DEAR Reader, it is our pleasure to present to you Proceedings of the 18th Conference on Computer Science and Intelligence Systems (FedCSIS 2023), which took place on September 17-20, 2023, in Warsaw, Poland.

FedCSIS 2023 was chaired by Jarosław Arabas and Sławomir Zadrożny, while Przemysław Biecek acted as the Chair of the Organizing Committee. This year, FedCSIS was organized by the Polish Information Processing Society (Mazovia Chapter), IEEE Poland Section Computer Society Chapter, Systems Research Institute of Polish Academy of Sciences, as well as Faculty of Electronics and Information Technology and Faculty of Mathematics and Information Sciences of Warsaw University of Technology.

FedCSIS 2023 was technically co-sponsored by IEEE Poland Section, IEEE Czechoslovakia Section Computer Society Chapter, IEEE Poland Section Systems, Man, and Cybernetics Society Chapter, IEEE Poland Section Computational Intelligence Society Chapter, Committee of Computer Science of Polish Academy of Sciences, and Mazovia Cluster ICT. Moreover, two years ago, the FedCSIS conference series formed strategic alliance with QED Software, a Polish software company developing AI-based products, and this collaboration has been continued.

FedCSIS 2023 was sponsored by QED Software, Samsung, Hewlett Packard Enterprise, Łukasiewicz Research Network – Institute of Innovative Technologies EMAG, MDPI, Sages, Efigo, and CloudFerro.

This year, another round of evolutionary adaptations, to the FedCSIS conference series, took place. Specifically, they concerned the conference structure. Post conference publications (Proceedings, Position Papers and Communication Papers volumes) illustrate the direction of this evolutionary process. In short, starting from 2023, FedCSIS conferences have Main Track with five Topical Areas, Thematic Tracks and, possibly, Competitions. The new structure emphasizes the integrity of the conference. For all five Topical Areas, situated within a general domain of Computer Science, the continually emerging topic of Intelligence Systems, stands as the common denominator. All Thematic Tracks refer to Intelligence Systems as well, from different perspectives. Even Competitions, having strong roots in the realm of AI, data science, machine learning, computer vision, and natural language processing, are regarded as a path toward introducing more Intelligence into Computer Science and IT.

In this context, these Proceedings consist of six parts. Part 1 contains Invited Contributions. Part 2 collects Main Track full contributions (arranged alphabetically, according to the last name of the first author, with Topical Area represented in the metadata). Part 3 contains Main Track short contributions. Part 4 contains full contributions, originating from Thematic Tracks. (Again, texts are arranged alphabetically, according to the last name of the first author, with the name of Thematic Track stated in the metadata.) Part 5 collects short papers from all Thematic Tracks. Finally, Part 6 is devoted to Competitions that run within the context of FedCSIS conferences.

Keeping this in mind, let us now introduce Keynote Speakers, the remaining Invited Contributions, and the five Topical Areas of FedCSIS 2023 Main Track.

I. INVITED CONTRIBUTIONS

FedCSIS 2023 invited four keynote lecturers to deliver lectures matching Topical Areas and thus providing a broader context for the conference participants. Moreover, two past FedCSIS keynote speakers have been invited to prepare contributions, which refer to the core focus of the conference series. There are also two contributions corresponding to the additional invited talks and three contributions corresponding to tutorials.

The aforementioned common denominator of all FedCSIS Topical Areas is clearly visible in this part. First, we can see here the core AI works on trustworthiness and robustness of neuro-symbolic and neural network models. Second, there are contributions related to the foundations of intelligent decision making and uncertainty modeling, using tools taken e.g. from soft computing and information theory. On the other hand, we have also contributions referring to machine learning and data science software, as well as examples of applications of AI methods in practical domains. This generally reflects our understanding of the place of Intelligence Systems in the realm of Computer Science. Namely, according to our vision, it is to develop and adjust the AI-related methods to let them work efficiently as the essential component of modern software systems and solutions.

II. ADVANCED ARTIFICIAL INTELLIGENCE IN APPLICATIONS

This Topical Area is a conceptual continuation of a series of international AAIA Symposiums, which have been held since 2006. It aims at covering wide range of core aspects of AI. Nowadays, AI is usually perceived as closely related to the data, therefore, the scope of this Topical Area includes elements of machine learning, data science, and big data processing, with important emerging aspects such as interactive learning and human-centered AI, as well as interpretable learning, explainable AI, and the aforementioned topic of trustworthiness. Furthermore, since the realm of AI is far richer, the ultimate goal of this Topical Area is to show relationships between all of AI subareas, emphasizing a cross-disciplinary nature of various research branches. In 2023, the collection of papers accepted to this Topical Area has reflected this cross-disciplinary nature particularly well. We can see here various areas of AI (also outside so-called “core AI”), as well as a mix of theoretical and practical contributions. From the perspective of the general scope of FedCSIS, this Topical Area embraces particularly AI methods and examples of their applications in different practical fields.

This Topical Area is curated by:

+ Corizzo, Roberto, American University, USA
+ Sosnowski, Łukasz, Systems Research Institute of Polish Academy of Sciences, Poland
+ Szczuka, Marcin, University of Warsaw, Poland
+ Zdravevski, Eftim, Ss. Cyril and Methodius University, Macedonia

III. Computer Science & Systems

This Topical Area aims at integrating and creating synergy between Computer Science and related disciplines, with AI being of the core interest. The area's scope spans themes ranging from hardware issues close to computer engineering via software issues tackled by the theory and applications of Computer Science. When compared to the previously-discussed Topical Area on "Advanced Artificial Intelligence in Applications", herein we are interested more in software system realizations and computational aspects. Therefore, we make a step from AI regarded as the set of methods towards Intelligence Systems understood as software systems with the elements of AI. As an example, the domains such as reinforcement learning or AI-based games and simulations are studied here not only from the perspective of the quality of obtained results but also taking into account their performance, resource consumption, and scalability.

This Topical Area is curated by:

+ Casalino, Gabriella, University of Bari "Aldo Moro", Italy
+ Ducange, Pietro, University of Pisa, Italy
+ Pawłowski, Wiesław, University of Gdańsk, Poland
+ Świechowski, Maciej, QED Software, Poland
+ Wasielewska-Michniewska, Katarzyna, Systems Research Institute of Polish Academy of Sciences, Poland

IV. Network Systems & Applications

Modern network systems encompass a wide range of solutions and technologies, including wireless and wired networks, network systems, services, and applications. On the one hand, network technologies are used in majority of areas that make human life easier and more comfortable. On the other hand, the rapid need for network deployment brings new challenges in network management and network design, which are reflected in hardware, software, services, and security-related problems. Going back to the main scope of FedCSIS, it is obvious that appropriate network solutions are one of the crucial layers of scalable modern software systems, including those with the elements of AI. On the other hand, equally obviously, AI methods can be useful to make network systems and their applications more efficient. Accordingly, the aim of this Topical Area is to bring more Intelligence into network systems. Moreover, besides network systems, one should think also about network models, network algorithms, etc. Therefore, this Topical Area covers not only the technological side, but also the societal and social impacts of network developments.

This Topical Area is curated by:

+ Armando, Alessandro, University of Genova, Italy
+ Awad, Ali Ismail, United Arab Emirates University, United Arab Emirates
+ Furtak, Janusz, Military University of Technology, Poland
+ Hodoň, Michal, University of Žilina, Slovakia
+ Suri, Niranjan, Institute of Human and Machine Cognition, United States

V. Information Technology for Business & Society

The aim this Topical Area is to integrate and create synergy between disciplines of IT, Intelligence Systems, and social sciences. Collected contributions address issues relevant to IT and necessary for practical, everyday needs of business, other organizations and society at large. Moreover, they take a socio-technical view on Intelligence Systems and, at the same time, relate to ethical, social and political issues that they raise. Thus, from the viewpoint of the FedCSIS as a whole, this Topical Area goes beyond Computer Science itself. It refers to the fact that every software system or solution, and especially a system or solution with some flavors of Intelligence, needs to be carefully deployed in real life. In other words, it is not only about machines – it is also about humans. Accordingly, this Topical Area embraces particularly research on methods and processes of adoption of AI and Intelligence Systems in society and particular markets of business applications. Going back to one of the aforementioned invited contributions, the means for trustworthiness can be regarded as an important tool in such processes too.

This Topical Area is curated by:

+ Cano, Alberto, Virginia Commonwealth University, Richmond, United States
+ Dias, Gonçalo, University of Aveiro, Portugal
+ Miller, Gloria, Maxmetrics, Germany
+ Naldi, Maurizio, LUMSA University, Italy
+ Wątróbski, Jarosław, University of Szczecin, Poland
+ Ziemba, Ewa, University of Economics in Katowice, Poland

VI. Software, System & Service Engineering

For decades, an open question in the software industry remains, how to provide fast and effective software process and software services, and how to come to software systems, embedded systems, autonomous systems, or cyber-physical systems that will address the open issue of supporting information management process in many, particularly complex organization systems. Even more, it is a hot issue how to provide a synergy between systems in common, and software services as a mandatory component of each modern organization, particularly in terms of IoT, big data, and Industry 4.0 paradigms. Therefore, the main goal of this Topical Area is to address open questions and real potentials for various applications of modern approaches and technologies to develop and implement effective software services in a support of information management and system engineering. We can see here a clear linkage to AI and Intelligence Systems as well. On the one hand (going back to one of invited talks reported in Invited Contributions), AI tools can be applied to improve the quality of software and to optimize the performance of computer systems. While on the other hand (going back again to one of the papers associated with the FedCSIS 2023 keynote lectures), AI-based models and algorithms need to be tested, maintained and monitored just like any other components of complex software systems.

This Topical Area is curated by:

+ Luković, Ivan, University of Belgrade, Serbia

- + Kolukısa Tarhan, Ayça, Hacettepe University, Turkey
- + Mernik, Marjan, University of Maribor, Slovenia
- + Popović, Aleksandar, University of Montenegro, Podgorica, Montenegro

VII. Zdzisław Pawlak Awards

The above-described five Topical Areas of FedCSIS Main Track reflect five fundamental aspects of understanding, developing, and applying Intelligence Systems. This topical integrity is emphasized by the Professor Zdzisław Pawlak award, considered in four categories: Best Paper, Young Researcher, Industry Cooperation, and International Cooperation. Over time, this award has gone through significant evolution together with the FedCSIS conference series. Originally, it was granted only to papers published within the series of AAIA Symposiums. However, although Professor Zdzisław Pawlak has been often recognized as "the father of Polish AI", his research achievements have gone far beyond AI itself, in particular, toward AI applications and Intelligence Systems as we mean them. Accordingly, over time, we decided to expand this award to the whole conference – not only all Main Track Topical Areas but also all Thematic Tracks.

This year, Award Committee (a part of FedCSIS Senior Program Committee) had a particularly hard task to select a single winner of Best Paper Award. Therefore, after discussion, additional paper was distinguished with Distinction Award. The following contributions have been awarded:

- In the category **Best Paper:** Julian Premm, Hagen Peukert, Dennis Rössel, Mareike Silber, for the paper „Analysis of a GPT-3 chatbot with respect to its input in a sales dialogue"
- Additional **Distinction Award:** Giovanna Castellano, Pasquale De Marinis, Gennaro Vessio, for the paper „Applying Knowledge Distillation to Improve Weed Mapping With Drones"
- In the category **Young Researcher:** Anastasiya Danilenka, for the paper „Mitigating the effects of non-IID data in federated learning with a self-adversarial balancing method"
- In the category **Industry Cooperation:** Mikołaj Pudo, Mateusz Wosik, Artur Janicki, for the paper „Open Vocabulary Keyword Spotting with Small-Footprint ASR-based Architecture and Language Models"
- In the category **International Cooperation Award:** Samaneh Mohammadi, Mohammadreza Mohammadi, Sima Sinaei, Ehsan Nowroozi, Francesco Flammini, Mauro Conti, for the paper „Balancing Privacy and Accuracy in Federated Learning for Speech Emotion Recognition"

Industry Cooperation Award was sponsored by QED Software, International Cooperation Award – by MDPI, while the remaining awards were sponsored by Mazovia Branch of Polish Information Processing Society.

Here, it is also worth noting that each of those five papers comes from a different Topical Area or Thematic Track. Yet, they are all aligned with what we described before as the FedCSIS common denominator.

VIII. Statistics

Each contribution, found in this volume, was refereed by at least two referees and the acceptance rate of regular full papers was approximately 19% (68 accepted contributions, out of 358 general submissions).

IX. Committees

The Senior Program Committee of FedCSIS 2023 consisted of:

- van der Aalst, Wil, RWTH Aachen University, Germany
- Alba, Enrique, University of Málaga, Spain
- Aiello, Marco, University of Stuttgart, Germany
- Armando, Alessandro, University of Genova, Italy
- Atiquzzaman, Mohammed, University of Oklahoma, Norman, USA
- Awad, Ali Ismail, United Arab Emirates University, United Arab Emirates
- Blum, Christian, Artificial Intelligence Research Institute (IIIA-CSIC), Spain
- Bosch, Jan, Chalmers University of Technology, Sweden
- Boustras, George, European University, Cyprus
- Bryant, Barrett, University of North Texas, USA
- Buyya, Rajkumar, University of Melbourne, Australia
- Cano, Alberto, Virginia Commonwealth University, United States
- Casalino, Gabriella, University of Bari "Aldo Moro", Italy
- Corizzo, Roberto, American University, USA
- Cornelis, Chris, Ghent University, Belgium
- Dias, Gonçalo, University of Aveiro, Portugal
- Djidjev, Hristo, Los Alamos National Laboratory, USA and Institute of Information and Communication Technologies, Bulgaria
- Ducange, Pietro, University of Pisa, Italy
- Duch, Włodzisław, Nicolaus Copernicus University, Poland
- Fill, Hans-George, University of Fribourg, Switzerland
- Fred, Ana, Instituto Superior Técnico (IST—Technical University of Lisbon), Portugal
- Furtak, Janusz, Military University of Technology, Poland
- Giancarlo Guizzardi, Free University of Bolzano-Bozen, Italy
- Herrera, Francisco, University of Granada, Spain
- Hinchey, Mike, Lero, University of Limerick, Ireland
- Hodoň, Michal, University of Žilina, Slovakia
- Kacprzyk, Janusz, Systems Research Institute, Polish Academy of Sciences, Poland
- King, Irwin, The Chinese University of Hong Kong, China
- Kolukısa Tarhan, Ayça, Hacettepe University, Turkey
- Komorowski, Jan, Uppsala University, Sweden
- Kwaśnicka, Halina, Wrocław University of Science and Technology, Poland
- Luck, Michael, King's College London, United Kingdom
- Luković, Ivan, University of Belgrade, Serbia

- Matwin, Stan, Dalhousie University, University of Ottawa, Canada and Institute of Computer Science, Polish Academy of Science, Poland
- Mernik, Marjan, University of Maribor, Slovenia
- Michalewicz, Zbigniew, University of Adelaide, Australia
- Miller, Gloria, maxmetrics, Germany
- Naldi, Maurizio, LUMSA University, Italy
- Pawłowski, Wiesław, University of Gdańsk and Systems Research Institute, Polish Academy of Sciences, Poland
- Pedrycz, Witold, University of Alberta, Canada
- Popović, Aleksandar, University of Montenegro, Montenegro
- Raś, Zbigniew, University of North Carolina, United States
- Segal, Michael, Ben-Gurion University of the Negev, Israel
- Skowron, Andrzej, Systems Research Institute, Polish Academy of Sciences, Poland
- Słowiński, Roman, Poznań University of Technology, Poland
- Sosnowski, Łukasz, Systems Research Institute, Polish Academy of Sciences, Poland
- Sowa, John F., VivoMind Research, LLC, USA
- Spanoudakis George, University of London, United Kingdom
- Suri, Niranjan, Institute of Human and Machine Cognition, United States
- Świechowski, Maciej, QED Software, Poland
- Szczuka, Marcin, University of Warsaw, Poland
- Wasielewska-Michniewska, Katarzyna, Systems Research Institute, Polish Academy of Sciences, Poland
- Wątróbski, Jarosław, University of Szczecin, Poland
- Zdravevski, Eftim, Ss. Cyril and Methodius University, Macedonia
- Ziemba, Ewa, University of Econmics in Katowice, Poland

The FedCSIS 2023 Program Committee consisted of:

- Abramowicz, Witold, Poznań University of Economics and Business, Poland
- Ahad, Mohd Abdul, Jamia Hamdard, India
- Ahmad, Muhammad Ovais, Karlstad University, Sweden
- Al-Naday, Mays, University of Essex, United Kingdom
- Almeida, Luis, University of Porto, Portugal
- Alshayeb, Mohammad, King Fahd University of Petroleum & Minerals, Saudi Arabia
- Anastassi, Zacharias, ASPETE School of Pedagogical and Technological Education, Greece
- Andres, Frederic, National Institute of Informatics, Japan
- Aneta Poniszewska-Maranda, Lodz University of Technology, Poland
- Arabas, Jaroslaw, Warsaw University of Technology, Poland
- Arruda Filho, Emílio José, University FUMEC, Brasil
- Atanassov, Krassimir T., Bulgarian Academy of Sciences, Bulgaria
- Atasever, Mesut, Uşak University, Turkey
- Azad, Mohammad, Jouf University, Saudi Arabia
- Aziz, Shariq, University of Lahore, Pakistan
- Babur, Önder, Wageningen University & Research, the Netherlands
- Bacco, Manlio, Institute of Information Science and Technologies, National Research Council, Italy
- Bachan, Jolanta, Adam Mickiewicz University, Poland
- Badica, Amelia, University of Craiova, Romania
- Badica, Costin, University of Craiova, Romania
- Bajdor, Paula, Czestochowa University of Technology, Poland
- Balazs, Krisztian, Budapest University of Technology and Economics, Hungary
- Baldán Lozano, Francisco Javier, University of Granada, Spain
- Ballas, Rüdiger G., Mobile University of Technology, Germany
- Banach, Richard, University of Manchester, United Kingdom
- Banaszak, Zbigniew, Warsaw University of Technology, Poland
- Barisic, Ankica, Université Côte d'Azur, France
- Barreiro, Anabela, Universidade de Lisboa, Portugal
- Bartosz Walter, Poznań University of Technology, Poland
- Bauer, Markus, InfAI, Germany
- Belciug, Smaranda, University of Craiova, Romania
- Bellinger, Colin, National Research Council of Canada, Canada
- Ben-Assuli, Ofir, Ono Academic College, Israel
- Białas, Andrzej, Institute of Innovative Technologies EMAG, Poland

X. Acknowledgments

In conclusion, let us emphasize that delivery of FedCSIS 2023 required a dedicated effort of many people. We would like to express our warmest gratitude to all Topical Area Curators, to the members of the Senior Program Committee and to the members of the Program Committee, for their hard work in attracting and reviewing all submissions. We thank the authors of papers for their great contribution to the theory and practice of Computer Science and Intelligence Systems. We are grateful to Keynote, Invited, and Tutorial Speakers, for sharing their knowledge and wisdom with the participants. Last, but not least, we acknowledge one more time Jarosław Arabas, Sławomir Zadrożny, and Przemysław Biecek. We are very grateful for your efforts!

