for each cluster according to UMAP result.
4. Graph generation with k-NN algorithm.
5. Communities detection according to LPA algorithm.
6. Marketing interpretation.

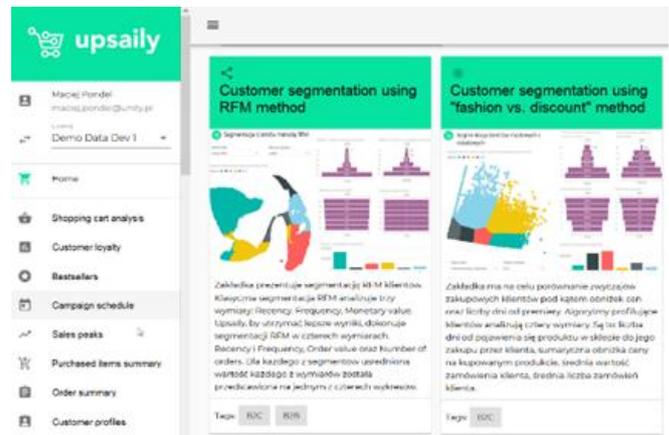

Fig. 3 Main screen of Upsaily platform

Details on the particular steps will be given in the next sections.

### III. CLUSTERING OF CUSTOMERS OF THE INTERNET STORE

Upsaily platform is equipped with two main business customer segmentations based on RFM and the “fashion vs. discount” method explained earlier. Upsaily uses four algorithms, namely:

- k-means based on the Euclidean distance between observations.
- Bisecting k-means acting on a basis similar to k-means, however, starting with all the observations in one cluster and then dividing the cluster into two sub-clusters, using the k-means algorithm.
- Gaussian Mixture Model (GMM), which is a probabilistic model based on the assumption that a particular feature has a finite number of normal distributions.
- HDBSCAN which is an extension of DBSCAN algorithm presented in [22]. The original DBSCAN identifies clusters by measuring density as the number of observations in a designated area. If the density is greater than the density of observations belonging to other clusters, then the defined area is identified as a cluster.

Experiments with each algorithm indicating their strengths and weaknesses as well as collaborative approaches have already been presented in [12].

In the current experiment, we would like to identify small but very precise segments of the most profitable customers. A profitable customer is one whose order values are high and at the same time they don't seek discounts. Authors have done corresponding clustering using k-means clustering algorithm in order to evaluate proposed method by comparison with the typical approach. Source data included 264127 rows describing customers (presented in Fig. 2). 140 segments were generated. Fig. 4 presents visualization of 7 selected clusters of the most profitable customers. Customers assigned to clusters (indicated by color) are presented in left hand side. Distribution of order values is presented in right hand side.

Methods of clustering assessment were presented in [12], [23]. For the interesting clusters, the measure of scatter within the cluster using the Davies-Bouldin index is computed. In general, the lower the value of the measure, the more consistent a cluster is. In this experiment measure of scatter was between 38.68 (best value) and 168.01 (worst value). Average value in seven selected clusters is 80.47.

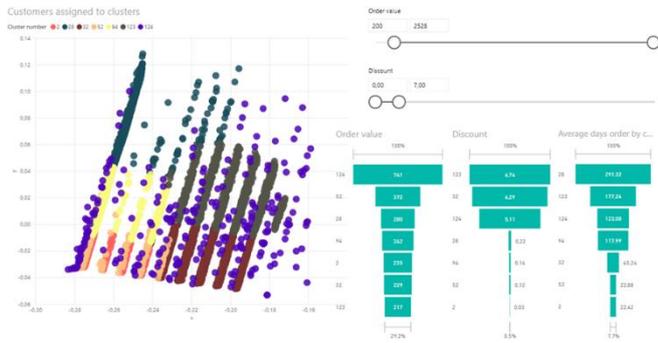

Fig. 4 Most profitable customers in k-means segmentation

In order to perform current experiment, HDBSCAN method was selected because of its marketing usage in effective discovery of clear patterns in given set of observations. It is worth mentioning that other algorithms are focused on assigning observations to a specific number of clusters defined by user upfront. HDBSCAN generates the number of clusters based on the number of patterns found in the data. It can also leave some observations without assigning them to any cluster if no pattern is found.

To understand the idea of HDBSCAN, the basic DBSCAN has to be explained.

The algorithm can be abstracted also into the following steps [24]:

1. Find the points in the  $\epsilon$ -neighbourhood of every point and identify the core points with more than  $\text{minPts}$  neighbours.
2. Find the connected components (subgraph) of core points on the neighbor graph, ignoring all non-core points.
3. Assign each non-core point to a nearby cluster if the cluster is an  $\epsilon$ -neighbor, otherwise assign it to noise (outliers).

The DBSCAN algorithm can be parameterized by  $\epsilon$  (eps) defining the minimum distance between two points and  $\text{minPts}$  denoting the minimum number of points to form a dense region.

DBSCAN algorithm in pseudo code is given [25]

```
DBSCAN(SetOfPoints, Eps, MinPts)
//SetOfPoints is UNCLASSIFIED
ClusterId := nextId(NOISE);
FOR i FROM 1 TO SetOfPoints.size DO
  Point := SetOfPoints.get(i);
  IF Point.CiId = UNCLASSIFIED THEN
    IF
      ExpandCluster(SetOfPoints, Point, ClusterId, Eps, MinPts) THEN
        ClusterId := nextId(ClusterId);
```

```
END IF;
END IF;
END FOR;
END; // DBSCAN
```

ExpandCluster function checks all points in neighbourhood of a given point. If number of those points is higher than  $\text{minPts}$  parameter, they are assigned to cluster otherwise to noise.

HDBSCAN converts DBSCAN into a hierarchical clustering algorithm, and then uses a technique to extract a flat clustering based on the stability of clusters. The following steps present the idea of HDBSCAN [22]:

1. Transform the space according to the density/ sparsity.
2. Build the minimum spanning tree of the distance weighted graph.
3. Construct a cluster hierarchy of connected components.
4. Condense the cluster hierarchy based on minimum cluster size.
5. Extract the stable clusters from the condensed tree.

The result of step 1, customers assigned to clusters using HDBSCAN algorithm, is presented in Fig. 5.

11	16,59	-11,57	86
12	25,85	4,09	124

Fig. 6 Cluster summary with cluster centroid calculated

Source data included 264127 rows describing customers, out of which 174297 were assigned to clusters by HDBSCAN algorithm. The remaining customers (89830) were assigned to cluster -1, which means that insufficient density was found in the area they were located (no pattern was detected). 2046 small but very consistent clusters were discovered. Such quantity of clusters is too high to effectively address managers' needs, hence the reason why the aim of the next step will be to aggregate small clusters into customer communities.

#### IV. DISCOVERY OF CUSTOMER COMMUNITIES - LABEL PROPAGATION

In [27], communities are defined as "*groups of vertices within which connections are dense, but between which connections are sparser*". According to [28], such communities can be considered as fairly independent spaces of a graph, sharing common properties and/or playing similar roles within it.

In our study, communities are groups of customer clusters whose elements share common properties and allow managers to apply the same measures to them or to identify strong similarities between groups in the same community.

Label Propagation Algorithm has been proposed by Raghavan et al. [14] for detecting communities in networks represented by graphs. The algorithm, due to its linear time complexity of  $O(m)$  for each iteration, simplicity, and ease of implementation, is commonly used to identify communities in large-scale real-world networks, such as social media.

An advantage of the algorithm is that it does not require prior information about number of communities or their cardinalities to run; neither does it require any parameterization. The number of iterations to convergence is barely dependent on the graph size, but it grows very slowly.

In [29] the LPA has been compared with other clustering algorithms: Louvain algorithm [30], Smart Local Moving (SLM) [31] and Infomap algorithm [32]. Results of that experiment favors LPA to be used with large scale data as it outperforms other algorithms for well-defined clusters.

These characteristics of the LPA method was the main reason for choosing it for detecting communities of customers and proposing a new method combining multiple methods: HDBSCAN creating numerous clusters, UMAP reducing dimensions, k-NN forming graph, and LPA finding communities.

The main idea behind LPA is to propagate labels throughout the graph from a node to its neighbor nodes. As a result, the groups of nodes sharing the same label and whose nodes have more neighbors than nodes in other groups make communities.

The algorithm consists of five steps [33]:

1. Initialize the labels at all nodes in the network. For a given node  $x$ ,  $c_x(0) = x$
2. Set  $t=1$

3. Arrange the nodes in the network in a random order and set it to  $x$
4. For each  $x \in X$  chosen in that specific order, let
 
$$c_x(t) = f(c_{x_1}(t), \dots, c_{x_m}(t), c_{x_{i(m+1)}}(t-1), \dots, c_{x_k}(t-1))$$
 where  $f$  returns the label occurring with the highest frequency among neighbors. Select a label at random if there are multiple highest frequency labels.
5. If every node has a label that the maximum number of their neighbors has, then stop the algorithm. Else, set  $t=t+1$  and go to (3).

Label propagation works as follows: at the beginning all clusters make own communities, by assigning unique labels to every cluster, then the following steps are being executed in a loop. In every iteration all clusters are processed in a random order and the labels are updated to one that occurs with the highest frequency among the direct neighbours. If the label cannot be chosen as there are multiple labels occurring with the same frequency, then one of them should be chosen randomly. If all clusters are processed in this iteration, stop condition is checked: all clusters should be labelled with the one that majority of adjacent clusters have and if the condition is met, the algorithm ends. Otherwise, the iteration is repeated until convergence defined as the stop condition is reached. In this way, labels will propagate across the graph, replacing other labels and eventually some labels will disappear, and others will dominate.

It is important to note that Label Propagation Algorithm operates on graphs, hence the input data must be converted into a graph. In our experiment, it was necessary to performed on "fashion vs. discount" case study a dimension reduction with UMAP, grouping customers with similar properties into clusters and determining centroids of each cluster accordingly.

In order to create a graph, the "k-Nearest Neighbors algorithm" (known as k-NN) was used that is one of the simplest, but perfectly fitting into the experiment context, and as a non-parametric method it is commonly used for classification and regression. For classification, the centroids with Euclidean distance between them are used and transformed into the normalized distances for all nodes while filtering out all that above a given threshold. More details about the results of LPA and k-NN on real marketing data will be given in section 5.

A graph was created, where the nodes represent clusters generated by HDBSCAN and edges are weighted links connecting clusters, determined by applying k-NN algorithm from the previous step and representing normalized distances between clusters. Centroids defined while executing UMAP method were crucial in the creation of a proper graph for LPA method.

Finally, using the data from the previous steps, a large graph was created, consisting of 2046 clusters (vertices) and

15364 links as represented in Fig. 7. The graph is shown only for demonstrational purposes, where lengths of links do not illustrate the real distances between clusters (weights), nonetheless cluster proximities have been preserved. Multiple dense cluster groups can be noticed. These are candidates to form communities and in compliance with the definition of a community, they have many connections within the group and few to clusters outside the group. More detailed information about the graph structure will be given in the next section.

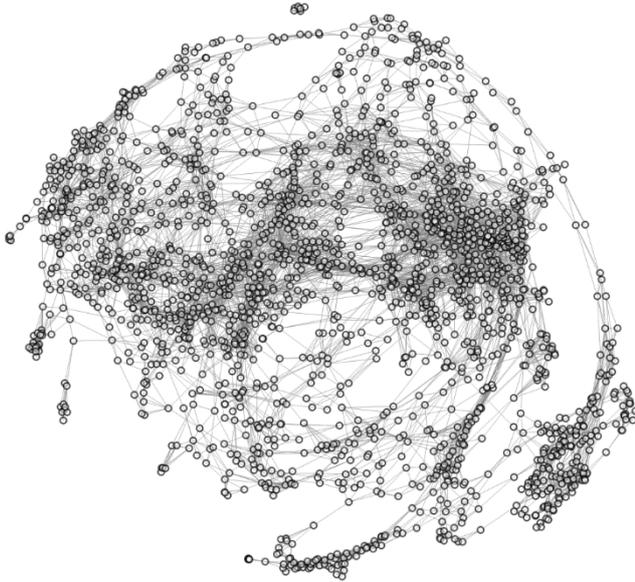

Fig. 7 Visualization of the graph representing communities and connections between them

Densely connected groups reach a common label quickly. When many such dense groups are created throughout the network, they continue to expand outwards until it becomes impossible to do so. Randomization of the order the clusters are processed has consequences: it may not deliver a unique solution, or the final solution may not be found at all (due to fluctuations in label assignment, adjacent clusters can interchange their labels in every iteration, preventing the convergence criteria from being achieved).

In our tests all partitions found were similar to each other, though.

Finally, the graph looks as in Fig. 8. The densest groups of clusters have been marked in color on the graph. They form communities characterized by common attributes.

## V. INTERPRETATION OF THE EXPERIMENTAL RESULTS

In retail businesses, managers would want to know about the customers in order to efficiently tailor offers for selected groups, and to increase efficiency and customer satisfaction, which in turn increases business profitability. On the other hand, there might be a group of customers that may abuse the system, searching for system weaknesses and resulting in a loss or very small benefit for the retailer. The promise of this experiment was to find clusters of most profitable

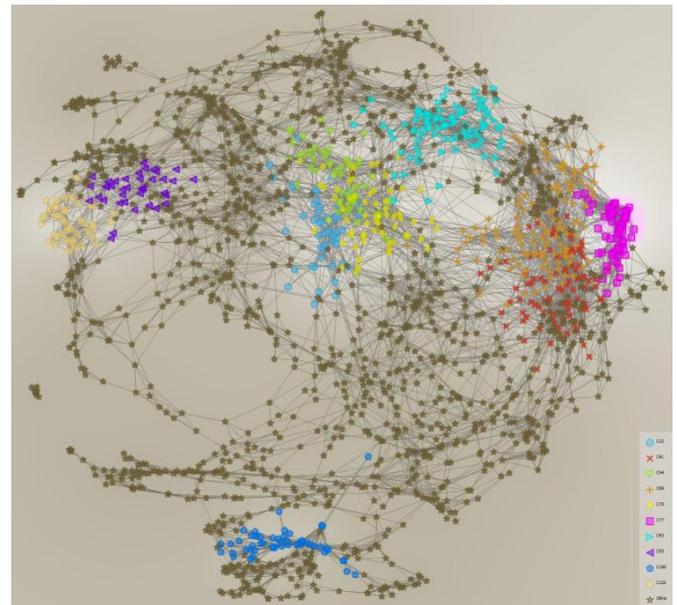

Fig. 8 Graph of clusters with highlighted communities

customers what has been already stated in previous part, and to provide marketing manager or analyst with appropriate knowledge about customer behavior respecting the value of products, discount, and “age” of the product.

In the experiment above Label Propagation Algorithm has been applied on clusters of customers having similar purchase characteristics and identified groups (communities) of similar clusters.

Let us analyze two groups: C77 and C122 among all groups identified by LPA in the experiment, as visualized below (Fig. 9 and Fig. 10).

First group C77, marked in pink color, consists of customers buying goods present in the shop for several months, but always with a price discount. The second group C122, marked in orange, seems to be very similar to C77, but it represents customers buying goods with the highest price discounts. For these two groups the measures applied by managers should be different. For the first group it could be running a marketing campaign in order to increase the average price of the order, while the second group can be used to address seasonal sale campaigns at the late stage

If a manager is interested in clusters of customers with the highest order values (as potentially most beneficial customers), they can filter clusters using the order-value property. Selected clusters of customers who buy goods valued at more than 350 PLN are presented in Fig. 11. There are 133 groups (communities) created by LPA out of 2052 clusters generated by HDBSCAN. On the left-hand side of visualization one dot represents one HDBSCAN cluster and the color of the dot represents LPA cluster (after community detection by LPA).

If a manager is interested in some specific clusters, they can observe the distribution of each feature in clusters. If one takes into consideration clusters C2 and C7 presented in Fig. 11, one can observe that these are customers not looking

Fig. 9 Clusters of C122 group forming a community

Fig. 10 Clusters of C77 group forming a community

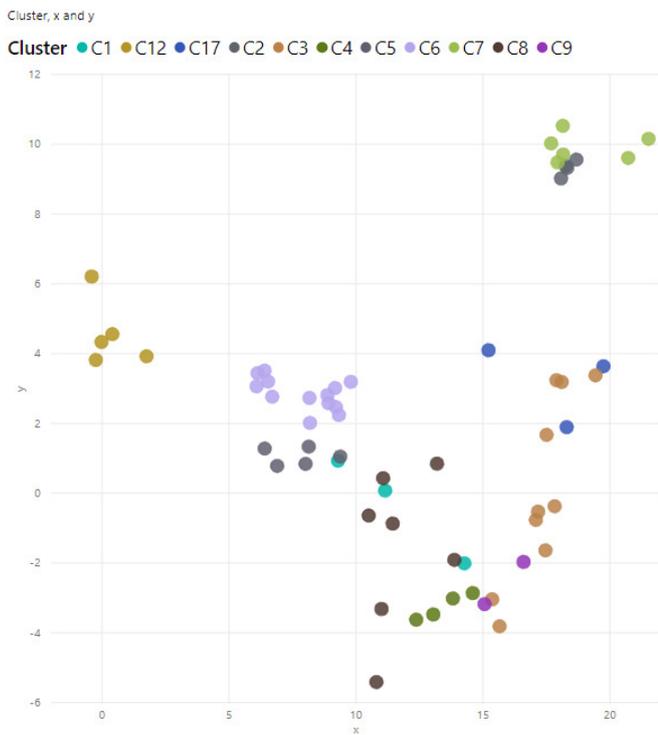

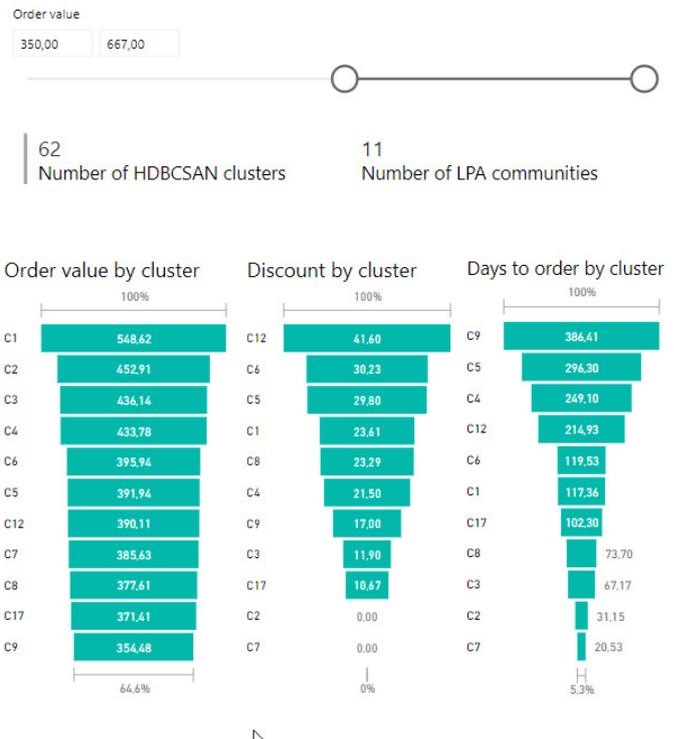

Fig. 11 Graphical representation of analyzed clusters meeting manager's criteria

for discounts (they buy with 0% discount), they buy new products (launched accordingly 31 and 20 days before purchase). The difference between those clusters is in the average order value (respectively 452 and 385 PLN). Having such knowledge, the recommendation system makes it possible to tailor the offer in order to meet customer's expectations.

For seven selected clusters meeting the assumed criteria (Fig. 12), the scatter within the cluster was calculated using Davies-Bouldin index in order to compare results with k-means result. In this experiment, the measure of scatter was between 14.44 and 46.27. Average value for selected 7 clusters is 34.13 which in comparison with the value of k-means 80.47 constitutes a significant improvement.

## VI. CONCLUSIONS AND FUTURE RESEARCH

The primary objective of the presented research was to develop a method to discover meaningful customer communities, using data mining techniques and tools. The outcome of this work is a new multi-level hybrid method for community discovery, implemented and validated on the experimental platform Upsaily. The research methodology is composed of six, closely integrated steps. Firstly, relevant information about customers is extracted from large marketing databases and partitioned by the clustering algorithm (HDBSCAN). Secondly, the space dimensions are reduced into two dimensions using the Uniform Manifold Approximation and Projection (UMAP) method. Thirdly, the centroids are computed for each cluster. The graph is generated in step four using the k-NN algorithm. To discover customer communities the Label Propagation Algorithm (LPA) is applied. The final step, most important for decision makers, concerns marketing interpretation of discovered customer communities. These experiments demonstrated that the “customer communities discovery” compared against “segmentation with k-means algorithm”, gave much more precise identification of group of customers and allows better understanding of clusters by managers and data analysts.

The multi-level clustering approach described in this paper has shown its advantage over single method clustering. Numerous small clusters were turned into communities sharing common properties. Specifically, running HDBSCAN alone against the data describing customer’s purchases resulted in a high number (2046) of dense, but small clusters, making it infeasible to predict customer’s needs or address tailored offerings. It is important to mention that using the simplest PCA method for dimensions reduction did not meet expectation. The clusters did not form homogenous communities, which in turn could not provide managers with reliable tools to support decision making processes. When the PCA method was replaced by the UMAP method, the clustering results met expectations and made it possible to calculate meaningful centroids for each cluster. Afterwards, the label propagation method was applied, making it possible to

determine customer communities, grouping them based on business needs.

The Upsaily platform used in the experiment, allows for parameterization of the multi-level approach to clustering, described in the paper, by defining the features used for clustering, business-oriented cluster identification, defining data range or specifying the size of expected clusters. The advantage of this customized approach is that it can be widely applied to any type/category of customers and it allows for performing advanced analytics on the business data.

The results obtained so far on real marketing data are very encouraging, in addition they have been positively validated by managers of internet shops. However, many algorithmic and business-oriented issues remain to be extended and tuned. For instance, a desirable extension of the approach will be to refine a method of feature construction describing a customer profile. An interesting future improvement will be on the implementation of collective and cooperative clustering with built-in business-oriented quality measures. One, but not the last, ambitious work will be focused on the dynamics and evolution of customer communities.

□

**Abstract**—Industrial symbiosis is a favored approach to balancing industry’s economic growth and its environmental impact on a regional scale. Although the scientific literature reports a multitude of examples of industrial symbiosis around the world, this approach and its related concepts are not considered to be widespread in practice, due to various barriers. Information and management barriers are seen as significant obstacles to industrial symbiosis; however, they have not been adequately investigated yet. Empirical research capturing the perception of industrial actors is lacking. This applies especially to information and communication technology designed to reduce informational barriers. Therefore, in this research-in-progress paper, we will first examine these aspects by discussing related publications. In the second step, we develop a study design involving an online questionnaire to examine the extent of managerial and informational barriers that prevent industrial symbiosis as well as the perception of corresponding technological support.

## I. INTRODUCTION

The term "sustainability" has become omnipresent and a central issue in discussions on industrial development. In this regard, one approach to sustainable industrial development that is attracting more and more research attention is industrial symbiosis. Industrial symbiosis aims to balance industrial activities and their impact on the environment. It involves regional, cross-sectoral, and cross-company cooperation to increase resource efficiency and to ecologically and economically benefit the parties involved [1], [2]. As a result, this approach can create so-called ‘industrial ecosystems’ or ‘eco-industrial parks’ from conventional industrial systems or parks, in which local industries adopt symbiotic behavior and commit to sustainable development policies [3], [4].

Nevertheless, reports show that industrial symbiosis is not widely implemented in practice, due to technical/physical, financial, economic, regulatory, social, informational, and managerial barriers [5], [6]. According to [7], less than 0.1% of 26 million active enterprises in Europe are engaged in industrial symbiosis. In particular, managerial (e.g., limited commitment) and informational (e.g., lack of information/knowledge sharing) barriers are regarded as

significant obstacles to industrial symbiosis [5]–[10], since they must be overcome for symbiotic opportunities to be identified. If these barriers are not addressed, subsequent processes—such as feasibility studies of identified opportunities—cannot be carried out and other related barriers (such as technical or financial issues) cannot be identified.

Different examples of industrial symbiosis around the world have been described in the scientific literature [11], [12]. These examples contribute to sustainable development in economic (e.g., reduced waste disposal and input costs), environmental (e.g., reduction waste production and resource use), and social (e.g., community awareness) terms. However, at this point, industrial symbiosis research needs more empirical and quantitative studies, which are currently lacking (as stated by [13]). In recent years, some surveys on industrial symbiosis activities and barriers have been conducted, both to examine the interest in and maturity of industrial symbiosis in a specific region and to capture the perception of barriers to adopting symbiotic behavior (see Table I). The surveys usually address companies (general or environmental managers) or policymakers but rarely the managers of industrial parks, despite the wide recognition of their potential role as facilitators [14], [15].

TABLE I.  
INDUSTRIAL SYMBIOSIS SURVEYS ON INDUSTRIAL SYMBIOSIS

□ This work was not supported by any organization.

<sup>1</sup> No. in brackets = No. of barrier categories

<sup>2</sup> No. in brackets = No. of follow-up interviews

Financial/economic and regulatory barriers are considered the largest barriers by many study participants. In terms of informational and managerial barriers, views are mixed, with large variation in perceived relevance. These differences can be caused by region and context, but also by the different barrier categorizations proposed in the different studies. Informational, managerial, and social aspects are not clearly separated with regard to how barrier categories are assigned. Informational barriers in particular are often linked with social factors such as trust, cooperation, and community. Although a cause-effect relationship may exist (according to [14] and [15], managerial barriers are a causal factor and informational barriers are an effect factor), the present inconsistency in barrier categorization and the lack of a uniform allocation of the underlying aspects make it difficult to compare the studies, reducing their clarity and validity.

Only [19] and [21] considered informational barriers separate from social aspects, albeit exclusively with reference to information systems. The survey of [21] reveals that some companies consider inadequate information management systems to be a barrier. The survey of [19] shows that 49 out of 50 respondents would use an online platform to search for potential partners if one was available. However, in both studies, no further information is given regarding the information system/online platform (information types, functionality, access structure, users, etc.). Therefore, the extent of informational barriers and their cause remain unknown.

A similar lack of empirical foundation can be seen in the efforts to support industrial symbiosis with information and communication technology (ICT), as a way to mitigate informational issues. These tools appear to be primarily research-driven, and the extent to which they are known, used, and judged useful by companies remains unclear [8], [23]. Therefore, we decided to set up a long-term research project to address this research gap. In our opinion, research must further explore the readiness of companies and managers in industrial parks to practice industrial symbiosis, as well as the opinions on informational issues and ICT support. An investigation into informational aspects regarding information availability, confidentiality, and relevance, as well as on the perception of ICT support, will especially contribute to understanding and uncovering gaps between research efforts and practice. Therefore, the aim of this research-in-progress paper—the first step of our research project—is to identify and clarify the necessary aspects of informational and managerial barriers and of ICT support for industrial symbiosis, in terms of problem identification. In addition, we will present our initial study design (an online questionnaire) and outline the next steps of our ongoing research.

This paper is structured as follows. Section II presents the theoretical background on industrial symbiosis and its barriers in terms of problem identification. Then, Section III describes our study design. Finally, Section IV concludes the paper with a discussion and future steps.

## II. THEORETICAL BACKGROUND AND PROBLEM IDENTIFICATION

### A. Business Models in Industrial Symbiosis

Originally, the term ‘industrial symbiosis’ covered the physical exchange of material, energy, water, and by-products between geographically close companies in order to achieve economic and environmental advantages [1]. Today, the term encompasses all business models of inter-firm exchange or sharing of under-utilized resources like material, energy, logistics, capacities, space, expertise, and knowledge [2]. The business models (synergies) are therefore either exchange-based or sharing-based and are commonly divided into three categories [24], [25]:

- By-product exchange and reuse
- Utility and infrastructure sharing
- Service sharing

*By-product exchange* refers to one company’s residual outputs (e.g., waste and by-products) being used as another company’s inputs (e.g., water, material, waste heat). Here, the principle of circular economy is followed. *Utility and infrastructure sharing* refers to joint use and/or operation of technical infrastructure and decentralized plants, such as a combined heat and power plant, water treatment plant, district heating grid, etc. *Service sharing* refers to cross-company management or joint provision of common services, (e.g., joint disposal/procurement, logistics and warehousing, staff training, knowledge exchange).

Depending on the business model and the role of the company (e.g., supplier or consumer), various economic and ecological advantages can arise for the parties involved and for the corresponding region: reduced resource consumption and waste generation, eco-innovation, revenues from residues and by-products, less raw material and disposal costs, development of new business and market opportunities, etc. [26].

The development mechanisms of industrial symbiosis can be divided into three categories—*self-organized*, *facilitated*, and *planned/designed*—with the degree of the involvement of coordinating/mediating third parties (e.g., research institutes, governmental agencies, park management) increasing [27]. Intermediaries are regarded as vital to supporting contact initiation, to collecting necessary information and knowledge, and to facilitating their exchange between companies [28]. Park managers are considered to be the best candidates to provide this social and informational infrastructure to the companies in an industrial park [5].

### B. Informational and Managerial Barriers to Industrial Symbiosis

#### 1) Informational Barriers

The availability of information and knowledge, as well as the willingness to share them with others, is essential to identifying and evaluating synergy opportunities for industrial symbiosis. For example, in the case of a potential

by-product exchange, this would include information on the incoming and outgoing resource flows of companies, as well as knowledge of relevant compatibility criteria and technical expertise to implement synergies. However, lack of trust, confidentiality issues, and motivational issues may lead to an unwillingness to share necessary information and knowledge [5], [28], [29]. Lack of internal information, lack of contacts and relationships with whom to share information and knowledge, communication issues, and difficulty to share knowledge limit available information and knowledge sources [6], [8], [30]. Confidentiality issues in particular have not been investigated in the context of industrial symbiosis.

Since we want to determine to what extent informational barriers exist, we want to keep them as separate as possible from social aspects, such as trust and relationships. Therefore, we consider the following issues to be informational barriers to industrial symbiosis:

- Unawareness of principles and benefits of industrial symbiosis
- Lack of available information and knowledge
- Unwillingness to and difficulty of sharing information and knowledge
- Non-transparency and inefficiency of the information and knowledge exchange
- Lack of information-sharing mechanisms and infrastructure

ICT support is considered to be promising in alleviating informational barriers and providing a space for interaction and exchange between companies [9], [10]. Generally, these tools (developed or conceptualized) are online repositories (e.g., ISData) and platforms (e.g., eSymbiosis) that provide various functions for disseminating and sharing information and knowledge as well as for facilitating byproduct exchanges via waste market functions and automatic matching engines.

However, industrial symbiosis ICT tools face various barriers [31], [32]. Currently, these ICT tools are not provided with enough data and information for them to be used effectively. This may be caused by lack of willingness to use the tools, confidentiality issues, manual effort required for data entry, lack of knowledge of the existence of such tools, and access restrictions—thus leading to a low number of potential users. Social networking approaches [33], [34] have increasingly addressed criticisms of early tools for not taking sufficient account of the social context [8]. In addition, many tools limit their functionality to the early stages of industrial symbiosis (synergy identification and assessment) [8], [10]. Moreover, many tools are not easily/publicly accessible, not operational, or still in the concept or development stages [8], [10]. Hardly any statements can be found on the operational tools as to the context in and extent to which they are used, how and by whom, and which specific functions they provide to (potential) users. Therefore, it is difficult to assess how useful current ICT support is to industrial symbiosis.

## 2) Managerial Barriers

In order to gather and share information and knowledge, there must be a willingness to commit to sustainable business models; to participate in workshops; and to provide time, personnel, and (likely) financial resources. Synergy identification and implementation do not only deal with resources, they also require resources. Without commitment to incorporating the concept of industrial symbiosis into a holistic strategy and business processes of participating companies, the discovered potential synergies may remain unused [8]. Since the potential benefits are unknown and difficult to predict at first, and since coordination and the exchange of information and knowledge are time-consuming, this commitment and willingness must continue beyond initial meetings and workshops. Therefore, we consider the following (organizational) aspects as managerial barriers:

- Lack of commitment to sustainable business and to the community/network
- Lack of management support
- Unwillingness to collaborate and communicate

The attitude of the company and park management not only influences the extent of informational barriers but can also determine how—and if—ICT tools are used for industrial symbiosis.

## III. RESEARCH APPROACH

### A. Overall Research Approach

In our research project, we pursue the design of an ICT tool (IT artifact) to mitigate and overcome informational and managerial issues in industrial symbiosis. Therefore, we follow the design science paradigm [33]. The steps for design science in information systems research are shown in Fig. 1.

Currently, we are in the first stages of our long-term research project. We initiated our research by identifying the problem (managerial and informational barriers) and solution space (ICT) in industrial symbiosis through a comprehensive literature review and discussions with industrial partners. As described in Section II, managerial and informational barriers still persist, and ICT solutions encounter a number of problems. Furthermore, design guidelines and best practices for ICT solutions that enable/support industrial symbiosis are lacking [31].

Like other researchers, we believe that ICT tools, particularly digital platforms, can contribute to overcoming managerial and informational barriers, but only if the design is tailored to the needs, circumstances, and restrictions of the intended users. Capturing these aspects requires capturing the general attitude of management towards industrial symbiosis along with the associated exchange of information and knowledge and the corresponding ICT. To this end, we will conduct a survey with the relevant industrial players in industrial symbiosis in industrial parks. This problem-centered approach underlines the relevance of the topic and clarifies the problems addressed in our research project.

Based on the answers and the information obtained in subsequent interviews, we aim to deduce where an ICT tool could and should be applied, and what it could achieve in terms of enabling industrial symbiosis. By conducting empirically-grounded problem identification and aligning it with the existing solution space, we aim to reconfirm our

research gap—thus thoroughly justifying our project—and to ensure that the ICT tool is designed in such a way that it can be embedded in existing strategies and processes to address this important issue [23].

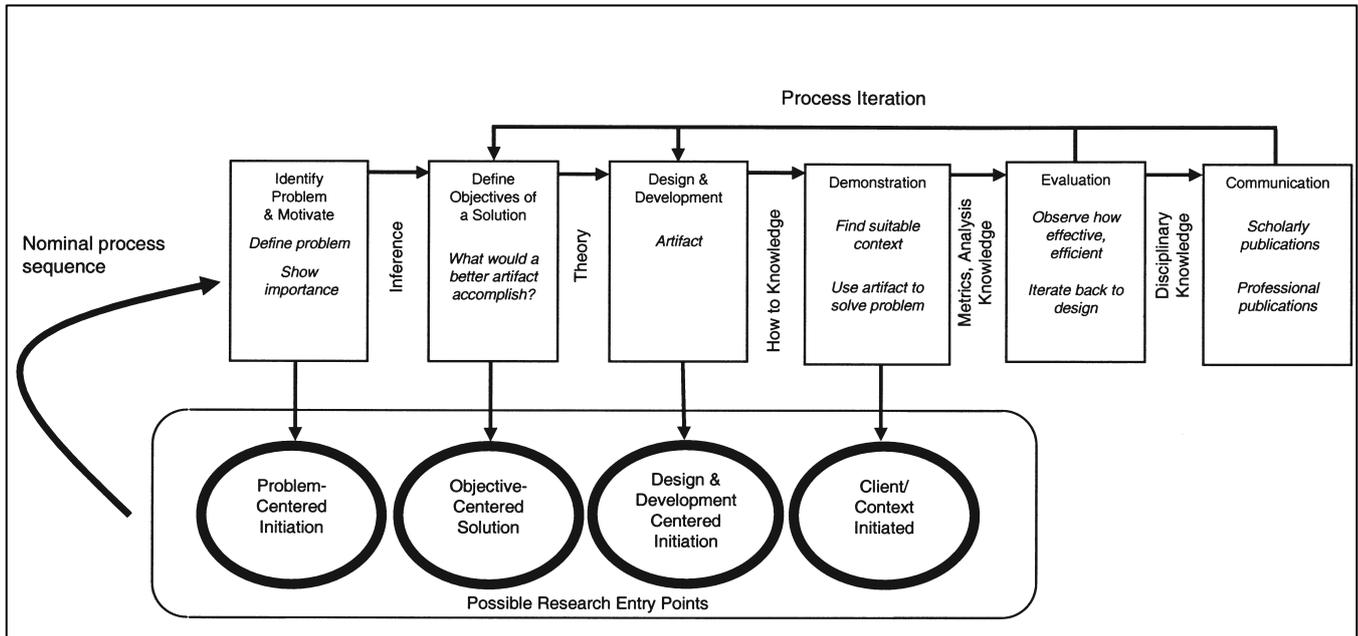

Fig. 1 Design Science Research Methodology [33]

### B. Proposal of Study Design – Online Questionnaire

To address the identified problems/barriers and to investigate them in more detail, thus filling this gap in the literature, we set up a study design based on an online questionnaire. The aim of this approach is to reach a large number of companies and to gather various opinions and perceptions of managerial, informational, and ICT-related aspects in the context of industrial symbiosis. The questionnaire will be provided in German for companies in Germany, Austria, and Switzerland and in English for other European companies. It will primarily be sent to companies in industrial parks and to park managers, as these companies and park management are predestined for industrial symbiosis. We aim to gain insights into the (estimated) willingness and ability of companies to cooperate in industrial symbiosis and into the willingness and ability of park management to act as a facilitator. The questionnaire is composed of four sections:

#### 1) General Data – Participant Characterization

In order to accurately analyze the answers of the participants, the participants themselves must be sufficiently characterized. Therefore, the general data section includes, for example, the following information:

- Size of company/industrial park (number of employees/companies), which indicates the human resources available and the number of potential synergy partners
- Length of stay at site (in years), which may influence the number of established contacts and (business) relationships
- Certification in energy (ISO 50001) and/or environmental management (ISO 14001/EMAS) and acknowledgement of the importance of energy and material consumption and waste, which indicates the relevancy of sustainability issues.

The characteristics of enterprises and the comparisons between them may reveal fundamental differences in readiness as well as in business and information attitudes towards industrial symbiosis, from which different conclusions can be drawn (e.g., requirement profiles).

#### 2) Managerial Aspects – Current Practice, Readiness, and Potentials

The extent of management-related barriers is reflected in the current practices and the readiness to adopt industrial symbiosis practices and business models. Therefore, the first block will question the current practice, including the type of the business model and the role of the company. This block

also examines awareness of the concept of industrial symbiosis regardless of specific terms.

Subsequently, the survey participants will be asked to assess the readiness, interest, and potential opportunities of the company/companies to practice industrial symbiosis. Questions related to readiness indicate a company’s ability to collaborate at the company level, while questions related to potential assess the company’s ability to collaborate at the network level (by questioning the perceptions of other companies in the industrial park). To measure readiness and potential, we use the proposed readiness areas of [34]. These areas involve the business models of industrial symbiosis (e.g., readiness for by-product exchange) and the company’s strategic orientation towards industrial symbiosis (e.g., readiness to pursue common goals or to provide time and personnel for industrial symbiosis activities). The answer options will use a 5-point Likert scale indicating low (1) to high (5) readiness/potential.

The questions regarding potential also help indicate the extent to which companies have information/knowledge of other companies at their location/industrial park. A screenshot of example questions in this section is provided in the Appendix (see Fig. 5).

3) Informational Aspects – Availability and Sharing

The extent of information-related barriers is reflected in concept awareness, internal and public availability of information and knowledge, and willingness to disclose the latter.

First, the company’s policies and practices in terms of internal and external exchange of knowledge are examined. ‘Policy’ refers to management support for facilitating knowledge sharing, while ‘practice’ refers to existing formal and informal communication channels and methods of knowledge sharing. Companies could benefit from improving or qualifying existing channels and practices, instead of developing and imposing new ones. An example question on communication channels is given in Fig. 2, and a screenshot of this question is provided in the Appendix (see Fig. 6).

<b>Which communication channels do you mainly use in your company to exchange experiences and knowledge with colleagues and partners?</b>					
	<b>Within your company</b>				
	Never	Rarely	Sometimes	Often	Always
	1	2	3	4	5
Face-to-face communication	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Virtual face-to-face communication	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
E-mail	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Intranet	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Expert systems	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Fig. 2 Example Survey Question – Knowledge Sharing

Second, the availability of needed information is investigated. To this end, we will ask whether certain information about inputs and outputs is known within the company, whether it is already published/publicly available (e.g., in environmental reports), and whether it is generally subject to confidentiality. The types of information to be addressed are listed in Table II. This information is typically used to identify synergies, but at a high level of detail [35]. In order to examine the willingness to share information, we will include questions on the relevance of the types of information, as well as questions on the disclosure of information and its level of detail. An example question concerning information confidentiality is given in Fig. 3, and a screenshot of this question is provided in the Appendix (see Fig. 7).

TABLE II. NECESSARY INFORMATION FOR INDUSTRIAL SYMBIOSIS

Information type	Examples/Level of detail
Resource type	Material, energy, water, EWC classification
Resource quantity	Average per year/per month/per day/per hour
Supply pattern	Constant/fluctuating, maximum/minimum, lot size
Resource property	Components/ingredients, pollution, temperature
Resource source	Plant type (e.g., processing/production plant), utilization (e.g., material input, drying, air conditioning, process heat), specific plant (e.g., industrial furnace)
Availability period	All year/seasonal, month details (e.g., April-August), date specification (e.g., 01.04.19-04.12.20), shift system (e.g., Mo-Fr 5:30 to 22:30)
Supplier/customer	Type, name
Price/cost	Total per year/per unit, upper/lower price limit

<b>Are the following types of information classified as confidential in your company and therefore subject to disclosure restrictions to other companies (e.g., non-disclosure agreements)?</b>			
	<b>Raw materials</b>		
	Yes	Uncertain	No
Resource type	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Resource quantity	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Supply pattern	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Resource properties	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Availability period	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Supplier/customer	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Price/cost	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Fig. 3 Example Survey Question – Information Sharing

Another important aspect related to information sharing is the type of information exchange:

- Direct: Other interested companies in the industrial park can receive or view information.
- Indirect: An intermediary receives the information, processes and analyzes it, and passes on the results of the analysis (e.g., that a synergy potential is presumed or not) to other companies, without the latter having access to the original information

Companies' preference for one type or the other can provide important insight into a suitable mechanism for information exchange in an industrial park and for the design of appropriate ICT support.

#### 4) ICT Support – Awareness and Design

In this section of the questionnaire, the awareness of ICT tools and the perception their usefulness are addressed on the basis of provided functions.

Based on [9], different types of ICT tools (e.g., online waste market, synergy identification system) will be presented with examples, in order to assess participants' awareness of them. Subsequently, selected functions of these tools (e.g., exchange market, matching engine, social applications) will be presented, in order to examine whether these functions are considered useful and/or would be used. At this point, a question is included inquiring whether a direct or indirect exchange of information is preferred. The questionnaire for both the companies in industrial parks and the park management should include a question of who should provide and operate such a tool (see Fig. 4).

<p><b>Who do you think should operate/provide such systems or platforms?</b></p> <p><input type="checkbox"/> Park management</p> <p><input type="checkbox"/> Focal company</p> <p><input type="checkbox"/> Third Party</p> <p><input type="checkbox"/> Uncertain</p>
----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Fig. 4 Example Survey Question – ICT

Since the questionnaire will be tailored to two different target groups (companies in industrial parks and park management), some questions will vary slightly according to the role of the participants, and some will only be accessible to one target group or another. While the companies in industrial parks will assess their own readiness for industrial symbiosis and their information level, the park managers will assess the readiness and the information levels of the companies located in their park, as well as their willingness to act as facilitator in coordinating industrial symbiosis activities or providing services.

#### IV. DISCUSSION AND FUTURE STEPS

In the existing industrial symbiosis research, managerial and informational issues and associated ICT support are not sufficiently addressed. In particular, empirical research capturing industrial actors' perceptions of these barriers and ICT is lacking. In order to develop an appropriate ICT tool to overcome the barriers (the aim of our long-term research), it is necessary to identify the specific underlying problems, needs, and resistances/aversions of the potential users.

Our first discussions with industrial park members and managers have shown that a general interest and a willingness to cooperate are present, but the human, time, and financial resources necessary to pursue and adequately implement the

concept are rarely made available in the companies. These conversations also revealed that the awareness of the concept of industrial symbiosis is not perceived as an issue; however, the exchange of information was always seen as problematic and in need of improvement. Furthermore, none of the discussion partners knew of existing ICT tools, but they imagined that using them would be beneficial. These findings confirm, contradict, and complement the statements made in previous studies mentioned in Section I and II.

Since implementing industrial symbiosis is highly context-dependent, small samples are not representative of a holistic understanding of the relevance of managerial and informational problems. Therefore, in order to reach as many actors as possible and to get a deeper and more holistic picture of these issues, we designed an online questionnaire targeting the relevant players of industrial symbiosis in industrial parks. By conducting the online questionnaire as the next step in our long-term research project, we aim to expand understanding of the problems/barriers that we have identified in the existing literature on industrial symbiosis, as discussed in Section II.

At this point in our research, the responses to the questionnaire are particularly important in providing guidance on how to design and use applicable ICT support in industrial parks and how to coordinate industrial symbiosis activities (e.g., information flow). After the results of the questionnaire have been obtained, the next steps in our research project will involve discussing the related issues in more detail with companies in industrial parks and with park management, using qualitative approaches such as interviews and focus group discussions. After that, we will use the results from both the questionnaire and the qualitative methods to develop an adequate, appropriate concept for an ICT support tool for industrial symbiosis for industrial parks, along with an instantiation of the tool. For the final step in our long-term research, the developed tool will be evaluated by companies in industrial parks and by park management, again using a questionnaire.

APPENDIX

**\*Please assess the current readiness of your company for industrial symbiosis in terms of business models and strategic orientation, regardless of whether cooperation opportunities actually exist.**  
 Your company (management) is ready to ...

	Strongly disagree 1	Disagree 2	Neutral 3	Agree 4	Strongly agree 5
replace raw materials with recycled materials and/or other waste and by-products from another company.	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
provide by-products or waste to other companies as raw materials.	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
invest in or share utilities or infrastructure with other companies.	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
use or coordinate joint services such as disposal, procurement, logistics or training concepts.	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
provide personnel and time resources for the activities of Industrial Symbiosis.	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
align business strategy and corporate policy towards sustainability and industrial symbiosis.	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
share the same goals with other companies or to develop and pursue common goals.	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
be part of a network that is strategically oriented towards industrial symbiosis and sustainability.	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>

**Abstract**—Due to advances in machine learning techniques and sensor technology, the data driven perspective is nowadays the preferred approach for improving the quality of maintenance for machines and processes in industrial environments. Our study reviews existing maintenance works by highlighting the main challenges and benefits and consequently, it shares recommendations and good practices for the appropriate usage of data analysis tools and techniques. Moreover, we argue that in any industrial setup, the quality of maintenance improves when the applied data driven techniques and technologies: (i) have economical justifications; and (ii) take into consideration the conformity with the industry standards. In order to classify the existing maintenance strategies, we explore the entire data driven model development life cycle: data acquisition and analysis, model development and model evaluation. Based on the surveyed literature we introduce taxonomies that cover relevant predictive models and their corresponding data driven maintenance techniques.

## I. INTRODUCTION

THE quality of maintenance is a relevant aspect in the assessment of any industrial product or process, and therefore a challenging research problem. Our survey shows that maintenance approaches are continuously evolving over time. Earlier, corrective maintenance also known as reactive maintenance was used. Preventive maintenance proves to be a better alternative, as the maintenance actions are employed before the failure occurs. This approach evolved into condition-based maintenance, where decisions are based on the evaluation of the machine status through inspections and measurements. Among all the existent approaches to maintenance, each of them varying in terms of efficiency and complexity, predictive maintenance seems to best fit the needs of a highly competitive industry setup, as argued by [1]. Predictive maintenance allows maintenance actions to be based on changes of the machine and process parameters, which are continuously monitored by sensors. Currently, due to recent advances in sensor technology, data communication, and computing, the ability to collect big volumes of

heterogeneous, raw sensor data produced by equipment under observation is exponentially increasing. Therefore, historical information about normal and abnormal patterns and the related corrective actions employed during the lifetime of an industrial asset is becoming available. In order to deal with such high-dimensional problems, the predictive maintenance strategy uses a variety of techniques and prediction models that study both live and historical information. Further on, this information is used to learn prognostics data and to make accurate diagnostics and predictions, as presented by [2], [3], and [4]. They argue that the implementation of effective prognosis for maintenance has a variety of benefits including increased system safety, improved operational reliability, reduced maintenance, inspection times, repair failures and life cycle costs. Past works on predictive maintenance show that maintenance actions are performed by employing various prediction models and modeling techniques. Among prediction models, the machine learning (ML) approaches are typically considered the most suitable to deal with high dimensional and unstructured data, as argued by [8] and [9]. Moreover, multimodal fusion techniques are increasingly used by ML models for combining data from multiple, diverse modalities and sources with the goal of retrieving new insights from the fused knowledge i.e. multiple sensors may collect complementary or concurrent information which is fused in order to obtain more accurate machine diagnosis and prognosis. There is a lot of previous work on data fusion, as the topic dates back in the 90es. Application scenarios that implement ML models and apply multimodal data fusion for maintenance optimization purposes are defined by [2], [3], [9] and [10]. However, to date, no standard, nor good practice recommendations for fusion and integration of multimodal data have emerged. Our research work reviews the model-agnostic data fusion techniques in order to find solutions for their optimal usage. We argue that understanding the capabilities and challenges of existing multimodal data fusion methods and techniques has the potential to deliver better data analysis tools across all domains, including in the maintenance quality and management field of research.

This work was partly supported by a grant from the German Federal Ministry for Economic Affairs and Energy (BMWi) for the Platona-M project under the grant number 01MT19005D.

### A. Maintenance Issues Relative to Prediction Quality

We envision the problematic of maintenance quality as a complex topic with many complementary aspects: economical, the conformity with the mainstream industrial standards and technical. The first aspect follows the classical optimization concerns relative to maintenance costs, by considering aspects related to maintenance investment costs and resulting benefits.

Traditional approaches consider maintenance only as cost related. However, the maintenance activities have direct implications to the production and quality, therefore should be treated as an investment, as argued by [11]. Moreover, appropriate timing for performing maintenance activities has economical justifications, as explained by [12] in the description of the damage model. The damage model recommends the usage of maintenance actions only when clear evidence about the machine or equipment status exists. It shows that based on the long-term, historical data, it is possible to adapt the predictive maintenance interval to the industrial item life cycle by forecasting the items wear, and the impact of it on the production chain, respectively. Reference [12] explains that the probability of an item to fail is high at the beginning of its operational life, in its burn-in period. During the burn-in period, the failure probability of an item is constantly decreasing. During the items working period, the failure probability is low and remains constant, therefore the prediction of the items failure during the working period is challenging. The probability of failure raises with the working hours so that in the wear period the probability for an item to fail is again high. Therefore, [12] recommends as a good practice to perform maintenance actions during the wear period of an items life cycle.

The second aspect which, we believe, influences the quality of maintenance is conformity with industrial standards during the development life cycle of a maintenance product. Our review of the literature shows the problematic of ad-hoc maintenance model development and implementations that do not comply with the existing mainstream standards. This situation leads to the absence of good practice recommendations or general solutions in the development of maintenance products. We briefly review two existing industrial standards for model development: Cross Industry Standard Process for Data Mining (CRISP-DM) and Industry Data Space [13]. CRISP-DM standard represents a guideline to follow in the process of prototyping a learning model for maintenance purposes. We shortly list the guideline steps i.e. business understanding, data understanding, data preparation, data fusion, model prototyping, model evaluation, and deployment. A complete description is provided by the reference [45]. On its turn, Industry Data Space standard represents the solution to the actual problems raised by the huge volume of heterogeneous data which need to be handled in a standardized way in the industrial setup, as defined by [13]. Among the expected benefits of any standard, we mention the knowledge sharing and re-use which helps building complex, operational models.

The technical aspect of maintenance quality is related to

the set of decisions concerning the appropriate techniques and approaches that should be used for the development of an operational and highly qualitative maintenance model. Our literature survey mainly focuses on analyzing the technical aspect, but it considers also its connections with the economic aspect. To our knowledge, none of the reviewed research works takes into account the conformity with industrial standards for model development and data management and security. One of the main issues of actual maintenance techniques and methods is exactly the absence of this holistic view in considering the problem of the maintenance quality as directly influenced by all the above three mentioned aspects. The rest of the paper is structured as follows: Section 2 starts with a review of maintenance approaches, according to the terminology defined by both [14] and [15] maintenance standards. We introduce a taxonomy that covers the surveyed approaches by categorizing the employed predictive models, the corresponding modeling techniques and the implementation algorithms, respectively. Further on, we review the literature works focusing on the technical steps of a maintenance model development process: data acquisition and analysis, data fusion, model development and evaluation, each of them being discussed in a subsection. Moreover, we present the concept of multimodal data fusion and we discuss a taxonomy of model-agnostic data fusion methods and their usage recommendations. Section 3 presents the review process we followed in gathering the literature for our survey. Findings and results of the investigated approaches are highlighted in Section 4. Finally, Section 5 concludes the paper with a discussion about the research challenges and future works.

## II. BACKGROUND

### A. Classification of Maintenance Approaches

The European recognized maintenance standards: DIN EN 13306 - Maintenance Terminology [14], and DIN EN 31051 - Fundamentals of Maintenance [15] are defining the maintenance related terminology and concepts. According to the DIN EN 31051 standard, the maintenance concept is defined as: *the combinations of all technical and administrative actions as well as actions of management in the lifetime of a unit, in order to be in the fully functional state or to recover in this one, so that this unit can fulfill his requirements.*

The main maintenance activities i.e. service, inspection, repair, and improvement are defined by the DIN EN 31051 standard. Their definitions together with other relevant maintenance concepts defined by the DIN EN 31051 maintenance standard are listed in Table I. The DIN EN 13306 maintenance standard defines the existing maintenance strategies: *corrective maintenance, preventive maintenance, condition-based maintenance, and predictive maintenance.* They are discussed in the following subsections. Moreover, the definition of a further maintenance strategy, namely *prescriptive maintenance* - which is not yet standardized, but already used in practice - is discussed in the following subsection.

TABLE I  
FUNDAMENTALS OF MAINTENANCE DIN EN 31051 STANDARD

Item	Defines a component, device, subsystem, functional unit, equipment or a system which can be described and considered as an entity.
Wear	Represents the reduction of wear margin due to chemical or physical processes.
Wear limit	Is the defined minimum value of the wear margin.
Wear margin	Defines the possible reserve function capacity under defined circumstances which a unit possesses.
Service	Includes all activities delaying the degradation of the wear margin. The activities include cleaning, conservation, greasing, oiling, complementing, changing and readjusting.
Inspection	Refers to all activities used to determine and evaluate the actual conditions of facilities, machines, assemblies or components. Inspection refers to collecting data, and related activities that can be measuring, verifying and monitoring.
Repair	Covers activities for retrieving the nominal condition, such as renewing, patching and adjusting.
Improvement	Defines the combination of all technical and administrative activities as well as activities of management in order to increase the reliability, the maintainability, or the safety of an item without changing its initial function.

1) *Corrective Maintenance*: According to the EN 13306 standard, the corrective maintenance is defined as *the maintenance carried out after fault recognition and intended to put an item into a state in which it can perform a required function*. A system that employs corrective maintenance is aware of all its predefined set of failures and damages. But, in the industrial, operational context new faults and their corresponding patterns appear over time, because of the items usage during the working hours. One main advantage of applying corrective maintenance techniques is that the wear-limit of an item, i.e. the service time is fully used. This implies that the effort for items inspection and for replacing the item is significantly reduced, compared with the case of preventive maintenance. The main challenge in applying corrective maintenance is that the item can fail at an unknown time not previously known or decided and consequently can produce damages and an additional cost that can be higher as the yield of full usage of its wear margin.

2) *Preventive Maintenance*: The EN 13306 standard defines preventive maintenance as *the maintenance carried out at predetermined intervals or according to prescribed criteria and intended to reduce the probability of failure or the degradation of the functioning of an item*. One main challenge of preventive maintenance in operational context is that industrial scenarios for data analysis do not provide tracking of the past, abnormal behavior or maintenance operations that were performed in order to correct or to prevent a faulty behavior. Consequently, preventive maintenance defines a set of actions carried out before failure and that are intended to prevent failures or degradation of a machine. Time-based maintenance is defined as the preventive maintenance approach that recommends performing all maintenance activities after a certain amount of operation hours, or by predefined scheduling, regardless of the items health condition. The assumption is that after several operational hours, the wear margin of an item is worn out. The employed approach is to change the item or to overhaul part of it before the wear margin is used. The advantages of time based maintenance are the reduced breakdown frequency and the increased service life compared with other preventive maintenance strategies. It is therefore recommended only when the safety of the environment can be harmed, or when the items lifetime is known, which is not the case in the operational environment. The economic justi-

fication behind the time-based maintenance approach is that the maintenance costs can be kept low when the maintenance interval is adjusted to the actual lifetime of the asset so that the item or some of its parts are changed just before they fail.

3) *Condition-based Maintenance*: The EN 13306 standard defines condition-based maintenance as *the preventive maintenance which includes a combination of condition monitoring and/or inspection and/or testing, analysis, and the ensuing maintenance actions*. Condition-based maintenance aims to anticipate a maintenance operation based on the evidence of degradation and deviations from a supposed asset normal behavior. The equipment is monitored with multiple sensors which are supposed to acquire relevant data about the equipment operation life. Additionally, contextual information like temperature, humidity, etc. may also provide significant information. Key Process Indicators (KPIs) or health indicators are usually computed and analyzed, in order to discover trends that lead to abnormal contexts and failure events.

4) *Predictive Maintenance*: According to the EN 13306 standard, predictive maintenance is defined as *the condition-based maintenance carried out following a forecast derived from repeated analysis or known characteristics and evaluation of the significant parameters of the degradation of the item*. Predictive maintenance is a sub-class of condition based maintenance. It uses a variety of approaches and ML techniques to study both recent and historical data and to learn prognostic models which are expected to make accurate predictions about the future status of a machine or equipment. The main challenge of predictive models is that they rely on the assumption that there are certain contexts in the equipment life time where the failure rate is increasing. In the industrial, operational context there are patterns in which the failure probability does not increase, but remains constant during the equipment life time, and therefore the equipment can fail at any time: it is the case of electrical and electronic components.

5) *Prescriptive Maintenance*: Terminologically, it is mentioned by neither the EN 13306, nor the DIN EN 31051 maintenance standards. But, its functionality can be consequently deduced and is seen as a recommendation of one or more courses of action based on the outcomes of models for corrective and predictive maintenance. The main challenge of prescriptive maintenance is the difficulty to build in practice operative models. Existing research models are based on ad-

hoc model development where ML methods and data fusion techniques are jointly used with fuzzy reasoning, simulation techniques, and evolutionary algorithms.

Tables II, III and IV introduced in Section 4 are constructed based on the reviewed literature on maintenance strategies i.e. corrective, preventive and predictive. The tables present the surveyed literature, i.e. a structured review of the maintenance type and goals, correlated with a specific statistical or data-driven operational method, and the corresponding results. For a better understanding of implementation techniques for maintenance purposes, the next section reviews the basic steps of a data-driven model development life cycle i.e. data acquisition and preparation, model development (including the multimodal ML methods discussion) and model evaluation.

### B. Data Driven Model Development Life Cycle Methods and Techniques for Maintenance Purposes

Understanding the specific application context, or the business requirements is the first step for any learning model developed and deployed in an industrial environment. The basic steps of a data driven model development life cycle for maintenance purposes are discussed in the next subsections.

1) *Data Acquisition and Preparation*: Predictive models learn patterns from historical, multimodal data and predict future outcomes with certain probability based on these observed patterns. The performance of any learning model is highly correlated with the relevancy, sufficiency, and quality of the training, validation and test data. *Data pre-processing* and *feature extraction* techniques are relevant in building reliable data driven models. Processing the raw data before modeling is improving the performance of the learned model. In practice, raw data in the form of sensor signals are complex and related information about the degradation process of the monitored component is not always available. Therefore, *pre-processing* raw sensor data is a mandatory step before building the maintenance models. Generally, data processing methods can be divided into two main tasks, namely *processing* and *data analysis*.

2) *Model Development*: In the context of a data-driven model development life cycle, the ML techniques for maintenance is considered the most suitable research perspective to deal with big volumes of heterogeneous data. ML techniques comprise two main approaches: (i) *supervised learning*, where the information about the occurrence of failures is present in the modeling data set; and (ii) *unsupervised learning*, where only the process information is available and no historic maintenance data exists. In an operational environment, predictive maintenance makes use of the following well-established supervised learning techniques from ML field: (i) *classification algorithms* which are used to represent groups of normal and abnormal health status of the item under observation i.e. Random Forest, Nearest Neighbors, SVMs and HMMs; (ii) *regression algorithms*; and (iii) *clustering methods* with anomaly detection algorithms. Multimodal machine learning (MML) represent an increasingly used set of ML methods for combining data from multiple and diverse modalities and

sources with the goal of retrieving new insights from the combined knowledge i.e. multiple sensors collect complementary or concurrent information which is combined in order to obtain more accurate machine diagnosis and prognosis. We provide in Section 4 an overview of the multimodal ML methods which shows that the multimodal fusion method seems to be the most employed for maintenance goals.

3) *Model Evaluation*: Once a model is built, an estimate of its performance is required. According to [41] there are two types of evaluation metrics that are giving insights about the quality of the model performance metrics: offline evaluation metrics that measure offline data of the prototype model and uses mainly historic data, and online evaluation metrics that measure live metrics on the deployed model on real-time data. Offline evaluation is used to estimate the performance of training and validating data, and therefore performance metrics like accuracy and precision-recall together with F1-Score are employed. An online evaluation usually is used for real-time, test data e.g. to estimate business metrics. Our survey focuses on reviewing the offline evaluation metrics used in industry for evaluation learning models for prediction maintenance purposes. The model evaluation is made on a different set of data, i.e. testing data set that is statistically independent of the data set that it was previously trained on. Mathematically speaking, the model evaluation means to estimate the generalization error of the learning model, i.e. to measure how good the model behaves under new data calibrations. A good practice is to split the data set into training, validation and test data, in a time dependent manner. Further good practice is to consider the training data earlier in time than all the validation and test data. Andrew Ng recommends a split such as training set (60%), cross-validation-set (20%) and testing set (20%). The confusion table (also called confusion matrix) it is used to show a detailed breakdown of correct and incorrect classifications and is applied for evaluating models that learn from highly imbalanced data. Performance metrics based on the confusion table are accuracy, precision, recall, specification, F1-Score, the AUC-ROC Curve.

## III. RESEARCH APPROACH

The aim of this research review is to increase knowledge in the field of maintenance techniques and their operationalization. This implies a sort of awareness in considering the appropriate predictive models and their corresponding implementation techniques depending on the available data and on the application scenario. The conference and journal publications selected for our review belong to the non-empirical conceptual and mathematical field of research. Consequently, they describe issues and perspectives related to maintenance strategies and their modeling techniques applied in an industrial setup. A systematic search using online databases was employed for a keyword-based search, in order to find journal and proceeding publications. We used the English language and the following keywords: *maintenance AND machine learning*. We iteratively continued the search using the following keywords: *predictive*

*maintenance, multimodal machine learning, multimodal fusion, multimodality, maintenance AND big data, maintenance AND Industry 4.0.* We finally obtained a shorter literature list which was further reduced by eliminating the duplicates, when similar topics and approaches were found. Science Direct, Scopus and Google Scholar literature databases were used for their wide coverage of journals, proceedings and books.

#### A. Description of the Criteria Used for Analysis

Our research perspective relative to the maintenance quality problematic focuses on: (i) the decision process to choose a specific maintenance approach i.e. maintenance goals, benefits, challenges and obtained results; and (ii) the implementation of the maintenance approach i.e. the employed prediction models and their corresponding modelling techniques. The selected literature was carefully examined in order to extract useful information based on the following criteria:

- *Prediction models* reveal a taxonomy of the most employed prediction models types employed in a maintenance process i.e. physical models, knowledge-based models, databased models and hybrid models.
- *Modelling techniques* represent the implementation pipeline (data analysis + algorithms) used. It is a relevant criterion which further helps us to select the set of the most used ML algorithms to be critical reviewed.
- *Dataset* comprises information about the involved sensor types and the kind of fusion applied. It is a relevant criterion which further helps us to provide a critical analysis of the quality of data involved in a maintenance process.
- *Industry* is concerned with the branch of industry where maintenance processes are applied.
- *Equipment parts* reveal the critical parts of equipment which are considered for maintenance.
- *Obtained results /performance metrics* extract the information concerning how the model was evaluated and give us a hint about how optimal the data analysis and learning algorithms were applied.
- *Maintenance goals* provide us with a taxonomy of topics showing the final decisions of the algorithms pipeline. Paired with the Modelling techniques criterion, it gives useful information about the successful algorithm pipeline used for a certain maintenance goal.

The overview of the reviewed maintenance literature is presented in Tables II, III and IV. We are not considering for our research works the empirical perspective, i.e. we are not discussing the maintenance strategies and their operationalization based on information obtained from interviews, or from analyzing case studies. The analytic literature review we conduct is formalized by [17] and [18] and starts with clarifying relevant maintenance terminology and definitions based on the accepted, European maintenance standards [15] and [14].

## IV. FINDINGS AND RESULTS

This section presents the reviewed results displayed in Tables II, III and IV. The surveyed works we consider are grouped by maintenance type, and further on they are grouped by prediction modeling types and relevant modeling techniques used in the implementations.

### A. Analysis of Maintenance Strategies

1) *Corrective Maintenance:* Our survey shows that the *fault recognition and diagnostic* is generally seen as a process of pattern recognition i.e. the process of mapping the information i.e. the features obtained in the measurement space to the machine faults in the fault space, as described in [19], [20], [21] and [22]. Diagnosis is a necessary part of any maintenance system, as only prognostics cannot provide in practice a sure prediction which covers all failures and faults. In case of unsuccessful prognosis, a diagnosis is a complementary tool for providing maintenance decision support. The methods employed in order to deal with fault classification and diagnostics are diverse: from expert systems [23] to Hidden Markov Models (HMM)s, as presented in [19], Artificial Neural Networks (ANN)s as described in [20], Support Vector Machine (SVM) as in [21] and fuzzy algorithms enhanced with spectral clustering and Haar wavelet transform, as described in [22].

2) *Preventive Maintenance:* The reviewed literature shows that a relevant class of preventive maintenance techniques are the prognostics through pattern recognition, classification and machine health status identification. Prognostics analyze data by automatically finding new insights in terms of behavioral patterns. The information extracted from the monitored data can help detecting patterns that characterize the machine working conditions or is anticipating and estimating critical events i.e. fault detection as in [3] and Remaining Useful Life (RUL) estimation as in [8]. Prognostics are considerate superior to diagnostics in the sense that they prevent faults and are employed for prediction problems with items spare parts and human resources, saving unplanned maintenance costs. The reference [5] proposes a data mining maintenance approach for predicting material requirements in the automotive industry by measuring the similarity of customer order groups. Identifying behavioral patterns in data means to classify similar data in some data-groups which share the same characteristics i.e. operational conditions, as described by [24], [25], [26], [27] and [28]. Within these classified groups there are data-points that are far from the identified pattern i.e. the outliers, or they may correspond to a distinctive property i.e. the mean point or the group distribution. Such patterns may help to identify faults or any other type of abnormal behavior. Large groups of data are interpreted as normal behavior, while small groups of data, or events that are far from the pattern are usually representing anomalies. Consequently, in modeling the learning model, there are only unlabeled input examples, i.e. we employ the the unsupervised learning perspective. ML algorithms and data fusion strategies are used to find new patterns in data therefore, in this case, clustering should be the most used technique,

together with a measure of similarity which should deal with showing the correspondence of data groups. When pattern classification is applied for describing training data, then we assume the availability of (i) historic data with abnormal behavior; and (ii) data concerning maintenance activities that were carried out. The learner looks for identifying the causes for confirmed, abnormal behavior and critical events, in order to predict them and to avoid them in the future. In this case, values for the target labels are available, and therefore the supervised learning strategy and the corresponding algorithms are to be employed. The target labels are representing features that are discrete or continuous, and they are always related to the diagnostic. Time-series analysis is employed to extract damage and fault-sensitive features from data. When a corrective action is made, the preceding data represent an abnormal behavior or abnormal data context. When events of interest or based on past maintenance actions are tracked, they are assumed to represent a normal data context. Another type of scenario is learning the normal behavior of the machine or parts from its equipment. This is a difficult process in the operational context, as it supposes that there are no outliers, nor operational faults, which is not the case of the industrial environment. Finding patterns in the monitored data requires a deep knowledge of the topic and of physics of the process so

that the issue can be theoretically understood. In the context of supervised learning approaches, feature engineering and mainly the interpretation of the assessment of the results represent always a challenge.

3) *Predictive Maintenance*: The survey shows that the predictive maintenance process has the goal of providing an accurate estimate of the RUL, but also it should assess the provided estimate, as argued in [31], [32], and [33]. Time-series analysis is used to anticipate anomalies and malfunctions in equipment and processes maintenance procedures. Traditional approaches are moving average over a time window, ARMA/ARMAX, Kalman Filter and cumulative sum, as described in [9]. Recursive Neuronal Networks (RNNs) show relevant characteristics for time series forecasting, as their loops allow information to persist, as presented in [8]. Multi sensor fusion ranges from multi signal combinations, as argued in [8] and [9], to more complex integration of conditional assessment, RUL estimation, and decision making, as presented in [2] and [10]. Operational predictive approaches are based on a schema that implies frequent, and sometimes unnecessary maintenance of the equipment and of the entire production process that leads to high maintenance time and costs. They use complex A.I. based algorithms, and data fusion strategies - in an ad-hoc manner, usually after trial and error approaches - which imply the usage

of consecutive fusion algorithms, as described by reference [26]. The uncertainty in prediction is always a challenge and to this time the fuzzy logic is used to represent uncertainties in prediction, as argued by [4]. As a particular case of condition-based maintenance, reference [29] shows that techniques for condition monitoring and diagnostics are gaining acceptance in the industry sectors, as they prove to be effective also in the predictive maintenance and quality control areas. The authors apply a feature based fusion technique implemented with the cascade correlation neuronal network to multiple sensor data collected from rotating imbalance vibration of a test rig. The results show that the multi-sensory data fusion outperforms the single sensor diagnostic. The reference [30] focuses on the capability of providing real-time maintenance by extracting knowledge from the monitored assets (with vibration sensors) on the production line. Using intelligent data driven monitoring algorithms (ADMM), data fusion strategies and the proposed three-levels layered (IoT, Fog with gateway nodes for sensors aggregation, Decision) system model, the authors argue on the efficiency of cloud oriented maintenance.

The uncertainty in prediction is always a challenge and to this time the fuzzy logic is used to represent uncertainties in prediction, as argued by [4]. The references [6] and [7] show that the problem of scheduling under constraint of completion time of all production jobs can also be solved using predictive maintenance algorithms. The efficiency of the algorithms for predicting machine failures is further evaluated using simulation tests. The results, i.e. the optimized jobs schedule shows a nearly 50% drop in the number of operations compared with the initial, nominal schedule. The classification of modeling techniques for predictive models is presented in Figure 1. Physical models use the laws of physics to describe the behavior of a failure [2]. *Knowledge-based models* assess similarities among observed situations and a set of previously defined failures. These models can be sub-divided in *expert system models* able to answer complex queries, as presented by [23], and *fuzzy models*, as in [4]. *Data-driven models* are based on the acquired data. This type of model can distinguish among *stochastic models*, *statistical models* and *artificial neural networks* (ANNs). *Hybrid models* use combinations of two or more modeling techniques as in [34], [35] and [44]. Stochastic models provide event-based information. Hidden Markov models and Kalman filters belong to this category too. Statistical models predict a future state by comparing the monitored results with a machine health state without faults. ML models, such as regressions, classifications, and clustering represent a category of data-based, statistical models relevant in the study of maintenance optimization. However, the ML models are focusing on increasing the accuracy of their predictions, while the classical statistical community is more concerned with the understanding of their models and of the model's parameters i.e. model calibration and inference.

4) *Prescriptive Maintenance*: The main challenge of prescriptive maintenance is the difficulty to build in practice operative models. Existing research models are based on ad-hoc model development where ML methods and data fusion

techniques are jointly used with fuzzy reasoning, simulation techniques, and evolutionary algorithms. The reviewed literature shows that prescriptive maintenance implementations show an ad-hoc grouping of methods including data fusion and ML techniques, combined with fuzzy reasoning algorithms, simulations [34] and multi-objective evolutionary algorithms for optimization [44]. When a predictive model raises an alarm before the fault occurs, the prescriptive model will work in the direction of reducing the probability that this alarm will rise in the future, by modifying the working parameters and variables of the asset or the process affected by the fault. When the fault is confirmed, the prescriptive models will work to minimize its impact of the work context and to re-routing assets to the non-faulty production lines.

The tables II, III and IV are constructed based on the reviewed literature on maintenance types: corrective, preventive and predictive. The tables present a structured view of the maintenance type and goals, correlated with a specific statistical or data-driven operational method, and the corresponding results.

## B. Analysis of Data Driven Development Life Cycle

1) *Data Acquisition and Preparation*: Predictive models learn patterns from historical, multimodal data and predict future outcomes with certain probability based on the observed patterns. The performance of any learning model is highly correlated with the relevancy, sufficiency, and quality of the training, validation and test data. Moreover, the data used for training and testing the model should be relevant for the application scenario, therefore the expertise and the guidance of a domain expert is important. The most relevant data sources for a predictive model application scenario are condition monitoring data referred to as hard data, and human generated data referred to as soft data. Condition monitoring data contains knowledge in the form of degradation patterns and other types of anomalies in data that leads to an item degradation. Time-varying features are expected to capture these abnormal patterns, and the models fed with these features are expected to learn to distinguish between normal and abnormal pattern behaviors of items and also to forecast the RUL for the monitored items. Condition monitoring data can be further decomposed into sensor data, asset data, operation data, offline inspection data, and historical data. On its counterpart, human generated data represents information about replaced components, repair activities performed on a certain item or on parts of it. Moreover, it consists also of software generated information e.g. event data information such as alarms and faults messages which are described in natural language, but it comprises also technical metadata for devices and processes i.e. model, manufactured date, the start of service, maintenance reports. The event-data collection implies always a manual process and includes qualitative information about the monitored item such as the description of the installation, breakdown, inspection, repair, overhaul, failure causes, etc., the severity of the failure and the description of what was done to fix the failure. In practice, the item under critical

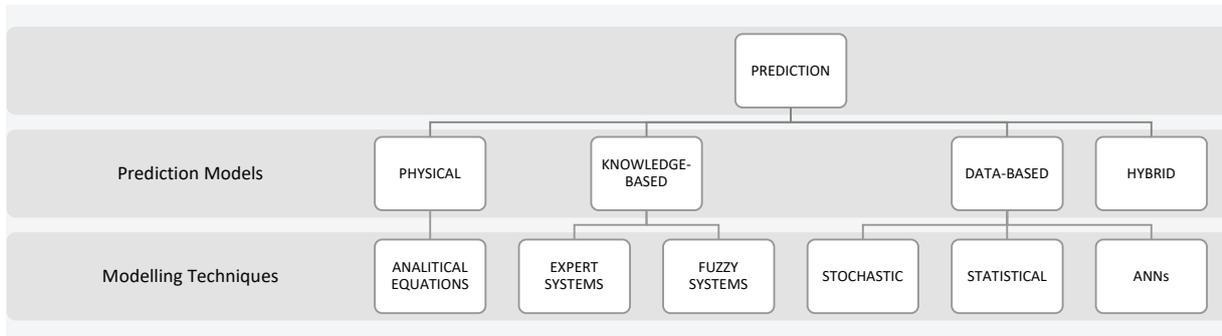

Fig. 1. Taxonomy of Prediction Models

conditions which is monitored continuously generates two types of data: event data and condition-monitoring data. Event data represent fault events which are considered critical to the system, and diagnostics messages when the events are alarm messages that described the item status. Events are triggered by the software component that monitors the item based on the item status information. Condition monitored data is collected every time when the events are triggered in order to form the context of the associated events and to ease their interpretation. Event data is characterized by attributes like type (i.e. fault, alarm, diagnostic), timestamp, item/sub-component where the event was triggered, severity, duration, and textual description, among many other possible attributes. After the acquisition process, the data sets must be pre-processed as they exhibit uncertainties that may affect the learning model performance. Data preprocessing and feature extraction techniques are relevant in building reliable data driven models. Processing the raw data before modeling is improving the

performance of the learned model. In practice, raw data in the form of sensor signals are complex and related information about the degradation process of the monitored component is not always available. Therefore, preprocessing raw sensor data is a mandatory step before building maintenance models. Generally, data processing methods can be divided into two main tasks, namely processing and data analysis. After processing the raw data coming from sensors, the resulting heterogeneous data may be categorized in the following types, depending on the quality of information they provide: (i) competitive, or redundant sensor data; (ii) cooperative, non-overlapping but partial sensor data; (iii) complementary, overlapping and partial sensor data; and (iv) independent, unrelated sensor data. Feature engineering is the next step prior to modeling the data. A feature is considered to be a predictive attribute for the model, such as temperature, pressure, vibration, etc. It is a good practice that the features extracted from the sensor data to comply with the following requirements: (i) features should

contain information required to distinguish between potential faults; (ii) features should not take into account the irrelevant variability which might be mixed in the sensor signals; and (iii) features should be limited in number to allow efficient computation.

2) *Model Development*: ML techniques for predictive maintenance comprise two main approaches: (i) supervised learning, where the information about the occurrence of failures is present in the modeling data set; and (ii) unsupervised learning, where only the process information is available and no historic maintenance data exists. In an operational environment, predictive maintenance makes use of the following well-established techniques from ML field: (i) classification algorithms which are used to represent groups of normal and abnormal health status of the item under observation: Decision Tree, Random Forest, Nearest Neighbors, SVMs and HMMs; (ii) regression algorithms; and (iii) clustering methods with anomaly detection algorithms, as presented in Figure 2. Binary classification algorithms are used to predict the probability that a piece of equipment fails within a future time period. The business requirements, the analyzed available data and the domain expert make estimation for e.g. (i) minimum lead time required to replace components, deploy resources and perform maintenance actions in order to avoid a problem that is likely to occur in the future time period; or (ii) minimum count of events that can be triggered before a critical problem occurs. Multi-class classification algorithms are used for making predictions in the following possible scenarios: (i) defining a plan maintenance schedule i.e. estimation of the time intervals when an asset has the bigger probability to fail; (ii) monitoring the health status of an asset i.e. estimation of the probability that an asset will fail due to a specific cause /root problem; and (iii) prediction that an asset will fail due to a specific type of failure. In this case, a set of prescriptive maintenance actions can be considered for each of the previously identified set of failures. Another type of algorithms for classification are the multiple classifiers which can be used in the process of knowledge discovery to discern particular patterns of data degradation for an asset or for a process. The benefits of the multiple classifiers reside in allowing the planning of the maintenance schedules using a statistical cost minimization approach. Regression models are typically used to compute the RUL of an item, as presented in [8]. RUL is defined as the amount of time that an asset is operational before the next failure occurs. The operational historical data is needed because the RUL calculation is not possible without knowing how long the asset has survived before a failure. Autoregressive models such as ARMA models assume that all future values are linear functions of past observations. e.g. fault predictions. A data-based ANN approach is recommended to be used for information clustering when there is no knowledge or understanding about the monitored system e.g. [8] and [10].

3) *Multimodal Machine Learning Methods*: Multimodality is defined by [36] as referring to the way something happens, or is experienced: we read textual information, we see objects and we hear sounds, we feel textures and smell odors. All

these perceptions represent modalities. A research problem, application or data set is multimodal when it includes multiple such modalities. In order to understand and to make sense of the world around us, A.I. techniques, in particular, multimodal machine learning (MML), must be able to interpret multimodal information and further to reason about it and make decisions. MML is a *multi-disciplinary field of research which builds models that process and relate information from multiple modalities*, as defined in [36]. The main idea is that *data from different sensor sources provide different representations of the same phenomena*. In MML literature, this is known as *multimodal, multi-view, multi-representation or multi-source learning*, as described in [37]. The main multimodal ML methods were identified and defined in [36] i.e. representation, translation, alignment, fusion, and co-learning. Their definitions according with [36] and [37] are listed in Table V. Understanding the capabilities and challenges of existing multimodal data fusion methods and techniques has the potential to deliver better data analysis tools across all domains, including the maintenance quality and management field of research. A relevant research challenge for the multimodal data fusion perspective is to identify patterns and commons governance rules that can be used to apply the appropriate multimodal data fusion technique for an application specific context or for a data set. Reference [38] arguments that data fusion is a multi-disciplinary research area with ideas raised from many diverse research fields such as signal processing, information theory, statistical estimation and inference, and artificial intelligence. Data fusion appeared in the literature as mathematical models for data manipulation. The diversity of the research fields is indeed reflected in the reviews of maintenance techniques in Tables II, III and IV. Multimodal data fusion represents the integration of information from multiple modalities, with the goal of (i) making a prediction; and (ii) retrieving new insights from the joined knowledge, as defined by [36]. There are many approaches to data fusion, as the topic dates back in the 90es. The model-agnostic technique to data fusion is discussed in [36] and [39] and later, described by [37], which also lays the grounds for the multimodal data fusion formal theory. Multimodal data fusion has the direct economic impact in the implementation of maintenance techniques which are based on aggregation data from heterogeneous sources into actionable decisions for maintenance purposes. Multimodal data fusion represents the core concept in MML, as argued in [36] [39]. The model-agnostic data fusion types that are used in the operational environment are listed in Table VI. The reference [37] lays the grounds for the multimodal data fusion theory by giving a solution to the research problem of determining the appropriate type of data fusion for a specific application context or for a data set. On his view, the main challenge in multimodal data fusion research resolves around the dependency-problem i.e. the arguments for choosing a specific type of data fusion. The assumption is that the optimal fusion type to be employed in an operational environment depends on the level we expect to see a dependency between the inputs in the modalities: (i) feature-based fusion assumes a

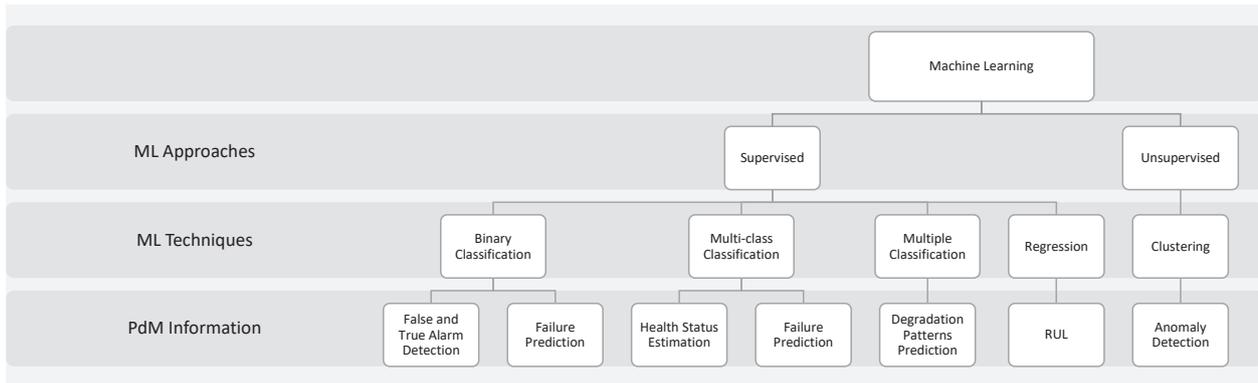

Fig. 2. Machine Learning Techniques for Predictive Maintenance

TABLE V  
MULTIMODAL MACHINE LEARNING (MML) METHODS

Representation	Learning to represent heterogeneous information in a unitary way, easy to be understood and processed by a learning model.
Translation	Mapping the information from one modality to another in a most accurate way.
Alignment	Identifying the inherent relations between sub-components. It also implies dealing with similarity measurements.
Fusion	Joining/combining in a meaningful way the information from different modalities.
Co-learning	Transferring knowledge among modalities: the modality with limited resources can benefit from another with more information.

dependency at the lowest level of features (or raw input unprocessed data), (ii) intermediate-fusion assumes a dependency at a more abstract, semantic level; and (iii) decision-based fusion assumes no dependency at all in the input, but only later at the level of decisions. The above described assumption has the following implications, as argued in [47]: (i) there are no established, standard methods to identify feature dependencies in multiple sensors and modalities; (ii) the technology exists, but there are no standard methods to extract unbiased feature from raw data, and therefore deep learning methods are preferred; (iii) there are basic techniques to handle modality fusion when dealing with missing information; (iv) it is unclear what are the relevant features to be learned, in the sense that a trial-and-error process of feature engineering is employed for the shallow ML algorithms, i.e. Decision Tree, SVM, kNN; and (v) multimodal data fusion best practices i.e. data sets, fusion algorithms, success stories, training and evaluation of results, should be recorded and shared. Moreover, the review of existing proposals for data fusion techniques and frameworks clearly shows that the actual trend for maintenance engineering is cloud maintenance i.e. maintenance-as-a-service, as argued in [2] and [11]. The envisioned platform is seen as a management system of smart services i.e. data-analysis-as-a-service, prognostics-as-a-service or data-as-a-service, that represent better solutions in terms of technology, performance, and costs. The list of challenges continues with: (vi) the absence of a clearly defined generic framework for smart services that standardize the usage of a data fusion pipeline it is clear that in an operational environment more than one data fusion techniques should be applied; (vii) there are no standard

techniques for dealing with temporal and spatial (context) data alignment and synchronization, i.e. the ontology-based proposal of [44] assumes some benefits due to knowledge access, reasoning and re-use of ontology web-standards; and (viii) lack of research studies to analyze the performance of ML algorithms in a cloud environment.

4) *Model Evaluation*: One challenge for evaluating the performance of learning models is represented by the availability of data: when the data set is not large enough to provide sufficient data quantities for the data training validation and test sets, then methods such as k-fold cross validation and bootstrapping are used to simulate new data. K-fold validation is used to split the original dataset into k folds, and run the learning algorithm k times. Another challenge on model evaluation is represented by the skew or imbalanced data. In any maintenance scenario, the minority data class is represented by the abnormal data i.e. the event-faults. Therefore, in the case of fault prediction, the algorithm needs to identify only a small group of data from the overall historical data. Incorrectly predicting a positive class as a negative may lead to a greater cost than the reverse situation, i.e. the problem of the asymmetric cost. Consequently, performance metrics based on the confusion table are used to evaluate how accurate the algorithm is. Boosted methods, such as boosted decision trees are also used as algorithms for solving the imbalanced data problem. Consequently, the time-dependent split of the imbalanced data is useful for avoiding data overfitting on classification models for fault predictions, and on regression models for predicting the RUL. Other problems to be avoided when evaluating a learning model are variance and bias. The

TABLE VI  
MODEL-AGNOSTIC FUSION TYPES

Feature-based (Early Fusion)	Features from all the modalities are concatenated as one long input and trained by a single learner.
Intermediate (Hybrid Fusion)	There is a single learning model which is trained with a preprocessed input from modalities in the fused layer. It is implemented by neural networks and multi-kernel support vector machines algorithms.
Decision-Based (Late Fusion)	Each modality is trained with a different learning model that independently makes a decision. All decisions generated by learning models are later combined based on a fusing schema.

reference [42] addresses these problems suggesting appropriate solutions.

## V. DISCUSSIONS

The present work reviews maintenance approaches with applicability in the industrial environment. The aim is to identify potential sources and ideas for delivering better data analysis tools and techniques for the optimization of the industrial maintenance processes. Past works on maintenance approaches show that maintenance actions are performed by employing various prediction models and modeling techniques. However, the existent literature does not inform us to which extent the new A.I. technology based on ML methods and techniques is influencing and changing the maintenance approaches in the industrial setup. Consequently, we provide an analytical literature review showing first that among all the existent approaches to maintenance, each of them varying in terms of efficiency and complexity, predictive maintenance seems to best fit the needs of a highly competitive industry setup. Next, we consider ML to be a prediction methodology and we show that ML methods enhance industrial maintenance with a critical component of intelligence: prediction. The approach we envision for the optimization of predictive maintenance actions investigates the MML perspective and consequently uses a variety of multimodal ML methods that study both live and historical information, in order to learn prognostics data and to make accurate diagnostics and predictions. Based on the surveyed literature we construct taxonomies that cover the main predictive models and their modeling techniques relative to maintenance goals. We show that among all the prediction models, the data driven, statistical inference based ML approaches are the most suitable to deal with big volumes of heterogeneous data. Their acceptance in the field is mainly due to the fact that prediction is easier than model inference i.e. the ML models are performing tests to check how well a learning model which is trained on a data set is able to predict new data. This allows ML algorithms to easily work with larger volumes of complex data. However, a critical analysis of ML algorithms and of the sensor data sets used for maintenance will directly show that there are no optimal ML models that always outperform all the other. Usually, their efficiency is based on the type of training data distribution. On its turn, multimodality is presented as an efficient ML method of combining data from multiple, diverse modalities and sources. Its main goals are: making better predictions and retrieving new insights from the combined knowledge. A model-agnostic taxonomy of the reviewed multimodal ML fusion methods is presented together with appropriate solu-

tions for optimal usage. In particular, we distinguish among: (i) feature-based fusion or early fusion a basic concatenation of features belonging to different modalities; (ii) intermediate-fusion typical for algorithms implemented by the artificial neuronal networks or by multi-kernel support vector machines; and (iii) decision-based fusion which applies a learning model for each modality independently, and the fusion takes place only at the decision level. Past works present multimodal fusion strategies made in an ad-hoc way, without following some standard implementation lines. We highlight the fact that there is a need for standardized solutions in applying multimodal ML methods for maintenance purposes. Moreover, we show that analyzing only the technical aspect i.e. the multimodal ML perspective, for improving the quality of maintenance is not sufficient. The connections with the economic aspect and the conformity of data science projects with industrial standards like CRISP-DM and Industrial Data Space are relevant. Consequently, we argue that quality of maintenance in an industrial setup can be improved only when in the development of a generalized architecture for maintenance purposes the following aspects are taken into consideration: (i) the technological aspect which recognizes the potential of multimodal ML methods for maintenance purposes; (ii) the business aspect which envisions a structured development of the implementation works starting with the business model's conceptualization, and assuring its conformity with the industry standards; and (iii) the economic aspect which follows the classical optimization concerns relative to maintenance costs. Future works are planned to analyze the usage of multimodal ML methods combined with semantic technologies in a cloud-oriented environment. The goal is to overcome the problem of sensor integration for efficient data analysis. We recognize that the actual trend for maintenance engineering is cloud maintenance. Within this context, the envisioned digital platform is seen as a management system of smart services i.e. prediction-as-a-service and maintenance-as-a-service, with expected benefits in terms of technology, performance and costs.

**Abstract**—Gamification is applied in different information systems to motivate the users and make their experience with the system richer and more engaging. Gamification employed in e-guides aims at enhancing the process of visiting a tourist attraction. Even though each tourist attraction is unique and requires an individual gamification scheme, similarities in the components and procedures used to develop such schemes led to the development of a generic e-guide gamification framework. One of its main principles is to store the gamification rules as a content separate from the engine to process them. This way, the rules can be easily edited by subject matter experts. This paper describes a visual rule editor developed to facilitate this process.

### I. INTRODUCTION

GAMIFICATION, understood as “the use of game-design and game psychology in non-game settings to engage the target audience and motivate specific behaviors” [1], has been considered as “one of the significant new trends in the development of services and applications in the software industry” [2]. It can be applied to information systems of various character [3]. One of these are multimedia visitor guidance systems, better known as e-guides, which may employ gamification to enhance the tourist attraction visiting process [4].

Tourist attractions may significantly differ in their character, and e-guides may as well differ in their form and functionality. For this reason, there cannot be a fixed scheme for e-guide gamification. Rather, individual gamification schemes have to be designed for respective tourist attractions with specific characteristics of their own. There is still significant similarity among components and procedures used to develop gamification schemes for different tourist attractions. Motivated by this observation, a generic e-guide gamification framework has been proposed, aiming to standardize architectural and design solutions so

that it could be easier to implement gamification to e-guides, reuse gamification layer among different e-guides, and maintain and update gamified e-guides [5].

An indispensable ingredient of any gamification scheme are the rules linking users’ actions to game-inspired consequences, such as specific rewards or feedback [6]. While they could be developed as a part of e-guide software, the framework mentioned above proposes not only the separation of the core e-guide functionality and content from the gamification engine and rules, but also the separation of gamification rules and the engine to process them, so that the rules could be treated as a kind of content, separately edited and transferred among e-guides [5].

For this purpose, a common notation of gamification rules for e-guides has to be used, and such notation has been proposed [7]. Although, the textual notation it uses was designed for readability, in the course of implementation of the BalticMuseums: Love IT! project [8], it was found that the tourist attraction personnel who was responsible for devising the e-guided tours featuring gamification, and who had no programming experience found it difficult to use.

In this paper, we describe a solution for this problem in a form of a dedicated visual rule editor, so that the prior knowledge of the notation syntax, keywords, and appropriate parameters is no longer required from the gamification designer. This approach follows the example of general-purpose task automation services where the provision of visual rule editor is considered as an architectural requirement [9, p. 13].

The structure of the paper is as follows: section II gives a short glimpse of prior work on this topic. In section III, we present the user interface of the visual rule editor, so that the reader could see how it can be used to define gamification rules. Section IV provides necessary technical information about the implementation of the visual rule editor. In section V, the results of its evaluation are reported. The final section concludes.

---

The presented rule editor was developed as a part of the BalticMuseums: Love IT! project and part-financed from the European Regional Development Fund within the Interreg South Baltic Programme.

This paper was developed with a financial support from a project financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019-2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.00.

## II. RELATED WORK

The idea of replacing text statements with a form to be filled in can be traced back to QBE database query language released commercially already in 1978 [10]. In its contemporary implementations (such as in Microsoft Access 2019), not only the query building form has a predefined structure (so that there is no need to know the syntax), but also the available options are simply checked or unchecked (rather than typed in) and wherever the set of possible parameter values is predefined, they can be chosen from a list rather than input as text (which has to be done with other parameter values).

Although some research results show that trained and experienced users prefer textual notation than forms (see e.g. [11]), for a first-time or occasional user, the advantage of using a form over writing text in a language unknown to him/her is obvious. This is a reason for which a number of similar query languages were developed, including [12]:

- Aggregates-by-Example, Summary-Table-by-Example, and Query-by-Statistical-Relational-Table designed for querying statistical and scientific databases;
- Time-by-Example designed for querying historical databases;
- Generalized-Query-by-Example designed for querying relational, network, and hierarchical databases;
- Picquery and Query-by-Pictorial-Example designed for querying image databases.

As gamification rules, like database queries, also have a well-defined context and structure, they are suitable for editing using forms. This has been proven by well-known enterprise gamification platforms, such as Bunchball Nitro [13] or Gametize [14], which use forms to specify the rules.

In the following two sections, we will show how this approach has been implemented to the e-guide gamification rule specification.

## III. VISUAL RULE EDITOR

The described visual rule editor forms a part of the e-guide content management system which in turn is a part of the e-guide gamification web platform developed within the BalticMuseums: Love IT! international project [8]. The purpose of the editor is to facilitate gamification designers to add, view, modify and delete gamification rules which are to be applied by the e-guide gamification web service [15], itself called by e-guide client applications running on tourist attraction visitors' mobile devices.

The visual rule editor features a list of defined rules along with the search and pagination mechanisms, as shown in Fig. 1. The editor follows the principle of a clear division of rule specification into three parts: the name (identifying a rule), conditions (required to trigger a rule) and results (caused by a rule) parts as presented in [5]. This allows for easy specification of rules having multiple conditions and results. Both the conditions and results regarding a given rule are displayed next to its name in a readable form and the standard functionalities of adding, viewing, modifying and deleting them are provided.

Adding and modifying rules is done using the "Edit rule" form presented in Fig. 2. Similar forms are used to add or edit a condition or a result for a selected rule.

Fig. 2 Rule edit form

No.	Name	Description	Results	Active	Conditions
1.	Baltic Adventure	Towards a new adventure.	<ul style="list-style-type: none"> <li>x text: Welcome</li> <li>x points: 3</li> <li>x badge: Captain Nemo:Captain Nemo</li> </ul> + Add result	✓	<ul style="list-style-type: none"> <li>x variable [Score] &gt; value [320]</li> <li>x location in [Flatfish and gobies, Giant clam and dartfish]</li> <li>x item in [Puzzle to solve]</li> <li>x date &gt;= [2019-05-01]</li> <li>x date &lt;= [2019-05-31]</li> <li>x time &gt;= [08:00:00]</li> <li>x time &lt;= [12:00:00]</li> </ul> + Add condition

Fig. 1 Rules definition module in the e-guide gamification system

Figure 3 presents a condition edit form with a *Var\_Value* type condition, which makes it possible to specify: the name of the variable that is to occur in the description of the event that triggers the rule, the comparison operator and the threshold value at which the condition is met. For the user’s convenience, other conditions specified for the rule whose condition is being edited are shown above the edit text boxes. The available comparison operators include those for comparing two values (=, <>, >, >=, <, <=) and checking the existence of a value in a set (*in*, *not in*).

Fig. 3 Condition edit form

Figure 4 presents a result edit form with an example of a *Badge* type result. The other two result types currently available are *Points* and *Text* (to be displayed to the visitor). The list of result types is to be extended in consideration of the detailed results of the evaluation survey (see section V). As with editing the conditions, for the user’s convenience, other results specified for the rule whose condition is being edited are shown above the edit text boxes.

Fig. 4 Result edit form

#### IV. DATA MODEL FOR REPRESENTATION OF RULES

The data model for the representation of rules of the gamification service is based on classes implemented in the Django framework (Fig. 5). During implementation, this model is translated into SQL, and then a SQL script is executed in the PostgreSQL database management system, which results in the creation of the respective tables. The

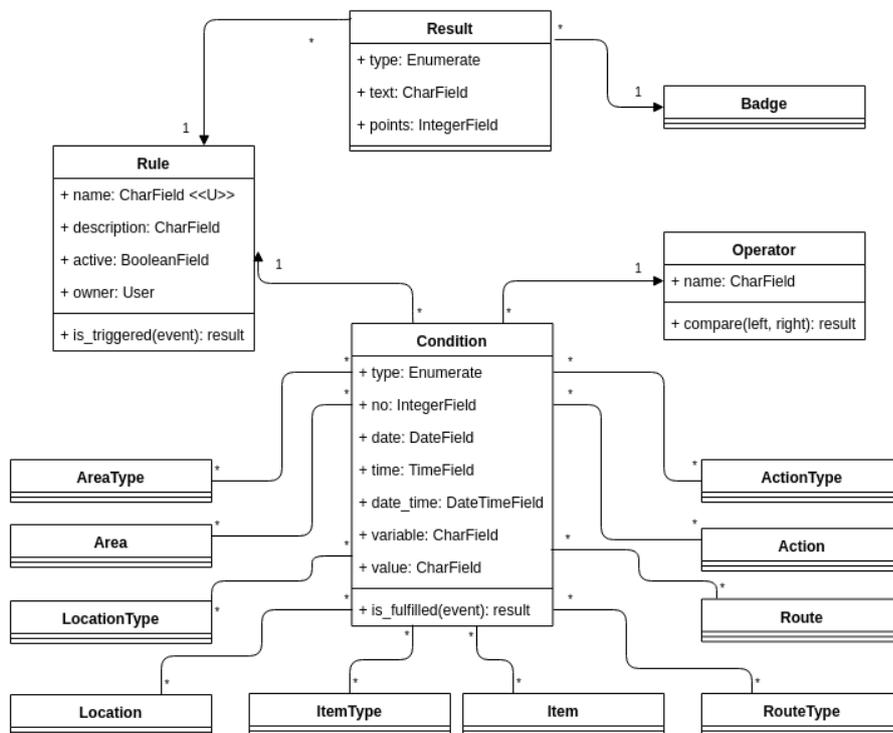

Fig. 5 Data model for representation of rules

main class of the model is the Rule class which defines objects storing basic information about each rule – its *name* and *description*. The content of the *name* field has to be unique (no two rules may have the same name). An additional *active* field has been introduced to indicate whether, for a given rule, the data stored in objects of associated classes (see below) can be modified or not, as well as whether the rule can be executed by the e-guide gamification web service. Each rule is assigned to the user who created it. This way, only an owner of the rule can see and modify it.

The *is\_triggered* method defined within the Rule class checks if the rule has been triggered as a result of an event (whose description is the input parameter) and if positive, returns the results assigned to the rule.

The Result class contains a field specifying the result type. Currently, there are three available result types: Text, Points, and Badge. Depending on the result type, the appropriate field is filled in. In the case of Text type, the *text* field is set to the result message to the visitor. In the case of Points type, the *points* integer field is set to the number of points to be received by the visitor. In the case of Badge type, an object from the Badge class specifying the badge to be awarded to the visitor is assigned to the Result class object.

The Condition class is meant to map any conditions associated with a given rule. One rule can have many conditions and a certain condition can be associated with only one rule. The *type* field specifies the object of the left side of the condition. There are several entities in the e-guide gamification system that can be used to form the right side of the condition. They can be seen on the data model associated with the Condition class, i.e.: *AreaType*, *Area*, *LocationType*, *Location*, *ItemType*, *Item*, *RouteType*, *Route*, *ActionType* and *Action*. Other available condition types include *Date*, *Time*, *Date\_Time* and *Var\_Value*. For the *Var\_Value* type, both the variable name and its threshold value must be specified.

The *is\_fulfilled* method, defined within the Condition class, specifies if a certain condition has been fulfilled, based on an event description (the input parameter).

Each object of the Condition class is associated with an object of the Operator class which defines the way of comparing both sides of the condition. The *compare* method of the Operator class is used to perform the comparison.

## V. EVALUATION

The preliminary evaluation of the described visual rule editor was based on a qualitative survey among the representatives of tourist attractions participating in the BalticMuseums: Love IT! project [8] who are in progress of development of their respective gamified e-guides and to whom the tool was presented earlier. The three rule editor

evaluation questions constituted a part of a larger survey aimed at defining future work directions and possible technical improvements, therefore the answers could be considered as objective. Out of the five tourist attractions participating in the BalticMuseums: Love IT! project, answers from four (Gdynia Aquarium, Experiment Science Center, Malmö Museums and NaturBornholm) were received (six answers in total as there were two organizations with two representatives from each of them participating in the survey). Note that though the number of the tourist attractions involved in the survey is low, they differ significantly in their character, which makes their answers far more representative than if they all belonged to a single category of attractions.

Answering to the first evaluation question, all the six surveyed representatives agreed that a form-based gamification rule editor is better than writing rules as text (using a dedicated rule definition language). This confirms the original observations that led to the development of the editor.

The second question asked whether there were rules that the tourist attraction representatives invented but did not manage to define using the editor. Half of the surveyed (three of six representatives from two of the four involved attractions) answered positively, with one respondent pointing to her (or her team's) possible lack of skills in using the tool, and the two other (from one attraction) suggesting that the rule definition form has to be extended.

In the third question, the respondents were asked if they encountered other problems with defining rules. Again, half of the surveyed (three of six representatives from two of the four involved attractions) answered positively. This time, all of them pointed to the lack of a good manual as a reason for those problems.

## VI. CONCLUSION

A key point in the implementation of gamification is the specification of rules governing the system. While such rules may be embedded in the gamification software, in many circumstances it makes a lot of sense to have them defined separately so that a change in gamification rules would not require a change in the software handling them.