We hope that you all had an inspiring conference. We also hope to meet you again for the 19th Conference on Computer Science and Intelligence Systems (FedCSIS 2024) which will take place in Belgrade, Serbia on September 8-11, 2024. Finally, we hope that you will find the evolution of the FedCSIS Conference concept as something that properly addresses the current needs of research and applications. We want to continue looking at Computer Science from different angles but in the same time, acknowledging the topic Intelligence Systems as the central point of everything that we are considering.

Co-Chairs of the FedCSIS Conference Series:

Maria Ganzha, *Warsaw University of Technology, and Systems Research Institute Polish Academy of Sciences, Poland*
Leszek Maciaszek (Honorary Chair), *Macquarie University, Australia and Wrocław University of Economics, Poland*
Marcin Paprzycki, *Systems Research Institute Polish Academy of Sciences, and Warsaw University of Management, Poland*
Dominik Ślęzak, *University of Warsaw, Poland and QED Software, Poland and DeepSeas, USA*

***Abstract*—*Neuro-symbolic* integration of symbolic and subsymbolic techniques represents a fast-growing AI trend aimed at mitigating the issues of neural networks in terms of decision processes, reasoning, and interpretability. Several state-of-the-art neuro-symbolic approaches aim at improving performance, most of them focusing on proving their effectiveness in terms of raw predictive performance and/or reasoning capabilities. Meanwhile, few efforts have been devoted to increasing model trustworthiness, interpretability, and efficiency—mostly due to the complexity of measuring effectively improvements in terms of trustworthiness and interpretability. This is why here we analyse and discuss the need for ad-hoc *trustworthiness metrics* for neuro-symbolic techniques. We focus on two popular paradigms mixing subsymbolic computation and symbolic knowledge, namely: *(i) symbolic knowledge extraction* (SKE), aimed at mapping subsymbolic models into human-interpretable knowledge bases; and *(ii) symbolic knowledge injection* (SKI), aimed at forcing subsymbolic models to adhere to a given symbolic knowledge. We first emphasise the need for assessing neuro-symbolic approaches from a trustworthiness perspective, highlighting the research challenges linked with this evaluation and the need for ad-hoc trust definitions. Then we summarise recent developments in SKE and SKI metrics focusing specifically on several trustworthiness pillars such as interpretability, efficiency, and robustness of neuro-symbolic methods. Finally, we highlight open research opportunities towards reliable and flexible trustworthiness metrics for neuro-symbolic integration.**

I. Introduction

A GROWING number of critical applications are being developed that rely on artificial intelligence (AI) solutions—mostly, on machine and deep learning (ML, DL), more specifically. In this realm, the most popular trend is by far the engineering of intelligent computational systems where hard-to-code tasks are automatically learned from data—promoting a data-driven problem-solving approach. Tasks that can be learned this way range from image [1], [2] to text processing [3], [4], stepping through graph learning [5], [6], [7] and time series forecasting [8], [9], among the many others. The popularity of (semi-)autonomous AI systems largely depends on their ability of outperforming humans in some specific tasks. Yet, AI agents – and especially ML agents – cannot be really trusted by humans, for the obscurity of their data processing and decision making pipeline, and for their limited interaction with human users as well. In the recent past, this lack of trustworthiness jumped to the news due to some AI systems' behaviour harming humans—such as chatbots suggesting deleterious practice[1] and facial-recognition technology recognising innocents as criminals.[2] Therefore, the need to assess the level of trustworthiness of AI system before its deployment it is nowadays apparent to all parties involved in the development of AI solutions. Targeting this need, the European Union (EU) has recently released the Ethics Guidelines for Trustworthy AI[3] as a part of its AI strategy.

While representing a fundamental stepping stone in the definition of AI trustworthiness, these ethics guidelines apparently focus on popular ML agents solutions in their definition process. Indeed, most trust requirements are clearly linked with the black-box nature of ML and DL solutions—such as the need for transparency, explanations, human interaction, and many others. However, AI is not just ML/DL, so AI systems are much more than ML/DL systems. Recent research efforts have focused on novel AI paradigms aiming at blending the subsymbolic perspective of ML and DL agents with symbolic AI solutions focusing on high-level symbolic (human-readable) representations of problems, logic, and search: this is where *neuro-symbolic integration systems* (NeSy) stand today. NeSy integrate neural (subsymbolic) and symbolic AI solutions aiming at suitably complementing their strengths and weaknesses, introducing reasoning and cognitive capabilities (the symbolic way) while preserving fast-learning capabilities (the subsymbolic way). The range of NeSy approaches is vastly distant from the AI systems accounted for in the definition of EU trustworthiness pillars, as they leverage symbolic (human-comprehensible) solutions which are in principle trustworthy by design. Therefore, NeSy introduces a further level of complexity in the definition of their trustworthiness value, given by the complex interaction between symbolic and subsymbolic elements. The result is the current lack of suitable definitions of the notion of trustworthiness in terms of NeSy systems.

This is why in this paper we deal with the definition of trustworthiness for NeSy systems, focusing specifically on two broad NeSy categories, namely:

[1] https://edition.cnn.com/2023/06/01/tech/eating-disorder-chatbot/

[2] https://www.nytimes.com/2020/12/29/technology/facial-recognition-misidentify-jail.html

[3] https://digital-strategy.ec.europa.eu/en/library/ethics-guidelines-trustworthy-ai

- *symbolic knowledge injection* (SKI) models—that is, systems featuring symbolic knowledge that can be explicitly provided so that subsymbolic predictions are either computed as a function of it, or made consistent with it;
- *symbolic knowledge extraction (SKE)* models, represented by the set of approaches accepting subsymbolic predictors as input and producing symbolic knowledge as output; the aim for the SKE system is to extract symbolic knowledge reflecting the behaviour of the predictor with high fidelity.

The definition of requirements for trustworthy NeSy systems represents a fundamental step towards their safe adoption. However, requirements definition by itself can not be considered as an exhaustive measure to ensure and calibrate the trustworthiness of NeSy systems. Instead, it is of utmost significance to define NeSy *trustworthiness metrics* that allow to actually measure the level of a system trust, possibly enabling an in-depth analysis of the components raising trust concerns. Whereas a few trustworthiness metrics definition already exist, tackling specific components of NeSy models – such as accuracy, robustness and efficiency –, the vast majority of NeSy most relevant aspects are still unexplored.

This is why in this paper we:

- define how the AI trustworthiness requirements translate to the NeSy realm, analysing in detail each pillar of trust and its implication on NeSy models.
- analyse the available metrics for each of the novel NeSy trust requirements as well as the potential future directions to explore in the analysis of NeSy trust;
- suggest some novel metrics to measure specific NeSy elements, focussing on SKI and SKE as two well-defined broad categories of NeSy models.

This article is organised as follows. Section II presents the transition from trustworthy AI requirements to their corresponding NeSy trust pillars, analysing in depth how NeSy elements impact each requirement. Section III showcases the need for defining trust metrics – rather than requirements – and analyses the complexity of that definition, the reason behind it, and how we propose to tackle it. We then introduce the relevant concepts of SKI and SKE needed to design trust metrics in Section IV, and propose a detailed analysis of available and lacking metrics in Section V. Finally, we conclude and present the future directions in Section VI.

II. From Trustworthy AI to Trustworthy NeSy

As a fundamental step of its AI strategy, the European Union (EU) has defined seven key trustworthiness criteria to meet during the development, deployment, and use of AI systems, namely: *(i) human agency and oversight*, as the need for oversight mechanisms enabling the informed interaction between the AI agent(s) and the human(s) counterpart; *(ii) robustness and safety*, as the need for accuracy, reliability, resilience and security of AI agent(s); *(iii) privacy and data governance*, as the need for ensuring legitimised access to data, while taking into account data quality and integrity; *(iv) transparency*, as the need for providing human users with explanations of the AI agent(s)'s decision process; *(v) diversity, non-discrimination and fairness*, as the need for avoiding unfair bias while enable everyone's access to AI technology; *(vi) environmental and societal well-being*, as the need for sustainability of AI agent(s) and the transition to their environmentally friendly development; *(vii) accountability*, as the need for mechanisms that ensure responsibility and accountability for the behaviour and outcomes of AI systems. The above requirements define a broad umbrella of concepts and means to identify relevant components in the deployment of AI systems and ensure their trustworthiness. However, being designed to be general enough to be applicable to any – or at least as most as possible – AI systems, they are actually too general to be used to define actual metrics to effectively measure every sort of AI systems. Therefore, to make them actually working, a more detailed specification of trustworthiness requirements is needed: in particular, the general EU pillars should be *translated* into domain-specific pillars, promoting the definition of trustworthiness metrics for each specific AI domain. Such a translation should also account for the current bias of EU trustworthiness pillars towards subsymbolic AI systems—where, for instance, the black-box nature of all components is given as understood when dealing with issues such as transparency, explainability, human interaction, even though it mostly concerns subsymbolic components only.

Thus, in the remainder of this paper we define the pillars of trustworthiness for AI systems based on Neuro-Symbolic (NeSy) integration. We analyse the seven EU-defined trustworthiness criteria for AI, and translate each of them into its NeSy counterpart, leveraging on the aspects of NeSy that promote fairness and explainability by design. On the other hand, leveraging both symbolic and subsymbolic paradigms, NeSy systems may be affected by robustness, safety, and bias issues from both sides – i.e., symbolic and subsymbolic –, hindering their overall trustworthiness. Therefore, a fundamental issue in the NeSy context is to identify whether and to what extent the blending of symbolic and subsymbolic techniques can either help or hinder trustworthiness, in particular in the perspective of the definition of ad-hoc trustworthiness metrics.

a) Human agency and oversight: in its original formulation this requirement stresses the need for the introduction of oversight mechanisms enabling informed interaction between AI agents and humans counterparts. The underlying assumption here is that humans can not understand AI system at all – or, can understand interaction with AI systems in a very limited way – so AI systems can never be considered as trustworthy, as human agents are incapable to fix the AI system when issues arise. When taking into account NeSy mechanisms, the symbolic and subsymbolic fusion component clearly affects the interaction with with its human counterpart. Instead, the symbolic component could represent the enabling agent for meaningful interaction between human and the system, promoting human-in-the-loop, human-on-the-loop, and human-in-command approaches.

> NeSy version
>
> The need for assessing to what extent the symbolic and subsymbolic *interaction* of NeSy components helps *improving* informed human-AI interaction and human oversight.

b) Technical robustness and safety: in its original formulation this requirement stresses the need for accuracy, reliability, resilience, and security of AI agents. Indeed, an inaccurate or unstable AI agent can not be considered trustworthy, as its behaviour may fluctuate radically throughout its life cycle. Let us consider for instance adversarial examples [10], [11], where slight perturbations of the input fed to the AI system result in radically different outcomes: AI system of that sort are inherently unreliable—thus untrustworthy. Even though this has motivated some research efforts focused on the identification of robustness issues of ML/DL systems, very small light has been shed on the robustness and safety issues of NeSy systems. NeSy agents rely on both symbolic and subsymbolic components, the former being – with some exception – verifiable and stable by design while the latter lacks of stability, verifiability or strong mathematical modeling of their behaviour and properties. The interaction of such elements introduce non-trivial behaviour in NeSy systems, where the symbolic components can be used as a helping tool for stabilising subsymbolic elements or the subsymbolic tools can be used to produce imperfect – thus unreliable – symbolic knowledge. Therefore, we consider relevant studying to what extent the verifiability of symbolic components alters during the integration process, and how the (in)stability of the subsymbolic element is impacted by the symbolic knowledge.

> NeSy version
>
> The need for assessing the impact of both symbolic (verifiable) and subsymbolic (not verifiable) *interaction* on the *stability* of the NeSy system.

c) Privacy and data governance: in its original formulation this requirement stresses the need for legitimate access to data, while taking into account data quality and integrity. This requirement identifies the untrustworthy nature of systems optimised over unreliable data, and promotes the introduction of open data for testing AI systems and their behaviour. To this end, NeSy systems differ quite heavily from their pure subsymbolic AI counterparts, as they – in most cases – require the processing of symbolic knowledge and data at the same time. Therefore, it is relevant to notice that data quality issues extend to knowledge quality issues when considering NeSy systems—even though symbolic knowledge is typically managed explicitly by AI programmers and is often verifiable in automatic way.

> NeSy version
>
> The need for ensuring the *quality* of both *data* and *symbolic knowledge* of a NeSy system, along with its accessibility.

d) Transparency: in its original formulation this requirement stresses the need for producing explanations of the AI agents' decision processes, deeming as untrustworthy those AI systems for which it is complex or unfeasible to obtain an explanation of its decision process. The definition of an AI system transparency depends on the complexity of the process of obtaining explanations, and their understandability. Indeed, in most AI scenarios multiple explanations can be drawn to render transparent the system at hand, depending on the level of detail needed and the process used. While being conceptually similar, the transparency level of NeSy systems – with respect to their pure subsymbolic AI counterparts – may differ a lot in terms of extraction complexity and understandability. Indeed, most NeSy systems represent a more transparent solution by design, as they leverage symbolic components, inputs or outputs, which are – to some extent – intrinsically understandable by humans. Therefore, we consider relevant to assess if – and to what extent – the integration components of NeSy systems impacts the transparency of the obtained agent(s).

> NeSy version
>
> The need for assessing the *gain* in terms of *transparency* obtained by a NeSy system with respect to its pure subsymbolic components.

e) Diversity, non-discrimination, and fairness: in its original formulation this requirement stresses the need for avoiding unfair bias and enable everyone's access to the AI technology. Indeed, biased AI technologies must not be deployed as they have been proven to increase the chance of harmful events against human agents. Given the relevance of fairness, several efforts have been put in place to investigate the nature of AI mechanisms' bias. However, biases of pure subsymbolic models and their NeSy counterparts differ conceptually in terms of their root causes: bias can rise in NeSy models as the consequence of any unexpected behaviour of their subsymbolic components, or their interaction with their symbolic elements. Indeed, similarly to what done for NeSy robustness, here it is relevant to highlight that the bias and fairness of symbolic components represent a verifiable and provable variable, while its interaction with subsymbolic elements does not, as it is not possible to define a-priori how the subsymbolic interaction impact the overall system behaviour. Therefore, it is fundamental for NeSy systems to consider possible biases rooted in each step of the fusion between symbolic and subsymbolic components. This is also valid for possible bias benefits that can be obtained from the interaction between symbolic and subsymbolic components in NeSy, as the symbolic elements can be used to tune the subsymbolic components to avoid biases that may arise during their optimisation.

NeSy version

The need for *measuring* biased and discriminative behaviour of NeSy agents rooted in the *interaction* between their symbolic and subsymbolic components.

f) Environmental and societal well-being: in its original formulation this requirement stresses the need for sustainability of AI agents and the transition to their environmentally friendly development, deeming as untrustworthy those AI agents that do not benefit all human beings, including future generations. While measuring the impact of pure subsymbolic AI agents on the environment has been the focus of several works in the AI community, the in-depth analysis of how NeSy mechanism can help reducing the environmental impact of AI. The symbolic component of several NeSy mechanism can be leveraged as a helping tool for reducing the amount of resources required for the optimisation of its subsymbolic component. Moreover, it is also possible for some NeSy mechanism to leverage symbolic approaches to achieve comparable performance – w.r.t. pure subsymbolic AI agent – while requiring a smaller memory footprint—resulting in smaller latency and energy consumption. On the other hand, the complex interaction between symbolic and subsymbolic components may introduce an overhead in the NeSy system, causing the waste of resources and thus decreasing the efficiency of the agent. Therefore, it is necessary to define a novel resource efficiency requirement for NeSy agents.

NeSy version

The need for assessing the *gain* in terms of *sustainability* of NeSy systems with respect to their pure subsymbolic components.

g) Accountability: in its original formulation this requirement stresses the need for mechanisms that ensure responsibility and accountability for AI systems and their outcomes. At its core, accountability can be defined as an obligation to inform about, and justify the AI's conduct [12]. Therefore, the fundamental property for AI's accountability is represented by *answerability*, which is the property of an AI system to allow for *interrogation* concerning a decision process. Accountability is closely tight to transparency, as it requires for an AI system to produce justification – a.k.a. explanations – for its actions. Therefore, a similar analysis to the one done for transparency applies to this context, where we stress the relevance of analysing the accountability gains obtained through symbolic and subsymbolic integration in NeSy systems over ML/DL counterparts.

NeSy version

The need for assessing the *gain* in terms of *answerability* obtained by a NeSy system with respect to its pure subsymbolic components.

III. On the Relevance of Trustworthiness Metrics

The trustworthy requirements proposed for both general AI systems and NeSy agents represent a general umbrella of concepts that should be covered in the system at hand. Indeed, none of the requirements defined so far give a specific characterisation of a target level – e.g., target fairness – for that requirement to be considered satisfied. Such general characterisation of trustworthiness is mainly caused by two contributing factors, namely

- *High variability characterising AI systems.* AI agents optimised to solve different tasks are expected to differ largely in terms of inner working principles. Therefore, identifying a common trustworthiness definition with the due level of detail represents a complex task
- *Conceptual complexity of trustworthiness building blocks.* Trustworthiness is defined as a collection of diverse features of a systems to be achieved for it to be worthy of humans' trust. However, some – if not most – of the trustworthiness sub-components are not easy-to-grasp concepts in their definition. For example, taking into account bias, we immediately understand that bias must be one of the sub-components required to achieve trustworthiness. However, the definition of bias by itself represents a complex task that have bogged researchers with troublesome questions like what is bias?, when is a system biased?, what is the minimum amount of bias for a system to be considered as such?. Being complex in their definition, these building blocks are also complex to measure effectively, hindering the overall level of trust measurement.

The issues connected with the general characterisation of AI trustworthiness hinder the applicability of such trustworthiness requirements. Indeed, while representing a valid starting point for analysing AI trustworthiness, these requirements do not fully allow to comprehensively grasp the extent of a system's trustworthiness. To this end, the definition of trustworthiness metrics – rather than requirements or pillars – represents an open issue of the utmost importance. Trustworthiness metrics make it possible to evaluate the extent of a system trust, allowing for a more detailed classification of the AI components to be deployed and the ones to block. However, the definition of a single general, flexible, and ubiquitous trustworthiness metric is made almost impossible by the same issues that affect the generality of trustworthiness requirements. Therefore, we here consider to translate the trustworthiness requirements into a set of equivalent trustworthiness metrics, taking into account the *high variability characterising AI systems* and the *conceptual complexity of trustworthiness building blocks*.

We first consider the issue connected with the *high variability characterising AI systems*. To enable the definition of rigorous trustworthy metrics, we here propose to consider the transition from the general AI trustworthy requirements to the corresponding pillars for each AI branch. Section II presents a similar transition from trustworthy AI into trustworthy NeSy. A similar transition can be identified for each and every AI domain, obtaining domain-specific detailed trustworthiness requirements. This step enables a stricter definition of trustworthiness for each AI domain, making it possible to focus more specifically on the peculiar approaches, components, and aspects that characterise the domain under analysis.

To tackle the *conceptual complexity of trustworthiness building blocks*, we here propose to avoid focusing on the proposal of single, overly-complex trustworthy metrics with the aim of obtaining a general formulation applicable to any AI system. Rather, we suggest to tackle the measurement of systems' trustworthiness through the adoption of a broad set of highly-specialised metrics that analyse single components of the trustworthiness definition. In this context, we consider proposing a single metric or a set of metrics for each pillar/requirement of trustworthiness. The proposed metrics should focus on a specific issue or feature of the AI system at hand – such as its robustness to specific input perturbation, or the bias towards a specific group –, producing as output a single numeric value, describing its safety level—i.e., how much that issue is alarming for the system. Highly-specialised metrics can then be arbitrarily combined to obtain a dynamic trustworthiness score, depending on the trustworthiness components that are to be considered more relevant for the scenario under examination. This simplified process allows not just the easier definition of each set of trustworthiness metric – e.g., bias metrics, robustness metrics, etc. –, but also the evaluation of set based on a given relevance. Consider for example a scenario where the bias requirement should be considered as more relevant w.r.t. the human oversight requirement. Our approach allows a higher weight to be assigned to the bias metrics before its combination with the human oversight metrics to obtain the general trustworthy measurement. Therefore, we here propose to tackle the trustworthiness measurement issue by adopting a dynamic broad set of highly specific metrics that can be combined depending on the given measurement requirements.

IV. Background on SKI and SKE

In this section we provide an overview of the two NeSy mechanisms we focus on, namely Symbolic Knowledge Injection (Section IV-A) and Symbolic Knowledge Extraction (Section IV-B).

A. Symbolic Knowledge Injection (SKI)

Symbolic Knowledge Injection (SKI) defines the set of NeSy systems characterised by explicit procedures aiming at affecting how subsymbolic components draw their inferences for them to be made consistent with some given symbolic knowledge. In their definition, SKI mechanisms require having a subsymbolic predictor – a.k.a. model – and a given symbolic knowledge which always hold true for the considered context. The given symbolic knowledge should consist of logic formulæexpressed in any logic language of choice. In their scope, SKI mechanisms are designed to either *(i)* leverage the given input symbolic knowledge to enrich the training of the subsymbolic predictor; *(ii)* process the given symbolic knowledge via subsymbolic computations to achieve a novel, more meaningful symbolic knowledge; *(iii)* combine both of the previous processes. To achieve any of these scopes, SKI requires the given symbolic knowledge to be converted into a specific numeric form processable by the subsymbolic potion of the NeSy mechanism, to enable the injection process. More in detail, the converted symbolic knowledge is leveraged by the SKI approach to steer the learning process of the underlying subsymbolic model in any of the following way: *(i)* penalising the subsymbolic component during its training, whenever it violates the given symbolic knowledge, usually through defining a custom-made hybrid loss function; *(ii)* construct (a portion of) the subsymbolic component in such a way to make it reflect the given symbolic knowledge; *(iii)* convert the given symbolic knowledge into numeric-array form to be used as training data for the subsymbolic components of the NeSy system. In other words, SKI can be seen as the proces of optimising subsymbolic predictors in such a way that they are helped by the given symbolical knowledge.

B. Symbolic Knowledge Extraction (SKE)

Symbolic Knowledge Extraction (SKE) represents the set of NeSy approaches accepting subsymbolic predictors as input and producing symbolic knowledge as output. More in detail, SKE mechanisms aim at distilling the knowledge that a subsymbolic predictor has grasped from data into symbolic form, expressed by a set of logic formulæ. SKE enables the construction of a symbolic surrogate model that mimics the behaviour of a subsymbolic component. The obtained symbolic rules may then be exploited to either *(i)* understand and explain the behaviour of the original predictor; or *(ii)* replace subsymbolic components of the system while retaining its learning capabilities; To achieve symbolic knowledge construction, SKE can either *(i)* inspect (even partially) the parameters of the subsymbolic component – i.e., decompositional approaches –; or *(ii)* rely solely on the subsymbolic component's outputs—i.e., pedagogical approaches. Depending on the SKE approach the obtained symbolic knowledge can be under the form of lists of rules, decision trees or decision tables, each of them composed by any statement structure, such as propositional rules, fuzzy rules or any other kind of logic formulæ. In other words, SKE can be seen as the process of optimising symbolic AI components in such a way that their behaviour mimics given subsymbolic components.

V. NeSy Metrics for Trustworthiness

In this section we present the trustworthiness metrics (both available and missing ones) for NeSy systems, specifically focusing on SKI and SKE. We analyse each of the seven trustworthiness pillars/requirements separately to obtain a thorough representation of the state-of-the-art and future directions.

A. Human Oversight

NeSy version of human oversight requirement is defined as the need for assessing to what extent the symbolic and subsymbolic *interaction* of NeSy components helps *improving* informed human-AI interaction and human oversight.

1) Available Metrics: Most approaches to measure human oversight in AI scenarios focus on aspects of human-AI interaction, where explanation of behaviours represents the most important component of the interaction process. As a results, much attention has been paid to the measurement of how explanations could guide people to respond to and predict the AI system behaviour [13]. A large number of studies exist in this realm, which mainly leverage on users to subjectively rate system predictability, likability, etc.[14] While useful in order to define systems predictability, these studies lack the assessment of human influence and control on the AI system at hand. The reason for this is to be found mainly on the black-box and data-driven nature of subsymbolic models that these works take into account. Indeed, most – if not all – subsymbolic models allow for limited control by the human users, given mostly by the data gathering and selection process.

2) Missing Metrics: Unlike pure subsymbolic systems, NeSy models intrinsically enable higher level of human oversight via the integration of symbolic knowledge. However, the extent of such oversight capabilities should be studied in depth through the proposal of ad-hoc metrics that measure how much the behaviour of a NeSy system can be controlled by a human user. To this aim, in the SKI context, we consider proposing a novel metric assessing the impact of the injection process to the underlying model. The impact can be measured as the amount of injected knowledge that is effectively absorbed by the underlying model. The metric would assess the level of available human oversight in SKI systems, allowing for a precise definition of the extent of human control. Meanwhile, the SKE context emphasises the need for measuring the modifiability of the extracted symbolic knowledge from an initial subsymbolic predictor. Indeed, SKE approaches by themselves do not allow for an in-depth control of the model behaviour, but rather enable their inspection. In this context, a desirable solution is represented by refining the extracted knowledge and using it as input for a SKI system acting upon the same subsymbolic model. This process would enable a sort of debugging loop of NeSy systems leveraging both SKE and SKI, with an increased potential for human oversight. Here, we require the definition of an ad-hoc metric capable of assessing the portion of symbolic knowledge that can be extracted, refined and injected back in the system with it being correctly assimilated by the model.

B. Robustness

NeSy version of the robustness requirement is defined as the need for assessing the impact of symbolic (verifiable) and subsymbolic (not verifiable) *interaction* on the *stability* of the NeSy system.

1) Available Metrics: The state-of-the-art picture of NeSy robustness emphasises the lack of a common agreement on the definition of robustness itself, thus leading to diverging works focusing on opposite aspects of NeSy systems. Indeed, in this context, several works focus on highlighting the robustness of NeSy models in terms of their performance over complex or out-of-distribution inputs [15], [16], [17]. Although relevant for pointing out the potential of NeSy approaches, these works propose somehow misleading definitions of robustness, mostly focusing on NeSy flexibility rather than its stability. NeSy systems may perform well on complex and out-of-distribution samples, while suffering instability on small input perturbations—causing robustness collapse. Several other concepts have been taken into account when considering NeSy robustness such as prediction coherence and consistency [18], subsymbolic verification through neuro-symbolic integration [19], avoidance of reasoning shortcuts [20] and many more. However, the majority of these approaches not only assess an ad-hoc concept of robustness, but also focus on its qualitative evaluation thus failing to assess the quantitative aspect required to achieve robustness metrics.

While it is true that there exists some confusion concerning the definition of NeSy robustness, there are few relevant works aiming at defining precise robustness metrics. More in detail, Yang et al. [21] present a novel learning approach for neuro-symbolic programs, showing its robustness against input perturbations in terms of provably safe portion of the learned model. In this context, NeSy robustness against adversarial attacks represents a popular area of research with several works aiming at proving either qualitatively [22] or quantitatively [23] the safety of NeSy approaches. Most of these works define robustness in terms of accuracy degradation over varying input perturbation intensity, independently of the input perturbation type and magnitude.

2) Missing Metrics: As a result of the mixed focus given to NeSy aspects when tackling robustness, several aspect of NeSy robustness and stability have not been thoroughly analysed, yet. Indeed, there exists the need to study if – and to what extent – the stability and verifiability of symbolic AI components is preserved throughout the integration process in NeSy models. In this context, focusing on the SKI realm, we suggest that a measure of integration stability – as the portion of symbolic elements that are correctly integrated in the injected model – is needed here. Such a metric would basically represent the portion of symbolic control that a NeSy system can attain during its integration step. Secondly, also those scenarios where the symbolic elements of NeSy models suffer from some sort of imperfection have to be taken into account. Here, it is important to measure the stability of SKI models when the injected knowledge is altered as a result of some imperfect automation process. Finally, it is also relevant to measure the stability of NeSy systems over symbolic representation variability, to assess how different symbolic representations – e.g., logic formulæ, knowledge graphs, etc. – may impact the integration process. To this end, we propose to measure the performance of SKI integration when two syntactically different yet equivalent chunks of symbolic knowledge are exploited in the same integration process.

C. Data & Knowledge Quality

NeSy version of the data & knowledge quality requirement is defined as the need for ensuring the *quality* of both *data* and *symbolic knowledge* of a NeSy system, along with its accessibility.

1) Available Metrics: Given the impact of data quality on the optimisation process of ML and DL systems, several quality metrics are available, namely: *(i)* class overlap [24], *(ii)* boundary complexity [25], *(iii)* label noise [26], *(iv)* class imbalance [27], *(v)* missing value analysis [28], and many more. Although designed for subsymbolic AI models, these metrics translate to the data-driven component of NeSy systems without particular issues, especially in those systems that follow a neural to symbolic – neuro $\rightarrow$ symbolic [29] – pipeline such as SKE approaches. In this context, these metrics makes it possible to check the correctness of the information that the subsymbolic components of NeSy gather from the data.

2) Missing Metrics: Unlike pure subsymbolic approaches – which rely solely on data for optimisation –, NeSy models gather information from both a data-driven and a symbolic knowledge component. In this context, it is fundamental to assess the level of compatibility or overlap between the data and the symbolic knowledge to be combined. In most NeSy systems quite a strong overlap is required between data and symbolic knowledge in order to avoid optimisation drift issues, where the integrated knowledge contrasts concepts learnt from the data. Meanwhile, a perfect overlap would also not be ideal in NeSy systems, as the optimisation process would gather the same information from both data and symbolic knowledge. Therefore, we here stress the need for new metrics that could measure the conceptual and technical overlap between data and symbolic knowledge at hand. Another relevant aspect to measure in this context is represented by the quality of the symbolic component of the NeSy system. While symbolic AI approaches are verifiable and deemed trustworthy, several NeSy – especially SKI – approaches rely on the integration of knowledge bases given a-priori and defined by human experts. Although mostly reliable, knowledge bases may be either incomplete or imperfect due to the human-centred building process. Therefore, metrics are needed that would make it possible to score knowledge components exploited in NeSy systems.

D. Transparency

NeSy version of the transparency requirement is defined as the *transparency gain* obtained by a NeSy system with respect to its pure subsymbolic components.

1) Available Metrics: When focusing on transparency, most of the available metrics for AI and NeSy models focus on explanations quality evaluation. Generally speaking, explanations quality is characterised by several key attributes [30], namely: *(i)* understandability – i.e., explanation complexity –; *(ii)* completeness – i.e., explanation coverage –; *(iii)* sufficiency of detail – i.e., explanations depth –; *(iv)* usefulness – i.e., explanation applicability –; and *(v)* feeling of satisfaction—i.e., explanation interactivity. By focusing on some of the above attributes, several works propose explainability and transparency metrics for AI and NeSy. Authors in [31] introduce a set of metrics to evaluate interpretability methods through measurements of simplicity, broadness, and fidelity of explanations. Meanwhile, Holzinger et al. [32] introduce a system causability scale to measure explanations quality, based on the notion of causability [33] together with the notion of usability scale. Although designed for explanations in general, these metrics nicely fit in the SKE frame, where they can be used to assess the quality of the extraction mechanism, as done in [34], where authors focus on unambiguity, interpretability, and interactivity of explanations.

2) Missing Metrics: Available explainability metrics aim at measuring the quality of explanations in absolute terms—i.e., how good are my extracted explanations? Meanwhile, our definition of NeSy transparency requires to measure the *gain* in transparency obtained from symbolic and subsymbolic integration. Therefore, there is the need for novel metrics for NeSy systems comparing the quality of a system's explanations before and after symbolic and subsymbolic integration. Moreover, we here stress the unbalanced nature of explainability metrics, as most metrics focus solely on features of explanations that are automatically measurable – e.g., correctness, coverage, length, etc. –, whereas there are basically no metrics focusing on human oriented specifications. A relevant issue for future research in this are is the definition of metrics that account for the subjective human factor in explanations, assessing the level of explanations satisfaction and understandability via human-assisted experimentation. Finally, it should be noted that transparency should not just focus on measuring the quality of the explanations that can be obtained from a system, but should instead assess the complexity of the process for extracting those explanations, too. Indeed, explanations obtained from a DL model using SKE may be complete, understandable and useful, but require a high computational burden to be extracted, rendering the overall DL and SKE process less transparent.

E. Fairness

NeSy version of fairness requirement is defined as the need for *measuring* biased and discriminative behaviour of NeSy agents rooted in the *interaction* between their symbolic and subsymbolic components.

1) Available Metrics: Given the nuances characterising a context-dependent notion like fairness, developing quantitative formulations for fairness metrics is challenging [35]. In the general context of AI systems, fairness is generally regarded as *outcome fairness*, which is the definition of equality of the decision making process outcomes. Here, fairness can be categorised into individual vs. group notions of fairness, and observational vs. causal approaches to assess fairness [36]. Observational fairness approaches are characterised by a number of existing metrics, such as: *(i) independence metrics* – e.g., statistical parity, group fairness, demographic parity, etc. –; *(ii) separation metrics* – e.g., equal opportunity, equalised odds, predictive equality, etc. –; and *(iii) sufficiency metrics*—e.g., groups calibration, predictive parity, etc.

While representing a fundamental requirement, fairness in NeSy setups is yet to be explored in detail. Indeed, only a handful of works have investigated fairness in NeSy systems. Authors in [37] propose to leverage the combination of symbolic knowledge extraction from Logic Tensor Networks [38] and injection of fairness constraints via continual learning to enforce fairness. Gao et al. [39] inject a fairness-based component in the loss function of subsymbolic models during their optimisation process to achieve higher fairness. Beyond their obvious relevance, these work focus solely on possible fairness benefits obtained through NeSy, as they rely on the application of SKI and SKE to reduce bias issues, leveraging the general AI fairness metrics. Therefore, available NeSy-specific fairness metrics are still missing that would aim at measuring just the impact of symbolic and subsymbolic integration upon fairness. This deficit is probably due to two aspects: *(i)* most observational fairness metrics are considered to be applicable to NeSy systems without modification; and *(ii)* most research focuses on measuring the fairness and assess it, rather than aiming at identifying its root causes.

2) Missing Metrics: In its NeSy version, the fairness requirement highlights the need to assess the possible fairness issues or improvements that arise from the use of symbolic and subsymbolic integration. It is clear that this requirement is not satisfied by available fairness metrics. Indeed, although most observational fairness metrics apply to NeSy systems, they do not allow for identification of the root causes of bias. One approach to tackle this issue would be to measure NeSy fairness as a differential of observational fairness between a SKI/SKE model and its ML/DL counterpart. However, such an approach would be over-simplistic, as it would not allow the specific sub-components of the integration process or of the symbolic knowledge that impact fairness to be captured. One possible solution would be to measure the fairness of NeSy systems over a set of symbolic knowledge bases, each representing a specific set of fairness goal. This process would allow fairness goal to be decomposed into its components/elements, then measure how well a NeSy system can enforce each fairness element.

F. Resource Efficiency

NeSy version of the resource efficiency requirement is defined as the need for assessing the *gain* in terms of *sustainability* with respect to pure subsymbolic counterparts.

1) Available Metrics: When dealing with resource efficiency of AI systems in general, the detailed definition of the set of resources to take into account represents a fundamental aspect. Several elements of the system at hand can be identified as resources, ranging from the energy required by the system to be optimised to its scalability—e.g., overall complexity. In this context, Agiollo et al. [40], [41] propose a rigorous definition of resource efficiency improvements achievable by SKI systems spanning over four different resource components. More in detail, the authors focus on the definition of energy, latency, memory, and data efficiency of any SKI model, aiming at addressing its environmental impact – e.g., energy and data –, and its scalability—e.g., memory and latency. These metrics are defined as the relative difference in terms of resources – e.g., energy, etc. – required to optimise a SKI model to reach the same level of performance of a subsymbolic counterpart. To this end, the authors define each of the resource analysed, and provide for a tool to measure them in a SKI setup, showing how SKI can improve energy and data efficiency, while degrading the system latency. Latency increments are linked with the increased complexity of the system given by the interaction between symbolic and subsymbolic components, which is however beneficial in terms of number of data required for optimising the model. Indeed, several other works show the data efficiency of NeSy models – such as [42], [43], [44] – even though they lack a proper definition for efficiency.

2) Missing Metrics: As data efficiency represents one of the declared advantages of NeSy systems, most of the literature focuses specifically on this aspect, leaving some space for investigation about other relevant aspects of resource efficiency. More in detail, detailed analysis of the environmental impact of AI and NeSy models development in terms of their carbon footprint are still mostly missings. Studying the energy consumption of the development of a single NeSy model is not enough, as the computation infrastructure used throughout this development – such as clusters and cloud infrastructures – strongly impact its environmental footprint. Moreover, whereas few metrics exist that assess the efficiency of NeSy under the SKI perspective, there are basically no metrics for resource efficiency in the SKE area. In this context, it would be desirable to have metrics similar to the ones obtained for SKI comparing the resource usage of the original subsymbolic model and its symbolic emulation. Depending on the SKE approach at hand, it is possible to consider extracting a small symbolic AI models mimicking the behaviour big DL frameworks. The small symbolic model obtained may help hugely reducing the amount of resources – especially energy, latency, and memory – required to deploy the AI system. Therefore, we here suggest as a future direction to investigate whether – and to what extent – SKE can produce small and fast counterparts of DL models. Here, the resource efficiency metric could be simply designed as the relative difference between the amount of resources required to run the original DL model and its symbolic emulation.

G. Accountability

NeSy version of the accountability requirement is defined as the need for assessing the *gain* in terms of *answerability* obtained by a NeSy system with respect to its pure subsymbolic components.

1) Available Metrics: As it is represented by the answerability of an AI system, accountability is closely tight to transparency. Indeed, accountability requires the underlying system to be explainable, and the explanations to be correct, reliable, and comprehensible. Correctness and reliability of explanations depend on the precision of the AI system and its explanation construction counterpart. Therefore, most efforts in this field focus on the explainability of the AI/NeSy system at hand. As a result, the set of available AI and NeSy metrics for accountability is basically represented by the same set of metrics presented in Section V-D.