This is especially true in the case of e-guide gamification where the rules should make use of the specificity of a tourist attraction, which strengthens the role of subject matter experts (such as guides and educators) rather than gamification experts. Another reason for such an approach to e-guide gamification is due to quickly changing content featured in many tourist attractions (such as those having seasonal exhibits or short-living fauna species on display).

While e-guide gamification rules can be effectively represented in textual notation [7], their editing by subject

matter experts (rather than IT professionals) could be much simpler using predefined forms.

The visual rule editor described in this paper was designed following this approach. All the surveyed representatives of the tourist attractions introduced to it unanimously agreed on their preference for the form-based rather than textual rule specification. On the other hand, the survey revealed that the decision to make the editor simple by limiting the possible scope of defined rules (as compared to the textual notation) resulted in some of the tourist attractions representatives being unable to define sophisticated rules they had invented. Moreover, even though the operation of the editor is intuitive, the users encountered some problems which could be addressed by providing a better user manual.

The identified drawbacks will be addressed in the next version of the rule editor, whose development constitutes the nearest future work, after which another evaluation survey is planned, having an extended scope and involving more tourist attractions.

# A Design and Experiment of Automation Management System for Platform as a Service

Alalaa Tashkandi

Saudi Aramco, Information Technology, Al-Midra Tower, Dhahran 31311, Saudi Arabia  
Email: alaa.tashkandi@aramco.com

**Abstract**—Security [11] and quality [4] of cloud computing (CC) services represent significant factors that affect the adoption by consumers. Platform as a Service (PaaS) is one of CC service models [14]. Management of database systems, middleware and application runtime environments is automated in PaaS [2]. PaaS automation management issues and requirements were collected in three rounds from information technology experts using Delphi technique. In this paper, PaaS automation quality and security management system (MS) layered model is proposed and validated. The aim of the MS is enabling PaaS model for mission critical platforms. Validation of the MS was based on experiment in a private cloud for an organization undergoing a transformation toward PaaS computing.

## I. INTRODUCTION

SERVICE interruption caused by Platform as a Service (PaaS) automation failure or security incidents may lead to reputation damage or reimbursement cost. PaaS management system (MS) should provide integrated proactive and reactive control for quality and security events.

The MS model was achieved based on analysis of experts' inputs using Delphi technique in a Cloud Service Provider (CSP) organization providing mission critical services. The model enforces secure rollout, update and monitoring of automation artifacts. Additionally, quality assurance (QA) process is enforced. After three rounds of communications, verifications and feedbacks, PaaS MS model was finalized. Observations based on MS experiment are summarized in Analysis and Discussion section of this paper.

In this research, we have collected the adoption factors and requirements of PaaS for mission critical platforms to drive a novel management model using Delphi approach. The model was experimented and validated in a private cloud environment.

## II. RELATED WORK

Applications in PaaS context can be classified based on computation model, resource utilization type, resource utilization variability or interactivity level. Examples of PaaS offering include Google App Engine and Amazon Web Services Lambda [2]. PaaS is one of three service models in

Cloud Computing (CC). In this model, customer does not have control over the infrastructure layer while he has control over the application and its configuration [14]. Middleware, application runtime environment and database systems are examples of components in PaaS model [3], [5], [10], [13]. PaaS provides self-deployment, monitoring and lifecycle management of applications [2], [4]. PaaS offers include middleware services, like Database as a Service (DbaaS), and reusable middleware components. Middleware components include application runtime environments that can be used as part of an application platform [5], [8].

PaaS provides flexibility and agility to developer team. By automating the deployment of application platforms and their components, different setup and configuration can be realized with minimal efforts and time. Interactions between developer team and operation team are minimized through automation [3], [7]. Infrastructure is abstracted by PaaS [5].

Private cloud and multicloud are now the convention of organizations that need to protect their information technology investment while seeking new technologies and opportunities. Use of resources in multicloud can be sequential or parallel. Support of multicloud minimizes vendor lock-in issue associated with the Cloud [2], [7], [12].

Two sets of users represent PaaS consumers. The first set represents software developers in organizations. The other set represents SaaS CSPs who needs to focus on Software development and services quality [7].

### A. PaaS Challenges

The use of CC in general provides speed and flexibility to organization. On the other hand, cloud raises challenges in terms of quality and security [4], [11]. When PaaS is evaluated by organization for production and business operation, security and QA are two significant adoption factors. Service Level Agreement (SLA) is one of the solutions that was studied in several papers [2], [16]. Service level quality is measured based on Service Level Objectives (SLOs). Service Level Agreement (SLA) grants SLOs based on contractual agreement between the service provider or a broker and the customer [2]. Sequence of events and logs of security control and QA must be forensically sound and reliable in case of a security incident or PaaS failure [1]. Under PaaS service model, wide varieties of technologies exist [4]. Spe-

This work was sponsored by Computer Operations Department, Aramco.

cific applications in PaaS are based on distributed computing. Managing the dependency between distributed components is complex [10].

### B. PaaS Automation

Application deployment automation is enabler for PaaS [6]. Automation performance can be evaluated qualitatively or quantitatively [5]. Operation automation approaches were classified into infrastructure management, plan-based configuration management, image-based configuration management, model-based management and platform centric management automation [9]. Automation of middleware and application deployment should be decoupled from Infrastructure layer. Encapsulating applications in virtual images reduces the flexibility of updating applications over time [6].

Automation standardizations; such as Topology and Orchestration Specification for Cloud Applications (TOSCA); are emerging. TOSCA has relatively small community. Released automation artifacts are limited [9], [15], [17].

## III. DATA COLLECTION

Standards in PaaS are emerging. Security and quality control processes in this context are under development. In this research project, efforts were devoted to build a MS for PaaS that is suitable for organization mission critical operations.

### A. Research Methodology

Delphi approach was followed to collect data and feedback from Information Technology experts within private cloud provider organization. The first round was started after building PaaS automation system without quality and security control in a dedicated computing lab environment. Several Automation scenarios were tested to deploy Database and

application servers, and to manage their lifecycle in PaaS context. Feedbacks from IT security team, datacenter infrastructure team and middleware operation team were collected.

Based on the feedback from the experts, the system was customized with control measures to control the execution of operating system (OS) privileged activities. The measures comprised providing central management of executing privileged commands and logging the activities on central server.

The second round of data collection was started after experimenting the control measures highlighted above. The teams in the previous round were approached to provide their feedbacks after implementing the updates and testing PaaS automation within the same organization.

The third round of data collection was triggered after summarizing experts' feedback and sharing the results of the second round with all participants. The proposed system in this paper was designed and built to address security and quality requirements. In this round, the design was shared with experts for their feedback. Based on their feedback, enhancements were added and final green light was received from experts to build the system for production operation.

### B. Data

Critics were received during the first and second round. Table I provides PaaS automation critics summary. The proposed design in the next section was developed based on the critics and the requirements gathered during the first and second rounds of Delphi process. The design was drafted during the third round of Delphi process. Minor updates were added to the system design in this round. Final design was validated through experiment.

TABLE I.  
SUMMARY OF CRITICS AND EXPERIMENT FINDINGS

#	Critic	Experiment Findings
1	Automation of application platforms is not reliable. Automation quality is low and cannot be used for mission critical systems.	Quality Assurance (QA) should be integrated in the process of PaaS automation development. The design includes lab environments to simulate scenarios and minimize the likelihood of failure. Control measures are added in the system to prevent direct update in production.
2	If automation is doing everything, labor will lose the technical skills and know how.	With new technologies, a shift in labor skills is required. The experiment findings related to this critic are summarized in Analysis and Discussion section.
3	The cost of building PaaS and the required automation is high.	Financial Return on Investment analysis is required to calculate cost against expected return. High level analysis is provided in Analysis and Discussion section.
4	Update of policies and procedures of managing and operating application platforms is required.	This is confirmed in the experiment. The update was mandatory to accommodate PaaS objectives.
5	Automating the deployment of applications involves multiple functional groups in Information Technology department.	The proposed design in this paper addresses Segregation of Duties (SoD) requirements. SoD is leveraged in the design to increase the level of automation quality and security.
6	Automation management server is empowered with privileged accounts and connected to applications and infrastructure components across the organization.	The design provides control for the privileged accounts. The power of PaaS production Orchestrator (PO) was contained by limiting the set of allowed operations. The system securely manages the distribution of automation artifacts. Unauthorized updates are detected by dual integrity control subsystem.
7	Specific experts expressed their ability to achieve the same results with traditional scripting approaches done at OS level.	Acceptable level of quality and security to implement mission critical PaaS is achieved in this experiment. To validate the claim, different approaches and designs should be experimented and compared objectively in future work.
8	Application platforms are updated regularly with new features, security and bug fixes. There is an overhead of keeping track of changes and updating automation.	A balance should be established between the value of update and automation development cost. Image based and plan based automation approaches were experimented. After the deployment of an older version, plans are executed to roll forward the platform to the required release.

#### IV. PROPOSED CONTROL DESIGN

In this section, quality and security management design for PaaS is provided. The design is divided into five layers based on roles and responsibilities to achieve the required quality and security control.

##### A. Layered Management System

The MS consists of Security Audit Layer, Infrastructure as a Service (IaaS) Management Layer, PaaS Management Layer, PaaS Automation Developer Layer and PaaS Consumer Layer. Segregation of Duties (SoD) concept is implemented to maximize security and quality control in mission critical systems without losing the opportunity of automating their deployment and routine operational activities. The five layers are reflected in Fig. 1.

Security Audit Layer includes Privileged Activities Management, Security Policies and Security Events systems. Security policies contain Delegated Privileged Commands (DPC)s which give delegate groups the authority to execute privileged commands. IaaS Privileged commands are executed in a controlled approach. First of all, IaaS administrator assess the impact of delegating and automating the command or infrastructure operation. Once assessed and approved, Security Analyst registers them and assigns them to a delegate group in a security policy within Security Audit Layer. Thereby, the infrastructure operation is utilized at PaaS layers as a self-service. Privileged Activities Management server enables a secure and central management of privileged commands. Security Events database logs the usage of DPCs remotely.

IaaS Management Layer is where infrastructure resources of the cloud are managed. Infrastructure resources include hypervisors, bare metal hosts, storage systems and network components. IaaS administrator manages this layer. His activities as a super user are controlled by Privileged Activities Management server. IaaS resources deployment and management are orchestrated by central IaaS orchestrator tool.

The third layer is PaaS Management Layer. This layer consists of PaaS Development Orchestrator (DO), PaaS Production Orchestrator (PO) and shared storage called Platform Images (PI). PaaS administrator manages these components to automate the deployment and management of PaaS applications. He also manages containerization platforms in contrast to hypervisors which are managed by IaaS administrator. PaaS DO consists of an application server and OS level Development Area. The application server is used to model PaaS automation processes by PaaS developer. It is also integrated with lab resources to conduct QA tests by PaaS developer in the next layer. Development Area is used to build OS level artifacts. The Orchestrator orchestrates PaaS automation in labs and provides pooling capability to logically isolate lab resources based on projects. Automation is developed and simulated in isolated environment before deploying it in production to verify security and quality. PaaS PO is generally similar to the DO. PO is connected to consumer assigned tenants and resources.

PI storage in PaaS Management Layer consists of Development Engine, Production Engine, Distributor, Repositories, Images and Shipment areas. PI storage is mounted in all PaaS resources. Development and Production Engines store automation artifacts. In order to release new automation artifacts from PaaS Development Area to Development Engine, Delegated Privileged Commands are used. PaaS Developer is delegated to update Development Engine using pre-approved delegated commands. These delegated commands verify integrity and analyze automation run time requirements. In addition, release event and content of developed artifacts are reflected in the Security Events system. The deployment to Production Engine is also protected. Only PaaS administrator is delegated to deploy through DPCs. This is enforced to verify the quality of automation before deploying them for production use.

The fourth Layer of the MS is PaaS Automation Developer which controls the development and QA of automation associated with PaaS. The control is enforced by system design. Developer cannot update a production artifact directly. Artifact represents automation logical unit. PaaS automation developers are PaaS automation experts who understand the requirement to deploy and manage applications' platforms.

The fifth layer is PaaS Consumer Layer. PaaS consumer can be SaaS service provider or Organization software developer [7]. PaaS consumer consumes PaaS automated services on his assigned resources through PO.

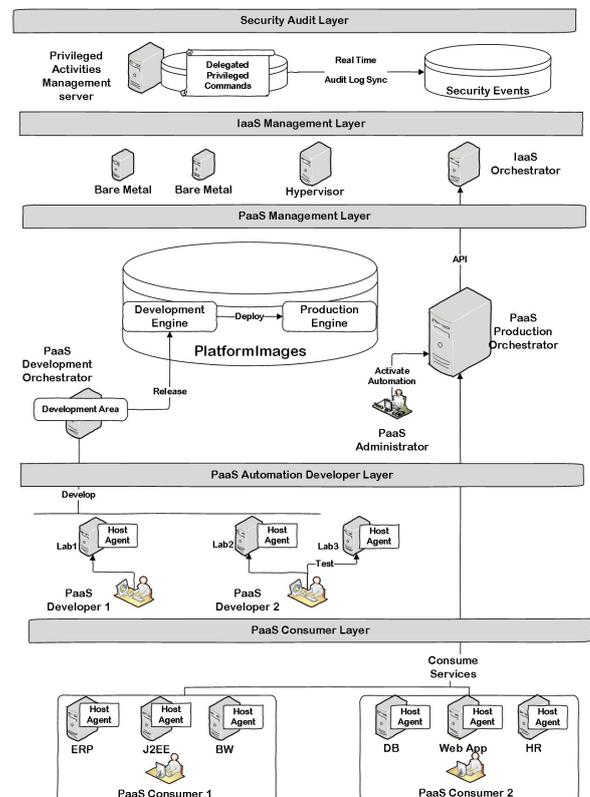

Fig 1. PaaS Management System

## V. EXPERIMENT

The design was internally validated through experiment. It was implemented in a private CC data center.

### A. PaaS Layers

PaaS orchestrators in PaaS Management Layer are implemented on Java platform with web user interface. Orchestrators are installed on LINUX OS. PI storage is based on Network Attached Storage (NAS). NAS is mounted with read only permissions on Developer and Consumer layers while it is mounted with write permissions on PaaS Management layer. This provides an additional layer of control at storage layer to prevent unauthorized update from a random cloud host. Lab in PaaS Automation Developer Layer consists of 14 servers and is divided into pools to simulate production environment and isolate developers' environments. A total of seven PaaS automation developers worked on the lab environment during the experiment. The developer models and defines automation processes to execute artifacts on the target managed cloud servers. Deployment of database, application server and web application server was simulated. Plans and artifacts were developed to patch and update middleware, database systems and application run time environment in PaaS.

PaaS Consumer Layer consists of 26 tenants hosted in 219 servers provided by IaaS layer. The hosts are integrated with PaaS PO through Host Agents (HA).

HAs are required by PaaS Automation Orchestrator in this MS. Secure HyperText Transfer Protocol (HTTPS) is used for the communication between PaaS Orchestrator and PaaS cloud resources. HAs are started automatically during the booting process of the servers and run with IaaS privileged accounts in the managed consumer servers. The agents digitally trust the orchestrator. Automation artifacts are whitelisted through definitions in the HAs. By that, HAs provide additional layer of control on cloud hosts.

### B. IaaS Management and Security Audit Layers

In IaaS Management Layer, 90% of servers are virtual and managed by hypervisor. The remaining 10% includes bare metals. The bare metals host web applications and multi-tenant platform containers in the experiment. During the provisioning process of an IaaS server, HA is installed automatically as a sub-provisioning plan and PI NAS is mounted automatically. Artifacts definitions in Production Engine are reflected in the HA to achieve automated and direct integration with PaaS orchestrator.

In Security Audit Layer, security policies for DPCs were created. The policies are assigned to PaaS developers and PaaS administrators based on roles. DPCs include PI management commands to add new components or definitions, commands to deploy from Development Engine to Production Engine, and commands to rollout automation definitions from Engines to Cloud HAs. Contents of automation artifacts and definitions are written to Security Events database during the release, deploy or rollout of these automation units. Management of HAs is also achieved securely using

DPCs by PaaS administrator. Events at HAs are monitored and logged in Security Events subsystem.

## VI. ANALYSIS AND DISCUSSION

In this section, critics collected as part of Delphi process are analyzed based on experimental observations. The experiment was conducted in CSP organization. Organizational factors may impose threats to the internal validity of the experiment such as management support and sponsorship.

Critic number one is related to the perceived service quality. PaaS automation cannot be guaranteed by 100% as observed in experiment. QA should minimize the probability of automation failure. Automation developer support is required to fix automation failure based on SLAs.

With respect to critic number two, the following was observed. PaaS automation requires deep understanding of how a platform is deployed and managed. PaaS automation developer needs to consider possible failure scenarios. These scenarios are simulated in lab. PaaS automation developer needs to be an expert in the platform being automated. After the deployment of PaaS automation, the developer is needed to troubleshoot, optimize and fix issues. Upon the release of a new platform version or patch, developer needs to review and update automation. In the experiment, modularity and reusability approaches were adopted. Based on observation, labor technical skills about application platforms were enriched. There was a shift in the type of work being done by the labor. Instead of doing a deployment task manually and sequentially, the work is shifted toward platform deployment automation analysis, PaaS automation development, PaaS automation QA, and PaaS automation lifecycle management. Throughput of one technical labor is increased.

Critic number 3 is related to the perceived relative advantage. Database platform deployment automation was analyzed from human hours' perspectives. To deploy 100 database systems manually, labor needs to work sequentially. Deployment of one database system manually requires 4 hours of work in average. In total, 400 human hours are required to deploy 100 servers. On the other hand, development and QA of automating database system deployment requires an average of 80 hours based on the study experiment. The created value is extended with the deployment of more servers while the initial investment cost from the CSP is the same. Breakeven is achieved after the deployment of the 20th database system. Additional benefit beside human hours saving include service agility. Deployment of the server automatically was done in less than 30 minutes. On the other hand, cost of operating PaaS MS should be considered. In addition, customer support service is required in case of automation failure. Accordingly, financial feasibility study is required to measure return on PaaS automation investment.

Critic number 4 is related to PaaS compatibility with the organization. Policies and procedures were updated to achieve the experiment in the organization. An example for that is handling the use of root user which is a privileged account at LINUX OS system level. By focusing on the com-

mon goal of providing competitive and secure services to customers and with organization management support, legacy policies were updated to fit with the proposed PaaS MS.

Critic number 5 can be related to organization size. The experiment was conducted in organization where OSs, database systems and application servers are supported by different functional units. Each team has a set of privileged accounts to manage its services. In the experiment, it was found that deployment of database requires OS and database privileged accounts. The proposed design described above resolved SoD issues associated with the use of privileged accounts owned by different functional group.

Critic number 6 involves the perceived security risk of PaaS. The unlimited power of PaaS Orchestrator was controlled using the proposed MS. Only authorized artifacts are allowed to be executed by the Orchestrator. Authorization is achieved through the definitions in the HAs. The distribution of definitions from PI to HAs is achieved securely by the MS. Integrity of the definitions and the associated artifacts is monitored through Dual Integrity check subsystem.

With respect to critic number seven, it is not believed that the proposed solution in this paper is the only possible management solution for PaaS. However, different solutions can be proposed and evaluated. Comparison between systems can be discussed in future research papers.

With respect to the last critic, it was confirmed in the experiment that there is an overhead of maintaining application platforms delivered by PaaS. In the experiment, flexibility, reusability, complexity and dependency automation properties [5] were incorporated in automation development to minimize the maintenance overhead. Modular and reusable components represent the logical units of PaaS automation plans. Parameter can be passed to these reusable units to control the use case. Also plan based automation and image based approaches were utilized. By that, a base image of the platform is maintained. Then, new functions, updates and patches are added to the platform using plan artifacts to roll-forward the platform to the desired version.

## VII. CONCLUSION

Based on this study, managing mission critical systems in private PaaS Cloud is practical. The study revealed PaaS adoption factors which can be categorized into organizational, relative advantage, compatibility, security and quality factors. Organizational, compatibility and relative advantage factors are analyzed in the previous section. Security and quality technological factors are incorporated in the MS model and experimented. The proposed model is considered a novel MS for CSPs aiming to provide high level of security and quality standards. The study also gives PaaS cloud users an understanding of how systems can be managed internally by CSPs which should lead to better SLAs in the future.

Comparison with other models and technologies can be done in future research. It is also suggested to validate the model under public cloud and examine the forensic aspects.

# Project Management Tasks in Agile Projects: A Quantitative Study

Gloria J. Miller

Managing Consultant  
maxmetrics

Heidelberg, Germany

<https://orcid.org/0000-0003-2603-0980>

**Abstract**—Recent studies have confirmed the efficacy of agile methodologies in project success. However, can projects skip several project management tasks and still deliver the expected results? How are traditional project managers engaged in agile projects? The results from this study quantify subjective and theoretical speculation on who performs the project management tasks in agile projects. Project managers are engaged in agile projects and the team, the product owner, and project sponsor are significantly involved in project management tasks. The agile coach is not a substitute for the project manager. The study identifies that agile and traditional methodologies should be updated to clarify team, product owner, and agile coach responsibilities.

## I. INTRODUCTION

WHILE the adoption of agile project management methodologies is widespread [1], the project management tasks in agile projects are uncertain and the lack of clarity is causing confusion in practice [2, 3, 4]. Agile methodologies provide events, processes, and artifacts that should allow projects to be flexible to change and deliver results in an iterative, incremental fashion. Some of the most popular agile project management frameworks, such as scrum, extreme programming (XP), and lean/kanban processes do not explicitly include a project manager role or project management tasks. For example, scrum includes three roles: a scrum master, product owner, and the team.

Hobbs and Petit [4] identified 827 articles that compare or integrate agile project management with project management practices. However, not once did the research reference the effect of agile methodologies on the project manager role. Other agile research recognizes the confusion and conflict caused by the lack of recognition of the project manager in agile methodologies [5]. There is some speculation that the project manager is better suited to take over the product owner role [2] than the agile coach. While other research starts with the premise that there is an agile project manager who is a facilitator or coach [6, 7, 8, 9]. Even the *Agile Practice Guide* issued by the Project Management Institute (PMI) in 2017 states that the “role of the Project Manager in an agile project is somewhat unknown” [10, p. 37]. In agile methodologies, some but not

all of the typical project management responsibilities have been distributed to other roles [9].

The success rate for agile methodologies is on par with, if not better than, those managed under a traditional methodology [1]. Thus, if agile methodologies are followed rigorously and exclude a project manager, then maybe the project manager role and some project management tasks are obsolete. Shastri, Hoda and Amor [11] found that the project manager role does still exist in agile projects. However, the study left open the questions for why and what activities the project manager performs. “The implementation of agile methods can have a very significant impact on the role of the project manager, but a better understanding of the circumstances under which the project manager role changes and how it changes is needed” [4, p. 11]. Other studies have investigated agility in projects or the effects of specific practices on the success of projects applying agile methodologies [1, 12, 13, 14]. Nevertheless, the topic of who performs what project management activities in agile projects remain unanswered. Specifically, *how are traditional project managers engaged in agile projects? Who executes what project management tasks in projects applying agile methodologies?*

First, we review the literature for understanding agile methodologies and the roles and tasks involved in the project work using agile and plan-driven methodologies. We map the responsibilities from an agile methodology to the project management knowledge areas and processes from the International Organization for Standardization (ISO) project management standard. Then, we define and conduct a survey to understand what roles perform which project management tasks. Finally, we quantitatively analyze the survey results and answer the research questions.

The results from this study quantify subjective and theoretical speculation on who performs the project management tasks in agile projects. The results contribute to the project management knowledge on agile methodologies by widening the perspective on the role of people, specifically the project manager, in agile projects. The next section reviews the literature and describes the research methodology, results, and discussions. The final sections of the study discuss the conclusions and implications.

## II. LITERATURE REVIEW

Traditional, waterfall or plan-driven methodologies follow a stage-gate or phased lifecycle. These methods have in common the creation of an upfront plan, where the time is limited with the limitation and termination conditions known from the beginning [15]. The methodologies and frameworks for traditional projects are codified in the project management standards and frameworks, such as “ISO 21500:2012, Guidance on Project Management” [16], *APM Body of Knowledge 6th Edition* [17], and *A Guide to the Project Management Body of Knowledge (PMBOK guide)* [18].

The *Agile Manifesto* is a set of four values and 13 principles that provide a framework for managing technology projects in a flexible way that responds to dynamic project situations [1, 19, 20]. There are at least 13 methodologies or frameworks that can be considered to follow the values and principles described in the *Agile Manifesto*. Each agile methodology has its own set of roles, rules, events, and practices; however, in general, they encourage iterative and incremental development life cycles, self-organizing teams, and evolutionary product development. Scrum, XP, lean, and Kanban are the most frequently referenced agile frameworks in surveys on agile adoption and in the project management literature [11].

The project manager is the authorized person who leads and manages project activities and is accountable for project completion [21]. The role is defined in ISO, APM, and PMI project management standards and frameworks. In addition, the standards describe knowledge areas that are expected of a project manager and processes that should be led or executed as part of managing a project. The project management literature agrees that the project manager has the sole responsibility for planning and managing projects [21]. The project manager should direct the performance of the planned project activities and manage the various technical, administrative and organizational interfaces within the project [16, 18]. The project manager role is not explicit in the agile methodology. Noll, Razzak, Bass and Beecham [2] found that the scrum master, a coaching role in the scrum agile methodology, combines project management activities in practice. However, there was tension created since the scrum master should balance management activities with coaching the team. The inherent suggestion in studies about project managers in agile projects is that the leadership style or skills, knowledge, personal attributes and behavior of the project manager must be adapted [8, 9, 22, 23].

There are 39 processes in 10 subject areas that cover five process groups described for the project management role in the ISO project management standard [16, 20]. The principles and values from the *Agile Manifesto* offer a framework on how people should work [20]. Consequently, the manifesto does not explicitly establish who should do the work. Binder, Aillaud and Schilli [20] correlated the 12 agile principles to the ISO processes to establish a hybrid model for managing agile projects. They identified gaps and

practice modifications that would have to occur to effectively manage agile projects.

Project management success evaluates performance against the time, budget, and quality constraints of the project, also known in modern terminology as project efficiency [1]. Agile projects have been shown to have similar performance as traditional methodologies for project efficiency [1]. Nevertheless, the only success measure given for agile projects is working software [19].

The project management tasks in plan-driven methodologies are centralized to the project manager role. For agile methodologies, some of the project management responsibilities are inherent in the methods, while the project management activities or tasks are not explicitly identified. Studies on project managers in agile projects have identified conflicts with other agile roles or assume project manager must adapt to manage agile projects.

## III. METHODOLOGY

The research used a literature review to define the project boundary and project management authority, tasks, and roles in projects using plan-driven or agile methodologies. Peer-reviewed journal publications from 2006 to 2018 were evaluated to identify project managers activities in agile projects. A web-based survey was used to collect data on the roles engaged in projects and the project management tasks they perform. A quantitative analysis method was used to explore the difference between the theoretical and practical applications of project management tasks.

The survey sample comprised 120 usable responses as follows: 33% of the respondents had a project manager role; 11% were program managers; 9% were from a project management office; 9% agile coaches or scrum masters; 8% product owners; 24% project team members from IT, business, software vendors, or others not in the selection list; 3% project sponsors, and less than 2% others. The organizations sponsoring the projects were spread throughout 20 different industries. The participants were balanced across geographic regions: Europe (25%), Asia (19%), Latin America, and the Caribbean (18%), North America (16%), and Oceania (3%). Most of the projects started in the last five years (81%), lasted more than one year (56%), and had less than 21 team members (81%).

The SAS Studio (Release 3.6, basic edition) was used to perform the statistical analysis and produce the tables and figures. The responses were checked for scope, completeness, consistency, ambiguity, missing data, extreme responses, outliers, and leverage. No bias was found, and the data were reliable and valid. The number responses is comparable with other agile studies: [9] with 20 agile practitioners, and [11] with 97 and [6] with 32 survey respondents. Thus, the data were considered valid for further analysis. The descriptive statistics, mean ranking, Wilcoxon score, and correlation analysis were used to explore the characteristics, establish the validity and reliability, and explain the relationship between the variables. The descriptive statistics provide insight into the content and

structure of the projects, the involvement of the different project roles, and the relationship between the involved roles and the methodology. The hypothesis testing uses regression analysis to explain the relationships between the roles that performed project management tasks and project efficiency.

#### IV. DATA ANALYSIS AND RESULTS

The analysis was performed for the four topic areas of project efficiency, methodology, roles, and tasks. Table I includes the mean comparison between methodology types; significant differences are based on the Kruskal Wallis being less than .05 for 95% confidence. Project budget, time, and quality performance were combined into a single project efficiency variable by taking the mean value of the variables. There is no significant difference between the composite *project efficiency* measure or the individual performance measures by methodology type. Different than some other research, the mixed and plan-driven methods have a higher mean than the agile methods [1].

Scrum and waterfall are the top methodologies at 22% and 20%, respectively. From the agile methodologies, scrum combined with the scrum/XP is the most widely used at 24%. This is consistent with other studies that found scrum to be the most popular agile methodology and agile methodologies are in wide-spread use [1, 11]. The methodology types and methodologies were not significantly correlated with any of the individual performance measures or the project efficiency factor.

The project manager role was involved in 67% of the projects, including 58% of the agile projects, 82% of the mixed methodology projects, and 79% of the plan-driven projects. The agile coach role was included in 35% of all projects and the product owner role in 42% of all projects. There was no significant difference between methodologies for the other roles. The agile coach, product owner, and team combination – a full scrum team – was not present in all scrum-related projects. This implies that the scrum methodology is not being rigorously applied in practice. The project manager was more prominent in the plan-driven and mixed methodology, and the agile coach and product owner were more prominent in the agile methodologies. Otherwise, there was no significant difference in the roles between methodologies.

Project management tasks are performed in all types of methodologies with no significant difference. Overwhelmingly, the project manager is responsible for the project management tasks in all types of methodologies. This involvement is significant for managing the team and stakeholders, identifying risks, establishing the team, and controlling resources. On the other hand, the team is more often identified as being involved in assessing, treating, and controlling risks in plan-driven methodologies, while it is more often the product owner in agile methodologies. The product owner is strongly represented in managing stakeholders. The team and agile coach are not significantly engaged in this task. The project team is involved in

procurement in plan-driven methodologies and not at all involved in agile methodologies.

Fig. 1 combines the qualitative results from the literature review with the quantitative results and provides a consolidated view of project management responsibilities for agile projects. The rows represented the 39 ISO processes grouped into the 10 ISO subject areas, the columns represent the method or the project roles considered in the study, and the color represents the relative degree the processes are executed. For example, the integration subject area includes 6 processes: 2 map to 2 agile principles, 4 to 1 principle, and 1 does not map to any principles. The agile coach role maps to 3 processes for the subject area, the product owner to 2, the team to 3, the project manager to 6, and the sponsor to 1.

#### VI. DISCUSSION

First, while agile project methodologies are popular; nevertheless, traditional methodologies continue to be in widespread use. No matter the methodology, the project management tasks as identified in the ISO standard for managing projects remain relevant. Project managers are engaged in agile projects to a larger degree than agile coaches or product owners. Project managers continue to perform management tasks and not only act as a “gatekeeper” as described by Taylor [3]. In this study, the sponsor and product owner undertook some management activities, while the agile coach did not. Thus, this partially supports the proposition by Noll, Razzak, Bass and Beecham [2] that assigning a former project manager to the product owner role rather than the scrum master role will result in a higher degree of project success. In practice, the project manager focuses on team management and risk identification

tasks, while the product owners focus on the scope and stakeholder management. The product owner is responsible for the scope before the project start, during the project, and after the project is completed. A project manager is a transitory role and is not typically engaged in the market and withdrawal phases of a product lifecycle. Stated differently, the boundary for the product owner is the product features, while for the project manager, it is the project processes. Thus, the pairing of sponsor and product owner is a logical for the long-term product success and the sponsor and project manager for short-term project success.

From the study, it was clear that the agile coach has a much more limited set of tasks than the project manager. A sizable percentage of projects succeeded without an agile coach. The agile coach has two primary responsibility areas: developing the team and supporting all stakeholders to understand and apply the methods. In this regard, the management style suggested for an agile coach is that of a good leader, facilitator, or coach [22]. This corresponds with studies that argue project managers that can practice a facilitator leadership style could lead agile projects [8, 9, 22, 23]. However, the finding by Noll, Razzak, Bass and Beecham [2] that there is likely to be conflict within the project related to the delegation and management styles required by the different sets of responsibilities is a valid reason to separate the project manager and coaching roles. Furthermore, the results show that the agile coach was relevant to project efficiency but not to any of the project management tasks under investigation.

## VII. CONCLUSIONS

The tasks that would typically be carried out by a project manager continue to be practiced while they are not (explicitly) addressed by the agile methodologies. The team, product owner, and project sponsors are taking on the informal role on some project management tasks; the project manager continues to be engaged, albeit with an altered task distribution and leadership style.

The practical implication is that project sponsor should consider the project manager an essential role for all project types and not assign the project management activities to the sponsor or the product owner. The agile methodology authors should update their practices to identify the role the project team takes in assessing, treating, and controlling risks and in planning and managing suppliers. Furthermore, they should reflect the project management tasks that may be outside of the team operations but necessary for project sponsors or project managers to execute. Fig. 1 provides a guideline for mapping specific project roles to project management activities. Furthermore, since the rigorous application of the method is responsible for some typical project management activities, care should be taken to consider project governance when tailoring agile methods.

The agile coach is a key role that can improve the productivity of project operations. Thus, the role should be formalized into traditional methodologies as a role separate

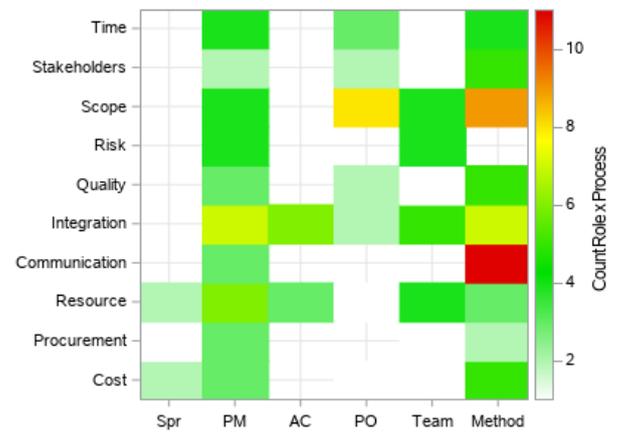

Fig 1. Heatmap of ISO process groups by scrum roles and agile methods based upon relative degree tasks, covered by the role after the analysis.

Legend: Spr-Sponsor; PM-Project Manager; AC-Agile Coach; PO-Product Owner; Method-Agile Principles

from the project manager. Finally, researchers on agile methodologies should consider the participants within the projects in future studies. We determined that less than half the projects following a scrum methodology consist of all the scrum roles. Thus, the actual results from project studies may inappropriately contribute the successful outcomes to the methodology.

The results from this study quantify subjective and theoretical speculation on who performs the project management tasks in agile projects. The results of this study contribute to the project management knowledge on agile methodologies by widening the perspective on the role that people, specifically the project manager. Although agile methodologies are in widespread use, this information was missing in practice and under-researched in academia. Conversely, the research is limited in several ways. The results of this study are not generalizable beyond the methodologies studied in this research; specifically, software development projects have been the most active in applying agile methodologies. There were no measures to determine whether the project type skewed or biased the results. The research did not have financial or factual data to measure performance. Thus, it could only evaluate the perception of project performance as judged by the participants. Furthermore, the findings are limited due to the small sample size. Future research could focus on a qualitative study of the agile project organizations or seek to quantify the engagement of the separate roles.

# 25<sup>th</sup> Conference on Knowledge Acquisition and Management

**K**NOWLEDGE management is a large multidisciplinary field having its roots in Management and Artificial Intelligence. Activity of an extended organization should be supported by an organized and optimized flow of knowledge to effectively help all participants in their work.

We have the pleasure to invite you to contribute to and to participate in the conference "Knowledge Acquisition and Management". The predecessor of the KAM conference has been organized for the first time in 1992, as a venue for scientists and practitioners to address different aspects of usage of advanced information technologies in management, with focus on intelligent techniques and knowledge management. In 2003 the conference changed somewhat its focus and was organized for the first under its current name. Furthermore, the KAM conference became an international event, with participants from around the world. In 2012 we've joined to Federated Conference on Computer Science and Systems becoming one of the oldest event.

The aim of this event is to create possibility of presenting and discussing approaches, techniques and tools in the knowledge acquisition and other knowledge management areas with focus on contribution of artificial intelligence for improvement of human-machine intelligence and face the challenges of this century. We expect that the conference&workshop will enable exchange of information and experiences, and delve into current trends of methodological, technological and implementation aspects of knowledge management processes.

## TOPICS

- Knowledge discovery from databases and data warehouses
- Methods and tools for knowledge acquisition
- New emerging technologies for management
- Organizing the knowledge centers and knowledge distribution
- Knowledge creation and validation
- Knowledge dynamics and machine learning
- Distance learning and knowledge sharing
- Knowledge representation models
- Management of enterprise knowledge versus personal knowledge
- Knowledge managers and workers
- Knowledge coaching and diffusion
- Knowledge engineering and software engineering
- Managerial knowledge evolution with focus on managing of best practice and cooperative activities
- Knowledge grid and social networks

- Knowledge management for design, innovation and eco-innovation process
- Business Intelligence environment for supporting knowledge management
- Knowledge management in virtual advisors and training
- Management of the innovation and eco-innovation process
- Human-machine interfaces and knowledge visualization

## EVENT CHAIRS

- **Hauke, Krzysztof**, Wroclaw University of Economics, Poland
- **Nycz, Malgorzata**, Wroclaw University of Economics, Poland
- **Owoc, Mieczyslaw**, Wroclaw University of Economics, Poland
- **Pondel, Maciej**, Wroclaw University of Economics, Poland

## PROGRAM COMMITTEE

- **Abramowicz, Witold**, Poznan University of Economics, Poland
- **Andres, Frederic**, National Institute of Informatics, Tokyo, Japan
- **Bodyanskiy, Yevgeniy**, Kharkiv National University of Radio Electronics, Ukraine
- **Chmielarz, Witold**, Warsaw University, Poland
- **Christozov, Dimitar**, American University in Bulgaria, Bulgaria
- **Jan, Vanthienen**, Katholike Universiteit Leuven, Belgium
- **Mercier-Laurent, Eunika**, University Jean Moulin Lyon3, France
- **Sobińska, Małgorzata**, Wroclaw University of Economics, Poland
- **Surma, Jerzy**, Warsaw School of Economics, Poland and University of Massachusetts Lowell, United States
- **Vasiliev, Julian**, University of Economics in Varna, Bulgaria
- **Zhu, Yungang**, College of Computer Science and Technology, Jilin University, China

## ORGANIZING COMMITTEE

- **Hołowińska, Katarzyna**
- **Przysucha, Łukasz**, Wroclaw University of Economics

# Analysis of Relationship between Personal Factors and Visiting Places using Random Forest Technique

**Abstract**—There has been research regarding relationship between human personalities and visiting places using Big Five Factor (BFF). However, other factors such as Social media usage, Hobby, Gender, Age, and Religion and so on are regarded as also major factors which effects the choice of visiting place of a person. Using questionnaire designed by authors, these factors as well as BFF were prepared for this research. The visiting places were collected by a smartphone app called SWARM and classified in 10 categories. In sum, personal data of 34 participants had been collected for several months. To figure out the relationship between these factors and visiting places, random forest technique of ensemble method was used.

## I. INTRODUCTION

PRIOR researches show that human personality and favorite visiting place have considerable relationship [1] [2] [3] [4]. However, there has been long belief that other than personalities, personal factors effect the selection of visiting location. To prove this belief, we collected personal factors other than personality from survey. Gender, Age, Marital Status, Religion, Salary, Vehicles, usage of SNS, Job, Educational Level, Frequency of travel for a year, Time spent on SNS per day, sort of hobby. Using Big Five Inventory (BFI), we collected person's Big Five Factor (BFF) Total 34 participants provided their personal data and location data. To collect location data, a smartphone application called SWARM is used and the duration of collection was up to six months. The method to analyze these data is Random Forest which is ensemble learning.

### A. Random Forest

Random Forest is suggested by Leo Breiman in 2001 [5]. Random Forest shows good performance and high accuracy in general and without overfitting. It can handle many input features and resistant to noise. In addition, the degree of effect of input feature can be numerically represented as importance value. We considered Random Forest as a suitable method for our research.

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST) (NRF-2019R1F1A1056123).

### B. Big Five Factors (BFF)

BFF is a factor of personality suggested by P.T. Costa and R.R. McCrae in 1992 [6]. It has five factors of Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. Set of questionnaires is answered by participants and each five factors will be valued as a score from 0 to 5 points. Since BFF can numerically represent conceptual human personality, many of research adopts BFF [7] [8] [9] [10] [11] [12].

### C. SWARM Application

SWARM application is used to collect geo-positioning data installed on smartphones [13]. Users actively check in visited places with SWARM. These actively collected location data are used as part of our analysis.

In section II, we will discuss random forest and our purpose in this research. Section III will show details of the data. The handling of personal factors and location categories will be discussed. Section IV will show results of analysis by Random Forest and evaluate the results. Section V will conclude this research with future works.

## II. RANDOM FOREST TECHNIQUE

### A. Ensemble

Ensemble is a technique which combines various machine learning models to generate powerful model. Random Forest is a sort of ensemble technique and has decision tree as its base model. Especially, Random Forest and gradient boosting have proven as useful method for classification and regression of various data set. These two distinguished models have base element of decision tree.

### B. Decision Tree

Decision tree is a widely used model for classification and regression. Basically, decision tree is a consequence of yes-no question of leaning process toward the final decision. For example, to classify bear, pigeon, penguin, dolphin with the smallest number of questions, several sequences of question are introduced. The first question to classify two animals is: "Does it have wings?" Then the second question is: "can

it fly?" Then pigeon and penguin can be classified. In case there is no wing, the following question will be: "Does it have fin", and dolphin and bear can be separated. These questions are called as test in machine learning. And decision tree is consisted as nodes for test and edge connected to the following test. In case of machine learning, continuous values can be used instead of yes-no question. In this case, test can be in a form that is feature  $i$  bigger than value  $a$ .

### C. Bootstrap Aggregating (Bagging)

Random Forest creates bootstrap samples of data to create several independent decision trees. Bootstrap samples are random choices of data by allowing redundancy. The size of the dataset is the same as the original dataset. Some data will be missing from the bootstrap sample and some data may be duplicated [14].

The disadvantage of the decision tree is that it can be overfitted to the training data whereas Random Forest can handle this problem. Random Forest is a bundle of different decision trees. Each decision tree is relatively good at prediction but can be overfitted in the training data. However, if we create many of decision trees and average its results, the prediction performance of the decision tree can be enhanced by reducing the overfitting. In addition, each branch of the decision tree uses a subset of different features because only part of the features is used in each node. This method makes all the decision trees in the Random Forest different from each other. Random Forest predicts with results from each decision tree. For the regressions used in this study, average of each result is used to make the final prediction.

Random Forest is one of widely used machine learning algorithm with excellent performance. It is strong in noise, works well even without much hyperparameter tuning, and does not need to scale data. It also works well on very large datasets and can parallelize the train simply. It is also appropriate to deal with many input features [15]. We can also know the value importance of the input value that affects the result. Due to this advantage and performance, a Random Forest was used for this study.

## III. PERSONAL FACTORS AND LOCATION CATEGORIES

### A. Personal Factors

Many of research adopts BFF as a measure of personality suggested by McCrae and Costa. [6] The five factors are Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. Each factor are measured as numerical numbers so that factors can be easily applied to training process. Table I shows BFF of several participants. We can figure out personality of a person through these values. Person with high Openness is creative, emotional and interested in arts. Person with high Conscientiousness is responsible, achieving, and restraint. Person with high Agreeableness is agreeable to other person, altruistic, thoughtfulness and modesty. While person with high Neuroticism is sensitive to stress, impulsive, hostile and depressed. For example, as shown in table I, person 4 is creative, emotional, responsible, restraint. Also considering

TABLE I: BFF of Participants

	O	C	E	A	N
Person 1	3.3	3.9	3.3	3.7	2.6
Person 2	2.7	3.2	3.2	2.7	2.8
Person 3	4.3	3.1	2.3	3.2	2.9
Person 4	4.2	4.3	3.5	3.6	2.6
Person 5	4	3.7	4	3.9	2.8
Person 6	3.8	4	3.1	3.8	2.3
Person 7	3.2	3.2	3.5	3.3	3.5
Person 8	2.8	3.8	3.8	3.3	2.3
Person 9	3.4	3.6	3.5	3.6	3.1
Person 10	3	3.6	2.5	3	3
Person 11	4.1	3.8	3.8	2.8	3
Person 12	3.1	3	2.8	3	2.8
Person 13	3.3	3.2	3.5	2.6	2.6
Person 14	3.7	3.3	3.6	3.8	3.5
Person 15	2.4	3.7	3	2.8	2.6
Person 16	3.4	3.2	3.0	3	2.6
Person 17	3.9	3.3	3.5	2.9	2.8

TABLE II: Personal Factors: Person 1

Personal Factors	Value
Age	2
Job	1
Marriage	2
The highest level of education	2
Major	4
Religion	1
Salary	2
Vehicles	4
Commute time	3
the frequency of a year's journey	2
SNS usage status	1
Time spent on SNS per day	3
cultural life	3
Openness	3.3
Conscientiousness	3.9
Extraversion	3.3
Agreeableness	3.7
Neuroticism	2.6

person 4's Neuroticism, person 4 is not impulsive and resistant to stress. The personality shown in table I will be used our experimental basis with other personal factors.

In the table II, the number corresponding to the response is as follows:

#### Age

1: 10s, 2: 20s, 3: 30s, 4: over 40s

#### Job

1: students, 2: administrative position, 3: expert, 4: an engineer, 5: office job, 6: service, sales position, 7: a functional worker, 8: equipment maneuvering and assembly engineer, 9: simple laborer

cf. Occupational classifications include the International Standard Classification of Occupation (ISCO) [16].

**Marriage**

1: married, 2: single

**The highest level of education**

1: middle school graduate, 2: high school graduate, 3: college graduate, 4: master, 5: doctor

**Major**

1: humanities, 2: sociology, 3: pedagogy, 4: engineering, 5: nature, 6: medicine and pharmacology, 7: art, music and physical education

**Religion**

1: no religion, 2: Christianity, 3: Catholic, 4: Buddhism

**Salary**

1: Less than 500 USD, 2: 500 USD to 1,000 USD, 3: 1,000 USD to 2,000 USD, 4: 2,000 USD to 3,000 USD, 5: over 3,000 USD

**Vehicles**

1: walking, 2: bicycle, 3: car, 4: public transport

**Commute time**

1: less than 30mins, 2: 30mins to 1h, 3: 1h to 2h, 4: over 2 hours

**The frequency of a year's journey**

1: less than one time, 2: 2 to 3 times, 3: 4 to 5 times, 4: over six times

**SNS usage status**

1: Use, 2: Not use

**Time spent on SNS per day**

1: less than 30 mins, 2: 30 mins to 1 hour, 3: 1 hour to 3 hours, 4: over 3 hours

**Cultural life**

1: static activity, 2: dynamic activity, 3: both

In case of Person 1, a number of personal factors are coming from 20s, such as students, single, a high school graduate, engineering, no religion, income in 500USD to 1000USD, public transport, commute in 1 to 2hours, two or three travels per year, one to three hours spent for social media per day, and both dynamic and static cultural life.

**B. Location Category Data**

Location Category data was used as Label (target data) for the supervised learning, Random Forest. The location category data is checked in to the visiting places using the SWARM application. Afterwards, the number of visits and visiting places were identified from web page of SWARM. Part of the location data of person 16 is shown in the table III.

TABLE III: Sample Location Data: Person 16

location	Count of Visit
Hongik Univ. Wowkwan	19
Hongik Univ. IT Center	7
Kanemaya noodle Restaurant	3
Starbucks	3
Hongik Univ. Central Library	8
Coffesmith	2
Daiso	3

The data collected were classified into 10 categories. Table IV shows the classification of person 16's location data into a category.

TABLE IV: Sample Classification of Locations: Person 16

Category	location	Visiting Ratio
Foreign Institutions	0	0
Retail Business	6	0.04
Service industry	6	0.04
Restaurant	29	0.1933
Pub	2	0.0133
Beverage Store	26	0.1733
Theater and Concert Hall	4	0.0267
Institutions of Education	62	0.4133
Hospital	6	0.04
Museum, Gallery, a historical site, tourist spots	9	0.06

To input categorized location data to Random Forest, visiting ratio of location categories are used as labels. The formula is as follows.

$$Visiting\_Ratio = \frac{\text{count\_of\_visit\_to\_location}}{\text{total\_count\_of\_visits}}$$

**IV. ANALYSIS OF RESULTS**

By analyzing data using random forest, you can see value importance, which is the degree of how each feature affects the prediction. Table V shows summary of result for each Location Category such as Symmetric Mean Absolute Percentage Error (SMAPE), Accuracy and the top five feature's importance values with the most impact. Table V abbreviated location category.

**FI:** Foreign Institutions

**RB:** Retail Business

**SI:** Service Industry

**BS:** Beverage Store

**TC:** Theater and Concert Hall

**IE:** Institutions of Education

**MG:** Museum, Gallery, historical sites and tourist spots

The result of the experiment randomly selected one of the decision trees is present in Fig. 1. The unbiased and well-made decision tree is found as shown in Fig. 2 when it has label of Restaurant. Several significant value importance graphs with meaningful accuracy are also shown Fig. 3.

**A. Discussion about Low Prediction Accuracy**

First, we analyzed the reason of very low accuracy, especially for foreign institutions and hospital. This is just because of shortage of data, since most of participants rarely went to foreign instruments. A handful of people have visited international airport only once or twice while traveling abroad.

It would have been difficult to predict because the person who went to foreign institutions lacked data. Hospital shows similar situation. Hospital is not a place to go by a person's

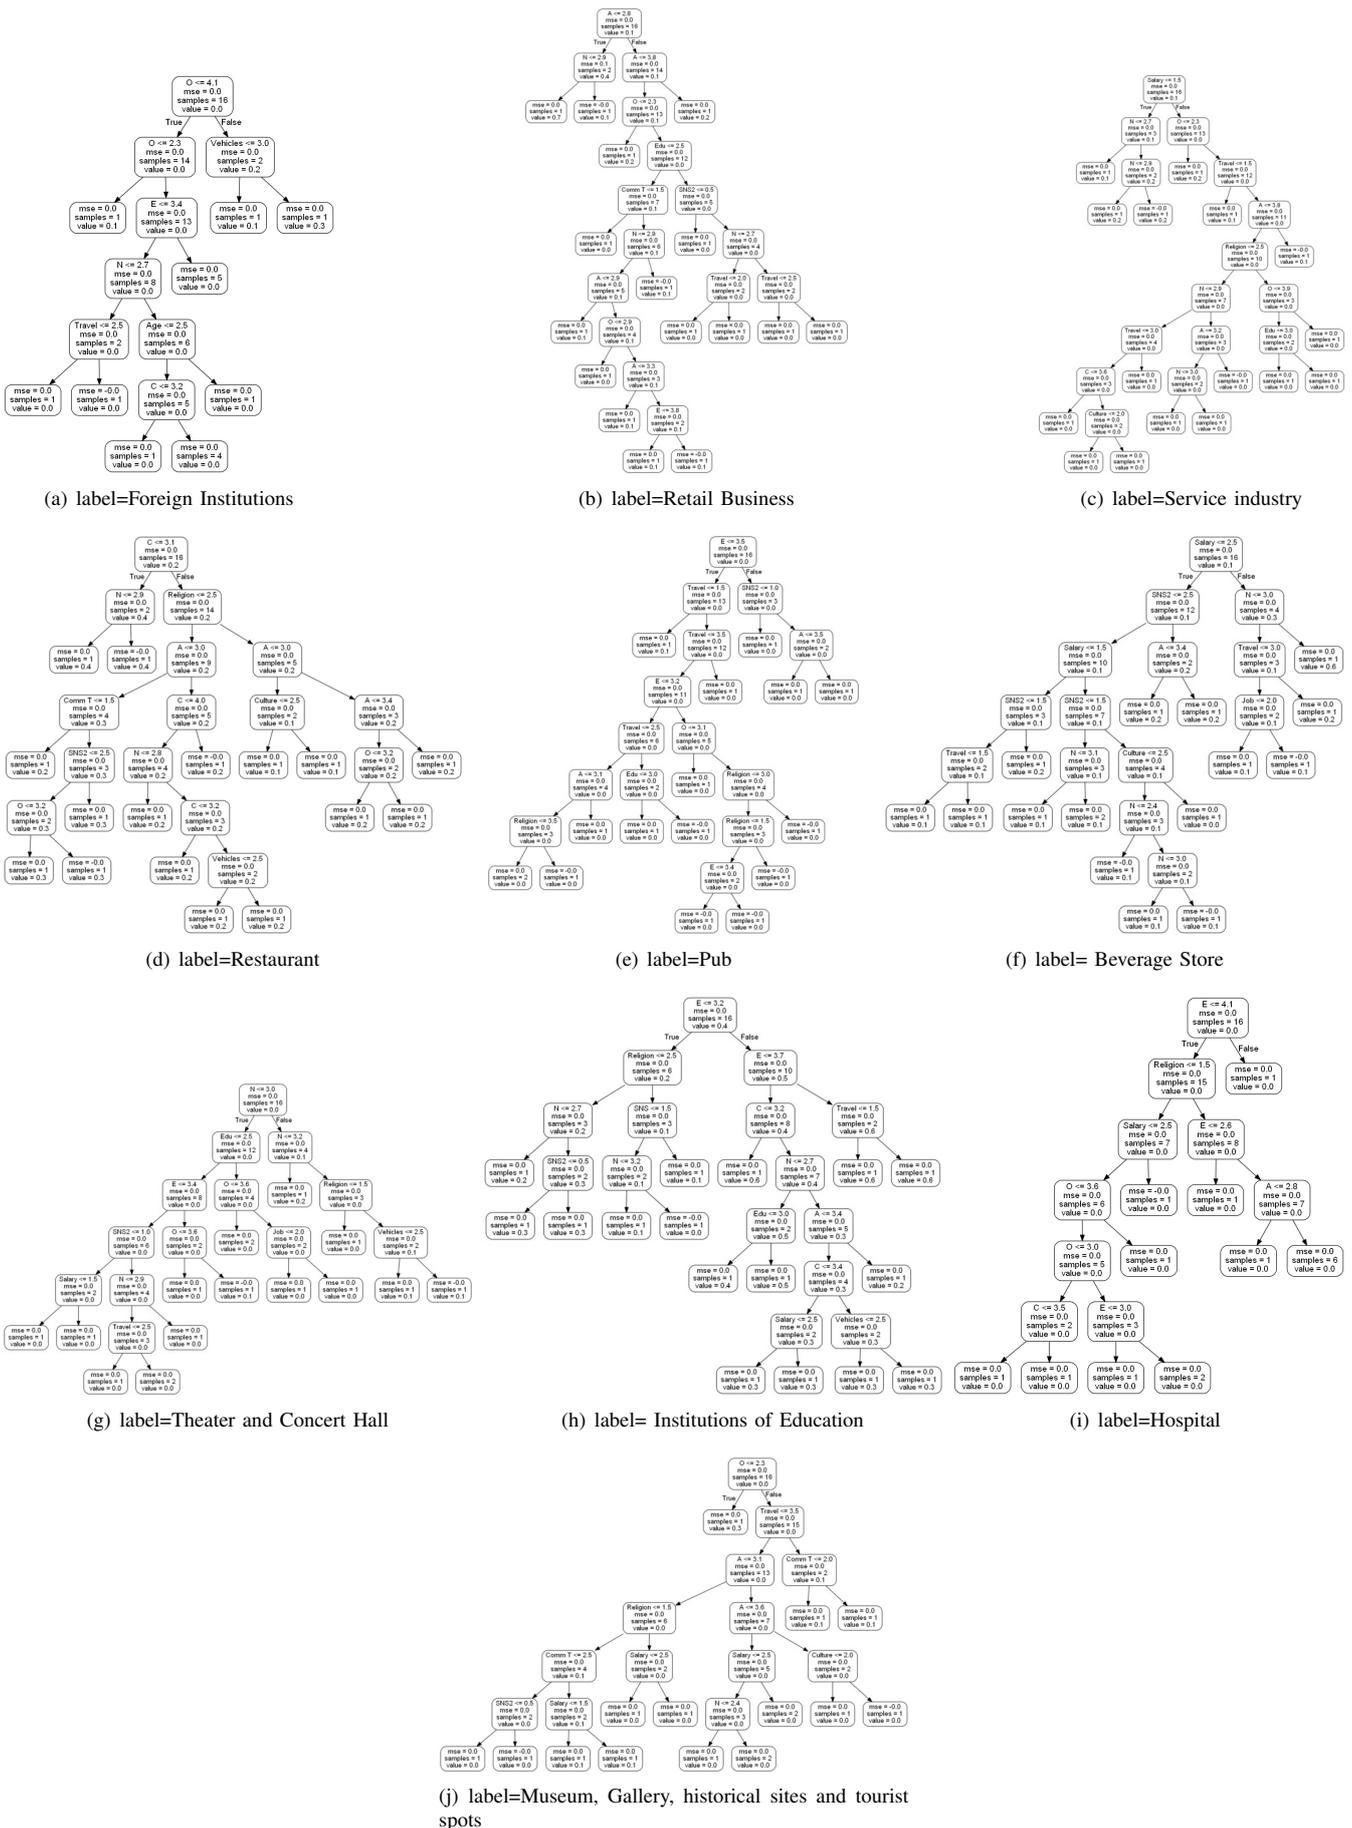

Fig. 1: Decision Tree

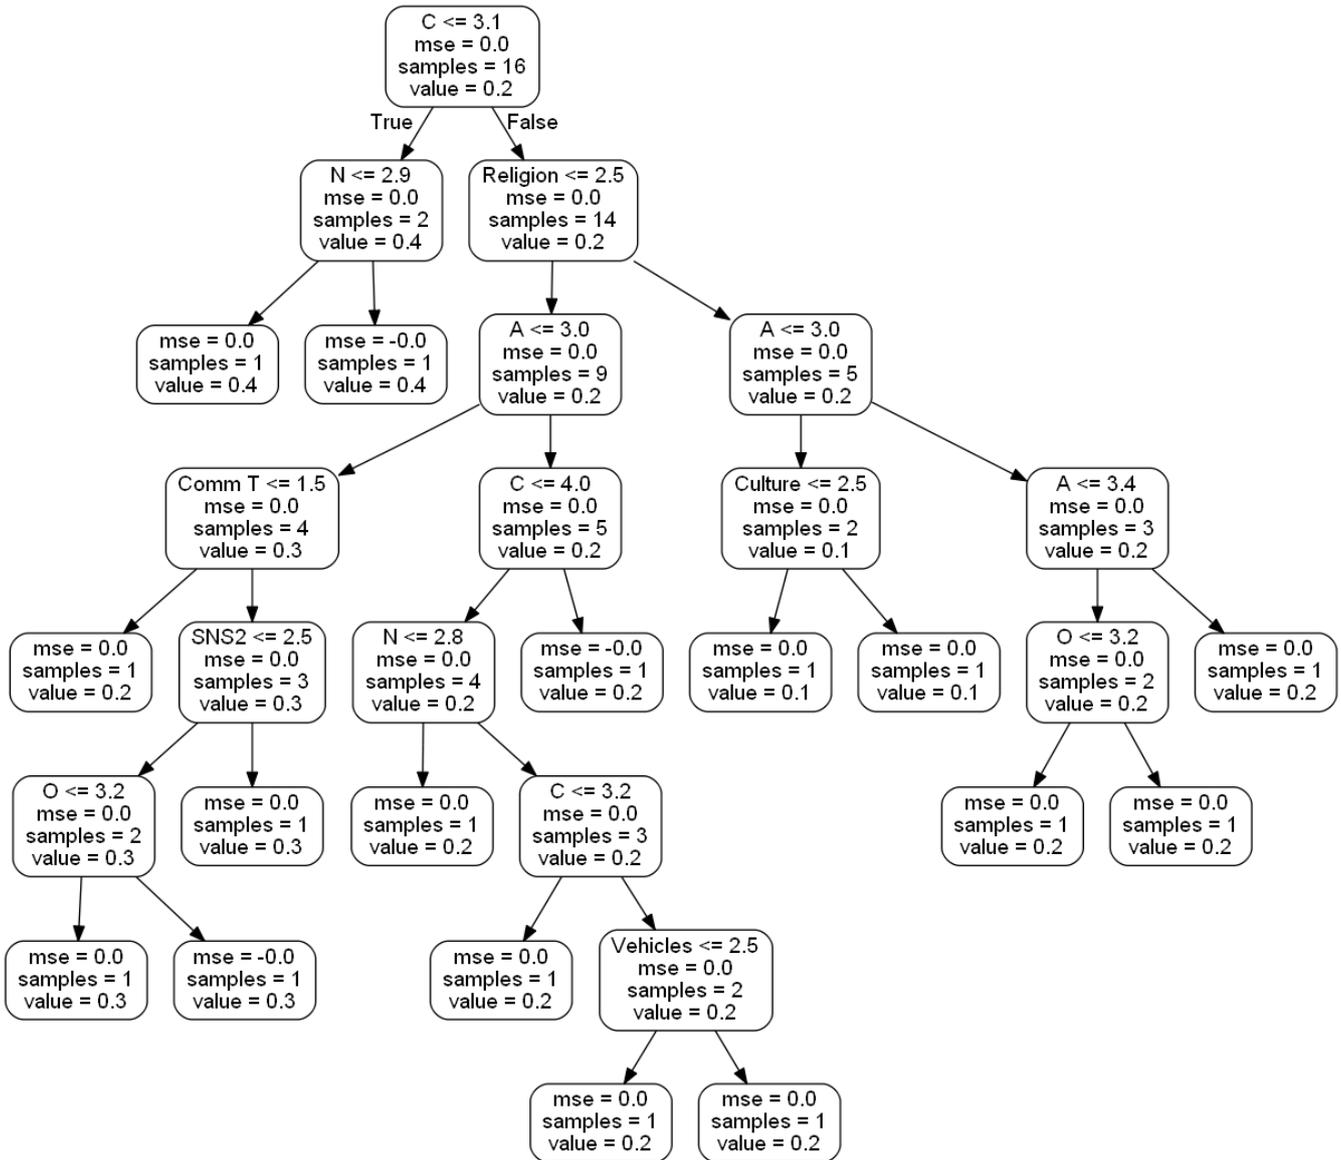

Fig. 2: Decision Tree for Restaurant

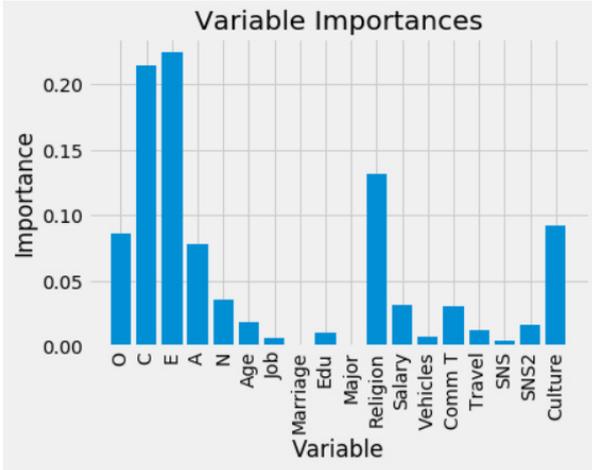

personality or preference. In general, once someone had disease or accident, visit to the hospital will be taken.

For these reasons, most participants rarely went to hospital. One participant frequently visited the hospital during the data collection period because of the need for continuous processing, and this was caused by accident but not by personality or other factors. For foreign institutions, we think significant results could be obtained if the number of participants increased and the age group varied.

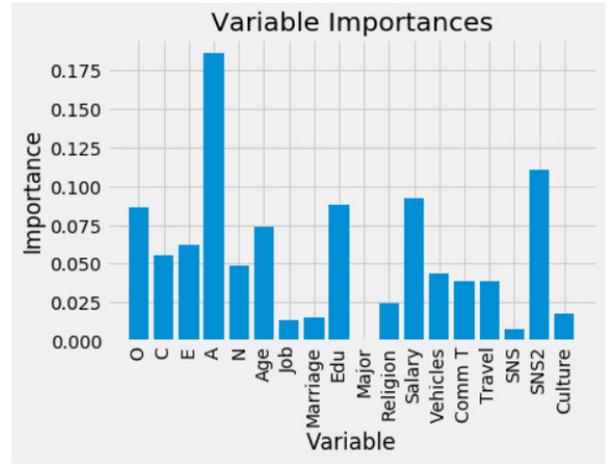

However, in the case of hospital, we decided that the visit frequency was not affected by personality or the personal factors we collected. In the case of service industry, it is difficult to describe this category as specific place because it contains too many locations as previously discussed. For

example, banks, beauty salons, massage parlors, bus terminals, hotels, guest houses and photo studios are included in service industry. These diversities of location category maybe attenuate the accuracy. Prediction accuracy is 59.79%, not very low, but it is also not that high. This would identify better predict accuracy and the affecting factors if the categories were more granular and grouped into units with one characteristic. For the category of museum, gallery, historical sites and tourist spots, the value importance is considered to have a significant result, although the predict accuracy 44.44% which was not high enough.

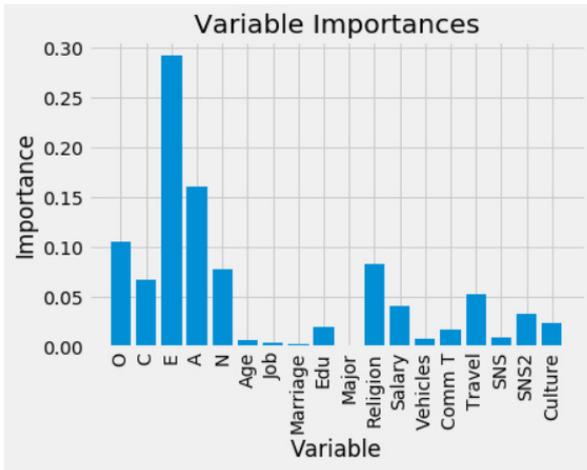

The results of experiments showed that openness and travel frequency affected the visit of museum, gallery, historical sites and tourist spots. Intuitively, open people like to travel because

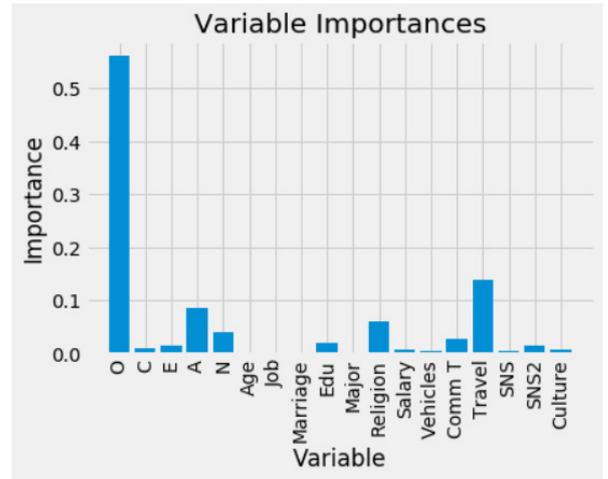

(a) label=Restaurant

(b) label=Pub

(c) label= Institutions of Education

(d) label=Museum, Gallery, historical sites and tourist spots

5							2						

they love adventure. Frequent travel increases the chances of visiting museum, gallery, historical sites and tourist spots. We also expect to have a high degree of predict accuracy if it gets data from a wider range of ages and occupational groups.

### B. Interpretation of Results

The experimental results show that the predict accuracy is usually high when the characteristics of the category are clear. For example, Restaurant, Pub, Beverage Store, Theater and Concert Hall, Institutions of Education are clear categories. While, Retail Business, Service industry, Museum, Gallery historical sites and tourist spots are not easy to clarify.

Therefore, it is hard to say that the category has one characteristic. For these reasons, it would have been difficult to predict by personality or personal factors. The highest predict accuracy was restaurant category, which was 78.26%. The most affected features are E (Extraversion) and C (Conscientiousness) among personality factors, and followed by Religion, O (Openness) and Cultural Life. For the institutions of education, the predict accuracy is 76.98%, followed by restaurant with a higher predict accuracy. Effective features include E(Extraversion), A(Agreeableness), O(Openness), N(Neuroticism), and Religion.

For the two categories of restaurant and school, we found distinguished results. At this time, it was determined that effective value importance value is greater than 0.1. Considering that most experimental participants of the study are students in their twenties, Extraversion, Agreeableness, and Openness leads to frequent visit to schools. Extraversion, Conscientiousness, and religion also affect the frequent visit to restaurant. To infer why these results came out, we expect that extroverted, enthusiastic and sincere students would have often eaten outside because they would often come to school and stay for a long. Otherwise extroverts are expected to engage in various activities. There would have been many visits to Restaurant in the process. In this context, visits to the beverage store will also have an impact on Extraversion.

Some of the questions in the experiment are that religion has a lot of impact on visiting the beverage store, and the theater and concert hall. In addition to religion, Neuroticism and salary affect theater and concert hall visits.

As mentioned earlier, people with high Neuroticism are stress sensitive and impulsive. Therefore, it is expected that stress will be solved through cultural life such as movie. Also, because cultural life costs, salary will also be effective. For the category pub, Agreeableness, SNS usage frequency, and

Openness are effective. It can be inferred that people who get along well with many people are cooperative, have a communal personality, and often have drinking parties.

### V. CONCLUSION AND FUTURE WORK

In this research, we found that various factors including personality factors effects the selection of visiting place. Especially, factors such as salary, religion, SNS usage were newly distinguished as effective factors for favorite location selection. Several matters must be considered for more precise evaluation. First, most of participants were in their twenties. Table VI shows that several values are skewed. Therefore, these skewed values attenuate the relationship toward visiting places. Once we can get more personal factors including more various age, we guess that more general results with more credible results can be analyzed. Second, we need to adjust location category. For the current categories of location service, two categories contain too many location subcategories. For example, large general retailing and service business contain restaurant and bar but such categorization cannot characterize the locations. This phenomenon leads to inaccurate prediction result. Therefore, ramified categories must be applied in such case so to improve accuracy of analysis. Third, the more data must be collected, especially the location data. Most of participants are not eager to collect their visiting location using SWARM app or does not know the usage of SWARM app. This sort of collection is called as 'check-in'. Collecting continuous geo-positioning data is passive, meaning that the geo-positioning data is automatically collected, while active check-in is required to use SWARM app. For the next research, we need to give more guidance of SWARM to participants. As well, some participants are too eager to collect check-in data so that even bus stops were checked in. This phenomenon may affect the analysis results. Several location categories are regarded as non-associated with personal factors we designed. For example, in case of hospital, accidents or disease may leads to the visit to hospital rather than personal factors. Therefore, personality, gender, hobby is regardless of such locations. Since most of the participants are students, educational locations are frequently visited. Maybe the job of students will affect the visit to educational locations. Therefore, we need to collect more various data to deduce meaningful result. Our analysis result could be applied to various area requiring visiting places prediction. For example, Location Based Service (LBS) and recommendation system

maybe best application area of our research. With the combination of personal factors and favorite visiting places, the usefulness of LBS and recommendation system can have more value added results and high quality of service.

**Abstract**—High complexity of business processes in real-life organizations is a constantly rising issue. In consequence, modeling a workflow is a challenge for process stakeholders. Yet, to facilitate this task, new methods can be implemented to automate the phase of process design. As a main contribution of this paper, we propose an approach to generate process models based on activities performed by the participants, where the exact order of execution does not need to be specified. Nevertheless, the goal of our method is to generate artificial workflow traces of a process using Constraint Programming and a set of predefined rules. As a final step, the approach was implemented as a dedicated tool and evaluated on a set of test examples that prove that our method is capable of creating correct process models.

**Index Terms**—business process management, process composition, workflow logs, constraint programming, BPMN

## I. INTRODUCTION

THE purpose of the existence of any organization or company is to carry out its mission effectively and efficiently. Lack of coordination of operational activities may result in the ineffective achievement of goals, and in extreme cases may lead to failure of the entire undertaking. This is a particular threat to enterprises, understood here as organizations whose mission is to provide specific products in the form of goods or services. In their case, permanent failure to meet the clients' needs usually results in bankruptcy or severe difficulties in operating in a competitive market. In order to minimize the risk of such turnover, the activities carried out within the organization in the form of processes are often created. As the processes are often complex, their modeling is a challenge for business analysts. To facilitate this task, it is possible to use some tools to assist analysts in their daily work. This paper combines issues in the areas of management (process approach in organizations) and Information Technology (Constraint Programming, Process Mining).

The main goal of the approach is to provide a method to generate complex process models starting from tasks and constraints obtained from the organization. The construction of the solution was preceded by the analysis of this topic.

This paper is organized as follows: Section II presents an analysis of the Business Process Management approach, including its origins, development, and current trends. The section also includes necessary information related to BPMN and process discovery. In Section III, as the next step to achieving the goal, the analysis and description of the proposed method are included. Next, a project of an IT tool, its assumptions,

requirements, and architecture (Section IV) was presented, as well as the technical description of its implementation (Section V). Section VI includes the evaluation of the proposed approach, the description of the developed tool, as well as the results of its application on a set of test data. The work is finished with conclusions and a description of the possible extension of the approach (Section VII).

## II. BUSINESS PROCESS MANAGEMENT

This Section discusses the issues related to business processes – from their role in management, through the applied notation of their recording, to the description of their research techniques.

### A. Overview

Business Process Management (BPM) [1] is one of the most common methods for improving the organization and implementation of the quality system. The ISO 9001 standard [2] introduced the obligation to apply the process approach as one of the key elements of a well-implemented, maintained, and functioning management system.

However, to talk about the process approach, let us look at the concept of a business process per se. There are many definitions of the business process. However, for this study, the definition presented in "Essential Business Process Modeling" will be adopted, where the process is described as step-by-step activities specific to the solution of various problems or business issues [3].

To answer the key question about the purpose of the process approach in enterprises, it is worth taking a closer look at the research carried out in 2009 [4], which shows the organization's goals at various stages of process development. Enterprises in the phase of introducing process-oriented approach set the implementation of the quality system and the creation of a process approach in their structures as the primary goal. In the case of enterprises from this group, the aim is usually to map processes existing in the organization, and less frequently to improve their effectiveness or implement IT tools supporting operational activities. For 38.5% of organizations in the growth phase, the key goal is to improve efficiency, and for 31% of organizations in this group, the most important goal is the development of applied IT systems, which will also improve the organization's efficiency [4]. Enterprises being in the improvement phase during the research indicated three

most important areas of application of the process approach, which are: improvement of quality, improvement of efficiency, and implementation of IT systems [4].

In the mid-nineties, Business Process Management was introduced as the next wave of approach to managing the processes in the organization. BPM postulates, inter alia, mapping, visualization, and analysis of processes in the organization. Thanks to these activities, it is possible to standardize the implemented activities, control their course, and perform much easier analysis of decision situations [5], [6].

Modeling processes in firms can be implemented using a variety of notations. Initially, many organizations used their own methods of describing and modeling processes, which, however, hindered readability and negatively affected cooperation between organizations. In response to this problem, many formal notations and languages of business process modeling were created. The most popular standards used to model business processes are the Unified Modeling Language (UML) [7] and Business Process Model and Notation (BPMN) [8].

In the last three decades, a change in the approach to information systems can be observed. Process-aware systems increasingly replace formerly used data-aware systems. To support business processes implemented within the framework of an organization, enterprise information systems must be somewhat aware of the existence of these processes and the organizational context within which they are implemented. Early examples of process-aware systems were called Workflow Management systems (WFM). In recent years, IT solutions companies have preferred a more precise term of BPM. Business Process Management systems cover a wider range than classical Workflow Management systems and do not focus only on process automation. Business Process Management systems attach more importance to supporting various forms of analysis (e.g. process simulation) and management (e.g. monitoring key performance indicators). Both Workflow Management systems and Business Process Management systems seek to support operational processes, which we refer to as workflow processes or simply workflows [9].

### B. Business Process Model and Notation

The BPMN standard consists of a set of graphic elements for constructing diagrams showing components of the process and the way in which it should be executed. Graphic symbols and the way of combining them constitute the syntax of the notation and have defined semantics. In addition to the graphical representation of the model, the BPMN specification [10] also describes the format of the record in the form of XML files.

The basic subset of BPMN symbols used in the developed model generator is presented in Figure 1, its elements are described below.

- Task – atomic activity performed as part of the process which is not subject to further decomposition. It presents actions taken by the end user or software.
- Gateways – elements used to control how sequential flows separate and merge as part of the process. They can

support many input and many output flows, although best practices suggest that the gateway should only perform one of these functions. Therefore, in the diagrams, the pair of gates usually serves first to separate and then connect the process flows.

- OR-gateway – flow object used to create alternative paths within the process flow. A single process instance contains only one of the possible paths selected. This gateway is interpreted as a decision at a given point in the process. It can be understood as a question, and sequence flows from it will be associated with responses.
- AND-gateway – flow object used to create parallel flows or synchronize them (join). Separation of the flow is not subject to any conditions, the connection, in turn, requires the completion of all input flows of the gate. A single process instance contains all possible paths associated with a given pair of parallel gates.
- Process start and end event – process start event indicates where flows begin within a given process. The process end event symbolizes the end of all flows.
- Sequence flow – indicates the order of flow objects in the process. It always has one source and one target element.

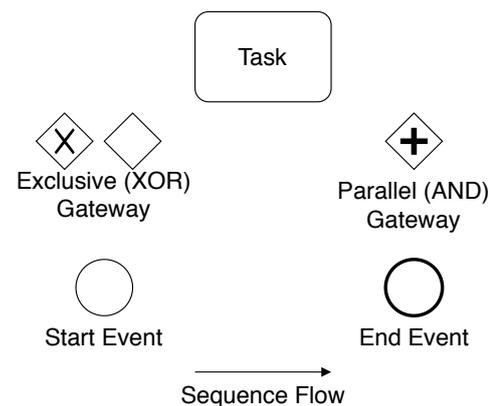

Figure 1. BPMN elements.

### C. Process Discovery

Process mining is a relatively new field of research, between machine learning and data exploration on the one hand, and modeling and analysis of processes on the other. Today's information systems store huge amounts of data about activities performed in the form of event logs. The assumptions for the exploration of processes are to discover, control, and streamline real processes by extracting knowledge from read-only event logs in these systems.

In general, process mining methods are often classified into one of the following classes [11]:

- process discovery,
- conformance checking,
- process enhancement.

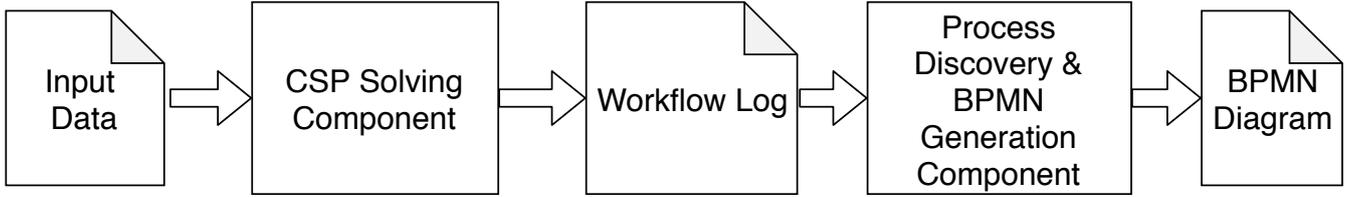

Figure 2. Overview of the process generation method.

For the purpose of this paper, our attention will be focused only on the first group – methods of discovering the process model. Discovery techniques rely on event logs and generate a process model without any known process information. An example is the  $\alpha$  algorithm, which results in a Petri net [12] that reflects the behavior recorded in the event log. Using dedicated algorithms, Petri nets can be automatically converted to BPMN [13], [14], [15].

Example algorithms of process discovery include:

- $\alpha$  algorithm [16], used in the developed tool,
- Inductive Miner [17], used in the developed tool,
- Heuristics Miner [18] and its Fodina variant [19],
- Evolutionary Tree Miner [20],
- Structured Miner [21],
- Region-Based Mining [22],
- Split Miner [23].

### III. METHOD

The process model generator presented in this paper uses the adapted method of generating process models based on the one described in the work [24]. It consists of three stages presented in Figure 2. In this Section, the formalization of the method is presented.

The first stage of the method is the preparation and provision of input data in the appropriate format. Such data can be extracted from a system-based source such as data warehouse [25] or acquired directly from business roles [24]. The approach described in this paper requires the provision of input data consisting of:

- matrix for prerequisite tasks,
- matrix of task effects,
- vector of the initial state,
- matrix of acceptable final states of the process,
- the maximum number of executions of each task.

The next stage of the method's operation is the use of a component that uses the Constraint Programming techniques, based on a model built of input data and predefined constraints. The result of its operation is an artificially created log of all possible traces of the process.

The final stage of the method is the part that explores the process (called *process exploration*) directly from the event log and creates a process representation in BPMN.

#### A. Expected Input Data

In our approach,  $\mathbb{T}$  denotes a set of all tasks:

$$\mathbb{T} = \{\tau^{(1)}, \tau^{(2)}, \dots, \tau^{(n)}\}.$$

Table I  
MEANING OF VALUES IN USED STRUCTURES.

Value	$M_{TC}$	$M_{TE}$	$M_{ST}$	$s_0$
-1	not relevant	not changed	not relevant	-
0	forbidden	deleted	forbidden	forbidden
1	required	created	required	required

Tasks, or activities, are performed within the course of the process. For our method, the concept of data entity was introduced. Unlike data objects used in BPMN, data entities do not exist in the generated model, but a part of the process specification that is required in the applied method. In other words, the data entity is a variable about a simple or complex type of data that accompanies the execution of the tasks of the process. The set of all data entities is denoted by  $\Delta$ :

$$\Delta = \{\delta_1, \delta_2, \dots, \delta_m\}.$$

Cardinality of  $\mathbb{T}$  and  $\Delta$  is equal to  $n$  and  $m$ , respectively. For the needs of the constraint model, it is necessary to build two matrices of dimensions  $n \times m$ :

- 1)  $M_{TC}$ : for the prerequisites required for each task,
- 2)  $M_{TE}$ : for the effects caused by each task.

The prerequisites and effects are understood as the occurrence of the data entity before and after the task.

Additionally, assuming  $g$  as the number of allowed final states, it is necessary to define the matrix  $M_{ST}$  of dimensions  $g \times m$ , which describes all acceptable terminal states. The  $m$ -element vector  $s_0$  is defined in order to give information about the presence of the data entity before the process is executed. All structures described can contain integer values from the set  $\{-1, 0, 1\}$ . Table I explains the meaning of values in the context of the data entity in each structure.

The last of the input structures is the  $n$ -element vector  $e_t$  containing the number of maximum executions for each task. By default, its values should be equal to 1 unless the process contains loops or tasks performed iteratively.

#### B. Workflow Log

Workflow log  $W = \{\sigma_1, \sigma_2, \dots, \sigma_L\}$  is a multiset of individual workflow traces  $\sigma$ , which can be defined as ordered sequences of activities in the course of the process:  $\sigma = (\tau_1, \tau_2, \dots, \tau_K), \tau_i \in \mathbb{T}$ . Although the workflow log definition permits the appearance of identical process traces

many times, the purpose of the described method is to generate a complete log artificially. The generated log contains all acceptable process traces. Therefore, in further considerations, the multiset  $W$  will be treated as an ordinary set.

### C. Constraints

For the purpose of finding a set of solutions, the concept of the process state  $S$  is introduced. It is represented by the state vector of the data entity in every step of the process. The state of the data entity  $s_i$  is the vector representing the occurrence of the data entity in  $i$ -th step of the process. The values 0 and 1 mean respectively the absence and occurrence of the data entity.

$$S = [s_0, s_1, \dots, s_K], \text{ where } K > 0, K \in \mathbb{N},$$

$$s_i = [d_{(i,1)}, d_{(i,2)}, \dots, d_{(i,m)}],$$

$$d_{(i,j)} \in \{0, 1\}, \text{ where } i \in \{1, \dots, K\}, j \in \{1, \dots, m\}.$$

Before specifying the constraints needed to generate the correct process flow log, it is necessary to define a predicate that determines whether the data vector state of the data entity  $s_i$  meets the requirements of the task to be performed:

$$sat(s_i, TC(\tau^{(i)})) \iff$$

$$\forall j = 1 \dots m : d_{(i,j)} = TC(\tau^{(i)})_j \vee TC(\tau^{(i)})_j = -1,$$

where  $TC(\tau^{(i)})$  is the  $i$ -th row of matrix  $M_{TC}$  and  $d_j$  is the  $j$ -th element of state vector  $s_i$ .

In addition, a predicate is defined, meaning that the state meets one of the allowed end states:

$$satSet(s_i, M_{ST}) \iff \exists j = 1 \dots g : sat(s_i, M_{ST_j}),$$

where  $M_{ST_j}$  means the  $j$ -th row of admissible solution matrix.

To generate a complete workflow log  $W$ , the problem being analyzed must be modeled using constraints over variables. This concept is based on three principles:

- 1) Search space: all completed task sequences.
- 2) Decision variables: single process flow, process state matrix.
- 3) Variable constraints: defined by the input data as well as by the set of predefined rules.

Predefined constraints that ensure the correctness of the generated process runs are:

- 1) The overall limit of task executions  $MAX_{EX}$ .
- 2) The number of executions of each  $\tau^{(i)}$  task must be less than or equal to the corresponding value in the vector of the maximum number of executions of the  $e_t$  task or the general  $MAX_{EX}$  limit.
- 3) Maximal length of a single workflow trace  $\sigma$  to  $K = n \times MAX_{EX}$ .
- 4) The input state of the first completed task is equal to  $s_0$ .
- 5) Every non-idle task  $\tau^{(k)}$  in the  $i$ -th step changes the elements of its successor state  $s_{i+1}$ :

$$s_{i+1} = [d_{(i+1,1)}, d_{(i+1,2)}, \dots, d_{(i+1,n)}],$$

$$d_{(i+1,j)} = \begin{cases} d_{(i,j)}, & \text{dla } TE(\tau^{(k)})_j = -1, \\ 1, & \text{dla } TE(\tau^{(k)})_j = 1, \\ 0, & \text{dla } TE(\tau^{(k)})_j = 0, \end{cases}$$

where  $TE(\tau^{(k)})_j$  means the  $j$ -th element of the  $k$ -th row of matrix  $M_{TE}$ .

- 6) The process ends when one of the specified final states is reached.

$$satSet(s_i, M_{ST}) \iff \tau_i = \tau^{(0)},$$

where  $\tau_i$  means the  $i$ -th task of a single workflow trace  $\sigma$  and  $\tau^{(0)}$  is an idle task.

- 7) The last process state  $s_K$  satisfies one of the admissible goal states  $M_{ST}$ :

$$satSet(s_k, M_{ST}).$$

- 8) The task can be performed only if the current state meets its initial conditions:

$$\tau_i = \tau^{(k)} \iff sat(s_i, TC(\tau^{(k)})).$$

The program built on the basis of the above-mentioned constraints and input data is performed by the system solving the problems of meeting restrictions (called *solver*). Executing a program by a solver to find all solutions results in an artificially generated process log  $W$ , needed in the next stage of generating the process model.

### D. Generating a BPMN model from a workflow log

In the work [24], two approaches to building a process model based on the delivered process log are listed. The first approach involves the use of process discovery algorithms from the delivered process log. These algorithms were described in more detail in Section II-C. The result of their operation is the process model in the form of a Petri net. One of the methods of converting Petri nets to BPMN was presented in [14]. The second approach is a process composition method based on activity graphs that does not require conversion of the Petri net to the BPMN form because the BPMN composition is directly from the artificially generated workflow log.

In the process model generator described in this paper, the implemented implementations of process discovery and conversion algorithms for BPMN contained in library *Numberjack* were used. The tool uses the  $\alpha$  and Inductive-Miner algorithms described in [26] and [17] respectively.

## IV. TOOL

This section presents the tool design – from specifying functional and non-functional requirements, by specifying the input data format specification, to the architecture description of the developed process model generator.

At the initial stages of work, functional (Section IV-A) and non-functional requirements (Section IV-B) were defined.

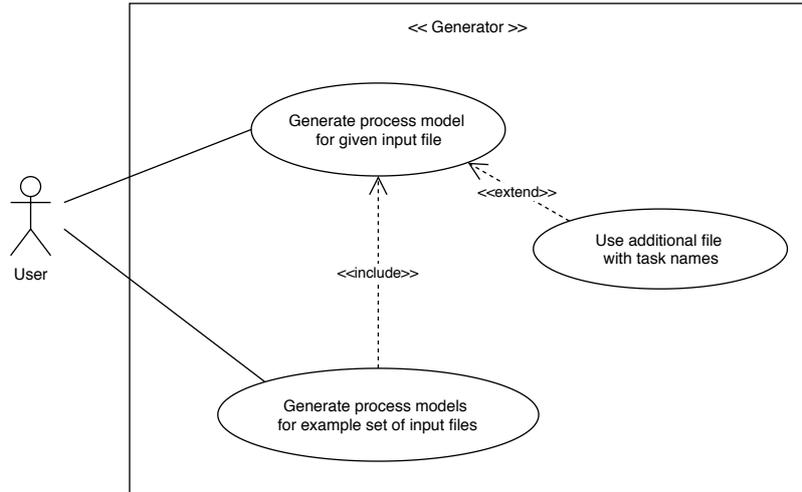

Figure 3. Use case diagram.

A. Functional Requirements

- 1) The tool should accept a set of input data in a specified format at the input.
- 2) The tool should optionally accept a file with the specification of task names at the input.
- 3) The tool as a result of the action should generate:
  - a) BPMN diagrams in graphic form,
  - b) BPMN diagrams in XML format according to the standard,
  - c) artificially generated process log,
  - d) Petri net diagrams resulting from the operation of process discovery algorithms.

Functional requirements are presented in the use case diagram (Figure 3).

B. Non-functional Requirements

- 1) The tool is distributed in an easy-to-use form, in particular without having to manually install all dependent libraries.
- 2) The tool is implemented with division into independent modules so that it can be further expanded.

C. Input File Format

The input tool accepts text files with the input data value definition described in Section III-A. The file should contain in sequence:

- initial state vector,
- matrix of task prerequisites,
- task results matrix,
- matrix of allowed final states,
- vector of the possible number of task executions.

The vectors and matrices should be separated from each other by at least one empty line. The line in the file may contain a comment beginning with the # character. Comments are ignored by the input data parser. The values of subsequent elements of the introduced vectors and matrices are separated by commas. An example input file is shown in Listing 1.

Listing 1. Example input file of the tool.

```
# s_0
0, 1, 0, 0

# m_tc
0, 1, 0, 0
0, 1, 1, -1
0, 1, 1, 0

# m_te
-1, -1, 1, -1
1, -1, -1, -1
-1, -1, -1, 1

# m_st
1, -1, -1, -1

# e_t
2, 2, 2
```

D. Architecture

While working on the tool, three functional areas were identified as separate modules. The modular division of the tool is aimed at introducing a clear structure of responsibility for individual parts, as well as facilitating further development by providing other implementations. The identified software modules are:

- 1) Parser module for input files.
- 2) Log module of the process log generator (based on programming techniques with limitations).
- 3) Module for process discovery and generation of process model diagrams.

The modules are presented in the component diagram (Figure 4). Coordination of the use of these modules by the tool is presented in the sequence diagram (Figure 5).

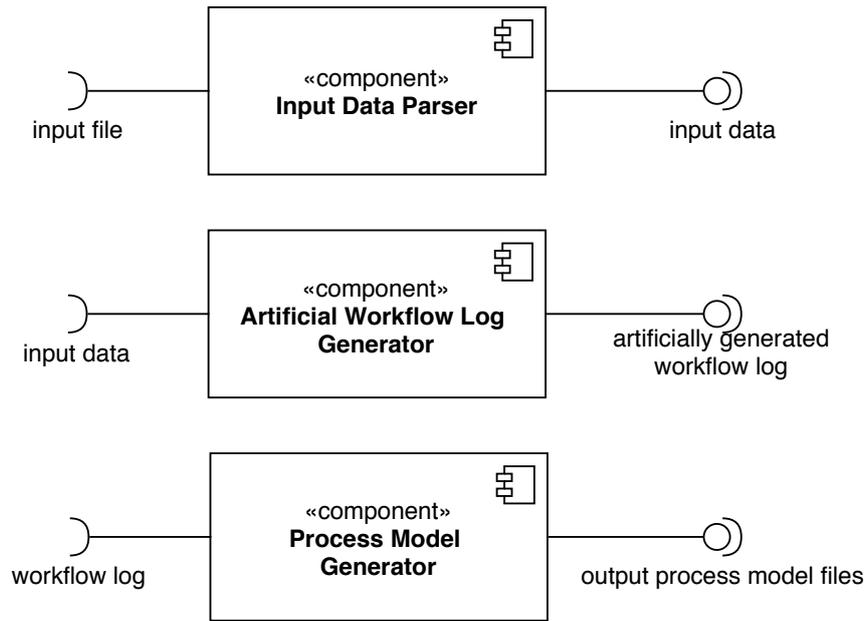

Figure 4. Components diagram.

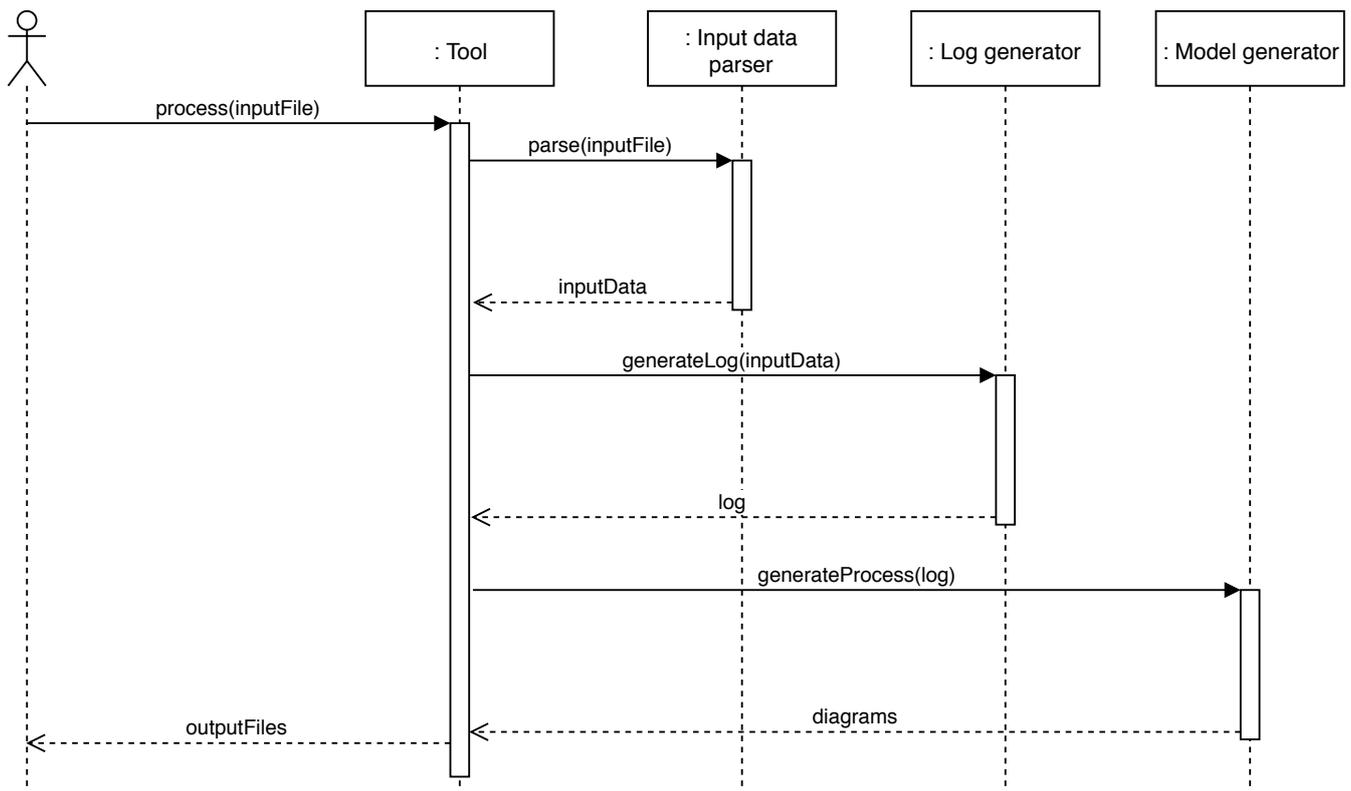

Figure 5. Sequence diagram of model generation.

V. IMPLEMENTATION

In this section, we present the details of the implementation of the process model generator.

A. Constraint Programming

Constraint Programming is a technique for solving the problems of satisfying constraints. These problems can be defined using variables that take values from their domains and the constraints over variables. The solution to the problem is a set of variable value assignments that meet the given constraints [27].

In addition, the problems expressed in Constraint Programming languages are characterized by declarativeness, i.e. a description of the problem becomes a program solving this problem [28].

The Constraint Programming technique can be used in imperative languages by means of libraries that allow building a problem model (variables and constraints) with the help of structures appropriate to a given language. These libraries can themselves implement solvers or provide an interface to solvers implemented in other languages. Examples of widely used solvers are: CP-SAT Solver from the Google OR-Tools package, Gecode, Mistral, Mistral2, ILOG Solver.

B. Used Techniques

Python was chosen as the implementation language of the developed tool. It is a popular language in the academic environment, as well as widely used in the IT industry. Support for programming with restrictions is ensured by the library *Numberjack* (<https://github.com/eomahony/Numberjack>), which allows for high-level modeling of problems and the use of several solvers. Discovering the process is carried out using the library *pm4py* (<http://pm4py.pads.rwth-aachen.de/>), which provides the implementation of the algorithms: *alpha* and *Inductive Miner*. It enables the presentation of discovered processes in the form of Petri nets, as well as their conversion to the BPMN diagram in XML and graphical format. Functions related to BPMN diagram support are currently in the implementation phase (they are not shared with a stable version of the library) and have been taken from the appropriate branch of the library version control repository. The result of their use is described in more detail in the Section VII.

For the purpose of easily recreating the entire working environment of the tool and simplifying its use on other computers, the *Docker* software (<https://www.docker.com/>) used for virtualization at the operating system level was used. The application image, containing the generator of process models and the configured environment for its launch and proper operation, was prepared.

VI. EVALUATION

As part of the research, tests were carried out on synthetic examples. Simple processes have been selected that contain:

- a single task,
- sequential submission of two tasks,
- two tasks covered by the XOR-gateway,

- d two tasks performed concurrently,
- e two tasks covered by XOR-gateway preceded and completed by one task,
- f two tasks performed concurrently preceded and ended with one task,
- g three tasks performed sequentially, in which the middle one is optional.

They are presented in Figure 6. For the needs of the tests, input data corresponding to these processes was prepared.

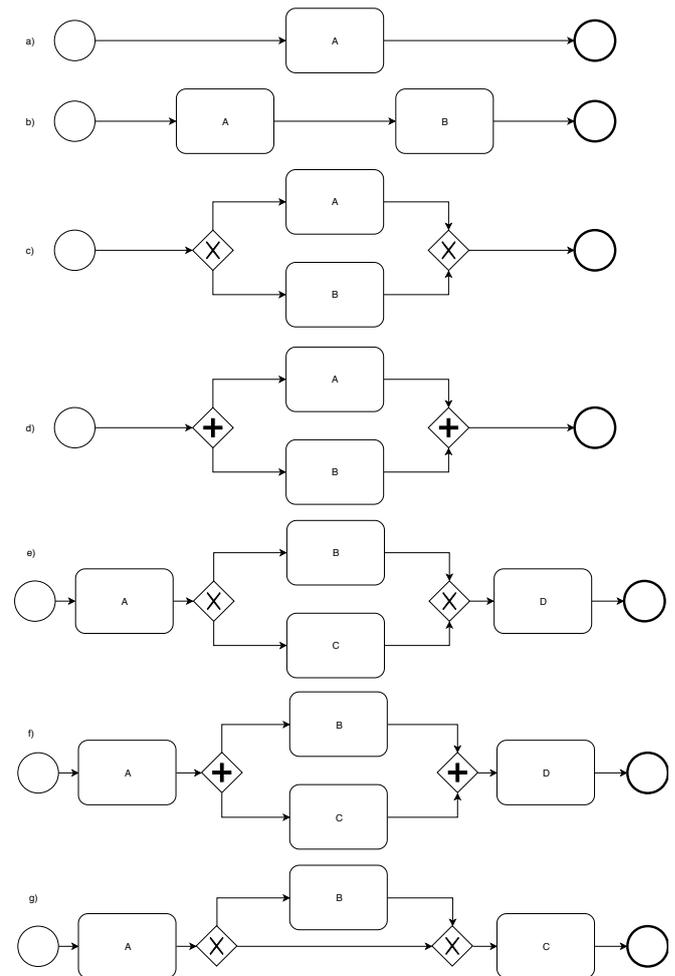

Figure 6. Example test cases in BPMN.

Analysis of test results was divided into two parts. The first one included verification of the correctness of the generated process logs. The second one focused on checking the generated model diagrams.

A. Generated Workflow Logs

The first of the test models – a process containing a single task – has only one possible trace consisting of this task. Also, the second test model, which is the composition of two tasks, should generate one pass. The generated process logs (respectively "A" and "A" "B" confirm the correctness of this stage of the tool for given models.

In the case of two successive process models (two tasks connected with the OR gate, two tasks performed concurrently), we expect logs consisting of two process runs. The correct behavior of the tool was also found here - logs were created with the forms "A", "B" and "A""B", "B""A".

The next two test cases are the extension of the previous ones by adding tasks at the beginning and end of the process. Here too, the proper generation of logs has been observed ("A""B""D", "A""C""D" and "A""B""C""D", "A""C""B""D").

The last example (optional execution of the task in the middle of the process) gives the tool the expected log in the form "A""B""C", "A""C".

The above analysis confirms the correctness of the method used to generate an artificial process log for each of the test cases.

### B. Generated Process Models

The result of the comparison of generated process model diagrams in the form of BPMN for test cases is shown in Table II.

The following deviations from the expected results were found during the analysis:

- 1) algorithm  $\alpha$  for example c) generated BPMN diagram without XOR-gateways (Fig. 7),
- 2) Inductive Miner for example c) generated a BPMN diagram containing doubled XOR-gateways (Fig 8),
- 3) algorithm  $\alpha$  for example d) generated a BPMN diagram without parallel gateways (Fig. 9),
- 4) algorithm  $\alpha$  for example f) generated a BPMN diagram not containing initial and final tasks (Fig. 10),
- 5) algorithm  $\alpha$  for example g) generated a BPMN diagram without the first task and with the wrong XOR-gateway instead of a parallel one (Fig. 11).

Table II  
GENERATED MODELS AND THE EXPECTED RESULTS.

Test case	$\alpha$ Algorithm	Inductive Miner
single task (a)	correct	correct
two tasks (b)	correct	correct
XOR-gateway (c)	incorrect	incorrect
parallel gateway (d)	incorrect	correct
XOR-gateway in a process (e)	correct	correct
parallel gateway in a process (f)	incorrect	correct
optional task (g)	incorrect	correct

### C. Example

Apart from test cases, the tool was also evaluated on the basis of a more complicated example – the process of opening a bank account. Synthesis of the input file was made on the basis of the process initially presented in [29]. The results of BPMN generation using the Inductive Miner algorithm are shown in Figure 12.

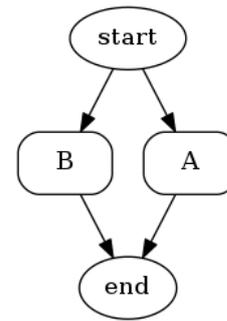

Figure 7. Diagram generated by the  $\alpha$  algorithm for case c)

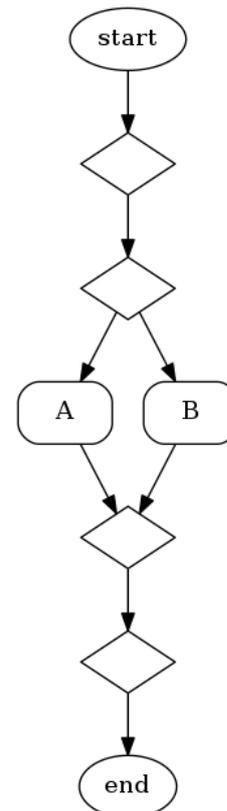

Figure 8. Diagram generated by Inductive Miner for case c)

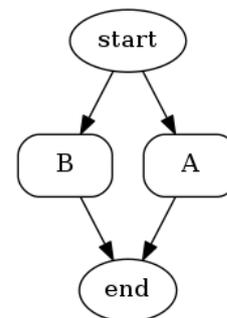

Figure 9. Diagram generated by  $\alpha$  algorithm for case d)

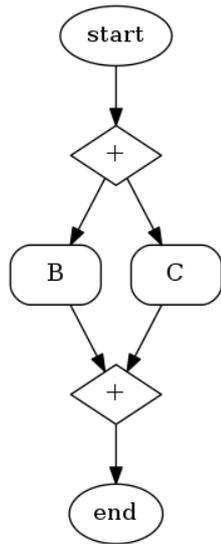

Figure 10. Diagram generated by  $\alpha$  algorithm for case f)

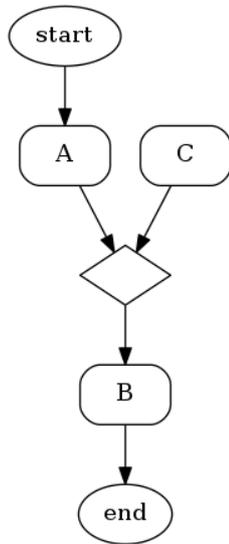

Figure 11. Diagram generated by  $\alpha$  algorithm for case g)

VII. CONCLUSIONS AND FUTURE WORKS

The works on the generator of process models presented in this paper are topped off with half-hearted success. The module for generating an artificial log of the process flow provides the correct results. They can be the basis for discovering the process. However, the process discovery and BPMN diagram generation module generates diagrams far from expectations. Inconsistencies appear at the stage of testing the test cases. If the observed behavior is recorded in an event log, it is possible to repair such a model [30]. However, our goal is to provide a prototype model based on the provided input data. Thus, in order to accurately diagnose the reason for this behavior of the module, a broader review of process discovery algorithms

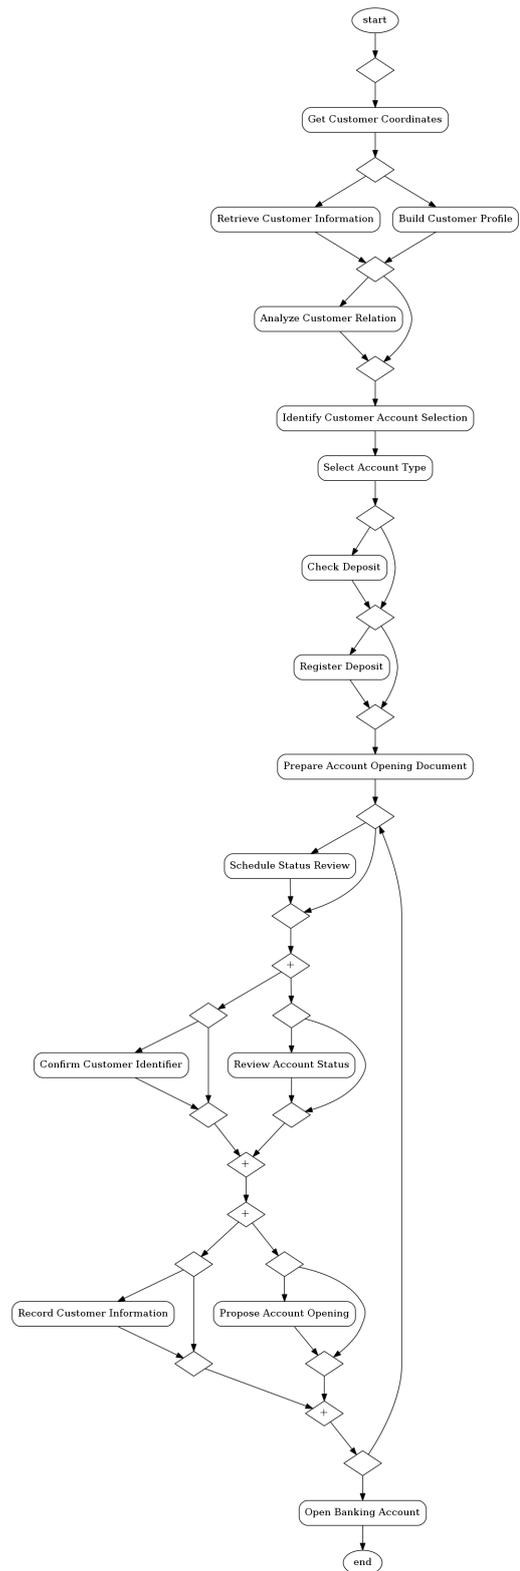

Figure 12. Diagram generated by Inductive Miner for the example process of bank account opening.

and a comparison of their properties should be made. The implementation of the Petri net conversion algorithm to BPMN provided in the experimental branch of *pm3py* can also be one of the causes of the problem.

The possibilities of the process model generator extensions are as follows:

- The use of other process discovery algorithms mentioned in the section II-C, in particular the implementation of the process composition method based on the activity graphs described in work [24]. The use of this approach should give better results during the process discovery phase from the artificially generated log flow of the process than the  $\alpha$  and Inductive-Miner algorithms used.
- Performing a GUI facilitating the input of data, or enabling cooperation with the organization's business roles in order to collect information about tasks, data entities and their relationships.
- Improving the layouting of the generated BPMN diagrams, arranging elements on the diagram in a way similar to how they are visualized in commercial tools.
- Extension of the tool to include information about various departments within the organization, linking them to tasks and extending the generated model with pools and lanes.
- Adding the possibility of exporting the generated process log to the standardized event log format. The XES format is the standard for text-event logs for further analysis using tools that implement the process discovery functions (for example, the ProM framework [31]).

**Abstract**—The paper analyzed the relationship between the person’s fourteen characteristic factors and place to visit. The personal factors consist of personality, marital Status, final education, majors, religion, monthly income, commuting means and time, frequency of travel, userage of social media, time spent on social media per day, cultural type. In addition, the analysis was done on which factors have the greatest impact. The analysis involved thirty-four participants and the boosting technique was used as a method of analysis.

## I. INTRODUCTION

RECENTLY, A number of services provides useful information to people by predicting their moving pattern and location data, especially for Location Based Service (LBS). However, most of the studies predicting people’s movements focus on analyzing past patterns of movement. Apart from this prediction method, we conducted another research on a relationship where a person visits with person’s various factors [1] [2]. Factors such as a personality, marital status, and final education and so on clearly affect a person’s favorite place to visit. In this study, the correlation between person’s characteristic factors and place to visit are analyzed using Boosting techniques. In addition, the analysis of the greatest influential factors to location visit is also addressed. Section II will describe the Boosting technique to be used for correlation analysis. Section III will describe the person’s characteristic data and location data used in the analysis. Section IV analyzes which factors have the greatest impact. Section V will describe the conclusions of this study and the future direction of study.

## II. BOOSTING AS AN ANALYSIS METHOD

### A. Boosting

The analysis technique used for this study is Boosting, one of the ensembles techniques [3]. Boosting is one of the techniques of generating a number of classifiers by manipulating initial sample data similar to Bagging, but the biggest difference is that Boosting is a sequential method. Boosting is a technique to train several weak learners sequentially, to

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST)(NRF-2017R1D1A1B03029788).

TABLE I  
PERSONALITY DATA OF 5 VOLUNTEERS USING BFF

	O	C	E	A	N
Person1	3.3	3.9	3.3	3.7	2.6
Person2	2.7	3.2	3.2	2.7	2.8
Person3	4.3	3.1	2.3	3.2	2.9
Person4	4.2	4.3	3.5	3.6	2.6
Person5	4.0	3.7	4.0	3.9	2.8

learn weight by adding weight to mispredicted data, and to predict using the finally generated learner. That is, the results of the previous learning will affect the next learning.

### B. XGBoost

There are a number of Boosting algorithms. In this research, we will use XGBoost boosting algorithm. XGBoost is an algorithm that visualizes how much the model relies on which factors [4] [5]. It also offers a variety of custom optimization options, including evaluation functions for flexibility. Therefore, it was appropriate to analyze which factors have the greatest impact on place to visit.

## III. INPUT DATA

### A. Personality Data

Personality data was digitized into five personality types in the Big Five Factor (BFF). BFF was developed by psychologists P. T. Costa and R. McCrae in 1976 and is a personality psychological model that explains human personality in terms of five mutually independent factors [6] [7] [8] [9] [10] [11] [12]. O is Openness, C is Conscientiousness, E is Extroversion, A is Agreeableness, and N is Neuroticism. Table I is personality data of 5 volunteers using BFF.

### B. Other Personal Factors

The person’s factor without personality were collected through a questionnaire made directly by Google Form and quantified the categories for each factor. Table II is the person’s characteristic factors without personality of four volunteers

obtained from the questionnaire. Age refers to age, with 1 in the teens, 2 in the 20s, 3 in the 30s and 4 in the 40s and older. Job represents a job and has been assigned a category by adding 'students' to the International Classification of Work (ISCO) standard [13]. 1 is for students, 2 is for managers, 3 is for technical workers, 5 is for office workers, 6 is for service and sales, 7 is for functional workers, 8 is for device and machine operation, and 9 is for simple labor workers. Marriage indicates marital status, 1 is married and 2 is unmarried. Edu represents final education, 1 is below high school graduation, 2 is a high school graduate, 3 is a university graduate, 4 is master's degree and 5 is doctoral degree. Major represents the major, 1 is the humanities, 2 is the sociality, 3 is the educational, 4 is the engineering, 5 is the natural science, 6 is the medicine and 7 is the art. Religion represents religion, 1 is Atheist, 2 is Christianity, 3 is Catholicism (the Catholic Church), and 4 is Buddhism. Salary represents monthly income, with 1 being less than 500,000 won, 2 being less than 1 million won, 3 being more than 1 million won, 4 being more than 2 million won and 5 being more than 3 million won. Vehicle indicates means of commuting, 1 is walking, 2 is cycling, 3 is using self-driving, and 4 is public transportation. Comm T indicates commuting time, 1 is within 30 minutes, 2 is less than one hour, 3 is less than one hour, and 4 is more than two hours. Travel indicates the frequency of travel, 1 is less than 1 time, 2 is less than 4 times, 3 is less than 4 times, and 4 is more than 6 times. Social M indicates usage of social media, 1 is on social media, and 2 is not on social media. Social M2 represents the daily usage of social media, 1 is less than 30 minutes, 2 is less than 1 hour for 30 minutes, 3 is less than 1 hour and 4 is more than 3 hours. Finally, Culture represents cultural type, 1 corresponds to a mixture of static activity, 2 to dynamic activity, and 3 to both static and dynamic activities.

Social M	1	2	2	1
Social M2	3	0	0	2
Culture	3	3	2	2

### C. Location Categories

The SWARM application was used to collect location data. SWARM is an application that records the location of a visit when a user visits a site. Location data was created by categorizing each visit data to ten industry classification and accumulating number of visits for each category [14] [15]. Ten Industry categories include Foreign Institutions, Retail, Service industry, etc. Finally, Location data is obtained by calculating the ratio of number of visits of each category compared to the total number of visits. Table III is part of location data of four volunteers.

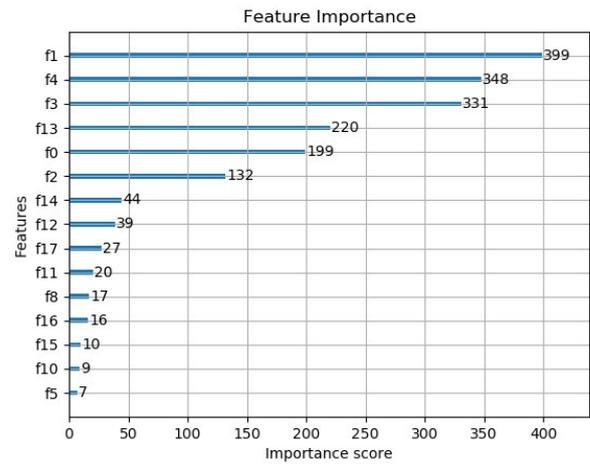

Fig. 1. Feature Importance Graph for Location Categories

## IV. EXPERIMENTAL RESULT

We used XGBoost mentioned in section II as an analysis technique. An independent variable is a person's characteristic data, which was created by merging personality data obtained using BFF, and data for the rest of the factors obtained through a questionnaire. Table IV is characteristic data of three volunteers. Dependent variable is location data. A regression model was created by inserting dependent variable and independent variables into `XGBRegressor()` in XGBoost. Then, `feature_importances` on this regression model and found what factors among the various characteristics of person including personality are most effective for location data.

Figs. 1 show the result of performing feature importance analysis using XGBoost for Foreign Institutions. The y-axis (Features) represents each factor included in the person's characteristic factors. The x-axis (Importance) represents the effectiveness of the independent variable for the dependent variable. Labels f0 through f17 are in the order of the factors listed in Table IV. For example, in Fig. 1, Foreign Institutions of Feature Importance shows that f1 (C, Conscientiousness) has the greatest impact on location data classified as Foreign institutions.

## V. CONCLUSION

In this study, we analyzed the correlation between various factors of people and place to visit through boosting. As a result, we were able to see how each characteristic of a person affects each place visit. However, there are many similar results for each of the ten place data, and the accuracy was not high. Therefore, we analyzed the reason in many ways. Firstly, many biased results were obtained because most of the volunteer were students in the process of collecting data. Therefore, in the next study, we will recruit the volunteer by various occupations and ages. Secondly, the number of volunteers was few, and the data of place to visit were also insufficient. This is because the volunteer does not use the SWARM application properly. SWARM does not automatically collect the places visited, but it is inconvenient because user has to check-in themselves actively. Therefore, in the next study, we

will recruit more volunteers and make detailed guidance on how to collect data with SWARM. Thirdly, there are several parameters when generating the XGBoost predictive model. When using XGBoost, tuning hyperparameters means that they are the most essential and important. There might be more way to tune XGBoost parameters for future research. Lastly, the accuracy is not great because most ambiguous places to sort are put into service industry or Historic sites in the process of applying the visited places to the industry classification. Therefore, location category classification should be improved by other than current industry classification standards.

Location-based services (LBS) is one of the emerging issues that have great potential for future service. In particular, understanding human mobility patterns is a key part of LBS. We can analyze human mobility patterns by using the correlations between various factors of people and visiting locations analyzed in this study. Therefore, this analysis result might be extended and can be utilized in LBS. It is also expected to be useful for recommendation systems. A recommendation system is a kind of information filtering technology that recommends information that might be of interest to a specific user, such as video recommendations of Netflix and YouTube. People with specific factors will be able to correlate the frequent visits to specific places and apply them to the recommendation system.

Location-based services (LBS) is one of the emerging issues that have great potential for future service. In particular, understanding human mobility patterns is a key part of LBS. We can analyze human mobility patterns by using the correlations between various factors of people and visiting locations analyzed in this study. It is also expected to be useful for recommendation systems. A recommendation system is a kind of information filtering technology that recommends information that might be of interest to a specific user. People with specific factors will be able to correlate the frequent visits to specific places and apply them to the recommendation system.

**Abstract**—The variety of hardware devices and the diversity of their users imposes new requirements and expectations on designers and developers of mobile applications (apps). While the Internet has enabled new forms of communication platform, online stores provide the ability to review apps. These informal online app reviews have become a viral form of electronic word-of-mouth (eWOM), covering a plethora of issues. In our study, we set ourselves the goal of investigating whether online reviews reveal usability and user experience (UUX) issues, being important quality-in-use characteristics. To address this problem, we used sentiment analysis techniques, with the aim of extracting relevant keywords from eWOM WhatsApp data. Based on the extracted keywords, we next identified the original users' reviews, and individually assigned each attribute and dimension to them. Eventually, the reported issues were thematically synthesized into 7 attributes and 8 dimensions. If one asks whether online reviews reveal genuine UUX issues, in this case, the answer is definitely affirmative.

## I. INTRODUCTION

WITH the rapid development of mobile devices, increasing numbers of mobile applications (apps) are being manufactured and deployed, and these apps are accompanied by rich user reviews. This informal type of communication, directed at an unspecified number of people using internet-based technology and related to the usage of particular goods or services is defined as electronic word-of-mouth (eWOM) [1]. Undeniably, this phenomenon has attracted considerable attention from application users as well as their vendors. According to Mobile App Daily [2], the most trusted and largest media source of the mobile app industry, more than 70 percent of people read app reviews before downloading, while, more importantly, 75 percent identified reviews as a key driver for downloading, and 42 percent consider app store reviews as equally or more trustworthy than personal recommendations [3].

Inspired by these findings, in our study we investigate the content of online reviews. The broad area of topics gaudily reported by users roughly corresponds to a similar number of application properties. Therefore, in this study the focus is on quality-in-use issues, which are recognized as the subject of interest of usability and user experience (UUX) practitioners. The evaluation of the UUX of a mobile application has been identified by many as one of the main challenges [4,5,6], eventually determining the success of its continued acceptance by users.

On the other hand, while the majority of recent studies on the perceived quality of an app have focused on quality assurance from the perspective of its development or testing, this study, on the contrary, solely concentrates on the end user's attitude to an app, expressed by eWOM. In particular, we put forward one research question: do online reviews reveal mobile application usability and user experience? In other words, by assumption, we attempted to extract valuable information from eWOM data concerning the facets of UUX.

The remainder of this paper is structured as follows. We first review the background and relevant literature in Section 2. Sections 3 and 4 introduce the research methodology and experimental setup, respectively. Section 5 presents the empirical results obtained in the study, followed by a discussion of the findings and implications, given in Section 6. Finally, Section 7 concludes the study.

## II. THEORETICAL BACKGROUND AND RELATED WORK

In the light of the results obtained in our previous study [7], in the context of mobile applications, the majority of studies have pointed to the usability definition adapted from the ISO 9241-11 norm. Here, usability is defined as “the extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use” [8]. Furthermore, along with these three already articulated attributes, in some studies, other attributes have also been considered, namely: learnability, memorability, cognitive load, errors, ease of use, navigation and operability [7].

Under the umbrella of user experience, all of a “person's perceptions and responses resulting from the use and/or anticipated use of a product, system or service” [9] are a subject of concern. Based on the existing body of knowledge [10], we elaborated a list of UX dimensions, from which we elected eight unique dimensions: aesthetics, enjoyment, hedonics, trust, support, engagement, discomfort and frustration.

It is worth noting that, according to the above norm, usability, when interpreted from the perspective of a user's personal goals, can include the kind of perceptual and emotional aspects typically associated with user experience. Moreover, usability criteria can also be used to evaluate aspects of user experience.

To capture usability and/or user experience, there are two not mutually exclusive approaches [11], which are applicable either during or after application usage. The former mainly concerns laboratory testing, while the latter is a retrospective analysis of data, gathered in the form of a questionnaire [12,13,14], video recording [15,16,17], or, more notably, online reviews [18,19,20,21].

Jacob and Harrison [18] argue that 23.3 percent of mobile app reviews represent feature requests, where users either suggested new features or expressed their preferences for the re-design of existing ones. The prototype experimental tool (MARA) was used to mine and retrieve feature requests from the data of online reviews. In particular, the data are processed in a fixed sequence: review retrieval, feature request mining, feature request summarization, and feature request visualization. During the first phase, a web crawler extracts the source page which contains the reviews of a given app and parses their content. The meta-data, including the posting date, the user's rating, and other fields, are also collected. The meta-data, as well as the content of the review are normalized to reduce noise in the final results, where the latter is also split into sentences, using [22], a toolkit for processing text by use of computational linguistics. The second phase uses the split review content as input and mines for feature requests expressed by users. The mining algorithm utilizes a set of linguistic rules defined for supporting the identification of sentences which refer to particular requests. During the third phase, the system summarizes the extracted feature requests according to a set of predefined rules. The applied rules aim to rank the extracted user requests based on their frequency and length. The more frequent and lengthier feature requests would be first in the summary. Finally, during the visualization phase, the results of the summarization are displayed to the user.

He et al. [19] propose a feature-opinion mining approach to automatically summarize the reviews, based on dependency parsing. The approach utilizes a regression model to generate sentiment words, consisting of a phrase and its sentiment weight. Next, the feature is extracted, based on the dependency relationship between the feature and sentiment words. Eventually, a score is assigned to the feature according to the dependency relationship. In general, the applied approach consists of three phases: (1) sentiment word generation, (2) feature extraction, and (3) feature scoring.

Jin et al. [20] illustrate a framework to select pairs of opinionated representative yet comparative sentences with specific product features from online reviews of competitive products. Sentiment analysis techniques were applied to identify opinionated sentences referring to a specific feature from product online reviews. To select a "small" number of representative yet comparative opinionated sentences from those identified, the authors investigated the representativeness, comparativeness and diversity of the information. The contribution of this study lies in three

greedy algorithms to analyse the optimization problem for suboptimal solutions.

A comprehensive study of existing solutions for mining online opinions is given by [21]. There are several methods identified, including LDA (Latent Dirichlet Allocation), ASUM (Aspect and Sentiment Unification model), statistical analysis, SVM (Support Vector Machine), EMNB (Expectation Maximization for Naïve Bayes), decision trees, manual tagging, keyword extraction with grouping and ranking, and others.

To sum up, having briefly depicted the main ideas from arbitrarily selected studies, in this study we performed a semi-automated review analysis, methodologically similar to the framework developed by Vu et al. [23].

### III. METHODOLOGY

In our study, the sentiment analysis is aided by the WordStat Sentiment Dictionary, designed by combining negative and positive words from three different sources: Harvard IV dictionary, the Regressive Imagery Dictionary (RID) and the Linguistic and Word Count dictionary. Eventually, more than 9526 negative and 4669 positive word patterns were gathered [24].

A user's sentiment is not measured by those two lists of words and word patterns, but instead by two sets of rules which are intended to take into account the negations preceding those words. For example, negative sentiment is measured by applying the following two rules:

- negative words are not preceded by a negation (e.g. no, not, never) within four words in the same sentence;
- positive words are preceded by a negation within four words in the same sentence.

On the other hand, positive sentiment is measured in a similar way by alternatively checking the following two rules:

- positive words are not preceded by a negation;
- negative terms are followed by a negation.

However, some argue that the latter rule shows less predictive properties, and in some cases, might even deteriorate the sentiment measurement [25,26].

In general, the sentiment analysis was carried out in a fixed sequence of five stages [27], as depicted and described below (Fig. 1):

Fig. 1 The sentiment analysis process

Data collection (A) involves downloading the text data from the Web and assembling one consolidated data set.

Text preparation (B) aims to clean and transform the collected data, comprising the following two tasks:

- data parsing, which means analyzing data and breaking them down into smaller blocks, which separately can be easily interpreted and managed, and

- data pre-processing, which concerns: (i) performing tokenization, where the words are transformed from the text into a structured set of elements (tokens); (ii) executing a stop word list, where the words which have low informative value or are semantically insignificant (e.g. *and*, *also*, *or*) are removed; and (iii) reducing the words by individually extracting a stem word (a root of words).

Sentiment detection (C) is to identify sentences with subjective expressions (opinions, beliefs and views) and to reject objective communication sentences (facts, factual information).

Sentiment classification (D) is the task of classifying a text in a document into a positive or negative class on various levels (e.g. document, sentence and aspect of entities).

Visualization of output (E) aims at transforming data, information and knowledge into a visual form (e.g. pie, bar, line graph) to take advantage of natural human visual capabilities [28,29,30].

In the next step, we assumed, after [31], that in textual analysis research, a higher negative (positive) word frequency indicates a more pessimistic (optimistic) sentiment. Therefore, we extracted all negative and positive words with the highest frequency of occurrence. Next, we consequently mapped these words to a particular usability attribute and/or user experience dimension. Finally, identifying the original reviews, based on keyword searching, enabled us to individually assign them to the relevant attributes and dimensions.

#### IV. EXPERIMENTAL SETUP

In total, we collected 399 reviews by WhatsApp users from the Google Play website using a self-made web crawler. The data set is both human and computer readable due to the JSON (JavaScript Object Notation) format applied.

Let  $i = \{1, 2, \dots, n\}$  be the ordinal number of a user's review. Each review can be defined as a set of six variables (s sextuple):

$review(i) = \{name: string, rate: [1-5], when: date, helpful: integer, short-review: string, full-review: string\}$ , where:

- *name* is the name of a user (reviewer), which may consist of first name, surname or any other string of characters (e.g. John, John Kowalski, JK);
- *rate* is the numerical evaluation of the mobile application in the range of 1 to 5, given by a user,
- *when* is the date of the rate, written in a short format (e.g. February 12, 2019),
- *helpful* is the number of thumbs-ups given by users for the review,
- *short-review* is a verbal evaluation of the mobile app,
- *full-review* is also a verbal evaluation of the mobile application, with a higher number of characters allowed.

It is worth noting that a user can add a review to a particular app if it has been downloaded and installed.

The sentiment analysis was conducted using the ProSuite commercial software [32], being an integrated collection of Provalis Research Text Analytics Tools that allow one to explore, analyse and relate both structured and unstructured data. The computing platform includes three major tools:

- QDA Miner for qualitative data analysis, including coding, annotating, retrieving and analyzing small and large collections of documents and images;
- WordStat for the content analysis of open-ended responses, interview or focus group transcripts, for information extraction and knowledge discovery from incident reports and customer complaints, and for the automatic tagging and classification of documents;
- SimStat for statistical analysis, supporting both numerical and categorical data, dates and short alpha-numeric variables, as well as memo and document variables.

These tools have also been used in other studies for content analysis and text mining [33,34,35], allowing researchers to integrate numerical and textual data into a single project.

#### V. RESULTS

The research material constituting reviews by WhatsApp mobile application users created a so-called bag-of-words (BOW). After transforming the text into a BOW, we can calculate various measures to characterize the text. In our study, the BOW model consists of 4 245 words (tokens). The most common words are shown below (Fig. 2).

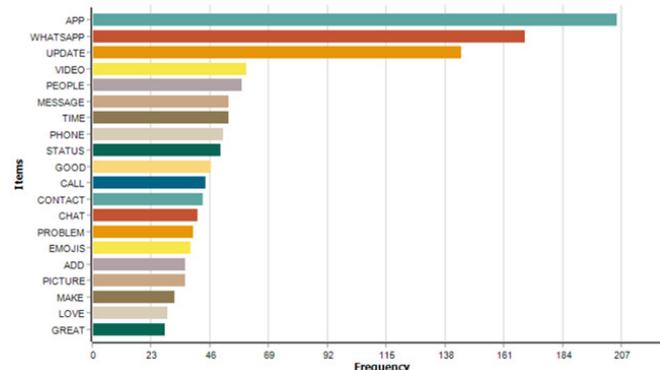

Fig. 2 The distribution of keywords by frequency

In the first step, the sentiment analysis was performed on the users' opinions. The sentiment analysis, conducted according to the stages shown in Figure 1, contained 904 negative words (21.30%) and 1217 positive items (28.67%). However, neutral words identified in the study (50.03%) can be ignored because they do not add value to the study. The obtained results are given below (Fig. 3).

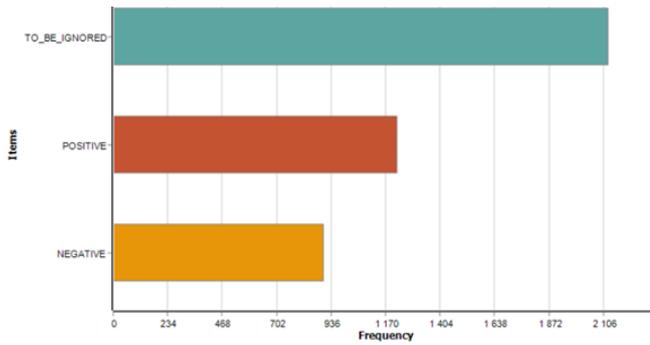

Fig. 3 The distribution of words after the process of sentiment analysis

In the WhatsApp users' ratings, the advantage of positive sentiment is clearly visible. The set of bigrams extracted from the users' reviews also show this trend (e.g. *great app*, *excellent app*, *good app*, *love WhatsApp*).

In the next step, we assumed, as already indicated above, that in textual analysis research, a higher negative (positive) word frequency indicates a more pessimistic (optimistic) sentiment. Therefore, we extracted the crucial negative and positive words with the highest frequency of occurrence (Table 1).

TABLE I.  
LIST OF THE MOST FREQUENT KEYWORDS

Negative		Positive	
Word	Frequency	Word	Frequency
fix	46	call	58
problem	39	contact	57
issue	36	good	46
number	19	friend	34
annoying	18	make	32
remove	18	feature	32
bug	17	share	31
hate	13	love	29
unable	11	work	29
stop	11	great	28
bad	11	open	15
delete	10	fine	14
sucks	9	easy	12
horrible	9	quality	12
reduce	8	make	11
lost	8	nice	11
error	8	free	10
limit	7	happy	9
wrong	6	awesome	9
miss	6	excellent	8

Keywords frequently appearing with negative reviews are likely to describe the issues or features of apps that cause a negative user experience, i.e. making users unsatisfied. Thus, such keywords would be of interest to app developers because they can help to identify the bad aspects of an app

and user opinions about such aspects (e.g. bigrams: *fix this issue*, *Feb update*, *app lock*, *dark mode*). And similarly, with positive words that point to the aspects that satisfy the user (e.g. bigrams: *good work*, *excellent app*, *good app*).

Based on selected keywords from the sentiment analysis, we searched for the actual user reviews that are the most relevant to those keywords. On this basis, we were able to assign usability attributes and user experience dimensions. An example of our work is included in Table 5 and Table 6 (see Appendix). The mappings between keywords and usability (Fig. 4) and UX dimensions (Fig. 5) are shown below.

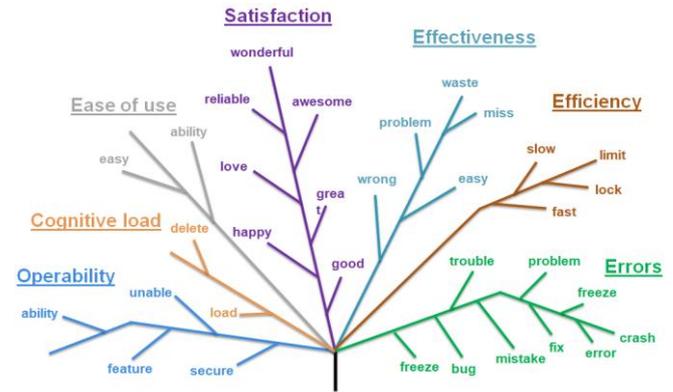

Fig. 4. The mapping between keywords and usability attributes

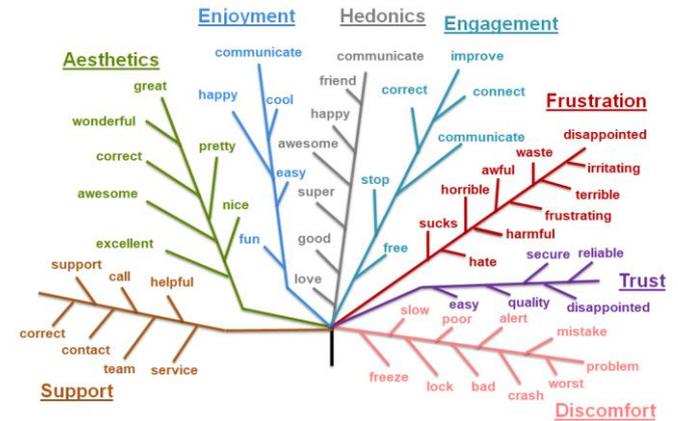

Fig. 5. The mapping between keywords and UX dimensions

The same keywords (e.g. *easy*, *awesome*, *problem* and *communicate*) can be used to describe different UUX attributes and dimensions. In addition, the negative words describe a larger number of dimensions and attributes than the positive ones. Similar conclusions were drawn by Provost and Robert [36].

Next, the bag of words was divided into seven clusters by applying the hierarchical grouping method (Table 2), where a cluster is a group (or class) of similar objects created as a result of data grouping. On further analysis, these clusters can be compared to the classes developed by grouping original user reviews, which have an absolute meaning and should not be standardized.

TABLE II.  
KEYWORD CLUSTERS

No	Keywords
1	problem, contact, message, send, people, time, fix, good, profile, chat, option, video, phone
2	unable, user, text, notification, nice, long, full, check, call, bug, communication, feature, easy, support, data, bad, delete, issue, quality, post, friend
3	view, team, set, screen, message, card, conversation
4	work, update, online, chat, fine, hate, voice, annoying, video, app, feature, photo
5	call, thing, change, friend, person, issue, great, version, group, picture, love
6	download, free
7	update, WhatsApp

The steps completed so far have provided a basis for the mapping of frequent keywords to usability attributes and user experience dimensions (Table 3 and Table 4).

TABLE III.  
THE MAPPING BETWEEN FREQUENT KEYWORDS AND USABILITY ATTRIBUTES

Attribute	Keywords
efficiency	limit, slow, lock, fast
satisfaction	good, love, great, awesome, happy, reliable, wonderful
effectiveness	wrong, miss, problem, easy, waste
learnability	–
memorability	–
cognitive load	delete, load
errors	bug, error, fix, freeze, crash, problem, trouble, mistake
ease of use	ability, easy
operability	ability, unable, secure, feature

TABLE IV.  
THE MAPPING BETWEEN FREQUENT KEYWORDS AND UX DIMENSIONS

Dimension	Keywords
aesthetics	correct, great, nice, awesome, excellent, pretty, wonderful
enjoyment	happy, fun, cool, easy, communicate
hedonics	friend, communicate, awesome, love, happy, super, good,
trust	quality, secure, reliable, easy
support	service, contact, call, support, team, helpful, correct
engagement	correct, stop, communicate, connect, improve, free
discomfort	alert, problem, bad, slow, poor, lock, freeze, crash, worst, mistake, disappointed
frustration	irritating, sucks, horrible, waste, disappointed, terrible, hate, irritating, frustrating, awful, harmful

Interestingly, two usability attributes are empty sets. In other words, none of the keywords were assigned, which indicates that users neither report on the ability to learn nor to remember. Moreover, one can classify UX dimensions as positive (aesthetics, enjoyment, hedonics, trust, support), neutral (engagement) and negative (discomfort, frustration). In Fig. 5 specific dimensions were marked off by labelling sets of the keywords with different colors, ranging from green and blue to red, respectively.

On the other hand, the words included in the above two tables indicate the importance of the reported UUX issues by the users. As a matter of fact, eWOM data are meaningful for app vendors not only because users often rely on this resource when making decisions, but more importantly, online reviews might leverage app design and quality.

## VI. DISCUSSION

There is no doubt that the ability provided to users to tell their stories about mobile applications in any way, has brought popularity as well as obstacles for apps. However, there are many examples of those who have taken an unfair advantage this ability. For example, in December 2018, as a response, Google announced a crackdown on app developers who buy ratings and reviews to deceive users or ruin their competitors' reputations [37].

Moreover, in the Notes section of the store, one can read that reviews are automatically processed to find inappropriate content (such as obscene, offensive, or meaningless language). Online reviews are also automatically scanned for spam (like messages sent by bots or repeated content posted multiple times or from multiple accounts). The company has no tolerance for fake reviews, which will be taken down if they are flagged as fake or are in violation of review policies. Therefore, in our opinion, the Google online store of mobile applications is a reliable source of information.

Although 50.03% of identified words were discovered to be valueless, we found the other half of great value. Indeed, eWOM involves positive and negative statements made by users about WhatsApp. This real user-created information has brought insight into users' direct experiences as well as application performance and properties. On the other hand, since software testers are not able to detect all bugs, defects and errors, the users act on their behalf unintentionally but competently.

Like any other similar research, this study has both its limitations as well as strengths. Firstly, only one app, as the source of the reviews, was explored in order to gather the necessary evidence to formulate an answer to the research question. Secondly, there is no mechanism implemented which could automatically process a relatively large volume of data, and set up keyword clusters in a non-supervised mode. Future research will address broadening the sample and implementing a relevant method. Additionally, while the present approach assumed off-line processing, online

processing will also be considered. Lastly, multiple experiments with different apps are being investigated and validated in order to elaborate the unified UX model.

## VII. CONCLUSIONS

In the case of WhatsApp, in this paper we were able to evidence a positive answer to the given research question. eWOM provides a new venue for software vendors to reach users and to influence their opinions. With zero cost for accessing and exchanging information, eWOM creates a new opportunity to better understand users' genuine concerns formulated toward the features and properties of apps, covered by UX theory and practice. In light of the evidenced results, it seems likely that users in increasingly larger numbers will either read and/or write reviews, expecting afterwards to have a better app in the next release.

## APPENDIX 1

TABLE V.  
EXTRACTED NEGATIVE UUX ATTRIBUTES AND DIMENSIONS FROM ONLINE USERS' REVIEWS

Word	Review	attribute/ dimension
fix	"I am not even getting any notifications from Whatsapp on the status bar nowadays and am very disappointed to say that even though I've double checked the settings for both message and group notifications, there's still no changes. Please <b>fix</b> this problem ASAP."	errors
	"I can't see any status updates from my contacts. The status feature just stops for a while and then returns and stops again. Can you please <b>fix</b> this bug."	errors
	"Useful little app but does come with frustrations. I want to view images and when I click on an image to load it downloads onto my phone which is annoying. Want to view the image not save it and clog up my phone. Same goes for gifs and videos. Please <b>fix</b> it, if you do I'd probably use this more than fb messenger."	errors
	" <b>fix</b> the change! I have contact photos in my phone and people that do not have profile photos would show up with the contact photo now it does not do that after this new update. change it back it was better before"	errors
	"I really like whatsapp messenger but one thing that annoys me is that I cannot forward message to more than (limit set by Whatsapp) five people i guess. Please <b>fix</b> this."	errors
	"do like this app, but the recent update keeps causing it to freeze and crash. Effecting my whole phone. Please <b>fix</b> bugs or whatever is causing it to freeze."	errors
	"Why are whatsapp emojis are looking soooooo badd. like after installing new update, emojis got worse, please <b>fix</b> this in next update."	satisfaction
	"Great App, but there is a bug I am not able to call or video call 3 people at once from the group chat video call option. The call don't respond and automatically disconnect without ringing. Please fix this issue and one more thing when we are getting feature for group video call more then 4 members..."	errors
	"Please <b>Fix</b> bugs . when I Video call , I can't touch anything and can't turn back to the Conversation and can't typing anything . my friend told me either ... please <b>FIX</b> the bugs soon"	errors
problem	"A great way to communicate, but since the last update, my contact's pictures aren't showing. Even though when I go into edit contact and there's a picture there, it's not showing on the main screen. Please <b>fix</b> this!"	errors
	"Plz do something the app has become slow on the two devices I own, one is the huawei p20 and the other is oneplus 6t.I checked my devices but others are all facing the same <b>problem</b> ."	efficiency
	"My WhatsApp crash twice in less than 2 months' time ... All my chats are gone. <b>Problem</b> is I didn't do anything. An error message just pop up and say there's something wrong with my chats history. I lost all my important work chats. This is bad. You can't expect me to do backup every single day."	errors
	"I have a <b>problem</b> sending videos to my contacts, each time I try to send videos that are five minutes long, it is reduced to a lesser minute of 3 minutes of streaming before it can be sent to my contacts. please how do I go about this?"	efficiency
	"I'm using WhatsApp, but I don't see blue coloured double tick after my messages are read. And my friend didn't change the setting on mobile. This not the first time of <b>problem</b> ."	satisfaction
	"Last three weeks I have a <b>problem</b> for message sending. I didn't send any message more than five people. Before 20 people but now 5. I don't know why whatsapp management reduce the conctects for sending messages."	effectiveness
bug	"I can't sent Voice Messages .... Same problem with both my Whatsapp accounts."	errors
	"Everything was fine but since last month's my old chat messages are being deleted by WhatsApp without my knowledge and I am shocked with this new <b>bug</b> ."	errors
	"I can't see any status updates from my contacts.. The status feature just stops for a while and then returns and stops again. Can you please <b>fix</b> this <b>bug</b> ."	satisfaction
hate	"After make video call, it's not getting minimized. Its hanged. New update killing it badly. My mobile note 5 pro.. please solve this <b>bug</b> ."	errors
	"I <b>hate</b> the new update. I lost contact photos to over half my contacts. I can't figure out how to restore contact pics. Also....as popular as this app has been throughout the years, you'd figure that they'd come up with different themes. Instead, same old boring green theme."	satisfaction
	"I <b>hate</b> the new update. I lost contact photos to over half my contacts. I can't figure out how to restore contact pics."	satisfaction
	"I <b>hate</b> the new version. The emojis are old , some are nice , but I would like if the emojis looked more realistic and not fake or something. I recommend this app, although the emojis are not cool. But I would and its useful."	satisfaction
	"I <b>HATE</b> THE NEW UPDATE. ... The previous version was way better. Please restore it."	satisfaction

	"I really love this app...however I and all of my friends <b>hate</b> the new emojis for android... They are awful. Please change the emojis so that they look like IOS emojis ... please"	aesthetics
	"Horrible update. <b>Hate</b> when the update makes the app worse, not better!"	frustration
	"I <b>hate</b> the new update. Pls get back the previous version."	frustration
	"It's still great for communication but I <b>hate</b> the new "upgraded" emojis. As if it wasn't enough that you ruined my favourite emojis, the moons, you've ruined the rolling eyes emoji for me as well. Please fix them and make them look like their past selves."	frustration
<b>bad</b>	"Recent whatsapp update is so <b>bad</b> , I only use it because I have contacts on it. All new icons have gone. Profile icons picked up from phone contacts for those who haven't loaded profile pics, is gone, so there are gaping holes where there should be a contact icon."	discomfort
	"New update is very <b>bad</b> . You can't send msg to more than 5 people, please give us new update and solve this."	satisfaction
	"When sending a video from your gallery, it comes up with an <b>error</b> message ... fix this too."	errors
<b>error</b>	"Unable to send pdf files. <b>Error</b> shows it's not a document what the hell is this.. I think I need to switch messenger."	satisfaction
	"Latest update has a few <b>errors</b> but the one that's bugging me is I had pictures assigned to my phone contacts that used to show as the profile picture on WhatsApp if the person didn't have a profile picture and after the update it's not showing."	errors

TABLE VI.  
EXTRACTED POSITIVE UUX ATTRIBUTES AND DIMENSIONS FROM ONLINE USERS' REVIEWS

<b>good</b>	"My experience is too <b>good</b> with whatsapp. I am happy to make a group and chat within it. It is very helpful and good for school work ... thank you so much."	satisfaction
	"Pros: Its free. Clarity pretty <b>good</b> . Not many adds."	satisfaction
	"It's just so <b>good</b> we can call free, video - chat, share safely, it's one of the necessities in life now. I'm impressed."	satisfaction
<b>feature</b>	"Great! It still remains the most used app in the world. But a <b>feature</b> that can allow us to save what we want needs to be added please."	operate
	"Getting better with each update. The swiping right to reply <b>feature</b> is something I really like."	pleasure
	"... indeed your new <b>features</b> are just amazing. Keep up the good work."	enchantment
	"Neat customization tools, group chat <b>features</b> , and easy location, and now money transfer payments sending & receiving money adding are all cool additions."	comfort
<b>easy</b>	"Fast (especially for sending images), more reliable than SMS, and everyone has it, so it's <b>easy</b> to connect with people."	enjoyment
	"awesome app in social world <b>easy</b> to use fantastic"	easy to use
	"This is the best messaging app ever! I love how it is laid out and how <b>easy</b> it us to use."	easy to use
	"It's quite simply, brilliant. User interface is a tad lame and boring but the app is efficient and <b>easy</b> to use."	efficiency, easy to use
	"Very <b>easy</b> and reliable app for communication. Thanks."	trust
<b>awesome</b>	"It is <b>awesome</b> . I love it. Whatsapp is my favorite app."	satisfaction
	"It's always <b>awesome</b> . It deserves full rating ..."	hedonics
	"You have it because everyone has it. A 'smartphone' is defined by its capability to run this app! <b>Awesome</b> . Saved me a whole lot of money undoubtedly."	satisfaction
<b>communicate</b>	"Great app to <b>communicate</b> quickly and easily ..."	enjoyment,
	"A great way to <b>communicate</b> with friends and family. So clear without a hitch."	enjoyment
	"It's very practical. Great audio in the calls. Simply the most consistent form of <b>communicate</b> on the internet."	enjoyment
<b>super</b>	"This App has made my texting so much quicker and is <b>super</b> -fast sending pics and video's. My wife and I love it and text each other only on WhatsApp! Get it and you won't be sorry!"	hedonics
	" <b>Superb</b> application...user friendly ... just there should be some kind of indications of those who are online like we have in Facebook ... a green signal or something like that should be there so that we don't have to check that who are online. Other than that it's perfect."	hedonics

# Parameter Setting Problem in the Case of Practical Vehicle Routing Problems with Realistic Constraints

**Abstract**—Vehicle Routing Problem (VRP) is the process of selection of the most favorable roads in a road network vehicle should move during the customer service, so as such, it is a generalization of problems of a commercial traveler. Most of the algorithms for successful solution of VRP problems are consisted of several controll parameters and constants, so this paper presents the data-driven prediction model for adjustment of the parameters based on historical data, especially for practical VRP problems with realistic constraints. The approach is consisted of four prediction models and decision making systems for comparing acquired results each of the used models.

## I. INTRODUCTION

THE problem of transport route optimization and optimal exploitation of the transport fleet has been explored and constantly improved for a long time. Vehicle routing problem is the name for the entire group of problems requiring the optimal route the transport vehicle or more of them (one vehicle can be used more than once during a single routing) can go around the specific number of customers (delivery points), starting from the central depot and returning there after the customer service. The optimal route is the one with the minimal cost of the road charges [1]. These optimization problems are becoming extremely complex considering a large number of customers. Additionally, those problems become a real challenge considering numerous constraints and facts such as time windows (TW) of customers, time of goods unloading, goods packaging into vehicles, predefined capacity and various vehicles, fixed and variable vehicle costs, etc. These indicators drastically increase the number of available approaches, models and algorithms which could be applied to a complex set of input data. The standard constraints VRP problems differ from are: the number of depots (one or more of them), maximum allowable timing or the length of the vehicle route, different vehicle capacities, customers' demands for delivery or collection of a certain amount of cargo during the service, time windows for beginning and finishing customer service as well as vehicle time windows.

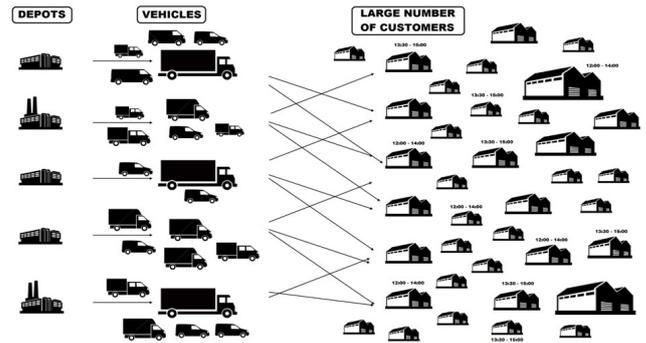

Fig. 1 Rich Vehicle Routing Problem

In a realistic surroundings, it is necessary to take into consideration a huge number of additional constraints, usually being the result of the specificity of the loading and/or unloading locations, specific business processes of the company performing the distribution (collection) or legal decisions and obligations (such as having a rest period for drivers). Such problems are often called Rich Vehicle Routing Problems (RVRP), and one illustrative example is shown on Fig. 1. There are two different approaches in solving RVRP. One of them is the exact algorithms with the aim of finding the optimal solution and proving it to be optimal. Another approach include approximate approaches (heuristic and metaheuristic), with the aim of finding the best possible solution, but without proving it to be optimal. Heuristic approaches and methods are commonly used in complex VRP problems. Neural Networks (NN) as well as Machine Learning (ML) methods have lately been used for the solution of complex VRP problems. Any of these approaches used for solving VRP problems also indicate there are constants and parameters of the algorithm, and their adjustment can make better or worse solution.

The next section presents the basic ways and approaches of adjusting the VRP algorithm parameters. The third section shows the access for adjustment of the control VRP algorithm parameters, consisting of several data transformations. Four algorithms are used for regression. Comparative analysis and discussion of the acquired results are presented in the fourth section. The final section depicts the conclusion of the paper, as well as the guidelines for future researches.

## II. APPROACHES TO ADJUSTMENT OF VRP ALGORITHM PARAMETERS

In most of the papers available in literature, there is the fact which points to every realistic VRP problem to be a bit different from its the most similar problem. Two groups of parameters (controlling ones) are the reason of that: (i) Some realistic constraints and constants of the input data, (ii) Constants of the used algorithm. Every company which requires their implementation of the VRP within their surroundings, has its own constraints, defined by the company business polices. Therefore, it is mentioned in literature that the constraints and restrictions in these kinds of problems are non-standard. In the paper [2], Lee describes in details one such problem with the possible solution of the particular example. With the development of modern technology, in the last few years, determination of the parameters based on the available information from GPS and/or GIS system, data on weather condition and forecasts, has also been performed. Several papers deal with the analysis of such systems, and especially interesting papers are [3] those with the data mining methods and techniques for determination of specific realistic constraints of the VRP problems, and [4] those using the predictions of time distances between knots for dynamic routing requirements for emergency vehicles.

One of the most interesting examples of the classical application of realistic and useful data is presented in paper [5], where the concept of data-driven solution of VRP problem is introduced for the first time. The additional phase is also mentioned for the first time in this paper, and it is used in examples that could be applied in realistic surroundings, and that is Human-Computer Interaction Mode (HCIM), which enables the end user to have the ability of manual modification of the suggested routes. No matter how the algorithm for solving VRP problems is considered perfect, there are always realistic situations that are impossible to predict and include in it, so the possibility of manual modification of the suggested routes in practical systems is of a great importance. Each of the analyzed approaches and algorithms for solving VRP problems is composed of specific constants and controlling parameters. Those parameters and constants are used for adjusting specific weight factors, punitive factors according to individual criteria depending on the importance of the very criterion on the final outcome of the realistic situation of vehicle routing, etc. In literature, this approach is defined as the Parameter Setting Problem (PSP). The most interesting paper on this subject was presented by Calvet et al. [6], describing the statistical approach for fine adjusting of the parameters for metaheuristic algorithms, which is also applied to VRP problem.

Analyzing the other available literature dealing with PSP problem, it can be concluded that these problems could be classified into two basic groups [7]: (i) *Parameter Control Strategies* (PCS), (ii) *Parameter Tuning Strategies* (PTS). In

papers [8]-[9], there is additional sub-group IPTS (Instance-Specific Parameter Tuning Strategies), which includes the characteristics of the instances being applied to. Although there are not many published scientific papers in available literature on the subject of PSP problems, it can be noticed that one of them most interesting applications of it is the improvement of certain segments of VRP, as well as the facilitating of solving VRP problems.

Battiti and Brunato [10] also presented an interesting paper on this subject in which they use the methods of machine learning in combination with statistical methods for fine adjustment of parameters of metaheuristic algorithms. They presented the model that could also be applied for parameters adjustment in other types of algorithms, and one of the most interesting examples is the application for the parameters of neural networks.

Some of the starting ideas for solving realistic VRP problems, and parameters (constants) settings problem are presented in paper [11], where the way of using GPS/GIS data for setting the attribute of the algorithms is presented. In paper [12], the cluster-based analysis and time-series prediction model for reducing the number of traffic accidents is presented.

## III. DATA-DRIVEN APPROACH FOR ADJUSTING THE CONTROL PARAMETERS OF THE VRP ALGORITHMS

There are three data sets VRP problem is consisted of: depot, vehicles and customers (users). At least one depot must be defined in the problem, and important information that should be collected for the depot is:

- *Location*: Address, Postal code and place, Geographic position (latitude and longitude)
- *Working hours*: Opening time, Closing time

If there are more depots distribution is made from, where customers can be served from any other depot, the problem can be modeled as a Multiple Depot Vehicle Routing Problem (MDVRP). But if customers are connected to a particular depot, it is necessary to model more individual VRP problems, for each depot and its buyers individually. In multiple depot problems, vehicles are usually the part of that depot. Basic information about the vehicle include:

- *Load space capacity*: Capacity [kg], Volume [m<sup>3</sup>], Number of pallet positions [pcs], Number of cargo units [pcs]
- Driver's working time
- Departure location
- Arrival location

The capacity of load space is limited by several criteria. For example, in distribution of goods, it is important to pay attention to limited capacity as well as the volume of load space to be sufficient for all the goods being transported. Certain types of goods can be light, but occupy a lot of

space, so it is necessary to fulfill both constraints. Goods are often put on pallets, so the capacity of vehicle can include the number of pallets possible to place into to load space. The simplest case is in distributing the goods of the same dimensions, so the capacity can be expressed by the maximum number of pieces that could be placed into the load space. Customers' data usually include:

- *Location*: Address, Postal code and place, Geographic position (latitude and longitude)
- *Order*: Weight [kg], Volume [m<sup>3</sup>], Usage of the pallets [%], Number of load units [pcs]
- *Time limits*: The earliest discharge time, The latest discharge time, Estimated discharge duration

Every implemented algorithm solving the realistic VRP problem is consisted of control parameters and constants. The value of these parameters and constants could be adjusted based on historical data, and the model depicting the way of that adjustment is presented in Fig. 2.

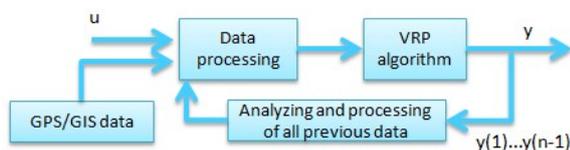

Fig. 2 Approach for adjusting the control parameters based on historical data

The primary goal of realistic VRP problems is to fulfill all constraints. Some of these control parameters are adjusted as described below, using some of the prediction methods and algorithms which will make conclusions based on historical data. On the basis of all the parameters that could have an impact to the final outcome of the solution of VRP problems, several basic ones are sorted out and stored for every route during the testing and production use, since the historical data of practical implementation of VRP algorithms have been used in several largest distribution companies in Bosnia and Herzegovina, dealing with product distribution from their depots to delivery points (shops, supermarkets, etc.). It resulted in creation of a knowledge base being enriched every day, and the main goal is the adjustment of control parameters and constants on the basis of historical data, which can later become a part of any implemented VRP algorithm. Attributes being sorted out as those affecting the routes are:

- The number of customers
- The number of available vehicles
- The number of available different types of vehicles
- The number of towns
- The total number of restrictions where a customer can't be served by a certain vehicle
- Total number of ordered articles [pcs]
- Total volume of ordered articles [m<sup>3</sup>]

- Total weight of all the articles [kg]
- Total duration of TW of all the customers [min]
- Are all the restrictions fulfilled (1: yes, 0: no)

The target attributes affecting the given routes and total cost presenting the control parameters of VRP algorithms in the case of distribution companies are:

- *ToleranceWeight*
- *ToleranceVolume*
- *PenaltyDelay*
- *PenaltyCustomersVehicles*
- *CostIncreasing*
- *PenaltyVolumePercentage*
- *PenaltyWeightPercentage*

During the implementation of VRP algorithms, the vehicle can be allowed to be overloaded in weight or volume, for the values of *ToleranceWeight* and *ToleranceVolume*. Algorithms for solving VRP problems allow the vehicle to be delayed for customer (to arrive outside of its time window). The violation of this parameter is presented by the *PenaltyDelay*. If the VRP algorithm is adjusted for solving Site-Dependent Vehicle Routing Problem (SDVRP), the attribute *PenaltyCustomersVehicles* is used for penalization of rules violations, where the customer can't be served by a particular vehicle. The constant used in increasing the cost, depending on the weight vehicle transports, is presented with the *CostIncreasing*. The constants penalize reloading of vehicles by weight or volume are *PenaltyWeightPercentage* and *PenaltyVolumePercentage*, and they present the cost increasing when the weight/volume of the vehicle is reloaded by 100%. Each of these parameters is determined independently. Firstly, there is a data preprocessing, by excluding only those historical data where all the constraints are fulfilled (value 1 in the column). Then, the removal of redundant attributes was performed by using the Transform Option. Using the Attribute Importance option, the determination of input attribute importance was made for every target attribute. Minimum Descriptor Length (MDL) algorithm was used for attribute importance determination. Before that, the normalization of attribute had been performed in a way the volume of the attribute was put to one decimal place.

After all the preprocessings and preparations of input values, the proposed model was created for determining the target attributes. Model for one attribute is shown in Fig. 3.

Fig. 3 Prediction model for one attribute

Four regression algorithms were used, and their results are compared: (1) Generalized Linear Models (GLM); (2) Support Vector Machine (SVM); (3) Decision Tree (DT); (4) Naive Bayes (NB).

The advantage of SVM over other methods is providing better predictions in unseen test data, providing unique optimal solutions for the problem and the existence of less parameter for optimization compared to other methods. The speed of performance is not crucial for the problem wanted to be applied on, so the lack of SVM regression method can be ignored. GLM regression algorithm is chosen because it represents the generalization of the linear regression and is often used in cases where output variables do not have normal distribution. Since the input data point to linear dependence, the GLM choice of the regression algorithm was a logical choice. Basic advantages of a Decision Tree method are: the possibility of generating comprehensive models, relatively small requirements for computer resources (time and memory) and precise importance of some attributes for the specific problem, as well as vast availability of software solution. The lack of Decision Trees is their instability, because small fluctuations in data sample can result in huge variations in assigned classifications. The advantage of the Naive Bayes classifier is its robustness to errors obtained in data collecting or missing attribute value in training session. Errors do not have a lot of impact on probabilities since they are of average value, while missing data are simply ignored during the calculating of probability. Also, the Naive Bayes classifier is robust to irrelevant attributes, too.

#### IV. RESULTS DISCUSSION

As previously mentioned, for each of the control parameters, the independent model was created with four regression algorithms: GLM, SVM, Decision Tree and Naive Bayes algorithm. After the results were obtained, for each of the parameters, the Decision Support System (DSS) was created which, on the basis of regression results, chose the predicted value of the algorithm that had higher Predictive Confidence. In order to enrich the control parameters knowledge base, VRP productive algorithms were run for more than 10.000 times, with all the constraints fulfilled for many different days and input parameters. Data with testing and validating of prediction models are provided at the 4TU Research Data Center [13], to be available to other researchers for their works and eventual comparison of results. For each of the control parameters, there was a result comparison of confidence/accuracy - Predictive Confidence [%], which was presented for each of the input data set in Table I.

As seen from the presented results, it is not difficult to conclude that the SVM always provided better predictive results for each of the control parameters compared to GLM algorithm (Table I – left), while the prediction models based on the Decision Tree and Naive Bayes algorithms, always showed much worse results (Table I – right), and therefore, the Decision Support System (DSS) preferred the prediction results of the SVM algorithm. Analyzing the Table I in details, it is easy to conclude that the lack of Decision Tree is

their instability, because small fluctuations may result in large variations in the assigned classifications, which was the case. The lack of the Naive Bayes prediction algorithm is presumably the independence of attributes, which make this classifier delicate to correlated attributes. Attributes in strong correlation can degrade performances of the classifiers, which can be solved by removing certain attributes, which is also the case in this example.

TABLE I - COMPARATIVE RESULTS OF USED REGRESSION GLM, SVM, DT AND NB MODELS – PREDICTIVE CONFIDENCE [%]

Parameter	GLM	SVM	DT	NB
<i>ToleranceWeight</i>	91.766	96.123	81.336	84.323
<i>ToleranceVolume</i>	81.995	90.201	79.928	80.905
<i>PenaltyDelay</i>	84.956	89.551	81.555	82.007
<i>PenaltyCustomersVehicles</i>	92.031	96.439	82.309	85.314
<i>CostIncreasing</i>	81.276	89.996	78.998	80.229
<i>PenaltyVolumePercentage</i>	89.133	91.853	83.892	84.934
<i>PenaltyWeightPercentage</i>	90.006	92.698	84.801	84.956

Implemented Attribute Importance segment at the target values in the prediction model enables to determine the importance of each of the input attributes on the target control parameter. The average importance of the input parameters on the input control variables, as well as their order, is shown in Table II. Analyzing the average value of input attribute influences for each of the control parameters, it is concluded that the input parameters affect the output prediction control parameters in that order shown in Table II. Such results were expected because routings made on realistic data were extremely complex with strict constraints, while the number of available vehicles was very small. The fact is that out of 8 available vehicles for routing, seven of them were of different type, which significantly affects the result and complexity of algorithm implementation. It is easy to conclude that these parameters are the most important for adjusting the algorithm control parameters. Also, the customers' time windows are significant for the control parameters, which affect the complexity of finding a solution.

TABLE II - ATTRIBUTE IMPORTANCE RESULTS

Input Parameter	Importance Number	Importance Weight
<i>The number of available different types of vehicles</i>	1	0.871
<i>The number of available vehicles</i>	2	0.861
<i>Total duration of time windows of all the customers [min]</i>	3	0.796
<i>Total number of ordered articles [pcs]</i>	4	0.758
<i>The number of customers</i>	5	0.747
<i>Total volume of ordered articles [m<sup>3</sup>]</i>	6	0.741
<i>The number of towns</i>	7	0.727
<i>Total weight of all the articles [kg]</i>	8	0.582
<i>The total number of restrictions where a customer can't be served by a certain vehicle</i>	9	0.303

According to Table II, the parameter with the least significance for adjusting the value of control parameters is the number of constraints the customer can't be served by a vehicle. The very number is presented in the form of the summary indicator, but if it were presented in terms of ratio

of the customer and the number of vehicles that could serve him, the significance of that parameter would certainly be much greater, even the most significant. For each of the control parameters, the results are graphically displayed, which is example of the *ToleranceWeight* parameter shown in Fig. 4 (left). The important indicator in these analyses is the Mean Absolute Error (MAE) prediction. Results of the MAE for the example of *ToleranceWeight* parameter are shown in Fig. 4 (right).

Fig. 4 Predictive confidence [%] and Mean Absolute Error results: SVM and GLM

It is also possible to observe the comparison of Residual (Residual is the difference between expected and predicted value of the dependent variable) for each of the control parameters. The example of the comparison of the *ToleranceWeight* parameter is shown in Fig. 5.

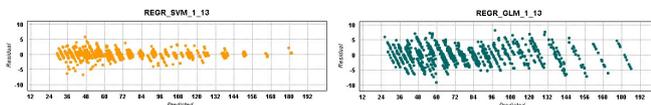

Fig. 5 Residual comparisons: SVM (left) and GLM (right)

Figure 6 shows that for the each attribute except the Predictive Confidence indicator, it is possible to obtain many other parameters (primarily refers to the prediction value errors), which enables to make comparisons and select the model which satisfies the needs and expectations more.

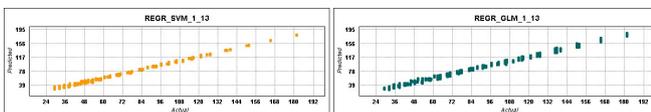

Fig. 6 Comparison of realistic and predicted values – SVM and GLM

It is also simple to make comparison of the actual and predicted value, and make the same conclusion that the SVM algorithm presented much better results compared to the remaining 3 prediction algorithms already used. Thus, every analysis points to the fact that the SVM algorithm is much more superior than other algorithms already used, as well as methods for the purpose of adjusting the control parameters of the practically applicable algorithms for solving the complex VRP problems.

## V. CONCLUSION

Regardless of what approach (exact or heuristics) is used for successful solving the VRP problem, most of the proposed algorithms are consisted of constants in control parameters whose adjustment give better or worse solutions. This paper presents the innovative approach of adjustment of these parameters on the basis of available historical data by

using the prediction models. Four of the prediction models were used, where SVM algorithm proved to have much better and more superior results for all the tests compared to other prediction models. For each of the analyzed control parameters in the case of SVM model, the predictive accuracy was over 90%. The advantage of SVM over other methods being used is providing better predictions in unseen test data, providing unique optimal solutions for the training problem, and the existence of less optimization parameters compared to other methods. The execution speed is not crucial for the problem, so the lack of SVM regression method can be neglected in this case.

Guidelines for the future researches in this area would include the application of neural networks for determination of the values of the VRP algorithm control parameters, or even the prediction based on time series. Surely, the progress should be realized by even more input set of realistic data in this segment of the proposed approach.

# Joint 39<sup>th</sup> IEEE Software Engineering Workshop and 6th International Workshop on Cyber-Physical Systems

**T**HE IEEE Software Engineering Workshop (SEW) is the oldest Software Engineering event in the world, dating back to 1969. The workshop was originally run as the NASA Software Engineering Workshop and focused on software engineering issues relevant to NASA and the space industry. After the 25<sup>th</sup> edition, it became the NASA/IEEE Software Engineering Workshop and expanded its remit to address many more areas of software engineering with emphasis on practical issues, industrial experience and case studies in addition to traditional technical papers. Since its 31<sup>st</sup> edition, it has been sponsored by IEEE and has continued to broaden its areas of interest.

One such extremely hot new area are Cyber-physical Systems (CPS), which encompass the investigation of approaches related to the development and use of modern software systems interfacing with real world and controlling their surroundings. CPS are physical and engineering systems closely integrated with their typically networked environment. Modern airplanes, automobiles, or medical devices are practically networks of computers. Sensors, robots, and intelligent devices are abundant. Human life depends on them. CPS systems transform how people interact with the physical world just like the Internet transformed how people interact with one another.

The joint workshop aims to bring together all those researchers with an interest in software engineering, both with CPS and broader focus. Traditionally, these workshops attract industrial and government practitioners and academics pursuing the advancement of software engineering principles, techniques and practices. This joint edition will also provide a forum for reporting on past experiences, for describing new and emerging results and approaches, and for exchanging ideas on best practice and future directions.

## TOPICS

The workshop aims to bring together all those with an interest in software engineering. Traditionally, the workshop attracts industrial and government practitioners and academics pursuing the advancement of software engineering principles, techniques and practice. The workshop provides a forum for reporting on past experiences, for describing new and emerging results and approaches, and for exchanging ideas on best practice and future directions.

Topics of interest include, but are not limited to:

- Experiments and experience reports

- Software quality assurance and metrics
- Formal methods and formal approaches to software development
- Software engineering processes and process improvement
- Agile and lean methods
- Requirements engineering
- Software architectures
- Design methodologies
- Validation and verification
- Software maintenance, reuse, and legacy systems
- Agent-based software systems
- Self-managing systems
- New approaches to software engineering (e.g., search based software engineering)
- Software engineering issues in cyber-physical systems
- Real-time software engineering
- Safety assurance & certification
- Software security
- Embedded control systems and networks
- Software aspects of the Internet of Things
- Software engineering education, laboratories and pedagogy
- Software engineering for social media

**Abstract**—Producing reliable and accurate estimates of software effort remains a difficult task in software project management, especially at the early stages of the software life cycle where the information available is more categorical than numerical. In this paper, we conducted a systematic mapping study of papers dealing with categorical data in software development effort estimation. In total, 27 papers were identified from 1997 to January 2019. The selected studies were analyzed and classified according to eight criteria: publication channels, year of publication, research approach, contribution type, SDEE technique, Technique used to handle categorical data, types of categorical data and datasets used. The results showed that most of the selected papers investigate the use of both nominal and ordinal data. Furthermore, Euclidean distance, fuzzy logic, and fuzzy clustering techniques were the most used techniques to handle categorical data using analogy. Using regression, most papers employed ANOVA and combination of categories.

## I. INTRODUCTION

THE competitiveness of software companies relies on the successful management of their software projects. One of the most important and difficult tasks in software project management is how to accurately estimate the effort needed to develop a software product. This task is known as software development effort estimation (SDEE). Delivering reliable and accurate estimates remains a challenging objective for software companies due to several factors including the human factor, the variety of software projects, the inherent uncertainty of feature measurement, and the diversity of development environments [1]. In attempt to get accurate predictions, various SDEE techniques have been proposed. These techniques fall into three main types [2]: parametric models [3], [4], machine learning (ML) models [5]-[10] and expert judgment [11].

SDEE techniques build their predictions based on a set of attributes (also called features or cost drivers) that characterize software projects [12], [13]. Most of these techniques derive their predictions based on numerical attributes. However, the information available at the early stages of the software life cycle is more categorical than numerical. Furthermore, the datasets used to build and validate SDEE models

involve a high number of categorical data. For example, in COCOMO'81 dataset [14], 15 attributes out of 17 are measured on a scale composed of six categories: very low, low, nominal, high, very high, and extra high. Another example is the International Software Benchmarking Standards Group (ISBSG) dataset [15], in which numerous attributes such as programming language, application type and development platform are measured on a nominal scale.

Categorical attributes may be measured on a nominal or ordinal scale. The nominal scale type allows the classification of entities into different categories [16], for example, primary programming language may be classified into five categories: Visual basic, C, Cobol, Visual C++, Oracle. Unlike the nominal scale type in which there is no order between the categories of entities, the ordinal scale type enables ranking the categories in a specific order [16]. An example of ordinal attributes is the application experience which may be measured as: 'low', 'nominal', 'high', and 'very high'. To deal with this kind of attributes, different approaches were used in SDEE literature [17]-[21].

In this paper, a Systematic Mapping Study (SMS) is performed to investigate the use of categorical data to estimate software development effort. As pointed out in [22], a systematic map is a method that concentrates on building a classification scheme and categorizing primary research studies in a specific domain with respect to a set of defined categories. Thus, it provides a common starting point for many researchers [23]. To the best of the authors' knowledge, no systematic mapping study has been carried out with focus on how to handle categorical data in SDEE.

This SMS aims to: 1) identify the existing SDEE papers dealing with categorical data and published from 1997 to January 2019; and 2) analyze and classify the selected papers according to 8 criteria: publication channels, year of publication, research approach, contribution type, SDEE technique, Technique used to handle categorical data, types of categorical data and datasets used.

This paper is structured as follows: Section II presents the research methodology adopted to carry out this SMS.

Section III, reports the results of the mapping study. Section IV presents the implications for research and practice. Conclusions and future work are presented in Section V.

## II. RESEARCH METHODOLOGY

In this study, the systematic mapping process suggested by Kitchenham and Charters [24] is used. According to Kitchenham, a mapping study aims to identify the research trends related to a specific topic and classify research works with respect to a set of defined criteria [22], [24]. The mapping process used comprises the following five steps: (1) define the mapping questions, (2) conduct an exhaustive search for candidate papers, (3) select studies, (4) extract data, and (5) summarize data. Each of these steps is described next.

### A. Mapping questions

Eight mapping questions (MQs) were formulated in this mapping study. Table I shows the MQs as well as their main motivations.

### B. Search Strategy

The aim of this step is to find the relevant SDEE papers that address the MQs listed in table I. To perform the search, four electronic databases were used: ACM Digital library, IEEE Xplore, Science Direct and Google Scholar. These libraries were chosen since they were used in previous systematic maps and reviews in SDEE to conduct the search for candidate papers [5], [25], [26]. All searches were restricted to the studies published between 1997 and January 2019.

TABLE I. MAPPING QUESTIONS

ID	Mapping Question	Motivation
MQ1	Which publication sources are the main targets for SDEE papers dealing with categorical data?	To identify the main sources where SDEE studies with focus on categorical data can be found.
MQ2	How has the frequency of handling categorical data in SDEE papers changed over time?	To investigate the publication trends of SDEE studies dealing with categorical data over time.
MQ3	What are the research approaches of the selected papers?	To discover the research approaches used by SDEE studies with focus on categorical data.
MQ4	What are the contribution types of the selected papers?	To explore the contribution types of SDEE papers dealing with categorical data.
MQ5	Which technique investigates the most the use of categorical data in SDEE?	To identify the SDEE techniques that handle the most categorical data.
MQ6	How categorical data are handled in SDEE?	To determine the different ways of handling categorical data in SDEE.
MQ7	What are the most investigated types of categorical data in SDEE?	To identify the types of categorical data that are the most investigated in SDEE.
MQ8	What are the datasets used for validation?	To explore the datasets used in the selected papers as well as the Percentage of categorical features

	used in the experiments.
--	--------------------------

To carry out the search using the four databases, a search string was defined. To do so, we derived the main terms based on the MQs. Then, we identified all alternative spellings and synonyms of the major terms. The Boolean operators OR and AND were used to combine the main terms [25], [26]. The final search string was formulated as follows:

(software OR system OR application OR product OR project OR development) AND (effort OR cost) AND (estimat\* OR predict\* OR assess\*) AND (categorical OR nominal OR ordinal OR "non-quantitative") AND (feature OR attribute OR data OR "cost driver").

To ensure that no relevant paper was missed, we adopted a search process of two stages. In the first stage, we performed the search in the four electronic databases using the above search string to identify the set of candidate papers. In the second stage, we applied the inclusion and exclusion criteria on each of the candidate papers based on title, abstract, and keywords to decide on its relevance to our study. If necessary, the full paper was examined. The reference list of each of the relevant papers was scanned to check whether a SDEE study with focus on categorical data was leaved out in the first stage.

### C. Study Selection

The purpose of this step was to select the papers that are relevant to our SMS (i.e., papers that addressed the MQs). To achieve this, a set of inclusion and exclusion criteria were applied on each of the candidate papers by each of the authors of this study to decide whether it should be retained or discarded.

#### Inclusion criteria

- ✓ Studies with focus on how to handle categorical data to estimate software effort
- ✓ Studies in which a technique is proposed or extended and which enables software effort estimation using categorical data or a mixture of numerical and categorical data
- ✓ Studies comparing different techniques that handle categorical data

#### Exclusion criteria:

- ✓ SDEE studies in which categorical features are not handled or discarded
- ✓ SDEE studies for which the main objective is not deal with categorical data and which use only transformation to dummy variables
- ✓ SDEE studies that fuzzify numerical inputs to get linguistic values without dealing with categorical inputs
- ✓ SDEE studies with focus on missing categorical data
- ✓ Duplicate publications of the same paper (In this case, only the most complete study is included)
- ✓ Studies estimating maintenance or testing effort

Using the above criteria, the two researchers independently evaluate the candidate papers. Based on the title and abstract (if necessary full text), a researcher might categorize a candidate paper as "include", "Exclude", or "Uncertain". A paper that was categorized as "Include" ("Exclude") by both researchers was retained (discarded); otherwise, the paper was discussed until an agreement was reached.

**D. Data Extraction Strategy and Synthesis Method**

Each of the selected papers was examined by both authors to extract the data necessary to answer the mapping questions of table I. To this end, a data extraction form was used and completed by both authors for each selected paper. Table II shows the data extraction form used in our mapping study.

The extracted data were, then, synthesized and summarized with respect to each MQ. To achieve this, a narrative synthesis approach was used. We also used some visualization charts such as pie charts and bubble plots to improve the presentation of the results obtained and facilitate their interpretation.

TABLE II. DATA EXTRACTION FORM

<b>Data extractor</b>
<b>Paper identifier</b>
<b>Author(s) name(s)</b>
<b>Article title</b>
(MQ1) Publication Channel
(MQ2) Publication year
(MQ3) Research approach (History-based evaluation, solution proposal, case study, theory, review, survey, other)
(MQ4) Contribution type (Technique, tool, comparison, validation, metric, model, framework)
(MQ5) SDEE Techniques used in the paper
(MQ6) Technique used to handle categorical data
(MQ7) Types of categorical data used in the study
(MQ8) Datasets used

**III. RESULTS AND DISCUSSION**

This section presents and discusses the results of our systematic mapping related to the questions of table I.

**A. Overview of the selected studies**

The results of the selection process are shown in Fig. 1. As can be seen, 1226 candidate papers were retrieved by applying the search string described previously on the four electronic databases. Afterward, the inclusion and exclusion criteria were used to evaluate each of the candidate papers and decide whether it should be retained or discarded. The evaluation was based on the title, abstract, keywords, and full text of the candidate papers. This process resulted in 27 relevant papers. No additional relevant studies were identified by checking the reference lists of the selected studies.

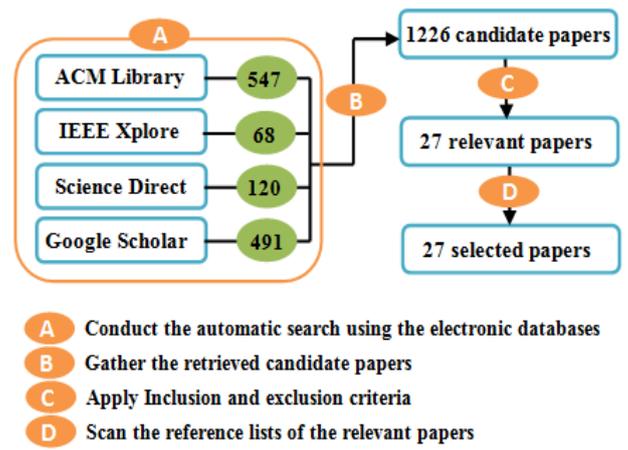

Fig. 1 Results of selection process

**B. Publications Channels (MQ1)**

We identified two main publication channels in which the selected studies were published: journals and conferences. Specifically, among the 27 selected papers, 15 (55.56%) papers appeared in journals and 12 (44.44%) papers were presented at conferences. Tables III and IV shows the publication sources of the papers identified in journals and conferences respectively. The number of studies per publication source is given in the second column of each table. Three journals were identified with 2 or more papers dealing with categorical data in SDEE: Empirical Software Engineering, Information Software Technology, and IEEE Transactions on Software Engineering. Only one conference was identified with 2 papers: International Conference on Predictive Models in Software Engineering (PROMISE). The remaining sources (journals and conferences) were used once to publish SDEE studies with focus on categorical data.

TABLE III. PUBLICATION SOURCES OF JOURNAL PAPERS

Publication venue	# of studies
Empirical Software Engineering	4
Information and Software Technology	3
IEEE Transactions on Software Engineering	2
The Journal of Systems and Software	1
International Journal of Intelligent Systems	1
International Journal of Computer Science and Engineering Survey	1
Software Quality Journal	1
Journal of Information Science and Engineering	1
IEEE Access	1

TABLE IV. PUBLICATION SOURCES OF CONFERENCE PAPERS

Publication venue	# of studies
International Conference on Predictive Models in Software Engineering	2
International Conference on Software Engineering Research, Management and Applications	1
Asia-Pacific Software Engineering Conference	1

Software Metrics Symposium	1
International Conference on Computer and Information Technology	1
International Conference on Software Engineering	1
International Conference on Computer Science and Automation Engineering	1
International Symposium on Software Metrics	1
International Conference on Enterprise Information Systems	1
International Conference on Communications, Circuits and Systems and West Sino Expositions	1
Empirical Software Engineering and Measurement	1

### C. Publications Trends (MQ2)

To get a global picture of the publication trends of SDEE papers dealing with categorical data, we analyzed the distribution of the selected studies over time. Fig. 2 shows the number of papers per year from 1997 to January 2019. As can be seen, the publication of SDEE papers with focus on categorical data is characterized by discontinuity. In fact, no paper was identified in some specific years (1998, 2000, 2003, 2005, 2014, 2017, 2018). Handling categorical data in SDEE has gained research interest in the period 2008-2013 (59% of the selected papers). Outside this period, poor number of studies was identified (not more than one paper per year except for 2001).

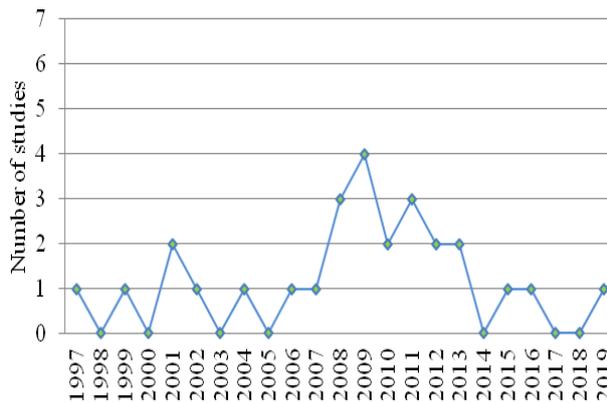

Fig. 2 Publication trends of the selected studies

### D. Research approaches (MQ3) and contribution types (MQ4)

As shown in Fig. 3, two main research approaches were used in the selected papers: solution proposal, and history-based evaluation. The solution proposal approach was adopted by 85% of the selected studies. Among them, 91% (21 out of 23) proposed new techniques, 4% (1 out of 23) proposed a new framework and 4% investigated the use of a new metric. Note that, all selected studies were included in the history-based evaluation approach. Among them, 15% (4 out of 27) performed a comparison of various SDEE techniques using datasets with mixed numerical and categorical data. The remaining papers used historical

datasets to assess the performance of their proposed approaches.

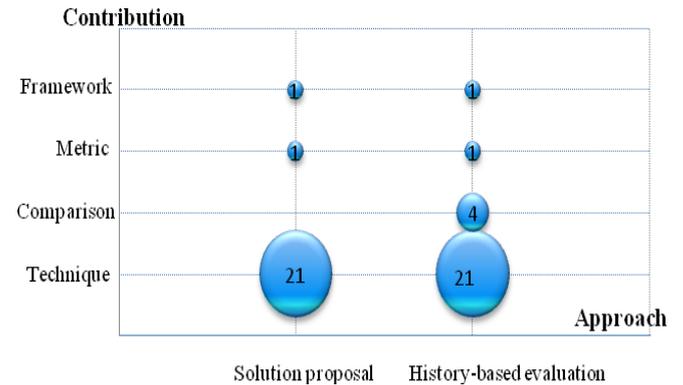

Fig. 3 Research approaches used in the selected studies and their contribution type

### E. SDEE Techniques investigating categorical data (MQ5)

Various approaches were used in the selected papers to estimate software effort using a mixture of numerical and categorical data. Table V shows the techniques used as well as the number of studies in which they were applied. Case based-reasoning (CBR), Regression (SR), Fuzzy Logic (FL), and Classification and Regression Trees (CART) were the techniques that investigate the most the use of categorical data in software effort estimation. Most of these techniques were not used alone. They were combined with each other to improve their prediction accuracy and to get accurate estimates. Specifically, 59% (16 out of 27) of the selected papers used a combination of two or more techniques to predict software effort whereas 41% employed a single technique.

TABLE V. TECHNIQUES USED IN THE SELECTED PAPERS

Technique used	# of studies	Studies
Case based-reasoning (CBR)	15	S3, S6, S7, S8, S9, S10, S12, S13, S15, S16, S17, S18, S19, S20, S24
Regression (SR)	9	S1, S4, S12, S16, S20, S22, S25, S26, S27
Fuzzy Logic (FL)	7	S2, S3, S8, S9, S14, S15, S21
Classification and Regression Trees (CART)	5	S11, S12, S14, S16, S21
Model Tree (MT)	2	S5, S7
Artificial Neural Networks (ANN)	2	S19, S26
Grey Relational Analysis (GRA)	2	S8, S9
Stepwise ANOVA	2	S12, S16
Bees Algorithm (BA)	1	S5
Kendall's Row-wise Rank Correlation	1	S6

(CRRC)		
Particle Swarm Optimization (PSO)	1	S10
Association Rules (AR)	1	S11
Mantel's Correlation (MC)	1	S17
Collaborative Filtering (CF)	1	S18
Genetic Programming (GP)	1	S23
IFPUG	1	S25

TABLE VI. CATEGORICAL (NOMINAL AND ORDINAL) DATA HANDLING

Categorical data handling	SDEE Technique	Studies
Euclidean distance	CBR	S6, S7, S10, S12, S16, S17, S19, S24
Combining categories / ANOVA	Regression	S4, S12, S16, S20, S22, S26
Classification by DT	Decision trees	S5, S11, S12, S14, S16, S21
Fuzzy logic	CBR / DT	S2, S3, S13, S15, S14
Fuzzy Clustering technique	CBR	S3, S13, S15
Quantification of data	Regression	S4
Grey Relational Coefficient	CBR	S8
Manhattan distance	CBR	S10
Local similarity	CBR	S18
Grammar Guided Genetic Programming	Genetic Programming	S23 [44]

*F. Handling of categorical data in SDEE (MQ6)*

To deal with categorical data, different techniques were applied depending on their type (nominal or ordinal) as well as the SDEE technique in which they were used. Table VI shows how both nominal and ordinal data were handled in the selected SDEE studies. Note that, some studies used the term 'Categorical' without specifying the exact data type (nominal or ordinal). As shown in table VI, using CBR, Euclidean distance is the most used metric to assess the similarity between two projects that are described by a mixture of numerical and categorical data [9], [27]-[33]. Fuzzy logic, and fuzzy clustering techniques were also used in many CBR/DT works to deal with categorical data [10], [17], [20], [34], [35]. Using regression, most papers employed one-way Analysis of Variance (ANOVA) and recorded categorical variables into new ones with fewer categories [2], [18], [30], [31], [36], [37]. Other studies employed classification and regression trees to handle categorical data [30], [31], [35], [38]-[40].

The above-mentioned techniques were applied to handle both nominal and ordinal data. Other techniques to deal with categorical data were identified depending on whether they are measured on a nominal or ordinal scale. Table VII shows how nominal data were handled in the selected papers. Using regression, four techniques were identified: Transformation to dummy variables, dataset segmentation, interaction, and use of a hierarchical linear model [30], [31], [36], [41], [42]. Using CBR, the equality distance was used to assess the similarity between projects that are described by nominal features [1], [36]. Regarding ordinal data, they were handled as if they were measured using an interval scale or converted to numerical values using regression [30], [43]. Using CBR, they were treated as interval scaled or handled using Grow's formula [1], [36] (see table VIII).

It is worth noting that, when investigating the use of categorical data in the selected papers, we found that some CBR works used categorical data not only to measure the similarity between software projects using Euclidean distance but also: 1) to adjust estimation by analogy; 2) to identify whether a categorical attribute is appropriate to yield predictions or 3) for feature weighting (see table IX).

Table VII. Nominal data handling

Nominal data handling	SDEE Technique	Studies
Dummy variables	Regression	S12, S16, S20, S27
Equality distance	CBR	S9, S20
Dataset segmentation	Regression	S25, S27
interaction	Regression	S27
hierarchical linear model	Regression	S27

Table VIII. Ordinal data handling

Ordinal data handling	SDEE Technique	Studies
Interval scale	Regression / CBR	S12, S20
Grow's formula	CBR	S9
Conversion to numerical values	Regression	S1

Table IX. Other uses of categorical data

Use of categorical data	SDEE Technique	Studies
Adjustment using MT	CBR	S7
Adjustment using ANN	CBR	S19
Weighting using PSO	CBR	S10
Appropriateness of attributes using CORR	CBR	S6
Dataset appropriateness using Mantel's correlation (dataset partitioning based on nominal data)	CBR	S17

*G. Types of used categorical data (MQ7)*

Fig. 4 shows the types of categorical data used in the selected papers. As can be seen, 59% (16 out of 27) of the selected studies dealt with both nominal and ordinal data, 7% (2 out of 27) dealt with only nominal data and 4% (1 out of 27) were concerned with ordinal data. Among the selected studies, 30% (8 out of 27) did not specify the exact

categorical data type that is handled in the paper. However, based on our knowledge and the datasets used in the experiments, we concluded that most of these papers dealt with both nominal and ordinal data types.

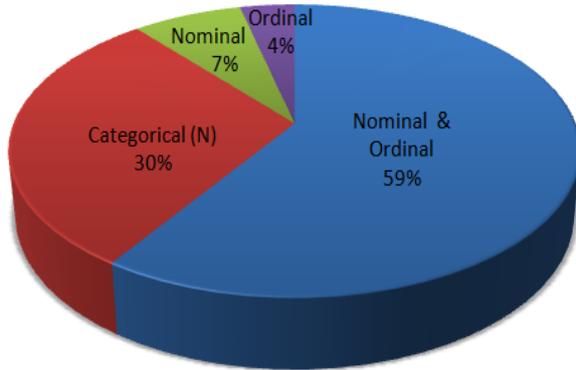

Fig. 4 Types of used categorical data

#### H. Datasets used (MQ8)

Several datasets were used in the selected papers to investigate the use of categorical data in software effort estimation. Table X shows the datasets used for validation as well as the number of studies in which they were used and the percentage of categorical data. The min, max, and mean columns show the minimum value, the maximum value and the mean value respectively of the percentage of categorical data used in the selected papers to conduct experiments. Note that, different studies may opt for different categorical features to conduct experiments. Therefore, the percentage of categorical data is not the same for all studies. Note also that, there were some studies for which it was not possible to extract the percentage of categorical features used in the experiments. As can be seen from table X, 21 datasets were used in the selected papers. Among them ISBSG, COCOMO, Desharnais, Kemerer, Albrecht and Maxwell are the most used datasets. In terms of categorical data percentage, COCOMO (93.52%) was the dataset with the highest mean percentage followed by Maxwell (88.83%) and Laturi (80.00%).

Even if ISBSG is the most used dataset and contains numerous categorical features, the mean percentage of the categorical data used in the selected papers was 49.13%. This is due to the fact that some studies used few categorical features to conduct experiments. Also, there was 1 study [29] that used only the numerical features of ISBSG. This study was included in our mapping study since the technique described in the paper may be applied on both numerical and categorical data. It is worth noting that, some papers employed datasets with numerical and mixed data to show the efficiency of their techniques to deal with both data types.

Table X. Datasets used in the selected papers

Dataset	# of studies	Percentage of categorical data		
		Min	Max	Mean
ISBSG	19	00.00	81.82	49.13
COCOMO	11	88.89	94.74	93.52
Desharnais	9	10.00	25.00	13.10
Kemerer	6	33.00	40.00	36.58
Albrecht	6	00.00	16.67	8.33
Maxwell	5	80.00	95.65	88.83
NASA93	3	60.00	94.44	77.22
Telecom	2	N	N	N
USP05-FT	2	52.94	63.64	58.29
USP05-RQ	2	52.94	63.64	58.29
China	1	00.00	00.00	00.00

Real-time 1	1	100.00	100.00	100.00

N: Not given in the paper

#### IV. IMPLICATION FOR RESEARCH AND PRACTICE

This study aims at presenting an overview of how categorical data are handled in SDEE. Based on the finding of our SMS, some recommendations to SDEE researchers and practitioners are provided. Dealing with categorical data is an important issue in SDEE especially at the early stages of the software life cycle where most of the existing attributes are more categorical than numerical. This study found that, the publication of SDEE papers with focus on categorical data is characterized by discontinuity. This implies that the use of categorical data in SDEE needs to be more investigated.

No case study was identified in the selected papers. Therefore, it is suggested to the researchers to cooperate with practitioners in order to explore the use of categorical data in industry to yield estimates. We also recommend for researchers to develop tools that enable software effort estimation using a mixture of numerical and categorical data to encourage the use of categorical data by practitioners and researchers.

This study found that CBR, regression and classification and regression trees are the techniques that investigate the most the use of categorical data in SDEE. It is therefore recommended to conduct further research works using other SDEE techniques. Researchers are also encouraged to develop new techniques to handle categorical data instead of

using traditional ones. Furthermore, previous studies revealed that ensemble techniques yield better results than single techniques [26], [45]-[47]. However, all selected papers used single SDEE techniques. No ensemble SDEE technique dealing with categorical data was identified. This implies that researchers should give more attention to the use of categorical data in ensemble techniques to investigate their impact on improving the estimation accuracy of their techniques.

#### V. CONCLUSION AND FUTURE WORK

In this paper, a systematic mapping study was carried out in order to identify and summarize the existing works on SDEE dealing with categorical data. A total of 27 relevant studies were identified and classified according to research approach, contribution type, SDEE technique, Technique used to handle categorical data, types of categorical data and datasets used. Research sources and publication trends were also identified and analyzed. Our findings are summarized as follows.

**(MQ1):** Dealing with categorical data has not been sufficiently investigated in SDEE. Besides, Journals were the most targeted publication channels followed by conferences.

**(MQ2):** The publication of SDEE papers with focus on categorical data is characterized by discontinuity. Dealing with categorical data in SDEE has gained research interest in the period 2008-2013.

**(MQ3):** Solution proposal and history-based evaluation were the two main research approaches used in the selected papers.

**(MQ4):** Most of the selected papers focus on developing new techniques especially to improve existing approaches.

**(MQ5):** Case based-reasoning, regression, fuzzy logic, and classification and regression trees were the techniques that investigate the most the use of categorical data in SDEE.

**(MQ6):** Euclidean distance, fuzzy logic, and fuzzy clustering techniques were the most used techniques to handle categorical data using CBR. Using regression, most papers employed ANOVA and combination of categories.

**(MQ7):** Most of the selected studies dealt with both nominal and ordinal data.

**(MQ8):** ISBSG, COCOMO, Desharnais, Kemerer, Albrecht and Maxwell were the most used datasets.

For future work, we will carry out a systematic literature review to analyze the use of categorical data in SDEE by taking into account the finding of this SMS.

**Abstract**—Big data processing in the Smart Grid context has many large-scale applications that require real-time data analysis (e.g., intrusion and data injection attacks detection, electric device health monitoring). In this paper, we present a big data platform for anomaly detection of power consumption data. The platform is based on an ingestion layer with data densification options, Apache Flink as part of the speed layer and HDFS/KairosDB as data storage layers. We showcase the application of the platform to a scenario of power consumption anomaly detection, benchmarking different alternative frameworks used at the speed layer level (Flink, Storm, Spark).

## I. INTRODUCTION

**B**IG data architectures are designed to handle ingestion, processing and analysis of data that possesses the five V's properties: Volume, Velocity, Value, Variety, Veracity [1], [2]. In the context of Smart Grids (SG), utilities have to deal with an increasing volume of data leading to typical big data problems. According to Zhang et al. [3], the five V's in the SG domain are represented by several needs: to analyze large amounts of data in real-time, like from smart meter readings (Volume), to deal with quick generation of records (Velocity), and diversity of data structures (Variety), with multiplicity of use case, such as anomaly detection or load balancing that bring value to the customers (Value), and inherent problematic of data in terms of possible measurement errors (Veracity). To exemplify, with a sampling rate of 15 minutes, a sample of 1 Million Smart Meter devices installed results in around 3 Petabytes of data in one year (3000TB, ~35Billion records at a size of 5KB each record) [4].

There are a plethora of use cases for the application of big data analysis in the context of SGs [5], [6], like anomaly detection methods to detect power consumption anomalous behaviours [7], [8], the analysis of false data injection attacks [9], load forecasting for efficient energy management [10], among others. Such data analysis requirements create needs to define architectures and platforms to support large scale data analysis.

In this paper, we focus on power consumption data anomaly as the application scenario: dealing with the identification of anomalous patterns from energy consumption traces collected from smart meters, that can have several benefits for utilities, such as load optimizations based on determined patterns of energy usage [5], [7] or clustering of customers [11]. The final

goal is the definition and evaluation of a big data platform for power consumption anomaly detection.

We have two main contributions in this paper:

- the provision of a big data platform for power consumption anomaly detection with the main components mapped to the reference architecture proposed by Pääkkönen and Pakkala [12].
- the results of a scenario run with public datasets to assess the applicability of batch-oriented (Apache Spark), stream-oriented (Apache Storm), or hybrid (Apache Flink) frameworks in the speed layer of the platform.

The paper is structured as follows. In Section II, we discuss the background of big data analysis in the context of Smart Grids. In Section III, we discuss big data energy management platforms that can be comparable to our proposal. In Section IV, we propose a platform for big data power anomaly detection with components mapped to the reference architecture in Pääkkönen and Pakkala [12]. In Section V, we propose a power consumption scenario aimed at showcasing the application of the platform and the evaluation at the speed layer level of three frameworks from the Apache Software Foundation (Spark, Flink, Storm). The conclusions are presented in Section VI.

## II. BACKGROUND - BIG DATA ANALYSIS ARCHITECTURES

Big data processing is assuming more and more relevance in many fields of modern society. For energy utilities, the needs to manage energy resources based on the vast amount of information collected from sensors and the ICT infrastructure is nowadays of paramount importance [3].

In the context of big data processing, we can have a first distinction between batch and stream processing. Batch processing is a type of processing executed on large blocks (batches) of data stored over a period of time. These data blocks are appended to highly scalable data stores and periodically analyzed in batches by big data processing frameworks. This approach to data processing is very effective in case of large datasets for use cases that are not time-critical, as the main drawbacks are higher latencies in processing requests [13]. On the other hand, stream processing allows dealing with data in real-time, getting approximate results that can be complemented, if needed, from the analysis of batch processing. Managing streams of data usually implies the capabilities of online learning. Some authors also consider

an intermediate category: micro-batch processing [13], that overcomes some of the issues of batch and stream processing: near real-time performance is granted by considering streams of data in micro-batches sent to the batch processing engine.

There are two popular architectures that were proposed over time, Lambda and Kappa [13], [14]. They were mainly based on the relevance that is given to batch and stream processing. **Lambda architecture** is a processing architecture designed to handle massive amount of data efficiently by taking advantage of both batch and stream-processing methods. Efficiency in this context means high-throughput, fault-tolerance and low latency [13]. The rise of the Lambda architecture is correlated with the growth of data and the speed at which they are being generated, real-time analytics and the drive to mitigate big latencies of map-reduce [15].

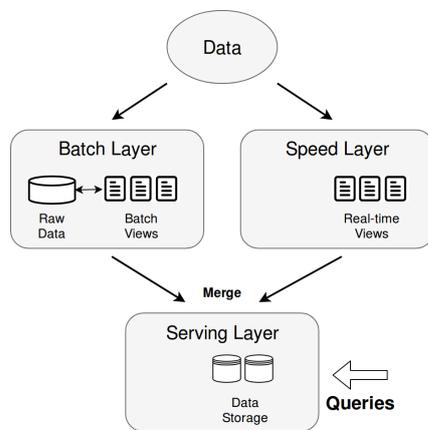

Fig. 1. Lambda Architecture

Generally, a Lambda architecture consists of three distinct layers (Fig. 1): a batch layer (batch processing), a speed layer (stream processing) and a serving layer (data storage). The batch layer is responsible for bringing comprehensive and accurate views of batch data while simultaneously, the speed layer provides near-real-time data views. Stream processing can take advantage of batch views and may be joined before presentation. Data streams entering the system are dual fed into both batch and speed layer.

The batch layer stores raw data as it arrives and computes the batch views in intervals. When the data gets stored in the data store using different data storage systems, the batch layer processes the data using one of the big data processing frameworks that implement the map-reduce programming paradigm. Popular frameworks that support batch processing are Apache Hadoop, Apache Spark, and Apache Flink.

The speed layer processes data streams in real-time with the focus on minimal latencies. Usually latencies vary from milliseconds to several seconds. This layer often takes advantage of pre-computed batch views. Popular frameworks that support stream processing are Apache Flink, Apache Storm, Apache Spark, and Apache Samza.

The serving layer aggregates the outputs from batch and speed layers, storing the data in a datastore. As storage, highly

scalable and distributed data lakes are often used. Among popular big data datastores belong Apache Cassandra, Apache HBase, Hadoop Distributed File System, OpenTSDB, and KairosDB.

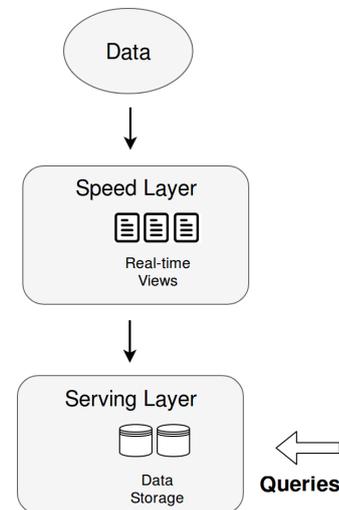

Fig. 2. Kappa Architecture

**Kappa architecture** is an alternative to the Lambda architecture proposed to overcome some of the limitations, like maintaining two code bases for batch and speed layers and the general complexity of the platform [16]. The Kappa architecture consists of two distinct layers (Fig. 2): a speed layer and a serving layer. The speed layer processes streams of data in the same way as Lambda architecture. The only main difference is that when the code changes, data needs to be reprocessed again. This is because parts of the Kappa architecture act as an online learner.

Big data analysis frameworks often do not support both batch and stream processing, thus a hybrid combination of frameworks is the choice, e.g., Apache Hadoop and Apache Storm can be used to fully support a Lambda architecture [17].

In the context of SGs, we can find some examples of the main constituting layers of both architectures. A batch layer in Spark, distributed in-memory computing framework, was used to pre-compute a statistical-based model using linear regression for anomaly predictions of energy consumption data [7]. A stream layer was used for the detection of defective smart meters, solution implemented using the Flink stream processing engine [18]. As a serving layer, KairosDB, time-series database built on top of Apache Cassandra, could handle the workload of a large city with around six million smart meters. During this experiment, KairosDB was installed in a cluster of 24 nodes [19].

The next section will discuss more in detail about big data energy management platforms that have been proposed so far.

### III. RELATED WORKS—BIG DATA ENERGY MANAGEMENT PLATFORMS

We have discovered several proposed big data architectures in the SG domain that we mapped to either Lambda or Kappa based on the available information. We found that the majority of the architectures are cloud-oriented and that several energy management architectures do not specify the applicability to the big data context. Therefore, they might use different architectural structure than pure Lambda or Kappa.

#### A. Big Data energy management architectures

Mayilvaganan and Sabitha [20] proposed a SG architecture which uses HDFS and Cassandra to store historical data for the prediction of energy supply and demand. In this work, only MapReduce processing was used.

Munshi and Mohamed [21] presented a SG big data ecosystem based on the Lambda architecture. Smart meter data are being ingested to a cloud with Flume. For the batch layer of the Lambda architecture Hadoop is used, and Spark for the speed layer. Authors also performed data mining and visualization applications on top of this ecosystem with real data.

Liu and Nielsen [22] designed a smart meter analytic system. The architecture is divided into data ingestion, processing, and analytics layer. It can process both batch and stream data. In the processing module, they list several tools which can be used, like Spark, Hive, or Python. In the end, the data are sent to the analytics layer, which contains a PostgreSQL database, analytics libraries, and applications for users. This architecture can be viewed as Lambda-based because usage of Hive can be considered as a batch layer and the usage of Spark as a speed layer. The analytics layer of this architecture can be mapped to a serving layer.