2) Missing Metrics: While being tightly linked with explainability, accountability also requires the extracted explanations to be correct and reliable. As correctness and reliability mostly depend on the precision of the AI/NeSy system, we here propose to define novel accountability metrics by opportunistically mixing transparency metrics (Section V-D) and robustness metrics (Section V-B). Therefore, accountability metrics should be defined as the result of explainability metrics applied over a set of input perturbations, measuring the rate of change of the obtained explanations.

VI. Conclusions

Trustworthiness of AI systems represents a fundamental requirement for their ubiquitous deployment. The notion of Trustworthy AI as defined by the EU is mostly a general one, yet implicitly accounting for issues coming from popular ML and DL techniques—so it fits well subsymbolic AI systems. A set of novel NeSy systems calls for a more specific definition of trustworthiness, as they rely on the integration of subsymbolic and symbolic AI where the symbolic components may affect – either positively or negatively – the trust level of the system. Accordingly, in this paper we analyse how the AI trustworthiness requirements defined by the EU translate to the NeSy realm, focusing on the relevant elements of the NeSy integration process impacting trust. First we analyse in detail each pillar of trust and its implication on NeSy models, then we focus on the available metrics for measuring such requirements. The state-of-the-art analysis highlights a lack of available metrics for most trustworthiness aspects when specifically considering NeSy systems. Therefore, we suggest potential future directions to explore in the analysis of NeSy trust along with with related metrics definitions. We believe that the rigorous definition of novel trust metrics tailored to NeSy systems is going to represent an essential step towards measurably reliable and trustworthy AI systems based on neuro-symbolic integration.

***Abstract*—Clinical notes that describe details about diseases, symptoms, treatments, and observed reactions of patients to them, are valuable resources to generate insights about the effectiveness of treatments. Their role in designing better clinical decision making systems is being increasingly acknowledged. However, the availability of clinical notes is still an issue due to privacy violation concerns. Hence most of the work done are on small datasets and neither the power of machine learning is fully utilized, nor is it possible to validate the models properly. With the availability of the Medical Information Mart for Intensive Care (MIMIC-III v1.4) dataset for researchers though, the problem has been somewhat eased. In this paper we have presented an overview of our earlier work on designing deep neural models for prediction of outcomes and hospital stay for patients using MIMIC data. We have also presented new work on patient stratification and explanation generation for patient cohorts. This is early work targeted towards studying trajectories for treatment for different cohorts of patients, which can ultimately lead to discovery of low-risk models for individual patients to ensure better outcomes.**

***Index Terms*—Clinical Notes, BioNER, Clustering, Anomaly Detection, Autoencoder, Shapley Value**

I. Introduction – Clinical Narratives and Their Uses

COMMUNICATION within healthcare systems is dominated by textual narratives. This includes a diverse array of documents generated by different sources for various purposes. These texts can be broadly classified as follows:

(a). Clinical notes, especially nursing notes attached to Electronic Health Records (EHR) of patients admitted to the hospital for treatment, contain valuable information about the patients, symptoms, diagnoses, treatments, chronic and past ailments, drug prescriptions, and adverse drug effects, if any, for the patient. Collections of such texts can be effectively mined to gather insights to improve healthcare for other patients [1]. If not explicitly, these texts also provide insights about a physician's possible reasons for following a path of treatment. Nursing notes are time-stamped and therefore can provide a view into the trajectories of recovery. Clinical notes are also highly sensitive in nature since they contain personal identification details. Hence, though large volumes of clinical data are generated across the world, restricted access to the data due to security and privacy concerns is a major bottleneck for researchers. The publicly available Medical Information Mart for Intensive Care (MIMIC) database [2] has eased out this problem to some extent. This data has been anonymized and specially made available for research purposes only. This database contains daily records of over $40,000$ patients with details about their illness, symptoms, medical history, results of diagnostic tests, treatments, nursing observations, discharge summaries along with some patient demographic details like age, gender etc. along with the number of days spent in ICU and other wards for each admission.

(b). Pathological and radiology reports - These are semi-structured narratives resulting from various targeted examinations like findings from radiology images, blood tests, etc. Researchers in the area of computer vision have been long engaged in developing predictive systems from the images for automated detection of diseased cells, tissues, or organs. Recent developments in the area of multi-modal analytics have spurred interest in using textual descriptions along with images for better predictive models.

(c). Bio-medical literature or technical publications that report scientific advances in the area of life sciences and healthcare, include documents like journal articles, case studies, systematic reviews, and clinical guidelines published by regulatory bodies. These documents are important sources of information for those who work in the areas of drug discovery, designing new treatment protocols, etc. Text mining of bio-medical scientific literature is an old established area. The aim is to come up with systems that can help in the easy assimilation of knowledge from this vast incremental repository using sophisticated information extraction and reasoning methodologies. A comprehensive review of text mining techniques for extraction information from bio-medical texts is presented in [3].

(d). Social Media texts - Patient-generated text like tweets or blog posts play a critical role in gathering insights about individual and collective experiences about a drug, treatment, clinical trials, or care facility. Social media text analysis has played a critical role in detecting and assimilating adverse drug effects, especially in obtaining new knowledge about preconditions or co-occurring conditions that cause adverse effects of a drug. With the increasing popularity of patient support groups like PatientsLikeMe, social media content analysis is gaining new heights. There are dedicated groups for different diseases offering hitherto undiscovered insights about rare diseases to the entire community [4].

The repository of clinical texts is huge, analysis of which can yield deep insights for clinical decision-making, drug discovery, and healthcare management systems. While text mining from reports, literature, and social media has been actively pursued for some time now, the mining of clinical notes from EHRs is a fairly new area, primarily due to the non-availability of such texts earlier. Even to this day, the volume of clinical records of patients available for study purposes is fairly low. This is a severe impediment to the development of machine learning systems, as these are known to require large volumes of data. Nevertheless, with increasing focus on personalized and optimized healthcare management, the analysis of clinical texts is gaining importance. Analytical applications of clinical documents can be broadly classified as -

- Descriptive analytics: which is targeted at knowledge discovery from the scientific literature. This is a fairly mature area of research actively pursued by researchers working in the areas of natural language processing and text mining. They often aim to discover information about new entities and relations reported in the literature. Dalianis provides a detailed review of clinical text mining and its applications along with the challenges of analyzing such data in the book [1]. This book also presents a comprehensive study of clinical text mining in non-English languages.
- Diagnostic analytics: this area digs deeper into clinical texts to unearth causal explanations about events.
- Predictive analytics: this area seeks to employ predictive models to predict possibilities of repeat occurrence of known events. One of the major consumers of predictive models designed using past patient data are hospital management authorities. Hospital admission notes have turned out to be very useful for the purpose, as these can be used to predict ICU length of stays [5], hospital readmissions, procedure requirements, etc. ICU stay prediction is an important problem for hospitals, since ICU facilities are expensive to set up, and their optimal use and availability are imperative to ensure better outcomes through proper resource planning [6]–[8]. Obtaining advance information about the possible length of ICU stay or duration of hospitalization are also useful for patients and their families, as it helps in better expectation management and planning from their side also. Predicting individual patient outcomes is gaining importance as clinical decision making is increasingly focusing on individualized care. Given the wide variability among individuals however, a step forward in this direction is to move towards understanding patient cohorts - that is group of patients who are more similar to each other, than to rest of the patients suffering from the same disease. This is known as patient stratification. Patient stratification is gaining interest from medical as well as machine learning researchers, as it holds the promise to deliver better outcomes to the exceptions. These are early days in this area, and most studies have been conducted on very focused dataset.
- Prescriptive analytics: this is an extension of predictive analytics, where the intent is to prescribe the best possible actions from among a set of possible actions, to achieve a desired outcome under a given state. Prescriptive analytics can be viewed as a natural follow-up of patient stratification. It ideally requires simulation of future possibilities to arrive at the best possible decision for an individual, by studying the current state, possible interventions and their effects using a simulation and then arriving at a feasible conclusion.

In this paper, we shall be primarily presenting our work done in the areas of predictive analytics and patient stratification using clinical text like hospital admission notes, with an end goal of providing decision intelligence for better care management and increased visibility into patient cohorts respectively. The rest of the paper is organized as follows. Section II provides an overview of the MIMIC dataset. Section III presents related work done in the area of predictive analytics, along with our earlier work in the area. It presents an overview of different types of predictions done with clinical data including text by different groups, and also an overview of our earlier work done for predicting ICU length of stay and procedure requirements for patients based on the first day's admission notes. Section III-A provides a comparative study of the performance of all the methods. This is followed by patient stratification work. Section IV presents an overview of related work in the area of patient stratification by other researchers. From section V onwards we present our work done in the area of patient stratification using clinical texts, which to the best of our knowledge has not been attempted before. We have presented deep learning based methods to generate explainable clusters from clinical notes of patients admitted with a specific disease. The explanations generated for the clusters provide more insights into the co-morbidities of each cohort present within the group. The cohort-treatment associations are also obtained. We present results of experiments done with pneumonia patients of the MIMIC dataset in section VII. Detailed insights into the cohorts obtained are presented in the form of cluster-wise patient statistics in terms of age and hospital stay, along with cluster-specific association of symptoms, treatments, and final recovery information obtained from the discharge summaries. We believe the insights can pave the way for analyzing the effectiveness of the treatment trajectories and thereby customizing them in future, to improve treatment effectiveness and reduce mortality, if possible. We conclude with a lot of future possibilities in section VIII.

II. The Dataset

As our primary data source, we have used the MIMIC-III v1.4 database [2], which contains the details of over forty thousand patients who stayed in critical care units of the Beth Israel Deaconess Medical Center (BIDMC) between 2001 and 2012. This database has pre-existing Institutional Review Board (IRB) approval, and researchers can access the data after successfully completing the training course "Data or Specimens Only Research" provided by the Collaborative Institutional Training Initiative (CITI).

The MIMIC-III database contains details of 46,520 distinct patients with 58,976 hospital admissions. This database includes both structured and unstructured clinical events documented for patients during hospital admissions. Importantly, the database adheres to stringent anonymization protocols, meticulously safeguarding patient privacy. Moreover, to ensure heightened privacy protection, precise dates and times of events have been intentionally obscured. Instructions for accessing this dataset are available in the website https://mimic.mit.edu/docs/gettingstarted/.

III. Building Predictive Models for Patient Care with Clinical Notes

In this section, we present an overview of work done in the area of predictive analytics with electronic health records.

In [9], a neural network based model is used to predict the length of remaining hospital stay for a patient at the time of exit from the ICU unit. In this study, authors used several medical attributes like patients' demography, CPT events, services, procedures, diagnosis, etc. of 31,018 patients from the MIMIC database. In another study [13], Harutyunyan et al. proposed a channel-wise LSTM model using multitask training for predicting mortality along with a forecast of the remaining time to be spent in ICU made at each hour of stay. Predictions were generated from 17 clinical variables like Capillary refill rate, blood pressure, fraction inspired oxygen, Glasgow coma scale, glucose level, heart rate, etc. of patients from the mimic database. Afterward, in 2020 [12], a deep learning architecture based on the combination of temporal convolution and pointwise convolution was proposed to predict the length of ICU stay. This work used the eICU critical care dataset [18], which contained records of 118,534 unique patients, and predictions were based on structured features like patients' gender, age, hour of admission, height, weight, ethnicity, Unit Stay, Physician Speciality, etc. In [10], a study was presented on the prediction of length of stay in ICU and mortality, using several machine learning algorithms on a set of patients from the MIMIC database based on their vital signs like heart rate, blood pressure, temperature, respiratory rate, and patient's demography like age, gender, height, weight, etc. In 2021 [11], Su et al. developed several machine learning models for predicting mortality, severity, and length of stay for a set of 2224 Sepsis patients who were admitted to the ICU of Peking Union Medical College Hospital. In their predictive models, authors used patients' clinical parameters such as age, $P(v\text{-}a)CO_2$ $/C(a\text{-}v)O_2$, SO_2, oxygenation index, white blood cell count, oxygen concentration, temperature, etc. from the first 6h in the ICU.

It is worth mentioning here that none of the above-mentioned works used textual data for prediction. Most of them have used only structured clinical parameters for predicting various clinical events. The richness of clinical notes has not been fully exploited for prediction. In particular, nursing notes play a crucial role in capturing essential patient information that extends beyond the physiological metrics recorded by laboratory tests or radiology reports. These notes encompass a wide range of details, including symptoms, overall health condition, administered medications, performed procedures, and devised treatment strategies. Moreover, they occasionally encompass insights into a patient's response to care and treatment, often described through behavioral observations meticulously documented by the caregiving professional.

Figure 1 shows a sample nursing note with different portions of text color-coded, to highlight the different categories of information that a note may contain. Use of linguistic expressions like *"severe multilobar pnx"*, *"worsening multifocal pnx"*, *"No abdominal pain, no further bleeding"* provide an added dimension of human assessment, that cannot be captured through numbers only, but can be important while distinguishing between two similar patients who are possibly responding differently to the treatment. The notes are very comprehensive in nature. With the database containing almost as many notes for each patient as the number of days of admission, this offers quite a rich collection to work with. Additionally, within the EHR system, a discharge summary is also a crucial component of the patient's medical records that provides a concise overview of a patient's hospital stay, their medical condition, treatments received, and instructions for follow-up care upon their discharge from the hospital. Often the information is repeated across these sources. The redundancy helps in data verification, especially since the data can be quite noisy. Other fields which are more structured in nature like age, gender, admission diagnosis, medications, mortality, etc. are also used for predictive modeling.

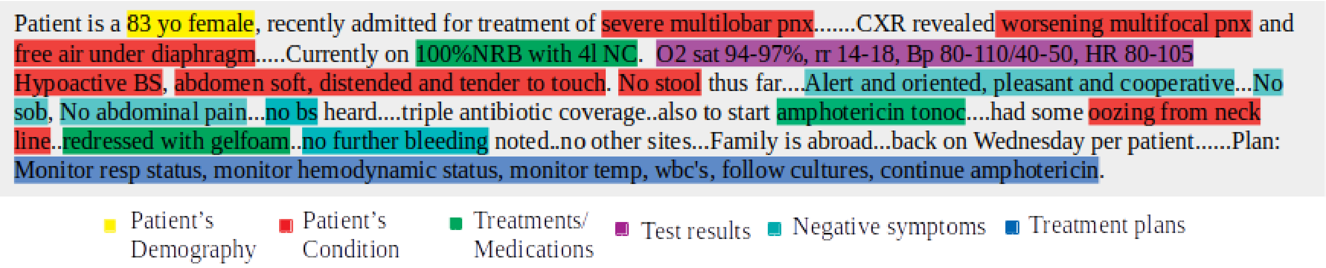
Recently, in 2021 Aken et al. [15], have introduced a model, called CORe, on top of BioBERT for predicting multiple clinical outcomes along with the duration of ICU stay. The authors devised a distinct note extracted from the discharge summary, leveraging it within their predictive framework.

In 2022 [16], we proposed a model which utilized nursing notes of the first day of ICU along with clinical parameters from laboratory tests, to predict whether a patient would need an ICU stay of short or long duration, where the partition of short or long stays was decided by median length of stay recorded in data. Further in [17], this work was extended to additionally predict the need for critical procedures such as bypass surgery, stenting, tracheotomy, and cholecystectomy - which were the most commonly occurring ones in the dataset, along with an ICU stay. The objective was to predict these procedures based on the first day's nursing notes in which these were not explicitly mentioned. We also proposed using a framework called "Local Interpretable Model-agnostic

TABLE I
PERFORMANCE ANALYSIS OF DIFFERENT MODELS FOR ICU LENGTH OF STAY PREDICTION.

Earlier Works	Dataset	Features used	ICU stay classes	Methods	Best Result
[9]	31,018 patients from MIMIC database	patients' demography, CPT events, services, procedures, diagnosis, etc.	ICU stay$\leq$5 days, class 0; ICU stay$>$5 days, class 1	neural network based model	80% accuracy
[10]	44,000 ICU stays from MIMIC database	patient's vital signs - heart rate, BP, temp, resp rate, age, gender, height, weight, etc.	ICU stay$\leq$2.64 days, class 0; ICU stay$>$2.64 days, class 1	Machine learning algorithms	65% accuracy using random forest algorithm
[11]	2224 Sepsis patients from Peking Union Medical College Hospital Intensive Care Medical Information System and Database (PICMISD)	patient's age, P(v-a)CO$_2$ /C(a-v)O$_2$, SO$_2$, oxygenation index, WBC count, oxygen concentration, bpm, temp, etc.	ICU stay (LOS) ($>$6 days, $\leq$ 6 days)	logistic regression, random forest, and XGBoost model	sensitivity = 0.79, specificity = 0.66, F1 score = 0.69, AUC = 0.76 using Random forest
[12]	eICU critical care dataset	patient's gender, age, hour of admission, height, weight, ethnicity, unit stay, Physician Speciality, etc.	classifying in 10 classes - one for ICU stays shorter than a day, seven day-long buckets for each day of the first week, one for stays over one week but less than two, and one for stays over two weeks	combination of temporal convolution and pointwise convolution	Kappa score = 0.58
[13]	MIMIC database 42276 ICU stays	17 structured clinical variables - capillary refill rate, blood pressure, fraction inspired oxygen, Glasgow coma scale, glucose, heart rate, etc from first 24 hours of admission	classifying in 10 classes - one for ICU stays shorter than a day, seven day-long buckets for each day of the first week, one for stays over one week but less than two, and one for stays over two weeks	LSTM-based neural network models	AUC-ROC = 0.84
[14]	22,353 patients from MIMIC database	Clinical Notes	Remaining ICU stay time is discretized into 10 classes {0-1, 1-2, 2-3, 3-4, 4-5, 5-6, 6-7, 7-8, 8-14, 14+}	multi-model neural network	Kappa score = 0.453
[15]	38,013 admissions from MIMIC database	created notes from discharge summaries	four categories - Under 3 days, 3 to 7 days, 1 week to 2 weeks and more than 2 weeks	pre-trained CORe model on top of BioBERT	AUC-ROC = 72.53%
[16]	**22,789 admissions from MIMIC database**	**nursing notes from first 24h along with 20 vital signs and lab measurements available in first 24h of ICU stay**	**"Short" if ICU LOS$<$4days and "Long" if ICU LOS$\geq$4days**	**trans-former based deep neural network model**	**Accuracy = 79.20%, AUC-ROC = 87.33% Kappa score = 0.594**
[17]	**28,659 admissions from MIMIC database**	**nursing notes from first 24h along with 20 vital signs and lab measurements available in first 24h of ICU stay**	**"Short" if ICU LOS$<$3days and "Long" if ICU LOS$\geq$3days**	**multimodal multiobjective transformer network**	**Accuracy = 84%**

Explanations" (LIME) to obtain explanations about the prediction outcome. LIME creates several subsets from the original data containing only a part of the original attributes. It then computes the influence of the attributes on the classification, based on the presence or absence of certain features in the selected text. To capture the details and the various nuances of a nursing note, we proposed using transformer-based models for representing them. Embeddings for the nursing notes were generated using BlueBERT [19] and Clinical BioBERT [20]. Along with this, for each admission, we computed four types of Severity of Illness (SOI) scores: APACHE II, SAPS II, SOFA, and OASIS based on data collected within 24 hours of ICU admission. This way, the proposed model made use of both structured as well as unstructured data. The novelty of the



Patient is a 83 yo female, recently admitted for treatment of severe multilobar pnx.......CXR revealed worsening multifocal pnx and free air under diaphragm.....Currently on 100%NRB with 4l NC. O2 sat 94-97%, rr 14-18, Bp 80-110/40-50, HR 80-105 Hypoactive BS, abdomen soft, distended and tender to touch. No stool thus far....Alert and oriented, pleasant and cooperative...No sob, No abdominal pain...no bs heard....triple antibiotic coverage..also to start amphotericin tonoc....had some oozing from neck line..redressed with gelfoam..no further bleeding noted..no other sites...Family is abroad...back on Wednesday per patient......Plan: Monitor resp status, monitor hemodynamic status, monitor temp, wbc's, follow cultures, continue amphotericin.