Fernández et al. [?] proposed an architecture that improves energy efficiency management in a smart home. It consists of four modules: data collection, data storage, data visualization, and a machine learning module. It is designed to work with both batch and real-time processing. The data storage module consists of three blocks: acquisition, real-time, and batch block. From those processing blocks, the data are available to blocks that can be mapped to a service layer of a Lambda architecture. Therefore this architecture is also considered as Lambda-based.

Balac et al. [23] proposed an architecture for real-time predictions in energy management. The data streams are collected to the server, which provides management functionality like dashboards, alerting, and basic reporting. From this server, data are transferred to their high-performance file system where the real-time analysis is performed. The analysis results are then passed back to the server but are also archived in the cloud storage for some later batch processing task. Based on this description, this architecture can be viewed more as Kappa-based.

Al-Ali et al. [24] proposed a system for energy management in a smart home. They specify both hardware and software architecture. The software architecture contains three modules: data acquisition, a middleware, and a client application

module. In this architecture, data are stored and then used by several services. Therefore it does not represent neither a Lambda nor a Kappa architecture.

Daki et al. [25] presented an architecture which is composed of five parts: data sources, integration, storage, analysis, and visualization that can be used for the analysis of customer data. They provide a set of technologies which might be used and can be considered as either a Lambda or a Kappa architecture, depending on the use cases.

#### B. Other energy management architectures

Yang et al. [26] proposed an energy management system that uses a service-oriented architecture in the cloud. For storage, they use distributed software as MySQL Cluster and HDFS. However, authors do not specifically mention big data. Ali et al. [27] proposed a computing grid based framework for the analysis of system reliability and security. The architecture consists of three layers: application, grid middleware, and resource layer, with focus on high-performance computing. Rajeev and Ashok [28] presented a cloud computing architecture for power management of microgrids, consisting of four modules: infrastructure, monitoring, power management, and a cloud service module.

### IV. PROPOSED PLATFORM

In this section, we propose our big data platform for smart meters power consumption anomaly detection, based on our previous research ([29], [8], [30], [31]). The goal of such platform is to process large amounts of data from smart meters and weather information sources to detect anomalous behaviours from the side of customers. Such analysis can allow to further create customer profiles that can be used to cluster users according to their power consumption behaviours [11]. The five V's in this area derive from several aspects, namely volume: the large amount of information traces generated by smart meters multiplied by the number of users [4], velocity: the needs for real-time analysis of such traces that are constantly generated [4], variety: multiple data sources involved, either structured or unstructured, mainly about power consumption and weather data [3], value: the added value that analyses can have for utilities, that can create customer profiles to optimize power production and balancing of the whole grid [11], and veracity: the many issues that measurements errors might pose, such as corrupted or missing data from smart meters [32].

We map our proposed architecture to the reference architecture by Pääkkönen and Pakkala [12]. The reference architecture for big data systems is technology independent and is based on the analysis of published implementation architectures of several big data use cases. We mapped all the functionalities, data stores and data flows contained within our platform proposal to the reference architecture diagram to allow for easier comparison with other platforms (Fig. 3):

**Data sources.** Our platform supports two possible data sources. First, a stream of semi-structured data is being collected from smart meters datasets. These can either be live data

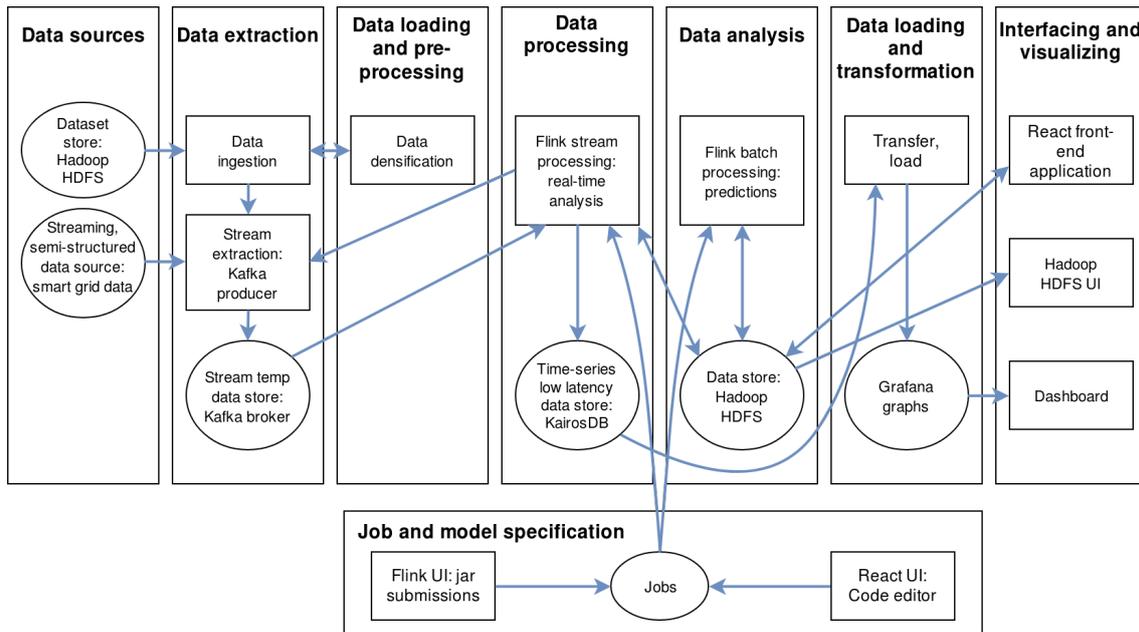

Fig. 3. Architecture Mapping to Pääkkönen and Pakkala [12] Reference Architecture

from smart meters or private/public available datasets. Another way for data to enter the platform is reading data available in the Hadoop Distributed File System (HDFS).

**Data extraction.** A Kafka producer corresponds to the stream extraction functionality and a Kafka broker serves as temporary data store. An ingestion manager extracts data from HDFS and sends data to the Kafka broker.

**Data loading and pre-processing.** Data extracted from HDFS using the ingestion manager can be further densified. Densification can increase the itemset for smaller datasets (e.g., for benchmarking reasons). Currently, two densification methods are available in the platform – multiplication (replicating  $n$  times the dataset) and interpolation (constructing new data points based on interpolating previous intervals  $n$  times). However, more advanced methods can be implemented, such as regression-based and probability-based methods [33].

**Data processing.** Flink's stream-processing jobs read incoming data streams from Kafka. These jobs can also access HDFS to read pre-computed models or datasets and merge them before producing results. The output of stream-processing jobs can be sent back to Kafka, HDFS or to the time-series datastore KairosDB.

**Data analysis.** Flink's batch-processing jobs can read data from HDFS and perform data analytics. The output can be further stored in HDFS.

**Data loading and transformation.** Results of stream-processing jobs stored in KairosDB can be loaded into a Grafana server. In this context, Grafana server serves as a temporary data store until the graphs are generated.

**Data storage.** The following data storage technologies (temporary or persistent) are supported by the platform: Kafka broker, HDFS, KairosDB and Grafana.

**Interfacing and visualization.** There are several user interfaces that allow interacting with the platform. HDFS provides an UI with information regarding storage and the file system. Flink UI gathers statistics about running jobs, e.g. records processed per second by an operator. A dashboard component displays graphs produced by Grafana. A React front-end application allows users to upload or delete datasets and shows datasets previews. It is also possible to select the dataset for ingestion, which invokes the ingestion Manager to read the dataset from HDFS and ingests the data into Kafka.

**Job and model specification.** Submitting stream and batch processing jobs can be done either by uploading a JAR file with all dependencies using the Flink UI or by submitting the code using an ad-hoc code-editor contained within a React front-end application. The JAR file has to include the source code for the processing job (e.g., an anomaly detection algorithm like in [7]), all the dependencies the job requires and the path to the entry Java file to be executed.

Discussing the platform's architecture (Fig. 4), data itemsets generated by smart meter devices are forwarded to the platform using a publish/subscribe messaging system. Kafka can be used as a data source and a data sink for Flink's jobs and the Kafka Connector provides access to event streams without manual implementation needs — making it a good choice for the platform. Each of the technologies is capable of running in clusters, providing scalability and fault-tolerance. Each technology can be scaled independently based on the use cases, making the platform flexible in terms of configuration.

Apart from the integration of existing big data tools, we implemented three separate applications to support the needs of smart meters data analysis (Fig. 4). These applications are: i) an ingestion manager, responsible for densification and

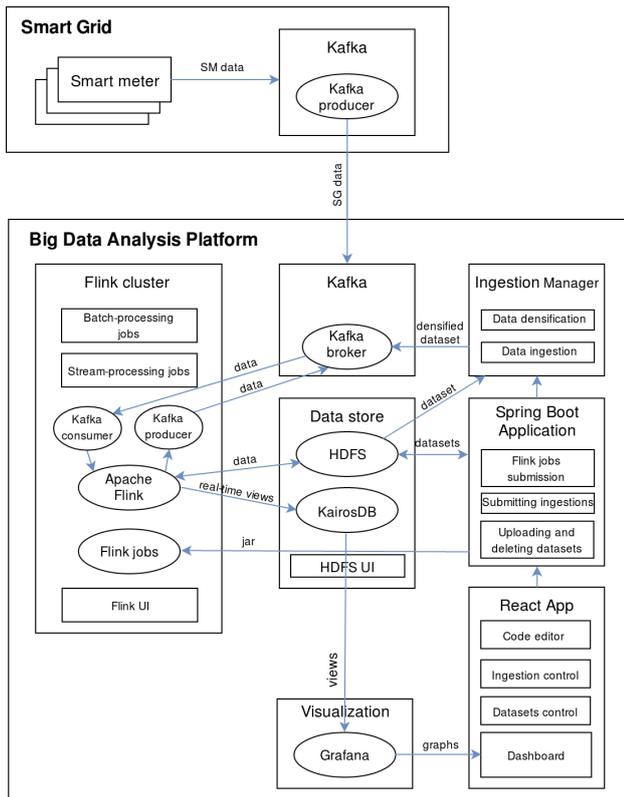

Fig. 4. Platform Architecture

ingestion of datasets into Kafka, ii) a Spring Boot Application, i.e. a back-end implementation with a RESTful API which enables execution of ingestions, Apache Flink job submissions, and uploading and deleting datasets to/from HDFS, iii) a React front-end application that allows users to submit ingestions, upload and delete datasets. Apache Flink provides both batch and stream processing of the data, thus a Lambda architecture is fully supported, as discussed in the background section. As the main data storage, HDFS was chosen and KairosDB is used to provide real-time views on the data. Grafana can be integrated with KairosDB and produce real-time graphs of data. Generated graphs can be further shown in the dashboard of the application.

### V. POWER CONSUMPTION ANOMALY DETECTION SCENARIO

We showcase the use of the platform in the context of power consumption anomaly detection. Studying unusual consumption behaviors of customers and discovering unexpected patterns is an important topic related to the use of smart metering devices in the smart grids domain, as discussed in the previous section and in related research ([7], [8]).

In this context, we propose a scenario to showcase the platform and to look into the performance of three different frameworks for the streaming part: batch-based (Spark), stream-based (Storm), and hybrid (Flink). As the speed layer

is a key part of the performance of the platform, the selection of the best framework is an important decision.

#### A. Compared Frameworks

**Apache Spark.** Created in 2009, is a general purpose processing engine suitable for a wide range of use cases. There are four libraries built on top of Spark processing engine: Spark SQL for SQL language support, Spark Streaming for stream processing support, MLlib for machine learning algorithms, GraphX for graph computations. Languages supported by Spark include: Java, Python, Scala, and R.

Spark applications consist of a driver program that runs the main function and executes various operations in parallel. The main abstraction that Spark provides is a resilient distributed dataset (RDD), which is a collection of elements partitioned across the cluster nodes. Operations such as map or filter executed on RDDs are executed in parallel. Spark Streaming discretizes the streaming data into micro-batches, then latency-optimized Spark engine runs short tasks to process the batches and outputs the results. Each batch of data is an RDD [34].

**Apache Flink.** Created in 2009, is a framework and distributed processing engine for computations on both batch and streams of data. Stream processing is supported natively and provides excellent performance with very low latencies. It also provides a machine learning library called FlinkML as well as a graph computation library Gelly. Supported programming languages are Java, Scala, Python, and SQL.

Flink provides different levels of abstraction that can be used to develop batch or stream processing applications. Abstractions from low-level to high-level respectively are as follows: Stateful Streaming Processing, DataStream / DataSet API, Table API and SQL. In practice, most applications would not need the lowest-level abstraction, Stateful Streaming Processing, but would rather program against the Core APIs like the DataStream API (bounded/unbounded streams) and the DataSet API (bounded datasets). These APIs provide very similar operations as Spark's RDDs such as map, filter, aggregation and other transformations [35].

**Apache Storm.** Created in 2011, is a distributed real-time processing engine. Storm is a pure stream processing framework without batch processing ability. Storm provides great throughput with very low latencies. It was designed to be usable with any programming language thanks to its Thrift definition for defining and submitting topologies. Zookeeper is also required to be installed because Storm uses it for cluster coordination.

The overall logic of Storm applications is packaged into a topology. A Storm topology is analogous to a MapReduce job with the difference that Storm applications run forever. A topology is an acyclic directed graph (DAG) composed of spouts and bolts connected with stream groupings. The stream is a core abstraction in a Storm application. A stream is an unbounded sequence of tuples that are generated and processed in parallel. Spouts serve as a source of streams in a topology. Analogically to Flinks DataStream/DataSet or Sparks RDDs operations, bolts are responsible for all the

distributed processing. Bolts can implement operations such as map, filter or aggregation [36].

We could not find any specific benchmarking study of the three frameworks based on smart grids related datasets, but previous studies found contrasting results in other domains.

Karimov et al. [37] found Flink to have more than three times faster throughput than Spark and Storm for aggregations. Joins were more than two times faster for Flink than Spark. Flink outperformed Storm and Spark in six out of seven benchmark categories including throughput and latency. However, Spark was found to perform better than the two other frameworks in case of skewed data, as well to improve the performance more than the other frameworks in presence of more than three nodes.

Wang et al. [38] developed a full benchmarking system to test the performance of Storm, Flink, and Spark. The results of the application of the benchmark showed that Flink is three times faster than Spark and six times faster than Storm in processing advertisement clicks. The final conclusion is that Storm would be the best choice if very low latency is requested, while Spark would be a good option if throughput is a key aspect of the use case. Flink gives a more balanced performance with low latency and high throughput.

Lopez et al. [39] found that Storm and Flink were consistently better than Spark in terms of throughput. Storm had in general better throughput than the other frameworks, while Spark had the worse performance due to the application of micro-batches, as each batch is grouped before processing. However, Spark was found to be more reliable in terms of node failures and recoverability of the functionality. The conclusion is that the lower performance of Spark Streaming might be justified in use cases in which absolute reliability is necessary, considering no messages loss in case of nodes failures.

Chintapalli et al. [40] performed a benchmarking of Spark, Flink, Storm Streaming focusing on latency. Storm performed the best with Flink, both having less than 2 seconds latency at high throughput. The latencies of Spark, on the other hand, were rising with higher throughput, resulting in latencies of over 8 seconds.

### B. Scenario definition

Our scenario contains three implementations of the same algorithm using the three different big data processing frameworks (Spark, Storm, Flink). Implementing the same use case we can easily compare the performance of each framework by measuring the processing time of the same dataset.

**Dataset.** Our first dataset consists of power consumption data collected from apartments in one building with a sampling rate of 15 minutes [41]. The apartment dataset  $(id, timestamp, consumption(kW))$  contains data for 114 single family apartments for the period 2014-2016. The second dataset contains weather data  $(timestamp, temperature, humidity, pressure, windspeed, \dots)$  with a sampling rate of one hour. The size of the apartment dataset is 2.1 GBs and contains 64 million records. For the scenario to better

represent a big data context, we replicated each of these records eight times. The ingestion manager part of the platform with multiplication densification method was used for this purpose. The result size of the testing dataset is 512 million records in CSV format.

**Scenario Setup.** The scenario was run with three server nodes: a Master node and two worker nodes (Fig. 5). Apart from Kafka, each technology runs in a cluster on all three nodes. Kafka was only running in the Master node, as we considered it could serve all other nodes without delays. For Kafka to operate, there is the need to have Apache Zookeeper to manage the cluster. Because Apache Storm uses Zookeeper for cluster management as well, we decided to install Zookeeper in all three nodes. Each of these nodes was configured with an Intel Xeon E3 (2.4GHz, 4 cores), 8GB RAM running on Ubuntu 16.04 LTS 64bit Linux 4.4.0 kernel.

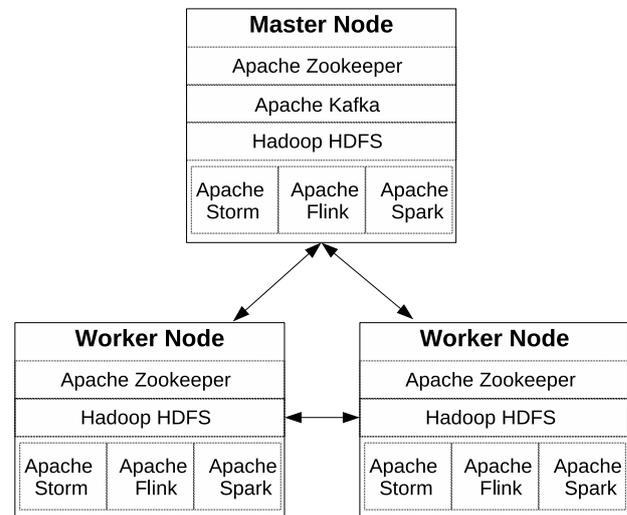

Fig. 5. Nodes involved in the experimental setup

**Anomaly Detection Algorithm Implementation.** We implemented a simple algorithm for finding consumption anomalies using a pre-computed model of consumption predictions (pseudocode, algorithm 1). For the computation of anomaly detection, we implemented a Spark batch processing program in the Java programming language. We did not implement this algorithm using other big data processing frameworks because our main focus was on measuring performance of stream processing. To decide whether a current power consumption item is an anomaly, we analyse power consumptions of three previous days. We take each hour of a day as a season, i.e.,  $t=[0, 23]$ , and use previous three days consumptions at the time  $t$  to compute our predictions. We also take into consideration outside weather because it is highly correlated with power consumption: during winter power consumption is higher due to heating, as well as in summer due to the cooling equipment in function. For each apartment, predictions are made individually because customers have different living habits and power consumption predictions cannot be

generalized to all of them.

```

Input:  $C, T$            ▷ Consumption and Temperature Datasets
Output:  $P$            ▷ Anomaly Detection Model
function CreateAnomalyDetectionModel( $C, T$ ):
     $P \leftarrow \emptyset$            ▷ Initialize Anomaly Detection Model
    foreach  $d \in \text{days}(2014 - 2016)$  do
        foreach  $s \in 0..23$  do
            foreach  $id \in \text{apartmentIds}$  do
                 $C1 \leftarrow \text{MakeAverage}(\text{GetConsumptions}(d - 1, s, id))$ 
                 $XT1 \leftarrow \text{Compute.XT}(\text{GetOutsideTemperature}(d - 1, s))$ 
                 $C2 \leftarrow \text{MakeAverage}(\text{GetConsumptions}(d - 2, s, id))$ 
                 $XT2 \leftarrow \text{Compute.XT}(\text{GetOutsideTemperature}(d - 2, s))$ 
                 $C3 \leftarrow \text{MakeAverage}(\text{GetConsumptions}(d - 3, s, id))$ 
                 $XT3 \leftarrow \text{Compute.XT}(\text{GetOutsideTemperature}(d - 3, s))$ 
                 $\text{Prediction} \leftarrow (C1 * XT1 + C2 * XT2 + C3 * XT3) / 3 + 7$ 
                 $P.\text{insert}(d, s, id, \text{Prediction})$ 
            end
        end
    end
    return  $P$ 

```

**Algorithm 1:** Anomaly Detection Model Pseudocode:  $s$ =season,  $n$ =day,  $C$ =avg power consumption,  $XT$ =outside temp variables

The evaluation of the performance of the frameworks happens at the speed layer. The speed layer of our Lambda implementation is taking advantage of the pre-computed model (algorithm 1), based on which we can detect anomalies of incoming power consumption data. First, we load the anomaly detection model from the datastore and then we compare smart meter readings against this model. If the new consumption value exceeds the value from the model, we consider it as an anomaly (pseudocode, algorithm 2).

We implemented the stream processing part in Java using each framework (Spark, Flink, Storm). Each implementation contains framework specific distributed operations such as map, filter, foreach.

```

Input:  $M, C$            ▷ Anomaly Detection Model and New
                        Consumption
Output:  $A$            ▷ Anomalies
function AnomalyDetection( $M, C$ ):
     $A \leftarrow \emptyset$            ▷ Initialize Anomalies
    foreach  $c \in C$  do
         $P \leftarrow M.\text{get}(c.\text{day}, c.\text{season}, c.\text{id})$ 
        if  $c.\text{value} > P$  then
             $A.\text{insert}(c.\text{day}, c.\text{season}, c.\text{id}, P)$ 
        end
    end
    return  $A$ 

```

**Algorithm 2:** Anomaly Detection Streaming Process

**Process Flow of Anomaly Detection.** The flow of the process of anomaly detection in this scenario is as follows. The power consumption dataset, as well as the weather dataset, were both stored in HDFS. First, Spark loads the datasets into

memory and performs operations in a distributed environment to generate the prediction model using Algorithm 1 (Fig. 6, steps 1-2). The output of Spark is stored back into HDFS (Fig. 6, step 3).

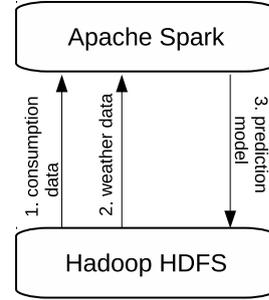

Fig. 6. Anomaly Detection Model Data Flow

**Real-time Anomaly Detection Data Flow.** The data flow of real-time anomaly detection is shown in Fig. 7. The prediction model is first loaded into memory from HDFS (Fig. 7, step 1). After the big data processing framework in use (Spark, Storm, Flink) is initialized and ready, we can start streaming data into Kafka. This is done using the ingestion manager. The ingestion manager reads consumption data from HDFS and sends each record multiple times to Kafka, in this scenario eight times (Fig. 7, steps 2-3) using the multiplication densification method. Big data processing frameworks subscribe to consumption topic and right after new data arrive, they start processing (Fig. 7, step 4). All found anomalies are sent to the Kafka topic "anomalies" (Fig. 7, step 5).

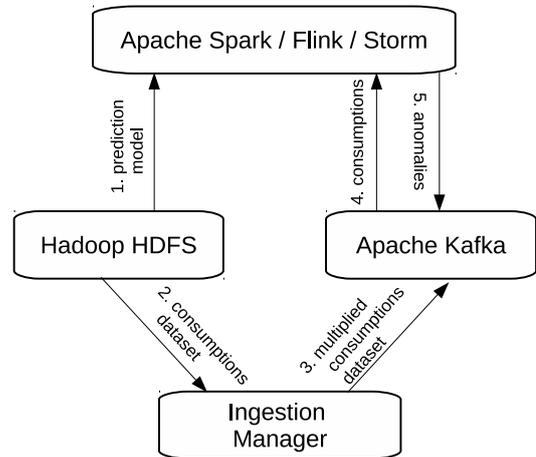

Fig. 7. Real-time Anomaly Detection Data Flow

**C. Results**

We can get several insights about running the platform with each of the three frameworks as the speed layer (we summarize them in Table I).

**Throughput.** Records per seconds processed (Fig. 8) showed that Storm (~378k records per second) and Flink

(~438k records per second) were significantly faster than Spark Streaming (~168k records per second). For the power consumption dataset used in the scenario (512 million records), this means average times of ~20min. (Flink), ~25min. (Storm) and ~50min. (Spark). If throughput is important, Flink seems to give the best results.

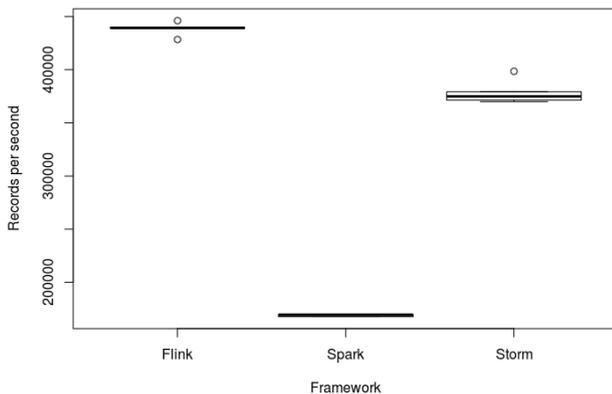

Fig. 8. Throughput. Records per seconds processed (5 runs per framework)

**Latency.** Internally, Spark Streaming receives live data from various sources and divides them into batches (micro-batches), which are then processed by the Spark engine to generate a stream of results. Thus, it is not considered as native streaming, but this way it can also efficiently support processing of big streams of data. However, Spark Streaming strongly depends on the batch intervals which can range from hundreds of milliseconds. During the scenario runs, both Flink and Storm had lower latencies, in terms of milliseconds, while Spark had latencies in terms of seconds. However, the selection depends on how important the batch layer (or micro-batch) is for the specific scenario. For the current scenario using a pre-computed (batch-level) model or an online learning algorithm at the speed layer, both Flink and Storm can be better options than Spark, considering latency.

**Support for batch processing.** In the scenario, the batch layer is only used for a pre-computed model, if updating the model is necessary, Spark natively supports batch processing and provides a very efficient batch processing engine. Batch processing in Flink is dealt with as a special case of stream processing. Apache Flink provides streaming API that can do both bounded and unbounded use cases, but also offers different DataSet API and runtime stack that is faster for batch processing use cases, so it is also possible to process batches very efficiently. Storm does not support batch processing in the current version. In this scenario, the pre-computed model was managed by Spark, so a hybrid combination of frameworks is necessary for a Lambda architecture, if adopting Storm.

**Effort to set-up and configure each framework.** Setting up the cluster nodes for the scenario with the default configuration requires very little time, several minutes to one hour for

TABLE I  
SUMMARY OF THE SPEED LAYER FRAMEWORKS COMPARISON

	Spark	Flink	Storm
Performance	Medium	Very good	Good
Latency	Medium	Very low	Very low
Batch processing support	Yes	Yes	No
Cluster configuration effort	High	Medium	Medium
Scale-up effort	Low	Low	Low
Machine learning support	Very good	Good	Medium

all the three frameworks, Spark, Flink, and Storm. However, fine-tuning each framework brings different considerations. Spark is very flexible and allows to fine-tune many aspects that require a deep knowledge of the framework's architecture. Such fine-tuning can require a large amount of effort. Also Flink requires some effort to tune up the configuration for better performance. This process can take some considerable amount of time, although we found to be simpler in some configuration aspects, as the flexibility of Spark can have drawbacks for the many parameters that can be configured. For Storm there are similar considerations to Flink in terms of configuration, understanding the architecture of the framework is essential for optimization, but also running some tests can give an evaluation of which parameters can give better results.

**Effort required to scale-up the framework.** Each of the three frameworks is relatively easy to scale-up to more nodes. For each framework is a matter of changes in the configuration and propagating the changes to the newly added nodes. The represented scenario can be scaled-up to use more nodes.

**Machine learning libraries and algorithms supported.** While in the scenario we used a simple anomaly detection algorithm, if advanced machine learning operations are necessary, Spark is the framework with the best support. Spark comes with a machine learning library called MLlib that provides common machine learning functionalities and multiple types of machine learning algorithms, such as classification, regression, clustering, etc. All of this is designed to distribute the computing across the cluster. FlinkML is a machine learning library for Flink. It provides algorithms for supervised and unsupervised learning, recommendations and more. The list of supported algorithms is still growing and there is an ongoing work in this area. Storm does not come with any machine learning library, but there is an ongoing work on third-party library called SAMOA, that adds machine learning support to Storm. SAMOA is currently undergoing incubation process in Apache Software Foundation and provides a collection of algorithms for most common data mining and machine learning tasks such as regression, classification, and clustering.

**Threats to Validity.** There are several threats to validity that we need to report. For internal validity, the configuration of the frameworks can have an impact on the results. We attempted to configure each framework for best efficiency (mainly at the level of memory management, parallelism and processor setup), but an exhaustive search of all best

configurations would be unfeasible. Our scenario was more exploratory with respect to power consumption anomaly detection. A full experiment would need to take into account changes to parameters and the impact on the performance. For example, the number of deployed nodes alone can have a different impact on each of the considered frameworks. In our case, we kept a rather simple nodes topology, but for more complex topologies the results can be different (as previous research has shown, e.g., [37]). Another internal threat to validity is given by the implementation differences of the algorithm on each platform. Each framework provides different abstractions to develop applications and it is not possible to implement the algorithm equally, although we believe this threat is limited due to the simple anomaly detection algorithm we applied for benchmarking. Another threat is related to construct validity, the scenario was meant to compare the frameworks in a common data processing context and not to be a full experiment in which many factors are varied, like the number of nodes to which each framework is distributed. Another threat is related to generalization, the results apply to the specific scenario discussed to showcase the platform, other scenarios might have other needs and lead to different results.

**Frameworks versions.** In running the power consumption anomaly detection scenario, the following frameworks versions have been used:

Apache Zookeeper 3.4.12, Apache Kafka 2.0.0,  
Apache Hadoop 2.8.5, Apache Flink 1.7.1,  
Apache Spark 2.4.1, Apache Storm 1.2.2,  
Scala 2.12, Java JDK 1.8.0201

## VI. CONCLUSION

Big data processing in the Smart Grids context has many applications that require real-time operations and stream processing. In this paper, we presented a big data platform for anomaly detection from power consumption data. The platform is based on an ingestion layer with data densification, Apache Flink as part of the speed layer and HDFS/KairosDB as the data store. We mapped the main components to the reference architecture proposed by Pääkkönen and Pakkala [12], and provided the results of a scenario based on power consumption anomaly detection to assess the applicability of different frameworks: batch-based (Spark), stream-based (Storm), or hybrid (Flink). Overall, we adopted Flink in the platform's speed layer, as it provided the best performance for stream processing and met the requirements for power consumption datasets anomaly detection in our scenario.

Currently, we are planning to deploy the platform to analyze large-scale power consumption datasets in our running projects, by comparing several anomaly detection algorithms to help in better identifying clusters of customers based on smart metering data traces.

## ACKNOWLEDGMENT

The work was supported from European Regional Development Fund Project *CERIT Scientific Cloud* (No.

CZ.02.1.01/0.0/0.0/16\_013/0001802). Access to the CERIT-SC computing and storage facilities provided by the CERIT-SC Center, provided under the programme "Projects of Large Research, Development, and Innovations Infrastructures" (CERIT Scientific Cloud LM2015085), is greatly appreciated.

**Abstract**—In high-level object languages, such as Java, a problem of unnecessary duplicates of instances can easily appear. Although there can be a valid reason for maintaining several clones of the same data in the memory, often it indicates that the application can be refactored into a more efficient one. Unnecessary instances consume memory, but in case of Java applications can also have a significant impact on the application performance, as they might prolong the time needed for the garbage collection. In this paper, we are presenting a method and a tool that allows detecting duplicity in the heap dump of a Java application, based on the shallow and deep object comparison. The tool allows to identify the problematic instances in the memory and thus helps programmers to create a better application. On several case studies, we also demonstrate that the duplicates appear not only in the student projects and similar programs that often suffer from poor maintenance but also in commonly available Java tools and frameworks.

## I. INTRODUCTION

JAVA language was designed to provide fully automated memory management and to shield programmers from errors caused by the memory leaks. The developers are often encouraged to design the data models based on the real world structures and not to think too much about the internal representation of the data they are using. This should lead to greater efficiency of programming, but at the same time hardware resources are often used inefficiently. Consequently, instead of memory leaks typical in C-language programs, programmers are creating different constructions that clog up the operational memory and can lead to unnecessary slowdowns of the application (or even to the termination of the application due to insufficient memory) due to excessive garbage collection.

In general, this problem is known as the memory bloat, and there are many different aspects of it [1]. We had previous experience with fixing an application that was suffering heavily from wasting memory [2], so our main goal was to create a tool that would allow us to easily identify the problematic objects retained in the Java heap. One of the issues we have encountered is (often multiple) duplication of the identical instances in the memory. Especially for less

experienced programmers, it might be difficult to identify the problem. We hope that our tool might help them to find the unnecessary objects in the memory of their programs. In the same time, we wanted to investigate how often the similar problem arises in other applications generally available in the Java community.

### A. Memory Bloat

There is no generally accepted definition of the memory bloat, but many examples are known both from the literature and from the real applications. In [1] Mitchell describes 15 anecdotal examples of the memory issues that might arise, classified into four main groups, and shows how Java Virtual Machine deals with them and how programmers might or might not make its work more difficult. Anecdote 12 mentions data duplication created during the communication between Java application and the outside environment. Mitchell also describes how different types of objects can have a significant impact not only on the memory consumption but also on the application speed, as the Java Virtual Machine has to perform garbage collections. Depending on the number of retained objects, it can significantly slow down the application.

The problem of the object duplication is partially solved also in Java Virtual Machine itself, currently only with the `String` class. Since Java version 8.20 [3] Java contains an implementation of the string deduplication – as long as `Strings` are managed by the virtual machine, they are created in the separate part of the memory. When a new `String` shall be created, it is first checked whether there already is an instance with the same content. If so, only a reference on the existing instance is provided. As `Strings` are immutable in Java, this is a safe way of dealing with them - all operations manipulating with `Strings` are in fact creating new instances, so when a programmer wants to change the content of the instance, a new, different instance with new data is provided.

This behaviour is possible mainly due to the simple nature of the `String` object – only an array of characters needs to be checked. However, not only `Strings` instances are

duplicated in Java programs. Our intention is not to provide a more general, runtime method for the deduplication, as the deep object comparison can be quite time-consuming. We only intend to provide a tool that will allow to analyze the program memory and to discover possible duplicates. We also do not claim that the duplicate objects can be automatically merged just because they contain the same data - this decision has to be made by a programmer with a deep insight into the application. However, if there are multiple identical instances of one class, it can be a strong indicator that the application can be refactored into a more efficient one.

### B. Motivation

Our motivation comes from two sources. First, we are often dealing with software created by students, which usually contains many types of problems and we were not able to find a tool that would be able to show how many duplicates are present in the memory of student programs. Standard profilers such as *VisualVM* can be helpful, but not suitable for this type of analysis. Furthermore, we wanted to see if this problem is present not only in the work of inexperienced programmers but also in software that is more widespread and freely available.

The remainder of the paper is organized as follows: Section II deals with the related work, focused mainly on the problem of the equality and comparison of the objects. Section III explains how the equality of the objects is implemented in our tool. In section IV we are showing the algorithm used for the duplicity analysis in our implementation. The method of validation of our implementation, as well as several results of duplication analysis of several Java application, is presented in section V. The last section concludes the paper and discusses possible future work.

## II. RELATED WORK

There are two main areas relate to our work. The first one is the problem of the memory efficiency of Java applications. This problem is discussed quite extensively and many different bad practices or problematic patterns were described in last years. Especially with the increasing interest in the embedded systems, the need for the memory efficient software grows [4].

The most common problem is the detection of the memory leaks, described for example in [5] or in [6]. As the Java is a language with garbage collection, the classical memory leaks with inaccessible memory are rare in it, and the works we are mentioning are focusing more on the detection of the objects with large overhead [5]. The typical example might be collections that contain mostly `null` elements. Another approach is the design of the more efficient ways of the garbage collection [6]. As one of the main sources of the performance issues and memory wasting is automated ORM (Object-Relational Mapping) when used incorrectly, it is also possible to find approaches focusing on the analysis of the ORM performance antipatterns and fixing them [7].

Other approaches are trying to find a way how to evaluate overall memory health of the Java programs. One of the most

useful works on this topic is [8], where the problematic structures are described in high detail and even a metric based on the ratio of the useful data and structure overhead is proposed to evaluate memory health. These ideas are further expanded in [1] and [9], where the memory impact of the complexity of the domain model is discussed, as each reference occupy some space. Several different antipatterns are presented, along with the proposed solutions. Unfortunately, the patterns described in this work are not discovered automatically, the authors rely mostly on the manual analysis of the data structures. Another approach to the memory optimization is based on the efficient memory partitioning [10].

One important inspiration for our work is [11], where both static and dynamic analysis is proposed as a tool for evaluating the usage of Java collections (or other structures that allows manipulation with a large number of elements). Another approach for the dynamic analysis of the collections efficiency is presented in the [12] – the technique proposed here aims not only to use collections more efficiently, but also to choose the most suitable collection for the application, based on the runtime analysis.

The second is more focused on the instances comparison or even automatic detection of the possibility of replacing one instance with another. In [13], a post-mortem analysis of the Pharo programs is proposed in order to determine if there are some redundancies in the suitable classes with inclination to the redundancy (such as `Point` or `String` classes), aiming to replace the redundant ones with one instance. This paper also contains an extensive description of different ways how to define an object equivalence. The possibility of the replacement of one instance with another is also examined in [14]. In this case, not only a comparison of the objects is performed, but authors also propose to instrument the original program in order to observe the usage of the candidates for the merging and automatically determine if such merging is possible without influencing the program behaviour.

As the search for duplicates in the whole namespace is time demanding task with a high complexity, some publications are focusing only on the classes which are known to contain duplicates very often. In [15], the methods used for the `String` deduplication is described in high detail. Similarly, the description of the approaches to get rid of the `String` duplicates is described in [3]. As this is typically performed at runtime, there is a great need to make these algorithms as efficient as possible. In [16], different methods for the decision whether the deduplication should be performed or not and their impact on the program performance is demonstrated.

## III. OBJECT EQUALITY

As was mentioned in previous section, there are multiple ways of how the object equality can be defined. As our application is working with the heap dump, we did not focus on the fast pre-analysis using some form of the hash code of the objects, such as in [17], but immediately on the analysis of the attributes of the objects, similar as described in [18]. In contrast with [18], we are not working directly with objects

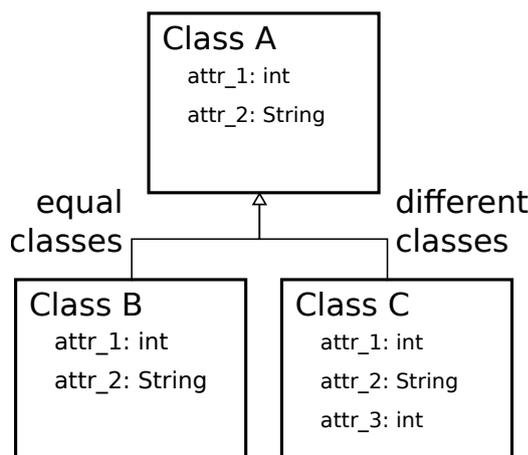

Fig. 1. Class equality in inheritance chain

in memory, but with their serialized form in the heap dump. So for the comparison, we cannot use in any way methods that are implemented in the objects, such as `equals()` or `compareTo()`.

#### A. Class Equality

The first aspect to consider is the class of the compared objects. If we are comparing instances with the same class, it makes sense to analyze the data field by field. If the values of all fields are identical, we can consider the instances identical as well. However, it is also possible to consider inheritance. The inheritance in Java cannot remove any field from the successor, only to add additional ones or to add or override its methods. In case that the predecessor contains the same fields as the successor, we can consider them identical from the data point of view as well. Of course, there is a question if such objects can be merged into one, but that is something that can not be decided automatically during the heap analysis. Thus, we consider instances identical in case all their fields are identical even when they belong to different classes, as long as they are part of the same inheritance chain and no additional fields are added in the successors (as you can see in Fig. 1). When such field is added, even if its value is `null`, it is considered different due to the different class definition and the matching of fields is not performed at all. You can notice that including inheritance chains in the comparison, in fact, broadens the definition of what are identical objects and can lead to a higher number of identified duplicates.

#### B. Fields Equality

When fields are compared, it is simple to deal with the primitive types, but more complicated to deal with the references (see Section III. C). Although `Strings` are references, Java deals with them in a special way. This enables us to treat them in a special way as well. As they are stored in a special part of memory and due to the string deduplication, we often do not need to analyze the actual content of the `String`, only to see if the reference leads to the same instance. When

references are different, the actual data of the `String` have to be compared. This can happen, as the string deduplication does not work for all `Strings` in Java application and the instance of the `String` can thus appear both in the regular heap space and in the area reserved for the `Strings`.

#### C. References Equality

Another aspect is dealing with the reference fields. The previously described method is suitable for the objects that are composed only of the primitive data types and `Strings`. However, in Java, most objects contain also references on other objects. In such a case, there are two different points of view. The shallow approach would consider two references identical only when they are pointing to the same instance. This can be checked very easily, as in the heap dump, the references are represented only as a `long` number, so we only need to compare those.

In order to obtain a broader set of results, we have also implemented a deep comparison approach. It means that, in addition to the identical reference numbers, two references will be considered identical when they point to two different instances that are internally identical. Again, this approach leads to a higher number of identified duplicates, but also significantly increases the complexity of the comparison, as it has to be used in a recursive way – the referred instances can point to other instances and so on. This also means that a stopping condition has to be defined, in order to deal with cycles and to improve the performance of the comparison.

The references can create an arbitrary graph, but it can be always reduced to a finite tree structure when the analysis is stopped after each node of the graph is visited once. Another option is to define a depth, in which the analysis should end. If the instances fields contents are identical till the required depth is reached, the instances themselves are considered identical as well.

The last aspect we need to describe is the dealing with arrays and collections. Java offers `List` and `Set` interfaces and several implementations that can be used to store a large number of data. In case when the deep object comparison is used, no special approach is needed and the structures are identical only when they contain identical instances in the same order. It would be possible to broaden equality definition even more and ignore the order of the instances within the array, but that would require even more complex calculation and specific implementation for each Java collection.

## IV. DUPLICATION FINDER

Our implementation of the duplication finder is created in the Java language. As we need to deal with a heap dumps in binary HPROF format, which is created by means of JVM, we were looking for a tool that would allow us to process the data easily and we used a Hprof Heap Dump parser library [19]. This library allows us to load the data from heap dump and reconstruct the content of each instance. It also provides access to the class descriptions so the data can be correctly interpreted.

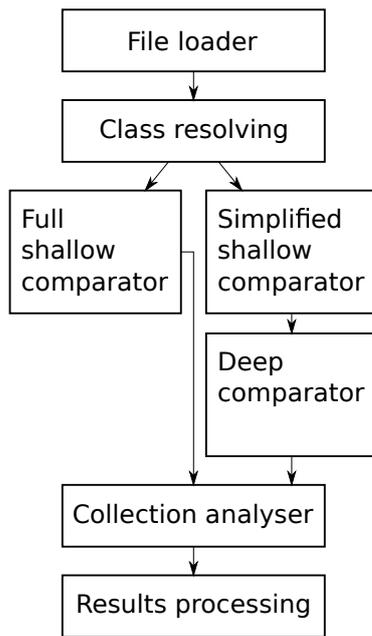

Fig. 2. Tool pipeline

### A. Tool Architecture

In order to allow easy modification of the analysis process (for example to be able to switch between shallow and deep comparison or to add additional modules searching for other memory anti-patterns), the tool is designed as a pipeline. Our tool sequentially reads the heap dump file and produce a basic representation of the loaded data. The overall behaviour is represented in Fig. 2.

These data are joined with the corresponding class descriptions and then further processed according to the class description (so the loaded byte streams are converted for example to long numbers or to `Strings` for easier processing). When the actual class of each instance is analyzed, it is also possible to decide if the analysis should stop or continue depending on the class or package name – this allows us to limit the duplicity search only on the certain classes in the memory dump and thus save some time during the analysis.

### B. Problem Identification

The prepared data are then passed to a module that is responsible for the duplicity analysis. The matching algorithm iterates over all loaded instances and stores them according to their properties in the two-level structure. At first, instances are divided according to their classes (as was described in the previous section – so the different classes can be considered equivalent if they are part of the same inheritance chain and they share the same set of fields). Then, within each class, the equivalent instances are grouped according to the values of their fields (see Fig. 3). Depending on the settings, the shallow or the deep comparison of the objects is performed in this phase.

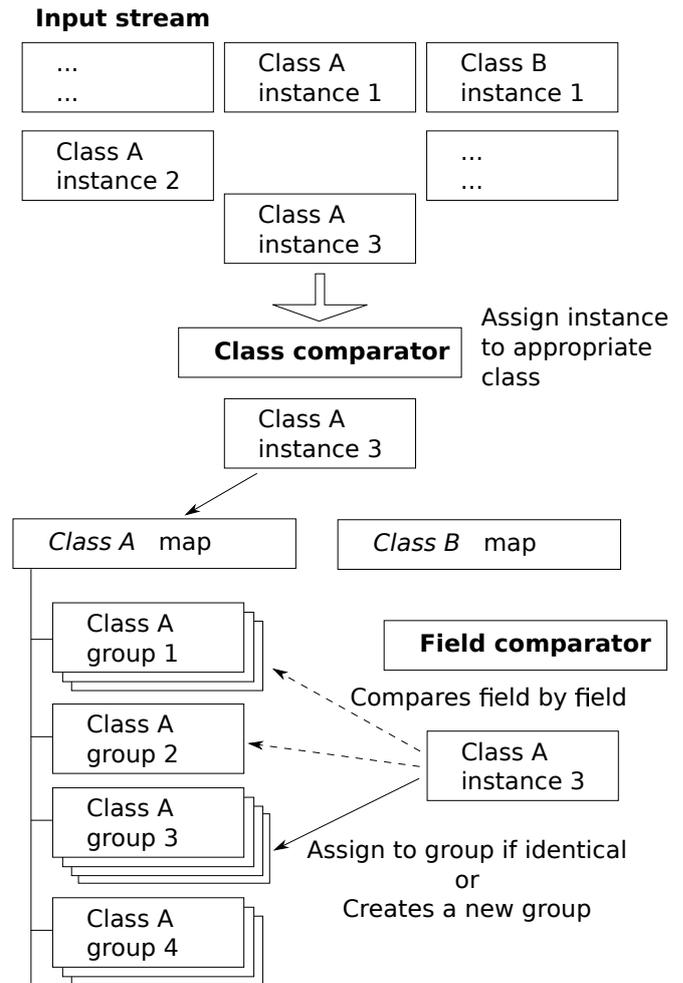

Fig. 3. Data structures for the equality classification

The shallow comparison is quite straightforward – the instances retrieved from the heap dump are compared field by field, including the references (see Fig. 4). If the instances are identical on this level, they are considered equal and became part of the group within the class. Each additional instance is compared against all existing groups and either is added to one of the groups or a new group is created if the new instance is unique.

Deep comparison is more complicated and more time demanding. The algorithm is similar to the deep object comparison algorithm we have described in [20], but for this purpose modified and made faster. There are two main differences – the first one is that we are now working with the heap dump data and not with the instances that are in memory of the executed application. The second is that we do not need to explore the structures of instances completely - the first occurrence of a difference is sufficient to claim that the compared objects are not identical. It would be possible to use the original version of the algorithm as well, but it would make the whole comparison process even more time demanding.

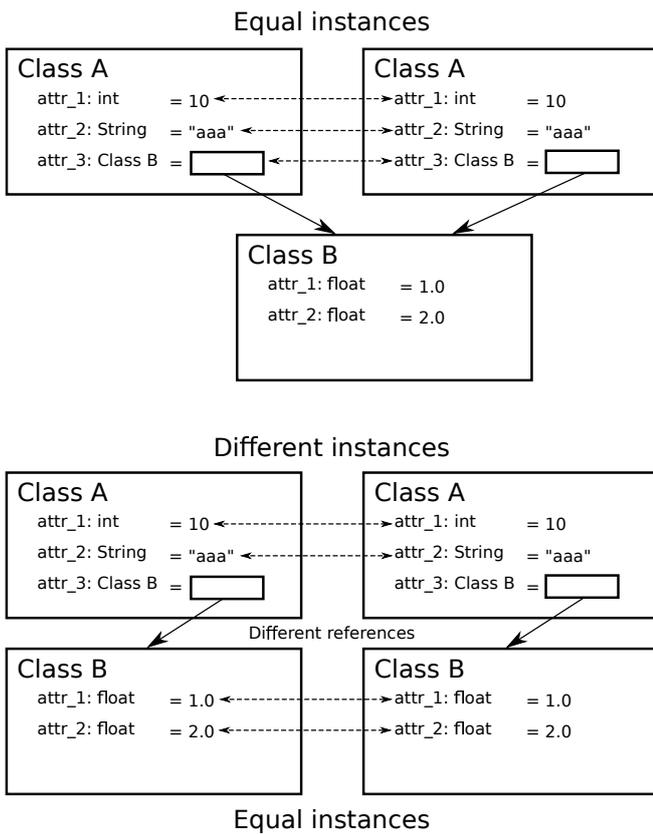

Fig. 4. Instances equality with Shallow comparison

In order to perform the deep comparison, a graph representation of both compared objects has to be created. In order to do so, the whole memory dump have to be processed (we have to be able to resolve references to create an object graph), so it is performed after the shallow comparison is finished. But for the purpose of the deep comparison, a modified version of shallow comparison is done. In this case, only primitive data types are compared to determine if the instances are identical and the references are ignored. This, of course, means that the instances that differ only in references will be considered identical during this modified shallow comparison. The reason for this is to allow faster evaluation of the deep comparison. These "duplicates" are not reported in the result of the algorithm, but only used in order to evaluate the equality of the referred instances during the deep comparison faster.

Each node of the graph corresponds to an instance and each edge corresponds to the reference. As we expect that, in most cases, the instances will not be identical, the graph is constructed on demand, as a modification of Breadth First Search (BFS) algorithm. When all fields of compared instances are identical, the references are resolved one by one (see Fig 5). As the deep comparison is actually performed after the shallow one, in the first step algorithm checks if the referred objects were identical during the shallow comparison. If not, the comparison can be terminated, as we are not looking for all

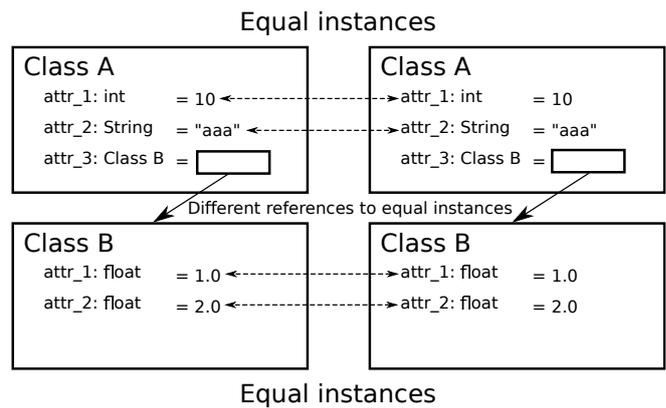

Fig. 5. Instances equality with Deep comparison

differences between instances, only one difference is sufficient to consider them unique. If the referred instances belong to the same shallow equivalent class, other references of the original object are analyzed. Only when all referred instances are considered identical, the algorithm starts constructing the next level of the graph.

Finally, the module for the analysis of the lists and arrays is used. For this analysis, we considered using the idea of collection health described for example in [8]. Collections are considered to be healthy (from the memory utilization point of view) only if they carry a sufficient amount of data. Programmers in Java often create unnecessary large pre-allocated structures, which are never sufficiently utilized, so the collection contains a significant number of null references. Such references, despite not carrying any data, still occupy memory space. For example, default instance of the ArrayList is created with 10 empty slots and often only small fraction is used (more specifically, the array is allocated when the first element is inserted to it, when the collection is created empty, the array is not created immediately).

This analysis is currently limited only on the offsprings of the AbstractList class, which are based on the array. As each collection requires a different approach and implementation, we focused only on the array types and not on the linked structures or maps. The analytical module is looking for two parameters. First, it calculates the ratio of the space occupied by the collection to its size. All collections that have this ratio below 0.5 are marked as underutilized. Second, the content is analyzed for duplicity and, if the collection is filled with identical elements, it is marked as problematic as well.

### C. Result Reporting

The last part of the processing is the results reporting. As the tool is so far only operated from the command line, the results are presented only in the text form in the standard output stream. The result report contains names of all classes that have at least one set of duplicate instances (including information about the package and the inheritance chain), the serialized form of fields of duplicate instances and also the list of collections that contain one of the marked problems.

#### D. Complexity

The complexity of comparing each instance with each other to determine if they are identical is implemented with quadratic complexity with respect to the number of elements to compare. It can be expressed as  $O(n^2)$ , where  $n$  is a number of elements to compare. However we do not really need to compare each element with each other across the whole heap dump - we need to compare elements only within the same class. In such case, complexity is still quadratic, but in a form  $O(k \cdot n_k^2)$  where  $k$  is the number of equivalent classes and  $n_k$  is a number of the instances within each class. This makes the comparison more feasible, the number of instances within a class is more manageable value. We have to note here that the time even for the shallow comparison itself can differ significantly according to the number of the fields in compared classes. In case of the deep comparison, it depends heavily on the complexity of the compared structures. This has a significant impact on algorithm performance as well. Theoretically, it would be possible to achieve linear complexity by calculating hash for each instance and compare only the hash codes, but the calculation of hash for the deep comparison would still require a complete reconstruction of the data structures, even in cases when they differ in first few attributes (and the comparison will quickly find differences), so we decided against this approach.

### V. VALIDATION AND RESULTS

In order to validate the functionality of our tool, we have at first created a simple test application with a known number of duplicates and half empty collections. The purpose was just to figure out whether the tool will be able to find all injected problems. Then we have continued with tests performed on several real-life applications, to investigate whether the duplicates occur in the real world software.

#### A. Testing Application

The testing application is able to generate an arbitrary number of instances of simple objects, containing numerical and string attributes, as well as simple reference structures. It uses only two simple classes, `Child` and `Parent` that can refer to each other. The testing application was run several times with the different number of the created instances, in order to verify the time complexity of the algorithm. In each test, there were only 5 deep duplicates.

The heap dump was obtained using `jmap` [21] tool, using command

```
jmap -dump:live , file=<file -path> <pid>
```

in order to ensure that only "living" objects (objects that would survive next garbage collection) are obtained and listed in the heap dump. The time measurements were done on the PC with Windows 10, SSD drive, Intel Core i7-4930K CPU, 3.40 GHz and 32 GB RAM. No parallelization was used at the moment. The analysis was limited only to the package with our data classes, other instances were ignored. The times were obtained as an average from 5 executions.

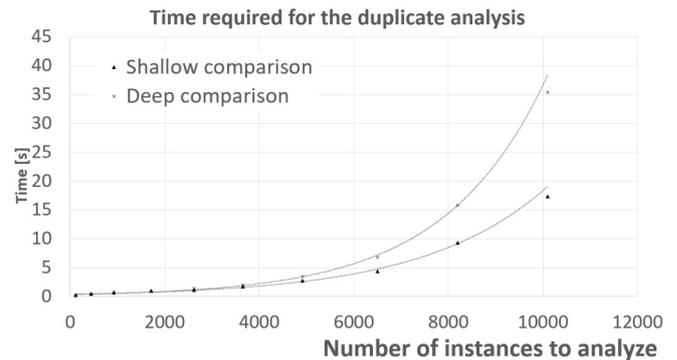

Fig. 6. Times required for analysis by deep comparison and shallow comparison algorithms

In Table I, the results for the testing application are presented. From these results, the deep and shallow comparisons can be compared both in their abilities and consumed computation time. In this simple case, our deep comparison algorithm was able to find all duplicates, while the shallow comparison version was not able to identify duplicates that were using different referred instances with identical data. On the other hand, the time required for the deep comparison grows significantly faster even when there are no significantly more deep duplicates (see Fig. 6). Running the deep analysis thus makes sense only if there is a strong suspicion that there might be such kind of problem. As expected, time requirements appear to grow quadratic in relation to the number of instances that are there for comparison, although the measurements, especially for the small number of instances might be influenced by the overhead of the processing.

#### B. Real World Programs

We have also attempted to run the algorithm on several real-world programs, to investigate whether if the problem with memory duplicates will be present in them. We have chosen four different programs – *Spring Boot framework* with a basic hello-world application, *Eclipse* with several projects open, *IntelliJ Idea* and *TomEE* with running map visualization server. Due to the time complexity of the deep analysis, we used only a shallow comparison in all four examples.

1) *Spring Boot*: The *Spring Boot framework* [22] in version 2.1.4 was used with only the very basic "Hello World" application. The dump of the whole framework has approximately 27 MB. For the purposes of the experiment, we have decided to limit our testing only to the classes from the `org` namespace.

In Table II, the results of the `org` namespace and its parts are summarized. One important find is that some duplicates were in fact found, but there is not a great number of them. Mostly, the duplicities were only pairs, but for example, the `Signature` class had 38 identical instances and class `DefaultFlowMessageFactory` 34 instances. Both classes only contain short `Strings` with basic framework settings, but their presence in the analyzed application shows that our tool is able to work with the real software.

TABLE I  
RESULTS FOR THE SIMPLE TESTING APPLICATION

Instance count	Dump size [MB]	Injected duplicates	Found duplicates (shallow)	Found duplicates (deep)	Duration shallow [ms]	Duration deep [ms]
120	2.1	20	15	20	221	227
440	2.6	30	25	30	493	401
920	3.0	40	35	40	725	705
1710	3.6	50	45	50	987	912
2620	4.0	60	55	60	1121	1409
3650	4.4	70	65	70	1753	2021
4910	5.4	80	75	80	2769	3517
6500	5.9	90	85	90	4379	6781
8200	6.4	100	95	100	9334	15789
10100	6.9	110	105	110	17351	35419

TABLE II  
ANALYSIS OF CLASSES IN SPRING BOOT FRAMEWORK

Package name	Classes	Instances	Found duplicates	Duration [ms]
org	2416	9093	347	14759
org.springframework	1555	6053	329	8214
org.springframework.boot	380	1506	27	4229
org.springframework.core	196	1585	5	4425
org.springframework.web	296	239	37	4108
org.springframework.boot.web	75	27	1	4002

Furthermore, as the Spring Boot framework is often used and well maintained, we did not expect to find many problems in it.

The second thing to notice is the ratio of classes and instances within one class. In the whole `org` package the ratio is approximately 1 : 4. For many classes, there are only a few instances. During drill down to the sub-packages, the ratio changes. For example in the package `org.springframework.boot.web` the ratio is even reversed – more classes were loaded from the namespace than was actually used to create instances.

2) *Eclipse*: We have analyzed *Eclipse* [23] in version 4.10.0 (build 20181214-0600). The IDE was only started and in the moment of heap dump collecting was not performing any particular task. The size of the Eclipse heap dump was approximately 92 MB. Measurements were performed for the packages `org`, `com`, `java`, `sun`, and `ch`. The results are summarized in Table IV.

This is the largest heap we have processed and, again like in the heap of the *Spring framework*, no large problem is present. However, the tool demonstrates that it is capable handling not only trivial examples but also larger datasets. The most duplicated was the class `org.eclipse.swt.widgets.TypedListener` with 444 identical instances based on the shallow comparison. Many of the discovered classes contained large fragments of the XML configuration of the tool (like `org.eclipse.sisu.plexus.ConfigurationImpl`

with 16 identical instances containing 750 characters each). The results also show the rapid growth of the required computational time for larger datasets, with the analysis of `java` package taking more than 6 hours. In this package, 75 ms on average was required for analysis of each instance. In comparison in the smallest package `ch`, only 13 ms on average were required.

3) *IntelliJ Idea*: Along with Eclipse, we also tried to perform analysis of IntelliJ Idea in version 2018.3. The dump of this IDE was smaller than in the case of the Eclipse, approximately 74 MB. Only packages `org`, `com`, and `sun` were available within. In a similar way as in the previous case, the IDE was not performing any particular task, it was just started. The results are summarized in the Table IV.

In this case, despite the lower number of the classes with duplicates, a large number of identical instances was found. The class `org.jdom.Text` contained several instances with many clones, the largest group had 11577 identical instances. All these clones contained only several unprintable characters (typically end of the line and some other character) and obviously were part of the loaded DOM of some data the IDE was requiring after starting. In this case, the tool demonstrates that it is capable of discovering large clusters of the identical instances. However further analysis of the source texts of the *IntelliJ Idea* would be required to determine if there is a way to mitigate this type of the duplicity. Other duplicity classes (with only several clones) contained for example the text of the library licenses.

4) *TomEE with Visualisation Server*: The last example we tried to analyze was Apache *TomEE* [22] server in version 7.1.5, with the running application dealing with the visualization of the power grid. *TomEE* is a version of the Tomcat server, with additional modules useful for building enterprise applications. In this case, we have decided to focus not on the classes from the technology itself, but on the domain objects from the visualization server. As previous examples showed, the frameworks that are intensively used will probably contain fewer issues than the applications that should be executed within them.

The size of the heap dump of the server was approximately 370 MB, significantly larger than the previous files. When the dump was collected, the server was working with 4 users at the moment, so 4 sessions with data models were loaded. We were focused on the proprietary package `cz.zcu.laps.pnp.domain`, which contains domain data of the application. The data were organized in the form of a graph, composed of the nodes representing elements of the power distribution network and power lines between them. Each user is able to work only with one model at one time. As the graph structure was maintained by the different package (*JGraphT* library), the nodes have no references to other objects except enums, so the only shallow analysis was required.

The package contained 48 different classes and 49096 instances. Further analysis showed that the instances are distributed only among 6 classes of the domain model. The shallow analysis of this namespace took 3.22 hours on the same machine. In this case, the structure of the results was quite different – in each class, multiple triplets of identical instances were discovered.

Further manual analysis of the result showed that the problem, in this case, was in the different sessions. As we went through the triplets, it became obvious that they are part of the same graph – in fact, the duplicates were not only the nodes of the graph, which were discovered by our tool, but the graphs themselves. The reason for this was that two of the users were visualizing the same graph and the server maintained a copy of all the data for both sessions and also – as a form of the cache memory – a third copy not related to any session. As only the visualization was required from the server, it would be possible (in this particular case) to merge all data and maintain only one copy for every user who needs it. This issue is similar to the problems described in [7], as the graphs are also mainly products of the ORM. However, in this case, we cannot really speak about the ORM antipattern, the problem is more in the design of the data structures and lack of sharing data between users in the moments when it is possible.

However, our tool was not able to discover this issue directly, as no package from *JGraphT* was analyzed, so there was no overview of the whole structure during the analysis. This shows obvious limitation when only part of the namespace is analyzed – the data structures that are keeping data are not part of the analysis and even if the deep comparison is used, the identical structures will not be visible.

TABLE III  
ANALYSIS OF CLASSES IN THE ECLIPSE IDE

Package name	Classes	Instances	Found duplicates	Duration [ms]
org	9647	141970	756	5007822
com	919	27906	865	90271
java	1155	313405	39	23596884
sun	929	28092	20	91228
ch	244	539	5	7335

TABLE IV  
ANALYSIS OF CLASSES IN THE INTELLIJ IDEA IDE

Package name	Classes	Instances	Found duplicates	Duration [ms]
org	2016	157743	283	8425230
com	7687	77927	261	1290908
sun	1119	15620	31	26023

Furthermore, for such big structures as the graphs in our case (49096 instances are in fact only data in 5 graphs, without the overhead of the *JGraphT* library), the deep analysis would be quite time demanding – especially if parts of the graph would be shared and only some parts would be changed. On the other hand, this type of the situation – data shared or cloned on the server among several sessions – can be an example when the analysis of the duplicities is useful.

## VI. CONCLUSION AND FUTURE WORK

In the paper, we have presented an algorithm and tool designed to search duplicates in the memory space of the Java applications. The analysis is based on the exploration of heap dump and comparing primitive fields of the objects with the same class. We have implemented both shallow and deep comparisons and demonstrated their functionality on the sample application. According to the results, the algorithm is capable of finding the duplicates that are present in the memory for both simple objects from the testing application and also in the data obtained from four real-world applications. The quadratic complexity of the algorithm, along with the need to compare deep structures, prevents processing a large number of instances, but even on the real heap dumps the algorithm was able to perform the analysis within hours. As this type of the analysis is not something that needs to be performed often, but mainly in the situation when there is a problem with resource consumption, we believe that the tool is practically utilizable.

Main goal of our immediate future work is to implement the parallelization of the task. The shallow comparison should be simply parallelizable, as when all instances from the heap are loaded to the memory of the analyzer, the comparisons need to be performed only within each class and thus can be distributed among the working threads.

As for deep object comparison, the problem is more difficult there, as all instances need to be present in the memory when

a graph of referred objects should be constructed. However, if sufficient memory is available, the task can be still distributed, as each worker can obtain the whole copy of the heap and then work on the analysis of objects within a particular class. The question remains if the communication between such workers would allow making the process faster, for example, if the sub-graphs of the compared objects are already processed and the information about their equality is available. This approach would require to determine a sequence, in which objects should be compared and evaluated, in order to have simpler objects processed before the complex one.

# Redesigning Method Engineering Education Through a Trinity of Blended Learning Measures

Sietse Overbeek and Sjaak Brinkkemper

**Abstract**—This paper presents a teaching case of a Blended Learning (BL) approach that was applied to a course on Method Engineering (ME) intended for graduate Business Informatics (BIS) students. The main reason for transforming a Master course on ME from traditional to blended is to take advantage of combining frontal instruction with e-learning based instruction and at the same time reducing lecturers' workload in times of increasing student numbers in BIS and Computer Science (CS) areas. The BL approach consists of three parts, as it consists of the introduction of computer-supported peer assessment, interactive e-lectures, and digital examination. The approach has been reflected upon by course lecturers themselves and it was evaluated through two separate student surveys, from which a variety of positive outcomes can be deduced. Increased generation of feedback, an increase in student motivation, and improved understanding of the course content are three of these outcomes that stand out. On top of student related advantages, especially the BL parts concerning peer assessment and digital examination reduce teaching load. These findings are informative for both education researchers and instructors who are interested in embedding BL in BIS or CS education.

## I. INTRODUCTION

Institutions of higher education are increasingly adopting Blended Learning (BL), the combination of face-to-face and technology-mediated instruction [1, p. 185]. In 2011, scholars noted an “explosive growth of blended learning” and acknowledged its potential to become the “new normal” in higher education [2, pp. 207-208]. In 2017 it was indicated that in the foreseeable future a strengthening will be seen of all kinds of digital learning forms, including various kinds of blended learning [3, p. 216].

The opportunities that BL has on offer provide possible solutions for dealing with current challenges in Business Informatics (BIS) degrees curricula. Prominent examples of such challenges are the preservation of quality education while experiencing increasing student numbers under tight budgets and to provide students an experience that fits their individual learning styles while reducing restrictions on time and place when offering education [4]. This paper explains a teaching case of how BL has been used to redesign a course on Method Engineering (ME) as part of a Master's degree programme in BIS to deal with the aforementioned challenges. The main research question that has guided the redesign process of this ME course is formulated as follows: “How can we provide Method Engineering students a teaching

experience that emphasizes the advantages of blended learning while reducing teaching load at the same time?”.

In section II, the course is outlined and the design of the course is explained before the actual application of BL took place. Section III provides an explanation of the BL approach that is used to realize a scalable and technology-mediated incarnation of the ME course. Students reflected on the BL approach through two surveys and the results of these reflections are found in section IV. Gathered insights and remaining challenges after reflecting on both the experience of running the BL version of the ME course and the student evaluations are discussed in section V. Section VI concludes this paper and gives an overview of future research.

## II. BACKGROUND

The ME course as discussed in this paper is part of a two-year Master's degree programme in BIS. The course is a mandatory course and is offered to students in the first year of the curriculum. Since its inception in 2004, the course has grown from twenty-four to eighty-three participants in 2019. The traditional design of the course consists of regular lectures, lab sessions, and two paper-based exams. During the lab sessions, the students worked individually on their method engineering project. For this project, the students performed a literature review on the topic of a self-selected Information Systems (IS) development method or technique and based on the gathered data from the literature study they designed a meta-model of the selected method or technique. This project was split in five parts and each of the parts was completed by providing a deliverable of which the final deliverable consisted of a term paper that is an integration of the previous deliverables.

The year 2017 was the final year when the ME course ran in a traditional way. With seventy-one participants producing a total of five deliverables and two written exams within a course period of eleven weeks there was substantial pressure on the teaching team to provide feedback on the student materials and grade them. The team consisted of two lecturers and three student assistants (SAs), sometimes also called teaching assistants. The SAs provided guidance during the lab sessions and provided practical support. With eighty-three participants signed up for the 2018 incarnation of the course, the time was ripe to implement proper changes in the design

of the course in order to deal with increasing student numbers without sacrificing the quality of the course while reducing the teaching load for the entire team. In the following section, the different measures in redesigning the course are further explained.

### III. METHOD ENGINEERING EDUCATION MADE BLENDED AND SCALABLE

From a birds-eye perspective, the application of BL in the ME course consists of three overall measures, which are: 1) the implementation of computer-supported peer assessment, 2) the introduction of interactive e-lectures, and 3) introducing digital exams. Each of these three overall measures are described in detail in the following sub sections.

#### A. Computer-supported peer assessment

The tool 'Revisely' (see: <https://revise.ly>) is used to cater for online submission of all different deliverables as part of the ME project and, more importantly, it allows for the introduction of peer assessment in the form of peer reviewing and peer grading. By introducing peer assessment, students are able to learn from each other's work. As the students have to work on their own topic for the meta-modelling project, they are able to acquire useful insights when reviewing the modelling choices made by fellow students. Moreover, the students gain experience in providing feedback and grading the work of peers. Finally, through peer assessment a student not only receives feedback from lecturers or student assistants but also from their peers [5, p. 132]. A total of three peer assessment exercises were introduced in the ME project. For the first exercise, students have to peer review and grade a deliverable in which the selected IS development method or technique is explained and positioned relative to existing literature. For the second exercise students have to peer review and grade a deliverable that includes the design of a meta-model of the selected method or technique and for the third exercise students peer reviewed the pre-final term paper without grading it. Based on the feedback acquired from their peer assessors, students write their final term paper that is subsequently assessed and graded by the lecturing team itself. Figure 1 shows a screenshot of the Revisely tool that is used for computer-mediating the peer assessment exercises. Students uploaded their deliverables as PDF documents in the Revisely tool, where a total of three randomly assigned peer assessors needed to provide both textual feedback, i.e., remarks and suggestions for improvement, and scores for the individual grading criteria. These criteria are made available in the Revisely environment and are in fact based on the grading criteria as used by the lecturing team itself in the previous year. To provide the peer assessors with a frame of reference, they are provided with examples from the previous year that were assessed as mediocre / weak, sufficient, and excellent by lecturers. To make sure the peer assessment exercises are conducted in a serious manner, they are required elements for course completion as they are part of the exam rules of the course. This has as a consequence that failure to

deliver a serious peer review leads to an inability to pass the course, while the peer assessment results, i.e., the quality of the peer feedback is not graded by the lecturers. For each peer assessment exercise, we found that almost everybody submitted a serious peer assessment. Both the fact that the peer assessments are required elements to pass the course and that three students peer assess each deliverable may further stimulate students to take this task seriously [5, p. 103].

After the passing of a peer assessment deadline, the student assistants are asked to inspect the peer assessments, i.e., the feedback and grades given by the peer assessors. In the Revisely tool, every student assistant is assigned an equal share of the deliverables that are indeed commented and graded by three students. A student assistant then checks if the grades that are provided are fair and in line with the quality of a deliverable, if there are outliers in the provided grades, and if the peer review is conducted according to the grading criteria as made available in Revisely. A student assistant also extends provided feedback if needed, or adds additional feedback if additions to the peer reviews are needed. As a final step, a student assistant proposes a final grade based on the grades as provided by means of the peer grading activities. When the student assistants are all done performing this 'meta review' of the provided peer reviews, the lecturers conduct a final 'meta meta review', i.e., discussing conspicuities as identified by the student assistants, performing a final check of the meta reviews, and determining the final grade based on the proposals made by the student assistants.

At the end of the day the utilization of this computer-supported approach to peer reviewing and peer grading provided at least six clearly identifiable advantages. First and foremost the lecturing team including the student assistants experienced a relieved teaching load as three project deliverables do not need to be reviewed and graded 'from scratch' by lecturers with assistance from student assistants. Secondly, in the past a student would receive feedback on a deliverable from a lecturer and a student assistant. With the peer assessment procedure a student now receives feedback from three fellow students, a student assistant, and possibly a lecturer. Before a lecturer determines the final grade, in fact four suggestions for such a grade are now made by those who have inspected the deliverable. Thirdly, the deliverable submission procedure is streamlined and automated because of the usage of Revisely. Grading criteria are provided online, a randomized match is made between the peer assesseees and assessors, student assistants are allocated a fair share of the assessed deliverables and all feedback and grades are made available online for every individual student. Fourthly, the university where this blended Method Engineering course is offered has a support team for lecturers who incorporate BL in their courses, which means that whenever a user of a BL tool that is supported by the university has a tool-related question the support team can step in and there is no need to communicate with the tool supplier itself. Fifthly, through the above approach students are able to experience an increased level of responsibility [6, p. 88], i.e., it is their task to not only run a successful ME project

The screenshot displays the Revisely interface. On the left is a dark blue sidebar with navigation options: Dashboard, Assignments, My students, My groups/classes, Management, Help, and Logout. The main content area shows two assignment cards. The top card, 'Assignment C: Meta-modeling with PDDs', is dated 2018-03-02 18:00 to 2018-03-17 10:00. It shows a score of 77/77 (Handed in) and 0 (To be corrected), with an average score of 7,27. The bottom card, 'Assignment A: Topic selection and description', is dated 2018-02-12 10:00 to 2018-03-09 22:00. It shows a score of 77/77 (Handed in) and 0 (To be corrected), with an average score of 7,21. Both cards include download options for reports and peer grading links.

Fig. 1. Screenshot of the Revisely tool

but also to conduct peer assessments in a serious manner. This way, they gain experience in giving feedback to peers and in grading each other's work. Fifthly, lecturers are able to identify those students who come up with high quality reviews, which is a factor in identifying whether they are potential candidates to become the students assistants of the future [7]. Sixthly and finally, introducing peer assessment exercises in addition to the tasks to deliver the ME project deliverables is a way to increase student engagement during the course, which is helpful in times where it is easy for students to spend time on non-study related activities [5, p. 132].

### B. Interactive e-lectures

Introduction of interactive e-lectures is the second of the three overall measures taken to apply BL in the ME course as discussed in this paper. A gradual approach is adopted to modify selected regular offline lectures into e-lectures. For the 2018 incarnation of the course, three of the in total eleven regular lectures are transformed into e-lectures. These three lectures are foundational lectures and discuss the topics of meta-data modelling, meta-process modelling, and the role of formalization in ME. Gaining experience in this new teaching mode first before modifying the other regular lectures that discuss advanced ME topics is the key reason for applying such a gradual approach. To modify regular lectures into e-lectures, the tool 'Scalable Learning' (see: [www.scalable-learning.com](http://www.scalable-learning.com)) is used and just as with Revisely this tool has an university-based support team. The e-lectures themselves consist of video material from previously recorded lectures and knowledge clips that were recorded by a student assistant. This student assistant was specifically appointed for this task and recorded short topical clips in a studio on the university campus. These topical clips are in line with what is taught in the three regular lectures. For each e-lecture in the Scalable Learning tool, multiple-choice quiz questions are

added to make the e-lectures interactive. The students are asked to prepare each e-lecture, i.e., watch them and make the questions at home or at whatever place they wish. In the lecturer view in Scalable Learning, it is then possible to see who has completed an e-lecture and the answers to the quiz questions can be inspected. The lecturer can then make a selection which questions need to be discussed offline in a classroom setting, for example, those questions that were difficult to answer correctly for the students. Students are also allowed to add their own comments or questions to the video material if there are unclarities while watching the e-lectures. These inaudibilities can also be highlighted for discussion in class. After the students finalized preparation of an e-lecture, an in-class discussion session followed of about an hour each where quiz questions that proved to be difficult and any other unclarities related to the online course material are discussed.

Clear advantages of the approach as described above are threefold. Firstly, students are able to watch the e-lectures anywhere and on their own learning pace, i.e., quickly going over those clips and questions that are easier to grasp for an individual student and more slowly watching material or even repeatedly watching material that is more difficult. Secondly, time is gained as the necessity to be physically present in lecture rooms is reduced. Thirdly, for the overall population of students the lecturer can identify which questions are particularly difficult or more easy to answer and by reviewing the quiz questions the lecturer can shape the offline discussion sessions in order to attune these to the specific audience.

### C. Digital mid-term and final exams

The third and final measure taken to realize a blended variant of the ME course is the transformation from paper-based exams to digital exams. This measure together with the electronic submission of the ME project deliverables in Revisely has as additional side effect that the ME course is

now entirely paperless. The university-supported tool Remindo (see: [www.paragin.nl](http://www.paragin.nl)) is used to design the digital exams. In previous years, the ME course included two paper-based exams, i.e., a mid-term exam and a final exam. The mid-term exam is meant to test knowledge on meta-modelling gained in the first half of the course, while the final exam is for the larger part meant to test knowledge on method engineering theories. The paper-based exams included open questions, while Remindo is ideally suited for administering multiple-choice exams. Introducing multiple-choice questions in both exams provides an opportunity to further reduce the teaching load, as no manual marking is needed for those question types. Transforming open questions where students are asked to design (meta-)models requires to be notably creative, e.g., such an open question can be transformed to a closed variant by dividing the open question in parts where for each closed question a student has to choose the correct modelling alternative from a set of choices [8, p. 464]. Another option is to show a partial (meta-)model that a student has to complete by correctly dragging-and-dropping modelling elements such as correctly dragging-and-dropping a meta-activity in the eventual (meta-)model or correctly positioning meta-concepts in the eventual (meta-)model.

The most prominent advantage of this approach is that the time needed for marking is reduced. Instead of grading two times eighty-three exams, Remindo takes most grading work out off the hands as it automatically checks closed questions and is able to deal with negate guessing. Needless to say, digital exams save time and paper as printing of big stacks of exams and carrying these to and from exam rooms becomes a thing of the past. Finally, in case of open questions Remindo removes the possibility of having to deal with unreadable handwriting, as students have to type their answers on notebooks that run Remindo.

#### IV. STUDENTS' REFLECTIONS ON THE BLENDED LEARNING APPROACH

The trinity of BL measures as applied in the 2018 incarnation of the discussed ME course has been evaluated by students through: 1) A customary online survey purposefully tailored with specific BL-related open questions that is presented to students at the end of all courses that are part of the Master's degree programme in BIS of which also the mentioned ME course is part of, and 2) through a survey offered by the university's BL support team. The latter survey measures student motivation, differences experienced in learning activities, and experienced learning outputs related to the computer-supported peer assessment part of the trinity [6], [9] and was also offered to students at the end of the course.

Inspired by Unkelos-Shpigel and Hadar [10, p. 189], the survey data has been analyzed in an inductive manner [11], [12] with respect to the part of the main research question that concerns the students' teaching experience by boosting the advantages of blended learning. The customary online survey shows insights on experiences of all three BL measures and it was filled out by thirty-eight of the eighty-three participants in

2018. The following responses on peer assessment are found and they happen to be rather self-explanatory:

*"I like Revisely and did not have any issues with it. Grading others' work gives better insight into your own work"*

*"I would keep the assignment format and Revisely. It is nice how each assignment builds into the final paper. It was really stress-free and I enjoyed it"*

*"Revisely provides an OK platform for submissions and peer reviews"*

The responses related to the interactive e-lectures show that students perceived an added value in the activating effect these kind of lectures have and in the 'blended' aspect of having online and offline lectures. The apparent usefulness of the e-lectures is also emphasized:

*"The e-lectures [...] demanded active participation [by means of answering] the [quiz] questions"*

*"Enjoyed the different elements in the course, [I] like the combination of the regular lectures with the e-lectures"*

*"e-Lectures are a great addition in my opinion"*

*"The e-lectures should [remain for next year, they were] very useful"*

The following responses concern the third and final BL measure which is the introduction of digital exams:

*"I found the flipped classroom [and] digital exams [...] very helpful"*

*"The mid-term exam was good. I'm a big fan of the digital exam and it was carefully constructed as to test the knowledge of [meta-modelling] despite the [common view] that open exams would be a better way to [test this kind of knowledge]"*

*"While I'm not a fan of multiple choice questions, I'm glad the majority of the questions were about understanding the content as opposed to [sheer memorizing of] it"*

One response concerned a positive impression of the course as a whole:

*"Compared to last year the course has really improved"*

This impression resonates when comparing last year's average grade given for the course by students in 2017 with this year's average grade, as the respondents in 2018 evaluated the overall quality of this course to be a 7.5 on a scale of 1 to 10 (N=32 with a standard deviation of 1), whereas last year this score was a 6.5 (N=26, standard deviation of 1.5).

The survey offered by the university's BL support team was filled out by a total of seventy-one out of the eighty-three course participants in 2018. The ME students provided their answers on a five-point Likert scale, where '1' means 'completely disagree' and '5' means 'completely agree'. In table I the averages are shown for the ME course and for two other courses that also used Revisely for computer-supported peer assessment with a total of one hundred and

fourteen respondents. In the rightmost column the averages are shown for all courses within the university that are using university-supported BL tooling since 2016. In that year the university's BL support team was formed and since then surveys are offered to those lecturers who use university-supported BL tools. The table shows that students indicated to have received more feedback and also gave more feedback by using computer-supported peer assessment in the ME course. This is an indication that the main aim of the peer assessment approach is largely met, which is to offer an environment to provide peer feedback and peer grading. On average, students were also highly positive about the way the peer assessment approach affected their motivation and that they were able to learn more and understand the course content better. The students were less positive about 1) the joy experienced while using computer-supported peer assessment, 2) the effect it had on their ability to pass the exams, and 3) the extent to which it helped them to understand the lectures better. In the future, it will be investigated how to improve on these three less positive aspects.

## V. DISCUSSION

After analyzing the results of the student surveys in full, there are other observations that are deemed relevant for further discussion apart from the three more critical aspects as mentioned at the end of section IV. After discussing these observations, some interesting points that are specifically related to the peer assessment part are mentioned at the end of this section.

### Meta-review to overcome peer reviews of varying quality

Concerning the peer assessments, respondents indicated that the quality of peer reviews may differ and grades given for peer graded deliverables are not always in line with each other. These effects were anticipated on in the design of the blended variant of the ME course by introducing three peer reviewers [13, p. 43] and by conducting a round of meta- and meta meta reviewing as discussed in section III-A. However, it does not prevent students from experiencing differences in quality and differences in grades given to their work as the results of a peer assessment are visible in the Revisely tool once a peer assessment is finalized by a fellow student. Although the final grade for their work is given by a lecturer, a respondent wondered what effect an outlier had on the final grade as this was not consistently articulated in the final feedback. Apart from an obvious solution to make explicit in the final feedback of the meta-meta-review what has been done with a possible outlier when determining a final grade, the introduction of an entire instructional lecture dedicated to peer assessment would be a plausible idea, instead of maintaining the current practice of instructing students in an ad hoc manner how to conduct a peer assessment as part of a topical lecture and during workshops where they work on their practical exercises [9, p. 103].

### Student opinions in two camps

In the responses concerning the interactive e-lectures it was found not every student liked the idea of having to watch the e-lectures and prepare the accompanying quiz questions. Some students feel a lack of opportunity to interact with others, i.e., lecturer and fellow classmates in a live classroom setting. However, the Scalable Learning tool offers the possibility for lecturers to comment on questions that are raised by students while preparing the e-lectures and to at least asynchronously interact with students before the actual in-class discussion session takes place. What will be done for the next iteration of the course is to explicitly emphasize in class the possibilities to asynchronously communicate with lecturers by making use of the option to raise questions and clearly indicate where unclarities are. Watching interactive e-lectures remains a different form of education when compared to a traditional lecture, however, and it depends on an individual's learning preferences how this modern educational form is experienced. Another notable aspect which is in fact sensible advice is that students indicate the e-lectures should always include knowledge clips that are of identical quality when compared to regular lectures and that lecturers should prevent knowledge clips from becoming second-rate replacements of regular lectures.

### Multiple-choice exams with an option to comment

From the responses to the customary online survey it becomes clear that among students who are unfamiliar with multiple-choice exams or who have a preference for open question exams there is a desire to provide comments in the digital exam environment next to only being able to select the proper answers. Multiple-choice exams with an option to comment provides students with an opportunity to write down their thought-line that led to the selection of an answer. Nield and Wintre [14] indicated that this approach reduces frustration and produces less anxiety among students. How to implement this in the digital exam environment is a different matter, i.e., it is not a standard option to choose from in the Remindo tool and as such how to deal with this challenge is part of future research.

### Overcoming glitches in technology-mediated peer assessment

Concerning the technology-mediated peer assessment part there are some noteworthy experiences from the point of view of the ME course lecturers. As mentioned before, after the submission deadline of a deliverable that was going to be peer reviewed in Revisely had passed, three reviewers were assigned to each submission. It was found that the tool supported random assignment of one reviewer only, meaning the assignment of three reviewers had to be done manually which is a more time consuming and error-prone process. The tool also

TABLE I  
COMPUTER-SUPPORTED PEER ASSESSMENT EVALUATION RESULTS

By using the computer-supported peer assessment approach I ... :	ME course <i>N=71</i>	Other courses <i>N=114</i>	Totals for BL courses <i>N=3135</i>
<i>Motivation</i>			
was motivated	3.69	3.49	3.46
experienced joy	2.69	2.91	3.33
had the impression it was useful	4.03	3.86	3.73
had the impression it supported me in passing the exams	2.92	2.99	3.19
<i>Learning activities</i>			
was more active with the content	3.33	3.02	3.47
was able to better study the content	3.32	2.95	3.17
was able to improve collaboration	3.00	2.91	2.72
received more feedback	4.37	4.27	3.32
gave more feedback	4.28	3.70	3.13
<i>Experienced learning outputs</i>			
learned more in this course	3.54	3.28	3.32
understood the content better	3.44	3.17	3.30
was better prepared for the exams	2.79	2.74	3.16
was better prepared for the lectures	2.97	2.85	2.84
understood the lectures better	2.69	2.53	3.01

has the functionality that if students finalize their peer review, the reviewee can immediately see the feedback. This has as an advantage that feedback is seen much quicker when compared to an instructor review approach. However, it was found that once a peer reviewer marks the review as finalized, there is no option to undo. It happened a couple of times that a peer reviewer would mark a review as finalized accidentally. As a workaround additional feedback could then be exchanged between the reviewer and reviewee by e-mail. Finally, a pressing issue was that three students were not allowed to review the same deliverable at the same time. If they did, added feedback could be lost. As a workaround students were asked to store their review on a local drive first and then they were asked to always communicate with the other peer reviewers of the deliverable in case one of the three reviewers would start performing a review. The above experiences were all communicated to the university's BL support team who maintained close ties with the tool supplier and as such formed improvement points for the next release of the tool.

## VI. CONCLUSIONS AND FUTURE RESEARCH

In this paper a redesign approach was presented for transforming a Master's course on Method Engineering as part of an BIS curriculum into a blended variant. A trinity of blended learning measures have been proposed, that were driven by the desire to realize 1) a course design that preserves quality education in a time where student numbers in CS and BIS curricula are increasing while university budgets remain tight, and 2) to offer a teaching experience that fits with individual learning styles while reducing time and place restrictions. The three measures included the introduction of technology-mediated peer assessment, interactive e-lectures, and digital examination. Most prominent advantages of the peer assess-

ment measure are the reduction of teaching load, increased generation of feedback itself, increased student experience in providing feedback, and increased student motivation and engagement. The introduction of interactive e-lectures enabled students to watch the e-lectures anywhere, anytime, and on their own learning pace. There is a time gain as e-lectures replace regular lectures, however, quiz results need to be reviewed by lecturers and then in-class discussion sessions need to be organized. This offers the advantage of tailoring these sessions in such way that the difficult questions as part of the e-lectures receive most attention. Clear benefits of digital examination include reduced marking time and elimination of paper-based exams.

For next year, the blended approach will be maintained in the Method Engineering course and improvements will be implemented, based on opportunities identified in the student survey results and by means of reflecting on the course from a lecturer's point of view. An instructional lecture purely dedicated to peer assessment will be introduced, possibilities to stimulate student-student and student-lecturer interaction will be explored when students are watching e-lectures, e-lecture quality will be double-checked and where needed further improved, and it will be investigated whether multiple-choice exams with an option to comment can be realized. Finally, based on the peer assessment survey results it will be investigated how students are able to experience more joy while using computer-supported peer assessment (and BL tools in general for that matter), in what ways peer assessment can make an impact on the ability to pass exams, and it will be inventorized how it helps students to increase understanding of the course content.

# 3<sup>rd</sup> International Conference on Lean and Agile Software Development

THE evolution of software development life cycles is driven by the perennial quest on how to organize projects for better productivity and better quality. The traditional software development projects, which followed well-defined plans and detailed documentations, were unable to meet the dynamism, unpredictability and changing conditions that characterize rapidly changing business environment. Agile methods overcame these limits by considering that requirements are not static but dynamic, while customers are unable to definitively state their needs up front. However, the advent of agile methods divided the software engineering community into opposing camps of traditionalists and agilists. After more than a decade of debate and experimental studies a majority consensus has emerged that each method has its strengths as well as limitations, and is appropriate for specific types of projects, while numerous organizations have evolved toward the best balance of agile and plan-driven methods that fits their situation.

In more recent years, the software industry has started to look at lean software development as a new approach that could complement agile methods. Lean development further expands agile software development by adopting practices from lean manufacturing. Lean emphasizes waste elimination by removing all nonvalue-adding activities.

## TOPICS

The objective of LASD is to extend the state-of-the-art in lean and agile software development by providing a platform at which industry practitioners and academic researchers can meet and learn from each other. We are interested in high quality submissions from both industry and academia on all topics related to lean and agile software development. These include, but are not limited to:

- Combining lean and agile methods for software development
- Lean and agile requirements engineering
- Scaling agile methods
- Distributed agile software development
- Challenges of migrating to lean and agile methods
- Balancing agility and discipline
- Agile development for safety systems
- Lean and agility at the enterprise level
- Conflicts in agile teams
- Lean and agile project production and management
- Collaborative games in software processes
- Lean and agile coaching
- Managing knowledge for agility and collaboration

- Tools and techniques for lean and agile development
- Measurement and metrics for agile projects, agile processes, and agile teams
- Innovation and creativity in software engineering
- Variability across the software life cycle
- Industrial experiments, case studies, and experience reports related to all of the above topics
- Gamification
- Affective Software Engineering

## EVENT CHAIRS

- **Przybyłek, Adam**, Gdansk University of Technology, Poland

## PROGRAM COMMITTEE

- **Ahmad, Muhammad Ovais**, University of Oulu, Finland
- **Akman, Ibrahim**, Atılım University, Turkey
- **Ali, Sikandar**, China University of Petroleum, China
- **Almeida, Fernando**, University of Porto & INESC TEC, Portugal
- **Alshayeb, Mohammad**, King Fahd University of Petroleum and Minerals, Saudi Arabia
- **Angelov, Samuil**, Fontys University of Applied Sciences, The Netherlands
- **Bach-Dąbrowska, Irena**, WSB Gdańsk, Poland
- **Bagnato, Alessandra**, SOFTEAM R&D Department, France
- **Belle, Alvine Boaye**, École de Technologie Supérieure, Canada
- **Benayed, Nourchene**, Higher Colleges of Technology, United Arab Emirates
- **Bernhart, Mario**, Vienna University of Technology, Austria
- **Bhadauria, Vikram**, Texas A&M International University, United States
- **Binti Abdullah, Nik Nailah**, Monash University Malaysia, Malaysia
- **Biró, Miklós**, Software Competence Center Hagenberg and Johannes Kepler University Linz, Austria
- **Blech, Jan Olaf**, RMIT University, Australia
- **Borg, Markus**, SICS Swedish ICT AB, Sweden
- **Brzeski, Adam**, CTA.ai, Gdansk University of Technology
- **Buchalceva, Alena**, University of Economics, Prague, Czech Republic
- **Buchan, Jim**, Auckland University of Technology, New Zealand

- **Buglione, Luigi**, Engineering Ingegneria Informatica SpA, Italy
- **Chatzigeorgiou, Alexandros**, University of Macedonia, Greece
- **Cruzes, Daniela**, SINTEF ICT, Norway
- **Daszczuk, Wiktor Bohdan**, Warsaw University of Technology, Poland
- **Dejanović, Igor**, Faculty of Technical Sciences, Novi Sad, Serbia
- **Derezińska, Anna**, Warsaw University of Technology, Institute of Computer Science, Poland
- **Diebold, Philipp**, Fraunhofer IESE, Germany
- **DUTTA, ARPITA**, NIT ROURKELA, India
- **Escalona, Maria Jose**, Universidad de Sevilla, Spain
- **Essebaa, Imane**, Hassan II University of Casablanca, Morocco

**Abstract**—This study utilizes citation analysis and automated topic analysis of papers published in International Conference on Agile Software Development (XP) from 2002 to 2018. We collected data from Scopus database, finding 789 XP papers. We performed topic and trend analysis with R/RStudio utilizing the text mining approach, and used MS Excel for the quantitative analysis of the data. The results show that the first five years of XP conference cover nearly 40% of papers published until now and almost 62% of the XP papers are cited at least once. Mining of XP conference paper titles and abstracts result in these hot research topics: “Coordination”, “Technical Debt”, “Teamwork”, “Startups” and “Agile Practices”, thus strongly focusing on practical issues. The results also highlight the most influential researchers and institutions. The approach applied in this study can be extended to other software engineering venues and applied to large-scale studies.

## I. INTRODUCTION

In every field of science, evidence for the importance of identifying emerging research topics is useful for researchers, funding agencies and policy makers. This helps to promote and enhance the development of potentially promising research topics. Citation is a way to judge influential work and build new studies on existing research results [1], [2], [3]. Citation analysis is a common way not only to judge but also to observe the most popular and influential work [1], [2], [4]. Bibliometrics, on the other hand, is a method used for statistical analysis of publications in order to provide quantitative analysis [5]. Bibliometrics based identification of active authors and institutions has many benefits, i.e. helping students and researchers to identify active and relevant institutes for their area of interest, and enabling employers to recruit the most qualified potential researchers [3].

In various fields of science, e.g., in medicine, physics and social sciences, it is common to identify the highly cited papers [6], [7], [8]. Bibliometrics and citation analysis studies have also been conducted in software engineering, computer science and other disciplines, e.g., [4], [2], [3], [9], [10], [11], [12], [13], [14]. The highly cited papers usually provide insights into new avenues of research, a significant summary of

the state-of-the-art in a research area and a measure of scientific activity, in general [1], [2]. One of the key outlets for Agile research, “*Agile Software Development Conference (XP)*”, has not been evaluated under the lens of citation analysis alone or as a sub-field of its own (processes). XP Conference (“*International Conference on Extreme Programming (XP)*” - formerly “*Conference on Agile Software Development (AGILE)*”) was included in a bibliometrics study of Karanatsiou et al. [14] in the general domain of software engineering (where XP conference was the only process oriented conference in that study). The study of Chuang et al. [13] assessed agile software development, in general, for 221 published primary articles on the topic.

The purpose of this study is to provide an overview of the literature published in all XP conference proceedings. This study helps readers to understand the development and evolution of the XP conference from three main aspects: (i) the citation landscape and the most cited papers, (ii) the most active authors, institutions and countries, in terms of number of publications, and (iii) the identification of emerging research topics in XP conference publications and use of indexed keywords.

This paper is organized as follows: First, we discuss the research method and the data extraction technique. Second, we present the results of the analysis including findings on active individuals and institutes, highly cited papers and authors, and trends in the covered topics. Third, we discuss the threats to validity of the study. Finally, we summarize the findings and provide recommendations for future research.

## II. RESEARCH METHOD AND DATA EXTRACTION

The research data were collected from Scopus<sup>1</sup> database on September 2<sup>nd</sup>, 2018. Scopus is claimed to be the largest abstract and citation database of peer-reviewed literature. Scopus

<sup>1</sup><https://www.elsevier.com/solutions/scopus>

TABLE I  
SEARCH QUERIES FOR EXTRACTING PAPERS FROM SCOPUS

No.	Query String and its explanation	Papers
1	<b>CONF("XP") AND (LIMIT-TO(DOCTYPE,"cp"))</b> Select XP conference and conference papers only	758
2	<b>SRCTITLE("Lecture Notes in Business Information Processing" AND VOLUME(77) AND (LIMIT-TO(PUBYEAR,2011) AND (LIMIT-TO(DOCTYPE,"cp"))</b> Select "Lecture Notes in Business Information Processing" and only vol. 77 which includes conference papers for XP 2011	31

also provides citation data and allows to save the search results to a csv-file, for further analysis.

We started with the search string "1" (see Table I), to collect data related to all published XP conference papers. The search resulted in 758 papers. To our surprise, the search string "1" did not retrieve papers for the year 2011. We learned that the papers for the year 2011 do not include the information about the XP conference in the Scopus database. Thus, to collect those missing papers <sup>2</sup>, we complemented the findings with the search string "2", resulting in 31 papers.

The complete search gave us 789 papers (758+31), covering the years of 2002-2018 (published by September 2<sup>nd</sup>, 2018). The data, including e.g., names of the authors, title, publication year, source title, number of citations, link and abstract, were stored as a csv-file. We were also able to extract data from Scopus, directly, for the analysis of the affiliations and countries related to the authors (analysis of the search results in Scopus) as well as the top 20 cited papers (overview of the citations in Scopus). We used both MS Excel and R/RStudio for analyzing statistics and trends from the data.

### III. RESULTS

In 2001, the first "XP Universe" hosted tutorials, lectures, panel discussions, posters, workshops, and other less traditional discussions. A year later, the 2<sup>nd</sup> "XP Universe" and 1<sup>st</sup> "Agile Universe" were brought together to attract software experts, educators, and developers<sup>3</sup>, in general. In 2003 and 2004, the two conferences, "Extreme Programming and Agile Methods - XP/Agile Universe" and "Extreme Programming and Agile Processes in Software Engineering" were organized separately, but reported together in a Springer database. In 2005, the conferences were merged and formed a single venue: "Extreme Programming and Agile Processes in Software Engineering". Since 2007, the conference has been called as "Agile Processes in Software Engineering and Extreme Programming".

The Scopus database search yielded 789 papers in the proceedings of XP conference published between 2002 and 2018, see Fig. 1. The high number of papers for 2004 (n=96) is explained by the fact that the two aforementioned conferences are recorded together. The first five years of the XP conference

TABLE II  
TOP 20 COUNTRIES WITH MOST PAPERS (2002-2018)

Country	Papers	Country	Papers
United States	116	Brazil	25
United Kingdom	110	Austria	20
Italy	81	Netherlands	20
Finland	66	Spain	20
Sweden	61	Denmark	15
Norway	58	Australia	14
Canada	57	Israel	13
Germany	50	Poland	13
Ireland	37	Switzerland	12
New Zealand	39	Belgium	8

TABLE III  
AFFILIATIONS WITH MINIMUM 15 PAPERS

Affiliation	Papers
University of Calgary	39
Free University of Bozen-Bolzano	29
Universita degli Studi di Cagliari	28
SINTEF, Norwegian Inst. of Tech.	22
Victoria University of Wellington	20
Norges Teknisk-Naturv. Universitet	19
Chalmers University of Technology	17
SINTEF Digital	16
Open University, Walton Hall	16

cover about 38% and the first 10 years cover nearly 70% of all those papers. In XP conference, the average number of papers per year is 46.4 with a standard deviation of 20.3, using STDEV.P. The lowest number of papers are from year 2012 (n=15). The low number of paper may be an indication of rigorous selection process. Alternatively, some of the volumes include only research papers and short papers, whereas, some include e.g., abstracts of the posters or the position papers of the PhD symposium. Such variations are quite normal in various publication forums. The topmost values in Fig. 1 are the values from Scopus and the values at the bottom represent the number of accepted full papers retrieved from the prefaces of the conference books. Two of the conferences (XP2014 & XP2012) did not report the number of submitted full papers, but for those that had the information available, the acceptance rate was between 20% (XP2011) and 49% (XP2003), arithmetic mean of the rates being 32%.

The analysis from the Scopus data shows that majority of the XP conference papers originated from the United States (116), United Kingdom (110), Italy (81) and Nordic countries (Finland (n=66), Sweden (n=61) and Norway (n=58)), see Table II. It seems that these countries have a strong culture of agile in software development which is actively reported in XP conference. Table III shows the most frequent contributing institutions in XP conference, in which the top three are University of Calgary, Canada, Free University of Bozen-Bolzano, Italy and Università degli Studi di Cagliari, Italy. It is notable, however, that the number of countries and affiliations is related to the number of related authors for each paper. The study of Chuang et al. [13] did not report the total number of papers per country, but reported the top publishing institutions to be from the United States, Norway and United Kingdom.

<sup>3</sup><http://www.xpuniverse.com/>

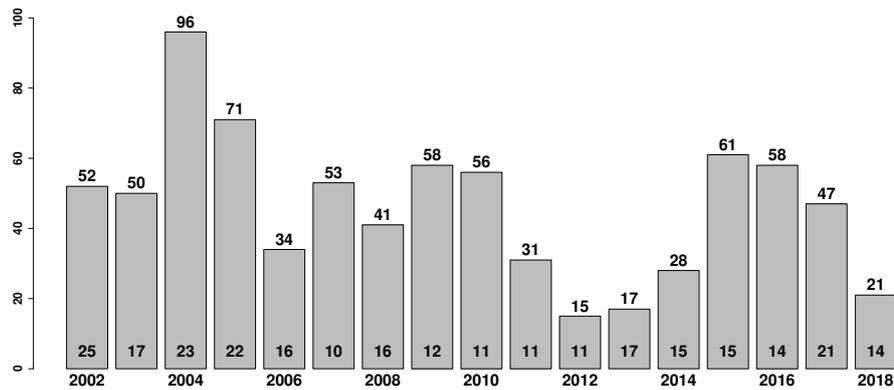

Fig. 1. Distribution of the Publications in Scopus (2002-2018) vs. total number of full papers in the conferences (value at the bottom)

### A. Authorship Trends

The results show that 1260 unique authors contributed to the 789 papers in XP conferences until 2018. The minimum number of authors for a XP paper was one whereas maximum was nine. Majority of the XP papers in 2018 (almost 35%) have four authors. In general, about 30% of all papers have two authors, 25% have one author, and 9% of the papers have five or more authors, see Table IV. The number of authors having contributed to three or more XP papers is rather small, as most authors have contributed to just one or two papers. About 75% of the authors (944) have an authorship to just one paper and about 88% of the authors (1108) have an authorship to only one or two papers, as a single or as a co-author. Chuang et al. [13] also reported a finding of a core intellectual pool contributing to the agile research realm.

During the first three years (2002-2004) of the conference, most papers were published by a single author. For the years 2005-2009, most papers were published by two authors, and for the years 2010-2012 and 2013-2014 by three and four authors, respectively. We consider the different number of authors for the papers as an indication of increased, high (international) collaboration among the contributors. In the 1970's, the average number of authors per paper in software engineering was around 1.5, while after 2010, the number of authors has typically been three [15]. The average number (i.e., arithmetic mean) of authors for the papers in XP conference is 2.6.

Asknes [16] studied a body of Norwegian articles (nearly 50000 articles having at least one Norwegian address). He concluded that at an aggregated, general level the “*highly cited papers typically involve more collaborative research than what is the normal or average*” [16]. In our study, the correlation between the number of authors and citations for a paper, for all papers, is weak ( $r = 0.13$ ,  $df = 787$ ,  $p = 0.0002$ ). However, for the set of top 20 cited papers (see Table VI), the correlation between the number of authors and citations for a paper is 0.59 ( $r = 0.59$ ,  $df = 18$ ,  $p = 0.0064$ ). Thus, the correlation coefficient suggests a strong positive correlation between the number of authors and citations for those top 20 cited papers.

Table V includes the 16 most active authors in the XP conference who have minimum number of 10 papers each. Maurer F. has been the most active author compared to the other top contributors of the XP conference. There are four authors that have their most cited papers published in 2010's (the publication year for the most cited paper in parenthesis), namely Abrahamsson P. (2015), Wang X. (2015), Concas G. (2012) and Bosch J. (2012); the rest of those most cited papers have been available for ten years or more. Interestingly, in a study “*Institutions, scholars and contributions on agile software development (2001-2012)*” by Chuang et al. [13], the list of the 18 most active authors included four of the 20 most active authors in this study, namely Abrahamsson P., Dingsøy T., Moe, N.B. and Sharp H. However, the list of the most active authors in that study [13] included also Boehm, B., Robinson H., Williams L., Dingsøy T., Moe, N.B. and Sharp H. who were among the authors of the top 20 most cited papers in this study.

### B. Citation Landscape & Most Cited Papers of XP Conference

A high citation count of a scientific work is an indication of the influential work and impact of a given paper [16], [17]. Our analysis shows that 62% ( $n=488$ ) of XP papers have been cited at least once, leaving about 38% ( $n=301$ ) as uncited papers, see Fig. 2. This is an indication of higher visibility of XP conference papers. When focusing on the first ten years of XP conference, i.e., the papers prior to 2012, nearly 65% of those papers (352/542) have been cited at least once. The findings are in line with prior studies [4], [18] in which about 43% of the papers were uncited (large body of software engineering publications). Similarly, about 42% of the papers of “*International Symposium on Empirical Software Engineering and Measurement*” [3] were uncited.

Garfield [1] argues about the citation count being the measure of *importance* or *impact* of a scientific work. He claims that citation count is rather a measure of *utility*, i.e., usefulness of the work for a large number of people or experiments [1]. Furthermore, a citation count can also be a measure of *scientific activity* and not necessarily related to the significance of the scientific work [1]. As in reality, only a

TABLE IV  
PROPORTION OF THE NUMBER OF THE AUTHORS PER YEAR

Year	Number of Authors

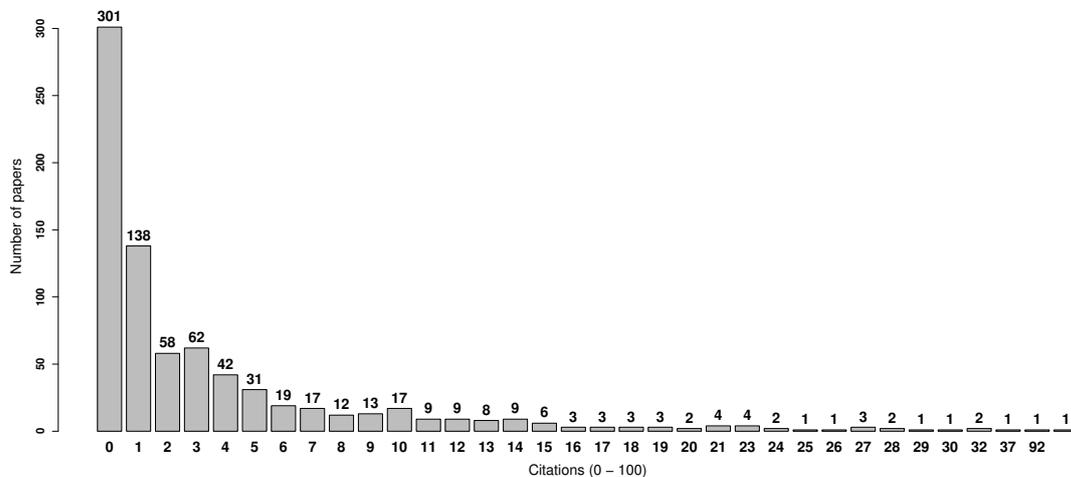

Fig. 2. Distribution of Citations (0-100) for the papers

rather small portion of the XP conference papers retrieved from Scopus are full research papers, the high number of uncited papers is not a surprise. Thus, it can be claimed that the samples from indexed databases may not be as representative as expected for citation analysis without rigorous filtering. However, such sample papers may well be valid for analysing author activity as well as research trends and topics.

The Table VI shows the top 20 most cited XP conference papers (each paper having minimum 23 citations). The total number of citations for the top 20 papers covers almost 25% of all citations (680/2920) which are mainly from earlier years of XP conference (2002-2009). However, one paper is published in 2015 and five papers among the top 20 papers are published in 2002. Table VI, shows that 92% of citations (624/680) are from papers not written by the authors (of the cited paper) themselves. Typically, a paper is cited the first time during the year of its publication or during the following year. However, the two top cited papers, “*Empirical findings*

*in agile methods*” by Lindvall et al. (2002) and “*Towards a framework for integrating agile development and user-centred design*” by Chamberlain et al. (2006), have been published over ten years ago, and have received the most citations since 2015. Chamberlain et al. (2006) had only a few citations right after its publication. After 2010 until 2015 the paper has received attention from both industry and academics in various fields of science, e.g., Computer Science, Mathematics, Decision science, Business, Management and Accounting, Social sciences or Psychology. In 2017, Chamberlain et al. (2006) received the most citations among the top 20 cited papers, and was the second most cited in 2018 (after Lindvall et al. 2002), at the time of the study.

### C. Highest Cited Papers Per Year

Many countries and evaluating bodies (for funding, promotions or appointments) are using figures like publication record or citation count in decision-making [3]. Such evaluations have two sides; firstly, it is fair to see the influential and trendy work

TABLE V  
MOST ACTIVE AUTHORS WITH MINIMUM 10 PAPERS

Author	#	Years (Papers)	Citations			1 <sup>st</sup> or 2 <sup>nd</sup> author <sup>c</sup>	
			Total	Avg.	Max <sup>a</sup>

<sup>c</sup> Number of times as first or second author in the publications

# Total number of publications

of specific investigator, and secondly, the appropriateness of such trends/counts can be questioned on scientific grounds. Rapid growth of citations for a paper may be a sign of a popular topic, or active author(s) building on their existing research, or both. Eight of the year-wise most cited papers are the same as reported in Table VI. Those papers have been available for the public for a long period of time, from years 2002 (5), 2004 (3), 2005 (1), 2006 (4), 2007 (3), 2008 (2), 2009 (1) and 2015 (1). The average number of citations for

top cited paper per year in Table VII is 26.6, which is less than the average from top 20 most cited papers, 34 in Table VI.

To compare the general interest on the published papers, we normalized the number of citations for years, see column C-Norm in Table VII. The values for normalized citations varied between 0.53–7.67. The highest number of normalized citations, 7.67, are for the paper “*What do practitioners vary in using scrum*” by Diebold et al. (2015) which received 23 citations in three years (ranked #8 in Table VII considering

<sup>a</sup>All = All Citations (including self-citations), NSC = All Citations excluding self-citations

purely citations). Similarly, the paper “*Empirical findings in agile methods*” by Lindvall et al. (2002) has been available for twelve years and has 92 citations (similarly, ranked as #2 in Table VII). The paper also ranked the highest for the number of citations (100, see Table VI) and has the fourth highest normalized citation count (6.25).

Garousi and Fernandes [18] claim that newer papers will first get to be known in the community. According to Raulamo-Jurvanen et al [3] the longer the paper has been available the better are the chances to be cited. However, according to our results, recent papers have received more attention in terms of citations. One reason can be that the software engineering community has grown over the years and recent topical papers may have a slight advantage when it comes to the number of citations per year.

We were curious to see whether the length of the title had impact on the number of citations for a paper. Letchford et al. [19] had studied the relationship between the lengths of paper titles and citations (across various journals) and concluded that a short title for a paper is an advantage for receiving citations. However, they also stated that the evidence is not as strong when adjusted for the journal where the paper is published. For the XP papers, the correlation between the length of the title, either in words or characters, and the number of citations is weak ( $r = 0.03$ ,  $df = 787$ ,  $p = 0.415$  and  $r = 0.04$ ,  $df = 787$ ,  $p = 0.235$ , respectively). The top 5 cited papers have rather short titles (length varying from 31 to 77 in characters and from 5 to 10 in words). The median length of all titles, in characters and words is 62 and 8, respectively.

#### D. Topical Issues

With topic modeling, we intend to analyze the abstract topics in the documents. We removed 66 documents from the original pool of 789 documents, as not including the abstract in Scopus. Thus, the set of documents for trend analysis included 723 documents. We combined the titles and the abstracts of the documents, converted the text to lowercase and removed all (english) stopwords in R.

For the trend analysis we utilized topic modeling and Latent Dirichlet Allocation (LDA) as described by Griffiths and Steyvers [12] with R scripts based on Ponweiser [20]. Our approach was identical to the process used by Raulamo-Jurvanen et al. [3] and Garousi and Mäntylä [4]. We created a document term matrix from the corpus (using R “text2vec”<sup>4</sup> package), excluding words having less than two characters or appearing in less than three documents. We generated a LDA model (using R “topicmodels”<sup>5</sup> package) by running the topic models from 2 to 100 by one, yielding 35 as the optimal number of topics.

In the analysis of the trend slopes (by publication year) the topics gaining interest among the authors are the “hot topics” and the topics declining interest are the “cold topics”. The five hottest and coldest topics, interpreted by the topic-specific

words (and related titles), and 10 significant terms for each of those, as shown in Table VIII(a) and Table VIII(b), respectively. The topics gaining the most interest are “Coordination” and “Technical Debt”, which include issues like largescale coordination and interteam objectives as well as metric and automation. Cold topics such as “Education”, “Methods and Practices” (including pair programming) and “Testing”, have been of less inspiration for the submissions during the recent years of XP conference.

In 2012, Dingsøy et al. [21] studied agile software development and outlined key research themes at the time, namely *Case Study Methodology, Traditional Software Engineering, CMM, Project Management, Software estimation, Pair Development, Distributed Cognition, Agile methods, User-centered design, Agile methodologies* and *Patterns*. Some of those themes seem still topical, e.g., *software estimation* as “Technical Debt” and some not, like *Pair Development* or *Agile Methods* as “Methods and Practices” (see Table VIII). In fact, Dingsøy et al. [21] report that in Agile2011 they had specifically asked people (mainly academics) what are the topics that should be researched less or further. Pair programming in educational settings and reuse of code were considered as topics not requiring further research while topics like agile across projects and across organizations and distributed agile were considered to be important. “*We concur that these are exciting research areas that can further our understanding of the effectiveness of agile methods and practices, particularly in different project/organizational contexts*” [21]. Such trend is also visible in our study, as “Education” and “Methods and Practices” (including pair programming) were found to be cold topics and topics like “Coordination” and “Teamwork” were among the hot topics.

Perhaps researchers should ask research topic related questions more frequently, not only among academics but also among the practitioners in the field, to support the needs or interests in the industry, too.

#### E. Indexed Keywords

To study the published topics from another perspective, we collected the indexed keywords from Scopus. It is notable that we used the indexed keywords (not the author keywords), as the indexed keywords outnumber the author keywords, providing more details. Additionally, there are papers that are not only missing abstracts (see Chapter III-D) but also keywords (see Scopus e.g., a conference paper “*Agile acceptance testing*” by Pettichord and Marick from 2002). There were 720 papers with indexed keywords. The minimum number of indexed keywords for a paper was 3, the maximum was as high as 25 (for one paper) and arithmetic mean 9.4. We checked the correlation between the number of indexed keywords and the number of citations for a paper, but that correlation is weak ( $r = 0.028$ ,  $df = 718$ ,  $p = 0.459$ ).

We paired the keywords for each paper (e.g., a paper having four keywords would eventually yield 6 unique keyword pairs) and converted the keywords to lower case. The pairing resulted in 32131 keyword pairs which we then stored in a CSV-file.

leadership	skill	standard	testdriven	switching
waterfall	classroom	tutorial	packages	assist
events	testable	certified	technical	standard
tester	selforganizing	exercises	classify	structures
userinterface	comprehensive	shares	methodological	expectations

We used the Cytoscape<sup>6</sup>, an open source software platform, for visualizing the network of the paired keywords (after removing duplicates), see Fig. 3. The lighter the color in the figure, the more the keyword had connections. The keyword “*software engineering*” was, unsurprisingly, the most used keyword, see Fig. 3. The nine other most used keywords were “*software design*”, “*agile software development*”, “*agile methods*”, “*computer programming*”, “*project management*”, “*computer software*”, “*agile development*”, “*extreme programming*”, “*agile*” and “*software testing*”. The keywords are rather generic, but still quite nicely represent the key research themes identified by Dingsøyr et al. [21]. However, a more detailed analysis of the keywords, to view the overall importance and reveal the topicality of the keywords, would be required to see the trends in the area of XP.

#### IV. THREATS TO VALIDITY

In this section, we discuss four perspectives of validity threats [17] and the steps that we have taken to mitigate those threats.

Internal validity reflects the extent to which a causal conclusion based on a study is warranted [17]. The approach used for the selection and extraction of XP conference paper from selected are discussed in Section II. In order to ensure repeatability and reproducibility of our study, the search terms have been defined carefully and reported in the research method Section II. Additionally, the raw data and the scripts used are provided to ensure transparency and replicability of our analysis. The material can be accessed via this link: <https://bit.ly/2LiqQ3S>.

Construct validity is concerned with issues that to what extent the object of study truly represents theory behind the study [17]. As a limitation w.r.t. construct validity, we assumed that all the papers were published in Scopus database properly. Scopus claims to be “*the largest abstract and citation database of peer-reviewed literature*”<sup>7</sup>. All the XP conference proceedings are indexed in Scopus and we fetched all the data from this database. However, 2011 papers are not properly indexed, so papers for the year of 2011 were fetched with a separate query and added to the research data manually.

Conclusion validity of a study deals with whether correct conclusions are reached through rigorous and repeatable treatments [17]. Throughout the paper, the discussions and conclusions are based on actual quantitative measures and statistics from the extracted data. The approach we used to identify and map the top papers assures that, the results of any replications of this study will not have major deviations from our results.

External validity is concerned with to what extent the results of this secondary study can be generalized [17]. The results of this study are not meant to be generalized to the whole SE field or outside SE. However, we believe that given the rigor of our approach that we used to identify top cited papers, emerging

hot topics, the results highlight the citation landscape of the top XP conference papers in SE area.

#### V. CONCLUSIONS AND FUTURE WORK

This is the first citation and topic analysis study on XP conference papers since 2002 until 2018. The paper identifies and classifies: the highly cited papers, topic trends, top individuals and institutes who have significantly published in XP conference.

The trend of the papers shows that XP conference has received interest from both the academic community and industry. The papers highlight that much of research is stirred by practices emerging in industry. Overall, 62% of the XP conference papers received at least one citation, which is a sign of good visibility relevance of the published papers. However, about 38% of the XP papers so far have received no citations at all. This raises concerns and questions such as: what are the reason(s) of large ratio of non-cited XP conference papers? Does this have anything to do with papers or venues quality? Or, is it about the topics of the papers, the indexed keywords, or the keywords provided by the author(s)? The data, which we make publicly available, can be used to conduct various analysis (i.e., characteristics of highly cited papers) on XP conference papers.

The analysis shows that XP community interest has been moving away from “Process Simulation”, “Education” and “Coaching & Experimenting” related topics to more practice and process oriented topics. According to the trend analysis, the hottest research topics, i.e., the topics gaining the most interest are “Coordination”, “Technical Debt”, “Teamwork”, “Startups” and “Agile Practices”. The identified trends are helpful for both researchers and practitioners to see topics that are more impact and align their future research activities.

The study found an active core intellectual pool of authors along with their highly cited work. The newbie researchers can start their journey from these papers and follow listed active researchers to stay up to date about latest trends in the Agile world. Additionally, the active publishing institutes in XP conference can be helpful for doctoral students to approach experts on the specific topic for further research and doctoral studies. We hope that this paper encourages further discussions in the software engineering community towards further analysis and formal characterization of the highly-cited software engineering papers in general and specifically in XP conference community. The important thing about citation count is that it is an “*objective measure of the utility or impact of the scientific work*” [1].

The following are among our future work directions:

- To replicate this analysis for other SE publication venues in order to conduct comparison between research venues and provide more depth to our analysis.
- To mine typical features for highly cited papers and to assess the extent to which papers inner quality, external features, reputation of the authors and journals, contribute to generation of highly cited papers in the future.

**Abstract**—Scrum is the most adopted Agile methodology. The research conducted on Scrum adoption is mainly qualitative and there is therefore a need for a quantitative study on Scrum adoption challenges. The primary objective of this paper is to present the findings of a study on the factors that have a significant relationship with Scrum adoption as perceived by Scrum practitioners working within South African organizations. Towards this objective, a narrative review to extract and synthesize the existing challenges was conducted. These synthesized challenges were used in the development of a conceptual framework for evaluating the challenges that have a correlation and linear relationship with Scrum adoption. Following this, a survey questionnaire was used to test and evaluate the factors forming part of the developed framework. The findings indicate that Relative Advantage, Complexity, and Sprint Management are factors that have a significant linear relationship with Scrum adoption. Our recommendation is that organizations consider these findings during their adoption phase of Scrum.

**Index Terms** — Adoption Challenges, Agile Methodologies, Diffusion of Innovation, Multiple Linear Regression, Narrative Review, Quantitative Research, Scrum.

### I. INTRODUCTION

SCRUM is regarded as one of the most under researched Agile methodologies [1], and the majority of research conducted in this field is qualitative in nature [2]. This paper focuses on bridging this literature gap between the body of qualitative knowledge on Scrum and the lack of sufficient quantitative literature on Scrum adoption within the South African (SA) context.

The author's previous paper on Scrum adoption challenges focused on developing a model that can be used to test and evaluate challenges to Scrum adoption [3]. To test and evaluate the Scrum adoption challenges a narrative review was conducted on the existing Agile and Scrum adoption challenges experienced globally and within SA. The synthesized challenges were used as the independent variables to the model. The first iteration of the Conceptual

Framework (CF) is known as the Scrum Adoption Challenges Detection Model (SACDM). The CF is a custom model adapted from the Diffusion of Innovation (DOI) theory and the study of the adoption of new technology by Sultan & Chan [12]. The model is divided into four constructs, namely, Individual Factors ( $X_1$ ), Team Factors ( $X_2$ ), Organizational Factors ( $X_3$ ), and Technology Factors ( $X_4$ ). The independent variables are the factors within the constructs  $X_1, X_2, X_3$  and  $X_4$ . The dependent variable is  $Y$  with  $Y=f(X_1, X_2, X_3, X_4)$ . When  $Y=1$ , the individual within an organization is an adopter of Scrum. When  $Y=0$ , the individual within the organization is a non-adopter of Scrum. The first iteration of the CF is similar to the second iteration except that the statistical analysis technique is modified from linear regression to logistic regression. For this reason, the first iteration is not depicted.

In the second iteration the statistical analysis technique used to evaluate the dependent variable changed from multiple logistic regression to multiple linear regression (MLR). The reason for this change was because of the need to test and evaluate whether there was a statistically significant linear relationship between the adoption challenges and Scrum adoption. Another reason was the small sample size which did not meet the requirement of a large sample size for logistic regression. Figure 1, displays the second iteration of the CF labelled as the Scrum Adoption Challenges Conceptual Framework (SACCF). Independent variables are depicted as factors within constructs  $X_1, X_2, X_3$  and  $X_4$ . The dependent variable is  $Y$  with  $Y = \beta_0 + \beta_1X_1 + \beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \epsilon$ . The constants  $\beta_i$  are the standardized coefficients (beta), and  $\epsilon$  is the standard error. The hypothesized relationships between the independent variables and the dependent variable are shown by the symbols in parenthesis.

The third iteration is the final version of the CF. The statistical analysis technique for the second and third iteration is identical. The third iteration creates a new set of 14 validated factors from the second iteration's 19 factors. This iteration of the CF is discussed in Section V. A quantitative survey was conducted using an online survey questionnaire. A set of 207 valid responses to this survey

was used to perform Exploratory Factor Analysis (EFA), and Cronbach's alpha analysis, which confirmed the validity and reliability of the survey instrument used.

The results from the correlational and MLR statistics were used to identify factors which have a significant linear relationship with Scrum adoption.

This paper consists of the following sections: Section II describes the background of the topic. Section III presents the methodology, including the statistical analysis techniques used to analyze and validate the data collection instrument. Section IV displays the results, followed by a discussion of the research findings in Section V. Section VI concludes the paper.

## II. BACKGROUND

### a) Scrum Defined

Scrum is one of many Agile software development methodologies available. Scrum has seen exponential growth in the past decade [7]. As a framework, Scrum allows organizations to improve on their project delivery objectives [17]. The Scrum guide written by Ken Schwaber and Jeff Sutherland describes this framework as lightweight, simple to understand, but extremely difficult to master [8].

Scrum embodies iterative and incremental development, and the framework is comprised of six artifacts, five roles, and four predominant activities [8].

### b) Agile Challenges

The introduction of new methodologies typically poses challenges for individuals and organizations who make use of them [9]. The adoption of Agile methodologies creates additional challenges such as management style, software development process, and software developer resistance [2].

The Agile adoption challenges in the context of this paper is taken from the author's previous paper on the Scrum Adoption Challenges Detection Model (SACDM) [3]. The challenges were derived from Agile, Scrum, Software Development Methodology (SDM), and Information Systems (IS) literature. These challenges are encountered both within South Africa (SA) and globally (non-SA).

Due to Scrum research within SA being primarily qualitative in nature [10], other Agile methodology challenges were included in order to attain a more comprehensive model. Common challenges such as lack of experience, the Organizational Culture, and lack of communication have been identified during the narrative review.

### c) Theoretical Framework

Research by Chan and Thong [11], and Mohan and Ahlemann [9] explains that previous IT adoption studies focused on the technical aspects of the innovation. These studies made use of technology adoption models, such as Technology Adoption Model (TAM). However, with complex Agile methodologies such as Scrum where

collaboration between individuals within teams and organizations are important, a more inclusive model was required. The mixture of factors which affect adoption led to the selection the Diffusion of Innovation (DOI) theory as the theoretical lens for the Conceptual Framework (CF) [13].

The DOI theory is used in both organizational and individual adoption studies, with the DOI model composed of five characteristics of innovation. The five characteristics of innovation are Compatibility, Complexity, Observability, Relative Advantage, and Trialability [13].

In the authors' custom model, as shown in Figure 1, Compatibility, Complexity, and Relative Advantage are the three characteristics of innovation that have been retained. The reason for this decision was based on the consistency of the relationship between the three characteristics and adoption behavior as identified within innovation studies [14].

## III. METHODOLOGY

### a) Research Design

The research design consists of a narrative review and survey questionnaire. The narrative review is a literature review to assess a topics body of knowledge [15]. This review was conducted due to the lack of quantitative literature on Scrum adoption. The review extracted and synthesized the Scrum and Agile adoption challenges to form the factors of the Conceptual Framework (CF).

The quantitative survey design operationalized the narrative reviews factors as the independent variables and Scrum adoption as the dependent variable. The online survey was used as the scale to measure the opinions of the Scrum practitioners working within SA organizations [16].

The validity of the scale was tested using a pilot study, Exploratory Factor Analysis (EFA), Bartlett's test for Sphericity, and Kaiser-Meyer-Olkin (KMO). Bartlett's test for Sphericity, EFA, and KMO are discussed in the analysis subsection. For reliability the Cronbach's coefficient alpha was used to measure internal consistency of the scale [16].

### b) Analysis

EFA is a statistical method used to describe the variability of the observed variables in terms of the unobserved constructs [4]. The validation of the questionnaire items against the initial 19 factors in the SACCF required a first order and second order EFA to be conducted. In the first order EFA we considered the 78 survey questionnaire items to construct the newly validated 14 factors. These factors were subjected to a second order EFA in order to develop the four constructs. The validity analysis proceeded by generating the first order EFA scores. Once the first order EFA scores were summarized, the second order EFA followed.

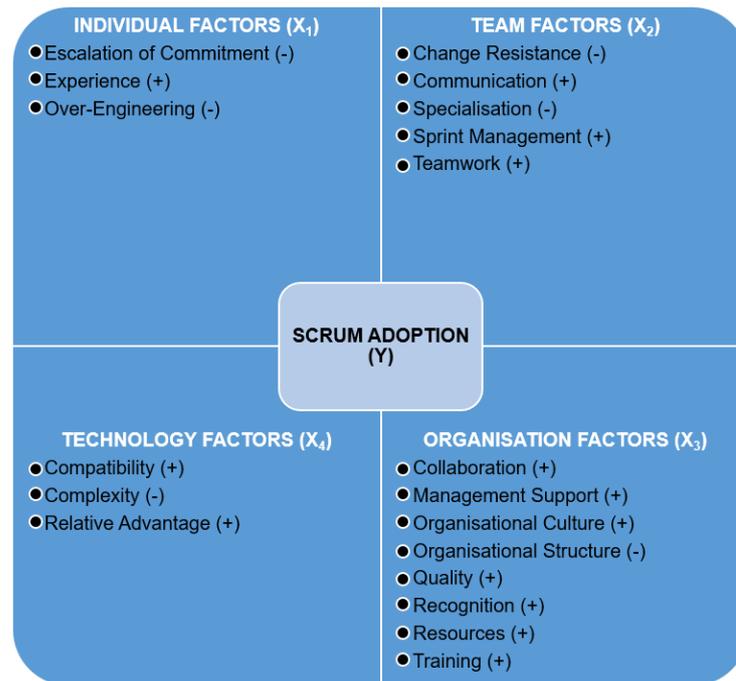

Figure 1: Scrum Adoption Challenges Conceptual Framework (SACCF).

To test the sampling adequacy, the KMO measure of sampling adequacy was used. The KMO value obtained was 0.88. The Bartlett’s test for Sphericity was conducted to determine if it was useful to conduct factor analysis. The Bartlett’s test for Sphericity significance level was 0.00. These test results indicate that it was, therefore, worthwhile to conduct the EFA on the dataset.

To determine the number of factors derived from the individual statements, Eigenvalues > 1 and the Scree plot were used. The constructs cumulative percentage was 75.8%.

The Principal Axis Factoring (PAF) extraction method with oblique rotation was used to seek a parsimonious representation for the common variance (correlation) between variables by latent factors. The oblique rotation implemented the Oblimin with Kaiser Normalization method because it was required to explore the correlations between the factors.

To summarize, of the 78 questionnaire items, 14 factors were retained for rotation due to their Eigenvalues being greater than or near one. The first 14 factors as a collective accounted for 75.8% of the total variance.

Because of the factor loading cut-off criteria of 0.40, 12 items were found to load on the first factor, and these were subsequently labelled "Organizational Behavior". Eight items loaded on the second factor, labelled "Sprint Management". Nine items loaded on the third factor, labelled "Relative Advantage". Four items loaded on the fourth, fifth, sixth, and the seventh factor respectively, labelled "Experience", "Training", "Specialization", and

"Recognition". Seven items loaded on the eighth factor, labelled "Customer Collaboration". Three items loaded on the ninth factor, labelled "Compatibility". Five items loaded on the tenth factor, labelled "Over-Engineering". Three items loaded on the eleventh and twelfth factor respectively, labelled "Escalation of Commitment", and "Complexity". Eight items loaded on the thirteenth factor, labelled "Teamwork", and four items loaded on the fourteenth factor labelled "Resource Management". Table 1 displays the mapping of the initial 19 CF factors to the validated 14 factors.

The second order EFA was conducted on the 14 factors derived from the first order EFA output. The PAF extraction method and the Oblimin with Kaiser Normalization (oblique) rotation method were used to calculate the scores. The second order EFA generated the KMO measure of sampling adequacy test result of 0.779 and a Bartlett’s test for Sphericity significance level of 0.00 which made it viable to conduct an EFA. The Eigenvalues generated from the PAF extraction method resulted in 4 constructs, with the Eigenvalues greater than or near 1 and the Scree plot identifying the valid constructs. The cumulative percentage explained by the four constructs is 67.8%.

In summary the second order EFA was applied to the 14 factors calculated in the first order EFA. The PAF method was used to extract the factors, followed by the Oblimin with Kaiser Normalization (oblique) rotation method. Of the 14 input factors, only four factors were retained for rotation, because of their Eigenvalue being

greater than or near one. The first four factors as a collective accounted for 67.8% of the cumulative variance. These four factors are consequently referred to as the four constructs of the SACCF.

#### IV. RESULTS

The previous section described the methodology used to derive to the validated factors and constructs of the Conceptual Framework (CF). A statistical analysis of the results derived with this methodology, is presented in this section.

##### **a) Testing the Fourteen First Order Factor Relationship Strength**

A correlation matrix was used to test for the relationship strength among the different factors. A Spearman correlation analysis was conducted on all the factors as opposed to a Pearson correlation analysis, due to the skewness of the data discovered during the normality tests. The Spearman correlation analysis

revealed statistically significant correlations for the relationships between Scrum Adoption and all the factors at the 0.01 level, except for Teamwork which was significant at the 0.05 level ( $p=0.018$ ), and Over-Engineering with no significance ( $p=0.514$ ), see Table 2.

##### **b) Testing the Four Second Order Factor Relationship Strength**

A correlation matrix was used to test the relationship strength among the four constructs, as well as between the four constructs and the dependent variable. A Spearman correlation analysis was conducted as opposed to a Pearson correlation analysis, due to the skewness of the data discovered during the normality tests. Spearman correlation analysis revealed statistically significant correlations for the relationships between Scrum Adoption and the four constructs at the 0.01 level, see Table 3.

##### **c) Testing the Statistical Significance of the Factor Relationship**

All the normality assumptions were met when a regression analysis was conducted on the 14 factors. Tolerance values were above .01, and all the VIF values were below 10, and the assumption of no multicollinearity was met. The Durbin-Watson statistic fell within an expected range, which suggests that the assumption of no autocorrelation of residuals was met. The assumptions of linearity and homoscedasticity were also met, since the Scatterplot of standardized residual and standardized predicted value did not curve or funnel out. The normal probability plot of the residuals was approximately linear, which suggests that the assumption of normality of residuals was also met.

For the 14 factors, Multiple Linear Regression (MLR) was conducted to examine whether Over-Engineering, Relative Advantage, Recognition, Experience, Teamwork, Specialization, Escalation of Commitment, Compatibility, Resource Management, Customer Collaboration, Complexity, Training, Sprint Management, and Organizational Behavior impact on Scrum Adoption. The overall model (predictors: Over-Engineering, Relative Advantage, Recognition, Experience, Teamwork, Specialization, Escalation of Commitment, Compatibility, Resource Management, Customer Collaboration, Complexity, Training, Sprint Management, Organizational Behavior) explained 52.9% of the variance of Scrum Adoption, which was revealed to be statistically significant ( $F(14,206)=15.40$ ,  $p<0.0001$ ).

N Missing 0

\*\* . Correlation is significant at the 0.01 level (2-tailed).

\* . Correlation is significant at the 0.05 level (2-tailed).

Table 3: Correlations between the Four Constructs and Scrum Adoption.

	Scrum Adoption	Individual	Organization	Team	Technology
Scrum Adoption	1.00	.29**	.30**	.20**	.53**
Individual <sup>1</sup>	.29**	1.00	.39**	.16*	.38**
Organization	.30**	.39**	1.00	.25**	.42**
Team <sup>1</sup>	.20**	.16*	.25**	1.00	.07
Technology	.53**	.38**	.42**	.07	1.00

N Missing 0

\*\* Correlation is significant at the 0.01 level (2-tailed).

\* Correlation is significant at the 0.05 level (2-tailed).

<sup>1</sup>=factor's negatively phrased questions were recoded.

An inspection of the individual predictors of the overall model revealed that Relative Advantage (Beta=0.688,  $p < 0.0001$ ), Sprint Management (Beta=0.109,  $p < 0.05$ ), and Complexity (Beta=0.041,  $p < 0.05$ ) are significant predictors of Scrum Adoption (Table 4). Higher levels of Relative Advantage are associated with higher levels of Scrum Adoption, higher levels of Sprint Management are associated with higher levels of Scrum Adoption, and higher levels of Complexity are associated with lower levels of Scrum Adoption.

For the four constructs, MLR was conducted to examine whether Individual Factors, Technology Factors, Team Factors, and Organization Factors impact on Scrum Adoption. The overall model explained 33.40% of the variance in Scrum Adoption, which was revealed to be statistically significant ( $F(4,206)=25.34$ ,  $p < 0.0001$ ). An inspection of the individual predictors revealed that Technology Factors (Beta=0.580,  $p < 0.0001$ ) and Team Factors (Beta=0.126,  $p < 0.05$ ) are significant predictors of Scrum Adoption (see Table 5). Higher levels of Technology Factors are associated with higher levels of Scrum Adoption, and higher levels of Team Factors are associated with higher levels of Scrum Adoption.

## V. DISCUSSION OF FINDINGS

It is important to note that initially, the Scrum Adoption Challenges Conceptual Framework (SACCF) had 19 factors (independent variables). However, during the validation of the scale, the Exploratory Factor Analysis (EFA) applied to the questionnaire items extracted 14 factors. The loading of the questionnaire items to new factors meant that the initial predicted model had to be evaluated. The questionnaire items with its commonalities and corresponding factor loadings were studied and it was found that the initial 19 independent variables loaded correctly into the 14 factors. The new factor loadings, therefore, made logical sense. In Table 1, as discussed in

Section III, the 19 hypothesized factors are mapped to the newly validated 14 factors.

While most of the mappings in Table 1 is self-explanatory, it is necessary to give an explanation of the four factors that have more than one variable. These four factors are:

- Organizational Behavior
- Sprint Management
- Customer Collaboration
- Teamwork

The term Organization Behavior (OB) is defined as the actions and attitudes of individuals that work within an organization. OB is, therefore, the study of human behavior within the organizational environment, how human behavior interacts with the organization, and the organization itself [5]. George et al. [5], also states that the manner in which managers manage others is significantly affected by OB. Given this perspective of OB, it is reasonable to load Organizational Structure, Management Support, and Organizational Culture as a single factor under the heading OB.

The loading of Sprint Management and Change Resistance into a single factor is also logically sensible since firstly, Sprint Management is a time-boxed activity. Scrum practitioners would be performing their tasks within a Scrum sprint under most circumstances although it is recognized that this may not be the case for every task performed. Consequently, if a team is resisting change, it would manifest when the change is requested or performed during the Scrum sprint. To reiterate the fourth value of Agile development, which is "responding to change over following a plan", it is therefore fitting that Sprint Management and Change Resistance loaded as the Sprint Management factor, since Change Resistance by default, is part of the Sprint Management cycle [6].

Table 4: Regression Coefficients of the 14 Factors.

Coefficients <sup>a</sup>						
Model		Unstandardized Coefficients		Standardized Coefficients Beta	t	Sig.
		B	Std. Error			
1	(Constant)	.506	.454		1.114	.267

Over-Engineering <sup>1</sup>	.004	.039	.005	.092	.927	

<sup>a</sup>. Dependent Variable: Scrum Adoption

<sup>1</sup>=factor's negatively phrased questions were recoded.

Table 5: Regression Coefficients of the 4 Constructs.

Coefficients <sup>a</sup>						
Model		Unstandardized Coefficients		Standardized Coefficients Beta	t	Sig.
		B	Std. Error			
1	(Constant)	1.197	.445		2.692	.008
	Team <sup>1</sup>	.126	.062	.123	2.040	.043
	Technology	.580	.064	.566	9.009	.000
	Individual <sup>1</sup>	.016	.053	.019	.303	.763
	Organization	-.033	.054	-.039	-.616	.539

<sup>a</sup>. Dependent Variable: Scrum Adoption

<sup>1</sup>=factor's negatively phrased questions were recoded.

The loading of Collaboration and Quality into the Customer Collaboration factor was easy to accept since Customer Collaboration entails working closely with the client in order to deliver what was requested at the expected quality. The last merged factor loading was Teamwork which consists of Teamwork and Communication. This factor loading was also a simple decision and with hindsight, these two factors had to be grouped together from the outset. The reason for this is because Teamwork requires individuals to work together to complete tasks, and communication is a critical component to complete sprint tasks within the team. It is important to note that the Resources factor has been renamed to Resource Management because resource shortage or surplus is a management related concern.

Figure 2 displays the third and final iteration of the CF. The hypothesized relationships between the independent variables and the dependent variable are shown in the parenthesis. As is evident from the diagram, the conceptual model is much more refined than the previous iterations. The Specialization factor which was previously under the team construct is now under the individual construct, and Over-Engineering which was an individual factor is now a team factor. The reason for these realignments is because Specialization or specialized skills can be narrowed down to the individual level. Over-Engineering, if encountered and allowed within a Scrum team environment, means that the team was not vigilant enough during their communication sessions to identify

when an individual was doing more than what was required.

Four of the initial 19 factors were revealed as having a significant linear relationship with Scrum adoption. The four factors are Relative Advantage, Complexity, Change Resistance, and Sprint Management. The factor that came close to having a significant relationship with Scrum adoption was Customer Collaboration with  $p=0.059$ . Because of the new factor loadings Sprint Management and Change Resistance loaded onto Sprint Management, as noted earlier.

## VI. CONCLUSION

Scrum and Agile software development, including Scrum adoption, is a growing phenomenon. The research presented in this paper contributes both towards the Agile body of knowledge and to Scrum adoption. A proposed consolidation of Scrum and Agile challenges, a Conceptual Framework (CF), and the evaluation of the CF using quantitative methods and techniques were explored in this paper. The primary objective of this paper was the investigation of factors that have a significant linear relationship with Scrum adoption as perceived by Scrum practitioners working within SA organizations. Three validated factors which have a significant linear relationship with Scrum adoption have been identified.

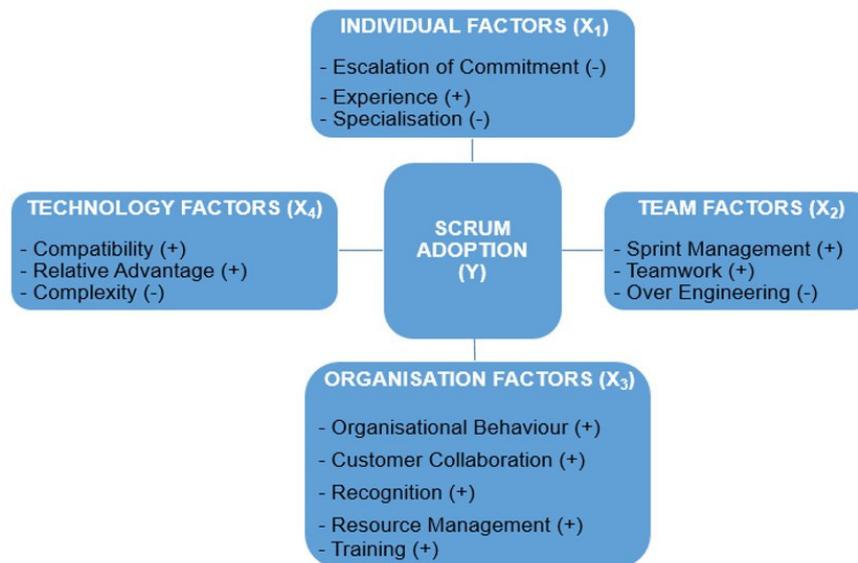

Figure 2: Final Iteration of the Conceptual Framework.

This research can be extended by a systematic review of existing Scrum and Agile adoption challenges, as well as a larger population sample for greater generalization of the findings. For future research it would be beneficial to develop a logistic regression model for predicting an organization's success rate at Scrum adoption based on the organization's current practices. The predictive analysis can be conducted by comparing the test data of the organization to the trained data model derived from the population sample.

**Abstract**—Agile methodologies conquer space beyond their industrial use. For applying them in a situation other than classic software development, one should first assess the features of this specific environment. As a next step, elements from various well-known agile methodologies (roles, events, products) can be considered as building blocks. These elements combined in a new way, adopted appropriately result in a specific, own agile methodology. In this study, we present a list of aspects that one should consider when creating a specific agile methodology for a R&D team. Our own agile methodology created for the txtUML R&D team from the Faculty of Informatics of Eötvös Loránd University is built along this list of aspects. Known and new agile elements were included in this specific methodology and are explained in this article in detail. The txtUML R&D methodology has been used with satisfaction since 2018, as evidenced by backward surveys.

## I. INTRODUCTION

THE introduction of agile methodologies has been of great interest in recent years in Central Europe [9], [10], [11]. They are used not only in software engineering, but also in other fields - such as economics-, and not only within the industry, but in research and development as well [1], [2], [3], [4], [6]. Naturally, every time agile methodologies are applied in a new area, the original agile framework needs to be adapted to the specifics of the new field.

In 2018 we decided to develop a specific agile methodology to manage the work of a research and development team at the Eötvös Loránd University. In the research and development teams of our university teachers, research staff and students work together. Students can be PhD students, master's students or undergraduates. The diversity of the team members influences the frequency of meetings. The fluctuation of team members results in different levels of knowledge, differences in the ability to work independently, as well as varied levels of motivation. Therefore, many aspects of collaboration need to be addressed in order to ensure the efficient operation of these teams.

In the second chapter of this paper we summarize some examples of agile methodology used within the research and development teams of other universities. In the third chapter, we present a list of aspects we used and recommend to be taken into consideration before creating a new methodology

The research project was supported by the European Union and co-financed by the European Social Fund (EFOP-3.6.3-VEKOP-16-2017-00002).

for a research and development team. In the fourth chapter we present our own methodology, along with the related feedback. Finally, the fifth chapter summarizes the results.

## II. AGILE METHODS IN R&D TEAMS

If we look at the characteristics of agile methodologies, we can see that they fit properly with the nature of research and development teams. Maik Sayfert, who has more than 10 years real project experience with agile software development, declares: “When considering research as an area of high uncertainty and open results, it smells like agile methods are perfectly suited. From all methods I personally can imagine Scrum with short/mid sized iterations it the best match, as Kanban (flow based) is more suited to connect several disciplines/departments and XP is more technically driven.” [15]

Jeff Sutherland, the inventor and Co-Creator of Scrum reports in 2016: “Many of the leading research labs in the U.S. use Scrum. The one I have worked with most often is the John’s Hopkins Applied Physics Lab, the leading Naval research lab. Their research plan is their backlog. They map it out like an AI tree. Time boxing the research stories gets them done twice as fast. And the quality of the research is much higher with daily meetings.” [16]

Some articles present concrete cases using agile methodology to manage a research and development team.

There are several cases where the introduction of agile methodology is related to the will of an industry partner, who uses agile methodologies from earlier. For the agile coordination of the research team and the industrial partner, traditional roles may be modified or extended. For example H. Sharp and co-authors in [1] reports such a case: “an important adaptation was the inversion of the semantic of the product owner, for in our context he is a member of the lab allocated at the client. This change was made because of the difficulties associated with having a client in the lab.” Some research teams have developed new agile methodologies for improving collaboration with industrial partner, such as the the Agile Research Network collaboration model. The creators of this model found the following key challenges in this kind of collaboration: timeliness, relevance, rigour, access. Based on this recognition they build the ARN model, which consists of the following sections: Collaboration Kick-off, Investigation of the focus area, Implementation, Evaluation. [2]

The introduction of agile methodologies in research and development teams are not necessarily motivated by cooperation with industry but rather by coping with other challenges, such as distributed teams. In such cases, new roles other than the original Scrum roles are introduced (eg. Unit Coordinator, Research unit, etc.). Events are mostly online, such as: Daily Scrum is done via instant messaging. [3]

The inventors of the SCORE agile method for research and development teams addressed another challenge: “Working with and mentoring Ph.D. students is the central activity in running an academic research group, with two broad goals: (1) to collaboratively produce high-quality research results, and (2) to help students to become independent researchers capable of working at research labs or academic institutions. At first, we followed a simple, fairly typical approach to mentoring: we met once or twice per week with each student in roughly half-hour or hour-long slots. Unfortunately, as the number students grew from two or three each to six or seven each, and as our outside commitments steadily increased, our simple approach reached its limits.” [4]

SCORE methodology uses elements such as status meetings (daily Scrum), on demand technical meetings, weekly reading group, weekly lunch; The core idea is to keep status separate from research. “The Scrum meeting is for status, and the on-demand meetings are for solving unforeseen problems. Keeping the two activities separate allows them to be undertaken more efficiently.” [4]

Based on the idea of “the last step of having a successful team is to build a supportive environment.” the authors of [5] proposed an approach for planning research projects, considering the use of 2-type fuzzy numbers for research project planning based on Scrum.

Many positive experiences were drafted regarding using agile methods in research and development teams. Some examples: “using Scrum contributed to the education of team members that were interns (students) and/or autonomous professionals (freelancers)” [6] “The involvement and commitment of members of the team with the results increased (...). We also realized that team members were motivated and open to changes in work.” [1] “Everything is visible to everyone, team communication improves, a culture is created where everyone expects the project to succeed.” [3] “Students say they are more productive, more enthusiastic about research, and have better interactions with other students and with their adviser. Students reported that there is now a real sense of community in the group that was never there before.” [4] “Though SCORE is conceptually simple, its benefits to us have been significant. (...) when students are struggling, it often only takes a day or two to realize something is not right, and to begin to address it. Our time is spent far more effectively.” [4]

The text-based feedbacks sound good, but unfortunately it is still a challenge to find a metric to evaluate formally the gain achieved by using agile methodologies in R&D teams [1]. Another claim is that university students do generally not have the maturity to understand the agile practices and their consequences. “The suitability of agile methods in education

is thus an ongoing debate.” [7]

### III. ASPECTS TO BE ANALYZED WHILE CREATING A SPECIFIC AGILE METHOD FOR A R&D TEAM

Based on literature and our experiences, we have gathered a list of aspects to take into consideration if someone wants to create an appropriate agile methodology for their research and development team.

- 1) Objectives of the research and development team: As we have mentioned, a research and development team may have several goals with varying degrees of emphasis. The team’s primary goal may be to develop a new product, but another goal may be to involve students more effectively in the research, or even to recruit researchers and teachers. These goals need to be clarified, prioritized and then tailored to the research team’s workstyle.
- 2) Proportion of research and development tasks: The new methodology should sufficiently support team members in both research and development tasks.
- 3) Type of members: The group may include undergraduate, master’s and PhD students, as well as research staff and teachers. These individuals have varying levels of prior knowledge, may differ in terms of their ability to work independently, and may be able to devote different amounts of time to the R&D team’s work.
- 4) Motivation of team members: Team members participate in the R&D work with different motivations. Some students volunteer on the team to get to know the world of research, while others have more specific goals, such as writing their thesis. There are also students who work for university credits and others to receive a scholarship. Research staff is mostly motivated by their interest in the topic of research and possible results. Teachers are primarily motivated by recruiting teachers and researchers. When developing a unique methodology, all these motivations need to be taken into account to create an engaged team.
- 5) Fluctuation of team members: It is important to consider turnover within a team. For example, while an undergraduate student stays on the team for an average of half a year, a PhD student is likely to remain a team member for several years. New team members have to be integrated into the team as early as possible, and keeping existing knowledge within the team when a significant member leaves is also very important.
- 6) Number of team members: The number of people who have to work together has always been a very important aspect of managing a team. Large groups can benefit from a greater knowledge base, but communication can become more difficult. The efficiency of events and different roles assigned is highly influenced by the number of people on the team.
- 7) Frequency of meetings: As students, teachers and researchers perform many different tasks at the university during working hours, it is not easy to organize team meetings. The team’s new working methodology will be

strongly influenced by the possible number and timing of meetings.

- 8) Relation between tasks: It is recommended to take into consideration how the potential research and development tasks are built on each other and how connected they are to each other. For example, if some tasks have the same topic, it is recommended that team members taking on these responsibilities work together and share their experience. Perhaps the creation of subgroups along task topics would be effective, including the appointment of a subgroup leader.
- 9) Documentation obligations: The level of detail needed in documenting the group's activities is an important factor. For example, if a company financially supports the research and development team, they may have to meet specific documentation requirements. Another purpose of detailed documentation could be to attenuate the effects of high turnover among team members; the group needs to ensure that the knowledge of its members remains in the team even after they leave. On the other hand, if the team does not need documentation for any purpose, creating a detailed record may be a waste of the members's valuable time.
- 10) External partners: Beyond the members of the research team, there may be a sponsor, a customer or a partner whose expectations they need to meet, such as performing a certain task by a certain deadline. Working with an external partner requires special attention: Who is the partner? What deadlines have they set for the team? How can the team achieve the fulfillment of the partner's requirements without sacrificing its own goals?

Please note, that the list is not exclusive. For example, there is a growing phenomenon that the members of the research team are not co-located, which poses additional challenges while creating a new methodology

#### IV. OUR SPECIFIC AGILE METHOD

##### A. The *txtUML* R&D team

The Faculty of Informatics at the Eötvös Loránd University currently has several functioning research and development labs. The Model Driven Development Research Lab has been operating since 2014, with a project called *txtUML* as one of its primary undertakings. A brief description of the software is: "The name *txtUML* stands for textual, executable and translatable UML. It is an open source project with the goal to make model driven development easier." (For a more detailed description see the website of *txtUML* [12]. Before we have created the agile methodology for the *txtUML* research team, I attended their meetings for half a year. I considered that the work of the team was not efficiently organized. The meetings consisted of telling everyone what they were doing last week and what problems they encountered. When someone came in, he/she talked about his/hers problems for a long time. One or two people who understood the topic discussed technical details, while others waited quietly. This took 2 hours, so the

meetings were long and demotivating. Students who joined the team from the beginning of the semester could not involve in the discussions till the middle of the semester. There was no time allocated for them to learn from the experienced students during the regular meetings. This would have been a great necessity and possibility, since the students in the team had different level of understanding of the subject, and there were also undergraduates, masters and doctoral students in the team. Many types of motivation were present in the team thanks to the many types of students - some of them joined the research group as a course named "Software Technology Lab.", others wrote their theses, etc. I saw that the methodology does not take into account the presence of different motivations and, as a result, there is not enough commitment to work. The research team was supported by a tender that required weekly logging and fulfillment of predefined goals. I considered that this methodology did not help students enough to fulfill this expectation. As a result of my observations I collected all the important factors which made the actual method work ineffectively. This list was the basis of the list I presented in the previous chapter.

In 2018 we decided to introduce an agile methodology to manage the *txtUML* team's work more efficiently. Taking into consideration the particularities of our team, designing our own agile methodology using elements from other agile methods as building blocks and inspiration seemed to be the best solution.

The particularities of our team were:

- 1) Objectives of the research and development team: The development of *txtUML* software and the involvement of students in the world of research are equally important objectives for us.
- 2) Proportion of research and development tasks: We predominantly perform development tasks (80%), with research tasks being less frequent (20%).
- 3) Type of members: Our team is currently comprised of 9 undergraduate students, 1 PhD student and 1 teacher. The individuals have different levels of prior knowledge regarding *txtUML*: three senior students who have been working on our team for more than a year; three students who joined the team six months ago and three completely new students.
- 4) Motivation of team members: The 9 undergraduate students gain 4 credits/semester for their work on the team, while 4 of the students also receive a scholarship as a result of participating in this research. The PhD student improves her PhD work with the help of this team, and the one teacher's primary motivation is the recruitment of new teachers and researchers.
- 5) Fluctuation of team members: 3 students are expected to leave the team at the end of the semester, while others may stay for 2 more semesters.
- 6) Number of team members: 10
- 7) Frequency of meetings: A 2-hour meeting/week is attainable.
- 8) Relation between tasks: The research and development

tasks of our team can be categorized in four groups. The following terms are used to refer to their topic: language front-end, visualization, C ++ export and model testing.

- 9) Documentation obligations: Due to the scholarship some student receive in relation to their work with txtUML, we must log the progress of the team members on a weekly basis. As three senior students leave the team at the end of the semester, we need to ensure that their knowledge is “saved” (documented) before they leave the group.
- 10) External partners: Currently, our only external partner is the scholarship program. At the beginning of each semester, we have to make commitments and present out progress at the end of the semester.

As a member of the txtUML team with a “team coach” role, I design a new agile method for the txtUML R&D team based on the team's characteristics. The methodology is presented below.

### *B. txtUML's agile methodology*

In the following, I will describe the agile methodology designed for the txtUML team and used by it since February 2018. I will group the elements of the methodology along roles, events and artifacts. Regarding each element, I will clarify the purpose for which it was introduced and between {} signs I will specify which aspects from the list “Aspects to be analyzed while creating a specific agile method for a R&D team” (Chapter 4.) are mostly related to the mission of that specific element.

1) *Roles*: There are five different roles in the txtUML team: project leader, Scrum master, technical leader, subgroup leader, developer.

**Project leader**: Represents the goals of the research team towards the university leadership and applications. He is the main contact person of the team, holds up the results of the team (for example, in the case of “University Open Day”, “Researchers’ Night” events). He has a word in any decision-making. His role provides a solid framework and direction for the research team. He participates on group meetings and is also easily accessible between them. { 1, 4, 9, 10 }

**Scrum master**: The name of the role was inspired by the Scrum methodology. Similarly, the responsibility of this person is to protect the team’s operational values. This can be achieved by initiating and coordinating of various events (for example, initiating and coordinating weekly Scrum for effective discussions; training the members to effectively report their blockers, etc.) and leading by example. The Scrum master participates on group meetings. She monitors the situation of each team member and the dynamics of the whole group. She does not have software development tasks. { 3, 4, 5, 6, 9 }

**Technical leader**: Has a comprehensive view of the software and is also familiar with many details. Coordinates team members’ work from a technical point of view. All important technical decisions must be agreed with him. It also has a mentoring role: to pass on the knowledge and experience of the previous developers. He is primarily available at group

meetings, but often responds to questions through online communication as well. { 1, 2, 3, 4, 5, 6, 7 }

**Subgroup leader**: The research and development tasks of our team can be distinguished in four groups. The following terms are used to refer to their topic: language front-end (3 members); visualization (2 members); C ++ export (2 members); model testing (2 members). Students working on the same topics form a subgroup led by a senior student who has the most knowledge and experience in that specific field. This student designates smaller research and development issues to subgroup team members and gives developers mentoring during meetings and through online communication. Usually he/she performs development tasks as well. During meetings he/she organizes discussions on its own topic to transfer its knowledge and presents the results of its subgroup to the entire research group. { 1, 3, 4, 5, 6, 7, 8 }

**Developer**: As a first step in joining the team, every new member gets acquainted with txtUML from the “txtUML user” perspective. Than he/she selects the area in which he wishes to contribute to the research and development work and thus becomes a member of a subgroup. With the help of the subgroup leader he/she chooses an appropriate task and contributes to the expansion and refinement of the txtUML software. Developers also participate on group meetings where they learn from others and pass on their experience as well. { 1, 3, 4, 5 }

Remark: It may be strange that the role of the Product Owner is not strongly emphasized, though it is a key role in the Scrum methodology for example. According to my observation, in the university environment, the role of Product Owner is often less powerful, perhaps because the role of the customer is not as definable as in the industrial environment. Most often, the teacher fills the role of the customer. For him/her, however, the functionality of the product is not the only focus, but there are also pedagogical goals. In our case, the role of the Project leader was as close as possible to the Product Owner: he pointed out the development directions; the developers, subgroup leaders talked about the functions to be realized and their acceptance criteria with him.

2) *Events*: The members of the txtUML team meet weekly in a two-hour session. Events related to the agile methodology are integrated into this meeting. In the intervening period everyone works individually on their own task and uses the slack ( [13]) tool for online consultation, if needed.

Our four major agile events are: preparation, weekly routine, retrospective, demonstration.

**Preparation**: The preparation phase takes the first 2-3 meetings of the semester. The project leader, technical leader and subgroup leaders discuss the main research and development directions of the semester. The new team members get to know the system, the other developers indicate what specific tasks they would like to take. The Scrum master presents the values of the group's operation and the methods that the group will use during the semester to support putting these values into reality (Example: Values: effective team discussions, sustaining motivation, transfer of knowledge; One

method used to support these values: weekly Scrum) {1, 2, 3, 4, 5, 6, 8}

**Weekly routine:** After the preparation phase come the weekly meetings with the following structure: short news, weekly Scrum, topic of the week, discussion with the whole team, discussion in small groups.

In the *news section*, after the greeting of team members, the Scrum master announces to the community if someone is going to miss the meeting or is going to be late; gives a brief reflection on the weekly reports submitted by the team members; notifies the group about the short news related to the R&D lab (For example: “We were invited to attend the University Open Day”). The *news section* grabs the focus of the team members and is an effective way to spread out the most important information regarding the team. {3, 6, 7, 10}

The *weekly Scrum* is a ritual with a timebox of 15 minutes. Technical leader, subgroup leaders and developers are required to participate. Each of them answers these three questions briefly: “What have I done since the last meeting?”; “What do I plan to do until the next meeting?”; “Is there anything that blocks me?”. There is a temptation to go into technical details that are important to one or two team members. It is important to avoid this, because if the other members aren't involved in that subject, they will become very bored and demotivated. If an important topic arises during the weekly Scrum the key words of that topic are recorded by the Scrum master and put on the table after the *weekly Scrum*, in the second half of the *weekly routine (discussion with the whole team, discussion in small groups)*. However, the weekly Scrum can include sharing of short tips with each other, as everyone is attentive to it. A positive side effect of the *weekly Scrum* is that as the team members speak out loudly about their rhythm of progress, they motivate themselves and each other as well. {1, 4, 6, 7}

The *topic of the week* is a 10-15 minutes period during which the Scrum master presents and trains a value of the team's operation. During the first half of 2018, there were topics such as: identifying individual motivation; identifying a common goal; understanding shared responsibility; formulating weekly reports in an effective way; estimating work left; etc. Discussion of such topics help new and old members to learn the values and methods that enable them to realize a true teamwork rather than working side by side. {1, 3, 4, 5, 6, 7, 10}

The *discussion with the whole team* and *discussion in small groups* phase provides an opportunity to discuss issues that have arisen during the weekly Scrum, but their extraction has been postponed to effectively assess the overall group situation anteriorly. For example, if a more serious technical decision must be made (that affects the overall structure of the product), the most involved members will present the question to be discussed and then everyone will argue about it. More of this kind of questions can come up at a weekly meeting, or not even one. If only a few people, or perhaps only one developer-and-subgroup leader-pair are involved in a question, then they separate and discuss it between themselves. An example of this kind of “pair cases” is when a developer gets stuck in his

own job and asks the subgroup leader for help; or is about to finish his/her task and asks for a new one. The *discussion section* provides an excellent opportunity for team members to share their experiences and develop their knowledge of a topic. {1, 2, 3, 4, 5, 6, 7, 8}

**Retrospective:** During the *retrospective* the team members can reflect on the quality of the team-work and formulate directions and methods that are likely to have a positive impact on it in the next iterations. In the first half of 2018, we held a retrospective during the seventh meeting of the semester. The retrospective was coordinated by the Scrum master, who handed out different-colored, small-sized paper sheets to each team member. One color stand for positive, the other color for negative feedback. On each sheet of paper, a key word or thought could be written by the team members in an anonymous way. The recollected sheets of paper were organized along the “negative / positive” and “technique / methodology / team” axes by the Scrum master on the board. She placed on top of each other the sheets of paper representing the same idea. The heaps appearing in this way warned: it would be worthwhile to deal with those feedbacks urgently, since they affect many team members. After reviewing all the feedbacks, a discussion took place during which the team formulated ideas for improving their team-work. A concrete example: more people have indicated that they perceive some administrative tasks as redundant - writing weekly reports, using GitHub [14], and participating on the weekly Scrum. During the meeting, we managed to clarify that each of them has separate goals. {1, 3, 4, 5, 6, 8}

**Demonstration:** The *demonstration* is the closing event of the semester, during which all members of the research and development lab summarize their work realized during the semester and present their results. Guests may also be invited to attend the event. The structure of the meeting is: the project leader presents the main research and development directions emphasized during the semester, the Scrum master gives information about the methodology used to organize the team work, and the developers, together with the subgroup leaders, demonstrate the implemented new functions. On July 2, 2018, this year's first demonstration took place, which was also a demonstration of the txtUML 0.7.0 release. On this occasion, old team members also joined us. Cake and champagne enhanced to the festive atmosphere, which aimed to emphasize the common success as motivation for upcoming team work. {1, 2, 3, 4, 5, 6, 10}

3) *Artifacts:* The primary product of the group's work is the developed code base, which is available on gitHub [14].

On the same website, you can find the tasks related to the software product, which can be considered as a *product backlog (under the issues tab)*. Developers, subgroup leaders, and technical leaders can add or select from these - of course, according to the priorities fixed by the Project leader. {1, 2, 6, 8, 9, 10}

Each of the subgroups has an *issue board* (also on the above-mentioned website, under the projects tab) that displays the current tasks of that subgroup. They include columns

like: 'to do'; 'in development'; 'under testing'; 'pull request'; 'done'. The board therefore provides a comprehensive picture of the current status of the subgroup's work. {1, 6, 7, 8, 9, 10}

In addition, there is an internal website, a form, used to collect information about the weekly progress of the members in a background table. It is called *weekly report*. The following data can be given on its surface regarding to a task: contributors name; type of the task (for example: research, development, mentoring, administration, etc.); a brief description of the task; a detailed description of the task (if the short description is not sufficient); associated GitHub task code (if any); lesson to be learned (if any). Developers must fill out the form every week before the meeting, for every task they worked on since the last meeting. In connection with the *weekly report*, the members of the team repeatedly expressed their disapproval. Nonetheless, we kept the weekly report because of its positive effect: since it precedes the *weekly Scrum*, it helps the group members to give a more focused report during the *weekly Scrum*; produces data series suitable for research and application accounting; can help in catching up for the team members that will join the team later on; collects data for self-reflection, logs personal performance; is a practice that develops the skills needed for group work (collaboration, organization, communication) and adapts to the administrative requirements of a general workplace. {1, 2, 5, 6, 7, 8, 9, 10}

4) *Bonus: Agile training*: In the second semester of 2018 I myself, as the agile coach of the team, organized an extra team event, called Agile training. The purpose of this was to consolidate agile values, strengthen team spirit, invent together new methods that improve team work.

The topics of the agile training were: getting know each other better - build trust, build relationships; clarifying the purpose and responsibilities of the different team roles; (re)defining the values of our team - taking inspiration from Scrum values and Google's research about effective team work; identifying the main motivation of each team member and the whole team (for that specific semester, regarding our research).

### C. Results and feedback

During the first semester of 2018, the methodology described above was applied for 18 weeks. Our observations were: weekly meetings were more efficient and dynamic than they were before; the number of communication interactions among team members has increased; the consciousness of group responsibility began to develop; regular administration of the tasks began to become accepted; individual and team goals related to the R&D lab have become clear.

At the review meeting (7th week), team members gave similar feedback: Teamwork was highlighted as a positive experience, even the collaboration between the subgroups. Shorter and useful meetings have been acknowledged. They were very positive about the senior students's competence, which, combined with the good meeting structure provided many learning opportunities for the new team members. The methodology used to provide the transfer of knowledge through group structure (hierarchical roles) and weekly routine

(mainly weekly Scrum and the discussion phase). Satisfaction with the effectiveness of the communication was also highlighted by more people. Three of the students reported that the collection and clear formulation of goals had a positive effect on them.

Negative feedback came primarily regarding the weekly report, which was indicated to be redundant. There was also a complaint regarding "over-formalizing the process". Our reaction was to give more time for these elements to prove their positive impact. If later reviews also highlight their demotivating effect, they can be omitted or modified following a common decision.

At week 17, team members filled out questionnaires regarding the whole semester. The questionnaires were filled by 7 people, i.e. 77% of the team. Some questions asked for a number as an answer, from a scale of 1 to 5, where "1" meant "the least", and "5" meant "the most". The question most relevant from the perspective of the methodology was: "To what extent do you think the value achieved during the semester is related to the project's management?" The average of the responses was 3.71. Another interesting question was "In what a measure did the values of the agile methodology prevail during the team work?" The average was a bit lower: 3.41. We don't consider these values very low, but we want to achieve a higher rating.

There were other aspects as well for that the rates received seemed to be considerably high. These could reflect the effect of the new agile methodology. These results are summarized in triplets below (question - average - possible explanation).

- To what extent was the task realized by you appropriate for you? - 4.28 - The *discussion in small groups* and the mentoring role of the subgroup-leaders helped team members to choose and succeed with a task appropriate for them.
- How satisfying was the number and quality of feedback you received regarding your work? - 4.57 - The *weekly Scrum*, the *discussion with the whole team* and *discussion in small groups*, the mentoring attitude of the subgroup leaders and the technical leader, provided space and possibility for giving individuals feedback.
- To what measure did the group work as a team? - 4.14 - The common reception of *news* at the beginning of the weekly meetings (for example, a joint congratulation to a team member success), the involvement of everyone in the *weekly Scrum*, the *topic of the week* helped to strengthen team spirit. The mentoring attitude of the technical leader and the subgroup leaders could also contribute to a sense of belonging to the team.
- How much did you enjoy being part of the team? - 4.71 - The *weekly routine* and the proper design of the roles helped to give every individual in the team enough attention and to work smoothly together.

According to some students, the best experiences were: "teamwork, development, encouraging each other"; "We have worked together on an interesting task." Concerning the "biggest challenges", we have noticed that team members who

had development and mentoring tasks as well struggled to allocate time for both of them. In the category of “What would you change?”, the fear of losing senior students (who complete their university studies) appeared, which was a warning to us that we should pay more attention to the transferring of the project knowledge. It appeared a need for deeper understanding of the methodology. (As a response to this need the above presented Agile training was introduced in the second semester of 2018, presented in chapter 5.)

For the results, please note that the research is still in an initial phase. The members of the group filled out the questionnaires, but since there are few of them, the feedback comes from a small number of people. Another lack of the research is, that team speed is not measured yet. Further iterations of the research are expected to improve regarding this aspects.

## V. SUMMARY

In order to manage the work of a software engineering research and development team operating at the university, we can get inspired by the agile methods used in the software development industry. There are some examples of how their use in a classical software development course has succeeded. However, if we want to use them in a research and development team, we have to keep in mind some characteristics like: the objectives of the research and development team, proportion of research and development tasks, type of members (student, teacher, researcher), documentation obligations, etc. A list of this aspects to be analyzed while creating a specific agile method for a R&D team is a result of this research.

Along these aspects, we developed an agile methodology for the txtUML research and development team. The *project leader's* guiding role assures well defined directions regarding the research, while the *Scrum master* assists for teamwork to run smoothly. *Technical leaders - subgroup leaders - developers* create a hierarchical chain targeting the efficient flow of the knowledge. Preparations, news section, topic of the week, and retrospective events are the key to raise awareness of team work values. *Weekly Scrum, product backlog, tables, and weekly reports* aim to enhance transparency and thus efficiency and motivation. The *discussion with the whole team* and *discussion in small groups* events assure knowledge transfer.

Regarding the usage of txtUML's agile methodology the feedback highlights: the communication between the team members has become more efficient; goals are clearer; the atmosphere is pleasant; teamwork is more effective; new members develop rapidly through the flow of the project knowledge. Feedback also highlighted further development opportunities, such as the introduction of on agile training for deepening agile values. All in all, we are satisfied with our methodology and we want to continue to “contribute to creating values for a group of people with passion and creativity, with the help of agile leadership” [8].

Mike Cohn, the famous Scrum trainer, the co-founder of the Scrum Alliance states “I hope we see an end to methodology

wars; Scrum vs. Kanban, SAFe vs. LeSS, Disciplined Agile, Enterprise Agile and every other scaling framework. Instead of arguing about methodologies, we need to focus more on agile as a large set of practices, some of which work well in combination.” [9]. We think that the approach presented in this article is a good example of how we can develop a suitable agile methodology for a team with specific characteristics by combining agile elements creatively, based on the analyses of some previously fixed aspects.

## ACKNOWLEDGMENT

I am grateful to all members of the txtUML R&D team who have welcomed all my ideas openly and helped to develop our own agile method.

The research project was supported by the European Union and co-financed by the European Social Fund (EFOP-3.6.3-VEKOP-16-2017-00002).

□ **Abstract—Context:** The use of agile software development is increasing, even in regulated domains like the automotive domain. At the same time, traditional sequential processes are still in use. Collaboration between agile and hybrid projects within these complex traditional product development processes is difficult. Especially the creation and synchronization of a qualification phase plan is challenging. **Objective:** The aim of this study is to provide insights into the state of the practice to understand challenges related to the combined use of agile and traditional paradigms in release planning in the automotive domain. **Method:** Based on semi-structured interviews, an online survey with 39 respondents was conducted at Dr. Ing. h. c. F. Porsche AG. **Results:** We present the challenges identified in release planning, such as lack of transparency regarding the status quo of related projects. Furthermore, we motivate how agile development methods could improve collaboration between projects in release planning. **Conclusions:** There are many challenges in the context of co-existing agile and traditional projects. We discuss how agile practices like daily standup or continuous integration could address the identified challenges.

### I. INTRODUCTION

**T**ODAY, it is a competitive advantage to develop and put products on the market as early as possible. Agile software development methods and practices are commonly used to achieve this goal [1]. Practitioners want to benefit from increased project visibility, faster response to change, and shorter time to market [1] by adopting agile development practices.

Nonetheless, traditional approaches like the waterfall or the V-model are still predominant in highly regulated domains. Within these domains, the adoption of agile practices is hard to achieve and even not always desired [2]. To overcome the factors that hinder an agile transformation, regulated domains prefer adopting single agile practices [3] into their development processes [4]. This inevitably leads to a mixture of different development processes ranging from completely traditional processes to agile adaptations [5][6], which in turn results in more and more complex interfaces

[7] between all involved methodologies. The mixture of traditional and agile development practices is called hybrid development approaches [5]. Such approaches are commonly used in the automotive domain [8].

In the automotive domain, the complexity of software and systems is constantly increasing [9]. As automotive projects are generally large projects with many subprojects and suppliers, it is necessary to preserve the benefits of the existing rich development processes [10] to coordinate all involved parties. In addition, current software development in the automotive domain is intended to address safety-critical functionality by means of standardized processes to satisfy requirements given by the law.

Thus, it is a challenge to speed up software release cycles [2]. Creating and updating a common release plan that considers all dependencies is challenging, even more so when multiple parties work with different processes.

The aim of this work is to investigate the challenges in the release planning of automotive projects when traditional and agile processes co-exist.

The contribution of our work is as follows: We identify and analyze challenges in the qualification phase to identify improvements in the context of co-existing agile and traditional projects from the perspective of an automotive Original Equipment Manufacturer (OEM).

The remainder of this paper is structured as follows: Related work is presented in Section 2. Section 3 defines the research approach including the research questions and design, the research site and the participants, the data collection and analysis procedure, as well as the data collection instrument. The survey results are reported in Section 4. We conclude our work and outline future research in Section 5.

### II. BACKGROUND AND RELATED WORK

In the automotive domain, a hybrid project environment consists of two conflicting parts. There is the strategic framework on one side consisting of processes with many milestones planned a long time in advance before projects related to production and distribution go live. This strategic framework represents the time and content requirements, such as the product development process and thus defines a

□ This work was not supported by any organization

superordinate process. On the other hand, there is the operational level, where projects are performed in the way that best fits the project's character. On this level, projects are developed in an agile, hybrid or traditional way. A solution has to be found that synchronizes both levels and which enables coordinated release planning.

The automotive domain is a strongly regulated domain. Therefore, this combination cannot start in a green field, as strategic frameworks define different phases of the development process.

The Qualification Phase (QP) is the repetitive integration and testing process of an Electronic Control Unit (ECU) network, its sensors and actuators.

This phase is typically defined at the beginning of a project. The maturity level is determined to release the ECU network for further testing, usage, and development. The maturity levels provide information about the development progress of functions and ECUs in relation to the target state.

The Additional Qualification Phase (AQP) is an extra qualification phase with a reduced testing scope if the level of maturity is found to be insufficient and refers to a reduced scope of ECUs. The reduced test scope refers to the inadequate target state and is defined application-specifically. An AQP is not planned in advance but established depending on the quality level of the QP. In such cases, it is necessary and has to be executed. The selection of the test cases and the duration of the tests strongly depend on the errors identified during the QP.

Release planning in a hybrid project environment has barely been considered to date in the literature. Software release planning matches features to releases under the condition that different types of constraints are considered [11]. Heikkilä et al. [12] identify "an obvious gap in the research of release planning in large-scale agile software development organizations" in a literature review. However, they did not consider the combination of releases consisting of software and hardware.

Sax et al. [13] describe software release and configuration management in the automotive domain. Bestfleisch, Herbst and Reichert [14] define requirements for controlling and monitoring dependencies on other release processes with the help of workflow support. Müller et al. [15] define requirements for IT support to improve release management in the automotive domain. Lindgren et al. [16] identified key aspects of release planning in the context of software and system development projects. Furthermore, they captured the state of the practice for release planning in industry.

There is literature dealing with release planning in agile software development projects, both for single projects and for scaled projects. Danesh et al. [17] evaluated the methods used by companies to plan new software releases. Heikkilä et al. [18] present a case study where the agile release planning process in a scaled Scrum environment was evaluated. Heikkilä et al. [19] describe the qualification phase and present a case study of multi-team agile release planning with the help of this practice.

Karvonen et al. [20] conducted a systematic literature study to identify agile release engineering practices. Ameller

et al. [21] conducted a literature study to report on software release planning models. Overall, there is no direct related work that considers release planning in co-existing traditional and agile processes in the automotive domain. Some work deals with agile release planning, but none of the identified sources deals with the targeted hybrid project environment.

The HELENA study [5][6][8] investigates the combined use of agile and traditional practices in hybrid processes, but does not consider the co-existence of agile and hybrid projects and their synchronization. Theobald and Diebold [7] investigate and classify problems at the interface of agile development and a traditional environment. The work of this paper can be classified in the problem field "project planning" at the interface "project team" [7].

The focus of the majority of publications on release planning models are various kinds of mathematical models and simulations [22], which are ineffectual in complex industries [23]. Practitioners reported that these approaches are either too simple to generate a benefit or so difficult that they cannot reconstruct the whole process created [24][25].

There is a research gap considering hybrid project environments where projects with different development paradigms meet. Our paper aims to address this research gap.

### III. RESEARCH APPROACH

#### A. RESEARCH QUESTIONS

This paper aims to answer the following research question: *What are the challenges and consequences of the qualification phase in an automotive hybrid project environment?* To answer this question, three research questions were defined:

- RQ1. What are challenges concerning the qualification phase in a hybrid project environment?
- RQ2. What are the specific challenges of agile projects embedded in a traditional development context?
- RQ3. How could agility address the identified challenges?

#### B. RESEARCH DESIGN

To answer the research questions, we selected a two-step research approach. First, we set up an exploratory, qualitative interview study within a German automotive OEM. An interview guide for identifying challenges and problems with regard to the release planning process was specified. The interview guide was tested in a pilot interview. Emerging issues, such as vague phrases, were addressed before the qualitative interview study was conducted. In the second step, an online survey questionnaire was developed to validate the challenges identified from the qualitative interview study in detail.

The data collection instrument was a questionnaire containing 31 questions. The survey questionnaire contained open and closed questions structured into six categories (cf. **Table 1**).

TABLE 1. SURVEY QUESTIONNAIRE

Category	ID	Question
Context	1	What is your current role? [free text ]
	2	How long have you been working in that role? [free text ]
	3	What are you working on in your project? [E/E ECU, software component, function, connect service, vehicle project]
	4	Please select a sector to classify your project. [powertrain electronics, body electronics, infotainment, project is safety-critical, others]
	5	What kind of development method do you use? (agile, hybrid, or traditional) [use of adapted agile methods, hybrid methods, traditional approaches]
	6	If you are using agile or hybrid methods, please specify the method. [free text]
Qualification Phase	7	What do you think about the current number of qualification phases (incl. additional qualification phase)? [too high, adequate too low]
	8	How often are you able to generate current software versions ready to deliver? [never, seldom, often, always]
	9	Do you receive feedback about the qualification phase on time? [never, seldom, often, always]
	10	How often should a qualification phase take place in order for you to be ready to deliver? [every week, once a month, every 3 months, at larger intervals]
	11	Would additional releases in terms of partial composites with reduced test scope be helpful for safeguarding dependent ECUs? [yes, partially, no]
Planning	12	Is an initial planning of content possible? [never, seldom, often, always]
	13	Does an initial planning of content make sense? [never, seldom, often, always]
	14	How often is the content of the initial planning still up-to-date at the beginning of a qualification phase? [never, seldom, often, always]
	15	How difficult is it to get planning information for the relevant counterparts? [very difficult, difficult, easy, very easy]
	16	To what extent do management decisions, external influencing factors, or externally determined decisions influence your development process? [no impact, weak impact, strong impact, very strong impact]
Integration	17	To what extent does bug fixing affect the timely implementation of planned functionalities for the next qualification phase? [no impact, weak impact, strong impact, very strong impact]
	18	It is inevitable that software versions are released that are suboptimal concerning quality or content. [yes, partially, no]
	19	What kind of activities dominate your daily routine during a qualification phase? [free text]
	20	Rate the following statement: Additional qualification phases are necessary. [yes, partially, no]
	21	Rate the following statement: Additional qualification phases are reasonable. [yes, partially, no]
Coordination	22	Is the status of development transparent to you at any time? [yes, partially, no]
	23	Is the status of development of your stakeholders transparent to you at any time? [yes, partially, no]
	24	How important is the transparency of the development status of your relevant counterparts to you? [totally unimportant, unimportant, important, very important]
	25	Rate the following statements: - Stakeholder/Interfaces are known [Disagree, rather disagree, rather agree, agree] - Quality of coordination is good. [Disagree, rather disagree, rather agree, agree]
Testing	26	Development can no longer handle the high number of bug reports. [Disagree, rather disagree, rather agree, agree]
	27	Problem resolution management can no longer handle the high number of bug reports. [Disagree, rather disagree, rather agree, agree]
	28	What are the reasons for the high number of tickets? [free text]
	29	Do all planned changes to the ECU network have to be fully tested for each qualification phase? [yes, partially, no]
	30	Do all types of tests have to be performed for every ECU for each qualification phase? [yes, partially, no]
	31	When do all ECUs have to be fully tested? [every qualification phase, depending on the changes, not mandatory]

The categories and questions were derived from the insights gained in the previous interviews. The questions were originally written in German. The questionnaire went through four review cycles by an independent researcher as well as by a specialist from the case company. Review comments were discussed by the authors and addressed to improve the questionnaire.

In the first category, we elicited the “Context”, such as role and experience of the participant, as well as project type, area, and the development method used (traditional vs. agile). The second category, “Qualification Phase”, aimed at evaluating how many qualification phases are feasible. The third category, “Planning”, was for evaluating the need to have an initial plan as well as external influences on such a plan. At a certain point in the development process, an initial planning of the functional scope of an ECU must be submitted for each release. In addition to general ECU information, deviations from the required functional, network and diagnostic maturity levels must also be specified. We examined the need for AQPs in the fourth category “Integration”. Integration is an upstream part of the actual process and represents the integration of one or more ECUs into a whole network. Transparency of the status quo and the quality of coordination were the focus of the fifth category, “Coordination”. Finally, we covered all questions related to “Testing” in the last category, trying to evaluate which kind and intensity of tests are necessary and if and why there are so many bug reports. The test phase focuses on the execution of the qualification phase and is therefore a main activity.

#### C. DATA COLLECTION AND ANALYSIS PROCEDURE

To identify the main challenges, the first researcher conducted 26 semi-structured interviews, which took between 30 and 60 minutes each. The information from each interview was incorporated into later interviews. Because these interviews did not allow for quantitative results, an online survey was conducted to confirm the challenges and to draw a more complete picture by consulting different participants. This allows for quantitative results, but gave every participant the chance to provide further qualitative results by sharing their experiences.

95 potential participants were selected based on their roles, to cover all perspectives. Then the participants were invited via an email motivating the goal of the study and outlining the contents and the time expected to answer the questionnaire. A reminder email was sent after one week. Also, one of the participants forwarded the questionnaire to an additional group of 25 people. The survey was open from November to December 2018.

After extracting the data from the online survey tool<sup>1</sup> into an Excel document, we analyzed the answers for completeness. There were 39 complete responses, meaning all six pages of the questionnaire had been answered and thus the survey had been officially finished. In addition,

there were 16 incomplete answers where the questionnaire was not finished. Of these 16 incomplete answers, 1 participant stopped after category 3 (Planning), another one stopped after category 5 (Integration), and all others had discontinued the questionnaire even earlier. Although we had access to the incomplete data sets, we decided to only consider the complete data sets for further analysis. Since the survey was distributed to 120 people with 39 respondents, our response rate was about 33%. Afterwards, we conducted a descriptive analysis of the individual questions and analyzed the textual answers to identify common opinions.

#### D. RESEARCH SITE AND PARTICIPANTS

This study was conducted at Dr. Ing. h. c. F. Porsche AG, a manufacturer that builds sports cars for everyday driving. The division EE within Dr. Ing. h. c. F. Porsche AG in Weissach, Germany, is responsible for the development process of electronic systems and its integration into the development process of the complete vehicle. For achieving this goal, transparent development, processes and hence accurate release planning are essential.

The target population of our survey included all roles involved in the qualification phase process of automotive products where the subprojects differed in terms of the development approaches used, including agile as well as traditional methods. The sample selected consisted of stakeholders from Dr. Ing. h. c. F. Porsche AG involved in release planning activities. The participants were expected to be motivated enough to answer the comprehensive questionnaire because they anticipated improvements based on the findings that reflect their current situation.

#### E. THREATS TO VALIDITY

As the results only represent one specific case, it might not be possible to generalize them. However, the fact that the case company has the same framework conditions (regulated domains, complex supplier relationships and high safety requirements) as similar OEMs, others could benefit from the findings. The issues that were identified in the earlier interviews were addressed in the questionnaire, whereas new survey participants did not have a chance to add more individual problems during the online survey. There might be a bias concerning the stakeholders who participated. Some roles are overrepresented, while other relevant roles were not represented by many participants. This might have led to results that are skewed towards the opinion of certain roles. Nonetheless, many different roles participated in the study, providing answers from many perspectives. As in all surveys, non-response bias could have led to missing the opinions of certain participants.

#### IV. SURVEY RESULTS

This section contains the demographics and context of the respondents, followed by the presentation and discussion of the results of this work structured along the research questions.

<sup>1</sup>[www.limesurvey.org](http://www.limesurvey.org)

## A. CONTEXT

The respondents' professional experience in their current role (Q1) was slightly below six years on average, with a minimum of one year and a maximum of 16 years (Q2). Most of the respondents had management roles (n=17; 44%), others were responsible for projects, products, functions, integration, testing, quality, data, processes, or other related disciplines. 10 participants (26%) represented the operational level. The remaining 12 respondents (30%) had roles with responsibilities related to the environment of qualification phases.

The respondents described their working environment using one or more categories (Q3). Most participants reported working in vehicle projects (n=24), development of E/E components (n=18), development of functions (n=14), development of software components (n=12), and connected services (n=8). Others (n=7) dealt with IT backend, cross-project integration, distributed functions, or quality.

14% of the respondents answered that their project was safety-critical. Most participants assigned their project to the area of infotainment (n=13), followed by electronics for car bodies (n=11) and electronics for engines (n=7). Regarding the 24 additional classifications, ten participants reported working on crosscutting topics (Q4).

Most respondents reported using traditional development or project management approaches such as the V-model or sequential approaches (n=26). Only six respondents used adapted agile methods, and seven persons used hybrid approaches, which was defined as strongly adapted agile methods or use of only single agile practices (Q5). This showed that only one third of the study participants were using agile concepts at the time.

Agile implementations were based on Scrum or the Porsche-specific adaption of agile methods. One person even reported scaled agile and lean at the unit level combined with an adapted Scaled Agile Framework (SAFe). Single agile practices like daily standups, user stories, backlogs, retrospectives, or the Scrum Master role were used in traditional projects. Some respondents reported using both agile and traditional approaches at different project levels. One answer stated that agile was being used at the team level together with the V-model for whole projects, while another respondent reported using a sprint-like approach within the V-model due to highly dynamic changes in requirements. Another respondent indicated the use of different development paradigms in different life cycle phases (Q6).

## B. RQ1: CURRENT CHALLENGES

In the following, the current challenges will be presented and discussed along the categories of the survey questionnaire. RQ1. What are challenges concerning the qualification phase in a hybrid project environment?

### 1) QUALIFICATION PHASE

The majority of the participants (n=22; 56%) stated that the current number of releases (p.a.), including all additional

qualification phases and special qualification, is too high (Q7). On closer inspection, there is a discrepancy between the answers by managers and those by developers with responsibility for products or functions. The former (n=17) reported that the existing number of releases is too high (56%), while the latter said it is too low (25%).

An analysis of the comments field of this question shows results relating to the regulated defined number of releases. The developers confirmed their opinion and asked for a higher number of qualification phases. The management group agreed with the regulated defined numbers.

Further information concerning the ordinary number of qualification phases was given by the group of developers using agile methods. For the majority of those participants, the absolute number of qualification phases is too low to use agile methods properly.

The next issue concerned the delivery results in the required form (Q8). 60% of the survey participants answered that the required deliverable is seldom available in the required quality. In contrast, 40% replied that it is always or at least most of the time possible to create a delivery version for every requested release.

74% of the participants answered that they mostly receive feedback about qualification phases on time (Q9). The next question dealt with the number of qualification phases with regard to generate software version (Q10). Two-thirds of the participants stated that qualification phases should take place at least each quarter of the year. In contrast to the last question (Q11) in this category, 46% called for additional qualification phases with reduced test scopes.

## 2) PLANNING

This category highlights the characteristics around planning. The first question (Q12) aimed at evaluating the feasibility of initial planning at the beginning of the project. 50% of the participants in our study reported that initial planning is possible, and the other half answered that such a plan is rarely possible. At the beginning of a project, the decisions for or against a supplier have sometimes not been made yet. That is one reason why it is difficult to generate an initial planning. Another person replied that requirements for functions are the results of testing, which is done further on in the development process.

In a further question, the participants were asked if such initial planning would be meaningful (Q13). A significant majority (74%) stated that planning at the beginning of a project is reasonable because it is a resilient starting point for further steps. Participants also mentioned the existing change management process, which permits updates at any time.

The next question (Q14) regarding this topic dealt with the projected content before the next release in terms of timeliness. The results show that scheduled content is frequently impossible to implement in practice (80%). The majority of the participants stated that awareness still exists for high quality in planning. Planning updates have to pass a committee, which is one reason why change requests are not implemented in the current release. Also some areas,

“connected car”, are very dynamic, which is another reason for the bad current state of planning, which is not up-to-date. Receiving information about planning details from the relevant stakeholders is perceived as challenging (Q15). 74% of the respondents replied that obtaining information on time is difficult because there are no regulated tasks nor a consistent workflow for changing the relevant information.

Another issue is the impact of management decisions during the development cycle (Q16), which implies that these cannot be implemented easily. 90% of the respondents rated this influence as strong or very strong and reported that the development of new functionality suffers from having to deal with unexpected changes demanded by management. Some respondents complained about management decisions that change the backlog priority and have severe effects on further procedures.

### 3) INTEGRATION

This category contains the results relating to the challenges of software and hardware integration during a development cycle.

During a qualification phase, new software versions are tested at different levels of integration. The test results and even bug fixing have a great impact on the subsequent procedure (Q17). 87% of the participants answered that bug fixing affects their timely implementation related to the next release. Because there is no hold available in the project plan, this even leads to delays of the next scheduled functions (Q18).

Another question in this category dealt with the activities during a qualification phase (Q19). The main activities or tasks linked to the respective role are: Management is engaged in coordination and ensuring the scheduled scope with regard to the next release. At the operational level, tracking of test results and analysis of upcoming bug tickets are the main concerns. Both groups have to handle the subsequent deliveries.

Almost all interviewees (96%) admitted that delivering software versions with high quality is infeasible when they also have to provide the content planned for the next release. The results considered for integration have low maturity, due to the increasing pressure of costs and deadlines.

For this reason, additional qualification phases have been established subsequent to the original deadline. We wanted to know if such additional qualification phases are necessary (Q20) and reasonable (Q21). 65% of the participants considered additional qualification phases necessary and 35% were convinced that they are reasonable.

The main reasons given by the participants for subsequent integration were poor software quality, lack of adherence to delivery dates on the part of the suppliers, poor scheduling without buffering, and no complete bug fixing from the previous qualification phase.

### 4) COORDINATION

Transparency and coordination were the relevant aspects in this category (Q22). We asked whether the current

development status of the respondents' own team or dependent teams is sufficiently transparent. Only 26% (n=9) reported that their own development is transparent. The majority of the respondents rated transparency as only partial (n=20; 51%) or non-existent (n=10; 26%).

Next, the results of questions Q23 and Q24 are presented. The questions dealt with the transparency of the status of projects by relevant stakeholders and relevant counterparts. Here, only 15% (n=6) of the respondents answered that the development status of other projects is transparent for them. Most participants (n=19; 49%) reported partial transparency, while 36% (n=14) reported a lack of transparency. Reasons for the lack of transparency were missing time and coordination mechanisms, and the use of outdated content of the release plans.

The transparency of the status quo of a certain development project is very important and closely linked to the quality of a release. 95% of the respondents supported the statement that having a transparent software version at any time is important. It is necessary due to the complexity, dependency, and connectivity of software engineering.

Another question aimed at getting information about the communication structures within the company and involved persons from the release planning process (Q25). The participants had to rate whether they knew their interfaces and relevant stakeholders and whether the quality of the coordination was good. This rating had to be done for several interfaces: within the team, between team and testing, within the case company, within the company group, as well as towards external suppliers.

The results presented in Fig. 1 (bottom figure) demonstrate that communication quality decreases with longer communication paths: Communication within a project was perceived as good, but the quality was perceived as decreasing in communication within the company and even worse in communication with suppliers (internal means company group and external suppliers). Similarly, the relevant stakeholders and interfaces of the wider project context were reported less known than those within the team (see Fig. 1, top figure).

### 5) TESTING

This category assesses the testing situation. The first question aimed to evaluate whether the number of bug reports is still controllable by development (Q26) or problem resolution management (Q27). Overall, 56% (n=22) of the participants agreed (n=7) or rather agreed (n=15) that development is able to control the high number of bug reports. The remaining respondents had a tendency to disagree (n=9) or disagreed (n=8).

Concerning problem resolution management, most participants (n=25) disagreed (n=8; 21%) or had a tendency to disagree (n=17; 44%). The minority of the participants agreed (n=5; 12%) or rather agreed (n=9; 23%)

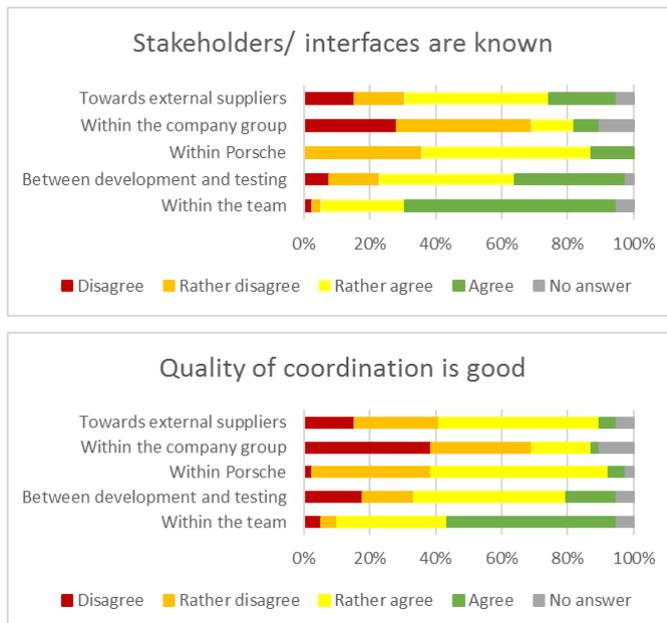

Fig. 1. Known interfaces (top) and quality of coordination (bottom)

Furthermore, the participants were asked about reasons for the high number of bug reports / tickets (Q28). The survey revealed that identifying errors is usually not done before the upcoming release due to insufficient development time, cost, and deadline pressure. It was reported that the intensity of testing by the supplier was not adequate. Other reasons given for the high number of error tickets are the rising complexity of the product itself, the lack of coordination within the team, and inadequate requirements engineering. Generally, it can be stated that the software quality before a qualification phase is insufficient and questionable, endangering the success of the qualification phase.

Software changes may have severe effects on interfaces, which is why tests have to be done. The need for testing the software changes to the full extent for every qualification phase (Q29) was not seen by 18% of the respondents (n=7), who claimed that this is not necessary. Most respondents (n=18; 46%) said that changes have to be tested to the full extent for every planned release. The remaining 36% (n=14) partially agreed that testing is always necessary and specified in the comments specific situations where more testing was necessary or less testing was acceptable. Some stated that the scope of testing depends on the number of changes made or on the development phase. One respondent commented that it is not possible to test all changes; another one said that full testing is always necessary because cross-dependencies only become visible by testing within a release.

Only 10% (n=4) of the respondents agreed that all types of tests have to be performed in every release cycle (Q30). 39% (n=15) disagreed with this statement and about half of them (n=20; 51%) partially agreed. The participants further pointed out that conducting all tests is not feasible or that the necessary types of tests are predefined in the test strategy and depend on the change itself. Others reported that regression tests are often sufficient, or that full releases need to be tested more accurately than partial releases.

To save testing effort, it is important to know when comprehensive testing (including all types of tests) of all ECUs needs to be done (Q31). 85% of the respondents (n=33) answered that testing needs to be done dependent on the software, hardware, or functional changes. Five respondents (13%) claimed that the ECUs have to be tested once per qualification phase, either at the beginning or at the end. 2% (n=1) said that testing is not always necessary. One participant commented that due to the high product complexity and low software quality, all ECUs have to be tested as an integrated system with all possible tests, or at least with good regression tests. Another one claimed that comprehensive testing is not possible for all system parts, but major parts can be covered with a good testing strategy.

### C.RQ2: AGILE-SPECIFIC CHALLENGES

Existing vehicle development processes emerged at a time when agility was not present yet and were formalized based on traditional development methodologies. Due to the regulations, strict production deadlines and the complexity in vehicle development, the need to have formal processes will remain. However, the potential to integrate agile processes must be evaluated in order to exploit the benefits of agility. New technologies such as cloud services implicate a stronger customer focus, to be able to respond more flexibly to customer needs, which results in conflicts with the slow and unresponsive traditional development. Innovation is happening fast in the automotive company, and companies have to react in time to stay competitive.

Iterative cycles are already incorporated into many processes, but other concepts of agile methods initially designed for small teams are more difficult to integrate or synchronize with the existing rigid processes. The OEMs are currently performing a balancing act between fixed framework conditions and scope for flexibility. On the one hand, legal requirements, standards and production requirements must be observed and on the other hand, developers want to act more freely without being restricted by guidelines. The results of this survey indicate that this is not a simple procedure.

The survey revealed that if departments are already working with agile methods, they only use them to a certain extent. Our initial expectation was that agile methods are commonly used at least in fields such as connected car, with its digital services and shorter development cycles. The differences between our expectations and reality may be caused by the lack of a common understanding of agile methods. This is confirmed by the inconsistency of the answers by the respondents, who considered additional qualification phases necessary but at the same time did not demand more qualification phases. The reason for this may be a lack of knowledge about agile methods.

There is also a lack of suitable means of communication for short, regular exchanges aimed at establishing transparency between all participants. Such possibilities for fast feedback would also increase the overall quality of voting and benefit the flow of information. Respondents

(n=7) from agile projects reported that the length of release cycles is too long and does not suit agile approaches.

The fact that management decisions have such a strong influence on the further course of development illustrates that decisions are made at higher levels of hierarchy. In an optimal agile environment, the development team makes the decisions. Based on the priorities set by the Product Owner and the requirements dependencies identified by the development team, a Scrum team knows best how to achieve the best solutions. At the beginning of each iteration, they commit to a product increment that is valuable and achievable. If management forces decisions upon the team during an iteration, results can be expected to be suboptimal.

However, this is only the point of view of a single team. If each single team cannot meet their commitments, the qualification phase of an integrated product is going to raise problems. One reason is that the release plan, which considers dependencies between different projects, gets unofficially changed without being updated. That means the developers change their release plans on the operational level without having the change approved and without informing the affected interfaces.

#### D.RQ3. IMPROVEMENTS WITH AGILE METHODS

There are many challenges that are predestinated to be solved with agility. The survey revealed that transparency and coordination are highly important for a successful qualification phase. Some of the interviewees states that the communication path in their department is too long, which causes loss of time and a lack of coordination. This argument is supported by the fact that some of the participants reported not knowing their interfaces and relevant stakeholders, resulting in bad synchronization and integration structures. By using agile development and small working groups with no typical hierarchy, interface management and short communication paths could become possible [26].

Currently, additional qualification phases are started to fix the remaining bugs or to finish some functionalities that had been planned for the previous release cycle. Due to the increased effort for these activities, the planned results for the next release cycle cannot be fully achieved, pushing a wave of additional efforts, e.g., for coordinating additional qualification phases, through the whole project. Increased transparency regarding the content that was finished in an iteration can be achieved with a definition of done and by incorporating time-boxed sprints. At the end of each sprint, the status quo is assessed, and unfinished requirements can be planned for the next sprint.

Another characteristic of sprints is that requirements are usually not changed, especially not from outside the team. This would also help to stabilize the release plan, which would help to achieve higher-quality products delivered for integration by each single team. Sprints are usually short iterations of several weeks. Respondents from agile projects reported that the length of release cycles is too long, and that they would prefer receiving feedback earlier. This issue leads to work overload and defined timelines not being

achieved, which ultimately leads to lower software quality. In addition, development costs increase due to many additional qualification phases. By using agile methods and more intermediate steps, including regular assessments of the project state, discrepancies could be identified earlier.

Agile teams use face-to-face communication and daily standups to synchronize their work in order to achieve their sprint goal. In a scaled environment, so-called Scrum-of-Scrums are scaled daily standups where representatives of different teams synchronize their development status and plan their dependencies. The Scaled Agile Framework (SAFe) uses an architectural runway to coordinate architectural decisions between the single development teams to facilitate integration.

Continuous integration is commonly used in agile projects and could be of benefit in qualification phases. Integrating smaller work products incrementally can replace a larger and more complex final integration and provides early transparency about the finished content of the release as well as raising awareness of dependencies.

In general, regular retrospectives can be held at the end of each sprint, helping the team to raise issues impeding their work and improve their development process. Conducting retrospectives together with relevant stakeholders and dependent projects helps to continuously improve collaboration between teams.

#### V. CONCLUSION AND FUTURE WORK

Agile development is being increasingly adopted even in regulated domains such as the automotive domain. There it has to be synchronized with co-existing traditional development approaches. Qualification phases of traditional, hybrid, and agile projects are difficult. An online survey was used to identify challenges in the release planning of a German automotive OEM. The results show that communication and information issues such as inadequate familiar counterparts predominate in the case company. Dependencies between input and output relations are key results, too. Furthermore dissatisfied software quality during the system tests leads to further challenges. Another key statement of the survey results is the limited capacity to act to the supplier relationships.

We presented the main challenges in detail and discussed the state of agility and the conflicts arising in the context of co-existing traditional and agile approaches. We outlined how agile concepts could improve some of the identified challenges and thus provided recommendations for practitioners.

In the future, we plan an in-depth analysis and interpretation of the results, including a more detailed analysis of the questions, by trying to identify further correlations. With a questionnaire adapted to collect experiences outside the case company, we want to check whether there are similar problems at other automotive companies or even companies from other regulated domains that are developing complex systems in a hybrid project environment.

□ **Abstract**— In this paper we present the results of an opinion survey among 52 agile practitioners who evaluated the importance of 26 selected elements of the agile mindset to the effectiveness of an agile team. In total, we have identified 70 unique agile mindset elements based on 11 literature sources and 5 interviews with industry experts. 7 elements belonged to the “support for business goals” category, 20 to the “relationships within the team” category, 24 to the “individual features” category, and 19 to the “organization of work” category. Our survey shows the relative importance of the selected 26 agile mindset elements according to our respondents which is not fully consistent with the principles behind the Agile Manifesto.

## I. INTRODUCTION

Agile Manifesto [1] together with the principles behind the Agile Manifesto [2] founded a set of driving values and key principles for the agile software development. Agile practitioners emphasize that effective performance of an agile team requires not only a given set of procedures, techniques and rituals, but, above all, a particular attitude, way of thinking and behavior of both the individuals and the entire team – a so called ‘agile mindset’ [3, 4].

Working in agile teams requires many non-technical and social competencies related to communication, organization, business, improvement and many more [5]. These are not the typical strong competencies among software engineers [6], which is why they require support of Scrum Masters, mentors and coaches to develop deep understanding of the fundamentals of Agile. Agile mindset, by addressing all of these competence areas and by suggesting important factors to the effective teamwork, supports practitioners in mastering Agile in their projects [4]. Altogether, developing the proper agile mindset contributes to the increasing success of agile software projects [7].

The principles behind the Agile Manifesto themselves [2] recommend such attitudes and behaviors as focus on customer satisfaction, openness to change, face-to-face communication, sustainable development, simplicity, self-organization and improvement by frequent reflection. The

□ This work was partially supported by the DS Funds of ETI Faculty, Gdansk University of Technology.

agile methods such as Scrum [8], Kanban [9], SAFe [10] and other elaborate these principles further on, however the evolution of the IT industry since the Agile Manifesto calls for deeper and more current insight into the concept of ‘being and working agile’. In our research, we assume the definition of ‘an agile mindset’ as a set of one’s attitudes, behaviors and ways of thinking that enhance their and their team’s effectiveness in working following the agile values and principles to the benefit of the customers.

This research aims at studying the elements of the agile mindset and their importance to the effectiveness of an agile team. We have formulated the following research questions: (RQ1) What agile mindset should the members of an agile team have? (RQ2) What is the importance of the particular agile mindset elements to the effectiveness of an agile team? (RQ3) What are the most important elements of the agile mindset to the effectiveness of an agile team?

The main contribution of this paper is the broad identification of the elements of agile mindset and the partial evaluation of their importance to the effectiveness of an agile team based on an industrial opinion survey. This extends the reviewed literature with deeper understanding of the concept of ‘agile mindset’ and the relative importance of its elements.

The paper is structured as follows. Section II presents our research method of identification, selection and evaluation of the agile mindset elements. Section III reports the results of the identification phase based on the literature review and the interviews with experts. Section IV presents the selection of the agile mindset elements for further evaluation. Section V reports the results of the survey together with the analysis of confounding variables and the comparison to the principles behind the Agile Manifesto. Section VI discusses the threats to the validity of this research, followed by the discussion in Section VII and conclusions in Section VIII.

## II. RESEARCH METHOD

Our research comprised three steps: (1) identification of the elements of an agile mindset and their categorization, (2) selection of the agile mindset elements for evaluation, (3) evaluation of the relative importance of the selected agile mindset elements to the effectiveness of an agile team.

The first step involved the review of current literature and the interviews with experts from industry. The literature review covered mainly grey literature (books, blogs, portals), as the scientific databases such as Scopus or Web of Science provided very few results. We have focused on Internet sources reporting on industrial practice or written by agile practitioners and published by renowned publishers or portals. In total, we analyzed 11 literature sources.

To identify the agile mindset elements more thoroughly, we have carried out 5 structured interviews with industry experts with 2 to 5 years of experience in agile teams. They mostly worked as developers and Scrum Masters with various agile methods. The characteristics of the interviewed experts are given in Table I. Experience is given in years.