Fig. 1. A Sample nursing note collected from MIMIC-III. Colored components are the extracted events and entities.

proposed model was its design as a multi-objective prediction model, where critical procedures also were predicted along with the duration of ICU stay. Different kinds of networks were experimented with, namely the Convolutional Neural Network (CNN) [21] and Long Short Term Memory (LSTM) [22] for prediction. Additionally, it was observed that the use of a Term Frequency - Inverted Document Frequency (TF-IDF) vector, impacts the performance of the model significantly. It might be due to the fact that the TF-IDF vector can capture the common and distinct features across the classes very effectively. Figure 2 presents the prediction architecture that performed the best along with the proposed representation scheme.

The input representation for a patient is the vector generated by concatenating the outputs of the BiLSTM layer as a result of embedding the corresponding first admission note, the TF-IDF feature vector for clinical entities extracted from the note, and the SOI scores of the patient. The concatenated vector embedding is simultaneously fed into two task-specific fully connected layers, one for predicting ICU length-of-stay and another for predicting the possibilities of each of the four surgical interventions – bypass surgery, stenting, tracheotomy, and cholecystectomy. For the length-of-stay classification, we have used the softmax activation function with binary cross-entropy loss L_{LOS}. For the intervention prediction tasks, since these are not mutually exclusive outcomes, we have trained the prediction layer using the sigmoid activation function with binary cross-entropy loss functions $L_{intervention}$. Finally, we have defined a joint loss function using a linear combination of the loss functions for the two tasks as:

$$L_{Joint} = \lambda * L_{loss} + (1 - \lambda) * L_{intervension} \qquad (1)$$

, where λ controls the contribution of losses of the individual tasks in the overall joint loss.

A. Evaluation of Predictive Models for ICU LOS prediction

As discussed earlier, one major aspect that distinguishes the models from each other is the set of predictor variables used. The choice of prediction method is often guided by the choice of the predictor features. The evaluation metrics used by the studies are also not always the same. This makes comparison of methods a little tricky. However, we have presented a compilation of the models, the metrics, and the reported performances of these models in Table I. The last two rows of the table I present the performance of our proposed models over a set of ICU patients from the MIMIC database. The prediction accuracies for bypass surgery, stenting, tracheotomy, and cholecystectomy were found to be $89\%, 83\%, 55\% and 54\%$ respectively. The performance of the last two categories were not so good due to lack of enough data in the set. Interestingly however, while only 3% of the total tracheotomy procedures done later were mentioned in first day's notes, our model could predict 70% of them in the first day. However, the false positive rates were high for the proposed model. This can be reduced with more data. Overall, the significant gains for acquiring valuable insights into procedure requirements on the first day itself are quite significant. Consequently, such an approach offers prospects for enhanced planning and decision-making. It was observed that a total of 15691 unique diseases are recorded in the MIMIC database as key reasons for which patients were admitted to ICU. It was found that in the dataset we used, the topmost category, which constituted about 4% of the entire set were patients of Pneumonia, followed by around 2% each of Sepsis, Coronary Artery Disease, Congestive Heart Failure, and Gastrointestinal bleeding. This somewhat explains the observation of the cardiac procedures as most frequent followed by tracheotomy and cholecystectomy.

As seen in Table I, the performances of predictive systems are improving over time. While these systems are good for hospital management, particularly in efficiently managing resources for heterogeneous sets of patients, when it comes to providing better patient experience, the trajectory of clinical decision-making is moving towards providing more personalized care management. While these are early days of designing personalized care management systems, existing literature strongly suggests that rather than working with very large groups, the stratification of patients into homogeneous subgroups or clusters is likely to play a major role in enabling personalized treatments. In the next section, after describing novel techniques for patient clustering, we will demonstrate the effectiveness of the methods utilizing patient data afflicted with Pneumonia, which was the predominant disease present in the dataset.

IV. Patient Stratification - a review of related works

Most of the predictive models that have been proposed earlier in literature, have worked on large heterogeneous patient

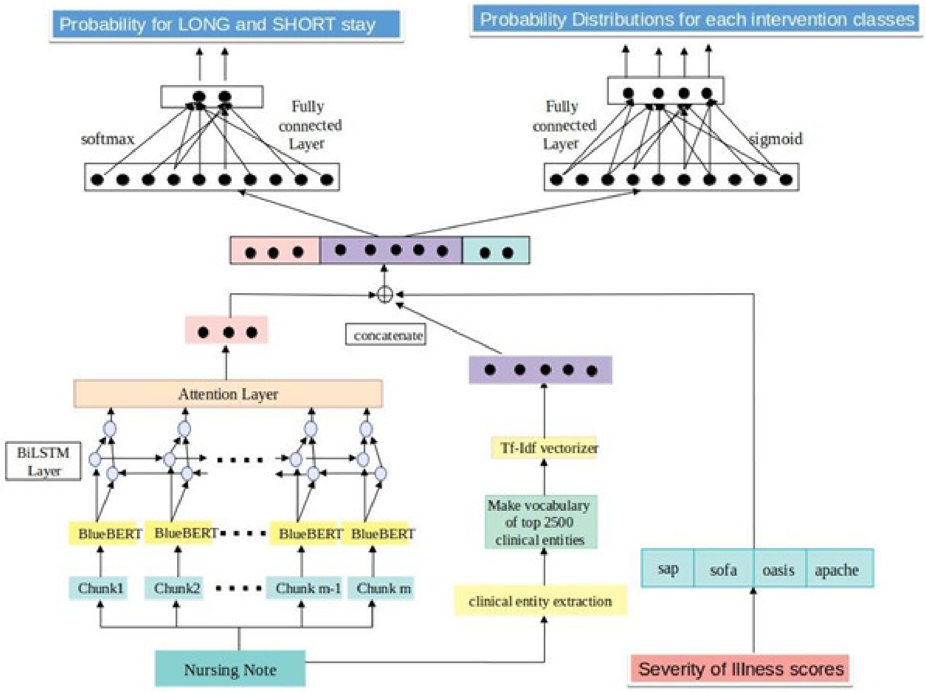


Fig. 2. Overview of proposed multimodal multitask framework for predicting the ICU length of stay and necessity of the interventions. Process the nursing notes in chunks by the BlueBERT model and add a BiLSTM-attention layer on the top. We also extract 2500 medical entities from these notes and make a TF-IDF representation. Then the note representations from the BlueBERT-BiLSTM -Attention network, TF-IDF representation, and four severity of illness scores are concatenated and two task-specific fully connected layers are applied to obtain the final predictions.

populations, which were not able to discover obtain much insights into risk factors for individual patients and hence not very suitable for personalized decision making. Patient stratification techniques that can identify homogeneous groups and thereafter group-specific risk factors, is therefore proposed as a better way to gain insights about outcome differences.

In recent years, several data clustering approaches have been proposed for patient stratification and subsequent analysis of the clusters using different cluster validity indices [23], [24]. In 2021, Alexander et al. [25] investigated the clinical heterogeneity of Alzheimer's disease patients using electronic health records (EHR). In 2022, Angelini et al. [26] proposed an explainable clustering method to identify dominant osteoarthritis endotypes using different biochemical markers, to design tailored treatments and drive drug development. In a recent paper [27], Bhavani et al. have applied hierarchical clustering (DTW-HC) and partitioning around medoids (DTW-PAM) from the first 8 hours of hospitalization records, to identify sub-phenotypes of infected patients. Chen et al. In [28] have presented a model for prediction and risk stratification of kidney outcomes in IgA Nephropath, which is a common disease worldwide. The intent is to predict long-term outcomes and stratifying risk for clinical decision-making. They have also stated that these kinds of work can be useful for designing future clinical trials. The model used was gradient tree boosting implemented in the eXtreme Gradient Boosting (XGBoost) system. The dataset itself was quite small. Kanwal et al. in [29] present stratification of patients suffering from Non-Fatty Liver Disease (NAFLD), which is largely asymptomatic, and success of treatment depends on optimal timing and accurate assessment of fibrosis risk. The work describes the NAFLD Clinical Care Pathway that was developed to assist clinicians in diagnosing and managing NAFLD with clinically significant fibrosis (stage F2–F4) based on the best available evidence using a statistical approach. In [30] Seinen et al. have presented a detailed review of prognostic prediction models that use unstructured clinical text.

V. Patient Stratification Using Nursing Notes - obtaining insights about patient cohorts and exceptions

We now present methods for generating explainable patient cohorts based on their condition at admission, by clustering first day's nursing notes of patients. Rather than using the entire dataset of all patients, our focus will now be on individual diseases. We propose the use of auto-encoders to represent patient health conditions, which is a different approach from using the transformer-based representations presented earlier. Further, we propose the use of SHAP values for explaining the clusters. We also show that the use of autoencoders within a disease category improves the accuracy of prediction of the duration of hospitalization.

While analyzing the prediction results using the LIME framework described in section III, we found that clinical notes, one factor that could affect the performance of prediction could be highly variable in style and content. While some caregivers record only the symptoms that are present on a given day, some others meticulously note down the absence of common symptoms, adverse reactions, psychological state of patients, appetite, etc. The use of non-standard terminology and abbreviations are known to be quite common. Using widely variable terms to describe the same condition is very common in clinical texts. For example - *icterus* and *jaundice* refer to the same disease. Similarly, the terms *brain abscess, intracerebral abscess, cerebral abscess* all refer to the same state. Over the years, bio-medical dictionaries like UMLS [31] have been prepared to document these. Though the BlueBERT embeddings that we used earlier, could capture linguistic nuances like difference between *severe pain* and *mild pain*, these could not always capture the similarities or differences between two notes based on the medical terms used. Therefore, before getting into the stratification work, where the similarity would play a significant role, we implemented an additional processing layer, wherein every clinical note underwent initial processing through the Biomedical dictionaries for standardization of terms. Using this step it was now possible to also distinguish different types of entities like symptoms, diseases, drugs, etc. which could help in grouping patients better. For example, people suffering from the same disease and undergoing the same treatment, but who showed different reactions to it, could now be put into different groups. This led to the idea of using a different embedding altogether which we shall now explain.

The details of the processing pipeline using the biomedical dictionaries are presented below.

Entity extraction: We have used Scispacy [32] and MetaMap [33] for extracting health conditions from patients' clinical notes.

Scispacy: ScispaCy is one of the most robust model for processing biomedical, scientific, and clinical texts on several NLP tasks such as part-of-speech tagging, dependency parsing, named entity recognition, etc. In our work, we have used the pre-trained scispaCy model *en_ner_bc5cdr_md*, which was trained on the BC5CDR corpus for recognizing disease names mentioned in a clinical note.

MetaMap: Nowadays, another entity extraction tool MetaMap is widely used for identifying medical entities. This was developed by the National Library of Medicine (NLM) to map biomedical text to concepts in the Unified Medical Language System (UMLS) [31]. We have processed clinical notes using MetaMap and extracted eight medical entities such as "Sign or Symptom", "Disease or Syndrome", "Acquired Abnormality", "Anatomical Abnormality", "Congenital Abnormality", "Injury or Poisoning", "Mental Process", and "Mental or Behavioral Dysfunction".

Detecting Negations: The Negex algorithm [34] which detects the presence of negative modifiers like "no", "not", etc. is then applied to detect negative mentions of entities in a text. The original list was enhanced to accommodate commonly appearing negation concepts such as "deny", "refuse", "absent", "decline" etc. that occur frequently in clinical notes. For example, given a sentence "*The patient has shortness of breath but denies any chest pain*", two symptoms identified should be *shortness of breath, neg chest pain*. These negative symptoms have a significant contribution to describing individual patients.

Entity Standardization: All the extracted entities are then standardized using the UMLS Metathesaurus [31], [35]. This is important since a single medical condition like "Hypertension" may be referred to as "High blood pressure", "Arterial hypertension" or "Hypertensive disorder" by different professionals. UMLS contains an exhaustive list of such situations and assigns a "Concept Unique Identifier (CUI)" to each. However, we have observed that several entities still did not have an exact match with any UMLS concept. These entities were mapped using an approximate string-matching algorithm [36], that found the closest UMLS concept based on Levenshtein distance measure [37]. For entities that could not be mapped to any UMLS concept, unique identifiers were created to ensure that no health condition was ignored. Examples of such entities from the MIMIC dataset include terms like "airway swelling", "overdistention of lung" etc. To avoid confusion, we refer to these also as CUIs.

Each clinical note can now be represented in terms of the CUIs present in it, either to indicate the presence or absence of a symptom. Consequently, a patient's status at a particular point in time can also be expressed in terms of these CUIs.

Let the collective list of CUIs describing the diseases and symptoms for a particular study be denoted by *health status (H)*. Given a patient p, the health condition at time t is denoted by a vector of $h_i \in H$, where the value of h_i is set to 1 if h_i mentioned in the corresponding clinical notes, -1 if it is mentioned negatively, and 0 if h_i is not mentioned. It may be noted that the CUIs associated with a patient are expected to change over time as treatment progresses. Consequently, the patient may be represented by different vectors over the same space as t changes.

Patient Medication Information: Besides health conditions, each patient also has medications that are prescribed based on these conditions. Considering a unified set of medicines M, at a given time t, each patient p is also associated with a binary vector $< m_i >, i = 1..|M|$, where $m_i = 1$, if medicine m_i is ongoing for p at time t, otherwise 0. This binary vector also changes over time.

A. Creating Dense Representation of Patients in Terms of Health Conditions using Autoencoders

While the number of unique diseases and symptoms obtained from any patient database is very high since all people do not exhibit all symptoms or diseases, the above vectors are high-dimensional and sparse. An autoencoder-based transformation is applied to obtain a dense representation in a lower-dimensional space [38], [39]. In an autoencoder (AE) model, the "encoder" network creates a compressed representation of the input data by capturing the essential characteristics and underlying patterns, while the "decoder" network learns to reconstruct the original input data from the compressed representation while minimizing the loss of information [40]. We next show how dense representations are used for prediction as well as clustering purposes.

B. Autoencoder-based Prediction of Duration of Hospitalization

Before getting into the details of clustering, we validated the representation using it in a predictive framework similar to the ones described earlier first. Figure 3 presents a CNN-based architecture that is used for the prediction of hospital / ICU stay duration using the autoencoded representation of the first day's clinical notes. The network performance was tested with a dataset of 2106 "Pneumonia" patients who had undergone one admission for the disease. The set comprises individuals both with and without ICU admission. Since the number of total patients in this category is still quite small for a deep neural architecture, we have used all the data for predicting long or short hospital stay, rather than ICU stay. The median stay for this set of patients was 9 days. We conducted two experiments to check the performance. For the first experiment, the cut-off between short and long stays was assumed to be 7 days, while for the second experiment, it was assumed to be 9 days. While the accuracy is found to be 83% for 7 days, it is 86% for 9 days, which is the median. Thus median appears to be a good estimator for deciding long or short stays. It was found that the system performed more errors for patients with short stays, which were erroneously classified as long. Some of these patients, had deceased after a short stay. Though not exactly comparable, the prediction performance is found to be much higher than all reported works presented earlier, which may be due to the focused dataset or the representation, or both. Whether this kind of performance can be observed for all other diseases also, needs to be further explored, but this would also need more data for each of the corresponding categories.

VI. Patient Stratification using autoencoders - Generating explainable patient clusters

The autoencoded vector representations are clustered using the k-means clustering algorithm [41], with Euclidean distance as the distance metric to identify similarity among patients. For a given value of k, a set of k cluster centers are chosen randomly, and then each data point is assigned to the cluster that is found by iteratively minimizing the within-cluster distance among the points. In order to determine the right value of k, we have made use of *silhoutte coefficient* [42]. The silhouette coefficient of each point measures how similar it is to other points within the same cluster in comparison to points in other clusters. The average silhouette coefficient computed from all the points provides a measure of the cohesiveness of each cluster along with their separation or distinctiveness from each other. Starting with 2, the value of k is iteratively increased as long as the silhouette score also increases with it. The ideal value of k is the one that yields the highest average silhouette score, beyond which the score starts to decrease steadily.

In order to generate human-interpretable explanations for the clusters, we used Shapley values [43], which can measure the contribution of each feature of each individual towards the final outcome, while preserving the sum of contributions of all. We wanted the explanations to be in terms of diseases and symptoms, including the dominant symptoms in a cluster, as well as the distinguishing aspects between the clusters. The CUI-based representation was used for the purpose. Treating the cluster labels as the target outcomes, a Random Forest classifier [44] was trained to predict the target labels, using the CUI vector-based representation of the patients. The trained model was then analyzed using SHAP TreeExplainer [43], [45], [46], to gain insights into the decision-making process. This method provides not only the contribution of each symptom to a particular label but also the SHAP values for each patient, thereby helping with the interpretation of why a patient has been assigned to a particular cluster. They also help in the interpretation of misclassifications by the model, if any.

A similar approach was followed to derive Shapley values for patients and clusters in terms of medicines. In this case, the Random Forest classifier was trained to predict the target cluster labels using the medicine vectors and then analyzed with the SHAP TreeExplainer. It helps in identifying the most significant medicines for each cluster, thereby providing insights about the common and distinct medicines administered to patients belonging to different clusters.

A. Identifying Anomalies within Clusters

The obtained SHAP values for patients' health conditions are now used to compute the anomaly score for each individual. Anomalous individuals - within a cluster who may demonstrate distinctive characteristics in terms of certain symptoms or response patterns, different from other members, should have higher scores. For a cluster C, the health condition anomaly score of a patient p is denoted by $\alpha_C(p)$ and computed as follows:

$$\alpha_C(p) = \sum_{h \in H} |\omega_h(p, C) * (m_h(C) - v_h(p))|,$$

where H denotes the set of all CUIs, $v_h(p)$ is either 1, 0, or -1 based on whether the symptom h is present for p or not, as described earlier, $m_h(C)$ is the median value of the symptom h in C and $\omega_h(p, C)$ denotes the SHAP value for symptom h for patient p with respect to C. $\alpha_C(p)$ is normalized for each cluster to keep the scores within 0 to 1. The higher anomaly score indicates that the patient is more distinctive from his/her neighbors.