TABLE I.  
CHARACTERISTICS OF THE INTERVIEWED EXPERTS

ID	Position	Exp.	Methods
A	developer	3	Scrum
B	developer, tester	2	Kanban
C	developer	2	Scrum
D	Scrum Master, Agile Coach	5	Scrum, Kanban, XP
E	Scrum Master	3	Scrum, Kanban, Scrumban

The interviews were carried out in late May – early June 2018 in a form of face to face meetings. Experts A to C were not provided the interview questions in advance, which resulted in limited answers. Thus, experts D and E were sent the questions before the interview, which allowed them to think over their answers and generally resulted in more original insight into the subject matter. We have followed the given interview guide:

I. Preliminary questions:

1. For how long have you been working in agile teams?
2. What methodology are you using in your projects (Scrum, Kanban, XP - Extreme Programming, others)?
3. What is your role in the team (developer, tester, Scrum Master, etc.)?

II. General questions about the philosophy of agility:

1. What is agility for you?
2. What does "agile mindset" mean for you?

III. Questions about agile mindset elements (at least 3 elements from each question):

1. Which beliefs do you think are necessary to have the agile mindset?
2. What are the most important values for a person with the agile mindset?
3. What principles should be followed by a person with the agile mindset?

IV. Questions about the importance of agile mindset elements (at least 5 elements from each question):

1. What are the most important attitudes, rules and behaviors at the interpersonal level in an agile team?

2. What are the most important attitudes, rules and behaviors in the work organization of an agile team?
3. What are the most important attitudes, rules and behaviors when dealing with customers in an agile team?

V. Questions about the impact of agile mindset on work efficiency:

1. What attitudes, behaviors and beliefs have the greatest impact on the efficiency of agile teams (name at least 5)?
2. Has your team worked inefficiently for reasons related to the agile mindset? What were these reasons?
3. Do you think it is necessary to have the agile mindset to work effectively in an agile team? Why?

Categorization of the identified agile mindset elements was done a posteriori based on keyword analysis in the results of the literature review. The same categorization was used for the interview results. The final list of identified agile mindset elements was elaborated by summing the sets of elements in the literature review results and interview results in each category, followed by merging the duplicates. We have noted the number of times each element was mentioned in the literature and the interviews (i.e. number of sources and number of experts, respectively, see Tables II and III).

The total number of identified agile mindset elements exceeded the capacity of a practical survey, so we had to select a subset of elements for further evaluation. As we aimed at one question per agile mindset element, we wanted to select no more than 30 agile mindset elements based on their frequency in sources (which is not importance). We have decided to include the elements found in at least 6 out of 11 literature sources or given by at least 2 out of 5 experts. These thresholds assume the majority of literature sources and some minimal agreement of the experts. Such thresholds favor the elements given by the experts, but this was our deliberate decision. Finally, such criteria resulted in 26 agile mindset elements selected for further evaluation. Other elements may be investigated in a separate study.

To evaluate the relative importance of the selected agile mindset elements to the effectiveness of an agile team, we have run a survey among agile practitioners in the IT industry. The survey was built on-line with Google Forms and distributed via e-mail, Facebook, forums etc. Respondents were asked to give their opinion on the degree to which a particular agile mindset element enhances the effectiveness of an agile team in the Likert-type 6 level scale of 0 to 5, where 0 meant "no impact" and 5 meant "key impact". The answers were optional which accounted for the cases of respondents' indecision or insufficient knowledge. The survey was organized by agile mindset categories. Additionally, we asked about the respondents' experience and their role in agile teams. Although basic Likert scale is ordinal, we used the Likert-type interval scale with assigned values of 0 to 5 in the survey and the data analysis [11].

III. IDENTIFICATION OF AGILE MINDSET ELEMENTS

A. Literature review

Using generic search engines such as Google, we have found the following literature on the topic of agile mindset:

1. “Agile Project Management: Managing for Success”, a book by James A. Crowder and Shelli Friess [12],
2. “The Agile Enterprise: Building and Running Agile Organizations”, a book by Mario E. Moreira [13],
3. “Being Agile: Your Roadmap to Successful Adoption of Agile”, another book by Mario. E. Moreira [14],
4. “The Agile Mindset – Making Agile Processes Work”, a book by Gil Broza [4],
5. “Five Agile Factors: Helping Self-management to Self-reflect”, a research paper by Christoph J. Stettina and Werner Heijstek [15],
6. “Learning Agile: Understanding Scrum, XP, Lean and Kanban”, a book by Andrew Stellman and Jennifer Greene [16],
7. “What Exactly is the Agile Mindset?”, an on-line article by Susan McIntosh for InfoQ portal [17],
8. “What does it mean to have an agile mindset?”, an on-line article by Leanne Howard for AgileConnection portal [18],
9. “It’s All About the Mindset”, an on-line article by Sayi Parvatam for Scrum Alliance portal [19],
10. “Fixed Mindset versus Agile Mindset”, an on-line article by V. Godugu for Scrum Alliance portal [20],
11. “Agile Is Not a Process, It’s a Mindset”, an on-line article by Lisa Rich for AgileConnection portal [21].

In total, we identified 58 elements of agile mindset in the literature. Table III lists these elements grouped into categories with the indication of relevant sources. The identifier of each element combines the “L” prefix (standing for the literature), the category symbol and the consecutive number of the element in each category. The list is ordered by descending number of sources in each category.

We have identified four categories of the agile mindset elements: (1) support for business goals, (2) relationships within the team, (3) individual features, (4) organization of work. The first category, denoted by G symbol in Table III, focuses on the product value and relations with the customer. The second category, denoted by the T symbol, covers the issues of collaboration and relations within the agile team. The third category, denoted by the I symbol, tackles the behavior and attitude of an individual in an agile team. Finally, the fourth category, denoted by the O symbol, involves the aspects of methods, techniques and rules.

B. Interviews with experts

The 5 interviews with experts A to E provided 16, 18, 16, 17, and 16 agile mindset elements, respectively. Repeating elements were merged. In total, we identified 39 unique agile mindset elements with the interviews. Table II lists these elements grouped into categories with the indication of

relevant sources. The identifier of each element combines the “E” prefix (standing for the experts), the category symbol and the consecutive number of the element in each category. The categories and their symbol are the same as in the literature review. The list is ordered by descending number of interviews in each category.

TABLE II. ELEMENTS OF THE AGILE MINDSET IDENTIFIED WITH THE INTERVIEWS

ID	Element name	Source	n <sub>E</sub>
E.G1	Cooperation with the customer based on partnership	B, C, D	3
E.G2	Attitude towards customer satisfaction and needs	B, D	2
E.G3	Continuous delivery of a valuable product in short intervals	A	1
E.G4	No assumption that the customer is always right	A	1
E.T1	Mutual trust	A, B, C, D, E	5
E.T2	Sincerity	A, B, C, E	4
E.T3	Helping each other	B, C, D, E	4
E.T4	Mutual listening	A, B, C	3
E.T5	Mutual respect	A, B, D	3
E.T6	Equality in the team	B, C, D	3
E.T7	Focus on achieving common goal	A, C, E	3
E.T8	Searching for a solution to the problem instead of finding the guilty	A, B	2
E.T9	Direct communication - face to face conversations	B, D	2
E.T10	Team responsibility	C, E	2
E.T11	Taking into account the opinions of other people	A	1
E.I1	Openness to change	A, B, C, D, E	5
E.I2	Positive attitude	A, B, E	3
E.I3	Continuous improvement and learning	B, C, E	3
E.I4	Being motivated	A, B	2
E.I5	Openness to criticism and feedback	A, D	2
E.I6	Openness to others	C, D	2
E.I7	Willingness to constantly acquire knowledge	B	1
E.I8	Pragmatism	B	1
E.I9	Individual initiative	B	1
E.I10	Courage	D	1
E.I11	Commitment	D	1
E.I12	Creativity, innovation	D	1
E.I13	Being a visionary	D	1
E.I14	Understanding the need for change	E	1
E.I15	Responsibility	E	1
E.I16	Understanding the significance of retrospectives	E	1
E.O1	Self-organization	A, C, D, E	4
E.O2	Finishing the current task before taking the next one	A, C, E	3
E.O3	Asking questions in case of insufficient knowledge	B, C, D	3
E.O4	Maintaining a steady pace of work	A, E	2
E.O5	Transparency in decision-making and actions	C, E	2
E.O6	Sharing knowledge and results	C	1
E.O7	Focus on the tasks performed	D	1
E.O8	Focus on cross-functional teams	E	1

TABLE III.  
ELEMENTS OF THE AGILE MINDSET IDENTIFIED IN THE LITERATURE

ID	Element name	Source	n <sub>i</sub>
L.G1	Continuous delivery of a valuable product in short intervals	[12], [13], [14], [4], [16], [17], [19]	7
L.G2	Attitude towards customer satisfaction and needs	[12], [13], [14], [16], [18]	5
L.G3	Belief that a working product is the basic measure of progress	[12], [13], [14]	3
L.G4	Continuous cooperation with the customer	[13], [14], [4]	3
L.G5	Accurate knowledge of who the customer is and what are their needs	[14]	1
L.G6	Cooperation with the customer based on partnership	[16]	1
L.T1	Mutual trust	[12], [13], [14], [4], [15], [16], [19], [20]	8
L.T2	Direct communication - face to face conversations	[12], [13], [14], [4], [15], [16], [19]	7
L.T3	Focus on achieving common goal	[12], [13], [14], [15], [18], [19]	6
L.T4	Mutual respect	[14], [4], [15], [17], [19]	5
L.T5	Helping each other	[12], [14], [15]	3
L.T6	Taking into account the opinions of other people	[13], [15]	2
L.T7	Respecting the experience and skills in all team members	[13], [14]	2
L.T8	Listening to the opinions of other people	[14], [15]	2
L.T9	Team responsibility	[14], [16]	2
L.T10	Treating team members as people, not a resource	[14], [20]	2
L.T11	Openness to others	[14], [20]	2
L.T12	Sincerity	[14], [21]	2
L.T13	A relaxed atmosphere	[19], [20]	2
L.T14	Equality in the team	[14]	1
L.T15	Sense of security	[4]	1
L.T16	Focus on people instead of on processes	[16]	1
L.T17	Not blaming each other	[16]	1
L.T18	Not covering up the failures	[18]	1
L.T19	Searching for a solution to the problem instead of finding the guilty	[18]	1
L.I1	Continuous improvement and learning	[12], [13], [14], [4], [15], [16], [17], [18], [20]	9
L.I2	Openness to change	[12], [13], [14], [4], [16], [17], [18], [20]	8
L.I3	Being motivated	[12], [13], [14], [16], [19], [20]	6
L.I4	Treating failure as an opportunity to learn, learning from mistakes	[4], [16], [17], [20], [21]	5
L.I5	Creativity, innovation	[13], [18], [19]	3
L.I6	Ability to accept failure and deal with it	[17], [18], [21]	3
L.I7	Taking risks	[4], [17]	2
L.I8	Willingness to constantly acquire knowledge	[15], [18]	2
L.I9	Positive attitude	[18], [19]	2
L.II0	Assertiveness	[14]	1
L.II1	Focus on the task being performed	[4]	1
L.II2	A sense of pride in the job	[17]	1
L.II3	Not giving up	[18]	1
L.II4	Inquisitiveness	[18]	1
L.II5	Pragmatism	[18]	1
L.O1	Self-organization	[12], [13], [14], [4], [15], [16], [19]	7
L.O2	Ability to collaborate	[12], [13], [14], [4], [16], [17], [20]	7
L.O3	Maintaining a steady pace of work	[12], [13], [14], [4], [16], [20]	6
L.O4	Sharing knowledge and results	[12], [13], [14], [18], [19], [20]	6
L.O5	Simplicity and maximization of unnecessary work, simplifying tasks	[12], [13], [14], [4], [16]	5
L.O6	Transparency in decision-making and actions	[12], [14], [4], [20], [21]	5
L.O7	Ability to make decisions together	[12], [13], [14], [15]	4
L.O8	Interdisciplinarity	[12], [13], [14]	3
L.O9	Attitude towards working in short iterations with small increments	[14], [16]	2
L.O10	Applying retrospectives to identify areas for improvement	[14], [16]	2
L.O11	Understanding the purpose and vision of the task before taking it	[4], [15]	2
L.O12	Focus on cross-functional teams	[15]	1
L.O13	Expressing feedback on the work of other people	[15]	1
L.O14	Estimating the results for a given timeframe	[16]	1
L.O15	Determining possible tasks instead of looking for excuses	[18]	1
L.O16	Asking questions in case of insufficient knowledge	[20]	1
L.O17	Focus on one task instead of many at once	[21]	1
L.O18	Finishing the current task before taking the next one	[21]	1

C. Final list merged from literature and interviews

Finally, we merged the lists of agile mindset elements identified from literature and with the interviews. The resulting list of unique agile mindset elements comprises 70 entries, which exceeds the limitations of this paper. However, all identified agile mindset elements were already shown in Table II and Table III. Table IV shows the number of agile mindset elements in each category identified in the literature and the interviews as well as the number of unique elements in our final list.

TABLE IV.  
NUMBER OF IDENTIFIED AGILE MINDSET ELEMENTS

Category	Literature	Interviews	Unique
Support for business goals	6	4	7
Relationships within the team	19	11	20
Individual features	15	16	24
Organization of work	18	8	19
Total	58	39	70

IV. SELECTION OF AGILE MINDSET ELEMENTS

Based on the criteria presented in section II, we have selected 26 elements of agile mindset out of 70 for further evaluation with the opinion survey. We selected 3 elements out of 7 in the “support for business goals” category, 10 elements out of 20 in the “relationships within the team” category, 6 elements out of 24 in the “individual features” category, and 7 elements out of 19 in the “organization of work” category. We could observe that 13 elements in the “individual features” category as well as 8 elements in the “organization of work” category were mentioned only in one source, be it literature or interview.

The list of elements selected for the survey is shown in Table V.  $n_L$  column presents the number of literature sources, while  $n_E$  column presents the number of experts mentioning each element. The final unique agile mindset elements were given new identifiers prefixed with the category symbol only, as described in section III. The identifiers of the merged elements from the literature (see Table III) and the interviews (see Table II) are given in columns  $ID_L$  and  $ID_E$ , respectively.

TABLE V.  
ELEMENTS OF THE AGILE MINDSET SELECTED FOR THE SURVEY

ID	Element name	$n_L$	$n_E$	$ID_L$	$ID_E$
G1	Continuous delivery of a valuable product in short intervals	7	1	L.G1	E.G3
G2	Cooperation with the customer based on partnership	1	3	L.G6	E.G1
G3	Attitude towards customer satisfaction and needs	5	2	L.G2	E.G2
T1	Mutual trust	8	5	L.T1	E.T1
T2	Direct communication - face to face conversations	7	2	L.T2	E.T9
T3	Focus on achieving common goal	6	3	L.T3	E.T7
T4	Helping each other	3	4	L.T5	E.T3
T5	Sincerity	2	4	L.T12	E.T2

T6	Mutual respect	5	3	L.T4	E.T5
T7	Mutual listening	0	3	-	E.T4
T8	Equality in the team	1	3	L.T14	E.T6
T9	Searching for a solution to the problem instead of finding the guilty	1	2	L.T19	E.T8
T10	Team responsibility	2	2	L.T9	E.T10
I1	Continuous improvement and learning	9	3	L.I1	E.I3
I2	Openness to change	8	5	L.I2	E.I1
I3	Being motivated	6	2	L.I3	E.I4
I4	Positive attitude	2	3	L.I9	E.I2
I5	Openness to criticism and feedback	0	2	-	E.I5
I6	Openness to others	0	2	-	E.I6
O1	Self-organization	7	4	L.O1	E.O1
O2	Maintaining a steady pace of work	6	2	L.O3	E.O4
O3	Ability to collaborate	7	0	L.O2	-
O4	Sharing knowledge and results	6	1	L.O4	E.O6
O5	Asking questions in case of insufficient knowledge	1	3	L.O16	E.O3
O6	Finishing the current task before taking the next one	1	3	L.O18	E.O2
O7	Transparency in decision-making and actions	5	2	L.O6	E.O5

V. EVALUATION OF AGILE MINDSET ELEMENTS

A. Characteristics of respondents

The evaluation survey was carried out in late June and early July 2018. The questionnaire comprised 5 sections: an introductory section and 4 sections with the agile mindset elements to evaluate grouped into their categories. In total, 52 respondents took part in the survey. Table VI shows the distribution of the respondents’ experience with agile. Most of the respondents (52%) had at least 2 years of experience.

TABLE VI.  
DISTRIBUTION OF THE EXPERIENCE OF SURVEY RESPONDENTS

Experience years	n
<1	7
1-2	18
2-3	13
3-5	7
>5	7

Table VII shows the distribution of respondents’ roles in agile teams. Most of them worked as developers (about 60%), while others worked mostly as Scrum Masters.

TABLE VII.  
DISTRIBUTION OF THE ROLES OF SURVEY RESPONDENTS

Role	n
Developer	31
Scrum Master	13
Tester	3
Product Owner	2
Agile Coach	1
Analyst	1
UX Designer	1

### B. Evaluation of agile mindset elements and categories

Table VIII presents the evaluation of the importance of selected agile mindset elements to the effectiveness of an agile team according to the respondents' opinion. E shows the mean evaluation of an agile mindset element in the Likert-type scale of 0 to 5 with standard deviation; n gives the sample size. The sample size slightly differs for some elements due to the option to skip an element in the survey. The elements are ordered by their decreasing evaluation.

TABLE VIII.  
EVALUATION OF THE IMPORTANCE OF AGILE MINDSET ELEMENTS TO THE TEAM EFFECTIVENESS

No.	ID	Element name	E	n
1	T9	Searching for a solution to the problem instead of finding the guilty	4.44 (0.79)	52
2	I3	Being motivated	4.44 (0.69)	52
3	T4	Helping each other	4.40 (0.63)	52
4	T7	Mutual listening	4.37 (0.71)	51
5	T3	Focus on achieving common goal	4.29 (0.77)	52
6	I5	Openness to criticism and feedback	4.23 (0.82)	52
7	O4	Sharing knowledge and results	4.21 (0.86)	52
8	T6	Mutual respect	4.11 (0.91)	52
9	T1	Mutual trust	4.10 (0.96)	51
10	T5	Sincerity	4.09 (0.97)	52
11	I1	Continuous improvement and learning	4.08 (1.00)	52
12	O7	Transparency in decision-making and actions	4.08 (1.03)	52
13	O1	Self-organization	4.04 (0.88)	52
14	I2	Openness to change	4.00 (1.02)	52
15	G1	Continuous delivery of a valuable product in short intervals	3.96 (1.04)	52
16	G3	Attitude towards customer satisfaction and needs	3.92 (0.83)	52
17	G2	Cooperation with the customer based on partnership	3.88 (0.97)	52
18	I6	Openness to others	3.88 (0.97)	52
19	O6	Finishing the current task before taking the next one	3.86 (1.06)	52
20	I4	Positive attitude	3.84 (0.77)	52
21	O3	Ability to collaborate	3.81 (0.90)	52
22	O5	Asking questions in case of insufficient knowledge	3.74 (1.06)	51
23	T2	Direct communication - face to face conversations	3.69 (1.26)	52
24	T8	Equality in the team	3.42 (1.28)	52
25	T10	Team responsibility	3.23 (1.31)	52
26	O2	Maintaining a steady pace of work	3.04 (1.34)	52

It can be seen that the top evaluated elements reached the evaluation of about 4.5 out of 5. 14 out of 26 elements reached the evaluation of 4.0 and above. They can be considered the recommended agile mindset elements in our survey. The lowest evaluated elements obtained the score of less than 3.5. However it should be noted that the standard deviation of the evaluations of the last 4 elements is the highest in all our study (about 1.3). Other elements were evaluated with the standard deviation of 0.69 to 1.06.

We have also calculated the mean evaluation of all agile mindset elements in particular categories which is presented in Table IX. It can be observed that "individual features" are evaluated as the most important category. Next is "relationships within the team", followed by "support for business goal". "Organization of work" scored the lowest mean evaluation of all categories.

TABLE IX.  
MEAN EVALUATION OF THE AGILE MINDSET CATEGORIES

Category	E	n
Support for business goals	3.92 (0.95)	156
Relationships within the team	4.02 (1.07)	518
Individual features	4.08 (0.91)	312
Organization of work	3.83 (1.09)	363

### C. Analysis of confounding variables

We have analyzed the respondents' experience and role as confounding variables in the evaluations of agile mindset elements. The results are presented in Table X and Table XI.

TABLE X.  
EVALUATION OF AGILE MINDSET ELEMENTS BY EXPERIENCE

ID	Element name	E <sub>exp&lt;2</sub>	E <sub>exp&gt;=2</sub>	p
G1	Continuous delivery of a valuable product in short intervals	4.08	3.82	0.362
G2	Cooperation with the customer based on partnership	3.88	3.93	0.870
G3	Attitude towards customer satisfaction and needs	3.88	3.85	0.914
T1	Mutual trust	4.20	4.00	0.465
T2	Direct communication - face to face conversations	3.76	3.67	0.795
T3	Focus on achieving common goal	4.40	4.19	0.323
T4	Helping each other	4.44	4.37	0.697
T5	Sincerity	4.28	3.93	0.194
T6	Mutual respect	4.12	4.11	0.973
T7	Mutual listening	4.32	4.42	0.614
T8	Equality in the team	3.48	3.37	0.763
T9	Searching for a solution to the problem instead of finding the guilty	4.60	4.30	0.175
T10	Team responsibility	2.96	3.48	0.158
I1	Continuous improvement and learning	4.12	4.04	0.770
I2	Openness to change	3.96	4.04	0.790
I3	Being motivated	4.56	4.33	0.246
I4	Positive attitude	4.04	4.67	0.083
I5	Openness to criticism and feedback	4.36	4.11	0.285
I6	Openness to others	4.24	3.56	0.018
O1	Self-organization	4.28	3.82	0.057
O2	Maintaining a steady pace of work	3.00	3.07	0.393
O3	Ability to collaborate	4.00	3.63	0.143
O4	Sharing knowledge and results	4.32	4.11	0.393
O5	Asking questions in case of insufficient knowledge	3.96	3.56	0.184
O6	Finishing the current task before taking the next one	3.92	3.93	0.981
O7	Transparency in decision-making and actions	3.96	4.19	0.443

We have used the t-Student test for independent pairs to analyze the differences in mean evaluations depending on experience and role. Treating our data as numerical, this test is suitable for such analysis [11]. We assumed equal variances of the grouped samples and the confidence level of 95% ( $\alpha=0.05$ ).

For the experience test we divided our sample into two groups: less than 2 years of experience and 2 or more years of experience (group sizes were 25 and 27, respectively, which satisfies the prerequisites to the selected test). The mean evaluations are given in Table X in the  $E_{exp<2}$  and  $E_{exp>=2}$  columns, respectively, followed by the p-value of the t-Student test.

For the role test we divided our sample into two groups: developers and non-developers (group sizes were 31 and 21, respectively). Other divisions were not possible due to insufficient number of samples for the prerequisites of the selected test. The mean evaluations are given in Table XI in the  $E_{dev}$  and  $E_{ndev}$  columns, respectively, followed by the p-value of the t-Student test.

TABLE XI.  
EVALUATION OF AGILE MINDSET ELEMENTS BY ROLE

ID	Element name	$E_{dev}$	$E_{ndev}$	p
G1	Continuous delivery of a valuable product in short intervals	3.98	3.91	0.832
G2	Cooperation with the customer based on partnership	3.87	3.95	0.775
G3	Attitude towards customer satisfaction and needs	3.87	3.86	0.959
T1	Mutual trust	4.00	4.25	0.371
T2	Direct communication - face to face conversations	3.39	4.14	0.035
T3	Focus on achieving common goal	4.36	4.19	0.459
T4	Helping each other	4.42	4.38	0.833
T5	Sincerity	4.03	4.19	0.571
T6	Mutual respect	4.19	4.00	0.463
T7	Mutual listening	4.47	4.24	0.269
T8	Equality in the team	3.48	3.29	0.595
T9	Searching for a solution to the problem instead of finding the guilty	4.52	4.33	0.426
T10	Team responsibility	3.19	3.29	0.808
I1	Continuous improvement and learning	3.94	4.29	0.222
I2	Openness to change	3.87	4.19	0.276
I3	Being motivated	4.52	4.33	0.359
I4	Positive attitude	3.84	3.86	0.934
I5	Openness to criticism and feedback	4.32	4.10	0.338
I6	Openness to others	3.94	3.81	0.655
O1	Self-organization	4.07	4.00	0.799
O2	Maintaining a steady pace of work	2.90	3.24	0.388
O3	Ability to collaborate	3.71	3.95	0.350
O4	Sharing knowledge and results	4.19	4.24	0.858
O5	Asking questions in case of insufficient knowledge	3.83	3.62	0.489
O6	Finishing the current task before taking the next one	3.65	4.19	0.070
O7	Transparency in decision-making and actions	4.10	4.05	0.870

Both tests showed that the impact of both experience and role on nearly all of the evaluations could not be considered statistically significant with the assumed confidence level of 95% and sample size of 52. However, two agile mindset elements stood out. The evaluation of I6 element “Openness to others” exhibited statistically significant difference in the evaluation depending on respondents’ experience ( $p<\alpha$  in Table X). It was evaluated much higher (4.24 compared to 3.56) by the respondents with less than 2 years of experience. The evaluation of T2 element “Direct communication - face to face conversations” exhibited statistically significant difference in the evaluation depending on respondents’ role ( $p<\alpha$  in Table XI). It was evaluated much lower (3.39 compared to 4.14) by the developers.

D. Comparison to the principles behind Agile Manifesto

We have mapped the elements of agile mindset in our study to the 12 principles behind the Agile Manifesto [2] and analyzed the evaluation and relative position of the agile mindset elements that map directly onto these principles. The results are shown in Table XII. P# column shows the Agile principle number.

TABLE XII.  
MAPPING OF AGILE MINDSET ELEMENTS ON AGILE PRINCIPLES

No.	ID	Element name	E	P#
2	I3	Being motivated	4.44 (0.69)	5
9	T1	Mutual trust	4.10 (0.96)	5
11	I1	Continuous improvement and learning	4.08 (1.00)	12
13	O1	Self-organization	4.04 (0.88)	11
14	I2	Openness to change	4.00 (1.02)	2
15	G1	Continuous delivery of a valuable product in short intervals	3.96 (1.04)	1, 3, 7
16	G3	Attitude towards customer satisfaction and needs	3.92 (0.83)	1
17	G2	Cooperation with the customer based on partnership	3.88 (0.97)	4
23	T2	Direct communication - face to face conversations	3.69 (1.26)	6
26	O2	Maintaining a steady pace of work	3.04 (1.34)	8

It can be seen that only the I3 agile mindset element mapped to the 5<sup>th</sup> Agile principle was evaluated very high (4.44, position 2). Elements mapped to most of the Agile principles were evaluated in the middle range (4.10 to 3.88, positions 9 to 17). However, the elements T2 and O2 mapped to 6<sup>th</sup> and 8<sup>th</sup> principle respectively were evaluated very low (3.69 and 3.04, position 23 and 26 (last)). Remaining 2 Agile principles mapped to the agile mindset elements that were excluded from the survey.

VI. THREATS TO VALIDITY

A. Threats to construct and internal validity

We have identified and reduced the following threats to the construct and internal validity of this research related to

the interviews and the survey: (a) interview moderator's bias and influence on experts, (b) misinterpretation of the interview outputs, (c) learning and tiring of the survey respondents, (d) forced answers to the survey.

We have controlled the interview moderator's bias and their influence on experts with the structure of the interview. Each interview followed the same protocol (Section II). To minimize misinterpretations, the interviews were recorded, transcribed and thoroughly analyzed while relistening to the recordings, if necessary. The results of each interview have been coded separately and only then merged together.

The survey questions were not randomized to minimize the impact of learning and tiring of the respondents due to the limitation of the Google Forms tool. However, the survey was conveniently divided into 5 sections and contained only 26 evaluation questions. The survey also allowed the respondents to skip the evaluation of a particular agile mindset element when unsure.

### B. Threats to external validity

We have identified the following threats to the external validity of the interviews and the survey: (a) low number of interviewed experts and survey respondents, (b) insufficient experience of interview experts and survey respondents, (c) interview experts and survey respondents as a convenience sample, (d) interview experts and survey respondents sample limited to Polish IT industry.

We have interviewed 5 experts from the industry. The interviewed experts had 2 to 5 years of experience in Agile. We aimed at covering various roles in an agile team and experiences with various agile methods. We engaged 2 Scrum Masters with broad experience (see Table I) Altogether, the input from experts supplemented the list of 58 agile mindset elements from the literature by 22 new elements (38%), which can be considered a substantial contribution (see Table IV).

We have collected data from 52 respondents in the survey, which definitely exceeded the typical threshold sample size of 30 for the choice of the statistical tests [11]. 52% of the respondents had at least 2 years of experience. 13.5% of the respondents had more than 5 years of experience (see Table VI). The respondents represented various roles in the agile team, which covered diverse points of view (see Table VII). Moreover, we have analyzed the impact of the respondents' experience and role as the confounding variables on the validity of our results, which showed marginal impact (Section V.C).

Our survey sample is not statistically random – it is a convenience sample, although we invited the respondents through various channels like personal and business contacts, interest groups, social media, and recommendations. This method provided for a fairly diverse group of experts and respondents with different experience. The experts and respondents used many agile methods such as: Scrum, Kanban, Scrumban, Extreme Programming, SAFe.

The survey was in Polish and possibly attracted most of the respondents among the peers of one of the authors (P. Gaida) working in the Tricity region of Poland, so the results it may exhibit some cultural or regional bias, which needs to be studied further. Comparison of the perception of the concept of agile mindset in Poland and other countries may bring valuable insights.

We have asked our respondents only for their (self-declared) experience in agile and their role in an agile team. We have not collected other data such as company size, age, industry sector or type of projects they worked on. Thus, our study provides only preliminary insight into the conceptual structure of the agile mindset.

## VII. DISCUSSION

The top 5 evaluated agile mindset elements are: "Searching for a solution to the problem instead of finding the guilty", "Being motivated", "Helping each other", "Mutual listening", and "Focus on achieving common goal". They belong only to two categories: "relationships within the team" and "individual features". This suggests that effective agile teamwork requires a specific attitude towards the team and other people as well as proactive and open mind of the individuals. This corresponds with the "growth mindset" concept from Dweck [3].

The 5 least important mindset elements in our survey are: "Asking questions in case of insufficient knowledge", "Direct communication - face to face conversations", "Equality in the team", "Team responsibility", "Maintaining a steady pace of work". They are related to organizational issues as well as shared responsibility and equality. This suggests that agile mindset is not about particular detailed practices or rituals. This is consistent with earlier findings [21, 22, 23, 24].

We have found that less experienced respondents evaluated the "Openness to others" mindset element much higher than those with more than 2 years of experience. Our working hypothesis is that it is related to learning and gathering experience at the start of the professional career. However, "openness" in general is crucial to being agile [2].

The developers considered "face to face communication" less important than the non-developers. Our working hypothesis is that they may see the meetings as (partial) waste of time that diverts them from coding. This may also indicate some overuse or misuse of meetings in the agile teams of our respondents.

We were also able to map the principles behind the Agile Manifesto [2] onto 10 evaluated elements of the agile mindset. These elements occupied positions 2, 11, 13, 14, 15, 16, 17, 23, and 26 (last) in our ranking ordered by the descending evaluation. This is an interesting discrepancy between what our respondents think is important to "being agile" and what the creators of the Agile Manifesto pointed out as the principles of Agile. We can hypothesize that this indicates insufficient understanding of Agile by our

respondents, partial or flawed implementation of Agile in the respondents' teams or companies, or even a shift in practical agility from the 18 years old principles of Agile. This may also be specific to Polish IT industry and have some cultural background. Definitely, it calls for more research.

Our study is based on limited data on the respondents themselves. We have clustered the data by two levels of experience (below and above 2 years) and two types of roles (developers and non-developers). The understanding of the agile mindset may also vary by the industry sector, company size, company culture and maturity, type of projects, national and regional culture and possibly more. Our initial set of agile mindset elements may be used in such further studies.

### VIII. CONCLUSIONS

We have identified 70 elements of the agile mindset from the literature and the industry experts, which answer our research question RQ1. We grouped the elements into 4 categories. Then, we have obtained an opinion-based evaluation of the importance of each agile mindset element to the effectiveness of an agile team, which answers our research question RQ2. Finally, we have analyzed and compared the evaluations to point out the most and least important elements based on the opinions of our respondents, which provides a preliminary answer to our research question RQ3. Further and more detailed study of the impact of agile mindset on the team effectiveness requires careful observation of a number of different types of projects and can be done in future research.

The detailed contribution of this paper is the identification of the elements of agile mindset as well as a preliminary evaluation of their importance to the effectiveness of an agile team based on an industrial opinion survey. This contributes to filling the gap in the literature related to the definition and scope of the agile mindset and the relative importance of its elements in the industry and education [22, 23, 24, 25].

The proposed list of agile mindset elements and their evaluations may be used as a guidance for developers, Scrum Masters and Agile coaches, where the possible applications include: (1) support for the Scrum Masters or coaches in improving the understanding of Agile by the Development Teams; (2) recommendations of improving the agile process and solving problems identified during retrospectives; (3) education and training both in the industry and academia; (4) self-development of the developers, in particular those seeking to switch to Scrum Masters or coaches. Full results of this research are available in [26]. The raw results of our survey are available in [27].

### ACKNOWLEDGMENT

The authors thank all the experts and respondents who took part in the interviews and the survey.

**Abstract**—Organizations are looking for ways of establishing agile and lean process for delivery. Many approaches exist in the form of frameworks, methods and tools to setup an individual composition for a best fit. The challenge is that large organizations are heterogeneous and diverse, and hence there is no “one size fits all” approach. To facilitate a systematic implementation of agile and lean, this article proposes a transition kit based on abstraction. This kit scouts and bundles state of the art methods and tools from the agile and lean community to align them with governance and compliance aspects of the specific enterprise. Coaching of the application of the transition kit ensures an adequate instantiation. The instantiation handles business domain specific aspects and standards. A coaching governance ensures continuous improvement. An example of the systematic application of the transition approach as well as its scaling is demonstrated through its application in the Volkswagen Group IT.

## I. INTRODUCTION

THE DIVERSITY of an enterprise’s business areas demands individualized implementations of lean and agile. Often the main goal of the agile transition is to gain delivery speed. According to Albert Einstein: “Make everything as simple as possible, but not simpler”, we have to find a way to achieve effectively the simple yet complete organizational setting. Furthermore, Conway’s law [44] leads us to develop something customizable to build a lean and agile organization for a best fit to the specific products and services, which the organizational unit creates and delivers. These two aspects have to be handled to realize a lasting and sustainable transformation.

Large established enterprises are built around different business areas with independent business units or divisions in a matrix structure [1]. Most of these business units have the size of a medium-sized enterprise. Furthermore, large enterprises are mostly based on large delivery pipelines oriented on the efficiency paradigm of the Taylorism [45]. Any transition aid for application within such context has to be able to handle this setting. More specifically during our first operational coaching of projects within the Volkswagen Group IT in past transformation initiatives we identified the following aspects an agile transition aid has to address:

- 1) Identify the target organization for the transition, including its boundaries.
- 2) Identify the organization’s value stream, including interfaces at the boundary to “external” partners.
- 3) Define and clarify the transition’s objectives.
- 4) Evaluate different approaches to lean and agile for their suitability in the particular organizational context.
- 5) Implement the selected approaches:
  - Train people in the approach.
  - Re-organize the workflows according to the approach.
  - Align the new setting with the enterprise’s governance and compliance structures.
- 6) Install cyclic checks for transparency and improvement:
  - on a local view of the transition for “self-optimization”;
  - on a global enterprise view to develop the “setting”;
  - offer an open networking platform to reflect transitions.
- 7) Support scaling of transitions

This leads to the investigation question: How is it possible to address these demands with an easy to handle approach, which can be applied by a team of coaches in a structured fashion? Our objectives for achieving this are the following:

- (O1) A transition kit is needed that is able to handle lean and agile approaches.
- (O2) Based on the organization’s stakeholders’ current mindsets a specific set of methods and tools for the workflows has to be implemented.
- (O3) The organization’s specific product setting has to be taken into account appropriately.

## II. RELATED WORKS

This section investigates related published work with a focus on a holistic approach to addressing those. There is a huge amount of relevant approaches to organizational development [2], alternative setups like holacracy [3] or transitions [34] starting on grounded theories [32] to practice collections of other enterprises [33]. We are interested in identifying well-known approaches, methods and tools that can be used as a kind of reference in various settings to reduce complexity. Our contribution is to bring together the

team setting with its cultural and mental history thanks to an adequate set of approaches, methods and tools to realize a effective and sustainable transition. We structured related work according to this scope, rather than elaborating on all kinds of available methods and tools at the time of writing this article.

#### A. Setting Analysis

The Cynefin [5] and the Stacey-matrix [7] are approaches to classify the product context into a complexity setting and the drivers of the transformation [36]. This are useful approaches to identify the development context of the transitions product environment. The spiral dynamics model [4] and the Group Development Questionnaire (GDQ) [8] classifies the maturity of a group of humans who focusing together on an objective or purpose. As setup point on the teams maturity for transition approaches and methods this is crucial. Value-stream mapping [6] is an approach to optimize processes in a given setting especially for software [35] which come for the production [46] to the software development [47].

#### B. Lean and Agile Approaches

Scrum [13] and XP [15] are team approaches focusing on agile working. Kanban [14] works in a team and in bigger organizations. SAFe [9], LeSS [10], Nexus [11] and Scrum@Scale [12] are approaches to handle the synchronization of more teams in a bigger organization. Furthermore a lot of variants are existing like Disciplined agile delivery (DAD [48] or Agile modeling (AM) [49].

#### C. Methods and Tools

Design Thinking (DT) [16] is a method to develop an initial product in an iterative hypothesis based manner. Minimum Viable Product (MVP) [17] and derivations like Simple Lovable and Complete (SLC) [18] are tools to define an initial product version for delivery. Business Model Canvas (BMC) [19] or Lean Canvas [50] and its variants like for organizations internal communication [20] are used to identify the setting of a business to optimize in a later step the value-stream for product and its revenues. The Product Vision Board (PVB) [21] is used to for focusing a team on a product. INVEST [22] is used to systematically identify requirements for a product. Definition of Done (DoD) [23] or derivations like Levels of Done (LoD) are used to ensure that product versions fit quality definitions. To keep the delivery procedure lean and focused Product Quality Risk (PQR) [24] mitigation can guide to the delivery.

#### D. Organizational culture and team psychology

The culture moves to a more internal lean start up [26] setting also in bigger enterprises. The objective of most digital business models [19] is scaling into the mass-markets [25]. Coaching approaches are reflected to be effective in the setting [27] to address the agile teams.

#### E. Governance, Risk and Compliance

Governance has to establish standards like ISO 9000 for quality management, standards for risk management like the ISO 31000 and additional domain specific standards. Approaches for agile risk handling exists [31]. For service management, the ISO 20000 is an established anchor. Some concepts for agile governance [28] and [29] exist, however their scope is limited to applying agile or lean principles outside a globally acting [30] enterprise context.

### III. TRANSITION PROCESS

Within Volkswagen Group IT, we do not use one given method, model or tool because the organizations' s size demands context adequate approaches. More than 2000 internal employees and a lot of divisions and organizational units indicates the complexity which the transformation has to deal with. Therefore we decided to start with the basis: the team.

A transition kit and process has been developed and maintained by a central team, the Agile Center of Excellence (ACE), which guides and coaches agile transitions. ACE is a department within the Group IT uniting initial agile users from the first agile projects. The transition process consists of three phases: the transition itself, as well as a pre- and post-transition phase to ensure sustainable transitions. ACE supports transitions in the Group IT and other business areas of the Volkswagen AG based on their transition process and kit that has been enhanced over years.

The coaches establish the initial setup and alignment during the coaching phase of the team's external process expectations (figure 1). This is the initial link to process safety and compliance for the teams. The long-term alignment is checked by the project review.

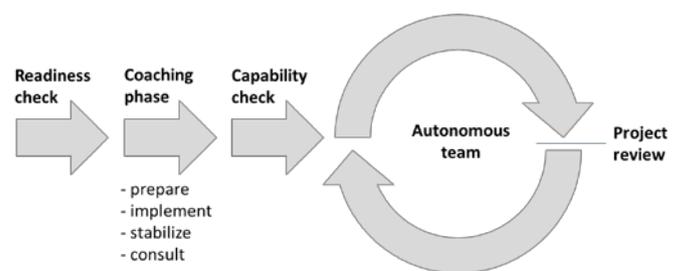

Fig. 1: Coaching to team autonomy with integrated compliance check

In the pre-transition phase, the “readiness check” is conducted to identify the status quo and objectives of the transition. The status quo identifies roles like sponsor of the transition, product/business owner and the team setting. Furthermore, agile artifacts like for the backlog and its items are investigated. Based on the evaluation of the acquired information, a transition can be recommend or not. In case of recommendation, the ACE can support the transition with the transition kit. In case of a non-recommendation to start a transition, the ACE will not support because there is low

chance to finish the transition in time successfully. The biggest challenge during this phase is the interlocutor's honesty. All transition aspects are based on it and conveying information honestly and completely is needed to give the transition a chance to be successful. Therefore we decided that we start the transition with motivated and voluntary units supporting the transition and meeting the prerequisites from the outset.

The main purpose of the transition kit is to enable teams to deliver most product benefit within in a continuously changing environment. The ACE coaches help start agile projects and teach the team how to deal with impediments. Additional ACE tasks are:

- first aid in network,
- promoting agile methods,
- connecting committees,
- supporting knowledge transfer,
- combining agility practices of brands,
- enable leadership to act in an agile way,
- sensitize the unit to get an agile mindset,
- pay attention to process safety.

Every transition phase starts with a contract clarification to get a clear understanding of what will happen. Referring to the Agile Manifesto [39], the contract does not describe the HOW, but rather the WHAT. Depending on the results of the "readiness check" and the needs of a team, product or project, the transition duration will be estimated and a coaching package will be offered (cf. Section V). The contract defines the purpose, deliverables from both sides and the organizational issues like contractor and cost issues. The transition itself has four steps:

1. Preparation (evaluation of team and product setting)
2. Implement the methods and the tooling
3. Stabilization
4. Consulting

The *preparation* includes the execution of a kickoff workshop, consulting (project leads, development team) and agile workflow creation. Also includes support, moderation, preparation of the management and creation of Definition of Ready/Definition of Done and initial product backlog with the team. The initiation of the first meetings like refinement, planning, review and retrospective is a task, too.

To *implement the methods and the tooling* the guide is always available for the team. The coaches train the team and the roles inside e.g. Scrum Master, Product Owner etc. to do the job to be done. The guide also moderates the necessary meetings like review, daily, retrospective, planning or refinement. Furthermore the guide assists the change management for motivation, conflict solving and workflow changes. The coaches are instantiating the initial setup and alignment of team external process expectations. This is the initial link to process safety and compliance for the teams. The long-term alignment is checked by the project review of the post-transition phase.

The *stabilization* step during the coaching (figure 1) is not so intensive for the coaches because the team should do their

first steps alone. The coaches are always available for support and assistance, and in special cases will also assume the role of moderators. In this step, their job is to motivate, inspect, adapt and strengthen the change to be sustained. Solving conflicts is also part of it.

The *consulting* step is demand driven and mostly the end of the transition phase (figure 1). If the customer needs help, the coaches will help and give answers for questions to events, roles and workflow. The guides help the change management manage conflicts and adapt innovations.

The post-transition phase starts with a hold back (capability check in figure 1) of the transition team during the stabilization step and ends with a report. The report reflects the coaching contract objectives and also the agile issues and elements. Furthermore, the team or organization is registered as "agile". This flag will be used for the future agile governance checks (cf. Section VI) to ensure sustainability of the transition and incremental development of the people to stay up to date about the state of the art about agile.

#### IV. TRANSITION KIT

For the demand of the Volkswagen Group IT to transform classic project management to business agility we developed the transition kit. It contains the methods and tools which are released during the transition process. Within the transition process, we try to find the best choice of approaches, methods and tools to create value faster. The transition kit addresses the implement step of figure 1. The transition kit focusses on the key parts of figure 2. These key parts are the product or service which is the delivery to the customer, the team realizing and supporting the products, as well as the governance ensuring organizational standards. Governance can also be triggered by external demands for example from legislative changes. The transition kit has to support the setup of the demanded skills and capabilities of the team from the outcome view (product/service). Furthermore the governance has to handle the product or service risks by guiding the teams to be able to balance the business value and risks related to the product or services they handle.

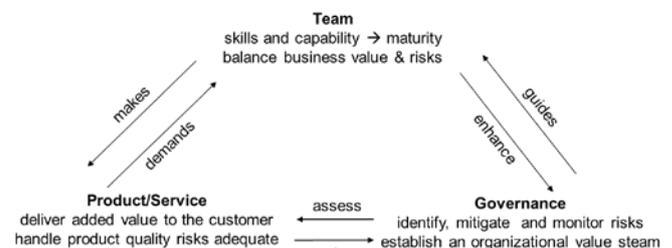

Fig. 2: Transition's key parts and their relationships

All three parts interact and need a holistic handling by the transition kit to realize a comprehensive product or service from the customer view who is using the product/service. The tool selection of the transition kit (table 1) is initially based on a first fit for purpose. This first fit was realized by a literature review [40] to identify artifacts for the initial transition kit. The transition kit contains approaches, methods and tools which helps the coach and team to go in an effective way into the right direction during the transition. Over the life cycle the transition kit will be enhanced by adding and changing artifacts to better fit the current organizational culture, for an easier integration into the coaching or simpler use in a self-service approach for teams without coaches. The enhancement is triggered by feedbacks. While everybody can suggest new artifacts for the transition kit, the ACE will evaluate and integrate relevant suggestions during their cyclic inspections. The objective is not to have a maximum of possible elements in the transition kit, but rather to have a lean transition kit that can be trained easily and is effective in most organizational settings. To make it easy to find the right artifacts the transition kit is aligned with the product complexity, team maturity and the agile approaches.

To identify the projects the ACE supports with coaches we use the Stacey matrix. It is an easy to use way to identify if agile is helpful or not.

The assignment of tools to phases is based on experience during the supported transitions. The determination of the appropriate transition kit artifacts is done according to the

following procedure: To start in a value-driven way, the initial focus of the transition is the product or service. The product is located on the Stacey-matrix. Over the product life-cycle, the complexity location is more or less stable in emerging markets – with a trend to reduction of complexity in mature markets or at the end of a product life-cycle. The current state is identified and the future result or objective will be considered to advance in the right direction. In a second step, the relevant governance guidelines are identified. Based on the product and governance demands, the current team skills and capabilities are focused on. The product team setting is located in the spiral dynamics model (table 2) color levels. This location is important because often organizations coined by Taylorism established over years, act on the “red level”. These teams have to make their mindset leaner to achieve the “blue level”. Agile teams typically act on levels of blue and higher. Each team has to grow level by level in their maturity. This leads to the adaptation of the used artifacts over the maturity journey of a team. Based on the team’s maturity and their product environment complexity, the appropriate agile approach will be selected mostly based on the suggestions of table 2, however the guide and the team can make adjustments if they think another artifact would fit better. The artifacts help the team to progress in the transition, but most of the transition effort is to enable and coach the team to deliver a product. Some examples about the experience-based labeling of the table: Why is Kanban applicable in beige teams? Kanban does not define a set on rituals like retrospectives from Scrum which demands a minimum level of trust in the team

TABLE I.  
TRANSITION KIT ARTIFACTS AND THEIR MAPPING TO TRANSITION SPECIFIC KEY-ASPECTS

Method/tool	Spiral dynamics team maturity	Stacey	Phase (average)	Application
Retrospective	Purple or higher	All	pre, mid, post	High (over 75%)
Design Thinking	Blue or higher	All	Pre	Low (under 25%)
Minimum Viable Product (MVP)	Orange or higher	Complex & complicated	Pre	Mid (25% to 75%)
Simple Lovable and Complete (SLC)	Blue or higher	Complex & complicated	Pre, mid	Low
Business Model Canvas (BMC)	Purple or higher	Complex & complicated	Pre	Low
Product Vision Board (PVB)	Purple or higher	Complex & complicated	Pre	Low
INVEST	Purple or higher	Complex & complicated	Mid	Mid
Definition of Ready (DoR)	Blue or higher	All	Pre, mid	Mid
Definition of Done (DoD)	Blue or higher	All	Pre, mid	Mid
Levels of Done (LoD)	Blue or higher	Complex & complicated	Mid	High
Product Quality Risk (PQR)	Red or higher	Complex & complicated	Mid	Low
Scrum	Purple or higher	Complex & complicated	Pre, mid	Mid
Extreme Programming	Green or higher	Complex & complicated	Pre, mid	High
KANBAN	Beige or higher	Complex & complicated	Pre	Low
SAFe	Red or higher	Complex & complicated	Pre, mid	Mid
LeSS	Blue or higher	Complex & complicated	Pre, mid	Low
Nexus	Orange or higher	Complex & complicated	Pre, mid	Low
Scrum@Scale	Orange or higher	Complex & complicated	Pre, mid	Low

TABLE II.  
MATURITY LEVELS OF THE SPIRAL DYNAMICS MODEL [4]

Name	Structure	Motives	Characteristics
Beige	Loose bands	Survival	Archaic, instinctive, basic, automatic
Purple	Tribes	Magic, Safety	Animistic, Tribalistic, Magical, Mystical
Red	Empires	Power, Dominance	Egocentric, Explorative, Impulsive, Rebellious
Blue	Pyramidal	Order, right & wrong	Absolutistic, Obedient, Purposeful, Authoritarian
Orange	Delegative	Autonomy, achievement	Materialistic, Strategic, Ambitious, Individualistic
Green	Egalitarian	Approval, Equality, Community	Relativistic, Personalistic, Sensitive, Pluralistic
Yellow	Interactive	Adaptability, Integration	Systemic, Conceptual, Ecological, Flexible
Tortoise	Global	Compassion, Harmony	Holistic, Global

to discuss issue frankly. Kanban itself is a more “mechanical” approach. Both approaches can be used to develop the teams to higher levels. With higher levels the teams are acting different within the same approach by discovering more opportunities with the higher team trust and openness. Why do we have small “item” like MVP and “big items” like Safe in the table? Depending on the context it is useful to start with small items to support individual transitions of teams. In case of a more top-down demand a big item reduces discussions about how to start because it is like a pre-defined “package” ready for rollout. This is also the reason why the transition kit does not add every approach, method or tool – it selects some (first fit algorithm based) which work in the industrial context and tries to reduce redundancy were it is useful and possible by offering enough variance for the individual coaching of teams. The objective for the transition kit is to offer a practicable way for the transition of a team, without proposing any way possible.

The transition kit does not focus on finance procedures of the enterprise however some programs are using for example MVP based finance planning to manage their annual budgets in an agile fashion. However the approaches, methods and tools can be applied to special functions. For example, the Group IT security organization was an early adapter.

The transition kit is designed to develop culture, team maturity and products/services together. Of course it is possible to enforce some methods or tools on lower leveled teams, but the real opportunities are only realized within the right culture and team context. The application column in

table 2 shows a current distribution of the application the line in teams.

## V. COACHING

ACE offers different volumes of coaching packages [37]. The package size is defined by the amount of time a team gets support from the transition team. The intensity depends on the time the guides (coaches) support the team. The coach sets up the team to address the demands and objectives of the transition by using the transition kit as guidance framework for the transition. The main focus of coaching is on the events, mindset, team performance, roles and their tasks, the used methods and how to inspect and adapt. Therefore the guide will use workshops with the whole team, as well as direct coaching.

Every coaching starts with a collection of information. This is necessary to find out what the transition (e.g. the project or team) really needs. To implement agility, the coach starts creating awareness of agile principles and values. With growing understanding, the flow will be created to support agile behavior. This means that the team can welcome and handle requirement changes having influence on the actors. The coach helps to give the team the power and knowledge they need. This is an ongoing process during all transition phases and may not be finished when the coach leaves the team.

When the transition goal is clear, the coach has to decide on which level to be most effective. If the transition has most effect on teams, the coach will focus on team members. The objective of the coach is to start small and establish the simplest possible set of artifacts from the transition kit to realize the objectives of the transition. For instance, if the coach decides implementing Scrum, he will support the Scrum team including the Scrum Master, the Product Owner and the development team. If the transition requires an organizational change, the coach will spend more time on management level where the responsibility for the portfolio is located. The tools and methods are all based on values and principles. The coach’s main task is to make clear what the effects of their actual application are. Furthermore, the coach facilitates the teams with methods and tools for generic product and service development. An example is requirements elicitation and engineering with the product vision board to align the requirements at least with epics and stories oriented with INVEST and PQR (cf. table 1).

## VI. GOVERNANCE

Each enterprise needs a governance structure ensuring that fundamental things are done in a deterministic way, and at minimum according to the state of the art. The state of the art is defined by organizational settings or derived from the market standard and regulations. Consequently, also all agile and lean teams have to establish and ensure the state of the art for their products and services. Depending on the product

specific aspects, on top of the state of the art additional factors have to be ensured, e.g. market advantages. During the coaching phase aligned with the transition kit this is delivered by a team external coach. The coach has to make the teams sensitive for this governance topic and their team responsibility to stay aligned in the future. After the coaching phase the teams are independent and have to care about the “update” to the developing state of the art on their own. To make it easier for the teams, the governance offers update information about state of the art changes, which can be adopted by the teams. However, the governance has to ensure the alignment with the rail guards and update them to fit the state of the art. Rail guards are typically artifacts ensuring that some basics are done by the teams like for example an approval evidence for a deployment. Furthermore, the governance has to verify the effectiveness of its settings. These effectiveness checks are realized with controls. Different (domain) standards for System and Organization Controls (SOC) like [42] exist, but all have in common that the effectiveness of the established procedures has to be adequately checked, and if needed an alignment action has to be triggered. To ensure alignment with the settings and the agile and lean mindset a project review is established [38]. The project review (see figure 1) checks different aspects of an agile team or organization. Depending on the project or product classification (based on risk etc.) it will be checked in a deterministic way or randomized picked for a review. This ensures a basic transparency of alignment with the state of the art of the current portfolio.

The reviews are conducted by some coaches who have been trained in the evaluation aspects and their rating criteria. This common understanding about the aspects and rating ensures comparable results to derive organizational issues. Furthermore, an objective is not to change existing review aspects to keep the historical results in the data-analysis pool.

The defined rail guards for the expected artifacts and outcomes for fulfilling external requirements like aspects of the GDPR [43] or quality standards like ISO 9000 are checked in the project review. The results are used on both levels, for the reviewed team as well as the overall organization. Most of the findings have to be addressed by the product teams, however some findings are seen in many teams. This is made by cyclic analysis of the project review results to identify “derivation pattern” which have to be addressed on the organizational level. A derivation pattern is identified if in a significant amount of the cyclic checks similar derivations are observed. This is the trigger to handle it not only on the specific product or service instance and start caring about it on a generic or organizational level. For each identified derivation pattern the governance checks why it does not fit to the product teams and their deliveries. This can lead to actions on the organizational level having a high bandwidth. Finally, there is the educational aspect that leads to inadequate setting – this is addressed by training or

coaching offers to establish the things as intended. This may lead to refactoring the rail guards or artifacts to fit better into the project teams and the organizational culture. Figure 2 shows the relation between the product, the team and the governance. The relation “enhance” in figure 2 leads to the learning that as much as possible should be structured as self-service for the teams to reach higher autonomy and better scaling. This initial higher effort to develop the governance outcomes as self-service capability empowers the teams to live their self-organization and responsibility. To give feedback to the teams in a gamification context, the top ranked project review results are posted on an intranet page as a “champions league table” involving the entire organization.

The development and update of the transition kit is an additional important task to assure alignment with current regulations and the developing state of the art over the time. The transition kit has to support the governance artifacts like the rail guards during the team settlement. To do this, external and internal triggers are established. For example, the PQR method from the transition kit directly helps to make transparent why things are done in this way for some governance measures. An objective of the improvement of the transition kit from the governance perspective is to integrate as many measures as possible into the product or service artifacts or their direct production procedures. This integration makes it leaner and easier for the product teams to align their work with the expected outcomes and measures.

The Volkswagen Agile Community (AC) is the chance for everybody to get updates and the information about current development of agile and lean. It is an open community for networking and share knowledge about agile and lean. This includes also topics about the transition kit and agile governance.

DACH30 [41] is a trans-enterprise network to share experience about agile and lean. Trainings and skills are developed together. This ensures that the transition kit is reflected by external experts and is updated to the current insights of other enterprises.

The objective of the governance is to give the teams as much freedom for agility as possible while still demanding sufficient discipline from the teams to fit the compliance framework.

## VII. EXPERIENCE REPORT

At Volkswagen AG Group IT, the transition kit development started in 2016 to support the coaches’ daily work and has been enhanced continuously by the ACE and the coach guild to address the challenges of migrating to lean and agile methods in a structured way. Currently more than 100 product/service teams and organizational entities have been coached based on the elements of the transition kit. All those elements have been deployed – some more often than others (see table 1, column application). The teams are from

the Group IT as well as other areas of the Volkswagen AG like plant production planning or vehicle development organizations, as well as smaller organizations like board member offices. The teams are supported during the transition in different life-cycle phases of their products and service. Some teams started on a green field, some were already established delivery teams. The range of software developed by the coached teams covers a wide range – from standardized ERP systems supporting human resources and production logistics to special software for supporting specific intellectual property of a business area. Also the architecture differs from established 3-tier architectures to cloud native micro-service based systems. The coaching phase differs in time from a few weeks to many months – depending on the size of the team or organization. Additionally, within the Volkswagen AG there exist a number of self-service based transitions which are often unknown to the ACE. By using the self-service, the teams have a low entry barrier because they can do it on their own way and speed, but the risk of applying inadequate elements of the transition kit is higher without an experienced coach.

The following parts of the case study reflect the objectives O1 to O3 and the observations of the application of the transition kit in the coaching phase as well as the results of the project reviews to have a long term perspective on the sustainability of the transition.

The lean and agile approaches are mapped to the transition kit artifacts to support the artifact selection. Depending on the approach, more or less options are offered to be chosen by the coaches and teams (O1). There is a trend in smaller teams without an end to end responsibility to use Kanban. This is motivated by the external process dependencies which limit the team's autonomy and freedom. The teams are often part of process driven value chains which drive the cycle time and delivery-dependencies. Hence, sprint commitments are not easy for the team. On the other side there is a trend to SAFe for transitions of multi-team organizations. Both show that the upper maturity levels are often not achieved.

The maturity derived from the spiral dynamics model of the teams is mapped to the transition kit artifacts to support especially lower leveled teams by choosing adequate approaches. With higher maturity levels the transition kit gets less importance because the teams have the capability of improving on their own and develop their appropriate way with supporting methods and tools to address their specific situation best (O2). Many teams have started their transition from the red or blue level Taylorism driven culture. However, some teams are built from scratch and in a greenfield area. Here, a quick move to “higher” levels is possible, because they do not have to learn to forget established habits and culture. The coaches typically can see some progress of one or two levels during their supporting phase. In the project reviews after a longer time a further progress can be observed. But in case of no strict application

of agile methods and mindset some teams also go down to their “roots” with Taylorism habits. For these teams a “refreshing” coaching phase is suggested, if they still want to become agile.

The specific product setting with the complexity and value stream is supported by the transition kit, too. The artifacts are mostly generic and fit to the typical product settings in the complex setting (O3). In the future it could be possible to simplify the transition kit more by substituting complexity specific artifacts by generic ones.

The fact that the agile teams investigated in the case study are not permanently co-located does not significantly impact the application of the transition kit because most of the teams have some cyclic common physical meetings like refinements or retrospectives and use in-between communication tools to setup virtual team rooms.

The case study identifies that all phases of the transition are applied and supported as intended by the transition kit as described in section IV. The transition kit makes it easier for new coaches to deliver transition support in a project-style to the teams in a standardized way. The integration of the transition kit in the holistic enterprise environment with a centralized product delivery process compliance helps the coaches and teams to be effective also from a compliance perspective. The controls of the effectiveness work because some transitions were not started because the environment did not fit according to the results of the readiness check.

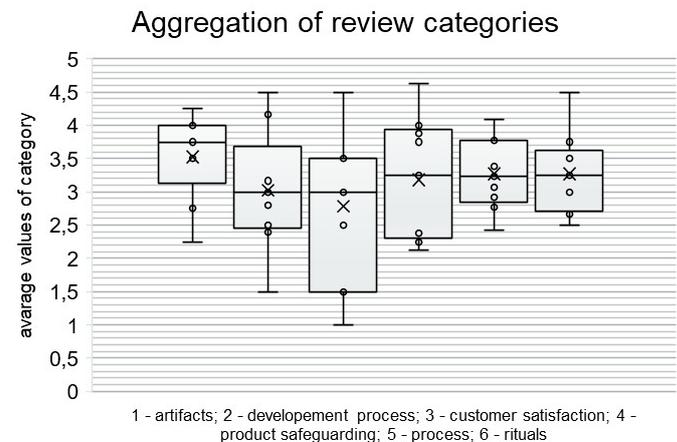

Fig. 3: Anonymized review results of the categories shows spreads and potentials (1 is most left bar – 6 most right bar)

The control project review with its check aspects helps to show the effectiveness of the transition and its sustainability in the teams later on (see Fig. 3). Based on these measurements and metrics for agile projects, agile processes, and agile teams the governance identifies improvement potentials. For example, one related to the agile development process (which is the 2<sup>nd</sup> bar in figure 3) effectiveness controls the re-thinking of the Group IT development process for a better alignment with agile and lean approaches and setting of guide lines which can easier integrated into operational excellence by the teams was indicated.

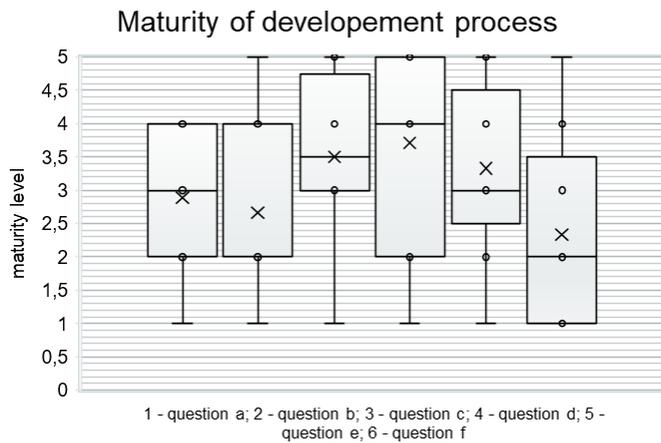

Fig. 4: Maturity of the agile development process (1 is most left bar – 6 most right bar)

Figure 4 shows the results of category agile development process of representative project reviews between 2017 and 2019. The x-axis are checked aspects of the project review which is aligned the teams agile adaption and the governance aspects. A more detailed description of the aspects and their grouping on the x-axis is in [38] described. The y-axis shows the fulfillment of the checked aspect. The bar in the middle shows the 2<sup>nd</sup> and 3<sup>rd</sup> quartile of values. The trend on derivations to the standardized templates of the development process is visible (every question has low values and almost all also high values – especially question f in figure 4). This derivation has led to the creation of a community of practice as a kind of working group whose mission is to enhance the Group IT development process to be better aligned with the state of the art habits of agile and lean working teams. This is one way of feedback to improve the environment to be more agile.

Often the coaches also identify new approaches, methods or tools which are evaluated as a kind of experiment during a selected team coaching. Results and lessons learned from this experiments are reflected in ACE to improve the transition kit. Furthermore, the case study shows that some transitions are not lasting or sustainable. The effectiveness of the transition is checked by the review with a delay to the coaching phase. By comparing the results achieved during the transition with the results of the progress reviews the progress or back-steps of the teams can be made transparent and thereby used for deriving the appropriate improvement actions. The selection of the reviews was made from feedback applications by randomized picking from the successful team transformation list and high-risk labeled projects/products. The highest frequency is one year for conducting reviews in a team. This is to avoid too many reviews in short time periods by random picking without the chance for the teams to improve in between reviews.

## VIII. CONCLUSION

The presented holistic scaling approach demonstrates that a centralized agile governance can help large enterprises

scale agile transitions in the product and service teams. This centralized ACEs coach guild and Agile Community are used to manage the agile knowledge and enhance the transition kit. The setup of a self-service driven team governance is a chance for establishing a lean governance approach. Furthermore the lean and agile mindset in governance offers the teams the chance to participate in the future “look and feel” of the governance, such as the development of higher automation of governance tasks and their evidences. This automation objective is a logical consequence of the automation with the everything as code approach [51] of devops. The governance will check the effectiveness of the participation driven development with the controls like the governance initiated reviews to ensure that the enterprise enhance in a positive way aligned with the strategy. A second observation is that the governance develops fast if they live the lean and agile mindset themselves. Their responsibility is to serve the teams in an effective way to be compliant with external and internal requirements.

The evaluation about the effectiveness of coaching with a transition kit is seen on two points:

- At the end of the coaching phase on which the readiness check situation and the current outcomes of the capability check are compared.
- At the project review with the distance view (at least 1 year) after the transition coaching.

The objective of the ACE is to be effective by the coaching support. This is realized with the transition kit by applying and enhancing the transition kit continuously with the lessons learned from the transitions coaching. The efficiency is seen on the higher team transformation throughput of coaches. The issue is to have a generalized kit which is easy to instantiate in the specific team setting. This trade-off is a current enhancement focus of the transition kit. Furthermore a contribution is that this transition kit explicitly handles the mental team setting by application of the spiral dynamics model to apply adequate approaches and methods during the transformation to support effectivity the progress and sustainability also after the coaching phase.

## IX. NEXT STEPS AND FUTURE WORK

Sustainability is a topic that needs more focus. Often the agile project review makes transparent that after the coached transition phase, the teams lose some of the leaned rituals etc. and fall back to pre-transition habits. We need to define or develop external triggers to reflect the team’s rituals and progress in the developing of the agile and lean mindset without the coaches. This is a topic for an effective governance of the agile and lean processes.

Furthermore, the amount of skilled coaches does not scale with the demand. We need to enhance the transition kit to a complete self-service approach. Then teams with some “basic” skills can work more autonomously, needing less coaching. This is a governance and training issue. The

training aspect is to enable the teams to do mostly everything in a self-service manner by offering a suitable transition kit. But on the other side the governance has to ensure that also self-service transitions have high quality outcomes.

Another open point is that the presented approach is only applied in a European enterprise culture. Its effectiveness in other cultural contexts still has to be investigated.

Next steps are the refactoring of the current process governance rail guards for a higher automation degree. The objective of the potential automation offers mature teams the integration into their automated product delivery pipeline (CI/CD chain). Some teams are currently experimenting and evaluating automated governance controls. The challenge is to find a balance between integrated standard tools and the freedom of the agile teams. Is automation an adequate indicator to determinate the product team maturity, especially in team's customized CI/CD chains? Will an individualized CI/CD chain slow down the integration of currently "independent" agile teams in future release trains of SAFe? Another interesting point is to extend the product based focus of the transition kit with a more lean and agile product finance scope like Beyond Budgeting [52].

**Abstract**—Skills demanded by the IT industry from graduates should be aligned with the curricula of Computer Science undergraduate programs. It is well-known that theoretical knowledge undergraduate students acquire during their studies needs to be complemented with practical experience; therefore, participating in university supported real life projects is a viable option for the students to get prepared for the industry. This paper reports findings from a survey applied to students who had been involved in an industry-based program meant to fulfill their graduation requirements, including the opportunity to develop a capstone project. We gathered their perceptions regarding what they learned during their studies, what they acquired in the industry-based program and what they consider useful for their current jobs. The results show that most topics are aligned between the Bachelor's degree program and the industry needs, but there is a strong separation in the cognitive levels students achieve at each stage. The paper provides insight into the needs of Computer Science students and contributes to finding ways of increasing undergraduate student satisfaction with skills acquired at university and their application in real contexts.

## I. INTRODUCTION

**A**N accelerated evolution of IT technologies demands software developers ready to get incorporated to IT workforce. The Bureau of Labor statistics of the United States of America estimates a 24% increase in demand for software developers in the period from 2016 to 2026, which is much faster than average growth [26]. Similarly, in other countries around the world the demand for software developers is growing in similar proportions. To obtain a desirable employment, a competent software developer is required to possess a wide variety of skills, such as managerial, engineering, team working and communication [1].

In undergraduate computer science (CS) and software engineering (SE) programs, educators provide experiences to support an adequate development of knowledge and skills in students. However, a crucial question remains open: how to educate software engineers to do their jobs efficiently and properly [25]. Current curriculum guidelines recommend that educational programs provide effective learning of SE skills and concepts by incorporating real-world elements, which

could be done through capstone projects and student work experience among others [1].

In capstone projects, students focus their effort on completing a significant real project while they practice learned knowledge and skills [1]. Capstone projects represent an important learning activity in SE, given that most of the SE concepts are abstract in nature. In consequence, they are difficult to understand by undergraduate students without adequate hands-on experience [17].

However, providing a real-life experience in undergraduate programs is a difficult task [9]. Another factor to be considered is the gap between skills acquired by IT graduates and skills demanded by the industry [25]. Although it is necessary to prepare students for incorporating into the software industry, this is still a very complex endeavor that many universities are struggling with [38]. Other than theoretical knowledge, future employers are always more interested in students who are equipped with hands-on experience [41].

Despite a considerable interest to find ways of helping students to quickly become efficient software developers and blend into the IT work place, there are few empirical reports of problems that students face in capstone projects as well as of learning outcomes students perceive to have achieved after completing a capstone project [37]. Thus, this paper aims to present an experience report of how a joint effort between industry and university can increase undergraduate student satisfaction with skills learned at university and their application in a real project.

In addition, this report provides a comparison between knowledge and skills learned at university against those learned in the industry. Moreover, the results of this experience have other effects over educational aspects, such as an increase in awareness for alignment of academic courses with industrial experience by CS and SE educators.

The paper is structured as follows. Section II presents an overview of capstone projects and agile methodologies used in them. Section III describes the context of CS Bachelor's degree of a Mexican university and the nature of the industry-based student program. Section IV reports the data collection process

and data analysis. The results are discussed in Section V and the conclusions and future work are presented in Section VI.

## II. BACKGROUND

### A. Capstone projects in CS

Capstone is defined as “the high point: crowning achievement” [24]. In a capstone project, “students solve real-life problems in the context of a large, realistic project” [37]. Working on a project helps students to develop SE skills and apply them in a realistic environment, providing them with an excellent opportunity to understand and experience various technological waves that would be present in their careers [16]. In order to improve learning outcomes, project courses can involve industry partners who provide real-world problems for students to solve, to develop both technical and soft skills, and to gain contacts to potential mentors in the industry [40].

Several papers address the use of capstone projects to enhance knowledge and skills of both CS and SE students. Vanhanen et al. [37] conducted a survey to understand the problems that arise during development of capstone projects, to gain insight into improvement in learning outcomes as perceived by students, and into customer satisfaction. They found that learning outcomes varied a lot among teams and team members since roles undertaken by students affected their level of learning. Considering common problems reported in capstone projects, the most common ones were related to testing, task management, effort estimation and technology skills [37].

In [21] students identified algorithms, programming, networks and databases, and contemporary technologies for developing software as essential technical skills in order to succeed in a capstone project. They can be seen as potential discipline knowledge gaps and become areas to better address in capstone project activities. The authors surveyed students’ feedback where the majority of students reported a general skill improvement or learning new technical or project management skills during their capstone project [21].

Projects often require students to use technologies (programming languages, web frameworks etc.) that they have not been taught in their previous courses [37]. Based on observing differential learning outcomes achieved by students, Karunasekera and Bedse [17] proposed a skill based learning framework to provide objective guidance to ensure that team based projects offer a balance of management, engineering and personal skills. In case of capstone project courses, Majanoja and Vasankari [21] suggest to organize them focusing on team work, communication and problem solving skills.

It can be observed that few quantitative empirical studies report problems encountered by capstone project teams [37]. The reported problems are related to poor communication among the team members, poor leadership, failure to compromise, procrastination problems, integration testing problems, and lack of cooperation, among others [37]. Besides, such problems as lack of skills for using tools, lack of organization, lack of technology expertise, and having to combine work and

study during the project are reported in [2]. Other risks are architecture complexity, quality trade-offs, personnel shortfalls, budget and schedule constraints, COTS and other independently evolving systems, customer-developer-user team cohesion, requirements volatility, user interface mismatch, process quality assurance, requirements mismatches, acquisition and contracting process mismatches [18].

Learning outcomes of capstone projects [37] include improvement in such students skills as familiarity with agile approach, programming, project planning and management, effort estimation, acquiring “a big picture” of a software development process, team work, customer interaction, and communication [20]. Improvement in learning is reported in skills related to requirements engineering, system design, modeling, programming, version control, release management, and usability engineering, among others [6]. Besides, Broman et al. report students’ learning technical knowledge of a specific SE role, time management, usefulness of agile methods, and team communication and collaboration [5]. As for guidelines to discuss student experience of participation in industrial capstone projects, SWEBoK offers a set of topics, understandable to students and widely used by researchers [32].

A realistic setting of a capstone project developed for a real customer also introduces challenges for the participants. The beginning of a project course is particularly difficult, as students have to familiarize themselves with development processes and tools, get to know the project’s problem domain, understand requirements, and deal with communication issues [9]. Besides, there are several organizational aspects to be considered when providing real-life experiences [38], [6], [4]. Despite the effort to provide students with real-world experiences, instructors should be aware that the level of exposure to these formative actions will be limited [1]. Instructors can only facilitate the initial stage of the process for students develop a mature understanding of the real world across their careers [1].

### B. Agile methodologies in capstone projects and courses

Providing students with an iterative work by means of agile and lean methods can both fulfill the industry needs and support the design of SE courses [23]. Considering agile methodologies, Scrum is one of the most adopted and/or adapted in a capstone course design [23], [27]. Indeed, in courses based on project-based learning, Scrum is very common. It can provide control over project progress and it is able to ensure a steady pace of development [12].

Fitsilis and Lekatos [13] conducted a survey study to understand the importance of agile practices and their relevance in the industrial context while relying on the Scrum method taught in a capstone course. As a result, the majority of the participants reported a general positive experience from the capstone course; in addition, they perceived such frequently used in the industry practices as unit testing, coding standards, test-driven development (TDD) and continuous deployment as the most useful. Other researchers studied how particular estimation techniques can be introduced in a software engineering

capstone course [28]. Another research line is focused on the assessment of particular practices of continuous integration, TDD, and work tracking, among others [12].

Both, supporting tools and adaptation of agile techniques, have been explored in capstone courses and projects. Rodríguez et al. [29] propose a virtual Scrum tool that simulates a Scrum-based team room by means of the 3D virtual world metaphor. The tool can support specific configuration and progress of each student team [29]. On the other hand, Krusche et al. [19] proposed Rugby, an agile model for supporting continuous delivery of software. The authors report that the Rugby method improves coordination across multiple teams and enhances communication between developers and customers [19].

Lean approaches, such as Kanban, have also been studied in the context of Scrum-based university courses by introducing Kanban at the end of instruction period [23]. Paasivaara et al. [27], on the other hand, report an effective outcome of a Scrum based capstone course with real clients. They found that students positively change their attitudes about the importance of collaboration and communication within the teams while experiencing less than expected difficulty in learning new technologies [27].

Moreover, agility in capstone courses have been explored in relation to other topics. Fagerholm and Vihavainen [11] have studied peer assessment to provide a full view of student performance in a project. In particular, self-assessment and peer review should provide insights with regard to learning goals. In software maintenance, Weissberger et al. [39] reported an experience of using agile principles in a maintenance project developed in a capstone project.

Academic software factory is another approach used in universities to enhance the quality of education by means of capstone projects. University laboratories emulate a real working setting where teams of students implement a project for real customers and real deadlines [33]. Similarly, Fagerholm et al. [10] report another experience of developing the software factory approach. They provide a collection of patterns and anti-patterns to support the design, implementation and operation of project-based startups [10].

### III. CONTEXT OF THE EXPERIENCE

#### A. Computer Science Bachelor's degree

The National Autonomous University of Mexico (UNAM) is the biggest university in the country with 356,530 enrolled students in 2019 [35] and sits the #2 in Latin America (#113 university in the world) according to QS World University rankings [7]. The UNAM consists of 15 colleges that offer 127 Bachelor's degrees; CS Bachelor's degree is one of them and is taught at the College of Science.

CS Bachelor's degree is designed to be finished in four years obtaining 376 credits; it consists of 28 compulsory and 6 elective courses based on seven knowledge areas: Mathematical foundations, Discrete structures, Programming, Software engineering, Theoretical computing, Theory and practice integration, and Systems architecture. In order to graduate, CS

students are required to complete 376 credits, 480 hours of social service and to develop a capstone project.

In Mexico, undergraduate students must meet the requirement of completing a social service to be able to graduate [8]. The goal of the social service program is to contribute to both academic and professional training of students. Student who have achieved 70% of undergraduate credits are eligible for social service program as they are supposed to apply their acquired knowledge and skills in an organization which is looking for social, cultural and economic development. The social service practice amounts to 480 hours that students complete in a time period of 6 to 24 months [34].

Mexican program of social service "promotes professional and human development of the student, developing an active and supportive social commitment applied to the solution of problems or needs of the country" [34]. It is similar to work experience placements required by universities around the world, however it differs from them due to its civic and social orientation. Nevertheless, there is no other alternative that would provide students with work experience previous to their graduation.

As for the capstone project, CS students are offered 10 options: writing a dissertation (thesis), participating in a research-based project, taking a research seminar, participating in a science popularization project, reaching the national stage of the ACM Programming Contest, being in the first quartile of the Graduate Record Examination for CS, obtaining an over 95 GPA (out of 100), carrying out tertiary teaching support activities (such as teaching assistant), obtaining industry experience and extending the social service.

The majority of these options are research- or teaching-based with the exception of the last two: industry experience and extended social service. In the case of the extended social service, most of the programs are research and teaching oriented. According to the information published in [36], 97 out of 272 available programs for CS students are IT related. From those, 80 are carried out within the UNAM schools and dependencies, 16 in government offices and only one is industry-based.

In addition, both options require a university professor who can supervise capstone projects based on an industry experience or an extended social service, however, there is not enough cooperation between university supervisors and industry available projects.

We identified a lack of opportunities for students to gain more industry-oriented experience both through social service or developing a capstone project. In order to improve this situation, we proposed to push for industry-based capstone projects and social service programs.

On the one hand, it would allow students to complete a social and civic service requirement as well as to obtain work experience in the current industry. On the other hand, it can lead to an increase in numbers of graduated students in CS as industry-based experience offers reasonable opportunities for developing a successful capstone project.

The current numbers of graduated students are extremely low: the terminal efficiency of CS Bachelor's degree since 1995 is 18.1%. In absolute numbers we find that 285 students graduated, 621 completed their credits but did not graduate and 672 neither graduated nor completed their credits. Only one of each five students is able to complete their credits, get through their social service and develop a capstone project. Looking at only eight last generations of students, the terminal efficiency is slightly higher: 19.7%. while only 155 out of 785 CS students graduated.

One of the reasons for the low numbers of IT-related graduates is their high level of employability, and CS students are no exception. Nowadays, there is an important demand to fill in constantly growing job offers in the IT sector. Deficit of employees with a IT profile is critical in many countries around the world; according to [25] it is growing at an exponential rate. Students are leaving the university because they are getting job offers even if they are not graduated yet.

In this context, undertaking this initiative was powered by a strong motivation to improve the exposure of CS students to relevant work experience in real projects aligning it with their graduation requirements, namely, social service and capstone project.

### B. Industry based program

The industry based student program described in this paper was divided in two stages. During the first stage students worked to complete 480 hours of social service. During the second stage students could opt for continuing working but with a condition of developing a capstone project based on the work done in the first stage.

This project was carried out in a joint effort by the College of Science and a Mexican software development organization. The expected outcome of the project was an information system for public administration. The first step to link the organization and the university was to define a social service program in which the student activities would be aligned with their civic responsibilities.

Once the program was created and approved by the University, any interested student could join the program. Actually, students joined the program voluntarily at different stages of the project during the year. There were no additional restrictions to join the program out of those already imposed by the University, so all students who applied for the program were accepted.

Each student was coordinated by a professor from the College and looked for the goals of the social service to be achieved. Students were required to work in the organization during a minimum of 6 months covering the 480 hours of their social service. They also received a monthly grant during the time they participated in the project.

The organization had a full development process in place; in consequence, the students were able to carry out a wide variety of tasks in different software engineering activities. During their first month of work, they were trained and introduced into the organization, the team and the project. Tasks assigned

during the initial period were related to requirements specification and testing with the intention to get them familiar with the project and system under development. Activities related to Software Configuration Management (SCM), such as version control systems and continuous integration, were specially relevant at this stage.

The organizational development process was a hybrid process based on [22] mixing agile practices with ISO/IEC 29110-5-1-2. Project management activities were assigned using boards (Kanban style) and the progress was reported through stand-ups (Scrum). Software requirements specification (SRS) was carried out first through wireframes and customer workshops and then specified as use cases. Programming tasks consisted in fixing bugs and pair programming sessions arranged on demand while continuous integration and deployment practices were in place. User acceptance tests were carried out mostly by using a Think Aloud! protocol, bughunt sessions to test the system were implemented, and a bug tracker system was used to report defects.

During the following months students rotated between different teams and carried out roles of analysts, programmers, testers and database developers. Table I enlists the tasks carried out by the students, where agile practices used for each task are provided in brackets. For standardizing purposes generic ISO/IEC 29110-5-1-2 [14] tasks definitions are used.

A student's timeline in the program was usually the following:

- **Day 1:** an introduction to the organization, team and project.
- **Day 2:** a walk-through the development process of the organization.
- **Day 3:** joining SRS and Testing teams.
- **Month 2:** joining Construction team.
- **Month 3:** joining Databases team.
- **Months 4 and 5:** joining the team of their preference.
- **Last two weeks:** writing a social service report required by the College of Science.

Students received training from the team leaders and participated in workshops obtaining knowledge in topics like:

- Version control systems with Git and continuous integration.
- Development frameworks with Grails.
- Web deployment using WebLogic Server.
- Stored procedures and packages in Oracle 12c.
- Test automation with JMeter.
- Mobile development.
- Basic accounting to deal with employment and workers' rights.

The students had regular control meetings with the project manager of the organization following a daily Scrum approach. In addition, they had regular contact with their respective team leaders and teammates.

From the College of Science side, two professors were in charge of ensuring that the purpose of the social service program was being fulfilled and the students received guidance

TABLE I  
TASKS CARRIED OUT BY STUDENTS

<b>Software Requirements</b>
Document or update requirements specification ( <b>User stories and Wireframes</b> )
Identify and consult information sources in order to get new requirements.
Verify and obtain approval of the requirements specification.
Validate that requirements specification satisfies needs and agreed upon expectations, including the user interface usability ( <b>Think Aloud!</b> ).
Participate in revision meetings with the customer.
<b>Software Architectural and Detailed Design</b>
Describe in detail the appearance and the behaviour of the UI ( <b>Wireframes and Think Aloud!</b> ).
Generate an architectural design, its arrangement in subsystems and components defining internal and external interfaces.
<b>Software Construction</b>
Construct or update software components ( <b>CI and CD</b> ).
Correct the defects found until successful unit test is achieved ( <b>Pair programming</b> ).
Perform backup according to the version control strategy.
<b>Software Integration and Tests</b>
Verify consistency among requirements specification, software design and test cases ( <b>Think Aloud!</b> ).
Design or update unit test cases.
Perform software tests and document results in the test report ( <b>Bughunt</b> ).
Correct defects found and perform regression tests ( <b>Pair programming</b> ).
Verify consistency of the software documentation with the software.
<b>Product Delivery</b>
Verify consistency of maintenance documentation with software configuration.

from the organization members. A non-conformity process was in place to inform any improvement opportunity or disagreement regarding the students' interaction and performance. This process was a two way communication channel that served to inform the College if students did not perform as expected or if they were absent without notifying.

Once the six months concluded and students completed the required 480 hours of their social service, they were invited to continue in the organization but developing their capstone project. The capstone project had to be related to their work in the last six months and was supervised by a professor from the College with a possibility to be co-supervised by a member of the organization. The only constraint imposed on students was to finish the capstone project in no more than six months.

This paper reports the participation of a cohort formed by 13 students. The time they spent in the program varied from 5 to 12 months. First results of the program are described in the following sections.

#### IV. MAPPING ACQUIRED AND REQUIRED SKILLS

As mentioned before, there is a need for aligning higher education practices to industry needs by exposing students to industrial processes [30]. It is often observed that a large gap separates software projects in industry from what can be experienced in the classroom [15]; therefore, students are unconvinced by the relevance of the material delivered in lectures. The challenge, in consequence, is to develop environments within universities that are sufficiently real to be convincing to students [31].

Our interest was to gain an insight into students' perceptions regarding the knowledge and skills they acquired during their

studies, during their participation in the program, and finally in their current job. To gather data, we designed a survey based on SWEBoK areas and topics; we were interested to know to what extent the students have been exposed to them, how the students perceived the preparation they received and what they considered necessary once they joined the industry.

The results were expected to allow for evaluation of the usefulness of the social service program as well as for an appreciation of an (non)-existing alignment between what CS students perceive that have learned and what they need once they graduated.

SWEBoK establishes a baseline for the body of knowledge in the field of SE [32]. It strongly influences the manner in which curricula are defined and how academic programs are accredited. In this study, SWEBoK was chosen due to its wide acceptance as a well-known SE body of knowledge that connects industry recommended practices and the knowledge expected from a software engineering professional.

The survey consisted of two sections, the first section was an online survey and the second section was answered in a spreadsheet. The time taken to answer the whole survey ranged from one day to one week; an incentive was given for each fully completed survey.

The first section contained questions about personal involvement in the program, and their current academic and professional situation:

- 1) How many months were you involved in the program?
- 2) What activities did you carry out during your participation in the program?
- 3) What skills do you think you developed the most?

- 4) Did you develop a capstone project derived from your participation in the program?
- 5) Did you complete the social service program?
- 6) Did this program contribute or is contributing to your graduation?
- 7) Did this program contribute or is contributing to you getting a job?
- 8) Do you currently work in the IT-related industry?
- 9) What do you consider to be the most beneficial in your participation in the program?
- 10) What improvements do you consider the program needs?

In the second part, the students were presented with a table which enlisted each of the SWEBoK topics grouped by area of knowledge, and had three columns representing stages (while studying my bachelor's, while participating in the program, in my job), during which the knowledge was acquired and/or applied.

Each SWEBoK topic (rows) was presented with an example in the form of tooltips. Figure 1 shows a fragment of the survey with answers retrieved from one student. The fragment was translated from Spanish into English.

Once the collected data were analyzed through general descriptive statistics of median, mode and mean, they were used to answer the following research question:

*How did participating in a real project transform the students' knowledge?*

It was decided to follow an adapted Bloom's taxonomy presented in [3], particularly three lower levels of the taxonomy (Remember, Understand and Apply) were used.

In the first column, respondents selected one of the following options for each SWEBoK topic to complete the claim "While studying my bachelor's ...":

- 1) I did not get familiar with this topic.
- 2) I got familiar with this topic but I did not apply it in practice (**Remember and Understand**).
- 3) I got familiar with this topic and had a chance to apply it in practice (**Apply**).

In the second column, the options to select were similar to the one in the previous question, but the claim was "While participating in the program ...":

- 1) I did not require this topic.
- 2) I was already familiar with the topic, but I applied it in practice (**Apply**).
- 3) I was already familiar with the topic, but I did not apply it in practice (**Remember and Understand**).
- 4) I got familiar with the topic and I had the chance to apply it in practice (**Remember, Understand and Apply**).

The second question of interest was:

*What software engineering topics/areas are regarded as most useful in the industry by the students?*

In this case, a 5-point Likert scale was used. In the third column, respondents selected one of the following options to complete claims corresponding to "In my job, <SWEBoK topic> is ...":

- 1) Not useful.

- 2) Slightly useful.
- 3) Useful.
- 4) Very useful.
- 5) Essential.

Besides it was of interest to know what positions they held in the industry once they finished their participation in the project. This information was collected via email.

## V. RESULTS AND DISCUSSION

### A. First section of the survey: Industry-based program

A total of 13 students participated in the program and 12 completed it successfully; Table II shows a summary of the students who participated in the program. The only student who did not complete the program accepted a job offer in the IT industry and left the program. This is one of main reasons of why students do not graduate and there is very little the universities can do to minimize its impact.

The first part of the survey was responded by 10 students. Eight out of 10 students reported that their participation in the program contributed to their graduation and nine out of 10 reported that it contributed to getting a job after the program. The following statements are examples of the students' opinions regarding their experience in the program:

*"Having a real-world experience that goes beyond a social service gave me a better position."*

*"The experience I have got was well valued by the recruiter."*

*"I met people with a lot experience in software development, I learned a lot from them."*

*"I interacted with real customers and teams, the experience I have got was real-life."*

Six students provided information regarding the position they occupied after the project:

- Database Developer
- SOA Java Developer
- Software Test Engineer
- Data Scientist Jr.
- Software Engineer
- SECaaS and DBaaS Engineer

Two of them worked in an organization that followed Scrum as its main methodology, allowing one of them to become a Scrum Master.

Last but not the least, four students concluded their capstone projects as based on their work during the program. Given the proportion of students who completed their social service (92.3%) and those who graduated (30.8%) we consider this an improvement for the historical data of graduated CS bachelors in the UNAM.

### B. Second section of the survey: SWEBoK areas and topics

Nine students completed the SWEBoK mapping. The first question to answer is:

*How did participating in a real project transform the students' knowledge?*

On a more general level, Table III displays an association perceived by students between each SWEBoK area

	0: I did not get familiar with this topic. 1: I got familiar with this topic but I did not apply it in practice. 2: I got familiar with this topic and had a chance to apply it in practice.	0: I did not require this topic. 1: I was already familiar with the topic, but I applied it in practice. 2: I was already familiar with the topic, but I did not apply it in practice. 3: I got familiar with the topic and I had the chance to apply it in practice.	1: Not useful. 2: Slightly useful. 3: Useful. 4: Very useful. 5: Essential.
<b>1. Software Requirements</b>	<b>While studying my bachelor's ...</b>	<b>While participating in the program ...</b>	<b>In my job ...</b>
1.1. Software Requirements Fundamentals	2	1	3

TABLE II  
PARTICIPANTS' DETAILS

ID	# Months	Roles carried out	Completed the program?	Developed a capstone project?	Got employed?
S1	5	Analyst and DB developer	No	No	Yes
S2	12	Analyst, Programmer and Tester	Yes	Yes	Yes
S3	8	Analyst and Programmer	Yes	Yes	Yes
S4	6	Analyst and Tester	Yes	No	Yes
S5	6	Analyst, Tester and DB developer	Yes	No	Yes
S6	7	Analyst and Tester	Yes	No	Yes
S7	6	Analyst and Tester	Yes	No	Yes
S8	7	Analyst and DB developer	Yes	No	Yes
S9	9	Analyst, Programmer and Tester	Yes	No	Yes
S10	11	Analyst, Programmer and Tester	Yes	Yes	Yes
S11	10	Analyst, Programmer and Tester	Yes	Yes	Yes
S12	9	Analyst and Tester	Yes	No	Yes
S13	6	Analyst and Tester	Yes	No	Yes

and cognitive levels. It is observed that, except for Software Maintenance, all the areas required in the program had been taught at the BSc (students got familiar with them) and most of them reached the next cognitive level (students applied them in practice).

It can be noted that Software Maintenance was perceived as an area not familiar to students during the BSc; however, by the end of the program, students perceived a shift from not knowing it to applying it in practice. Software Engineering Economics is another area perceived as unknown by students, and this area of knowledge was not required during the program either.

Students reported that after participating in the program, cognitive levels improved in nine areas and remained at the same level in three. These results allow to conclude that, in this particular case, real experience in a controlled environment offered an important advantage for the student development.

Going down on a more detailed level, we found an increase in cognitive levels associated to SWEBoK topics as 45 topics were perceived as improved and for 25 their cognitive levels remained the same. Only topics required during the project were analyzed (70 out of 102 SWEBoK topics).

In particular, three topics changed their states from Unknown to Apply, as well as from Unknown to Remember

and Understand. Their breakdown is shown in Table IV. An important message is the lack of Software Maintenance and Software Configuration Management in the curricula. The gap between students' knowledge acquired during their studies is large as compared to the importance of this area for their job in the industry. This could be caused by the lack of opportunities to work in long projects and over an existent software product, where it is possible to show the effects of good/bad maintenance practices or SCM strategies.

The second question to answer was:

*What software engineering topics/areas are regarded as most useful in the industry by the students?*

The data showed that Software Engineering Professional Practice is the only area with a median of 5 (essential), while eight other areas obtained a 4 (very useful). It is worth mentioning that the least useful, according to the student perception, turned out to be Engineering Foundations. The analysis consisted in calculating the median of topics per each area; see Table V for the results.

A more granular analysis performed on the topic level showed that nine topics got a median of five (see Table VI).

Students reported to know all of those topics from their university background, however, only when participating in the project they had an opportunity to apply three of them in

TABLE III  
COGNITIVE LEVELS OF SWEBoK AREAS ACCORDING TO STUDENT PERCEPTIONS

practice (see Table VII).

In the context of software development, Software Release Management and Delivery constitutes a fundamental area of knowledge for every practitioner. On the other hand, Group Dynamics and Psychology together with Communication Skills are abilities strongly required for teamwork. It was a favorable outcome that students were presented with an opportunity to applied these topics during the project.

The most developed during the project areas are shown in Table VIII while the least developed ones are presented in Table IX.

### C. Limitations and Threats to Validity

Construct validity: the data collection, particularly the survey on SWEBoK areas and topics, included examples of each topic presented to students for clarification. Also, in order to properly define the cognitive level of each SWEBoK topic, an adaptation of the Bloom's taxonomy was used. Although the insights of this experience are based on a limited number of sources, the data were obtained directly from the main stakeholders, namely the CS students. However, the results, in order to be generalized, require more generations of students to join similar programs.

External validity: it is worth to mention that the social service is specific for the Mexican context, however, it is representative of the country. Besides, we consider this program to be an initial step towards demonstrating the usefulness of running industry-based programs within university contexts.

Internal validity: the students joined the program voluntarily, and the information about the program was disseminated in the same way as the rest of the programs. A distinctive feature of this program was the grant offered to the students, which is not common to the majority of the programs; therefore, it could be a factor for the students to choose the program.

The findings are based on the perception of students and could be improved by applying specific assessments at certain phases of the program. Nevertheless, an important advantage of this study relies on the fact that we traced student data from studying a bachelor's degree till joining the IT workforce, which provides a deeper insight into the problem.

## VI. CONCLUSIONS

In Mexico, university graduation requirements consist of developing a capstone project in the form of a thesis and its oral defense, completing credits of the BSc and 480 hours of social service.

As an alternative for providing students with relevant working experience, the UNAM College of Science put in place a social service program run in conjunction with a software development organization. In this program students had the opportunity to cover their graduation requirements while being immerse in a real project. In this first experience, 13 students participated representing around 11% of the CS students of a generation (114 students).

A total of 12 students completed their social service, which was the primary goal of the program, and 4 students finished their capstone projects and graduated (30.8% of the students who joined the program).

Despite differences across countries, there is definitely a growing interest in establishing a university-industry collaboration in order to promote well-prepared graduates, where these initiatives are welcomed by the students [30]. Teachers in charge of capstone project courses could benefit from a better understanding of what kind of problems students typically encounter in capstone projects [37].

We hope that this type of experiences will help to increase academic success, improve students' skills, reducing numbers of dropouts. It is worth to mention that all the students who participated in the program were employed in the IT sector after finishing the program.

Finding of the study showed that area 12: Software Engineering Economics was neither required during the project nor covered by the curricula according to the participants' perception. On the other hand, two important areas are perceived as not covered by the curricula but were required during the program: 5: Software Maintenance and 6: Software Configuration Management.

Finally, there is a clear cut division between cognitive levels developed by the students: *remember* and *understand* during their studies, *apply* when working. It was an expected outcome; however, it reinforces the idea of looking for alternatives for providing students with opportunities to apply their knowledge in practice in order to obtain an integral education.

As future work it is expected to run more programs involving IT companies in order to demonstrate the usefulness of aligning social service with relevant work experience, thus helping students to achieve their academic goals and to successfully join the industry. Besides, it is expected to explore potentials of this approach in other universities in the country. In parallel, an in-depth analysis of the current curricula should be carried out with the aim of including such missing topics as Software Maintenance and Software Configuration Management.

### ACKNOWLEDGMENT

The authors would like to thank Mauricio Morgado and Ricardo Cruz for leading the project, the professors Guadalupe

Ibargüengoitia and Hanna Oktaba for coordinating the capstone projects. Also, thanks to the CS students that participated in this initiative for their contribution: Gerardo González, Adolfo Marín, Aarón Guerrero, Alan Gutiérrez, Jhovan Gallardo, Julio Chávez, Rafael Robles, Diana Góngora, Marco Estrada, Edson Servín, Edgar Tapia and Rodrigo Casiano.

**Abstract**— In this paper, we report on a replication of the study by Przybyłek & Kotecka [2017]. The aim of our study was to revise the work practices related to Sprint Retrospectives in Bluebay Polska Sp. z.o.o. by adopting collaborative games. The feedback received from two Scrum teams confirms the findings from the original study and indicates that collaborative games improve participants' creativity, involvement, and communication as well as produce better results than the standard retrospective.

### INTRODUCTION

AGILE methods appeared as a reaction to traditional ways of developing software and acknowledged that customers are unable to definitively state their needs up front [Przybyłek, 2014; Przybyłek & Zakrzewski, 2018]. In agile software development requirements and solutions evolve through the collaboration of all stakeholders. The Agile Manifesto [Highsmith & Fowler, 2001] advocates principles and values such as face-to-face conversation within a development team, motivated individuals, self-organizing teams, and retrospectives at regular intervals. Furthermore, agile team members are expected to be proactive and creative in resolving complex software development problems [Highsmith & Cockburn, 2001; Crawford et al., 2012; Przybyłek & Zakrzewski, 2018; Przybyłek & Kowalski, 2018; Jarzębowski & Ślesiński, 2018; Miler & Gaida, 2019; Zakrzewski et al., 2019]. However, agile methods do not provide techniques to promote these attitudes. Responding to this challenge, Przybyłek and his team [Przybyłek & Olszewski, 2016; Przybyłek & Kotecka, 2017; Przybyłek & Zakrzewski, 2018; Przybyłek & Kowalski, 2018; Zakrzewski et al., 2019] proposed to equip agile teams with collaborative games.

Collaborative games refer to structured techniques inspired by game play, but designed for the purpose of solving practical problems [Przybyłek & Kotecka, 2017], for example they are quite widely used as a requirements elicitation technique [Marciniak & Jarzębowski 2016, Przybyłek & Zakrzewski, 2018]. By involving visual activities like moving sticky notes and drawing pictures, they leverage multiple dimensions of communication, which results in deeper, richer and more meaningful exchanges of

information [Przybyłek & Kowalski, 2018; Hohmann, 2006]. Besides, various studies suggest that fun is a powerful tool in unleashing creativity and facilitating collaboration [Hohmann, 2006; Trujillo et al., 2014; Ghanbari et al., 2015].

Przybyłek & Kotecka [2017] demonstrated that the promised benefits of collaborative games were materialized when running a game-based retrospective in 3 teams in Intel. The Sprint Retrospective is a meeting in which the team inspects and adapts its way of working [Ilyés, 2019]. Its purpose is to recognize the successes and failures of the last Sprint and to link the related experience to action proposals for improvements. In this paper, we report on a replication of the study conducted in Intel [Przybyłek & Kotecka, 2017]. The feedback received from 2 Scrum teams confirms the findings from the original study and indicates that collaborative games improve participants' creativity, motivation, communication, knowledge sharing, make participants more willing to attend Scrum meetings, and produce better results than the standard retrospective.

The remainder of this paper is organized as follows. Section II provides an overview of the previous studies. Section III explains the employed research methodology. Section IV reports the research project and its results. Finally, the last section concludes the paper.

### RELATED WORK

Recently, there has been lots of interest in adopting collaborative games to aid agile teams. Przybyłek & Olszewski [2016] defined an extension to Open Kanban, which consists of 12 collaborative games broken down into four categories in accordance with four Open Kanban principles. The extension was proved to assist unskilled team members better understand the principles of Kanban and promote the teamwork.

Przybyłek & Zakrzewski [2018] proposed a framework for extending Scrum with 9 collaborative games. The framework was proved to boost agile requirements engineering.

Przybyłek & Kowalski [2018] developed a web portal which provides 8 collaborative games to be used in agile software development.

Przybyłek & Kotecka [2017] adopted 5 collaborative games to support running an effective and enjoyable retrospective meetings. Our study is a continuation of their work, since we evaluate these games in other company and teams.

#### RESEARCH METHOD

Our study was conducted as Action Research [Baskerville & Myers, 2004]. In Action Research, the researcher works in close collaboration with a group of practitioners, acting as a facilitator, to solve a real-world problem while simultaneously expanding scientific knowledge [Przybyłek & Zakrzewski, 2018]. The researcher brings his knowledge of action research while the practitioners bring their practical knowledge and context [Baskerville & Myers, 2004]. A precondition for Action Research is to have a problem owner willing to collaborate to identify a problem, engage in an effort to solve it, analyze the results, and determine future actions [Przybyłek & Zakrzewski, 2018]. The problem owner in this research was Bluebay Polska Sp. z.o.o.. The company was interested in auditing its work practices related to Sprint Retrospectives and improving identified deficiencies. Two Scrum teams participated in the study (Table I). Team 1 developed a web store for Aclari Diamonds, which is a jewellery company, while Team 2 developed print management software for POSperita, which is a printer & advertising agency.

#### ACTION RESEARCH IN BLUEBAY POLSKA

We identified that our teams encountered similar problems related to Sprint Retrospective as those presented in the original study [Przybyłek & Kotecka, 2017]. Accordingly, we decided to implement all the games except Mad/Sad/Glad, which was depreciated in the original study and revised by Mood++. In addition, we decided to try one new game, i.e. 360° Appreciation.

360° Appreciation [Caroli & Caetano, 2016] is a game to foster a conducive working environment that strengthens people relationship and increases team morale. It allows open positive feedback within a team as well as appreciating the time and energy spent by the team members. In other words, it focuses only on the developers' strength instead of

their weaknesses, which can be rather discouraging. The game is not complicated as it can be conducted in any environment. What is more, no additional equipments such as blackboards, posters and sticky notes are required. To run this activity, the facilitator asks everyone to write down their appreciations about one another on a piece of paper. After that, the team is asked to form a circle with one participant sitting in the middle. The other participants are asked to read their appreciation feedback to the one in the center. The same process is repeated until everybody in the team has received feedback.

Each game was implemented twice in each team. Before a game was run for the first time, it was presented to the team. After each game session, we issued a questionnaire to collect feedback from the participants. The responses were made on a five-point Likert scale. Finally, the results were analyzed and discussed with the participants.