Since the duration of sickness also varies largely among patients, a normalized anomaly score is also computed in terms of duration. For a patient p with duration of sickness d, the

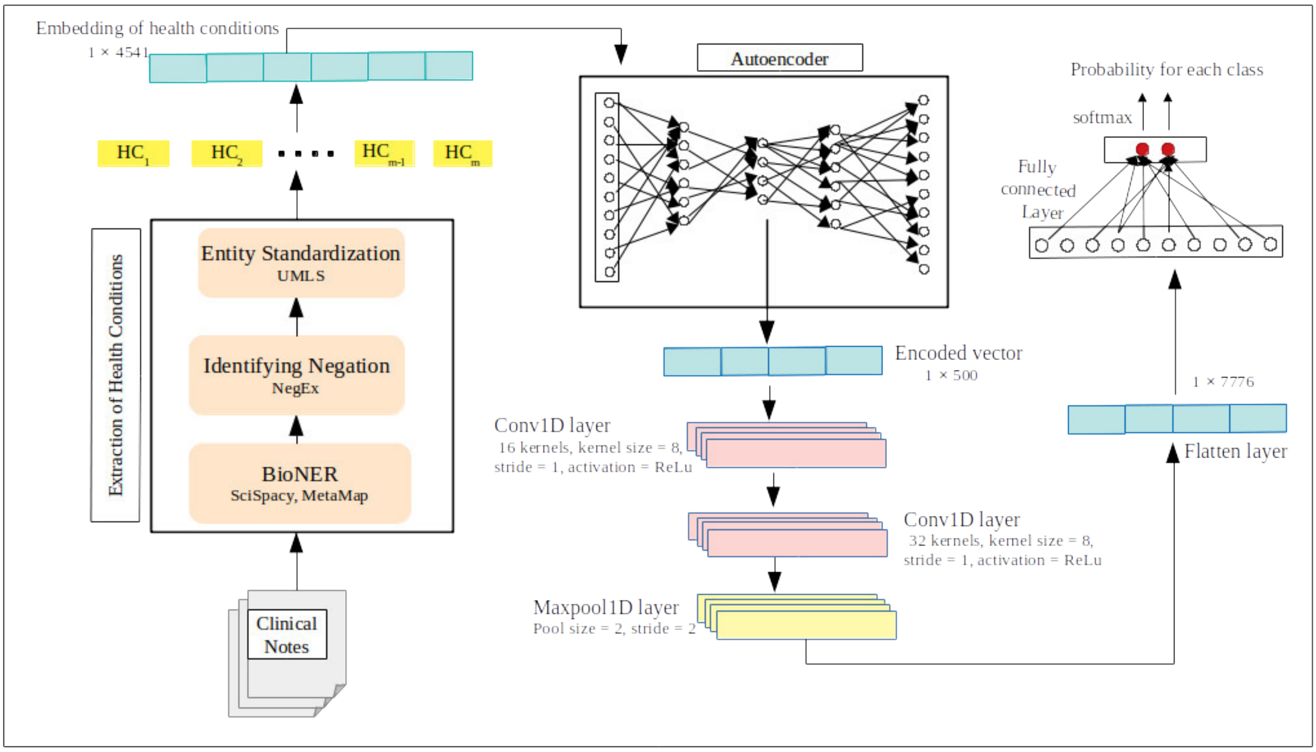

Fig. 3. Overview of the proposed framework for processing clinical notes, generating representations with an autoencoder, and subsequently applying CNN to predict hospitalization duration.

duration anomaly score denoted by $\gamma_C(p)$ with respect to other members of C is computed as follows :

$$\gamma_C(p) = |d - m_C| / \max_{i \in C} \gamma_C(i),$$

where m_C is the mode value of duration of disease for cluster C.

Absolute anomaly score $\chi(p)$ is computed using the following formula:

$$\chi_C(p) = 0.5 * \sqrt{\alpha_C(p)^2 + \gamma_C(p)^2},$$

This distributes the scores within the first quadrant of a unit circle, centered at the origin. The anomaly score is high for the set of points that are far away from the origin, the higher with the x and the y axes values providing insights about the symptom anomalies and duration anomaly respectively.

B. Assessing Causal effects of Significant Medications within Clusters

We further propose the use of causal analysis of clusters to analyze the effect of medications on patients. Causal analysis attempts to identify the effect of different treatments on groups of patients, based on observed outcomes. For patient stratification, the duration of sickness may be considered as an observed outcome, while medications or procedures are the treatment variables.

Causal analysis was done using the DoWhy package [47]. Given the diseases and symptoms as common cause variables, the duration of sickness as the outcome, and the medications as treatments administered, DoWhy generates an initial causal graph then estimands are identified using the graph. The final causal estimates are obtained using Propensity Score Weighting [48] as the estimator, and refutation as the validation technique. The causal estimates are validated using two different methods namely "adding random common cause" and "data subset validation" [49]. While the first method estimates the effect of a treatment by adding random independent variables, the second one does the same taking subsets of data. Either way, causal estimates are assumed to be good if the results don't show high perturbations, indicated by the p *value*.

VII. Results of Patient Stratification for Pneumonia Patients in MIMIC dataset

In this section, we present results for analyzing data of 2106 patients from the MIMIC-III v1.4 database [2], who were all admitted to the hospital and diagnosed as suffering from "Pneumonia", using the above methods. The intent was to:

(a) Obtain explainable clusters of patients based on their health conditions recorded in the first set of clinical notes on admission.

(b) Identify anomalies within each cluster and also generate explanations for the anomalous behaviors.

(c) Identify the significant medicines for each cluster using the SHAP values.

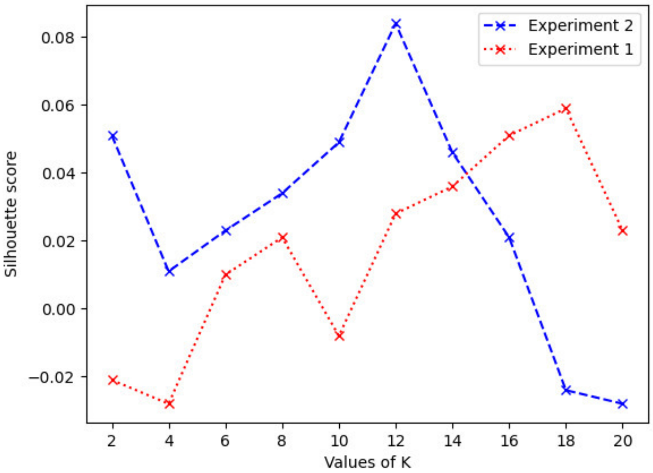

Fig. 4. Average silhouette scores for k = 2 to 20 for Experiment 1 (red) and Experiment 2 (blue).

(d) Study the causal effect of significant medicines on the duration of disease for the clusters.

As mentioned earlier, each of these patients had multiple clinical notes attached to them, approximately one per day of admission. The notes varied quite a bit in content. While some contained only incremental information, some were detailed and overlapped with earlier ones. A total of $23,737$ notes were obtained. After pre-processing all the notes as described in section V, a comprehensive list of 4800 unique health conditions was identified. Initially, the entire set of $23,737$ records was used to generate 500-dimensional autoencoded representations for the patients. However, the clustering results were not satisfactory. Hence, after some experimentation, this was changed to use only the first day's notes. The number of unique health status reduced to 2803. The 500 dimensional auto-encoders were then generated using the vectors for the first-day notes only. Figure 4 presents the average silhouette scores for k values ranging from 2 to 20 for both experiments. The best score was achieved for k equal to 12, using the second method. Figure 5 presents the distribution of these 12 clusters plotted using tSNE [50]. It shows that the clusters are fairly distinct and well-separated. Analysis of the SHAP summaries also revealed that the clusters were distinct and well-segregated from each other.

Since the trade names of drugs varied a lot, though their compositions were same, therefore the drugs corresponding to the notes were obtained from the database and mapped to their drug classes using the pre-trained *gpt-3.5-turbo* model [51]. However, the drug summaries generated by SHAP were not found to be very distinct from each other. This can be because the same drug might be prescribed for two different health conditions, or two different drugs might have been administered for the same health condition by different physicians. This needs to be analyzed in depth further, which remains a future task.

Figure 6 presents the SHAP summaries in terms of major health conditions present and absent, and the drugs identified for a few clusters. It shows that cluster 0 predominantly consists of patients suffering from *Endometriosis* and *Diabetes* along with pneumonia, and do not exhibit *Paroxysmal familial ventricular fibrillation*. Similarly, patients belonging to cluster 4 are found to suffer from *Lung consolidation* and do not have *Paroxysmal familial ventricular fibrillation*. Cluster 6 predominantly comprises patients with *Atrial Premature Complexes* and does not exhibit *Lung Consolidation* or *Paroxysmal familial ventricular fibrillation*. It may be observed that the most common co-morbidity was some or the other form of cardiac disease. The SHAP summary for drugs for clusters 0, 4, and 6, show that the most significant medicine administered to cluster 0 patients is *antidiabetic hormones*, which is obviously to handle diabetes, for patients of cluster is *proton pump inhibitor* and *hypoglycemic agent*, and the most prevalent medication for patients of cluster 6 is found to be *Vasopressor* which is for regulating blood pressure.

Anomaly scores revealed that the most anomalous patient in cluster 0 is a 67-year-old patient with a hospital stay of 62 days, deviating significantly from the cluster's mode value of 7 days. This anomaly can be attributed to the coexistence of Endometriosis, Paroxysmal familial ventricular fibrillation, and Acquired abnormality of atrium, a combination not observed in other members of this group. For cluster 4, while most patients were aged between 60 to 80, the most anomalous patient was a 33-year-old person who spent 81 days in the hospital, against the cluster mode value of 6 days. This person had all significant common symptoms of the cluster along with *Paroxysmal familial ventricular fibrillation*. The top two most anomalous persons of cluster 6 are aged 72 and 52 years, with 58 and 46 days of stays against cluster mode of 8 days. The anomalous symptom for the first person is *renal cyst*, while for the second patient, they are *lung consolidation* and *liver failure*. While most patients in this cluster are aged between 60 to 80, a third anomalous patient is aged 33 and suffered from multiple comorbidities but was admitted for only 3 days. Thus, it can be seen that the anomaly score is able to identify patients who are demographically outliers, even though age was not taken into account for computing the score.

Consequently, causal analysis was done for the drugs that were found to be significant for these clusters. For cluster 0, the effect of *antidiabetic hormone* is -0.459. The negative values indicate that these medicines contributed towards reduced duration of stay. Also, we have observed that this medicine is given 83% of short-stayed patients. On the other hand, the effect of *proton pump inhibitor* is 2.746 and this medicine is given to 89% of long-stayed patients. For cluster 4, the causal effect values of medicine *beta-blocker* was -2.7, for *Analgesic anti-platelet* it was -2.02, and for *Bronchodilator* it was -1.51, contributed towards in decreasing in the duration of hospital stay. *Opioid analgesic* had the highest positive value, indicating that this did not play a role in reducing the duration. For cluster 6, in which 84% of patients suffer from *arterial premature complexes*, medicines *Corticosteroid (-3.17), Anticonvulsant/ neuropathic pain agent (-3.02), Opioid*

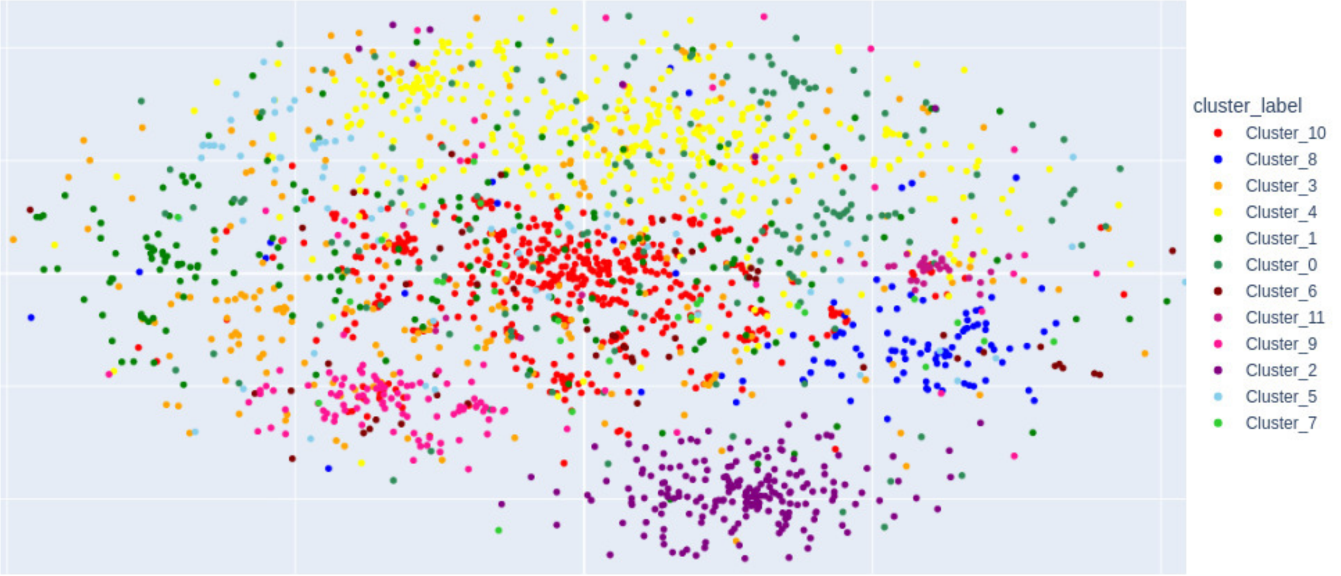

Fig. 5. t-SNE visualization of 12 clusters.

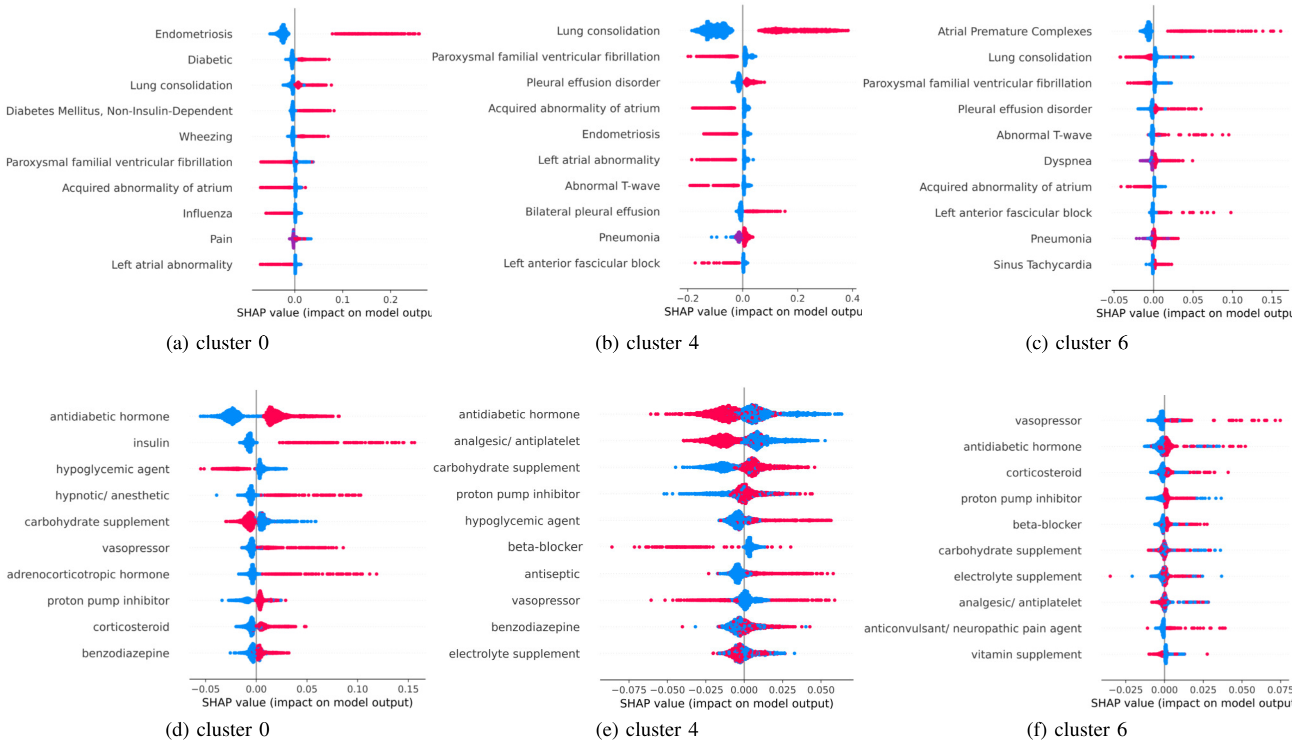
analgesic (-2.4), Vasopressor (-1.02) are found to causally reduce the duration of stay. Further analysis for cluster 6 reveals that 58% of patients with less than 6 days of hospital stay, 52% of those with 6 - 10 days, and 50% of those with higher than 10 days, were administered with *Corticosteroid* on the first day. The manual inspection also reveals that *Corticsteroid* was not administered to the top three anomalous patients, whose details were presented earlier, on the first day. Likewise, we conducted similar analyses for the remaining clusters. Though the exact implications of the results are best analyzed by healthcare experts, our analysis reveals that the results obtained from anomaly detection, their explanations, and causal analysis are all consistent with each other.

We also extracted the final recovery status of the patients from the discharge summaries. Based on the descriptions, we identified three major states at the time of discharge - (a). deceased patients, (b). patients whose vital signs were stable, could ambulate independently, and were coherent, (c). patients who were lethargic but mentally alert and ambulated with assistance. Figure 7 shows the distribution of the different clusters of patients identified earlier (based on their initial states) across these three categories. The top three categories of deceased patients are from clusters 7, 0 and 11, who suffered from comorbidities like ventricular hypertrophy, endometriosis or showed severe signs of edema. The results indicate that there is a need to look deeper into these cohorts, especially into the symptoms presented by the deceased patients. Comparative analysis of lengths of hospital admission for all patient clusters and deceased patients of each cluster are shown in Figure 8. It can be seen that the medians of the deceased patients for each cluster are almost same as those of other patients, which is around 10. While majority of the patients survived, a small percentage could not, and future work would be to delve deeper into the reasons for these differing outcomes. Superficial analysis at this point reveals that these patients had higher number of co-morbidities at admission time, some uncommon ones like *Septic embolus, Kidney Failure, AIDS-Associated Nephropathy, sepsis* etc. Data and the trajectory of treatment of these patients can be analyzed further to see what could have been done to ensure a positive outcome.

Figure 9 presents cluster-wise classification accuracy of predicting LOS for test patients, obtained by the classifier mentioned in section V-B. It is observed that there were no classification error for patients of cluster 6, which also incidentally had the least variation in terms of length of stay for patients as shown in 8. In future we would like to work on prediction of outcomes for patients within individual clusters. We are also exploring the role of SHAP values in explaining the prediction outcomes since though the LIME framework used earlier provides measure of associations between words and classes, it does not provide any explanation about why a particular class was assigned to an individual based on a collection of features.