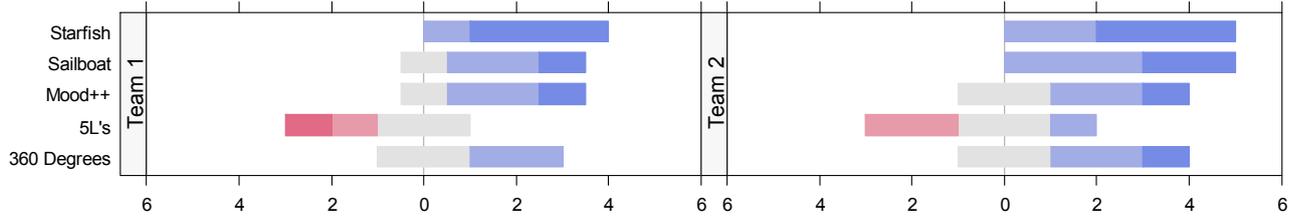

All games except 5L's and 360° appreciation were evaluated positively with respect to all categories. Playing 5L's consumed too much time, while the obtained results were worse when compared to Starfish, Sailboat or Mood++. As for 360° appreciation, even though it got low scores for questions 3-6, it is still successful overall, because it was not designed to promote these issues. The game was considered helpful in relieving the tension or getting to know new team members. Since this game does not provide any feedback on the issues during the Sprint, it should be combined with other collaborative game when performed during the retrospective. In turn, Sailboat was especially appreciated for allowing participants to identify risks in a project. The detail results are presented in Fig. 1.

#### CONCLUSIONS

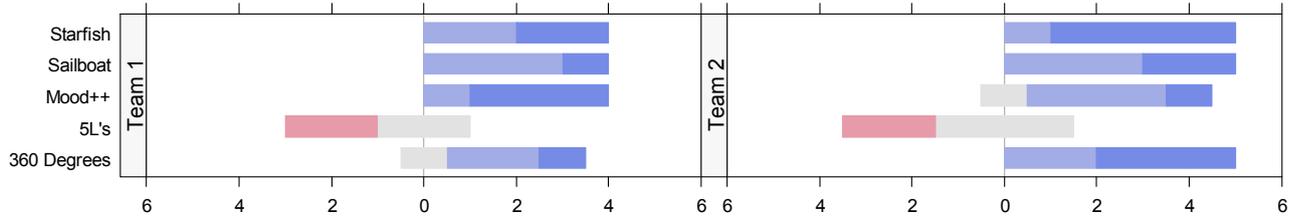

This paper reports on an Action Research project in conducted in Bluebay Polska Sp. z.o.o. Following the best practices developed by Przybyłek & Kotecka [2017], we revitalized retrospectives by adopting collaborative games. The feedback gathered from two Scrum teams confirms the previous findings that game-based retrospectives produce better results than standard retrospectives and lead to a variety of measurable societal outcomes. In particular, Starfish, Sailboat, and Mood++ improved participants' creativity, motivation, communication, knowledge sharing and make participants more willing to attend Scrum meetings.

As future work, we want to measure in a quantitative experiment with settings similar to [Przybyłek, 2018] whether game-based retrospectives are more effective than standard retrospectives. Moreover, after collecting more data, we plan to build a recommender system [Karpus, 2019] that will help scrum teams to choose a retrospective game suitable for a given context.

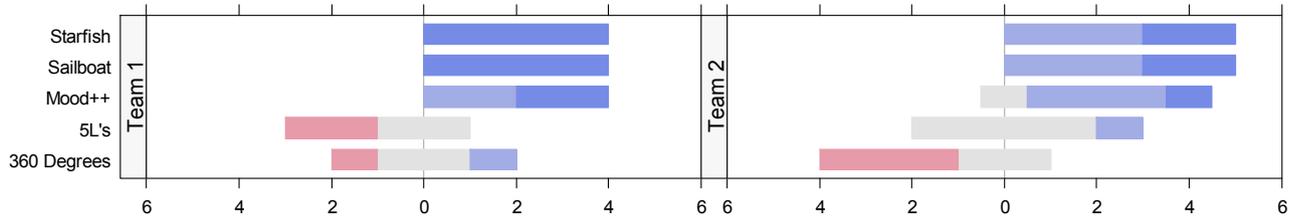

**1. The game produces better results than the standard approach**

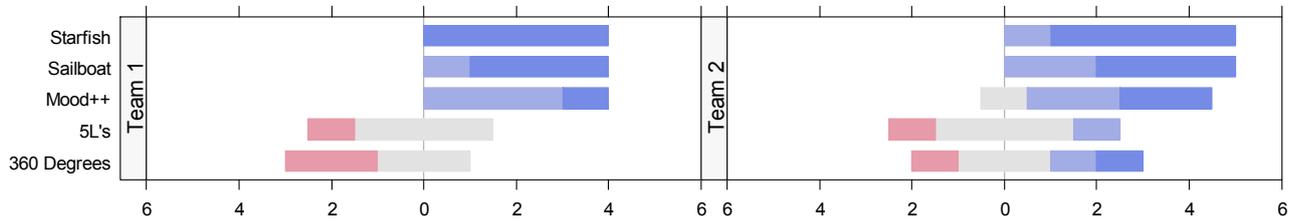

**2. The game should be permanently adopted by your team**

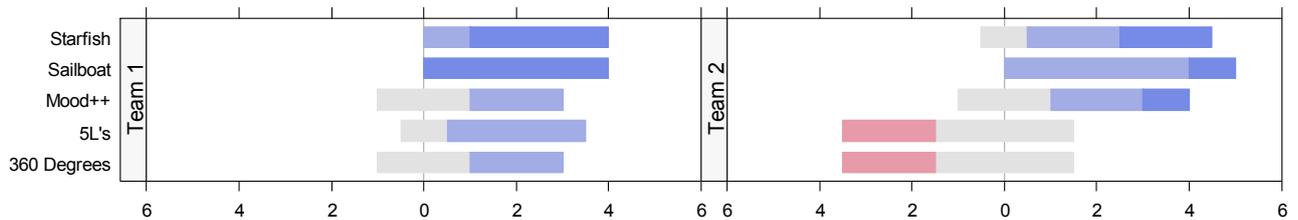

**3. The game fosters participants' creativity**

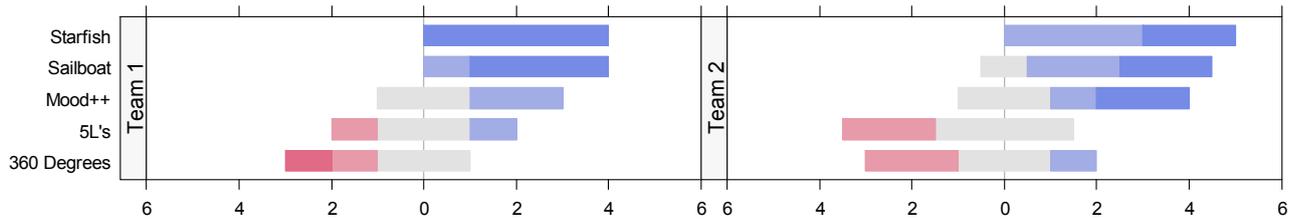

**4. The game fosters participants' motivation and involvement**

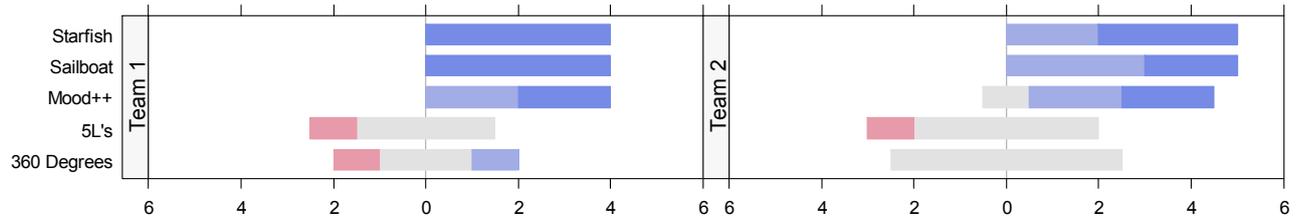

**5. The game improves communication among the team members**

**6. The game facilitates knowledge sharing among the participants**

### 7. The game makes participants more willing to attend the meeting

### 8. The game is easy to understand and play

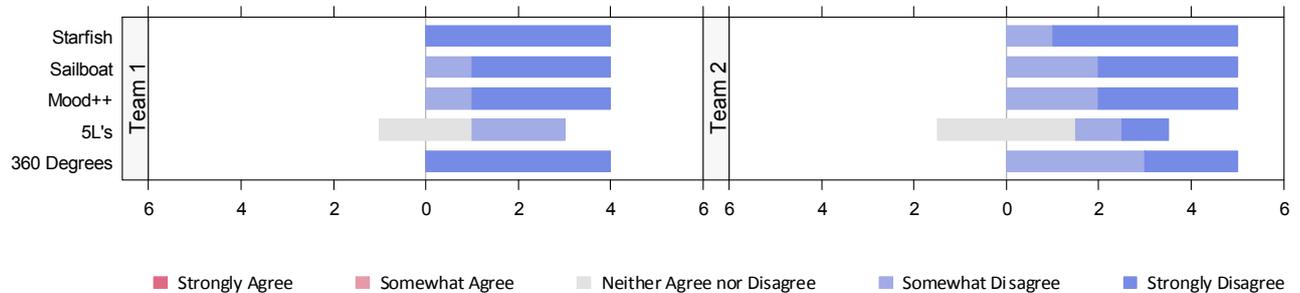

Figure 1. Aggregated results

**Abstract**—In this paper we demonstrate a security enhancing approach based on a method called AgileSafe that can be adapted to support the introduction of OWASP ASVS compliant practices focused on improving security level to the agile software development process. We also present results of the survey evaluating selected agile inspired security practices that can be incorporated into an agile process. Based on the survey's results, these practices were used as an input to AgileSafe method as well as to demonstrate their potential to comply with OWASP ASVS requirements.

## I. INTRODUCTION

THE concern for providing secure systems has become increasingly important throughout the years. With the rapid progress in the IT domain, expansion of the internet solutions and the level of general computer science knowledge, the problem with security affects multiple domains. At the same time, the changing markets and need for flexibility encourages many companies to adopt agile approach [1].

The goal of the research described in this paper was to identify security-focused agile practices, evaluate their usability and impact so that the positively assessed practices could be incorporated into an OWASP ASVS [2] compliant process, as a part of AgileSafe method [3].

## II. BACKGROUND

### A. Agile methods

Ever since the announcement of the Agile Manifesto [4], the agile methods such as Scrum [5], eXtreme Programming [6] or Kanban [7] have been growing increasingly in popularity. The reports of the benefits experienced by numerous companies [8][9] encouraged the trend to shift from traditional, plan-driven methods to the agile ones. What is important is that this shift has not only concerned small and evolving companies which are considered a target of the agile approach. Bigger organizations with larger teams or corporate structures have also sought ways to incorporate agile approach, which resulted in methods such as SAFe [10] or DevOps [11].

### B. OWASP ASVS

The name of the OWASP Application Security Verification Standard (OWASP ASVS) comes from the organization with same name, which created it - The Open Web Application Security Project [12]. Its two main goals are to help creating and maintaining secure software and help in defining requirements between service providers and their clients.

OWASP ASVS has been chosen for this research due to its versatility, open access and popularity among practitioners [13]. The domain of web applications is at the forefront of security issues, with frequent news about major security breaches [14]. For this reason, catering a solution that would allow combining agile security practices with OWASP ASVS requirements could be of interest to many organizations.

## III. AGILESAFE

In the safety context, quite similarly to the security one, norms and standards are vital to ensure the level of trust and quality of high-integrity systems. In order to enable safety-critical software companies to adopt hybrid agile approach while satisfying the regulatory requirements of applicable standards, AgileSafe [15] method has been proposed. It presents a framework for collecting and suggesting the most suitable agile practices for a given project, as well as the means for managing and monitoring conformance with the applicable regulatory requirements.

### A. Overview

As an input to AgileSafe takes the characteristics of a project in which the new approach will be implemented (Project Characteristics) as well as a list of regulations (Regulatory Requirements), which the project needs to comply with.

Based on this information, the user is guided through the process of practices suggestion as well as the process of preparing a set of assurance arguments [16] that will help the user to maintain conformance with given norms and standards. As a result, the user obtains a tailored Project Practices Set, which would best suit a project with given characteristics and regulation restrictions as well as a set of

assurance arguments to monitor compliance with the chosen regulations.

### B. Practices Knowledge Base

The information about practices available in AgileSafe, their capability to answer given Project Characteristics and Regulatory Requirements, is kept in the Practices Knowledge Base. Each practice is described using the same template that is then translated into OWL and managed using Protégé [17].

### A. Assurance arguments

In order to ensure that the Regulatory Requirements will be met when applying the new agile approach, AgileSafe uses a set of assurance arguments. The highest level of abstraction is represented by Practices Compliance Argument. It is created separately for each standard added to the method and collects all of the practices from Practices Knowledge Base that have a potential to answer the standard's requirements. Such practices are arranged accordingly in the argument structure for a given standard requirements.

In this particular research, we focused on the most general Practices Compliance Argument for OWASP ASVS and the security-oriented practices identified in the course of this research, to keep it independent from any particular software project.

## II. SECURITY-ORIENTED AGILE PRACTICES

In order to propose agile security practices that could extend the Practices Knowledge Base of the AgileSafe method, a review of the scientific literature and articles on blogs and industry portals was carried out.

### A. Identification of security-oriented agile practices

While there are many well-known security-oriented practices such as threat modelling or attack trees, in this research we wanted to expand this list and focus on less obvious, agile inspired practices, to enrich the Practice Knowledge Base of AgileSafe method.

A literature review has been performed and as a result 10 articles were selected to be used in further work [18][19][20][21][22][23][24][25][26][27].

### B. Selected practices description

Based on the articles identified in the research, 10 hybrid agile security-oriented practices were identified:

*Abuser Stories.* They describe, using a form similar to regular User Stories, how the system might be attacked and how assets might be put in risk. They should be estimated in accordance to how much damage they may potentially cause and probability of a successful attack. [19]

*Evil user stories.* This practice describes actions of malicious user (e.g. "As a hacker I want to steal payment information of other clients, so I can sell it."). They may be used as a starting point for threat modelling. [20]

*Misuse cases.* They are negative use cases. They illustrate behavior not wanted in the system, that can cause a security breach and can be described using UML diagrams. [21]

*Protection poker.* This is a software security game intended to create a list of each requirement relative security risk. It derives from Planning Poker technique of estimation. [22]

*Second delivery.* This is a process, that aims to integrate security related solutions to the project that already satisfies functional requirements. It is based on XP methodology. [23]

*Security engineer.* It calls for adding an expert role, that brings up-to-date security knowledge to developers' team. His insight is useful during multiple phases and actions in project.

*Security Sprint.* This is a practice inspired by Scrum. It's similar to regular Sprint except that it focuses on security issues. [24]

*Security-focused code reviews.* Such reviews should be performed for every story separately – no story can be completed without security review, fixing findings from review and then passing re-review. [25]

*S-Mark and S-Tag.* Originating from Secure Scrum, they are a way to document identified security issues in Scrum Backlog by creating system of tags (security issues) and markings for stories related to respective tags. [18][27]

*Spikes.* They are a way to include security analysis and design within Scrum. They accommodate activities that don't produce customer-valued product, like security analysis or system designing. [26]

## III. SURVEY

In order to evaluate the usability and accessibility of the selected security-oriented agile practices in projects with high security requirements a survey was conducted. It tackled 10 specific agile security-oriented practices, asking the respondents to rate their respective ease of use and security enhancement potential.

Subjects chosen to participate in the survey were 24 IT practitioners (both development and operations) from 7 different software companies, ranging from small to corporate ones, from Poland and UK. The questionnaire was distributed mostly by email and direct messages in social networks, eliminating probability of acquiring responses from random, unrelated to the field respondents. The respondents were also provided with the practices detailed descriptions.

### A. Results

For each practice two closed questions were asked about its ease of use and if it's improving security in the project. In total, 15 of all the participants made their choices in those questions. Also, each practice was open to comments from the respondents. The results are presented in the Fig. 3 and Fig. 4.

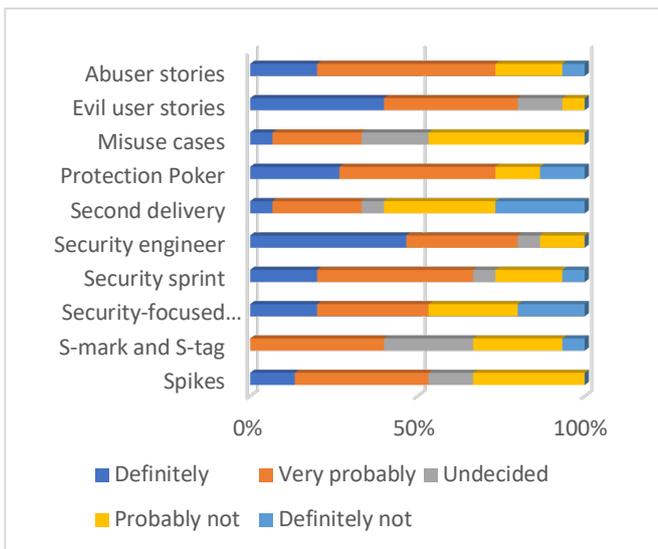

Fig. 3 Is this practice ease to use?

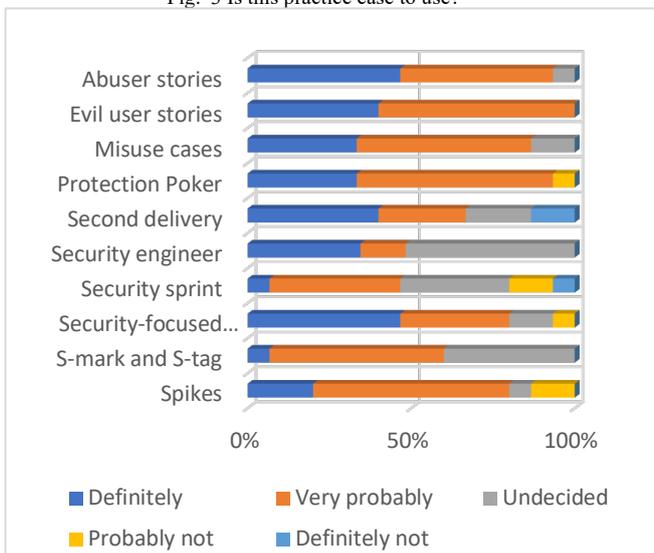

Fig. 1 Does this practice improve security in the project?

**Abuser Stories.** None of respondents chose negative answer for this practice security improvement potential and not many had doubts about its positive influence. But 26,67% believed it would not be easy to use - as the reason they mostly described difficulty in estimating attack probability. Despite this fact, this practice has potential benefits in the projects wanting to comply with OWASP.

**Evil user stories.** This practice was also positively rated in terms of security improvement. What's more, only 20% expressed doubts or were undecided about its ease of use. Those results categorize it as both efficient and easy to get started with. Respondent commented on possible threat to project agility in case of creating a large number of evil user stories.

**Protection Poker.** Majority of respondents found this practice easy to use – among the benefits they listed possible automation of prioritization. The doubts were similar to those for Abuser Stories practice – difficulty in

estimation of attack ease and probability. Another noticed difficulty is the necessity for security experts to participate in the process. Despite that problems only 7% didn't rate the practice positively in terms of security.

**Second delivery.** This practice didn't occur as easy to use to most respondents. A lot of them were concerned about the need to re-implement huge parts of system in order to satisfy security requirements. 67% of answers in question about security were positive, but considering its difficulty, this practice might not cause some problems in actual development process. Also, a significant problem with security was noticed, that during the first development unexpected security flaws might be introduced to the system that are not addressed in the second delivery.

**Security engineer.** Most of respondents rated this practice positively in terms of ease of use, as it wouldn't require additional amount of work from the team and it would be beneficent to have an expert that is not writing the code himself. Among listed problems were difficulty in finding the suitable person for this role and risk of putting all of responsibility for security on one person. Despite those issues, rating in security improvement area was positive, with only 7% of participant undecided and none rating it negatively.

**Security Sprint.** The majority of respondents rated this practice as easy to use, but doubts were expressed that it could lead to development work duplications. Also, the question was asked about the case in which not enough security tasks are defined to fill the whole sprint. 47% of answers were positive in terms of security improvements, but as much as 33% of participants were undecided. This can indicate that practice description should be clarified when added to the AgileSafe Knowledge Base.

**Security-focused code reviews.** Opinions on this practice's ease of use are divided – the results for "Definitely" and "Definitely not" are equal (20%). Among mentioned problems were difficulty with finding a suitable expert and a lot of additional effort required for conducting such reviews. Despite that, most of respondents decided that this practice improves security in the project (80%). But the expected improvement seems not to be worth the effort required.

**S-Marks and S-Tags.** None of the respondents found this practice definitely easy to use, and 40% decided it's probably easy to use. Considering amount of answers "Undecided" in both questions, this practice might be too complicated to take up without previous training. Practice gained no negative rating in terms of security, but concerns were raised that it might be possible to lose track of some tags and marks and therefore omit some security issues in development. Also, the question was asked about support in existing project management tools, which could solve tracking problem.

**Spikes.** Although the majority of respondents (53%) rated this practice as easy to use, 33% doubted it – some commented that it's difficult to understand. However, in terms of security, most of participants expressed no concern

about its influence on project security. A question was also asked about other practices that can be used in security projects development. Only two answers were provided – bug bounty and security hackathon. This shows that it's not a common knowledge among developers.

The results show that, although not all practices are easy to use, most of them serve their purpose well by explicitly requiring some security assurance activities. Some of those that scored lowest in terms of easiness might be improved by description clarification, training or providing supporting tools.

#### IV. OWASP ASSURANCE ARGUMENT

Because of the positive results of practices security assurance evaluation, the next step was to add them to the Practices Knowledge Base. The selected practices were analyzed according to the AgileSafe practice description template and incorporated into the knowledge base. Newly added security practices were assessed with respect to their OWASP conformance potential.

OWASP ASVS requirements has been added to the method and based on the Practices Compliance Assurance Argument Pattern, were mapped to the Practices Compliance Assurance Argument using NOR-STA tool [28].

All of the OWASP ASVS requirements were successfully mapped into the structure. The practices that were able to answer specific requirements were attached with a relevant rationale in the NOR-STA tool. None of the requirements were left without a practice that might be able to provide conformance.

It is worth noting that there was not one practice that would sufficiently address all of the OWASP ASVS requirements, which means that in a project wishing to comply with the standard, implementing a combination of the analyzed practices would be needed.

The prepared Practices Compliance Argument has been accepted as a part of the AgileSafe potential extension for security assurance domain. Based on this argument, depending on a given project's Project Characteristics, a new hybrid approach with OWASP ASVS compliance potential could be suggested.

#### V. CONCLUSIONS

During the literature review, 10 security-oriented agile practices were identified. The practices were positively assessed in the conducted surveys and successfully enriched the Agile Practices Knowledge Base. The OWASP ASVS was mapped into the method and formed, along with the identified practices, the Practices Compliance Argument, which after updating it with all of the other applicable practices available in AgileSafe, might be further used to support practices selection in specific projects. A case study carried out with such projects, going through the whole practices selection process of AgileSafe might be performed as next step of the research.

# 7<sup>th</sup> Conference on Multimedia, Interaction, Design and Innovation

**M**IDI Conference provides an interdisciplinary forum for academics, designers and practitioners to discuss the challenges and opportunities for enriching human interaction with digital products and services.

The main focus of MIDI Conference is exploring design methods for creating novel human-system interaction, developing user interfaces and implementing innovations in user-centred development of advanced IT systems and on-line services.

## TOPICS

Topics of interest include (but are not limited to) the following areas:

- interactive multimedia and multimodal interaction design
- novel interaction techniques, voice interfaces, interactive multimedia
- ubiquitous, multimodal, pervasive and mobile interaction, wearable computing
- novel information visualization and presentation techniques, Augmented/Virtual Reality
- design methods for usability, accessibility and outstanding user experience
- prototyping of user interfaces and interactive services
- human-centred design practices, methods and tools, user interface design
- unfolding trends in HCI research and practice, customer experience, Service Design
- advances in user-centred interaction design
- understanding people and interactions: theory, concepts, models and methods
- understanding people and interactions: contextual, ethnographical and field studies
- critique and evolution of methods, processes, theories and tools for human-computer interaction
- novel methodologies for conceptualization, design and evaluation of interactive products and services

## EVENT CHAIRS

- **Marasek, Krzysztof**, Polish-Japanese Academy of Information Technology, Warsaw, Poland, Poland
- **Romanowski, Andrzej**, Lodz University of Technology, Poland, Poland

- **Sikorski, Marcin**, Gdansk University of Technology, Gdansk, Poland, Poland

## PROGRAM COMMITTEE

- **Biele, Cezary**, Information Processing Institute, Warsaw, Poland, Poland
- **Forbrig, Peter**, University of Rostock, Germany, Germany
- **Guttormsen, Sissel**, University of Bern, Institute of Medical Education, Switzerland, Switzerland
- **Korżinek, Danijel**, Polish-Japanese Academy of Information Technology, Warsaw, Poland, Poland

**Abstract**—The number of older drivers will be increasing therefore, their needs and requirements need to be taken into account when designing in-car user interfaces. Current solutions in car industry tend to use big touch screens for controlling the secondary tasks, such as navigation. These solutions are proved to be very distracting while driving. We present a design of conversational assistant for older drivers to improve secondary-task performance, help with decision making in primary tasks with reduced stress. We conducted a user study in the laboratory (N = 7) and gained initial knowledge about how the conversational assistant should support older drivers in secondary tasks. Our exploration revealed potential opportunities for the future design of such in-car assistants.

**Index Terms**—Driving, Voice Interfaces, Multitasking, User Centered Design

## I. INTRODUCTION

THE number of older drivers will be increasing, as the percentage population aged 65 and over was 13,8% in 2000 and 18,8% in 2017, it is expected that it will rise to 24% by the year 2030 [1]. Whatmore, seniors use individual car transport much more compared to the past [2].

With growing age drivers start to experience more frequent problems with their visual perception, attention and fast decision making [3].

Unrelated to the driver's age, all drivers are exposed to a steadily increasing number of distractors. According to [4] and [5] distractors can cause secondary task distraction, which diverts the driver's attention away from the primary task - driving. The driver becomes occupied with events which are unrelated to driving, occur away from the forward roadway and urge the driver also to look away from the forward roadway. We can divide these distractors into two groups - internal distractors (inside the vehicle) and external distractors (objects located outside the vehicle). In this paper, we are investigating only the internal distractors, which in our case are navigation system and messaging while driving. The distraction has a significant contribution to driving accidents [4] (23% of all crashes and near-crashes are caused by secondary task distraction). According to [6] the potential for a secondary task to distract the driver is determined by the task complexity, current driving demands, driver experience and skills, as well as driver's willingness to engage in the task

The influence of distracting tasks on driving performance is bigger for more complex activities, especially when drivers are

older [7]. Therefore our goal is to reduce the secondary task complexity and workload with the help of a conversational assistant. It is now possible to implement conversational assistants into cars, thanks to the progress in speech recognition systems in recent years. Also with the arrival of car-to-car and car-to-infrastructure communication, these intelligent assistants can become safer and less distracting, as they will take into account broader context, for instance, road situation, nearby traffic, etc.

In this paper, we present results from a Wizard of Oz user study with older drivers where we explored the experiences with conversational assistant designed for older drives to help them handle the secondary tasks (navigation task and messaging task) with maintaining the safety and lowest distraction as possible. Our goal was to explore how such system as a conversational assistant will be accepted by older drivers and what benefits it could bring them. Our design evoked various reactions: some drivers found the conversation with the system while driving still too distracting, but some were satisfied with our design mainly in messaging task where our proposed semi-autonomous messaging system was rated very positively.

## II. RELATED WORK

In this section, we examine existing solutions and concepts related to secondary tasks, distractions and use of conversation interaction while driving. We focused mainly on studies where the target groups were mostly older people or where the studies aimed at problems related to our case of study.

### A. Distractions while driving

Distraction can be often caused by other persons - passengers or someone on the phone, but the effect is not usually the same in both cases. Passenger is a direct participant in traffic so the conversation can be modified according to the situation on the road. In opposite, a phone call cannot be naturally suppressed according to conversation suppression hypothesis [8]. Bruyas et al. rescheduled these real-time tasks to become asynchronous. Their results show that it can help to reduce pressure on driver compared to synchronous phone communication, as a suitable place can be chosen in respect of traffic situation. Another most common problem is manual (frequently finger touches on the screen) control of infotainment systems which leads to long or frequent off-road glances

causing great danger. The study by Lee et al. [9] examines how errors in interacting with infotainment systems influence driving performance, specifically input of the words using a touchscreen, and how drivers recover from these errors. They suggest that for preventing high distraction caused by secondary task, sufficient but not greater than necessary visual information should be provided.

Although the speech-based interface has also some negative impact on driver's workload, according to Maciej and Vollrath [10] it is still better than displays and manual controls.

### B. Multimodal Interaction in the Car

One possible approach to overcome the limitations of speech-only interfaces can be multimodal interaction, which may provide fine-grained control with immediate feedback and easy undo of actions. Pfleging et al. [11] designed an interaction that combines speech and gestures on the steering wheel. To adjust distraction when interacting with infotainment systems some novel interactions techniques are becoming popular, e.g. mid-air gestures. However, the problem is with the feedback, which is still mainly through visual displays, Shakeri et al. [12] investigated different types of feedback modalities. Their study concludes that non-visual feedback (auditory, tactile) can significantly reduce distraction. In the work of Tashev et al. [13] authors created multimodal dialog system for infotainment and also formulated key requirements for voice enable infotainment systems, concerning the efficiency of multimodal interaction during high cognitive load situations.

### C. Older drivers

It is obvious that older drivers have special demands. Besides some physical impairments (visual, motion, etc.), they are more sensitive to time pressure and complexity of the tasks. On the other hand, older drivers are calmer, less reckless and less daring drivers than earlier in life and there are many aspects from which older drivers can profit. For example from their life-long driving experience, maturity and flexibility to drive at times and places that they perceive as being safer [6]. According to Bjelkemyr et al. [14] this flexibility closely relates to a phenomenon of self-regulation, which can manifest as avoiding certain conditions (e.g. driving at night or during rush hour) or difficult traffic situations (e.g. driving through specific intersections), next reducing speed, avoiding motorways, big cities, long distance travels and avoiding unknown cities, etc.

### D. Secondary tasks

There is a wide variety of secondary tasks that can be performed while driving. For our research, we have chosen two tasks: navigation on the unknown route and messaging as they are highly distracting the driver [15]. The navigation system is common equipment in cars with a lot of useful functions nowadays, but design low-distracting user interface is not an easy task, many drivers also use their mobile phones as a navigation aid. Use of mobile phones (hand-held) in

many European countries is prohibited, but drivers keep using it. Hands-free use is also proven to be distracting while driving [16]. On the other hand, there are cases in which phone calling or sending messages is necessary for drivers, therefore they need to be supported by intelligent systems to finish these tasks safely.

1) *Navigation*: The navigation task is typically supported by navigation systems that heavily rely on the visual (displays with maps) and physical (touch screen with user controls) interaction. The distraction level, especially in some stressful situation is very high [6], [10], [14]. For the purposes of an experiment, we focused on dealing with stressful error situations. According to research by Bjelkemyr et al. [14] older people reported to be calmer, less reckless and less daring drivers than earlier in life, but less busy roads are more important to them than the duration of the trip, because of their time-flexibility [6]. Bjelkemyr et al. also found out they have problems in finding their final destination and need to plan their travel in advance. Whatmore, mental states during driving can influence mood after arrival (stress), the passenger is often used as a co-pilot when in some stressful traffic situation. The researchers conclude that support systems for older drivers should increase comfort and decrease their level of stress.

2) *Messaging*: For the messaging task, there are several insights and notes that we took into account. The use of a mobile phone and even the hands-free phone calls while driving are proven by research to be very distracting and dangerous secondary tasks [16]. Atchley et al. [17] examined interview with 348 young responders, and the results show that sending, replying and reading of text messages have been recognized as riskier behavior compared to talking on the mobile phone. On the other hand, when having a mobile phone conversation driver's reaction time is increasing with the increased time of the conversation [18]. Moreover, according to Dula et al. [19] more emotional and intense phone conversations tends to cause more dangerous driving behaviors. Fofanova and Vollrath [6] also state that older people have worse driving performance when using a mobile phone. According to Lipovac et al. [16] with the growing age, the percentage of those who considered mobile phone use while driving an unsafe activity increased.

## III. DESIGN

In this section, we propose a concept of conversational assistant designed for older drivers. For the beginning of our research, we focused only at two selected tasks and the design process started with the following scenarios.

### A. Dealing with error stressful situation.

This scenario covers the recovery from error and stressful situations (see sections III-A1 and III-A2). The error situations can be identified either by the system, or they can be identified by the user itself. When the system identifies this situation, the driver will be informed about it. Then the driver can confirm or refuse that the situation is erroneous. The system then will suggest the driver how to solve the situation. Furthermore, the driver can modify the suggested solution or accept it.

TABLE I

EXAMPLE 1 OF THE DIALOG BETWEEN THE USER (U) AND THE CONVERSATIONAL ASSISTANT (A) FOR SCENARIO 1.

- A:** It seems that is hard to turn left now, is this true?  
**U:** Yes, I can't make it.  
**A:** That is no problem, you can continue straight this lane, there is another way and the delay will be only one minute.  
**U:** Okay, that's good.  
**A:** After the crossroad, try to get to the left lane when it is possible. You will be informed about next steps, don't worry.

TABLE II

EXAMPLE 2 OF THE DIALOG BETWEEN THE USER (U) AND THE CONVERSATIONAL ASSISTANT (A) FOR SCENARIO 1.

- A:** It seems that it is hard to turn left now, is this true?  
**U:** Yes, I can't make it.  
**A:** That is no problem, you can continue straight this lane, there is another way and the delay will be only one minute.  
**U:** I rather turn right, the situation in front of me looks complicated.  
**A:** Okay, turn right. There is a better way, which is more peaceful and the delay is insignificant - only 4 minutes more. You have plenty of time to get to your final destination.

1) *Wrong lane on a crossroad:* The driver is arriving at the crossroad with three lanes. Traffic is heavy, s/he is in the most right lane but according to the navigation, s/he should be in the most left lane to turn left. System evaluated that s/he is too close to the crossroad to change the lane safely (see dialog examples in I, II and III).

TABLE III

EXAMPLE 3 OF THE DIALOG BETWEEN THE USER (U) AND THE CONVERSATIONAL ASSISTANT (A) FOR SCENARIO 1.

- A:** It seems that is hard to turn left now, is this true?  
**U:** No, I just want to turn right to the fast food on the corner.  
**A:** Okay, do you mean "McDonald's" restaurant?  
**U:** Yes.  
**A:** Perfect, go ahead and the parking lot is in 200 meters. The entrance to the drive thru is few meters further.

2) *Lack of fuel:* Driver noticed that a gasoline indicator shows that there is no much gasoline in the tank, feels insecure, thus starts conversation with the system (see dialog example in IV).

### B. Semi-autonomous messaging system

For our first design iteration of messaging task we selected model situation described in the following scenario. The scenario represents situation when the driver wants to send informative sms messages about the journey to someone (e.g. a partner, relatives). See dialog example in V.

*It is Thursday morning and in a town's swimming pool ends regular lecture for seniors. One of the participants is*

TABLE IV

EXAMPLE 4 - EXCERPT FROM THE DIALOG BETWEEN THE USER (U) AND THE CONVERSATIONAL ASSISTANT (A) FOR SCENARIO 1.

- U:** I have a low amount of fuel, is it enough to get home?  
**A:** It should be enough to get home, but I recommend to stop at petrol station due to the traffic situation. Do you want to find petrol stations?  
**U:** Yes, find the stations.  
**A:** There is a petrol station OMW twelve kilometers ahead on the road you are going. Do you want to stop there?  
**U:** Nah, is there any Shell station? I have their VIP card.

TABLE V

EXCERPT FROM THE DIALOG BETWEEN THE USER (U) AND THE CONVERSATIONAL ASSISTANT (A) FOR SCENARIO 2.

- U:** I want to write an sms.  
**A:** I see that you are driving home, do you want to set sending sms to Peter (husband) or someone else?  
**U:** To Peter, please.  
**A:** Got it. Should I send him that you are about to go home?  
**U:** Yes.  
**A:** Do you want to add something to the message?  
**U:** No.  
**A:** Okay. I have sent the message to Peter. *Maria had started driving but after few kilometers she got stuck in a traffic jam.*  
**A:** It seems that there will be a little delay due to this traffic jam. Should I send a message to Peter about it?  
**U:** Yes, please.  
**A:** I will send him this text: "Hi Peter, I am in a traffic jam on the Neibolt street, it seems that I will arrive ten minutes later, around 6:45. Maria." Should I add something?'

*70-year-old Maria, who is an enthusiastic swimmer and she never misses a lecture. She lives with her husband Peter in the nearby city, but the connection by public transport is not good, so she uses car for transportation. Her husband is worried about her drive back as she could be tired after an hour of swimming. Unfortunately, there is no other option. Thankfully, they have got a semi-autonomous messaging system in their car so he can be calmer when gets messages about the journey of his wife. After the engine had started, Maria got information that the messaging system is ready and asked if she wants to send a message to her husband that she is about to go. The system reads a prepared message and asks for confirmation. During the way home, Maria got into the rush hour of a city so got stuck in a traffic jam. In that moment the system asked if she wants to inform her husband about the traffic situation and delay. After her reply, the system sent a message to Maria's husband about the situation and estimated delay and then informed her that the message had been sent. Both Maria and her husband can be relaxed, because they know that everything is alright.*

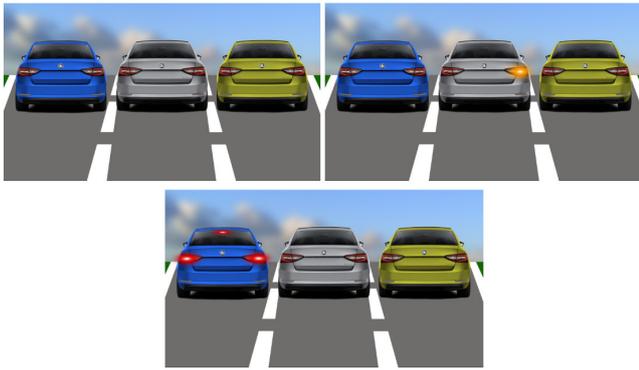

Fig. 1. Screens of primary task script in three different states (none action, middle car signals right turn, left car is braking)

#### IV. FIRST EXPERIMENT

##### A. Participants

Target group for our experiment were people over 60 years old. Having a currently valid driving licence was not required but the participants should have driving experience. We recruited 7 participants. They were aged from 61 to 74 years ( $mean = 68.71$ ,  $SD = 5.47$ ). All of the participants were native *Anonymized* speakers. For more information see Table VI

##### B. Apparatus

**Primary task simulation.** The primary task was designed for simulation of paying attention while driving. It was being handled by a script, which showed static pictures of three cars (see in Figure 1) from the back view on the computer screen. After a period between 6 to 10 seconds (randomly selected), one of the cars performs action of braking, signals turning right or left (illustrated by turning on back brake lights or blinking of signal lights). All of these parameters are chosen randomly. Participant should react immediately to these actions by pressing the correct key on the keyboard (spacebar - brake lights, left/right arrow for turning signals).

**Secondary task.** Wizard of Oz technique was used for simulation of interaction with designed dialogue system for each task. For this experiment moderator played pre-recorded phrases according to the participant's responses and the current state of dialogue. For the uncovered states (unexpected participant's answer or request), universal recovery phrases were prepared. Furthermore, the participant could ask for repetition of question/answer. Playing of pre-recorded phrases was handled by the moderator using the web application (HTML and JS), which allows controlling playback of phrases for specific states. The control interface also contains a dialog state diagram (see example in Fig.2) for the given scenario for better orientation of moderator in the dialog flow.

**Equipment.** The experiment was done by using two notebooks, the primary task simulation script was running on the first one (with an external keyboard connected) and the second one for controlling the Wizard dialog application by

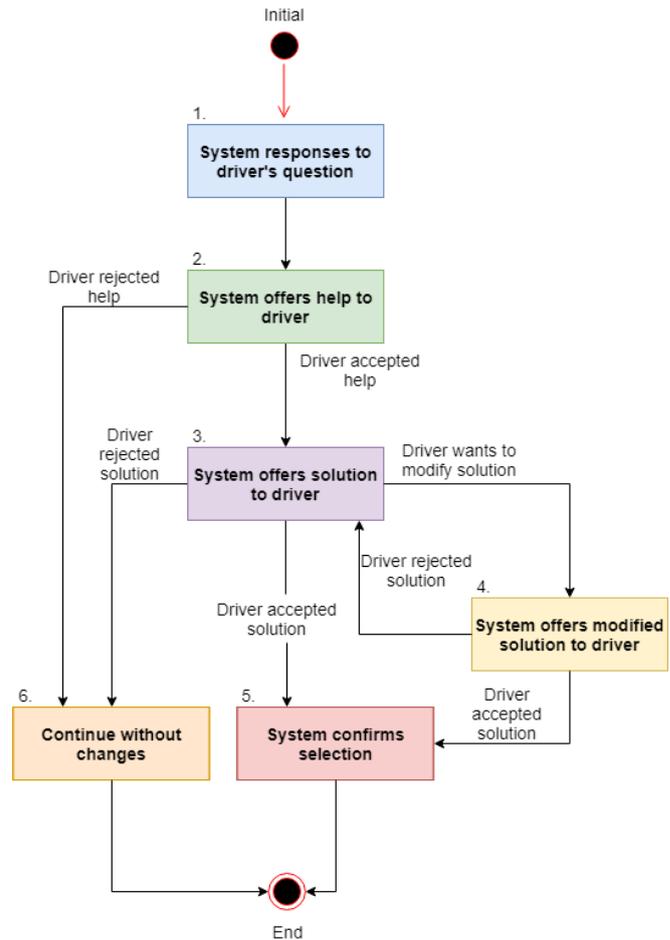

Fig. 2. Dialog state diagram example (Task B1).

the moderator. Each use-case was complemented by a printed map for better illustration of situational context described in the scenario presented to the user. Furthermore, we used a small car model for showing participant's position on the map. Experiment setup (without the moderator's notebook) can be seen in Figure 3.

**Data Collection.** During each session, the audio was recorded. The reaction time and correctness of the pressed key were also measured. However, the number of participants is not sufficient for quantitative testing and measured values are not significant for this time, it can be used for later experiments or evaluation.

##### C. Procedure

The experiment was divided into the following individual tasks, which were based on previously described navigation and messaging tasks with selected scenarios.

###### 1) Experimental tasks:

- Training: primary task only
- **A1**: Stressful situation on the crossroads - false negative
- **A2**: Stressful situation on the crossroads - false positive
- **B1**: Low fuel

TABLE VI  
TABLE WITH DETAILED INFORMATION ABOUT PARTICIPANTS

Participant ID	Balancing	Age	Gender	Active driver	Infotainment exp.	Voice interface exp.	Visual Impairment
P01	AB	61	male	yes	yes	yes	reading and distance eyeglasses (5-6 dioptre)
P02	BA	62	female	yes	yes (not using navigation)	no	distance eyeglasses (2 dioptre)
P03	AB	74	male	no	no	no	uses eyeglasses only when the light conditions are not good
P04	BA	74	male	yes	no	no	reading eyeglasses
P05	AB	67	male	yes	yes	no	no
P06	BA	72	male	yes	yes	no	distance eyeglasses (2 dioptre)
P07	AB	71	female	yes	no	no	uses eyeglasses for reading and driving

Fig. 3. Experiment setup, without second notebook for experienter

• **B2:** Semi-autonomous messaging assistant

2) *Balancing*: For the experiment we chose the balancing of the experimental tasks as AB – BA. With that every participant will go through Training phase, interacting only with primary task. Task assignment to participants can be seen in the Table VI.

3) *Surrounding scenarios*: Before the beginning of each task, it was necessary to empathize the participant into the situation. For that we used following surrounding scenarios together with printed maps (map for task A1 and A2 can be seen in the Figure 4, map for tasks B1 and B2 in the Figure 5). After the simulation is started, the moderator initiates interaction with the participant through a dialog system, following the state diagram of the dialog (this is repeated for all tasks).

**A1.** The driver arrives at a crossroad in the right turn lane. The moderator shows to the participant where his/her final destination is, using the map, and where it is best to get to it (turn left). At the same time, moderator points out that the participant is in the right lane and on the traffic situation in other lanes. The participant begins with an imaginary approach

to the intersection and the moderator launches the primary task simulation.

**A2.** The driver arrives at a crossroad in the right turn lane. The moderator shows to the participant where his/her destination is, using the map, and where it is best to get to it (turn left). At the same time, moderator points out that the participant is in the right lane and on the traffic situation in other lanes. However, the participant is instructed to "make a small break" and stop at a fast food restaurant that is a few meters after turning right. The participant begins with an imaginary approach to the intersection and the moderator launches the primary task simulation.

**B1.** The driver is on his/her way home. Finding out that he/she does not have too much fuel and many miles ahead of him/her, theoretically, there might not be enough fuel in the tank to complete the trip. The participant is also informed that s/he owns a Shell VIP card, thanks to that a liter of gasoline is much cheaper than the normal price. The participant is instructed to try to deal with a possible fuel shortage. To add more weight to a given situation, s/he is once again informed of the long journey waiting for him/her and the fuel tank indicators, which for the time being are not signaled by the indicator light, but it is clear that this may happen soon. The participant starts when s/he is already on the road and the moderator launches the primary task simulation.

**B2.** The driver sets out on his/her way home to his son David. S/he is very caring and would like to have an overview of the course of the driver's journey (when he set off, delay, etc.). The moderator informs the participant that it is possible to activate the messaging assistant at the beginning of the trip, which can help him/her to inform the son. It is up to the participants to activate the assistant. Moderator informs the participant that use-case ends after imaginary arrival home. The participant begins the situation when he sits in the vehicle and sets out on the road. Moderator launches primary task simulation. After the simulation is started, the moderator waits for the participant's stimulus and then initiates interaction with the dialog system by following the status diagram of the dialog. If the suggestion does not come for a longer period of time, the moderator initiates the dialogue initiation phrase (in the post-questionnaire asks why the participant did not start the communication).

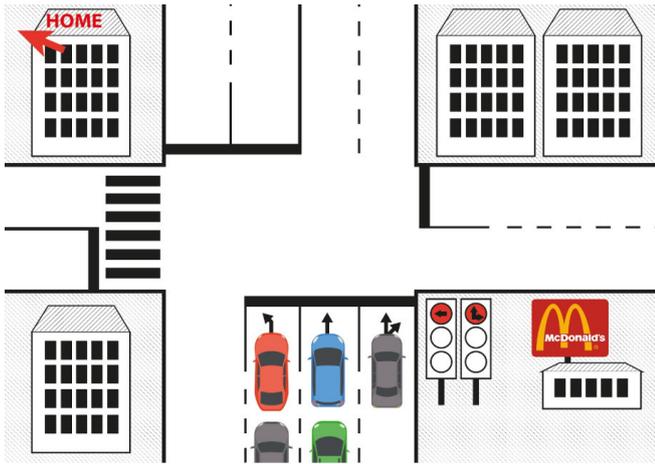

Fig. 4. Map for better illustration of the Navigation scenario

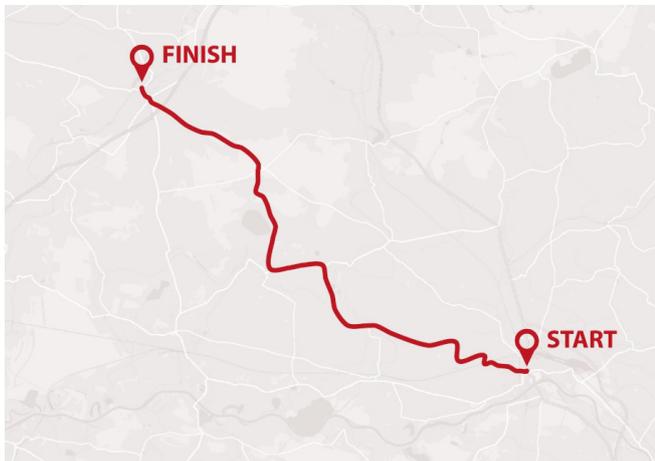

Fig. 5. Map for better illustration of the Navigation scenario and Messaging scenario

4) *Post-interviews*: Three post-interviews were executed to get feedback from participants about the subject of testing. One cumulative for tasks A1 and A2, and two separate for each B1 and B2 task. The open questions about their first impressions and how did they liked the dialogue with the conversational assistant, were posed to participants. We also asked participants about their subjective judgements about the level of comfort (“*I felt comfortable when I was using the system.*”), comprehension (“*I think that the system spoke comprehensively.*”), intuitive conversation (“*I think that the conversation was intuitive.*”) and level of acceptance in traffic (“*I can imagine that I would use the system in traffic.*”) on a 5 point Likert scale as a level of agreeing with presented statements.

## V. RESULTS

### A. Wrong lane on the crossroad

**Trust and distraction.** In general, situation in scenario A was hard to imagine for participants, P07 said she had never

been in this situation in the real life, P02 did not trust the advice from the system to continue straight, because it is not sure what will be the situation on the next junction, P03 cannot imagine using the system in this situation. He does not like larger dialogues while driving (also with passengers), he rather focus on driving. P06 said it was excellent, that system reacted immediately to the situation. Regarding the deviation to the restaurant, it understood me and provided me even with the distance information.

**Complexity of answers.** Participants P01, P02 preferred shorter speech. They answered mostly with short answers, he used answers like: “*Yes/Yep/No*”, etc. , therefore, did not get enough information to go into the right state. On the other hand, P06 answered the first question with a complex utterance (“*Yes, but I will change the route to the McDonald’s restaurant*”).

**Modification of system suggestion.** Some of the participant modified the suggestion from the system, P01 for instance, did not declined or accepted the suggestion from the system, but said: “*To the right*”. Even if he was told he want to turn left to reach the destination, he chooses the third option. P05 replied yes to the question if he cannot turn left (“*It seems that is hard go left now, is this true?*”). But the answer to the question if he wants to continue straight was: “*Not really, we will try it for now.*”

P04 would like to have more additional information for making his decisions. For instance availability of parking lots, which can be also found on road signs, but they are not so important and he can miss them because he is focusing on the driving.

### B. Low fuel situation

**Start of the conversation.** P01, P03, P04, P07 did not initiate the dialogue by themselves or were not sure how to initiate it. P04 expected that the system will offer him his preferred petrol station automatically. P05 was continuously talking about the situation (thinking aloud), about worries if there is enough fuel to reach the destination, it would be hard for the system to recognize his intent.

**Modification of system suggestion.** P01, P05 correctly rejected OMW station as they were instructed they had VIP card for different petrol station. P03 did not ask about searching for his preferred petrol station, he waited for information given by the system. P06 was asking the system to find Shell gas station (“*Find closest Shell*”). Participant refused offered Shell (because of the deviation from the route) and asked for another Shell gas station. System offers OMW station which is directly on the route. Participant refuses and asked for Shell station (“*How far will be Shell*”). System offered the same Shell (with deviation). Participant refused and asked for another Shell. System refused and participant asked why it is not possible to find another Shell Station. Participant tries to refine the request by specifying to find Shell station without deviation (“*Find closest Shell without deviation*”). Finally participant accepts the Shell station with deviation. P06 disliked the offer of the gas stations. There for sure must be another Shell station

closer to the route, what is a problem of the database of POIs rather than problem of the dialogue.

**General.** P01 was often answering before the utterance from system was completed, he seemed to be impatient. P02 used “Thank you” to end the conversation, she said it was great and she liked it, also understood it well. P03 did not like risky situation, when he was not sure if the amount of petrol is enough to get to final destination. P04 did not know that he can ask about his favorite petrol station, so the system was still repeating information about the same petrol station. It was annoying for him. On the other hand, P07 liked the fact that she could ask the system about different petrol stations.

### C. Messaging assistant

**Distraction.** P01 mentioned that the sending of messages should be automatic, when he starts the route navigation. P01 also said the amount of the conversation during this scenario was too big. He would like it to be more automatic, because this semi-automatic system can be still too distracting. P03 appreciated the ability to send message without distraction.

**Message preparation.** Participant P05 dictated all parameters in one sentence (time, contact phone number, message). P06 was dictating the content of the message only and as an appendix adds “...and then I will finish the sentence”.

**Sending message.** On the way P06 asked to send a message to David by means of clear request to the system (“Send a message to David.”). Participant requested to add time to arrive to the message.

**Complexity of answers.** P05: The answer to the question “Do you want to send an SMS” was complex “Well, definitely, because I will be late, I guess.”. The answer to the question “Do you want to add something to the SMS” was also complex “No, that is enough, it is exactly what I meant.”

**General.** P02 started conversation or activated the messaging system with “I’m just leaving”, system then asked about the purpose of the drive, participant answered “I am going to see you”. Participant P03 appreciated using of messaging assistant. P06 requested confirmation of the message delivery.

### D. Post-interview

P01 said that the system was too verbose. P02 mentioned it would be difficult for her to learn how to use this system, because she does not use the navigation system in her car and she drives only on known routes. On the other hand, she would welcome the messaging system in her car. P03 had doubts about the reliability of these systems in nowadays cars in general. P05 mentioned he was a bit nervous about what and when will happen, it means it is not clear when and what the system will start talking about. “The system could maybe continuously talk about the situation. Long silences makes me nervous if the system is functioning and the question is surprising me.” P07 liked that he can control message sending with voice and did not have to use hands or make a phone call.

### E. Subjective judgements

Fig. 6 shows that system acceptance in traffic was positive mainly for tasks B1 and B2, regarding tasks A1, A2 almost half of the participants would not accept this system in real traffic situations. Almost 100% of participants strongly agreed that the conversation with system was intuitive, only one participant was neutral in task B2. 90% of participants agreed or strongly agreed that the system spoke comprehensively. 2 participants disagreed in task B2 about the comprehension. 95% of participants agreed or strongly agreed the system was comfortable to use.

## VI. DISCUSSION

The qualitative results show that drivers often did not know how to start a conversation with the system. First, older drivers have mostly no voice control experience. Second, the tasks were hard to imagine for the participants. It was our intention not to tell them how they should start the conversation before we started the study, and we just wanted to observe their behavior without previous experience with our system.

The complexity of the participant’s utterances to the system varied widely across the participants, some were talking to the system in complex sentences so that current natural language understanding systems would have a problem identifying the user’s intent. Conversely, there were users who talked to the system very briefly and austere.

The messaging assistant was perceived with a predominantly positive attitude among the participants. They would find it practical and could imagine using it in the car. Some participants would expect the messaging assistant to be even more autonomous and found it unnecessary verbose. Here arises an opportunity to personalize the assistant, for example, based on verbosity and level of automation.

In the navigation task, the biggest problem for the participants was to imagine the scenario situations, but many of them were positive about the contextual information the assistant offered them. The results show that the assistant should be able to offer alternatives, for example, when choosing a gas station. For instance, an assistant informed in advance about the low fuel level, but with the assurance that there is still enough to reach the destination, the participants welcomed and then freely decided whether to stop at the gas station or not. Similarly, in the simulated crossroad situations, drivers freely decided whether to accept the system’s recommendations or not.

### A. Limitations

The main limitation of a user study we conducted was the fact that we did not use a high-fidelity driving simulator instead, we used our low-fidelity simulation of the primary task described in the section IV-B. Therefore, some of the participants had a problem to imagine the context in scenarios we presented them. Furthermore, because of our experimental setup, we were not able to simulate real stressful road situations and so we do not claim that our design will reduce the stress of older drivers, but rather see an opportunity

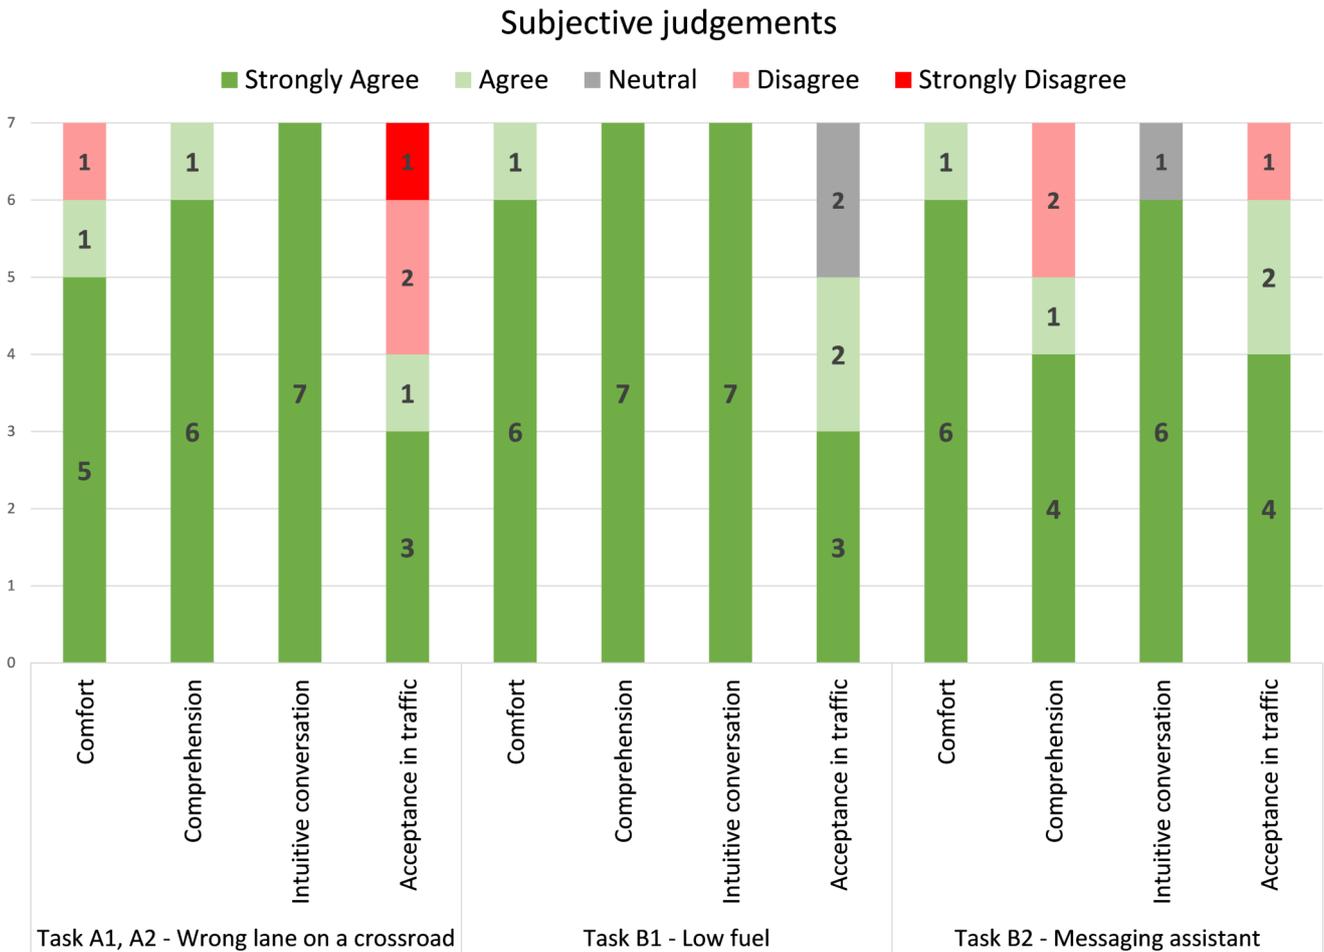

Fig. 6. Subjective judgements about level of comfort, comprehension, intuitive conversation and acceptance in traffic ( $N = 7$ ).

in development such intelligent system which would respect older drivers according to our findings.

### B. Future Work

Given our findings and limitations, future work should further investigate the use of other modalities for supporting the older drivers in tasks that require more rapid action from the driver. For instance in situations on the crossroad and also other fast and stressful situations, the haptic interface, we believe, could be more suitable.

We would also like to further explore the ways how to announce the driver that system is going to talk to him/her, as some participants were surprised when the system started to speak after a longer pause. Again multiple modalities should be investigated. The use of the context of the car, road situation, surrounding traffic or drivers preferences and skills should be explored to determine when is the right time for the system to start a conversation with the driver.

## VII. CONCLUSION

We designed a low-fidelity prototype of conversational assistant for two secondary tasks, navigation and messaging. We also conducted a qualitative user study with 7 older drivers, using the Wizard of Oz method. The results of our study show that support in secondary tasks for older drivers while driving can be carried out by the conversational assistant. But still, there are some limitations when using only speech-based interface, therefore, the use of other modalities should be investigated.

### ACKNOWLEDGMENT

This research has been supported by grant no. SGS19/178/OHK3/3T/13 (FIS 13139/161/1611937C000) and by project RCI (reg. no. CZ.02.1.01/0.0/0.0/16 019/0000765) supported by EU.

**Abstract**—We present a user modeling approach tailored to the user group of older adults with vision impairments. Our previous work with this user group has been followed by qualitative user research with the staff of a residential care facility for visually impaired older adults. We defined the structure of a user model that represents aspects related to personal psychological development and attributes that affect interaction with technologies. Furthermore, we present two generations of prototypes of administration UI for the user model. Results of the qualitative evaluation are discussed in the paper. This effort aims to help the personnel of specialized care institution in providing personalized care and make the interaction with technologies accessible for the group of visually impaired older adults with vision impairments.

## I. INTRODUCTION

ACCORDING to [1] the prevalence of blindness is globally 0.48 %, and 2.95 % of world population deals with moderate to severe vision impairment. The majority of visually impaired people appear among older adults, as 52.9 % of visually impaired people are older than 70 years.

The proportion of older adults in the population is steadily rising. In addition, according to WHO this trend will continue (due to increasing life expectancy and decreasing birth rate) [2]. During ageing, a large proportion of the population is acquiring some kind of health impairment. This fact can be also seen in data of Czech statistical office (data were processed in 2013) [3], 18.6 % of people between the ages of 60 and 74 have some kind of disability. In category 75+ years old, percentage of disabled people rapidly rises, it is around 42.1 %.

Unfortunately, the research attention on older adults with vision impairments (VI) is limited. We have analyzed 39 papers focusing on people with VI presented on last three CHI conferences (2016-2018). When excluding studies focused mainly on children and young adults, the average age of study participant was 37.3 years (weighted average, sample sizes as weights). Hence, the current research focus is in the case of VI people biased in favor of the younger part of the population.

User research conducted in a specialized residential care facility for visually impaired older adults [4] showed that clients are also often challenged with other age-related health issues. Frequently, those people are challenged with cognitive issues (mainly dementia), or mobility issues. The facility

provides individualized care based on personal psychobiographical modeling of individuals [5], [6].

In our previous research, we focused on the development of solutions to support orientation in space tailored to needs and preferences of visually impaired older adults [4]. The evaluation indicated that adaptation of user interfaces and interaction method based on individual needs and preferences could improve usability of particular solutions as well as maximize their acceptance among the target user audience.

In this paper, we present a user modeling approach tailored primarily for the user group of visually impaired older adults living in residential care facilities. The user model can represent individual aspects related to personal biography as well as aspects important for adaptation of user interfaces and interaction methods.

## II. RELATED WORK

In this section, we discuss various technical approaches to represent personal attributes related to interaction with other human beings as well as with technologies – user models. Furthermore, we describe specific approaches for geriatric and gerontopsychiatric care. Finally, we list technological approaches where user model is used for adaption of user interfaces and interaction methods and for providing personalized care.

The original user modelling approaches emerged from the medicine and rehabilitation engineering. The World Health Organization (WHO) comes up with models, which are based typically on measurement and quantification of human performance, which is examined in rehabilitation engineering. The WHO defined ICD (International Statistical Classification of Diseases and Related Health Problems) [7] and ICF (International Classification of Functioning, Disability and Health) [8].

Ability-based design method proposed by Wobbrock et al. [9] suggests leveraging specific individual abilities rather than focusing on disabilities. The use of user-specific abilities and capability of interactive systems to adapt accordingly could make the interaction more efficient, natural, and broaden the audience of users that can successfully use a particular technology.

Peißner et al. [10] come with the idea of individual patterns for accessible and adaptive user interfaces, which are built on information about the user, the context and the devices,

which is gathered through system interaction and sensors. All information about the user is stored in the User profile, which variables include his abilities, disabilities, preferences and his current environment. All the values of the user profile are numeric between zero and four. The context manager continuously updates the user profile. The user profile mixes different variables, and some of them are not so typical for user models (e.g., ambient light and ambient noise).

Heckmann et al. [11] introduce the general user model ontology (*GUMO*) for the uniform interpretation of distributed user models in intelligent semantic web enriched environments. *GUMO* uses *UserML* (User Model Markup Language) [12], which is Resource Description Framework (RDF)-based user model exchange language.

Kikiras et al. [13] present a user model for navigation systems, which is represented through a Semantic Web ontology (User Navigation Ontology – *UNO*). For that purpose, they use the Web Ontology Language (OWL) for describing the user classes and their properties. During ontology development, they extended some of the concepts specified in the *GUMO* ontology [11]. They also adopted the International Classification of Functioning, Disability and Health (ICF) [8] of World Health Organization (WHO) for representing certain functioning and disability issues of an individual. Their model comes up with so-called "*User profile*", which captures user's demographics, mental-cognitive characteristics, sensory abilities, motor capabilities, navigational preferences and interface preferences.

The Böhm's model [5], [6] is an internationally recognized nursing model which is currently used at most in German-speaking countries in the field of geriatric and gerontopsychiatric care. The model is aimed to support the self-care of old and confused people and it is also focused on how to retain or restore the self-care ability for as long as possible by the principle of recovery of the senior's interest by reviving his psyche. Daily life and normality for patients is one of the core issues of Böhm's nursing model. The theory of Böhm is based on understanding of patients, their biography and coping strategies. The biographic assessment and knowledge of coping strategies is crucial for the psychobiographic nursing concept. Patients should stay as long as possible independent and self-reliant and should keep their social competence. Böhm comes up with the theory that learning copings takes place in the first 25 years of life, and in regression, one returns to their own lower copings.

Hoey et al. [14] present a summary of customizable and adaptive technologies for assistance for persons with cognitive disabilities. Authors describe decision-theoretic model based on Partially Observable Markov Decision Process (POMDP) that can be applied to various activities. The system allows user customization, system adaptivity to user and general purpose sensing abilities. Authors state that the concept of *inclusive design* works only for large and uniform segments of population, but fails for individuals with diverse and changing needs like older adults with Alzheimer's disease. A system itself must adapt to people over time as they change.

Internet of Things sensor network as source of heterogeneous contextual information is mentioned in [15]. The contextual information (e.g. daily activities) is integrated into personalized care management processes to support automatic and better decision making in an effective and user-friendly manner. There is set of sensors that recognize personal activities, and the system can provide guidelines how to proceed when one experience an issue when carrying out a particular task. These context-aware services can help older adults to stay at their homes safely.

There are several approaches for user modeling, however, only few leverage specific user abilities (what user can do and can be used for interaction) rather than representing disabilities (what user cannot do and must be compensated by assistive technologies). User group of visually impaired older adults requires a specialized approach for both care provided and interaction with technologies. User research described in section III leverages these specifics. The available user modeling approaches cannot represent the necessary user attributes to a sufficient extent. Also, there is a lack of technological support for psychobiographical modeling of individuals and corresponding care model.

### III. USER STUDY

To learn more information about application of psychobiographical care model in practice, the user research was conducted in the institution for visually impaired people (104 employees and 125 clients in 2019).

#### A. Participants

User research was conducted with three participants (P1–P3), all women, average age 44.33 ( $SD = 15.95$ ,  $MIN = 26$ ,  $MAX = 55$ ). *P1* and *P2* work as activation services workers and *P3* works as direct care worker (social worker). None of the participants worked in a similar type of facility before working in the residential care home we cooperate with. Mean duration of current job title was 7.83 years ( $SD = 7.18$ ).

#### B. Procedure

The user research has the form of a qualitative semi-structured interviews with employees of the institution for visually impaired people. The topics were focused on the activities of activation services workers and direct care workers, the usage of the psychobiographical care method in practice, and the usage of technologies in the institution. One interview lasted approximately 35 minutes (short briefing, 30 minutes interview and short debriefing).

#### C. Results

**Job description.** The main task of the **activation services worker's** job is to give clients the opportunity of self-realization even in older age. Activation services workers prepare for clients various types of activities, both individual and group. These include, for example, cooking, singing, memory training and many more. The activities are tailored to individual clients according to their preferences and habits

from their previous life and are often related, for example, to the client's profession. All activities are voluntary, and it is up to clients whether they want to do any of them. Activation services workers cooperate with health professionals and direct care workers, and it is very important to create one compact team of workers.

**Direct care workers** are responsible for the social aspects of care. They help clients with a wide range of activities, such as personal hygiene, dressing, moving, and eating. An important part of their work is also communication with clients and supporting them in their favorite activities. Every direct care worker is in charge of three clients as a so-called "key worker". He/she should know the most about these clients, map their needs and preferences and share this information with the entire team.

**Daily programme.** The residential care home daily programme has three reference points – breakfast, lunch, and dinner. Between breakfast and lunch, and then between lunch and dinner, there are group, as well as individual, activities that are provided by activation services workers and direct care workers. For clients, the program is voluntary, and it depends only on them what activities they choose, each client has different interests and preferences. Within the individual activities, workers chat with clients, read, sing, go out, etc. There are plenty of group activities in the residential care home – rehabilitation exercises, workshops, singing, cross-words solving, memory training, art therapy, canistherapy, music therapy and more. Group activities take place regularly, usually once a week. Cultural events, such as concerts or theatre performances, are held twice a week at the Great Hall, and these events are very popular. There are also held, approximately four to five times a year, excursions outside of the residential care home, for example, trips to castles and chateaus, trips to theatres and a trip by steamboat.

**Technology use by clients.** The use of computers and similar technologies is limited in the residential care home due to various limitations of clients. Most clients also have a barrier between them and modern technologies. "People, clients, who come here can't work with modern technologies. Maybe they have never seen a computer during their lifetime." (P2)

In the residential care home, there is a device called a reading magnifier, which is used by some clients. In some departments, some gramophones are used to play old records and also to induce the atmosphere of the times when gramophones were commonly found in households. In addition, they use voice-output clocks to inform clients of the current date, time, weather, and so on. Unfortunately, for most clients, these clocks are too complicated. "The voice clocks we use here are too complicated. For most clients, clocks report too much information, which can lead to a big cognitive burden on clients." (P3)

#### **Biography and Böhm's psychobiographic method.**

In the residential care home, Böhm's psychobiographical model of care is applied, specifically its modification, which is adapted to work in the institution. "We use the Böhm's method

*adapted for our needs.*" (P3) The client's biography is a key element of the psychobiographical model. "Biography is such a client's book of life." (P2)

The process of collecting information into biography and its processing begins in the period before the client comes to the residential care home. In this period, the client and his family may be asked to provide some information. "Even before the client arrives, the client and his/her family are asked to think about providing information and photos of the client and to write a client's life story at their discretion." (P2) Unfortunately, cooperation with family and clients is sometimes difficult. "Sometimes collaboration with client's family is complicated because they are reluctant to provide sensitive information about a close person." (P2) However, it is essential that neither the client nor his/her family is pushed into anything and that the provision of information must be based on a free decision.

After the client's entry to the facility, the "key worker" assigned to the client has to start the processing of biography. "We then communicate with the client and start processing the mapping, where we write down the information that client provides to us. Based on it, we create the client's life story, which is written into a biographical book with attached photographs." (P2) Workers must establish a relationship with the client to get as much information about the client as possible. "The amount of information that clients are willing to convey is different, someone is willing to tell everything, someone almost nothing. It is up to us to establish a relationship with the client to tell us something, but at the same time, we must understand that client have told the information to us and may not want the information to appear somewhere. I had a client who directly wished for some information not to appear anywhere and did not even want to publish information under her name, so she invented a fictitious one." (P3)

Biography is in paper form. It has a fixed structure according to which workers must proceed during its creation process.

In the biography, there is a client's life story with photographic documentation. The life story contains information about the client's childhood, youth, adulthood, old age, and this information is then used to work with the client. There is a need to find out what the clients have gone through in their lives, about their families, their interests, their education, their occupations and then specific patterns of behaviour can be derived from this knowledge. "Biography should tell us about client's behaviour patterns, in which environment he grew up, and we must realise that man in old age is hardly going to change his behaviour." (P3) It is also necessary to put the information about the client's life in the historical context. Many clients have experienced the First Czechoslovak Republic, the Nazi occupation, the putsch in 1948, the totalitarian regime, the Soviet invasion in 1968, and of course all these events influence man. "We should have a basic, maybe even advanced, knowledge of history to know what it does to a man when he experiences during his active life such turbulence as in the 20th century in Europe, especially in Czechoslovakia." (P3) It is also necessary to learn negative information about

the client to avoid possible misunderstandings and unpleasant situations. *“It is also good to know topics that client doesn’t want to talk about. Some clients have experienced war or totalitarianism. Some of them don’t mind talking about it, but some clients don’t want to hear German or Russian. So it is necessary to know negative information, experiences, etc.” (P2)*

Also, the biography includes a client’s tree of life (lineage), where information about his relatives, friends, etc. can be found. *“In deeper dementia, clients become more likely to think that we, caregivers, are their friends when they were ten years old and they address us with the names of their friends. And when we know that he/she is addressing us on behalf of a friend, we know he/she has such a relationship with us.” (P2)*

Furthermore, so-called *“activities of daily living”* are part of the biography. These are divided according to the tasks of the ordinary day. They describe what is typical for the client, what he was used to and how to transfer this fact to residential care home reality as faithfully as possible so that the client feels at home. The biography also affects activities such as client dressing up, which can be taken as an example of such a task of daily living. *“We had a client who belonged to the almost highest social class in the First Czechoslovak Republic. She was very fond of wearing luxury costumes with pearls. Thus, in dressing, it would be written in the activities of daily living, that she was used to the luxury, that she still keeps these habits and that even when she is infirm, we will not give her sweatpants even if it is easier for us to provide her with care.” (P3)*

If a client with dementia enters the facility, it is necessary to collect the information as soon as possible. *“When a new client with dementia comes here, we need to find out as much information as soon as possible. There is a need for cooperation with the client’s family. It may happen that the client enters the residential care home and in two months period, he will not be able to provide us with further information. Then, work based on the biography is complicated.” (P2)*

Biography is constantly maintained and updated with new information. *“Biography is handled by everyone except medical staff. Maintenance of biography is the work of the whole team.” (P2)* Access to biography, which is located in the nurses’ room in locked safes, is available to all department workers and can be provided to the client or his/her family upon the client’s request. *“Biography contains sensitive personal information, often even intimate, so trainees or anyone else who does not work in the department does not have access to it.” (P2)* Employees have regular weekly meetings where they discuss individual clients. *“We always have a meeting on Wednesday, where clients are discussed according to Böhm’s method. We all, including health professionals and a psychologist, discuss the client’s score (differential diagnosis), the activities of daily living and so on. The key worker then selects all the relevant information he needs for further working with the client.” (P2)*

The biography is fundamentally reflected in the work of caregivers. *“Activation and communication with the client are tailored to the biography.” (P2)* *“For example, the client was a seamstress all her life, so she works with a fabric that reminds her of a long period of her life.” (P1)*

Based on a biography, caregivers try to bring clients closer to the environment they have been familiar with during their active life. For example, listening to music and recordings from that period can help. *“The music of the 1950s is playing right next door – Chladil, Simonová and other singers. We play recordings from Semafor every day, so these days we get slowly to 1960s.” (P2)* Then, for example, reading books about the time, when clients actively lived, about places, which clients could visit and about the activities they could perform can also help to induce well-being. *“We read autobiographies of actors, musicians, and writers. We also read about countries and places where clients often travelled in the 1970s – Hungary, Poland, East Germany, we read for example, about Rügen and Lake Balaton. We also read about camping or pig-slaughtering.” (P2)* The aim is to retrospectively return clients to a time when they were actively living their lives. *“We are going back to the age when clients were about 25 years old.” (P2)*

For less oriented clients, workers read fairy tales, various stories and poems. *“We read mainly the fairy tales of Božena Němcová, Karolína Světlá and other authors. We read especially the shorter ones, such as The Red Riding Hood. We also read some poems that are clients familiar to.” (P2)*

The activities of clients and activities of workers with clients are recorded in the system. However, clients have the freedom of movement around the residential care home, and so, for example, a visit from a client’s family is not recorded. *“Clients have freedom of movement, but most of them report such activities. If the client leaves the home, we write down the fact that the client left and also the expected return.” (P2)*

*“The biography must be handled carefully, and workers must maintain a professional approach without an evaluation approach, even though some client’s habits may, for example, seem weird to them.” (P3)* *“The problem is with the increasing difference between clients and workers. There are two completely different worlds, the world of young workers on one side and on the other side the world of clients who are still ageing. Therefore, the worker must understand the client, which is also very difficult and some misunderstandings may arise.” (P3)*

**Technology use by workers.** A barcode readers system for recording client’s activities, which is used in the residential care home, helps employees. Each activity is assigned a unique barcode that is scanned with the reader and all records are downloaded to the system at the end of every day.

All participants can imagine the electronic version of the biography, but the current form is more acceptable and enjoy-

able for most of them (P2 and P3). “It’s nice to have it in the form of the book, it’s more natural and easier to pass on to someone.” (P2)

The user research with employees of the residential care home indicated that personal psychobiography is frequently used for purposes of providing care. The collection of data begins even before a client arrives at the institution. It contains information about client life in the historical context, their specific patterns of behavior, or activities such as client dressing customs. Furthermore, the biography contains so-called “activities of daily living” that describe what is typical for the client and what he was used to. The psychobiographical sheet, which includes all the relevant information about the client’s biography and nowadays is in the paper form, is shared among personal, and there is limited access for others. Workers also routinely record activities performed with clients into the system using a barcode scanner. The research with employees and our previous research with clients described in [4] showed, that clients have a barrier in using modern technologies. However, our previous research showed that technological products that are well-adapted to needs, preferences and abilities of them could help clients with daily activities like orientation [?] or leisure [16].

#### IV. PROPOSED SOLUTION

The whole solution consists of the user model, user interface for its maintenance and appropriate API, which will provide all the relevant information from the user model to user interface and client’s devices. The architectural overview is depicted in Figure 1. The user model and user interface are described in detail in following sections. The solution also takes into account the connection to an existing system from which records of client activities could be obtained (see Section III). Various devices will be connected to the solution. There are two groups of users, whom the solution will serve – primary group, represented by the workers (caregivers) of the residential care home and secondary group, represented by the clients, who will use the user model indirectly through their devices and provided care.

##### A. Proposed User Model

Based on the analysis and requirements of other projects, there can be deduced information categories – user model components:

1) *Demographics*: This category contains basic information about client including the client’s name, surname, birth date, birthplace, address, gender, education, department, room number, key worker, contact persons and photographs of the client. The user model also allows to model and maintain the relationship between client and workers. The relationship also captures the rights of workers (view/edit various information categories).

2) *Biography*: The client’s biography is divided into four sub-categories. The first one is the biographical sheet, which represents the life story of the client. Then, there are the

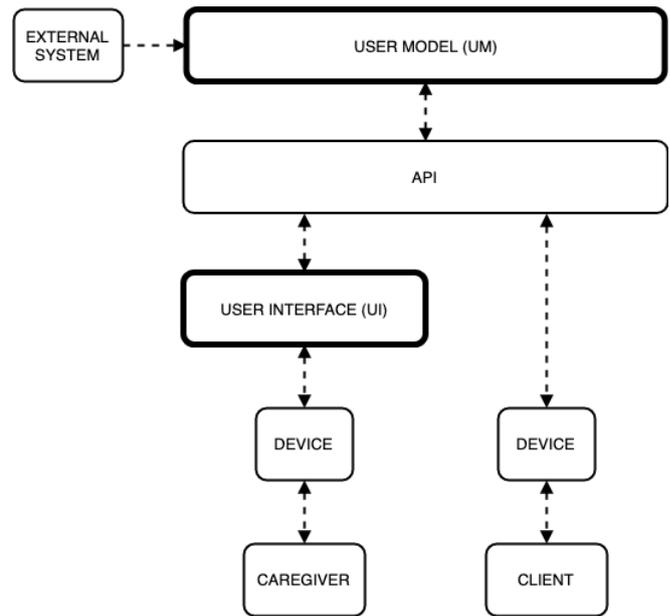

Fig. 1. Proposed solution – High level view.

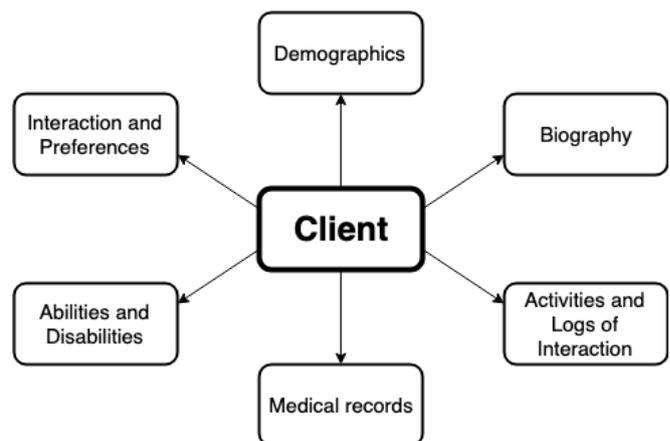

Fig. 2. User model components.

activities of daily living, which are represented by seventeen different tasks of the ordinary day (see Section III). The next category is the lineage which captures the family tree of the client. And finally the form of care, which is composed of three different types of care (activation, reactivation and stimulation) and the differential diagnostics score (eight areas of older adult behavior – psychomotor, orientation, emotions, memory, contact ability, formal thinking, will and content thinking).

3) *Activities*: This category contains records of the client’s activities. According to the conducted user research (see Section III), the employees use a barcode readers system for recording client’s activities. Each activity is assigned a unique barcode that is scanned with the reader and all records are downloaded to the external system at the end of every day. There are also logged the activity of the clients during interaction with devices, which will bring the possibility of

device adaptation.

4) *Medical records*: To this category belongs medical records of the client including the client's height and weight, diseases, injuries, allergies, diets and prescribed medication.

5) *Abilities and Disabilities*: The abilities and disabilities of the client are divided into three sub-categories – sensory, motor and cognitive.

The *sensory* category contains information about sensory abilities and disabilities of the client. Information is divided into sight, hearing and touch, additionally for each eye, ear and hand separately.

The *motor* category captures mobility information, such as motor impairment but also, for example, the ability to stand alone or ability to move independently.

The *cognitive* category contains information about cognitive abilities and limitations of the client, for example, the client's knowledge of his room or level of independence.

Information about impairment captures the severity, origin, progression and other characteristics of the impairment. There are also captures of the abilities of the client, for example, the ability to perceive object shapes or level of client's tactile abilities. If the attribute is expressed in scale, a range of 0 to 6 is used. For example for the visual impairment, the *ICD 9D90* classification [17] is used.

6) *Interaction and Preferences*: This category contains information about interaction with client and preferences of the client (for example client's dominant hand or dominant modality), including the client's attended activities, hobbies, favourite places, interests in services and client's equipment.

The categories of the user model are depicted in Figure 2.

## B. Administration UI Design

For the purpose of the creation of the prototypes, two different development tools were used. Each prototype has been implemented to support the interaction needed to accomplish the tasks performed during prototype evaluation.

1) *Low-fidelity prototype*: A very first prototype (low-fidelity prototype) of the user interface was created in the form of a paper prototype and was implemented using tool Balsamiq Mockups [18]. All application screens and all necessary interaction elements were implemented. The prototype was then evaluated in paper form (see Section V-A).

The structure of the proposed user interface reflects the user model structure (see Section IV-A) and user interface requirements, collected in time before the creation of the low-fidelity prototype. The goal was to create a prototype that is easy to maintain and minimalist, clean and intelligible. This prototype was evaluated in the usability study with three representatives of the target group. The user interface consists of five main screens, which further branches into sub-screens. The complete structure of screens can be seen in Figure 3.

**Login page.** The *Login page* is the first screen the user encounters when interacting with the application. The screen allows the user to enter username and password to log into the system.

**Home page.** The *Home page* acts as the main application signpost. It allows the user to go to the client search screen or to add a client screen. At the top of the screen, there is a panel that informs the user about the current location, allows the user to view notifications, displays the user's name and surname, and allows the user to log out of the system. This panel then appears on all other screens.

**List of clients page.** The *List of clients page* displays the list of clients and allows the user to apply filtration of records.

**Client detail page.** The *Client detail page* consists of seven sub-pages:

- **Basic information.**

The *Basic information* screen displays basic information about client. As an example of the low-fidelity prototype, screen can be seen in Figure 4.

- **Biography**

The *Biography* consists of four sub-pages:

- **Biography – Biographical sheet.**

The *Biography – Biographical sheet screen* displays biographical sheet text and attached photographs. The user is able to edit text and maintain attached photographs.

- **Biography – Activities of daily living.**

The *Biography – Activities of daily living* screen displays table with seventeen different activities of daily living. The user can edit each table row (activity) separately.

- **Biography – Lineage.**

The *Biography – Lineage* screen displays the family tree of the client. The user can maintain the lineage.

- **Biography – Differential diagnostics sheet.**

The *Biography – Differential diagnostics sheet* screen displays table with differential diagnostics score of the client and corresponding form of care.

- **Activities.**

The *Activities* screen displays activities of client. The screen is only used to show activities, the data is located in an external system (see Section IV). The user can filter activity records.

- **Medical records.**

The *Medical records* screen shows health information. It shows the client's height and weight and further diseases, injuries, allergies, diets and prescribed medication. The user can maintain all this information.

- **Abilities and disabilities**

The *Abilities and disabilities* consists of three sub-pages:

- **Sensory.**

The *Abilities and disabilities – Sensory* screen shows information about the client's sensory abilities and disabilities, such as severity, origin, progression and other characteristics of visual, hearing and tactile impairment and also corresponding abilities of the client, for example, ability to perceive object shapes.

- **Motor.**

The *Abilities and disabilities – Motor* screen shows

information about the client's motor capabilities, such as severity, origin, progression and other characteristics of motor impairment and also corresponding abilities, for example, ability to stand alone.

– **Cognitive.**

The *Abilities and disabilities – Cognitive* screen shows information about the client's cognitive capabilities, such as the ability to read Braille, knowledge of the room, knowledge of residential care home interior and other abilities.

• **Interaction and preferences.**

The *Interaction and preferences* screen displays information relevant to client interaction and client's preferences, such as dominant hand, primary modality etc. On the screen, there are also tables for records of client's attended activities, hobbies, equipment which client use, favourite places and interests in services. The user can maintain all this information, including adding and removing records in tables.

• **History.**

The *History* screen displays a history of client information changes. The user can filter records of changes.

**Add client page.** The *Add client page* allows the user to add a client into the system. Some fields are marked with an asterisk, indicating that they are mandatory. The user has the option to save the new record (and get on the Client detail page screen) or to cancel the process of the creation and return to Home page.

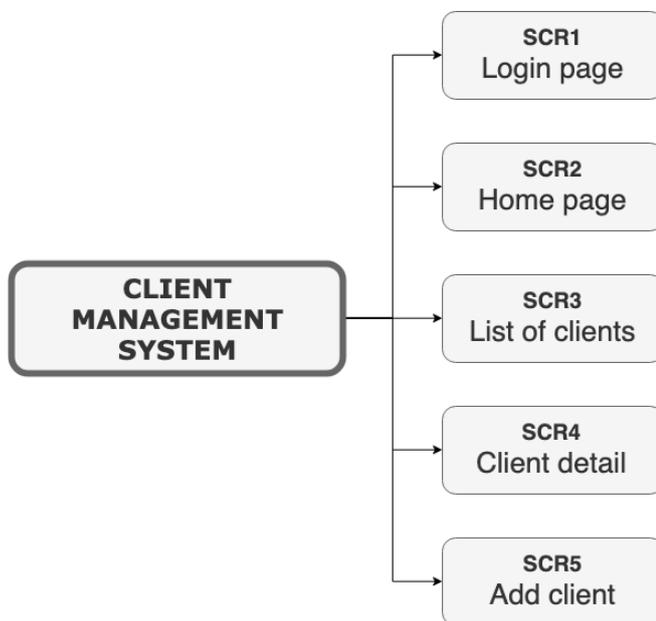

Fig. 3. Low-fidelity prototype – overview.

2) *High-fidelity prototype:* After the low-fidelity prototype evaluation, the high-fidelity prototype was implemented. The tool Axure [19], which enables the creation of more advanced prototypes, was used for this purpose. The prototype was then

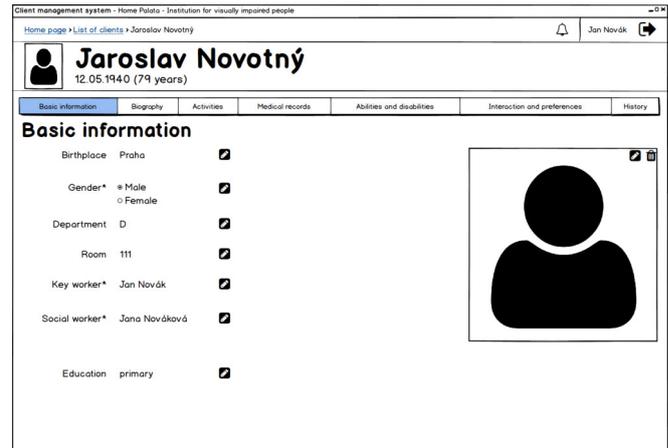

Fig. 4. Low-fidelity prototype – SCR4a – Client detail – Basic information.

evaluated in the form of interactive computer application (see Section V-B).

The concept of the user interface remains the same as the low-fidelity prototype. There are used screens specified in the low-fidelity prototype but the visual appearance of the user interface is improved to get closer to the final product. The experience is also enhanced by the implementation of simple animations or effects, for example, animation of expanding notification detail or buttons hover effect. There are also changes based on the requirements, comments and suggestions, gained during the low-fidelity prototype evaluation as well as changes reflecting the findings of the evaluation of the low-fidelity prototype. The example high-fidelity screen prototype can be seen in Figure 5.

As described above, there are some changes based on the requirements, comments and suggestions, gained during the low-fidelity prototype evaluation and also changes reflecting findings of the evaluation of the low-fidelity prototype, see section V-A. The main changes are listed below:

***Naming of screen Differential diagnostics sheet***

The naming of the screen *Differential diagnostics sheet* has been changed to *Form of care*, which should eliminate the problems that occurred during low-fidelity prototype evaluation.

***Highlight of notifications***

The notification is highlighted by red color. This change should fix the problem of feeble notification, that was faced by participants during low-fidelity prototype evaluation.

***Unsaved data alert***

The notification about the unsaved data has been added to the prototype. This should eliminate the situation, when users omitted the final confirmation of data change.

***Extended attribute values options***

Text description is added for “other” attribute value option.

Also, an undefined value of attributes, which values are selected through radio buttons is possible.

### Client information print

There has been added a possibility to print out the information about the client.

Fig. 5. High-fidelity prototype – SCR4a – Client detail – Basic information.

## V. EVALUATION

We evaluated two generations of prototypes of the administration UI with employees of the residential care home. The relatively low number of participants was determined by complicated methods to reach such a specific user group and correspondingly high costs per participant. More information about determining sample size for hard-to-reach user audience can be found in [20], [21].

### A. Administration UI Design Low-Fi prototype

**Participants.** Low-fidelity prototype evaluation was conducted with three participants (P1–P3), all women, average age 33.33 ( $SD = 11.09$ ,  $MIN = 25$ ,  $MAX = 49$ ). All participants work as activation services workers. One of the participants (P2) was previously interviewed in the user research. None of the participants have participated in usability study before. Mean duration of current job title was 1.33 years ( $SD = 0.47$ ).

**Procedure.** The usability study was conducted with employees of the institution for visually impaired people. The test session was under non-laboratory conditions, and it took maximum of an hour. Paper low-fidelity prototype and The Wizard of Oz technique were used. The participants were recorded on a camera in order to log the testing session afterward. Firstly, the participants were informed about the process of the testing session. After the briefing, they filled in a pre-test questionnaire. Then, the system (application) was introduced to them briefly, and they were informed about the purpose of the system. Participants were encouraged to comment aloud their activities. After that, participants were

asked to complete a list of three complex tasks focused on intended typical interaction with the user interface:

- logging in and out
- searching for a client
- viewing information
- editing information
- adding client

After completing all tasks, participants filled in the post-test questionnaire. Finally, participants were asked to share their opinion on the application and on the testing session.

**Results and conclusion.** During the usability study of the low-fidelity prototype, the basic functionality of the user interface was verified.

The usability study also revealed three problems of the proposed design, which must be fixed in the next stages of the design process. The biggest problem faced by all participants was the incomprehensible and misleading term “*Differential diagnostics sheet*”, which was used based on literature analysis. It turned out that none of the participants could imagine anything under this term. This problem can be fixed by renaming the item to “*Form of care*”, which was also suggested by all the participants. Another, quite fundamental problem was feeble notification, which was represented by a tiny black circle. This problem was faced by two participants. The solution to this problem is to make notification more visible. And the last problem, also faced by two participants, was the problem of leaving out the final confirmation of the information editing. The solution is to notify the user, if he/she does not confirm editing and he/she intends to move to another screen. Highlighting the buttons could also help to improve interaction.

The usability study also provided valuable feedback from the participants, and the knowledge gained during testing and post-test interviews can be useful to improve the design of the user interface. Post-test interviews also brought a requirement for new functionality – printing of client information.

The positive information is that all the participants quickly became familiar with the application, even searching for information (attributes) has become easier after a while. All the participants also emphasise the clarity of the proposed design.

### B. Administration UI Design High-Fi prototype

**Participants.** High-fidelity prototype evaluation was conducted with six participants (P1–P6), all women, average age 43.5 ( $SD = 14$ ,  $MIN = 26$ ,  $MAX = 64$ ). Three participants work as activation service workers (P1, P2, P3), two participants as direct care workers (P4, P6) and one participant (P5) works as speech and occupational therapists. Two of the participants (P2, P3) have participated in previous low-fidelity prototype evaluation. Mean duration of current job title was 6.87 years ( $SD = 4.7$ ).

**Procedure.** As same as low-fidelity prototype evaluation, the usability study of the high-fidelity prototype was conducted with employees of the institution for visually impaired people. The test session was under non-laboratory conditions, and it took a maximum of 45 minutes. Participants were using

a computer (MacBook Pro, screen size 13 inches, Google Chrome), and remote computer mouse. The screen of the computer was recorded with sound captured by the internal laptop microphone to log the testing session afterwards. Firstly, the participants were informed about the process of the testing session and after the briefing, they filled in a pre-test questionnaire (the questionnaire contained the same questions as in the low-fidelity prototype evaluation). Then everything went on the same way as evaluation of the low-fidelity prototype, the system (application) was introduced to participants briefly, they were informed about the purpose of the system and they were encouraged to comment aloud their activities. After that, participants were asked to complete a list of three complex tasks focused on intended typical interaction with the user interface. After completing all tasks, participants filled in the post-test questionnaire (the questionnaire contained the same questions as in the low-fidelity prototype evaluation). Finally, participants were asked to share their opinion on the application and the testing session.

**Results and conclusion.** During the usability study of the high-fidelity prototype, the more advanced functionality, compared to low-fidelity evaluation, of the user interface was verified.

The usability study revealed three problems of the proposed design, which may be fixed before the final product will be released. The biggest problem faced by all participants was a difficulty of searching for individual attributes. The problem is caused by a large number of attributes and also the ambiguity of distribution into the individual categories. The problem can be fixed by adding a search box, which can be used for the individual attributes search. Another problem is the unclear difference between screens *Activities* and *Activities of daily living*. Five participants out of six have faced this problem. During the first walkthrough through the application, screens naming may be confusing and also, *Activities of daily living (SCR4b2)* screen is hidden by default as a *Biography* sub-page. The solution is to rename the screen *Activities* to improve user orientation in the application, for example, the screen could be renamed to "*Activities of the client*". And the last problem, which was faced by three participants, were small and feeble radio buttons and checkboxes. The participants complained about the size of the radio buttons and checkboxes and these interaction elements were also very feeble in their point of view. This problem can be fixed by increasing the size of active elements of the interaction.

The knowledge gained during testing and post-test interviews can be very useful to improve the design before releasing the final product. Post-test interviews also brought a requirement for new attribute – information when the client joined the residential care home.

Despite all the problems faced by the participants during the application evaluation, very positive feedback on the application's clarity was obtained.

## VI. DISCUSSION

The evaluation of both generations of the prototypes indicated that the user interface is generally clear for employees of the residential care home. Although some employees in the user study indicated that they like the paper form of the biographical sheet, the electronic form can bring further benefits. It would be possible to track the progress of clients disease by analyzing the biographical sheet and activities performed with the client. Also, the electronic form will bring better privacy security by authorized access and by tracking the access to the biographical sheet.

The validity of the user study and evaluation is limited due to relatively low number of participants and the fact the research has been conducted in a single residential care institution. However, there is a strong evidence that older adults, especially those with cognitive issues like Alzheimer's disease require personalized care. Also, interaction with technologies needs to be adapted to their needs, preferences and changing abilities. This fact is also supported by literature, e.g., [14].

Mutual connection of the personal psychobiography [5], [6] and user profile in one user model could bring various benefits for interaction with technologies. It would be possible to adjust a user interface according to the needs and preferences of a particular client. Properties like rate of speech, information complexity, the volume can be automatically considered. Also, a significant part of the clients has some remaining residual sight that can be used in interactive scenarios. Knowing particular client abilities can improve interaction significantly. For instance, some clients have central vision quite intact, others have peripheral vision only while some can only sense high contrast patterns. Also, the personal psychobiography can be used to make the interaction more natural and personal. Data in the user model can be used for client identification utilizing biometry. Upon this, it is possible to address the client by her/his name in an appropriate form. Also, technological applications like interactive indoor orientation system can provide personalized information like instructions on how to navigate to one's own room.

## VII. CONCLUSION

For the specific user group of older adults with vision impairments, we proposed a solution that consists of the user model structure, corresponding administration user interface and appropriate API. The user model design connects aspects of personal psychobiography that is already successfully applied in the gerontological care and aspects that are important for interaction with technologies.

It is the subject of the future work to fill the user model with data of real clients of the residential care home. Then, the model will be evaluated for the purposes of providing personalized daily care. Furthermore, technological applications will use the model for adaptation of user interfaces and interaction. It would be possible to adapt properties like information complexity, speech rate, or volume. Also, it will be possible to provide more personal communication by addressing the client by her or his name in an appropriate way.

Selin and Rossi [22] propose a method to design safer buildings based on information models. They propose to use *Building Information Modelling (BIM)* for simulation of various situations individuals can deal with in an interior, including evacuation. They use a gaming engine and artificial intelligence to simulate individual with different capabilities. It is the subject of the future work to incorporate modeling of the indoor environment and the ability to plan routes based on needs, preferences, and capabilities of individual users.

#### ACKNOWLEDGMENT

This research has been supported by the TACR research program TE01020415 and the project RCI (reg. no. CZ.02.1.01/0.0/0.0/16\_019/0000765) supported by EU and by the project Navigation of handicapped people funded by grant no. SGS19/178/OHK3/3T/13 (FIS 13139/161/1611937C000).

**Abstract**—Augmented Reality and Gamification are displaying beneficial effects to enhance user experience and performance in many domains. They are widespread across many areas like education, industrial training, marketing, and services. However, the idea of combining the two approaches for an innovative training instrument is fairly new, especially in assembly training. Moreover, learning about the effects of gamification on human, user engagement, in particular, is a complicated subject. There have been several efforts toward this direction, yet the overall situation is still nascent. In this work, we present a gamified augmented reality training for an industrial task and investigate user engagement effect while training with the gamified and the nongamified system. The result shows that people perform better and engage to a greater degree in the gamified design.

## I. INTRODUCTION

**A**UGMENTED Reality (AR) is growing stronger than ever. Market research predicts a 70 to 75 billion revenue for AR by 2023 [5] and by 2019 AR for training, in particular, will take place in 20% of large enterprise businesses [6]. AR is the novel technology which superimposes virtual objects upon the real world subjects or environment while enabling real-time interactions [1]. In recent years, AR has captured the research interests in many areas such as education and training [2], [13], assembly and production operations [3], [4]. As a result, the outcome of teaching and learning, skill acquisition and development as well as user experience have shown outstanding beneficial effects.

Gamification, on the other hand, is the term for adapting the design elements which commonly characterize entertainment games into other settings but gaming. While the academic world is still debating on the consensus of definition and scope, the benefits that gamification brings are undeniable. It is not uncommon to say that games are addictive, yet beyond entertainment purposes, they are believed to better life in many aspects [9]. Gamification's ultimate goal is to simulate the fun elements that enhance the user experience, improve worker productivity or advance student engagement. Since gamification is often mistaken with the meaning of the "serious game," which is any full-fledged game that used for other purposes exceeding pure entertainment, we limit the work in this paper to the most widely accepted definition of gamification [10]:

Fig. 1. The GAR design with gamification elements: points, progress bar and signposting.

*“Gamification is the use of game design elements in non-game contexts.”*

Since both AR and gamification already have their certain contribution into the education field, in the context of training especially, it is surprising that gamified AR systems have not been popular for training in the production environment. Accountable for this probably is the fine line between making work fun and making fun of work [7]. Due to the nature of productional work, the misuse of the gamified systems could take away the user's focus attention and result in damages or even injuries. Therefore, here we attempt to form a gamified AR application for an assembly training task following special design requirements for a production environment. Our focus is on the user engagement aspect because it is an important factor contributes to the effectiveness of training.

## II. RELATED WORK

Although the term “gamification” is relatively new, since around 2003, its applications have already widespread across many industrial as well as scholarly fields. Recently in the Gamification 2020 report, Gartner predicted that gamification in combination with emerging technologies will create a significant impact on several fields including the design of employee performance and customer engagement platform [8]. In this context, there are numerous examples of studies for

either AR training or gamified training, yet there was hardly any work on the combination of those.

A recent survey of Seaborn et al. [14] provides a good overview of gamification from a Human-Computer-Interaction perspective in both theoretical and practical lights. The work showed that gamification is primarily practiced in the domain of education, e-learning especially. In the theoretical foundations, there was a dynamic movement towards carving the boundaries between gamification and other similar concepts. The applied research, meanwhile, painted a positive-leaning but mixed picture about the effectiveness of gamified systems. Despite usual expectation, similar gamified designs under different settings returned clashing result over user experience along with performance. The reason was believed to be highly context-specific requirements. Furthermore, learning about the effects of gamification on the human is a complicated subject. The overall effort toward this direction is still nascent.

While the gamified system was well accepted in business contexts, it is not necessarily the case in production training, left alone Augmented Reality training. K. Lee [13] showed that AR for education and training innovation was leaning towards the “serious game” pole while gamification was left outside of the picture. According to Lee, AR games were particularly interested in by both “educators and corporate venues.” A role-playing game for teaching history [11], for example, proved the benefit of enabling students for problem-solving, increasing collaboration and exploration via the virtual identities.

However, whether we like it or not, production training is different from traditional classroom training. When transforming the operational work into a game, a serious game, there will always be a risk of taking the focus away from the task at hand. This is when gamification comes to play as integrating gamification can provide the fun aspect while still keeping the workers’ full attention on the operative job [12].