VIII. Conclusion

Clinical notes are the backbone of healthcare systems. Well-written documents can provide valuable insights about diseases, patients and treatment effectiveness. They can provide a wealth of information about the similarities and diversity of situations across different situations. Deciphering the notes themselves however is a difficult problem due to the inherent variations in terms of style and content, which result from individual and organizational preferences. Obtaining these notes for analytical tasks is also a difficult problem. Though their utility is well-acknowledged, still these are not available in volumes that can help in designing machine-learning models for analyzing them. The key concerns are those of security



(a) cluster 0 (b) cluster 4 (c) cluster 6

(d) cluster 0 (e) cluster 4 (f) cluster 6

Fig. 6. SHAP values for Cluster 0, 4, and 6 of health conditions (top) and drugs (bottom). Red indicates high significance and blue low. Right side indicates presence and left side indicates absence of a feature.

and privacy violations. Various groups however have started reporting their work on proprietary data. While this does establish the legitimacy of the problem, it is often not easy to reproduce the results in another setting or conduct a comparative analysis of the results obtained. The MIMIC dataset available for researchers alleviates some of the problems. It is a fairly large dataset with substantial number of clinical notes associated with details about diseases, treatment and outcomes.

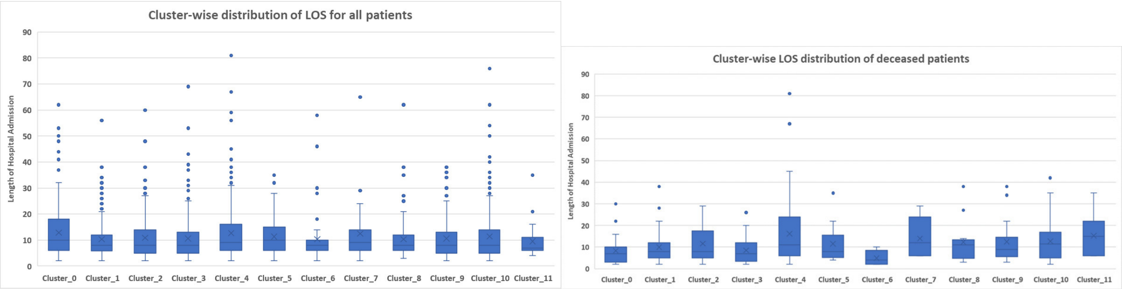

Fig. 8. (a) Clusterwise distribution of length of stay for all patients (b) Clusterwise distribution of length of stay for deceased patients.

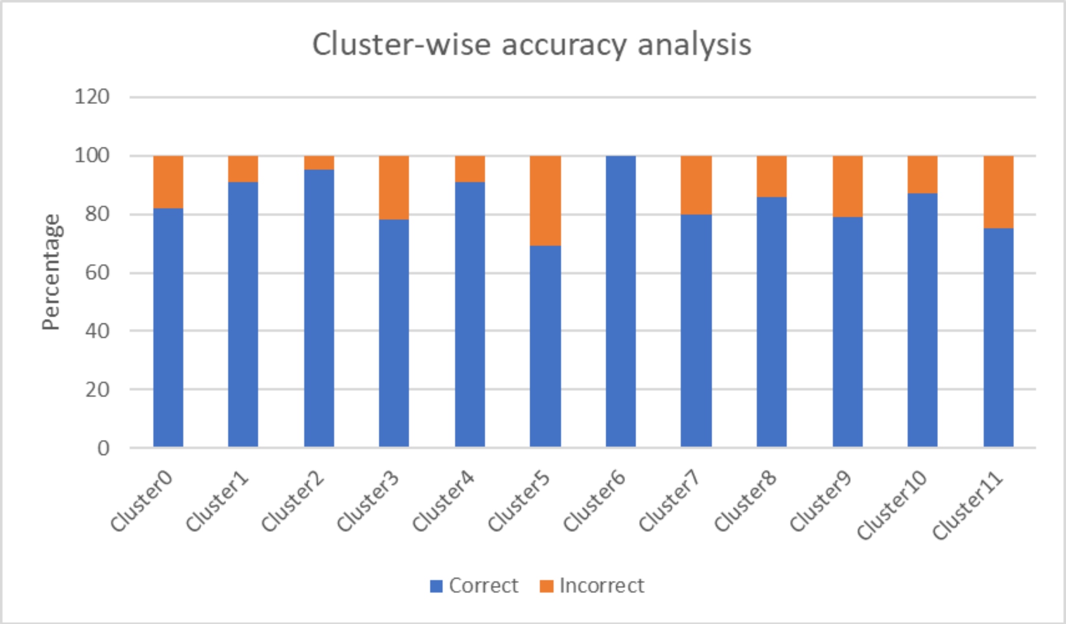

Fig. 9. Clusterwise accuracy of length of stay classification.

The use of clinical notes in predicting length of hospital admission, readmission possibilities, treatments as well as expected clinical outcomes has been prevalent for quite some time. Presently, the use of unstructured clinical notes is on the rise for development of prognostic prediction models. The focus is on developing explainable models. It is expected that robust and trustworthy prediction models will change the course of clinical practice as treatment procedures will move from majority focused designs to more customized designs.

In this paper, we have presented some initial work that we have started for explainable patient stratification. We have shown that deep learning based representations can effectively capture the richness of clinical notes and thereby be used to provide valuable insights about patient cohorts as well as exceptions within them. In future, we intend to extend our work in generating complete trajectories using the proposed representations. These trajectories in conjunction with the outcomes can help in risk assessment for patients, and thereby help in steering towards low-risk trajectories, especially for patients who are outliers.

***Abstract*—Artificial intelligence (AI) has been advancing at a fast pace and it is now poised for deployment in a wide range of applications, such as autonomous systems, medical diagnosis and natural language processing. Early adoption of AI technology for real-world applications has not been without problems, particularly for neural networks, which may be unstable and susceptible to adversarial examples. In the longer term, appropriate safety assurance techniques need to be developed to reduce potential harm due to avoidable system failures and ensure trustworthiness. Focusing on certification and explainability, this paper provides an overview of techniques that have been developed to ensure safety of AI decisions and discusses future challenges.**

I. Introduction

ARTIFICIAL intelligence (AI) has advanced significantly in recent years, largely due to the step improvement enabled by deep learning in data-rich tasks such as computer vision or natural language processing. AI technologies are being widely deployed and enthusiastically embraced by the public, as is evident from the take up of ChatGPT and Tesla. However, deep learning lacks robustness, and neural networks (NNs), in particular, are unstable with respect to so called *adversarial perturbations*, often imperceptible modifications to inputs that can drastically change the network's decision. Many such examples have been reported in the literature and the media. Figure 1 (left) shows a dashboard camera image from [1], for which a change of a single pixel to green changes the classification of the image from red traffic light to green, which is potentially unsafe if there is no fallback safety measure; while this is arguably an artificial example, some modern cars have been observed to mis-read traffic signs, including the physical attack in Figure 1 (middle), where the digit 3 has been modified. Traffic sign recognition is a complex problem to specify and solve, see Figure 1 (right), which shows a real traffic sign in Alaska. As with any maturing technology, it is natural to ask if AI is ready for wide deployment, and what steps – scientific, methodological, regulatory, or societal – can be taken to achieve its trustworthiness and reduce potential for harm through rushed roll-out. This is particularly important given the fast-paced development of AI technologies and the natural propensity of humans to overtrust automation.

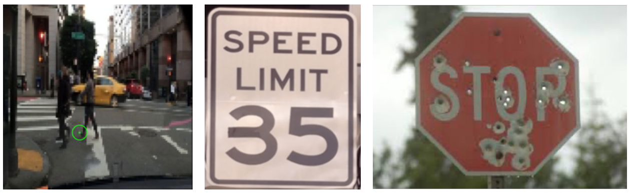

Fig. 1: Challenges of safe traffic sign recognition. Single-pixel adversarial attack from [1] (left), physical attack (middle) and a real traffic sign (right).

For AI to be trusted, particularly in high-stakes situations, where avoidable failure or wrong decision can lead to harm or high cost being incurred, it is essential to provide *provable guarantees* on the critical decisions taken autonomously by the system. Traditionally, for software systems this has been achieved with *formal verification* techniques, which aim to formally prove whether the system satisfies a given specification, and if not provide a diagnostic counter-example. Founded on logic, automated verification, also known as model checking, achieves this goal by means of executing a verification algorithm on a suitably encoded model of the system. Software verification has become an established methodology and a variety of tools of industrial relevance are employed in application domains such as distributed computation, security protocols or hardware. Beginning with [2], [3], over the past few years a number of formal verification techniques have been adapted to neural networks, which are fully data-driven and significantly differ from the state-based transition system models of conventional software, and have given rise to practical, algorithmic techniques that provide provable guarantees on neural network decisions [4].

This paper aims to provide an overview of existing techniques that can be used to increase trust in AI systems and outline future scientific challenges, while at the same time raising awareness of potential risks with early adoption. It is taken as granted that safety assurance of AI systems is complex and needs to involve appropriately regulated processes and assignment of accountability. The topics discussed in this paper are by no means exhaustive, but offer a representative selection of techniques and tools that can be used within such safety assurances processes, and can be adapted, extended or built upon to increase robustness and trustworthiness of AI systems. The paper will focus on highlighting the following two aspects:

- **Certification**: focusing on individual decisions (possibly critical to the integrity of the system) that are made by neural networks, we provide an overview of the main methodological approaches and techniques that have been developed to obtain provable guarantees on the correctness of the decision, which can thus be used for certification. The sources of computational complexity of neural network verification will be discussed, as well as limitations of existing methods and ways to address them.
- **Explainability**: neural networks are 'black boxes' that are trained from data using obscure optimization processes and objectives, and it is argued that users of AI systems will benefit from the ability to obtain explanations for the decisions. We summarise the main approaches to producing explanations and discuss that they may lack robustness and how this issue can be addressed.

The overview includes high-level description of main algorithms, which are illustrated by worked examples to explain their behaviour to the interested reader. This is followed by a selection of case studies of robustness analysis and/or certification drawn from a variety of application domains, with the aim to highlight the strengths and weaknesses of the approaches. Finally, future challenges and suggestions for fruitful directions to guide the developments in this actively studied and important area will be outlined.

The paper is organised as follows. Section II introduces the main concepts, focusing on neural networks in the supervised learning setting. Section III provides an overview of the main (forward and backward) analysis approaches, with a description of the working for a selection of algorithms illustrated by worked examples. Section IV includes a few excerpts from a selection of verification and certification experiments, aimed at highlighting the uses of the main methods, and Section V outlines future challenges. Finally, Section VI concludes the paper.

II. Safety, Robustness and Explainability

In the context of safety-critical systems, safety assurance techniques aim to prevent, or minimise the probability of, a hazard occurring, and appropriate safety measures are invoked in case of failures. In this paper, we focus on critical decisions made by neural networks, which we informally refer to as safe if they satisfy a given property, which can be shown or disproved by formal verification. Before discussing formal verification techniques, we begin with background introduction to the main concepts of deterministic neural networks, their (local) robustness and explanations.

A. Neural Networks

We consider neural networks in the supervised learning setting. A neural network is a function $f : \mathbb{R}^n \to \mathbb{R}^m$ mapping from the input space to the output space, which is typically trained based on a dataset $\mathcal{D}$ of pairs (x, y) of input x and ground truth label y. A neural network consisting of $L+1$ layers (including the input layer) can be characterized by a set of matrices $\{W^{(i)}\}_{i=1}^L$ and bias vectors $\{b^{(i)}\}_{i=1}^L$ for linear (affine) transformations, followed by pointwise activation functions, such as $ReLU$, $Sigmoid$, and $Tanh$, for nonlinear transformations. We use $\hat{z}^{(i)}$ and $z^{(i)}$ to denote the pre-activated and activated vectors of the i-th layer, respectively. The layer-by-layer forward computation of neural networks can be described as follows:

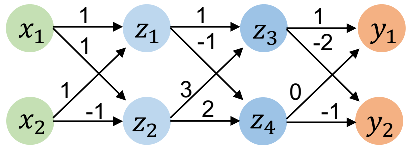

Fig. 2: A feed-forward neural network.

- *Linear transformation.* The linear transformation generates a pre-activated vector $\hat{z}^{(i)} = W^{(i)} \cdot z^{(i-1)} + b^{(i)}$ $(i \in [1, L])$ from the output of the previous layer, and $z^{(0)} = x$ denotes the input vector.
- *Pointwise nonlinear transformation.* The pointwise nonlinear transformation generates the activation vector $z^{(i)} = \sigma(\hat{z}^{(i)})$ $(i \in [1, L])$. In practice, $softmax$ is usually employed as the activation function for the output layer in classification tasks, which provides the normalised relative probabilities of classifying the input into each label.

Given an input $x \in \mathbb{R}^n$, the output of f on x is defined by $f(x) = f^{(L)} \circ \cdots \circ f^{(1)}(x)$, where $f^{(i)}$ denotes the mapping function of the i-th layer, which is the composition of linear and pointwise nonlinear transformations.

Example 1. *Figure 2 shows a simple feed-forward (and fully connected (FC)) neural network with four layers and ReLU as the activation function. x_1, x_2 represent two input neurons. z_1, z_2 and z_3, z_4 represent the activated neurons of the two hidden layers. y_1, y_2 are two output neurons. The forward computation from the input layer to the output layer is as follows (ReLU is denoted as σ).*

$$z_1 = \sigma(x_1 + x_2), \quad z_2 = \sigma(x_1 - x_2) \tag{1}$$

$$z_3 = \sigma(z_1 + 3z_2), \quad z_4 = \sigma(-z_1 + 2z_2) \tag{2}$$

$$y_1 = z_3, \quad y_2 = -2z_3 - z_4 \tag{3}$$

We will use this neural network as a running example to illustrate different problem formulations and methods to address them.

B. Robustness

Robustness focuses on neural networks' resilience to adversarial attacks, noisy input data, etc., at test time, known as evasion attacks [6], [7], [8]. Attacks at training time are known as poisoning attacks [9], which have been omitted from this overview.

Adversarial robustness [7] of neural networks formalizes the desirable property that a well-trained model makes consistent predictions when its input data point is subjected to

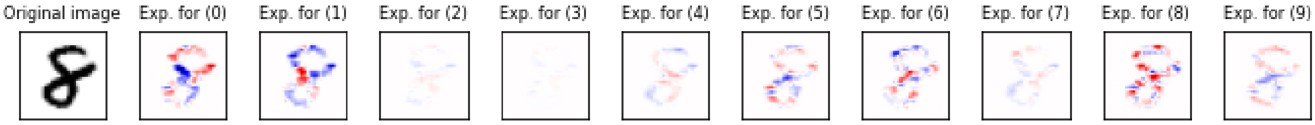

Fig. 3: The IG explanation for each of the classes of the MNIST dataset, where red indicates a positive contribution and blue a negative. Figure taken from [5].

small adversarial perturbations. *Local (adversarial) robustness* pertains to a given input point x with ground truth label y, and is usually defined in terms of invariance of the network's decision within a small neighbourhood $\mathbb{B}_p(x,\epsilon)$ of x, for a class of perturbations bounded by ϵ with respect to the ℓ_p norm.

Definition 1. *Given a (deterministic) neural network f, a labelled input data point (x, y), and a perturbation bound ϵ, the local robustness property of f on x is defined as*

$$\forall x' \in \mathbb{B}_p(x,\epsilon).\ \arg\max_{i=1,\cdots,m} f_i(x') = y,$$

where $\mathbb{B}_p(x,\epsilon)$ denotes the adversarial ℓ_p-ball of radius ϵ around input x.

Should there exist a point x' in the neighbourhood whose class is different than y, it is referred to as an *adversarial example*.

A related concept is that of a *maximal safe radius (MSR)* [10], denoted $MSR(x)$, which is the minimum distance from $x \in \mathbb{R}^n$ to the decision boundary, and is defined as the largest $\epsilon > 0$ such that $\forall x' \in \mathbb{B}_p(x,\epsilon).\ \arg\max_{i=1,\cdots,m} f_i(x') = \arg\max_{i=1,\cdots,m} f_i(x)$. Computing the value of MSR, say γ, provides a *guarantee* that the decision is robust (safe) for perturbations up to γ. On the other hand, finding an adversarial example at distance γ' is witness to the failure of robustness.

Global robustness [11] concerns the stability of predictions over the whole input space and is omitted.

C. Explainability

Explainability [12], [13] aims to understand and interpret why a given neural network makes certain predictions. The term explainability is often used interchangeably with interpretability in the literature, though interpretability usually refers to explaining how the model works. In this overview, we focus on local (pointwise) explainability for an individual *model decision*, which is categorised into *feature attribution* methods, which heuristically estimate feature attribution scores for model predictions and include *gradient-based* [14], [15] and *perturbation-based* techniques [16], [17], and *abduction-based* methods [18], [19], which identify the features that imply the decision and can thus provide (safety) guarantees. Attribution scores can also be used for feature importance ranking [20] to provide an overall understanding of the importance of different input attributes on the model decisions.

1) Gradient-based methods: Gradient-based methods aim to estimate feature attribution scores for model predictions. Among these, a prominent method is the integrated gradients (IG) [15], which measures the attribution score of each input feature to the model's prediction by integrating the gradients of the model's output with respect to the input features along the path from a baseline input to the actual input.

Definition 2. *Given a neural network f, an input x and a baseline input x', the integrated gradients for each input feature $i \in [1,\cdots,n]$ are defined as the weighted (by input feature difference) integral of the gradients over the straight line path between x and x':*

$$IG_i(x) = (x_i - x'_i) \times \int_{\alpha=0}^{1} \frac{\partial f(x' + \alpha \times (x - x'))}{\partial x_i} d\alpha \quad (4)$$

Figure 3 from [5] presents an illustrative example of IG explanations, showing the explanation for each class of a correctly classified handwritten-digit “8” from the MNIST dataset. In this example, positive contributions are highlighted in red, while negative contributions are indicated by blue.

2) Perturbation-based methods: LIME [16] and its successor Anchors [17] are representatives of explainability methods that deploy a perturbation-based strategy to generate local explanations for model predictions. LIME assumes local linearity in a small area around an input instance and generates a set of synthetic data by perturbing the original input. Anchors [17] explains the model predictions by identifying a set of decision rules that “anchors” the prediction. Compared with LIME, Anchors generates more explicit decision rules and derives local explanations by consulting x's perturbation neighbourhood in different ways. In particular, Anchors evaluates the coverage fraction of the perturbed data samples sharing the same class as x, matching the decision rules.

3) Robust explanations: The explanation techniques mentioned above use different heuristics to derive local explanations, demonstrating effective generality beyond the given input but lacking robustness to adversarial perturbations. The robustness notion for explanation is important to ensure the stability of the explanation in the sense that the explanation is logically sufficient to imply the prediction. Intuitively, the computed explanation for a perturbed input should remain the same as the original input.

To this end, [18], [19] introduce a principled approach to derive explanations with formal guarantees by exploiting abduction reasoning. This ensures the robustness of the explanation by requiring its invariance w.r.t. any perturbation of the remaining features that are left out. The explanation method of [19] focuses on *optimal robust explanations (OREs)*, to provide both robustness guarantees and optimality w.r.t. a cost function. Optimality provides the flexibility to control the desired properties of an explanation. For instance, the cost function could be defined as the length of the explanation to derive minimal but sufficient explanations.