Probably the most well-known gamification in production is a series of works from Korn et al. [15], [16], [17], [12]. The center of his works is to evaluate users’ acceptance of gamification in modern production environments. Different designs, “Circles & Bars” and “Pyramid,” were proposed [12]. Both designs were used to visualize work steps as well as their sequences. Color-coded from dark green to yellow, orange and red is employed to indicate user specific time progression. Later on, they were projected into users’ working space as an assistive application for impaired individuals. The result indicated a good acceptance level for gamification designs and the “Pyramid” approach was favorable in general. While the study showed a promising outcome, it focused on user acceptance and did not measure the quantitative factor of gamification on task completion time and error rates.

### III. IMPLEMENTATION

In this section, we present the implementation of the application under study. A process of replacing the battery for a robot arm was implemented based on the instruction manual of the Mitsubishi Industrial Robot RV-2F Series [18]. The application ran on the Microsoft HoloLens [19]. Two

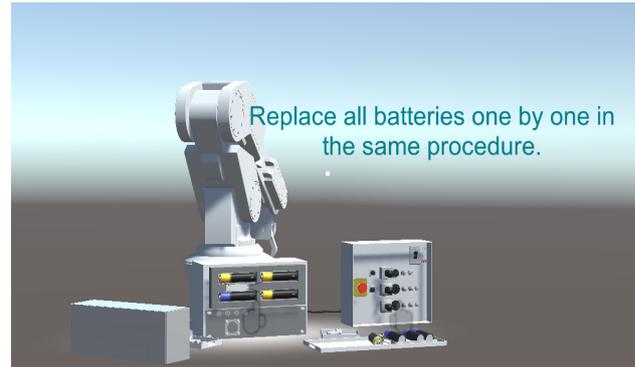

Fig. 2. The NGAR design with no gamification elements. Only text instruction was provided.

prototypes were made, one with the gamification design and the other without. The designs were named Gamification AR (GAR) and Non-Gamification AR (NGAR) according to their characteristics. Due to Microsoft HoloLens small field of view, around 35 degrees, here we provide the user interfaces captured from Unity Editor to showcase the whole scene setup. Figure 1 and Figure 2 illustrate the GAR and NGAR design respectively.

#### A. The application

The process for changing the battery was identically built for both prototypes. There were 21 actions made up 10 steps. Disassembling the cover of the battery compartment, for example, included two steps of removing the screws and removing the cover. While removing each of the screws was counted as an action.

For navigating the process, we augmented the instruction text for each step as a head-up display which was always facing the user at the top right corner of the user view. An instruction manager was used to control the flow of text visualization. The requirement from the instruction manual specified that the steps of the process had to be performed in a fixed order that’s why only one instruction was displayed at a time. The next instruction triggered when the user carried the current step correctly.

Two main interaction types were used to simulate different interactions. Air tap [19] was used for interacting with static objects (e.g. pressing a button) while we utilized drag and drop for assembling actions (e.g. removing the screw). Similar to the real working space, disassembled objects were designed to be placed at a specific location. For instance, the screws needed to be placed inside a designated tray instead of dropped on the floor.

To simulate a sense of reality, sounds such as robot arm were running or turned off were used.

#### B. Gamification Design

The game design elements were implemented only for the GAR version. It allows to isolate and analyze the effect

of gamified system on the user. This could be reflected by comparing the outcome of the two experiments.

As a result of Korn's investigation [12], gamification in the production environment has its own specific requirements. To avoid resistance from users or the potential of taking away their main focuses, we followed the identified requirements in designing gamified application for production settings. First, "keep the visualization of gamification simple." This focuses mainly on avoiding animation, moving elements and using complex graphical structures. The second and third requirements come together as "avoid explicit interaction with gamification elements" and "support implicit interaction with gamification elements." For that matter, in our designs we did not ask for any user's effort to direct input or reach out to the gamified items.

1) *Point System*: The point system was built based on users' actions. There was a maximum of 21 points according to 21 actions. Points were rewarded to the user when the action was done. As the first attempt to study the effect of gamification design on user engagement, we did not implement a complex point system with losing points or rewarding extra points at this stage.

2) *Progress Bar*: While the points were based on actions, progress bar visualized the steps. As stated as one of the requirements, the user interface was intentionally kept simple with only one color. Additional text was in place for indicating the percentage.

3) *Signposting*: Signposting aims to direct the user in the right direction. While users without background knowledge could be confused with the mechanical part names (e.g. Controller box), signposting highlighted the part corresponding to the currently displayed instruction. It provided the "just-in-time" hints for the trainees, especially the totally beginner one.

#### IV. EXPERIMENT DESIGN

The experiment was conducted to investigate how gamification in AR training impacts user engagement and performance. The studies for both conditions (GAR and NGAR) took place in the same room at our research laboratory. To avoid the learning effect, we employed the between-group design in which each participant randomly exposed to only one design, either GAR or NGAR.

Due to the fact that Microsoft HoloLens requires specific hand gestures for interaction, the participants were asked if they have experience with this device. In the case of none, the participant used the default HoloLens "Learn gesture" application. This was especially important because the main task could not be carried on without this step. Before the experiment, regardless of the HoloLens experience, we repeated the main information about the interactive gestures to all participants.

Once the participants were confident interacting with the device, the main experiment task proceeded. When the user hit the "Start" button at the first scene of the application, the timer for measuring task completion time was started until the last step completed.

As we focused on the user engagement we used a post-study questionnaire with the refined User Engagement Scale (UES) [20]. UES is a five-point rating scale: strongly disagree, disagree, neither disagree nor agree, agree and strongly agree, respectively from 1 to 5 point. Given the task was not complicated, the level of fatigue after that was expected not to be high so that we decided to use the UES long form (UES - LF). The UES - LF consists of 30 items covering 4 factors:

- 1) FA: Focused Attention
- 2) PU: Perceived Usability
- 3) AE: Aesthetic Appeal
- 4) RW: Reward Factor

As constructed in the guide to use of UES, all items were randomized and the indicators (e.g. AE.1) were not visible to the users.

#### V. RESULTS

Most of the participants reported having little or none experience with AR technology, in particular, Microsoft HoloLens, before this experiment. So, a potential novelty effect when initially establishing interaction with new technology might influence the research result. The test population was 22 participants with 11 regarding each condition. Participants ages vary from 18 to 34 years old, 15 male and 7 female subjects. Although some unease and uncertainty were expressed at the beginning, all participants were more certain after the learning gesture phase.

Figure 3 displays that the GAR design was rated better in all sub categories. In general, it was clearly preferred to the NGAR approach. The overall Engagement score was 15.2 (SD=1.8) in GAR and 13.3 (SD=3.5) in NGAR. However, this did not make up a statistically significant difference between the two groups. Table I provides the results in more detail, looking at the average score, standard deviation and also the result of a t-test for both the overall engagement score and its factor.

The standard deviation in the overall user engagement score was much lower in the GAR design (SD=1.8), versus SD=3.5 in NGAR, which shows that the GAR subjects more homogeneously perceived the result throughout the group. This tendency, lower standard deviation, remained true for all four subfactors in the GAR design as shown in Figure 3. On the other side, the opinions of NGAR subjects seem to be more diverse.

Looking at the training performance, the difference regarding average task completion time (in seconds) between the two study conditions is statistically significant. The t-test resulted in  $p < 0.032$ . The average time was 306.9 (SD=123.2) and 439.5 (SD=134.4) for GAR and NGAR groups respectively. This positive outcome probably directly influenced by the signposting design element.

#### VI. DISCUSSION AND FUTURE WORK

As a preliminary result, this work demonstrates the potential of gamified AR training for assembly tasks in improving user engagement and performance. Nevertheless, there is a need for

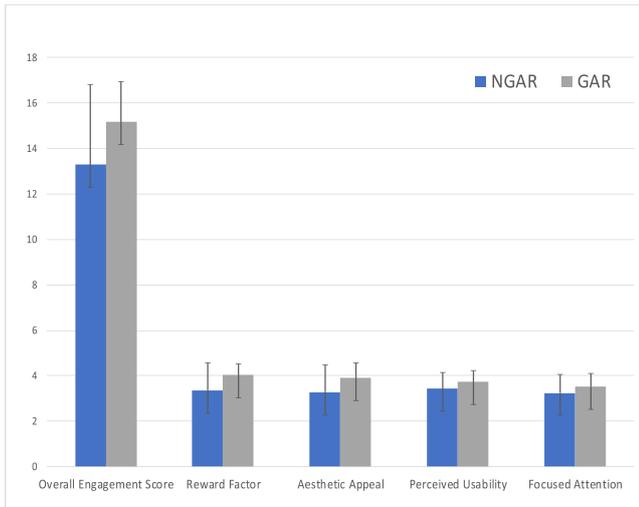

Fig. 3. User Engagement Score as a bar chart with indicated standard deviations.

TABLE I  
COMPARISON OF USER ENGAGEMENT SCORE

Factor	Mean Score (SD)		p value
Design	GAR	NGAR	GAR vs. NGAR
Focused Attention	3.5 (0.6)	3.2 (0.8)	0.418 not significant

further investigation focusing on both short-term and long-term training effectiveness. A consideration over skills and knowledge acquisition should be taken into account. To serve this goal more complex tasks should be implemented with a higher level of gamification, different training levels and challenges design for individual specific demands for example.

As we focused on the improvement of user engagement in gamified AR training, we did not take in to account the isolated effect of how each game design elements affects the user. As mentioned in the Related Work, gamification design is highly context-specific so that the next important step will be a qualitative study on how the users perceive different design elements and their impacts.

## VII. CONCLUSION

The use of gamification in combination with AR for production training is still new and its potential needs further exploration. In this paper, we developed a gamified training for an assembly task in AR setting and studied its effects on user engagement.

The result showed that the users displayed a higher level of engagement as well as better performance with the support of

gamified AR training. The statistical analysis, though, did not indicate a significant difference.

While the implementation of gamification may not yet fully integrate into the training process, this work certainly contributes to the existing knowledge body of gamified AR training for production domain. This research area also needs a greater amount of works to identify its benefits alongside with how to tackle its challenges.

# 6<sup>th</sup> Doctoral Symposium on Recent Advances in Information Technology

**T**HE aim of this meeting is to provide a platform for exchange of ideas between early-stage researchers, in Computer Science and Information Systems, PhD students in particular. Furthermore, the symposium will provide all participants an opportunity to get feedback on their studies from experienced members of the IT research community invited to chair all DS-RAIT thematic sessions. Therefore, submission of research proposals with limited preliminary results is strongly encouraged.

Besides receiving specific advice for their contributions all participants will be invited to attend plenary lectures on conducting high-quality research studies, excellence in scientific writing and issues related to intellectual property in IT research. Authors of the two most outstanding submissions will have a possibility to present their papers in a form of short plenary lecture.

## TOPICS

- Automatic Control and Robotics
- Bioinformatics
- Cloud, GPU and Parallel Computing
- Cognitive Science
- Computer Networks
- Computational Intelligence
- Cryptography
- Data Mining and Data Visualization
- Database Management Systems
- Expert Systems
- Image Processing and Computer Animation
- Information Theory

**Abstract**—This paper deals with a possible approach to controlling marine fish stocks using the prey-predator model described by the Lotka-Volterra equations. The control strategy is conceived using the sliding mode control (SMC) approach which, based on the Lyapunov theorem, offers the possibility to track desired functions, thus guaranteeing the stability of the controlled system. This approach can be used for sustainable management of marine fish stocks: through the developed algorithm, the appropriate number of active fishermen and the suitable period for fishing can be determined. Computer simulations validate the proposed approach.

## I. INTRODUCTION AND MOTIVATION

Marine ecosystems provide humanity with a multitude of goods and services, including water quality, flood control and food supply, all of which are critical for human welfare. Since the human population is growing continuously, the demand for these goods and services is also increasing and progressively exerting more pressure on aquatic ecosystems. As many fish species migrate frequently and the oceans are mostly defined as public areas, the definition of clear boundaries and property rights regarding marine resources is rather complicated. As a result, most natural resources exploited by the fishing industry are defined as common-pool resources. This has resulted in many pelagic ecosystems experiencing high levels of depletion and overexploitation [2], with 46 % of European community fish stocks currently below their minimum biological level (European Environment Agency, [1]). The increasing intensity of human fishing activities in turn diminishes the biodiversity within the affected systems, which is positively correlated with the provision of the goods and services of the ecosystem that are of benefit to the human population, see [5]. Levels of biodiversity have been shown to determine the stability of marine ecosystems and their ability to recover. Consequently, Worm et al. suggest that business as usual in the fishing industry could potentially threaten global food security and water quality, as well as ecosystem resilience, and thus jeopardise present and future generations, see [5]. The observed trend is thus of increasing concern, so the topic of the conservation and restoration of aquatic biodiversity through sustainable fishery management is increasingly

visible in scientific and political agendas. The United Nations has included this issue in its sustainable development goals, dedicating goal number 14 to the conservation and sustainable usage of the planet's oceans, seas and marine resources, [4]. The successful implementation of this goal includes the adaptation of sustainable methods to manage marine and coastal ecosystems in order to avoid significant adverse effects, which is indicated by the proportion of national economic zones following ecosystem-based approaches. By 2020, the United Nations aims to regulate destructive fishing activities and end overfishing, alongside implementing a science-based management approach to restore natural fish stocks (United Nations, 2019). In addition, the European Union has conducted several reforms of the Common Fisheries Policy (CFP), establishing different approaches to attempt to bring the situation under control, with the goal of reaching and maintaining a sustainable level of fish in the oceans and in fishermen's nets. As common practice in this field, scientists estimate the existing level of fish stocks within an area and suggest a number of total allowable catches (TACs) to political fishery ministers. In turn, those ministers try to bargain and receive the highest shares for their regions, which often leads to the amount of TACs exceeding the maximum level recommended by scientists, rather than levels being allocated for mutual benefit and optimal conservation purposes. As a result, the methods of the EU are rather unsuccessful for maintaining a sustainable yield of fish and achieving the targets adopted by all member states of the United Nations: as [3] claims, the decision-making process within the catch allocation should be managed by scientists rather than by politicians. One possible approach to enhancing this decision-making process and expanding it based on an independent and objective component, driven by scientific data, is to translate the observed ecosystem into a mathematical model using MATLAB and simulate them with the integrated tool Simulink. Thus, this paper aims to offer a first attempt at exploring how MATLAB and Simulink can be utilised to facilitate the implementation of sustainable management approaches in the fishing industry through strategic policy testing. The software will be used

to formulate a simple mathematical description of a marine ecosystem based upon the prey-predator system represented in the Lotka-Volterra equations. A number of papers dealing with simulated prey-predator systems have been published previously; however, adaptation of the model to a marine ecosystem including fish stocks and human fishers has not yet been covered. In order to simulate the consequences of various possible policies through different controllers, these have been incorporated into the code to eventually reach and maintain a certain setpoint equal to the maximum sustainable yield of fish. In terms of the proposed control technique, sliding mode control (SMC) is taken as one of the first possible approaches. In fact, the controllers obtained by an SMC approach show robust properties with respect to parameter uncertainties, as well with respect to more general dynamic uncertainties and to unknown signals. Another application for which SMC has suitable qualities is the field of fault-tolerant control (FTC). In this area, due to intrinsic robustness, SMC models are able to overcome faults and uncertainties. The paper is organised in the following way. In Section II the Lotka-Volterra model is presented. Section III is devoted to the control design performed using SMC. Section IV presents the obtained results and the paper ends with the conclusions drawn.

## II. MODEL DESIGN

The designed model is inspired by the ecological concept of the prey and predator relationship. This concept was formulated by Lotka and Volterra, and is based upon different mathematical theorems.

### A. Lotka-Volterra equations

The assumptions of Lotka and Volterra are taken as a basis to describe the relationship between natural fish stocks and the fishing activities of humans. Lotka and Volterra first describe the population dynamics of two species in a prey and predator relationship through two first-order nonlinear differential equations, as follows:

$$\frac{dx(t)}{dt} = \alpha x(t) - \beta x(t)y(t), \quad (1)$$

$$\frac{dy(t)}{dt} = \delta x(t)y(t) - \gamma y(t), \quad (2)$$

where  $x(t)$  represents the number of prey and  $y(t)$  represents the number of predators.  $\frac{dx(t)}{dt}$  and  $\frac{dy(t)}{dt}$  represent the growth rates of the populations based on the respective changes within their population sizes over time, which is denoted by the term  $t$ .  $\alpha, \beta, \delta, \gamma$  are positive real parameters and describe the interaction between the two populations. The expression (1) represents the dynamics of the prey population, which are calculated by subtracting the rate of predation from the population's intrinsic growth rate. Since it is assumed that the prey has an unlimited food supply, its population grows exponentially if the population of predators and the rate of predation equal zero, which is expressed by the term  $\alpha x(t)$ . In turn, the rate of predation upon the prey is assumed to be proportional to  $\beta x(t)y(t)$ . Thus, if either  $x(t)$  or  $y(t)$  equals

zero, there is no predation.

Equation (2) describes the dynamics of the predator population, which are determined by the rate at which it consumes the prey population, minus its intrinsic death rate. Since the growth rate of the predator population does not necessarily equal the rate of predation of the prey, it is expressed by  $\delta x(t)y(t)$ , which is similar but not equal to the term representing the rate of predation in Eq. (1). In this equation,  $\gamma y(t)$  denotes the loss rate of the predator population due to natural death or emigration. This results in an exponential decay if there is no prey available to be consumed. Since the main objective of designing this new approach is to achieve and maintain sustainable levels of fish stocks and harvests alike, an equilibrium point between the two populations is intended. This point is reached if:

$$\frac{dx(t)}{dt} = 0, \quad (3)$$

$$\frac{dy(t)}{dt} = 0. \quad (4)$$

As a result, putting the corresponding equations also equal zero, wherefore one has:

$$0 = \alpha x(t) - \beta x(t)y(t), \quad (5)$$

$$0 = \delta x(t)y(t) - \gamma y(t). \quad (6)$$

These equations yield two different solutions. One solution states that both populations become extinct:

$$x(t) = 0, \quad y(t) = 0. \quad (7)$$

Given the second solution, a fixed point can be achieved at which both populations sustain their current non-zero numbers, depending on the settings of the four parameters  $\alpha, \beta, \delta, \gamma$ . This yields:

$$y(t) = \frac{\alpha}{\beta}, \quad (8)$$

$$x(t) = \frac{\gamma}{\delta}. \quad (9)$$

## III. SLIDING MODE CONTROL

As the goal of the simulation is to realise and establish sustainable fishing activities in order to ensure the continuity of both marine ecosystems and the human species, the current situation of overfishing and ocean depletion has to be stopped and managed in a way that enables fish stocks to recover. Therefore, the error between the desired setpoint, being the equilibrium point of the fishery system, and the actual value, represented by the current level of fish, has to be ascertained, harmonised and stabilised. This is explored through application of the Lyapunov theorem. With zero being the intended value for  $\dot{x}(t) = f(x, u, t)$ , the theorem defines that if:

$$V(x(t)) > 0, \forall x(t), \quad (10)$$

$$V(0) = 0, \quad (11)$$

the function is positive and if:

$$\dot{V}(x(t)) < 0, \forall x(t) \quad (12)$$

and one has:

$$\dot{x}(t) = f(x, u, t), \quad (13)$$

then  $x(t) = 0$  is an asymptomatic stable point for function  $\dot{x}(t) = f(x, u, t)$ .

In order to reduce the error and harmonise the actual value of fish with the desired value of fish associated with a sustainable population size, an SMC is used as follows:

$$S(t) = (x_d(t) - x(t)) + k_s \int_0^t (x_d(z) - x(z)) dz, \quad (14)$$

where  $k_s$  is a parameter to be designed. Since the V-function is a positive-definite function of  $x(t)$ , it can be employed in the function above. Therefore, one gets:

$$V(S(t)) = \frac{1}{2} S^2(t). \quad (15)$$

Thereupon, the function is differentiated, which yields:

$$\dot{V}(S(t)) = \frac{1}{2} 2S(t)\dot{S}(t), \quad (16)$$

$$= S(t) [\dot{x}_d(t) - \dot{x}(t) + k_s(x_d(t) - x(t))], \quad (17)$$

$$= S(t) [\dot{x}_d(t) - (\alpha x(t) - \beta x(t)y(t)) + k_s(x_d(t) - x(t))], \quad (18)$$

if:  $y(t) = y_{eq}(t) =$

$$\frac{-\dot{x}_d(t) + \alpha x(t) - k_s(x_d(t) - x(t))}{\beta x(t)}, \quad (19)$$

then  $\dot{V}(S(t)) = 0$  and if:

$$y(t) = y_{eq}(t) - \frac{\eta \operatorname{sgn}(S(t))}{\beta x(t)}, \quad (20)$$

with

$$\operatorname{sgn}(S(t)) = \begin{cases} 1 & \text{if } S(t) > 0 \\ 0 & \text{if } S(t) = 0 \\ -1 & \text{if } S(t) < 0, \end{cases} \quad (21)$$

then, if  $\eta > 0$ :

$$\begin{aligned} \dot{V}(S(t)) &= S(t)[- \eta \operatorname{sgn}(S(t))] \\ &= -\eta S(t) \operatorname{sgn}(S(t)) = -\eta |S(t)| < 0. \end{aligned} \quad (22)$$

In order to accelerate the process and reach the desired value more quickly, term  $\lambda S(t)$ , with  $\lambda > 0$ , can be included in the equation. The resulting control law is as follows:

$$y(t) = y_{eq}(t) - \frac{\eta \operatorname{sgn}(S(t))}{\beta x(t)} - \frac{\lambda S(t)}{\beta x(t)}. \quad (23)$$

#### A. Euler Method

Since the system in question has a relatively slow dynamics, it is not intended to measure its state second-by-second, but rather on a monthly basis. Therefore, the equation is discretised according to the Forward Euler method, where  $k$  represents the known counting integer variable, which yields:

$$\begin{aligned} \dot{x}(t) &= \frac{x(k) - x(k-1)}{T_s} \\ &= \alpha x(k-1) - \beta x(k-1)y(k-1) \end{aligned} \quad (24)$$

$$\rightarrow x(k) = x(k-1) + T_s(\alpha x(k-1) - \beta x(k-1)y(k-1)). \quad (25)$$

At this point, the respective equations are integrated into Matlab. With the number of predators and respectively the number of fishermen represented by  $y(t)$ , being the leverage point to control the level of fish stocks in the regarded aquatic ecosystem, Eq. (23) represents one of the main equations in the SMC. Since the goal of the applied controller is to harmonise the desired and actual amounts of fish, measured in kilogram biomass, the desired amount of fish (denoted by  $x_d(t)$ ) and the actual amount of fish (represented by  $x(t)$ ) are the two main data inputs for the equation. Eq. (23) represents the main equation within the SMC strategy.

#### IV. SIMULATION RESULTS

In order to test the designed model it is assumed that a sustainable level of fish stocks is reached at a minimum of 10,000kg of fish. The goal is then to test how the attendance of fishermen affects the dynamics of the prey population and how a meaningful policy designed to regulate the activities of the fishermen could be framed. Figure 1 shows the number of fishermen in a system that is not restricted by political regulations. The line graph shows the development of the number of fishermen over a period of 60 months. In the absence of political regulations, the number of fishermen immediately increases to 1,000 and remains stable over the entire period of time. The line graph depicted in Fig. 2

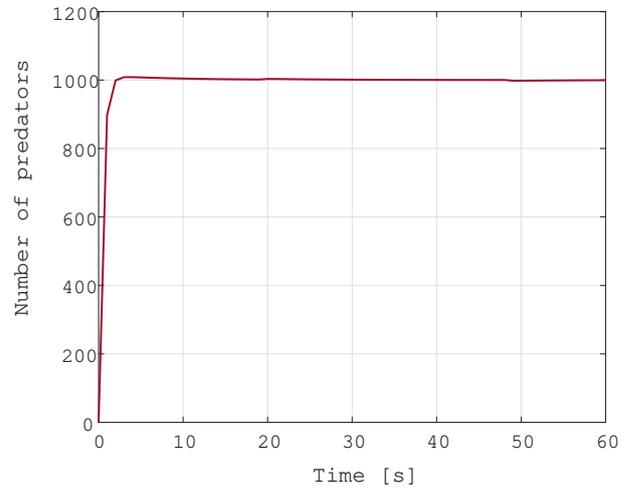

Fig. 1. Number of predators without regulation

shows the corresponding dynamics of the fish population over a period of 60 months, given the same situation that no political regulation of fishing activities exists. In this scenario the amount of fish peaks at 11,000kg after approximately three months and stabilises at the desired amount of 10,000kg after 60 months. In order to test how a political regulation regarding the number of active fishermen affects the system, a hypothetical regulation has been assumed demanding that all

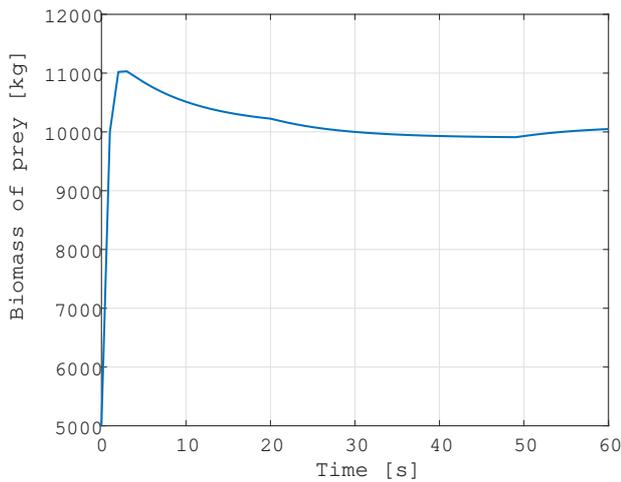

Fig. 2. Biomass of prey without regulation

fishing activities are prohibited between the 5<sup>th</sup> and the 8<sup>th</sup> month of the period in question. This regulation is realised through an if-clause in the m-file of Matlab, as follows:  $if((T < 5)|(T > 8))$

$$y(t) = y_{eq}(t) - \frac{\eta \text{sgn}(S(t))}{\beta x(t)}. \quad (26)$$

As a result, the number of fishermen depicted in Fig. 3 rises to 1,000 and remains at that level until it drops to 0 at the five-month mark. It then remains at 0 until the 8<sup>th</sup> month and temporarily increases to 1,100 after this point. Subsequently, the number slowly decreases again until it returns to a level of 1,000 after 60 months. The consequences of the regulation

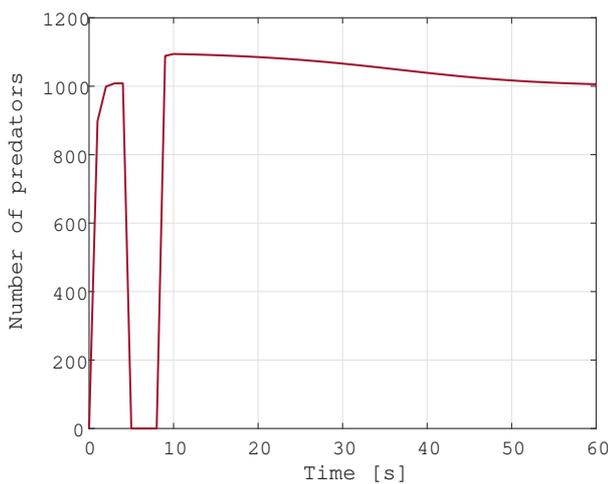

Fig. 3. Number of predators with regulation

regarding the level of fish stocks in kilogram biomass is depicted in Fig. 4. At the beginning of the time period in question, when the number of fishermen is high, the fish

biomass level is at 10,000kg. As soon as the regulation takes effect, the fish biomass increases exponentially, peaking at 17,500kg at eight months. Since the fishermen resume their activities from the 8<sup>th</sup> month onwards, the biomass level decreases again, stabilising at the desired level of 10,000kg after 60 months. The results show that the designed model is

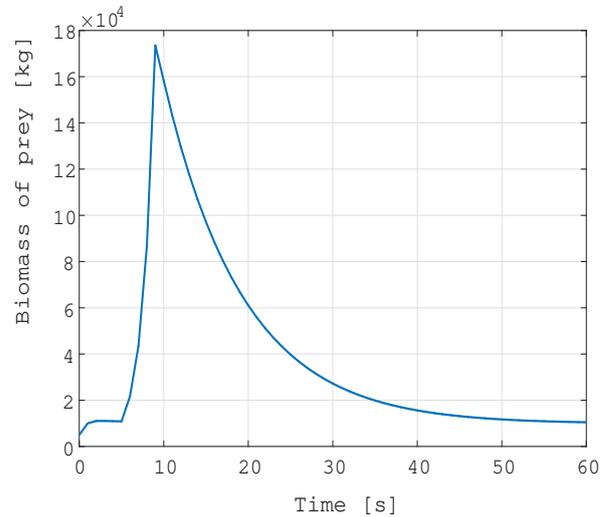

Fig. 4. Biomass of prey with regulation

indeed sensitive to regulatory changes, and that it is able to depict the dynamics of the interdependent populations.

## V. CONCLUSION AND FUTURE RESEARCH

Since the implementation of a regulating if-clause in the m-file yields a reasonable result, the model seems to work and to be appropriate for policy testing in the fishing industry. However, further research will be necessary in order to construct more complex models, and thus more realistic ones, by including additional variables that may influence the system. In addition, appropriate measurements must be taken and the values within the models must be adapted accordingly in order to obtain realistic and meaningful results.

## ACKNOWLEDGMENT

This work was realised within the lectures for the Complementary Studies course at Leuphana University of Lüneburg during the winter semester 2018-2019.

**Abstract**—Requirements of increased productivity and flexibility in manufacturing processes reflect the concept Industry 4.0. Essential to achieving these targets is the implementation of intelligent and robust distributed control systems focused on interoperability and scalability. New approaches and technologies based on the Industrial Internet of Things (IIoT), cloud computing and Big Data are an emerging field of industrial control that comprises Internet-enabled cyber-physical devices with the ability to link new smart technologies. With this perspective, manufacturing devices can be easily monitored, operated and controlled even from remote locations. Conventional industrial control approach, that use programmable logic controller (PLC), is enhanced with intelligent industrial gateway IoT 2040 as a hardware and Node-RED software environment in order to provide interoperability, robust and reliable control system. Collected process data and parameters from embedded sensors and other connected devices can be quickly collected, processed, transformed and used for device control from remote production environment. This paper deals with an industrial gateway framework adopting the idea of Internet of Things for the development of robust industrial control approach. The concept is tested in real industrial environment.

### INTRODUCTION

INDUSTRY 4.0 represents the fourth industrial revolution in manufacturing industry with complex automation, cyber-physical systems, data exchange and Industrial Internet of Things (IIoT) principles. The ability of integration and cooperation of intelligent machines, methods and human beings to interact is essential condition for increased productivity and flexibility in manufacturing processes [1].

Interconnection of machines, embedded sensors, digital devices and people continues to extend. The aims of this approach are improved industrial manufacturing processes, efficient ways to operate production plants, services and supervision for industrial installations, reduced operational cost in relation to requirements of improved human safety. The IIoT offers interconnection and intelligence to industrial systems and machines through sensing devices and actuators with ubiquitous networking and computer abilities [1], [2].

The expectation toward industrial applications related to intelligent hardware, software and serviceability are high.

Nowadays, many IoT academic research studies, publications and applications related to the IIoT principles are being developed. The development of intelligent control prototypes has increased mainly due to educational development kits, such as Raspberry Pi, Arduino, etc., that are usually not certified for the use in industry.

The difference between industrial hardware and regular development kit are in UL/ CE certification that indicates conformity with health, safety, and environmental protection standards for industrial continuous operation applications. Secure installation within machine and electrical panels allows minimal industrial IP 20 housing and easy connection with other DIN rail industrial devices, such as relays, power supplies or PLC. For continuous operation in industrial environment must be this hardware built with industrial grade components resistant to vibrations, dust, high temperature and electromagnetic interferences. Regarding communication with other industrial hardware, it must be possible by using secure industrial protocols, such as Profinet, MQTT or ModBus [2].

Developing an effective industrial control approach and IIoT application according to the IIoT principles requires meeting the following requirements on increased [3]:

- Robustness.
- Intelligence.
- Reliability.
- Standardization.
- Safety and security.
- Cost reduction.

The architecture of conventional industrial control system consists of distributed embedded devices, such as PLC that control physical processes and supervisory computer that gather data and command PLC. Modern industrial control systems are distributed, offer higher performance and often connected to the internet or intranet [1], [4].

Machines from different manufactures and on different technological levels often do not use the same communication protocols or programming language. In order to satisfy the need for intelligent and robust control solution suitable for industrial production that harmonizes communication between the various data sources, the

architecture of industrial control system must be enhanced with an industrial certified gateway [4].

IIoT gateway builds the bridge between sensors and actuators of manufacturing device on one hand, and the internet or intranet on the other hand. IIoT gateway moreover comprises other capabilities such as filtering the amount of data or security implementation as depicted in Fig.1.

Industrial gateway represents the reliable open platform for collecting, processing and transferring data in the production environment. It is intelligent gateway between a company's IT department and industrial solutions and it is important to note that the role as an interface can be used in both directions.

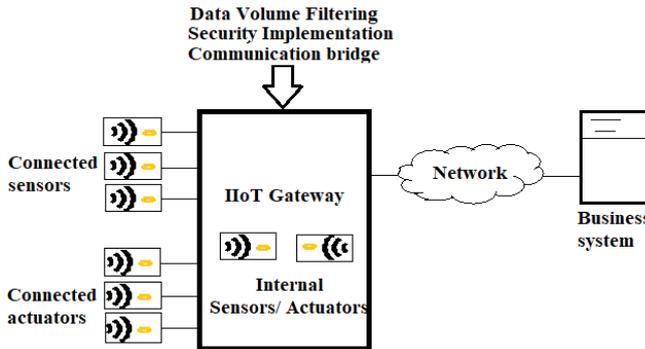

Fig. 1 Industrial IIoT gateway function principle

The paper consists of four parts. In the first part requirements for effective industrial control according to the IIoT methodology are defined. The second part deals with the problem formulation of industrial control systems current state and intelligent gateway. The third part of the paper provides a description of the proposed approach and system implementation in terms of hardware (IoT 2040) and software components (Node RED). The fourth part deals with case study – verification of proposed approach.

#### PROBLEM FORMULATION

This paper proposes a robust, effective and modern approach of process control and remote monitoring system of a real physical model represented by an automated working system in compliance with the main IIoT requirements, interoperability and scalability [4]. This stand-alone system is depicted in Fig.2 and represents an autonomous working station of production line with sorting mechanism and consists of industry certified hardware, such as power supply, engine with frequency inverter, conveyor belt, proximity sensors, pneumatic actuators and programmable control unit. The main functionality of this system is to move packages along the conveyor belt to the sorting mechanism, which divides packages according to the shapes into individual containers. Control of actuators and monitoring of process parameters in manual or automatic operation is only possible by touch panel or control buttons.

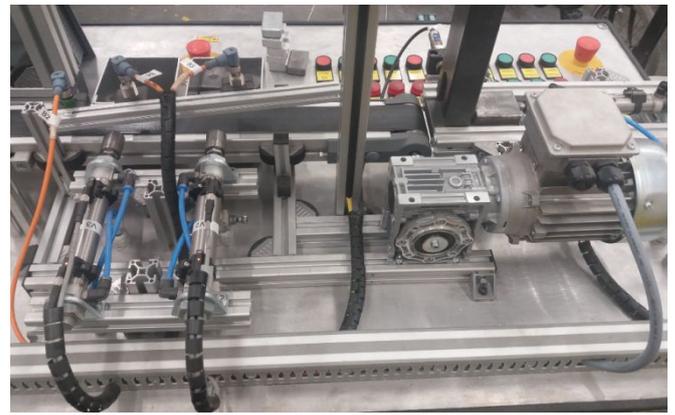

Fig.2 Autonomous stand-alone working station of production line

If there is a system error or breakdown, the operator has to check all process conditions, quit error messages and start the automatic operation through the touch panel.

If there is one system, it is a simple task. If the system is more complex or without the operator's permanent control, there is no possibility to control and improve production processes of the system.

As it is a stand-alone system without access to any network, intranet or internet, interoperability with cloud based systems, other cyber-physical systems or remote monitoring system is not possible. To improve interconnection, scalability, time and cost savings, it is necessary to enhance the stand-alone system with external hardware which enables the connection of working station with a local network [4].

As the best candidate for solving this problem in industrial conditions, Simatic IoT 2040 shown in Fig.3 has been chosen as the open industrial gateway [6]. IoT 2040 is an open platform for collecting, processing and transferring the data between production and IT systems or clouds in the production environment. It is designed for 24/7 operation and the role as an intelligent gateway interface can be used in both directions transferring data. This gateway supports programming languages such as Java, Python or C++, and multiple communications protocols such S7 Protocol, OPC UA, Profinet, TCP IP, MQTT via various interfaces, including RS232/422/485, serial USB, Ethernet or Wi-Fi.

Fig. 3 Industrial gateway IoT 2040

SYSTEM IMPLEMENTATION

Typical industrial control systems consist of distributed embedded devices such as PLC S7-1500 that control physical processes. For effective and robust industrial control approach according to the principles of IIoT, it is essential the hardware and software implementation and configuration of intelligent gateway as depicted in Fig. 4.

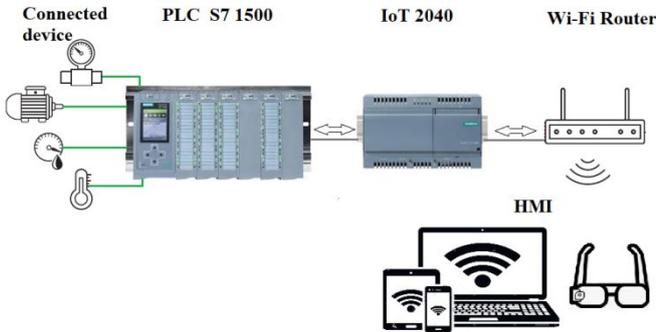

Fig. 4 Implementation of gateway IoT 2040 in to typical control system

In following parts, the exact approach of hardware and software implementation and configuration of IoT 2040 will be analyzed.

A. Setting up S7-1500

Based on environment and technical requirement, PLC S7-1500 was used for real-time control of the stand-alone system described above. Devices, such as sensors, actuators or frequency inverter are connected via Profinet cable directly to the I/O modules of PLC. Communication between these devices is possible via libraries in Totally Integrated Automation (TIA) software [4].

B. Hardware implementation

To the existing real physical model represented by automated working system controlled via PLC the intelligent gateway can be attached horizontally or vertically on a DIN rail or to a wall. Connection to the power supply can only be supported by 9-36 V. The Ethernet cable connected to the port X1 P1 LAN provides the gateway connection with Wi-Fi router. Communication between IoT 2040 and PLC S7-1500 was ensured via Ethernet cable connected to the gateway port X2 P1 LAN as depicted in Fig. 5.

Fig. 5 Hardware implementation of industrial gateway IoT 2040

C. Software implementation of PLC S7 1500

The first step in software implementation of PLC S7 1500 and connected devices, such as sensors and actuators, is to set communication between PLC and I/O modules via device configuration.

Once the communication is established the variables type, address and tag table need to be defined. Networks with appropriate variables from a list are an essential condition for creating automated control system as shown in Fig. 6.

To allow communication with other devices connected to the network, the permission access with PUT/GET communication from remote partner, such as PLC, HMI or OPC must be enabled [7].

Fig.6 Setting of control program with the use of PLC S7 1500

D. Software implementation of IoT 2040 in Node-RED

Industrial gateway IoT 2040 is certified hardware for industrial application. According to the type of application, the image must be created and uploaded to the gateway [5]. The first step for working with industrial gateway IoT 2040 is to set up a micro-SD card with appropriate image and install it to the gateway.

To create IIoT application, the interconnection of the physical layer with Node-RED needs to be established. To start Node-RED, a special command must be typed into the gateway terminal. Once the Node-RED has started, the user interface can be open in the web interface after typing the correct IP address 192.168.43.200:1880 and logging in with user credentials. Basic settings such as IP address of PLC, port, rack, slot, cycle time must be defined to establish the interconnection between correct hardware components. In order to allow remote control and remote visualization of connected devices using gateway IoT 2040, in PLC defined variables need to be defined as well in Node-RED variable list. After completing of basic communication and variables settings, it is possible to continue with the creation of application flows.

The process of flow creation is similar to the PLC flow-based programming. To the input nodes that are located on the left side of Node-RED web editor it is appropriate to assign them in the workspace with a proper variable and other relevant settings [5]. The same logic is used to create output debug nodes. To establish the connection between input and output nodes the wire in web editor is used.

## CASE STUDY

The aim of this case study is to verify the proposed methodology on a diminished form of gearbox production line with sorting mechanism by which parts are divided into individual containers. Individual parts are stored in a magazine and are in regular intervals positioned on the moving conveyor belt. According to the evaluation of the sorting mechanism, individual components are then moved by means of pneumatic cylinder. A HMI (Human Machine Interface) is used as a touch panel. B1, B2, B3 and B4 represent sensors, V1, V2 and V3 represents pneumatic actuators. According to the above mentioned methodology of IIoT application, the data from PLC are used for remote control and visualization. To create a simple application, input nodes connected to the sensor variable (I0.4) and engine variable (Q1.2) are wired with different types of output nodes, for example pneumatic actuators (Q0.0), conveyor belt (M50.1) as depicted in Fig. 7.

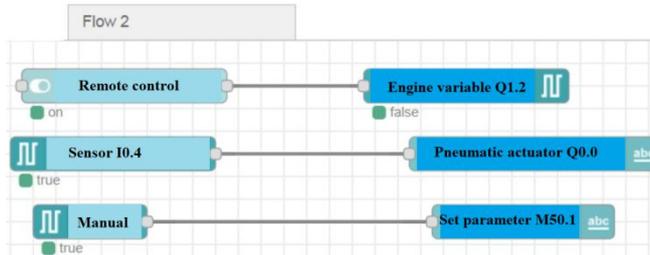

Fig. 7 Settings of input and output nodes in IIoT application in Node-RED

According to the specific requirements of different applications, output information from PLC can be presented in form such as gauge, switch, email, twitter, etc. After all nodes are created, the whole flow needs to be deployed.

Once the whole flow is deployed, remote visualization of the station and its connected components in real time is possible via any smart devices connected to the same local network after typing the correct IP address and log in using safety log in credentials. In the start page of the application, there is the option to set the device to automatic or manual operating mode, as well as to allow the remote control.

In the manual operating mode, using smart phone or other device connected into the same network, is it possible to see remote visualization of variables as depicted in Fig. 8.

Fig. 8 Manual operating mode of mechatronic system via smart phone

To change variables defined in variable list and control the process by changing parameters on switch, gauge or conveyor belt in real time is possible even via smart phone.

## CONCLUSION

In this paper, we managed to interconnect an industrial PLC via intelligent gateway IoT 2040 with web based platform Node-RED. Relevant data for remote control and visualization, such as current state of connected devices or process data can be easily obtained directly from PLC to intranet or internet without the need of additional sensor installation. A case study according to the proposed methodology was applied to verify this approach.

Using this approach, process data is easily accessible even from remote locations, can be analyzed and evaluated to improve production or maintenance processes. This scalable result is a solution that can be extended to the cloud based systems.

Further research and experiments should focus on applying of proposed scalable approach to the more complex industrial equipment for further possibilities of collecting, evaluating obtained data, as well as the use of secured cloud based systems in real time.

Email: erik.kucera@stuba.sk

**Abstract**—The main aim of proposed paper is the design of new software system for modelling and control of discrete-event and hybrid systems using Arduino and similar microcontrollers. In this article we propose a new tool. This new tool is based on Petri nets and it is called PN2ARDUINO. It offers a capability of communication with the microcontroller. Communication with the microcontroller is based on modified Firmata protocol so control algorithm can be implemented on all microcontrollers that support this type of protocol. The developed software tool was successfully verified for control of laboratory systems. It can also be used for education and also for research purposes as it offers a graphical way for designing control algorithm for hybrid and mainly discrete-event systems. Proposed tool can enrich education and practice in the field of cyber-physical systems.

## I. INTRODUCTION

Development of various systems is a complex discipline that includes many activities, e.g. system design, a specification of required properties, implementation, testing and further development of the system. As these operations are challenging and important for the final product, it is appropriate and necessary to create a model of the system. Development of control methods of discrete-event and hybrid systems belongs to the modern trends in automation and mechatronics. Hybrid system is a combination of continuous and discrete event systems. Control of such systems brings new challenges because it is necessary to join control methods of discrete event systems (where formalism of Petri nets can be helpful) and classic control methods of continuous systems. With good methodology and software module, these approaches can be synergistically combined. This will give us an appropriate and unique control system that allows harmonizing discrete event control methods with the methods of control of continuous systems (e.g. PID algorithms). Effective cooperation of these approaches allows to control hybrid system. This method would be useful in systems where it is necessary to use different control algorithms (for example PID controllers with different parameters) according to the state of the system. The concept of Petri nets is capable of covering a management of these control rules in a very efficient, robust and well-arranged (graphical) way. This paper is aimed to present new

Petri Net tools for modelling and control of discrete-event and hybrid systems. Case studies for control of laboratory fire alarm system and DC motor are also presented.

In [1] author developed an interesting software tool that supports hybrid Petri nets named Visual Object Net++. There a lot of papers (mainly from Romanian author [2]) that describes capabilities of Visual Object Net++. This tool is not open-source and it is not further developed.

As an interesting way of research, a Modelica language and open-source tool OpenModelica appeared. There is a library that supports modelling by Petri nets in this tool. One of the advantages of OpenModelica is that PN model can be connected with other components of Modelica. The first Petri net toolbox was introduced in [3]. An extension of this toolbox was described in [4]. The greater addition to the toolbox was made by the German author who enriches it by a support of extended hybrid Petri nets for modelling of processes in biological organisms [5] and [6]. This tool was developed primarily for commercial tool Dymola and not for OpenModelica, so applicability in scientific research and extensibility is limited. During 2015 the team that developed PNlib published modified version of PNlib that partially worked in OpenModelica. Unfortunately, it was not possible to use OpenModelica for control purposes using microcontrollers because of lack of COM port communication support.

According to the survey made during the described research project, it was realized that it is necessary to develop the own solution for control of discrete and hybrid systems using Petri nets based on microcontrollers as there is a lack of tools that support control of real systems using Petri net formalism.

## II. DESCRIPTION OF DEVELOPED SW TOOL PN2ARDUINO

As it was realized that there is no complex SW solution to support control of discrete event and hybrid system by microcontrollers using High-level Petri nets, it was necessary to develop it. As a basis for such software, PNEditor [7] was chosen. This tool is open-source. The developed extension of this tool is named PN2ARDUINO and is fully tested in [8] and [9]. The main topic of this paper is an introduction to this

Fig. 1. Simple scheme of proposed solution - Petri net's logic in microcontroller

Fig. 2. Simple scheme of proposed solution - Petri net's logic in PC

developed software that can be used for control of discrete event and hybrid systems and its verification on laboratory discrete-event and hybrid system.

There are more concepts of control using Petri nets. Petri net as a control logic is necessary to connect with the controlled system (e.g. using microcontroller). One of the main aspects of the control system design is the question whether the Petri net's logic should be stored in the microcontroller or into the PC (which can communicate with microcontroller). Both approaches have their advantages and disadvantages.

If the Petri net's logic is stored in the microcontroller, the main advantage is the independence of control unit from the software application (program on PC). The Petri net logic is modelled using PC, and then the Petri net is translated into program code which is loaded into the microcontroller. Then PC and microcontroller can be disconnected. The advantage is also the capability of control in real time. Disadvantages are limited computational and memory resources of the microcontroller. Following disadvantage is the need of repeating compiling and uploading the program into the microcontroller (mainly during development phase). The proposed solution is shown in Fig. 1.

When the Petri net's control logic is stored in specialized SW application on PC, this solution gives an opportunity to control the system directly from it. In the microcontroller, only the program with communication protocol is stored. This communication protocol (in our case it is Firmata [10]) is used for communication between PC and microcontroller. This solution eliminates the necessity of recompiling and reuploading the program during development. The next advantage is the elimination of restrictions on computing and storage resources because PC has (in comparison with microcontroller) almost unlimited resources. One of the disadvantages is that the control system cannot react in real time. The proposed solution is shown in Fig. 2.

In Table I, these differences are specified.

New software module PN2ARDUINO was based on the second approach. The Petri net runs on the personal computer. For communication between SW application and microcontroller, the protocol Firmata [10] was used. Firmata is a protocol that is designed for communication between microcontroller and computer (or mobile device like a smartphone, tablet, etc.). This protocol can be implemented in firmware of various

Fig. 3. PN2ARDUINO - Use-case diagram

microcontrollers. Mostly Arduino-family microcontrollers are used. On PC the client library is needed. These libraries are available for many languages like Java, Python, .NET, PHP, etc. Firmata protocol is based on MIDI messages [11].

On the Arduino side, Standard Firmata 2.3.2 version is used. The client application on PC is based on Firmata4j 2.3.3 library which is programmed in Java. The advantage of using Firmata is that another microcontroller compatible with Firmata can be used.

PN2ARDUINO extends PNEditor with many features. For Petri nets modelling, there is a capability of adding time delay to transitions and capacity for places. Also, automatic mode of firing transition was added for automatic system control purposes as only manual mode was present in PNEditor.

PN2ARDUINO brings a new communication module to PNEditor. This module communicates with the compatible microcontroller. This module consists of two parts. The first one provides the creation of connection with the microcontroller, so it sets COM port where the microcontroller is connected. The second part provides the implementation of a capability of adding Arduino components to Petri net's places and transitions. These types of Arduino components are supported: digital input and output, analog input, servo control, PWM output, message sending, custom SYSEX message [10] sending.

In Fig. 3, the use-case diagram of developed SW tool can be seen.

As it was stated, transitions and places can be associated with Arduino components. Digital and analog inputs serve as enabling conditions for transitions in Petri net. Digital and PWM outputs and messages serve as the executors of the respective actions.

TABLE I  
COMPARISON OF TWO CONCEPTS OF SYSTEM CONTROL USING PETRI NETS

Petri net logic in PC	Petri net logic in microcontroller
limited capability of real-time control	real-time control
much more computation and memory resources available	limited computation and memory resources
code in microcontroller does not need recompiling	during development repeated compiling is needed
PC must be still online	independence of control unit

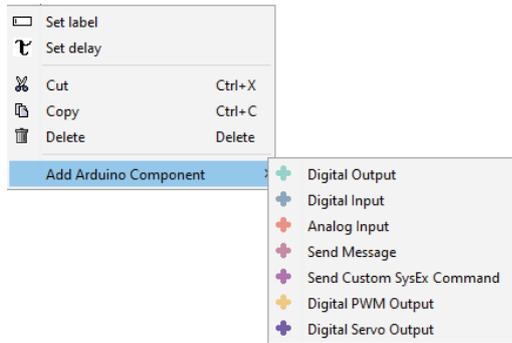

Fig. 4. PN2ARDUINO - Adding of Arduino component

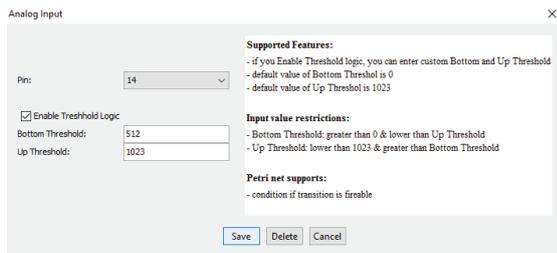

Fig. 5. PN2ARDUINO - Analog input

The interesting functionality is a capability of sending custom SYSEX messages. The user must enter SYSEX command ( $0 \times 00 - 0 \times 0F$ ) and optionally also the content of the message. The message is sent when the token comes to the place or when the transition is fired. For example, SYSEX messages are used in the proposed example of hybrid control in the last section of the paper. Here, the SYSEX message notifies the microcontroller that a different PID algorithm should be used for system control. Then PID algorithm is switched, and the controlled system remains stable.

A main window of PN2ARDUINO consists of a quick menu, main menu, canvas for Petri net modelling and log console. PN2ARDUINO supports two modes - design mode and control mode. Control mode is manual and automatic.

Firstly, it is necessary to initialize communication with Arduino (Setup board in the menu). Then it is possible to add Arduino component to the place or the transition (Fig. 4). The example of analog input can be seen in Fig. 5.

Time politics are also supported. To the transitions, it is possible to add time delay which can be deterministic or stochastic.

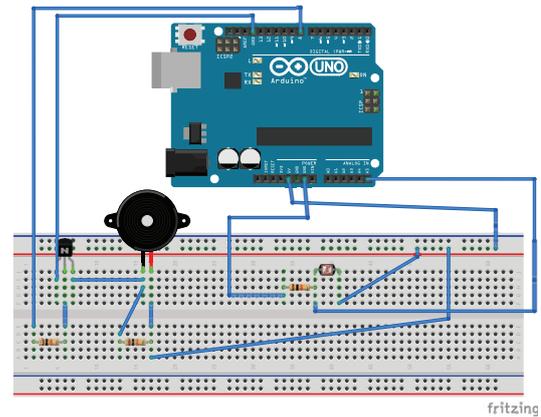

Fig. 6. The scheme of laboratory model of fire alarm

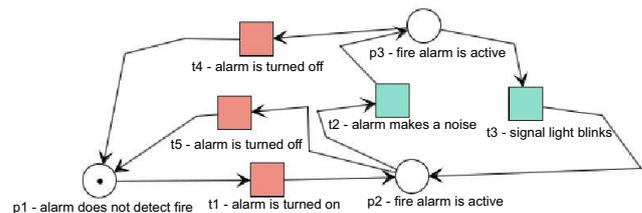

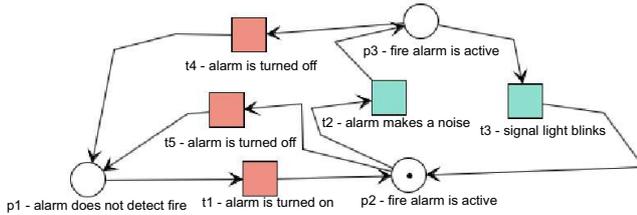

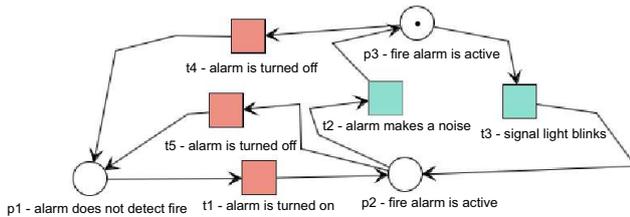

Fig. 7. PN for fire alarm (initial marking)

### III. CASE STUDY: CONTROL OF LABORATORY DISCRETE-EVENT SYSTEM

For verification of proposed software tool and method of discrete-event systems control it was necessary to design an education laboratory model of such system. A fire alarm model was built. The scheme can be seen in Fig. 6.

This model consists of an active buzzer, photo-resistor, three resistors and NPN transistor. NPN transistor is mandatory for active buzzer connection. The LED of Arduino in pin 13 is also used. Photo-resistor was used instead of the smoke sensor because of the less complicated feasibility of experiment.

Then the behaviour of the system must be defined. When the photoresistor detects an excessive lighting (it was experimentally determined as input value greater than 799 in the analog pin of Arduino Uno which resolution is from 0 to 1023) the intermittent tone of the buzzer is turned on. This tone alternates with LED lighting. When the value on the analog pin lowers below 800, these sound and light effects stop. This is repeated cyclically.

Fig. 8. PN for fire alarm ( $t_1$  is fired)Fig. 9. PN for fire alarm ( $t_2$  is fired)

Initial marking of modelled timed Petri Net interpreted for control (or sometimes called as interpreted timed Petri net) in PN2ARDUINO is shown in Fig. 7.

Places of Petri net (Fig. 7 - Fig.9) corresponds with these states:

- $p_1$  - alarm does not detect fire
- $p_2$  and  $p_3$  - alarm is active (fire was detected)

Transitions of Petri net (Fig. 7 - Fig.9) corresponds with these actions/events:

- $t_1$  - alarm is turned on
- $t_2$  - alarm makes a noise
- $t_3$  - signal light blinks
- $t_4$  and  $t_5$  - alarm is turned off

The token is in place  $p_1$  which corresponds with the state when the fire alarm is not activated because the photo-resistor does not detect light intensity threshold.

At the time when the value greater than 799 is detected on the analog pin of Arduino - the transition  $t_1$  is fired. This transition is associated with Arduino component *Analog Input* where a range of input values is set. This range determines when the transition is enabled.

Now the token is in the place  $p_2$  (Fig. 8). Transition  $t_2$  is associated with Arduino component *Digital Output* (in this case pin 8) where the buzzer is connected. This transition has also associated the function of time delay - 2 seconds. That means that transition firing (and sound effect of buzzer) lasts for 2 seconds.

Now the token is in the place  $p_3$  (Fig. 9). Transition  $t_3$  is associated with Arduino component *Digital Output* (in this case pin 13) where the build-in LED is connected. Time delay is set to 1 second. LED diode turns on for 1 second.

This process is repeated cyclically, and it is stopped when the value on the analog pin is lowered under the value 800. Then the transition  $t_4$  or  $t_5$  is fired and token moves to the place  $p_1$  when fire alarm does not detect the fire.

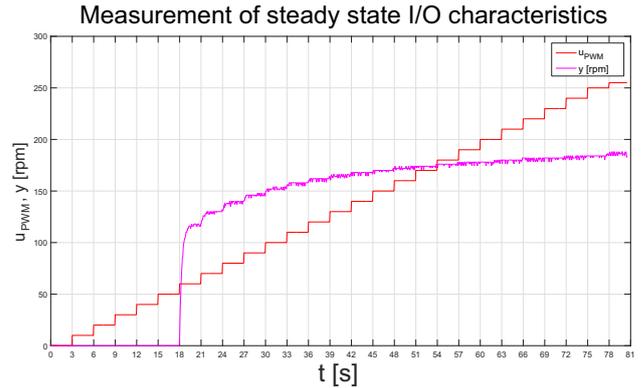

Fig. 10. Measurement of steady state I/O characteristics of DC motor

We can conclude that the ability of discrete-event control with PN2ARDUINO was successfully verified a generalized for other applications.

#### IV. CASE STUDY: CONTROL OF LABORATORY HYBRID SYSTEM

For verification of proposed software tool for hybrid systems control, it was necessary to design a laboratory model of such system. A DC motor with encoder was chosen. The encoder is used for feedback in the system because it is used for speed measurement. The actual speed of the DC is in is measured process value.

DC motor was connected to Arduino Uno using the motor shield module. Arduino motor shield is based on dual full bridge driver L298. Using the motor shield, it is possible to independently control speed and motion direction of DC motor. The encoder in this motor is of incremental type. For speed measurement, it is necessary to use hardware interruptions functionality of Arduino Uno.

The speed of the motor is set by pin described as "PWM A". When the input is set to "PWM = 255" the Arduino program shows 186 rpm which approximately corresponds with parameters stated by the manufacturer.

The next step was a measurement of steady state I/O characteristics. The input is a voltage supplied to the motor. These inputs are of size from 0V to 5V which corresponds with PWM signal from 0 to 255 (8-bit resolution). Sampling is 0.05 seconds. In Fig. 10 the process of measurement of steady state I/O characteristics is shown. The signal was filtered by 1-D median filter of 2nd order. Red line is input to the system (voltage or PWM). Output (rpm) is shown by magenta line. Steady state I/O characteristics is in Fig 11.

In the process of working points choosing it was necessary to choose points which meet the certain condition. This condition is that behaviour of the system must be close to the linear behaviour around these points. From I/O characteristics two values of input ( $u_{P_1}$  and  $u_{P_2}$ ) and output ( $y_{P_1}$  and  $y_{P_2}$ ) were chosen (these values will be our working points):

$$u_{P_1} = 80 \rightarrow y_{P_1} = 140rpm \quad (1)$$

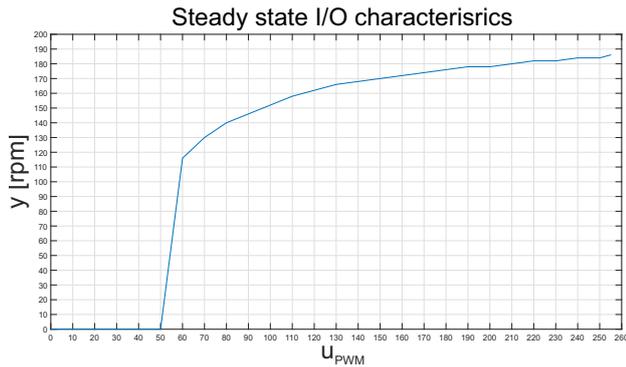

Fig. 11. Steady state I/O characteristics of DC motor

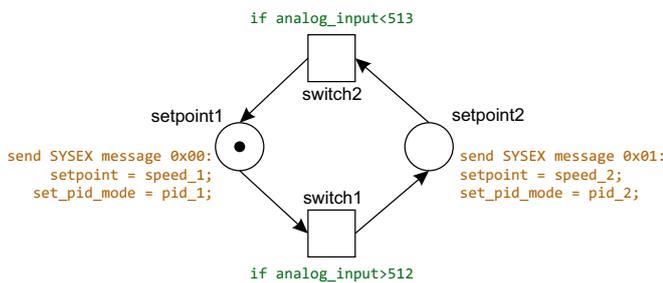

Fig. 12. Control scheme for hybrid system using PN2ARDUINO

$$u_{P_2} = 170 \rightarrow y_{P_2} = 174 \text{rpm} \quad (2)$$

From solution analysis, it is obvious that for each working point it is necessary to use a different controller. One of the solutions is an option to switch between multiple controllers according to the working point - speed (rpm) of DC motor. It is possible to use developed software module PN2ARDUINO. It is possible to switch between controllers and setpoints using SYSEX messages. Arduino and other microcontrollers that support Firmata protocol can be used. Development and verification of this software module are one of the most interesting results of presented research.

For illustration see the scheme in Fig. 12. It is an example for a demonstration of proposed control method. Assume the mentioned DC motor. We require to operate it in 2 modes (working points or rpm). For effective settlement of speed value to the setpoint, controllers with different parameters are needed (different controller for each mode). We switch between rpm using potentiometer connected to the analog input of microcontroller Arduino Uno. The switching between controllers is provided by transitions of Petri net named *switch1* and *switch2* according to the input value from potentiometer. Input from the analog pin in Arduino is represented by value between 0 and 1023. As the threshold, a half value was used (512). In the moment when the token in Petri net is moved to the place named *setpoint1* or *setpoint2*, a SYSEX message is sent. This message ensures the execution of user defined program code on the Arduino side. In this case, the control algorithm is executed. An algorithm (PID controller)

for continuous control is independent of Firmata messaging, so it provides real-time control.

The case study of hybrid systems control proposed a basic example. Researchers in the field of hybrid control design can use it for different and more complicated scenarios.

## V. CONCLUSION

The paper presents the new software tool named PN2ARDUINO which extends PNEditor with the capability of communication with microcontrollers that supports Firmata protocol. Then it is possible to control discrete-event and hybrid systems using timed interpreted Petri nets with developed software tool. This tool uses the control paradigm when the microcontroller has implemented only the communication protocol. Petri net's control logic is stored in the computer which communicates with the microcontroller and sends control orders. The next research will focus on the concept of control with Petri nets where control logic will be directly implemented on the microcontroller.

**Abstract** - The paper deals with a web application that allows simulating 3D model of mechatronic system in holographic devices. Purpose of this application is to bring new perspective to interactive education and simplify the process of studying. Background of an application is driven by Scilab Xcos simulation software communicating via web service, which provides data. The resulting animation is displayed on a holographic device, which allows visualization. The displayed system is a 3D model of the mechatronic experiment, which represents digital model of real device. Accurate movement of experiment is obtained by linking data from Scilab Xcos with 3D model. The 3D model visualization should help with easier understanding of the subject matter.

**Keywords** - mechatronic system, simulation, animation, holographic technology

## I. INTRODUCTION

THE goal of each educational institution should be to improve and innovate the educational process. New methods of educating students should be formed to make the process easier, such as in [1]. Also, it is necessary to increase its efficiency. The ideal outcome is to bring education and research activities together, creating innovations that support the industry [2]. The latest trend in education is to bring an application that gives a better understanding of the issue. Simplifying device designs, understanding technical specifications, facilitating device prototyping, or even making manufacturing process cheaper are just a few of the many different uses of 3D hardware digitalization [3]. There are many three-dimensional environments around the world that try to incorporate, work, and simulate knowledge from different areas [4]. Study says that at laboratory sessions 58% students agreed that methodologies like simulations, demonstrations and virtual labs make them more comfortable in lab sessions [5]. Nowadays, we can observe the trend of digitizing [6] and simulating equipment in almost every working segment. It allows us to face real situations before they happen, to learn from them, see issues from another perspective, respond to them much faster and, finally, to save costs. Lately many institutions have specialized in virtual and augmented reality, like in [7] and brought attention to it. However, our project wants to focus on an area that is not so widespread. The aim of our work is to show students another angle of learning. To do so, we used holographic technology.

Optical holography for recording three-dimensional scenes can be traced back to the early sixties. Since then, the art of holography has been applied in many areas, primarily as a tool for 3D imaging, processing, and display [8]. Study in [9] says that 45.5% of teachers believe that hologram technology would have affect in the field of teaching. The use of holographic technology could be used in various areas of life. The first example is using it in car, which is published in [10]. The authors attempt to present a holographic display, that would help reduce the time when drivers were guided to the dashboard. Hologram would be projected onto the front glass, so time of inattention would be reduced. Another example is in medicine. There is a possibility of displaying real heart beating on a model of heart in four-sided hologram pyramid, which authors published in [11].

The aim of this paper is to help students with understanding of the subject matter dealing, for instance with the basics of automatic control. Our system can simply help to visualize the behavior of mechatronic experiment parts as 3D digital model in holographic device.

## II. STATE OF TECHNOLOGY

The “Hologram” word refers to a three-dimensional picture made by laser light reflected onto a photographic substance without the use of a camera [12]. Hologram device could be used to play video, represent some system behavior, show object models, etc. We know many varieties of holograms, and there are variable ways of classifying them. For our purpose, we can divide them into three main types: reflection, transmission and hybrid holograms.

### A. Reflection holograms

The reflection hologram (Fig. 1) is the most common type of the hologram. They can be seen in galleries and in presentation places. This hologram is formed when the reference beam and the object beam are incident on opposite sides of the holographic surface. They interfere and record an image. To reconstruct the image, a point source of white light illuminates the hologram from the proper angle, and the viewer looks at it from the same side as the light source. Reflection holograms require the simplest setup and are visible without laser light [13].

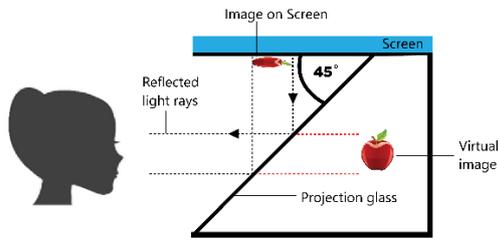

Fig. 1 How reflection hologram works

### B. Transmission holograms

Transmission holograms (Fig. 2) are also known as Laser-Transmission Holograms. This type is created when the reference beam and the object beam are incident on the same side of the holographic surface. They are viewed by shining a spread-out laser light through the emulsion side of the hologram at the same angle the hologram was recorded at, with the viewer looking on from the opposite side. The light is transmitted from behind the hologram device to the side of the observer [13]. Image which is displayed can be very precise.

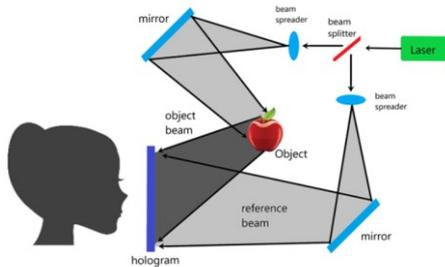

Fig. 2 How transmission hologram works

Materials, methods, and processes used to make transmission hologram are the same as reflection holograms.

### C. Hybrid holograms

As hybrid hologram could be considered a combination of transmission and reflection hologram. Hybrid hologram can be specified as multichannel holograms, holographic interferometry, integral holograms, embossed holograms, and computer-generated holograms. For example, embossed holograms are used for authenticity applications such as security hologram stickers, passports or credit cards. Computer-generated holograms are used to make optical elements, for scanning, splitting, in general for controlling laser light, example can be CD player [14]. These types of hologram are not relevant for our work, because of their technology, so we will not pay attention to them.

## III. PRODUCT RESEARCH

Looking on the market the most advanced holographic device suitable for our purpose can be considered Microsoft HoloLens. HoloLens is a pair of mixed reality smart glasses, which is a holographic computer built into a headset that lets you see, hear, and interact with holograms within an environment such as a living room or an office space [15]. It is a wearable device that permits to look at holograms that are

connected to the world and interact with them using gestures, voice commands and gaze. For instance, one of its advantages is plugin for Unity engine. However, due to its higher price (3500\$), it is unlikely that will be massively adapted soon.

Next, the Realfiction company offers a range of holographic devices. These devices have different sizes and differences in the number of display areas. They also have higher prices (2000\$ - 10 000\$). In our project we approached to use the Realfiction Dreamoc HD3.2. Device has three-sided view, HDMI port, RJ45 port 23" screen and built-in loudspeakers. More details can be found in [20]. We chose it because this device has connectivity advantage - HDMI.

For everyday use it is possible to buy quite cheap holographic devices and use it with smartphones or tablets for example from company Holho. Price can be from 40\$ to 160\$. Disadvantage of these devices is that only video can be played, so when we want to control behavior of real-time experiment it is not possible to change anything in process without connection to another device via cable.

## IV. APPLICATION

We had following requirements for the application:

- to make realistic view of 3D mechatronic experiment,
- to control the behavior of the 3D model using parameters entered by the user.

### A. Hardware

As it was said before, it's necessary to have hardware to generate holographic image. This hardware consists of two main parts. The device from the front side is shown in Fig.3.

Fig. 3 Hologram device from the front side

The first part is the image-emitting screen. A conventional computer screen could be used, but the resolution of screen increases the quality of the image. Our device has a screen up and emits the image from top to bottom. The second part is a projection glass with a semi-permeable layer, which is placed at a 45-degree angle below the screen. Therefore, the screen provides an image that is reflected on the glass. By placing the glass at this specific angle, the image is presented as if it is behind the glass, which creates virtual image of the represented object.

### B. Software and system architecture

Application with minimal requirements and possibility of massive adoption in future led us to use standard web technologies (HTML, CSS, JavaScript and Three.js). It is necessary to realize that the display area is in the hologram, so it is not possible to change the control parameters from there. To do so, we needed to use two browser windows. The

first one is opened in hologram as a view and the second one in computer screen as a control window. It is allowed via multi-screen mode. Of course, whole system is more complicated, and its architecture is shown in Fig.4.

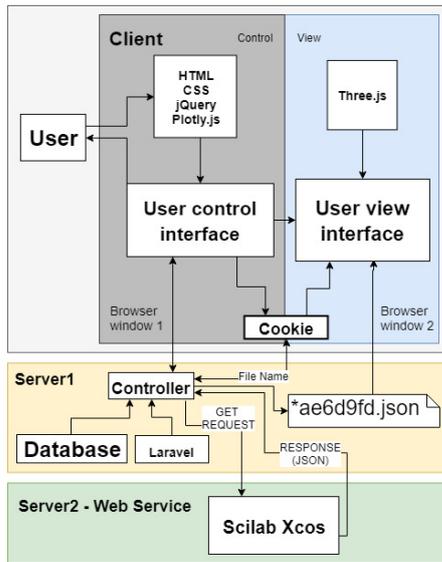

Fig. 4 System architecture

Back-end side of the application is managed from the server using a Laravel framework. When control interface is opened, data for specific experiment are automatically downloaded from MySQL database and a HTML form is generated. This form is generic, to ensure the possibility of adding new experiments in the future. The realistic movement visualization can be achieved thanks to numerical data received from Scilab Xcos simulation environment where the experiment is represented as a block diagram. Scilab allows to simulate a block scheme by accessing it through a terminal. Module with Scilab has its own interface, works as standalone application and it is used as a web service. It is necessary upload block scheme to the server before the first simulation. Then, it is used by an authorized program, accessed via URL. The main problem of showing data in 3D model is to send them from control to view interface or to change the simulation parameters during the visualization. Since each client window works separately, it is necessary to inform view interface about parameter changes in control interface. Solution we used is simple, when control view is opened, random SHA code is generated and saved as cookie value. This cookie is used then as a file name for data from simulation. Data are sent as a HTTP response from service and always saved to this specific file during entire session. User view interface gets these data and starts to render movement of experiment.

C. Web Service

There are several simulation programs on the market, like Matlab, Scilab Xcos or Octave. In our case, we have chosen Scilab Xcos, which is an open source distribution modeling and simulation software for numerical computation. The choice was done from several reasons. Matlab as the most

used software requires license and not everyone have access to it. Therefore, it was not suitable for this implementation. Octave from the open source category does not provide a block diagram option, which is suitable for easier creation of controllers. There exist also other programs that have a graphical editor for building block diagrams and have also appropriate numerical methods to solve differential equations. However, Scilab Xcos is the closest open source option to Matlab.

Secondly, since we want the system to be modular, it is very useful to have an Application Programming Interface (API) that allows us to use this simulation software as a web service. The advantage of the simulation environment that is located on the server and works as a web service is that everyone who requires to retrieve the data needs to know only the URL and how to access the software through the appropriate API. We have already had API for Scilab Xcos at the time of implementation, so we decided to use it. Since the entire data processing module is running as a web service, it can be easily replaced by other software. In this way the application can be expanded by a different simulation environment in the future.

V. ONLINE EXPERIMENT

In Fig.7 a model of the Furuta pendulum for our holographic device is depicted. The holographic device we used renders three-side projection, so it is necessary to have the model displayed three times and rotated by ninety degrees. The one on the bottom is then shown on the front side of the device and the other two on each side.

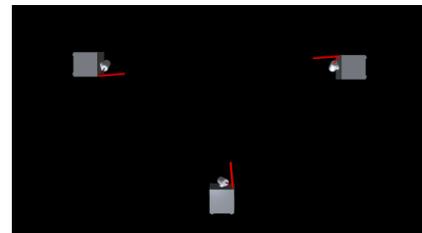

Fig. 5 Furuta pendulum view in system

Firstly, it is necessary to open view interface (Fig.5) in holographic device.

The control interface is a web form titled 'Controllers'. It contains several input fields and a 'Start simulation' button. The parameters are as follows:

Program	K1	Required angle
Scilab	-3.5443	60
Controller	K2	Sampling period
State	-2.1498	0.01
	K3	Animation time
	-20.0816	5
	K4	
	-4.6941	

Start simulation

Fig. 6 Control interface for input data

Secondly, data are required. They are coming from control interface where the block scheme is simulated. In our case the control structure includes model of Furuta pendulum and the state space controller. Its parameters (i.e. gains  $K1$ ,  $K2$ ,  $K3$ ,  $K4$ ) can be defined via user interface shown in Fig.6. User can specify also *required angle*, *sampling period* and *animation*

time. After sending the request to the server (by clicking on the button *Start simulation*), the data will arrive within seconds and the model simulation will automatically start. The input parameters can be altered by sending a new request. The process is designed to change movement automatically. In Fig. 7 is shown holographic device Dreamoc HD3.2 with connected computer via HDMI.

Fig. 6 Control interface in computer screen and Furuta pendulum model in holographic device

## VI. CONCLUSION

The paper describes web application for holographic devices, developed mostly for educational purposes. It can be used as a tool for interactive teaching in subjects dealing with automatic control theory. With this technology, for students it is simpler to imagine mechatronic systems behavior and that should be goal of every educational institution. The application acts as simulation software for 3D objects that helps students to understand how to operate with specific devices and systems. The application uses Scilab Xcos as simulation environment for computing block schemas. Achieved simulation data allow to see realistic movement of experiment 3D model. The 3D model, which is shown as holographic mechatronic experiment projection of the specific device. Holographic device that was used to show model and the behavior of the experiment, cannot be considered as a solution that could be used massively, due to its higher price. The tool can be used as a display device for teachers during lessons. However, the application can be simply modified to a device that is not subject of a high price and this version could be deployed for every student.

As a future work, authors would like to extend the application by directly embedding it into the online laboratory portal, which deals with real-time control of experiments. This portal is currently in the implementation phase. Also, they would like to extend the application to use it through augmented reality, using Google ARCore platform.

## ACKNOWLEDGMENT

The work presented in this paper has been supported by the Cultural and Educational Grant Agency of the Ministry of

Education, Science, Research and Sport of the Slovak Republic, KEGA 030STU-4/2017 and by the Tatra Banka Foundation within the grant program E-talent, project No. 2018et016 (Holographic technology and augmented reality in online experimentation). Authors would like to thank to all contributors for help with implementation.

# Proposal of Mechatronic Devices Control using Mixed Reality

Erich Stark, Erik Kučera, Peter Drahoš, Oto Haffner  
Slovak University of Technology in Bratislava  
Bratislava, Slovakia  
Email: erich.stark@stuba.sk

**Abstract**—The Internet of Things and mixed reality are now among the most important areas in research or in practice. The aim of this paper is to propose an appropriate way of connection of these two areas, where is possible to control and monitor mechatronic devices using a mobile device with augmented/mixed reality support. The main task will be to explore these options in the area and implement this solution as prototype. The proposed methodology for control and diagnostics of mechatronic devices is modern as it combines hardware management, a Unity3D engine for mixed reality development, and communication within the Internet of Things network.

## I. INTRODUCTION

CURRENTLY, computer networks are no longer just for connecting conventional computers like they once were. Their purpose gained a new dimension when mobile devices and embedded systems began to connect to these networks. At present, these boundaries are shifted to the level of connection of individual sensors, various household appliances, and even autonomous cars to the network [1]. This expansion of connected devices has also happened because of the rise of microcomputers like Raspberry Pi, DragonBoard, and similar prototyping solutions. At the same time, people begin to realize the value of data that these sensors generate. They can help us streamline processes in industry and services or make life easier with smart home solutions. As a result, the emergence of new types of networks such as Internet of Things (IoT) are needed. The concept of IoT can be found at almost every conference in the field of information and communication technologies or in scientific articles [10], [11], [12]. The Gartner company makes regular analyzes and research into the use of various technologies. Earlier in 2017, an analysis was made that states that IoT will have up to 20.5 billion connected devices in 2020 [2]. These paradigms would not take place without the development of new networks, data transmission protocols and the necessary software tools. At present, IoT devices are controlled by console, web, or mobile applications. Using these conventional methods of controlling IoT devices in a small room can be quite simple. Because the list of devices is on one screen, we can see and set properties almost instantly. But if there are multiple rooms or buildings, the segmentation of these devices may be totally unclear and cumbersome. Here is the opportunity to use current trends and modern technologies in the field of virtual, augmented and mixed reality. These technologies are able to put digital objects into the real world. Their convenience lies

in the fact that objects from the real world are enriched with information relevant to the given object that one is looking at. This camera stream processing is real-time. Mixed reality can now be developed and tracked with compatible headset - such as Microsoft HoloLens or compatible mobile devices (smartphones and tablets) from both leaders in the segment - Google Android and Apple iOS. The implementation of the proposed project involves the use of mobile devices for their wide availability - whether for household or industry. Compatible headsets are currently not suitable for this purpose, as businesses (especially small and medium-sized ones) are often unwilling to invest in these headsets. The proposed methodology for controlling and diagnosing IoT devices is modern as it combines hardware management, a 3D engine for mixed reality development, and communication within the Internet of Things network - all areas of mechatronics. The proposed solution is unique and will contribute to the scientific field of mechatronics.

## II. COMPUTER GENERATED REALITY

### A. Virtual Reality

Virtual reality (VR) is a term that is mentioned in various areas, not only in information and communication technologies. Films like Matrix have brought virtual reality from the sci-fi world to the human mind. Examples of virtual and extended reality are becoming more and more real-life, from military air simulators to simple smartphone applications. Everyone can have their own idea of virtual reality, so it is necessary to introduce a suitable definition.

Virtual reality consists of an interactive computer simulation that senses the state of the user and replaces or extends sensory feedback information to one or more senses in such a way that the user gets a feeling of being immersed in the simulation (virtual environment).

### B. Augmented Reality

Augmented reality (AR) is an overlapping of content in the real world, but this content is not embedded or part of it. The content of the real world is not capable of responding to computer-generated content [3]. Augmented reality is therefore a live, direct or indirect view of a real world that is complemented by computer generated (CG) elements such as audio, video, graphics, or GPS data. Augmented reality is a layer of content above the real world, and this content is not

anchored to this world or its part. As has been said, elements of the real world and CG content can not react with each other.

The purpose of Augmented reality is to improve user perception and improve its effectiveness through additional information. The user retains awareness of the real world, but in an ideal extended reality it would not be able to recognize the difference between information from the real world and the virtual world.

Fig. 1. Augmented reality example

### C. Mixed reality

Mixed reality (MR) is an overlap of the real world with synthetic content that is embedded in it and interacts with the real world. The key feature of MR is that real-world synthetic content and content can respond in real time to one another. Mixed reality is thus a combination of the real world and the virtual world, creating a new environment and visualization where physical and digital objects coexist and interact with each other in real time. Mixed reality is the layer of artificial (digital) content in a real world that is anchored and interacts with the real world. An important fact is that, in the case of mixed reality, advanced mapping of the environment is required for the placement of additional CG elements.

If information is to be successfully combined, virtual objects must act physically in a suitable way. If a real and virtual object collision occurs, both must respond appropriately. In addition, virtual objects must overlay the view of real objects and also shadow on them. All this can only be achieved by a precise model of real and virtual environments.

The first hardware for mixed reality, currently the most advanced device of the segment, is Microsoft HoloLens. The problem is still a relatively high price, but there is also an emulator for development.

Based on the information we have mentioned, mixed reality seems to be the most exciting. However, it is possible to imagine the future in which synthetic content will be able to react in some way and even communicate with the real world [3].

### III. INTERNET OF THINGS

Internet of Things is currently a very widespread term in the field of modern information and communication technologies.

Fig. 2. Mixed reality example

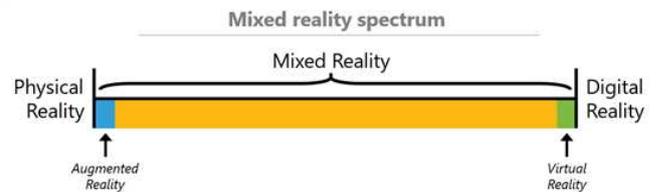

Fig. 3. Mixed reality spectrum

This issue is the subject of various debates as its deployment in industry and services brings about more effective action, but it also raises various issues, such as safety. Thus, IoT concerns almost all fields of human activity [4].

In general, IoT can be defined as a set of physical objects (or things) embedded in electronics, software, sensors and connected devices that are connected together in the network to allow data exchange with other interconnected devices to achieve higher value and more services for users. These IoT devices create a linked network in which each is uniquely identifiable with a unique IP address and capable of communicating with existing network infrastructures.

### IV. RELATED WORK

In the paper [5], the authors presented the Augmented Things concept, where computer objects contain all the information needed to track and expand the information required by AR applications. This allows the user to connect to them, retrieve information using their mobile device, and get expanding information like, for example, maintenance, device, or usage information. The authors have created also a simple 3D framework that allows you to track objects using high quality 3D high resolution scans.

Phillipe Lewicki has attempted to create a demonstration program to help control the Philips Hue light bulb using the Microsoft HoloLens device as seen in Fig. 5. He realized that today's solutions allow you to control the bulbs using the mobile application they need to open, to find a particular room, and then a particular bulb. Often, such applications are limited because smart bulbs contain more features than just turn on / off.

Thanks to the HoloLens on the head, it was only possible to look at the light and turn it into a simple gesture or change

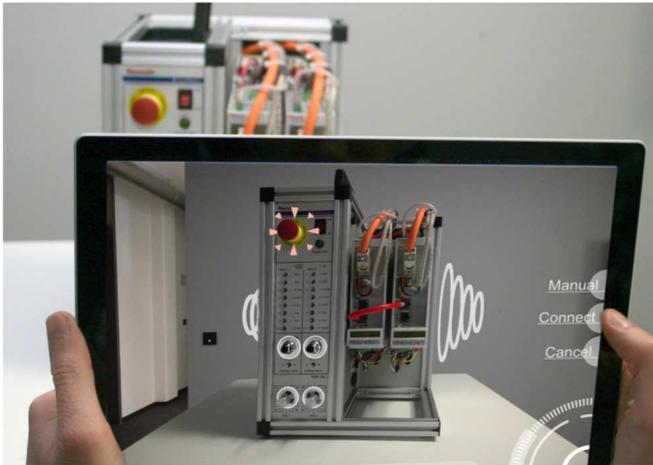

Fig. 4. Augmented Things objects contain and share their AR information

Fig. 5. Application for HoloLens, enabling color adjustment of light

the color of the light. It was faster than a wall switch [6]. Fig. 6 shows Proof of Concept (PoC) by designer Ian Sterling and software engineer Swaroop Pala. Their concept shows how smart devices could be controlled by gestures. The task of this project was to provide a 3D user interface with Android Music Player and Arduino light fan [7].

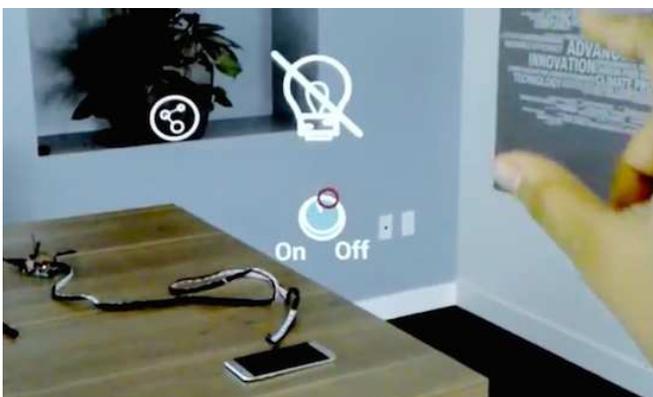

Fig. 6. Light control using HoloLens and Arduino devices

### V. SYSTEM PROPOSAL

The diagram of the proposed system can be seen in the Fig. 7.

System description:

- 1) At the beginning of the system is mixed reality device which is able to analyze data stream from camera and detects QR code.
- 2) Application can connect to identical object in the cloud.
- 3) Data from the device sensors are sent to the cloud.
- 4) Mixed reality application gets information about device and shows tailored user interface.
- 5) The user can interact with that device using mixed reality experience.
- 6) It is possible to send some control commands to the cloud.

This system can be decoupled into several components described in subsections below.

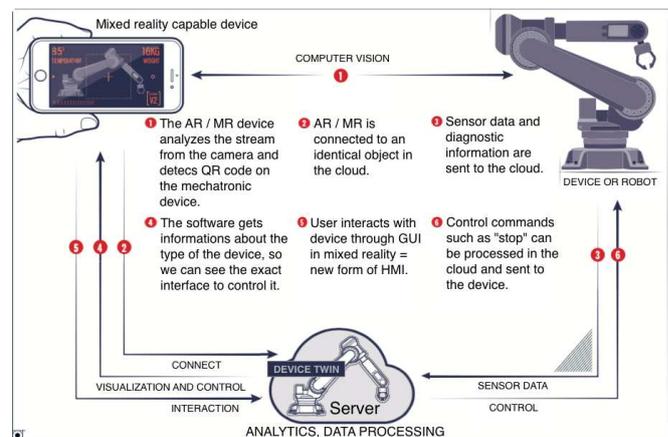

Fig. 7. Diagram of system proposal

#### A. Camera Device with Mixed Reality Support and Computer Vision Tools

The best option for mixed reality experiences nowadays is smartphone when comes to price or availability for masses. Basically, there are two options: Android system with ARCore SDK or iOS with ARKit SDK support. ARKit SDK was chosen because of greater support of functions needed for this project. For example, like persistent content or 3D object recognition in recently announced ARKit 2.

At first it has to be created software which can analyze video stream from smartphone camera and detects physical objects. ARKit can be used with support of framework Vuforia inside Unity 3D editor, which helps a lot with software development. The main features of Vuforia SDK is *Multi Target detection*, *User Defined Targets* or *Cloud Recognition*.

#### B. Software Platform for IoT

OPC is currently the most advanced standardized data exchange process for automation technology. It allows the collection and transmission of data in a unified form from

various devices, control systems and applications throughout the organization. The design of this standard allows mapping almost all industrial data into the OPC data structure. OPC UA is an enhanced version of the OPC standard that has a unified architecture that makes it a platform-independent protocol. In addition, it has built-in security mechanisms and applications are fully scalable from microcontrollers to corporate servers.

### C. IoT Prototyping Hardware Kit

There were many options for prototyping devices from single hardware to complex IoT kits. It was not easy to find IoT kit which meet system requirements the most.

BigClown is a modular hardware and software system that allows to prototype and build real-world telemetry, automation and other applications including IoT. BigClown can be imagined as a set of components with a single interface that can be connected together depends on application needs.

The core of each device is the so-called Core Module. It is powered by a single core CPU with the Cortex-M0+, specifically STM32L083CZ. This chip was chosen for a number of reasons: it is proven and used ARM CPU from STM32 series, has a very low consumption (which is important for powering the nodes from battery), has integrated USB with ROM bootloader, enough number of interfaces, (Flash, RAM and EEPROM), and above all, it has two cryptographic components: TRNG (True Random Number Generator) and AES-128 computing accelerator [8].

Fig. 8. Whole BigClown ecosystem [8]

## VI. CONCLUSION

The upcoming trend Internet of Things has an impact not only on applications for various services, households and intelligent buildings, but also significant impact on industry and industrial production. The application of IoT principles in industry is called Industrial Internet of Things (IIoT), where in this case instead of interconnected devices is used individual machine parts or their sensors and actuators, as well as sensors and actuators for HVAC (Heating, ventilation, and air conditioning) security. Device interconnection should be wireless in particular and should bring new interaction capabilities not only between systems, but also bring new capabilities to control, track and secure advanced services.

This proposal of interconnection IoT and mixed reality can bring new form of Human Machine Interface which can save time for users or companies.

The future work will focus on developing such a solution with technologies mentioned before.

### ACKNOWLEDGMENT

This work has been supported by the Cultural and Educational Grant Agency of the Ministry of Education, Science, Research and Sport of the Slovak Republic, KEGA 030STU-4/2017 and KEGA 038STU-4/2018, and by the Young researchers support program, project No. 1324 – VZRI4 (Virtual and Mixed Reality for Industry 4.0) and project No. 1325 - ODIZPZR (Monitoring and Diagnostics of IoT Devices using Mixed Reality).

**Abstract**— Nowadays, deep learning methods have been used in many areas such as big data analysis, speech and image processing with the increasing processing power and the development of graphics processors. In particular, face recognition systems have become one of the most important research topics in biometry. Light direction, reflection, emotional and physical changes in facial expression are the main factors in face recognition systems that make recognition difficult. Training of the system with the available data in small data sets is an important factor that negatively affects the performance. The Convolutional Neural Network (CNN) model is a deep learning architecture used for large amounts of training data. In this study, a small number of employee images set of a small-scale company has been increased by applying different filters. In addition, it has been tried to determine which data augmentation options have more effect on face recognition. Thus, non-real-time face recognition has been performed by training with new augmented dataset of each picture with many features.

**Keywords**— deep learning; convolutional neural networks; image processing; face recognition; data augmentation

## I. INTRODUCTION

### A. Deep Learning

Deep learning is a series of machine learning algorithms that try to model high-level abstractions of data with model architectures from multiple nonlinear transformations. Deep learning systems are used in many areas such as big data analysis, speech recognition, image classification, pedestrian recognition, generic visual recognition and face recognition along with improvements in power of processor and in graphics processors [1].

Deep learning, a class of machine learning uses many nonlinear processing unit layers for feature extraction and conversion. Each subsequent layer calculates the output of the previous layer as input [2].

Algorithms can operate supervised or unsupervised. Deep learning is based on learning with the representation of data. For example; when a representation is represented for an image, properties such as a vector or edge sets of density values per pixel may be considered. Some of these features represent data better, while others may represent worse. Deep learning methods are advantageous by using effective algorithms for hierarchical feature extraction that best represent data rather than manually extracted features [3,4].

The difficulty of generalizing the new examples becomes even more difficult when working with high dimensional data,

and the mechanisms used to achieve generalization in traditional machine learning are not sufficient to learn complex functions in high dimensional areas. Such areas also often require high computational costs. Deep learning is preferred to overcome these and other obstacles [5]. Particularly in the case of large amounts of training data, the deep learning method is an area of considerable work [6-8].

### B. Convolutional Neural Networks (CNN)

In recent years, Convolutional Neural Network (CNN) models, which are deep learning models as an alternative to traditional feature extraction and artificial neural network methods, have started to be developed. CNN-based methods are preferred in order to reduce the effects of different species such as exposure, illumination, facial expressions and better features in image analysis [9].

The CNN has a convolution layer, nonlinearity layer and pooling layers and a flow from simple attributes to complex attributes. Class estimates are obtained as CNN outputs. The filters used in CNN's convolution layers update themselves to minimize the error throughout the training. As the filters are updated, the attributes obtained in the layer outputs also differ. This iterative improvement throughout the training phase provides more distinctive features [1]. The success of this method has been proven, especially in the case of processing large data [6,7,10].

Figure 1 shows a generally accepted CNN model AlexNet architecture.

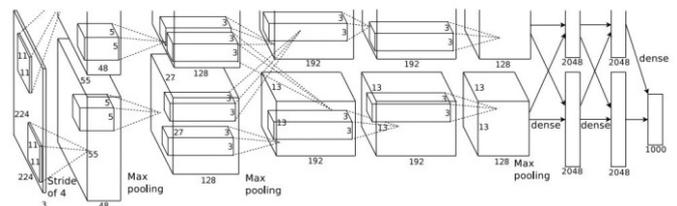

Figure. 1. AlexNet Architecture [11].

## II. PREVIOUS STUDIES

With the increasing amount of data, especially in the image processing area, problems such as image classification and object recognition stand out. Deep learning methods that prove themselves as a method that can cope with large data are frequently used and give the most successful results [4]. However, it is important to increase the amount of data without compromising the integrity of the data format for application areas with a limited set of data.

In their study, Si Liu et al. increased the image size to 1 and 1.2 times in order to increase the sensitivity rate in the cropped human-centered regions and to reduce the excessive compliance, with the filters such as horizontal reflection, 4 variations of each image. However, this study was carried out to include only the image area, and no facial separation was performed [12].

In their work, Vittorio et al. produced a vastly increased image collection to enrich the distinctive features of the painting and tried to eliminate the constraints such as lighting, exposure, facial expression, and low resolution [13]. In their study, Buslaev et al. performed a fast and efficient album creation process by performing multiple image conversion with image enhancement method [14].

Galdran et al. have added color coherence algorithms to the data sets of convolutional neural networks based on convolutional neural network studies for segmentation and classification of skin lesion analysis [15]. Cengil and Çınar performed image classification with CNN model on 8 different images selected from CIFAR-100 data set. In order to be used in the training process of the study, they trained the system they designed for 9 hours with the data increase process [16].

Doğan and Türkoğlu, with deep learning, designed the leaf classification for the model, AlexNet, Vgg16, Vgg19, ResNet50, GoogLeNet algorithms were used to compare the performance. They stated that if the amount of data increases, the performance will increase but the processing time will increase accordingly [17].

In order to increase classification performance in his work, Salman produced artificial data sets by adding different levels of noise through the existing training dataset [18].

In the above mentioned studies, it was emphasized that increasing the data set will increase the educational performance of the system but it is not explained how a performance difference is between the original data set and the increased data set. Increasing the data improperly depending on the type of data used and the application purpose may not yield positive results. The filters used to increase the data set and the proper size of these filters are very important for determining the characteristics.

In this study, on the data set containing few samples; firstly, the classification is made in its original form, then, applying different filters to the data set, the classification has made with the increased new data set. Thus, the performance of data augmentation on the face recognition system has revealed. In addition, it has been tried to determine which filters give more effective results in non-real-time face recognition.

### III. PRESENTED STUDY

#### A. Aim

The purpose of the study is to obtain training data for use on the CNN model, which is designed to obtain a large number of samples from the face images containing a small number of samples in the source dataset without disturbing the integrity of the original image. This will reveal how the non-real-time face recognition system is affected by the classification performance. The process diagram of the proposed study is shown in Figure 2.

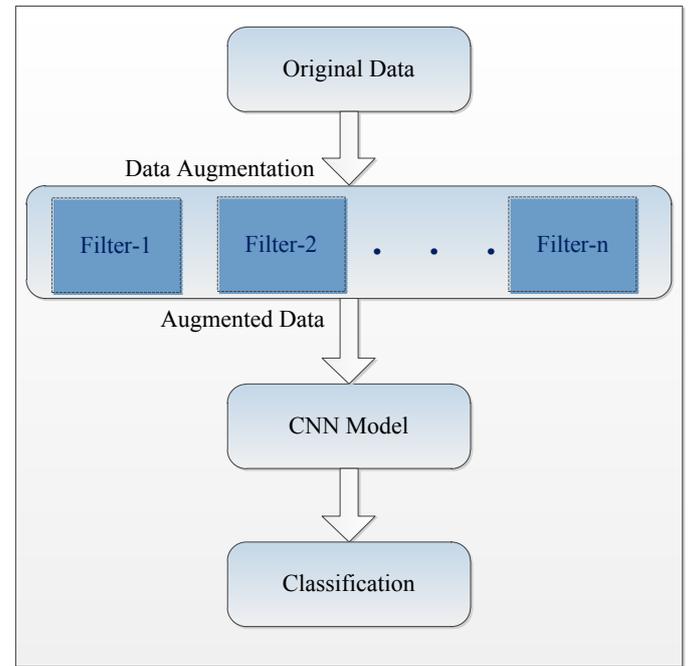

Figure 2. Process Block Diagram

#### B. Method / Architecture

Deep learning architectures include CNN. CNN is a special type of feed forward neural network. The main characteristic of this method is that it can learn features at various levels by providing a more abstract representation of the input data. Thus, it can be applied to the network without attribute extraction. Therefore, a CNN is an end-to-end classifier. Another advantage is the structuring of feature extractors based on data used for training [19].

The processes of the method applied in this study are shown in Figure 3.

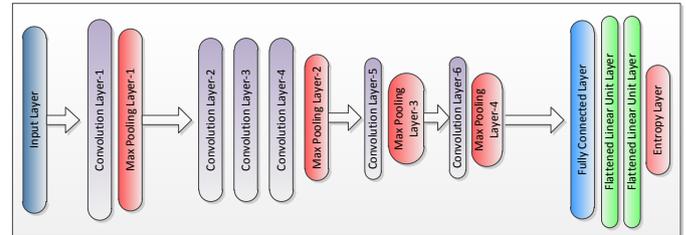

Figure 3. Applied CNN Model

## IV. EXPERIMENTAL SETUP

#### A. Data Sets

150 face images of a small-scale company have been used for the data set. According to the principle of confidentiality of the data, the pictures are not used in their original form. In addition, we have compared the random picture of 150 people with the data set, known as Labeled Faces in the Wild (LFW) [20].

##### 1) Data Preprocessing

All images have taken to 256x256 pixels and the image to be placed on the input layer has obtained in 256x256x3 size.

#### Data Augmentation

The best way to generate a machine learning model, perform better generalization is to train the model using more

data. However, the amount of data we have in practice is limited. One way to overcome this problem is to create artificial data and incorporate it into the training set. This approach is the easiest method for classification. The task of a classifier is to take a complex, high-dimensional input  $x$  and summarize it with a single category  $y$ . That is, the main task of a classifier is to be unchanged against a wide variety of transformations. By converting the  $x$  entries in the training set, new  $(x, y)$  binaries can be created easily [5]. In this way, the variety of data is increased by artificial methods and it affects the learning performance to a great extent. With this process, the pictures are subject to some distortion. On the image, it is attempted to increase the variety of pictures by performing operations such as angular rotation, changing perspective, scrolling and zooming [21].

Many processes, such as rotating or scaling the image, have been shown to be effective in enhancing educational performance. However, it is necessary to avoid making transformations that may perceive the correct class as false. For example, in an optical character recognition system, the letters b and d or numbers 6 and 9 may cause misclassification because they can be likened to each other. It is not appropriate to use data augmentation methods such as horizontal translation or rotation at 180-degree angle for these systems [5].

### B. Implementation Setup

The application has been implemented using the Keras library on the Python platform. To increase the data, Keras's ImageDataGenerator parameters have been used. Using the data enhancement techniques, the number of pictures with separate filters for each face image is gradually increased from 150 to 3300, 6300 and most recently to 9450.

These data sets; angular rotation, scrolling, cropping, zooming, turning filters have been applied and k-nearest neighbor algorithm has chosen to fill the resulting gaps.

TABLE I. AUGMENTED DATA SAMPLES

### C. Calculation of Performance Ratio

The performance of the system has been measured by the accuracy percentage of the training set. The results are presented in Tables I and II. The data quantity and performance ratios obtained from the incremental increase of the original data set are presented in Table II. No data augmentation is applied to compare to 150 images randomly selected from the LFW dataset given in Figure 4. The performance graphs of the original dataset, which are incrementally augmented, are given in Figure 5 and Figure 6.

TABLE II. SUCCESS EVALUATION TABLE

Total Number of Data	Training Time	Performance Rate (%)
150	58sec.	50
3300	20min.	62
6300	44min.	66
9450	1h. 4sec.	76

## V. CONCLUSION AND EVALUATION

Deep learning systems are used in many areas such as big data analysis, speech recognition, image classification, pedestrian recognition, generic visual recognition and face recognition along with improvements in power of processor and in graphics processors. In particular, in order to extract better attributes in image analysis, traditional feature extraction and an alternative to artificial neural network methods, Convolutional Neural Network (CNN) models, which are deep learning models, have started to be developed.

It is important to increase the amount of data without disrupting the integrity of the data for application areas with limited data set. As the amount of data we have in practice is limited, one way to overcome this problem is to create artificial data and increase this data.

In this study, angular rotation, scrolling, cropping, zooming and turning filters are applied on a small number of data sets and the source data set is increased without disturbing the integrity of the original data. In addition, it has been tried to determine which data augmentation options have more effect on face recognition. Thus, non-real-time face recognition has been performed by training with new augmented dataset of each pictures with many features.

Experimental results show that the performance of the training is significantly increased depending on the amount of data. The filters used in this study, especially angular rotation and brightness filters have more effect on success. Because the LFW dataset contains more than one image for some people, no data augmentation is applied to this data set. This dataset has been used to compare with the augmented original dataset. According to these results, the LFW data set should also be increased for more performance. Although the original data set contains a sample for each person, face recognition is more efficient because only one person is in the pictures. However, the performance achieved with some filters is more effective than others. For example, horizontal flip or mirroring filters may be more suitable instead of vertical flip filter. At the same time, the parameter values used are also very effective. Excessive angular rotation for the data set used did not yield positive results.

## VI. FUTURE STUDIES

In order to further increase training performance, the appropriate filters can be designed to produce more data with reasonable parameter values and new models can be created with AlexNet, ZFNet, GoogLeNet, Microsoft ResNet, R-CNN architectures that can be considered successful in image classification. However, it should be taken into consideration that the training period will increase in proportion to this increase for very high data numbers. In addition, the effects of the filters can be discussed by using different filters than the filters used in this study.