III. Certification for Neural Networks

In this section, we present an overview of recent advances for certification of neural networks, with a focus on formal verification. Given a neural network $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$, we consider the formal verification problem [4], defined for a property specified as a pair $(\phi_{\mathsf{pre}}, \phi_{\mathsf{post}})$ of precondition and postcondition, by requiring that $\forall x \in \mathbb{R}^n. x \models \phi_{\mathsf{pre}} \implies f(x) \models \phi_{\mathsf{post}}$, that is, for all inputs satisfying the precondition the corresponding (optimal softmax) decision must satisfy the postcondition. Typically, $\phi_{\mathsf{pre}} \subseteq \mathbb{R}^n$ and $\phi_{\mathsf{post}} \subseteq \mathbb{R}^m$, but can be respectively induced from subsets of input features or sets of labels. Formal verification then aims to establish algorithmically whether this property holds, thus resulting in a *provable guarantee*. Otherwise, the property may be falsified, in which case a witness is provided, or inconclusive. Sometimes, we may wish to compute the proportion of inputs that satisfy the postcondition, known as *quantitative verification* [21].

Various formal verification methods have been proposed to provide provable guarantees for neural networks. We classify existing verification methods into forward and backward analysis, depending on whether they start from the input or output space.

- *Forward analysis:* Forward analysis methods start from the precondition $X = \{x \in \mathbb{R}^n \mid x \models \phi_{\mathsf{pre}}\}$ defined on the input space, and check whether the outputs (corresponding to the input region) satisfy the postconditions ϕ_{post}. For example, robustness verification approaches [22], [23], [24], [25] start from the perturbation neighbourhood of a given input, e.g., an l_∞ ball around an input point x, and compute bounds on the outputs to check whether the predicted labels over the adversarial region are preserved.
- *Backward analysis:* Backward analysis methods start from the postcondition $Y = \{y \in \mathbb{R}^m \mid y \models \phi_{\mathsf{post}}\}$ and aim to find the set of inputs that lead to such outputs. For example, preimage generation (inverse abstraction) approaches [26], [27], [28], [29] start from the output constraints, e.g., a polytope constraining the probability of the target label is greater than the other labels, and derive the input set that provably leads to this particular decision.

We remark that, similarly to formal verification for conventional software, certification for machine learning models is computationally expensive, and it is therefore recommended for use in safety- or security-critical settings. In less critical situations, diagnostic methods [30], which approximate model decisions to analyse their predictions, can be employed to investigate both model- and data-related issues.

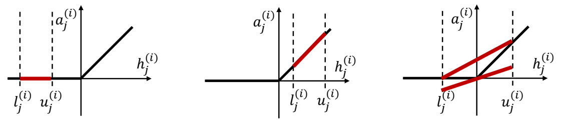

Fig. 4: Illustration of the convex relaxation for inactive (left), active (middle) and unstable (right) ReLU neurons.

A. Forward Analysis Methods

We categorize the forward analysis methods into two groups: *sound but incomplete* and *complete* methods. Soundness and completeness are essential properties of verification algorithms, which are defined as follows.

- *Soundness:* A verification algorithm is sound if the algorithm returns True and the verified property holds.
- *Completeness:* A verification algorithm is complete if (i) the algorithm never returns unknown; and (ii) if the algorithm returns False, the property is violated.

1) Incomplete methods: Incomplete verification methods leverage approximation techniques, such as search [1], [10], convex relaxation [31] and abstract interpretation [32], respectively to compute lower/upper bounds on MSR or the non-convex optimization problem. A safety property is verified when the reachable outputs satisfy the postcondition; otherwise, no conclusion can be drawn. At the same time, due to the relaxation introduced by the approximation techniques, incomplete methods have better scalability than complete ones.

a) Game-based search: Knowledge of the maximum safe radius (MSR) can serve as a guarantee on the maximum magnitude of the allowed adversarial perturbations. Unfortunately, MSR computation is intractable, and instead approximate algorithms have been developed for images in [10], and extended to videos in [33], that compute lower and upper bounds on MSR with provable guarantees, i.e., bounded error. The method relies on the network satisfying the Lipschitz condition and can be configured with a variety of feature extraction methods, for example SIFT. Given an over-approximation of the Lipschitz constant, the computation is reduced to a finite optimization over a discretisation of the input region X corresponding to the precondition ϕ_{pre}. The resulting finite optimization is solved in anytime fashion through a two-player game, where player 1 selects features and player 2 perturbs the image representation of the feature, and the objective is set to minimise the distance to an adversarial example. Under the assumptions, the game can be unfolded into a finite tree and Monte Carlo Tree Search (MCTS) used to approximate MSR upper bound, and Admissible A* MSR lower bound, respectively.

b) Bound propagation: A common technique for incomplete verification is applying convex relaxation to bound nonlinear constraints in neural networks. This way, the original non-convex optimization problem is transformed into a linear programming problem. With the relaxed linear constraints, the global lower and upper bounds can be computed more

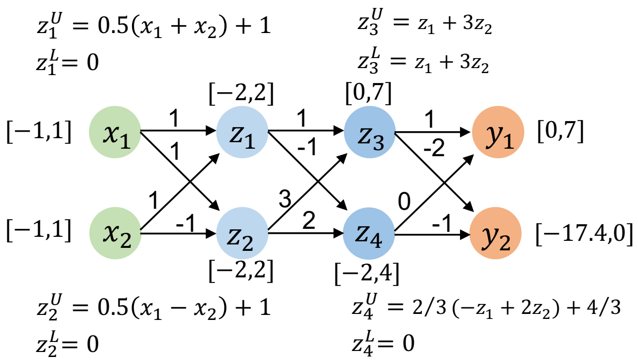

Fig. 5: Verification via bound propagation.

efficiently for the associated (relaxed) linear program. Representative methods that adopt efficient bound propagation include convex outer adversarial polytope [31], CROWN [34] and its generalization [35], [25]. Figure 4 illustrates convex relaxation using linear bounding functions to bind ReLU neurons. Note that relaxation is only introduced for unstable neurons, while the ReLU constraints for inactive and active ones are exact. For unstable neurons, the lower and upper bounding function for the j-th neuron of the i-th layer $a_j^{(i)}(x)$ (activated value) with regard to $h_j^{(i)}(x)$ (before activation) are:

$$\alpha_j^{(i)} h_j^{(i)}(x) \leq a_j^{(i)}(x) \leq -\frac{u_j^{(i)} l_j^{(i)}}{u_j^{(i)} - l_j^{(i)}} + \frac{u_j^{(i)}}{u_j^{(i)} - l_j^{(i)}} h_j^{(i)}(x) \quad (5)$$

where a flexible lower bound function with parameter $\alpha_j^{(i)}$ as in [35] is used, which leads to a valid lower bound for any parameter value within $[0, 1]$.

By propagating the linear (symbolic) upper and lower bounds layer by layer, we can obtain the linear bounding functions f^L, f^U for the entire neural network f, and it holds that $\forall x \in X.\, f^L(x) \leq f(x) \leq f^U(x)$. The non-convex verification problem is thus transformed into a linear program with the objective linear in the decision variables. The certified upper and lower bounds can be computed by taking the maximum, $\max_{x \in \mathbb{B}_p(x,\epsilon)} f^U(x)$, and the minimum, $\min_{x \in \mathbb{B}_p(x,\epsilon)} f^L(x)$, which have *closed-form* solutions for linear objectives (f^U, f^L) and convex norm constraints $\mathbb{B}_p(x, \epsilon)$.

Example 2. *Consider the neural network illustrated in Example 1. The verification problem we consider is given by the pre-condition* $\phi_{\text{pre}} = \{x \in \mathbb{R}^2 | x \in [-1, 1] \times [-1, 1]\}$ *and the post-condition* $\phi_{\text{post}} = \{y = f(x) \in \mathbb{R}^2 \mid y_1 \geq y_2\}$, *and we want to prove that* $\forall x.\, x \models \phi_{\text{pre}} \implies f(x) \models \phi_{\text{post}}$.

Figure 5 shows the overall bound propagation procedure for this verification problem, where the interval $[\cdot, \cdot]$ *represents the concrete value range computed for each neuron.* z_i^U, z_i^L *represent the linear upper and lower bounding functions for nonlinear neurons, which are computed according to Equation 5 based on the concrete value intervals. Starting from the input layer, we can first compute the concrete bounds (*$[-2, 2]$*) for* z_1 *and* z_2 *(before activation). The bounding functions* (z_1^L, z_1^U), (z_2^L, z_2^U) *are then computed according to Equation 5, where* $\alpha = 0$ *is taken as the lower bounding function coefficient. The linear bounding functions can directly propagate to the next layer via the linear matrix transformation. Then, by taking the minimum value of the lower bounding function and the maximum of the upper one, concrete value ranges (*$[0, 7]$ *and* $[-2, 4]$*) are computed for* z_3 *and* z_4*, based on which symbolic functions* (z_3^L, z_3^U), (z_4^L, z_4^U) *can be derived and further propagated to the output layer. In the end, we compute the global lower and upper bounds for* y_1 *and* y_2*, which are* $[0, 7]$ *and* $[-17.4, 0]$*, respectively. From the certified bounds on the output layer, it holds that* $\min(y_1) \geq \max(y_2)$ *for any input* $(x_1, x_2) \in [-1, 1] \times [-1, 1]$*. Therefore, the bound propagation method certifies that the neural network is robust in the input domain with respect to the ground-truth label* y_1.

c) Abstract interpretation: Abstract interpretation [32], [36] is a classic framework that can provide sound and computable finite approximations for infinite sets of behaviours. To provide sound analysis of neural networks, several works [22], [37], [38], [24] have exploited this technique to reason about safety properties. These methods leverage numerical abstract domains to overapproximate the inputs and compute an over-approximation of the outputs layer by layer. To this end, an abstract domain is selected to characterize the reachable output set for each layer as an abstract element. The choice of abstract domain is essential to balance the analysis precision and scalability. Commonly used abstract domains for neural network verification [39] include *Interval*, *Zonotope*, and *Polytope*, of which the general formulations are summarized in the following (increasing in precision):

$$\text{Interval:} \quad \{x \in \mathbb{R}^n | l_i \leq x_i \leq u_i\}$$

$$\text{Zonotope:} \{x \in \mathbb{R}^n | x_i = c_{i0} + \sum_{j=1}^{m} c_{ij} \cdot \epsilon_j, \epsilon_j \in [-1, 1]\}$$

$$\text{Polytope:} \{x \in \mathbb{R}^n | x_i = c_{i0} + \sum_{j=1}^{m} c_{ij} \cdot \epsilon_j, F(\epsilon_1, \cdots, \epsilon_m)\}$$

where ϵ_j ($j = 1, \cdots, m$) denote m generator variables. The generator variables are bounded within the interval $[-1, 1]$ for zonotopes and constrained by F for polytopes, where F takes in the form of a convex polytope $\mathbf{c}\mathbf{x} \leq \mathbf{d}$.

With the abstract domain capturing the reachable outputs of each layer, abstract transformers are defined to compute the effect of different layers on propagating the abstract element. Affine transformers are usually supported by the underlying abstract domain, such as Zonotope and Polytope, to abstract the linear functions. For nonlinear functions, case splitting and unifying is proposed in [22] by defining the *meet* and *join* operators to propagate zonotope abstraction through piecewise-linear layers. Convex approximations are adopted in [24] for abstract transformers of nonlinear functions where the approximation can be captured with the proposed polyhedra abstraction. At the end of the analysis, the abstract element of the output layer is an over-approximation of all possible concrete outputs corresponding to the input set. Then we can directly verify the over-approximation of the outputs against the postcondition ϕ_{post}, i.e., check whether the over-approximation is fully contained within ϕ_{post}. One drawback of this method is that the over-approximation may be quite loose.

2) Complete methods: Early complete verification approaches for neural networks [40], [3] encode the neural network into a set of constraints exactly and then check the satisfaction of the property with constraint solvers, e.g, SMT (Satisfiability Modulo Theory) or MILP (Mixed Integer Linear Programming) solvers. Since such constraint-solving methods encode the neural network in an exact way, they are able to ensure both soundness and completeness in providing certification guarantees. One limitation is that these methods suffer from exponential complexity in the worst case. To address the computational intractability, Branch and Bound techniques are adopted and customized for neural network verification, where efficient incomplete methods can be exploited to speed up the bound computation.

a) SMT solver: Reluplex [3] is proposed as a customized SMT solver for neural network verification. The core idea is to extend the simplex algorithm, a standard algorithm to solve linear programming problems, with additional predicates to encode (piecewise linear) ReLU functions and transition rules (*Pivot* and *Update*) to handle ReLU violations. The extended Reluplex algorithm allows variables that encode ReLU nodes to temporarily violate the ReLU constraints. Then, as the iteration proceeds, the solver picks variables that violate a ReLU constraint and modifies the assignment to fix the violation using *Pivot* and *Update* rules. When the attempts to fix a ReLU constraint using *Update* rules exceed a threshold, a ReLU splitting mechanism is applied to derive two sub-problems. Reluplex is then invoked recursively on these two sub-problems. Compared with the eager splitting on all ReLU neurons, Reluplex proposes a splitting-on-demand strategy to reduce unnecessary splitting and limit splits to ReLU constraints that are more likely to cause violation problems. Due to the exact encoding nature, Reluplex suffers from exponential complexity in the worst case and thus cannot scale to large neural networks.

b) MILP: MILP-based verification methods [41], [42], [43] encode a neural network with piecewise-linear functions as a set of mixed integer linear constraints. To encode the nonlinearities, they introduce an indicator decision variable δ to characterize the two statuses of unstable ReLU neurons. An unstable ReLU neuron $z = \max(\hat{z}, 0)$ with concrete bounds (l, u) can be encoded exactly using the following constraints:

$$\begin{aligned} & z \geq 0, \quad z \leq u \cdot \delta, \\ & z \geq \hat{z}, \quad z \leq \hat{z} - l \cdot (1 - \delta), \\ & \delta \in \{0, 1\} \end{aligned}$$

Note that the MILP constraints require the pre-computation of finite bounds for the nonlinear neurons, i.e., (l, u). It is known that the tightness of lower and upper bounds in the indicator constraints is crucial to the resolution of the MILP problem [44], [42], and consequently, the verification efficiency. MIPVerify [43] thus proposes a progressive bound tightening approach to improve upon existing MILP-based verifiers. The algorithm starts with coarse bounds computed using efficient bound computation procedures such as *Interval Arithmetic*. Bound refinement is performed only when the MILP problem can be further tightened. In such a case, more precise but less efficient bound computation procedures, e.g., *Linear Programming* (LP), are adopted to derive tighter bounds. This progressive bounding procedure can also be extended to other bound computation methods, such as dual optimization, to achieve a trade-off between tightness and computational complexity.

Example 3. *In this example, we encode the neural network, shown in Example 1, into the exact MILP formulation. The verification problem is the same as shown in Example 2, i.e., to determine whether $\phi_{\text{post}} = \{y \in \mathbb{R}^2 \mid y_1 \geq y_2\}$ holds for all inputs in the input domain $[-1, 1] \times [-1, 1]$. We encode the output property by specifying its negation, i.e., $\phi'_{\text{post}} = \neg\phi_{\text{post}}$. If there exists an instance where ϕ'_{post} does hold, then a witness to ϕ'_{post} is the counter-example for ϕ_{post}. If ϕ'_{post} is unsatisfiable, then the property ϕ_{post} is proved.*

Assume we have computed the concrete value of lower and upper bounds of z_i employing efficient bound propagation techniques. Then the neural network and the verification problem can be formulated as follows:

$$x_1 \geq -1,\, x_1 \leq 1,\, x_2 \geq -1, x_2 \leq 1\, (\phi_{\text{pre}}) \tag{6}$$

$$\hat{z}_1 = x_1 + x_2, \quad \hat{z}_2 = x_1 - x_2, \quad \delta_1, \delta_2 \in \{0, 1\} \tag{7}$$

$$z_1 \geq 0,\, z_1 \leq 2\delta_1,\, z_1 \geq \hat{z}_1,\, z_1 \leq \hat{z}_1 + 2(1 - \delta_1), \tag{8}$$

$$z_2 \geq 0,\, z_2 \leq 2\delta_2,\, z_2 \geq \hat{z}_2,\, z_2 \leq \hat{z}_2 + 2(1 - \delta_2), \tag{9}$$

$$\hat{z}_3 = z_1 + 3z_2, \quad \hat{z}_4 = -z_1 + 2z_2, \quad \delta_4 \in \{0, 1\} \tag{10}$$

$$z_3 = \hat{z}_3, \textit{(stable neuron)} \tag{11}$$

$$z_4 \geq 0,\, z_4 \leq 4\delta_4,\, z_4 \geq \hat{z}_4,\, z_4 \leq \hat{z}_4 + 2(1 - \delta_4), \tag{12}$$

$$y_1 = z_3, \qquad y_2 = -2z_3 - z_4 \tag{13}$$

$$y_1 < y_2\, (\neg\phi_{\text{post}}) \tag{14}$$

The lower and upper bounds l_i and u_i ($i \in \{1, 2, 3, 4\}$) are derived as shown in Example 2. The binary variables δ_i ($i \in \{1, 2, 4\}$) are introduced to indicate the status of unstable ReLUs and it holds that $\delta_i = 0 \Leftrightarrow z_i = 0$ and $\delta_i = 1 \Leftrightarrow z_i = \hat{z}_i$. Checking the feasibility of the above model using MILP solvers (e.g., Gurobi) will return infeasible, thus proving the original property.

c) Branch and Bound: To improve the scalability of verification algorithms to larger neural networks, a branch and bound framework (BaB) [45] has been proposed. The BaB framework mainly consists of two components: a branching method that splits the original verification problem into multiple subproblems and a bounding method to compute the upper and lower bounds of the subproblems. This modularized design provides a unifying formulation paradigm for different verifiers, with the main difference lying in the splitting function and the bounding method. For example, the verifier

ReluVal [46] performs splitting on the input domain according to sensitivity analysis, e.g., input-output gradient information, and computes bounds using symbolic interval propagation. The aforementioned SMT-based verifier *Reluplex* [3] performs splitting on ReLU neurons guided by the violation frequency of the ReLU constraints and computes the bounds on the relaxed problems by dropping some constraints on the nonlinearities (which yields an over-approximation of the constraint optimization problems).

To further improve neural network verification, the BaB method introduces two new branching strategies: BaBSB for branching on input domains and BaBSR for branching on ReLU neurons. Both branching methods adopt a similar heuristic to decide which dimension or ReLU neuron to split on. BaBSB computes a rough estimate of the improvement on the bounds obtained with regard to every input dimension, where the estimation makes the split decision be set more efficiently. On the other hand, BaBSR estimates the bound improvement with regard to each unfixed ReLU neuron by computing the ReLU scores. The bounding methods resort to LP solvers to tighten the intermediate bounds on the subdomains or use more computationally efficient methods such as Interval Arithmetic.

B. Backward Analysis Methods

Backward analysis methods for neural networks, also known as preimage generation or inverse abstraction, aim at computing the input set that will lead the neural network to a target set, e.g., a safe or unsafe region. They complement the forward analysis methods, which may result in over-approximated bounds worsening as the computation progresses through the layers of the network. In the following, we categorize the representative approaches broadly into two groups: *exact* and *approximate* methods.

1) Exact methods: Exact backward analysis methods reason about the preimage of a target output set by encoding the neural network behaviours in an exact manner. These methods are able to compute the exact symbolic representation of the preimage for different output properties. One limitation suffered by these methods is that they can only process neural networks with piecewise-linear activation functions (e.g., $ReLU$), as they aim at an exhaustive decomposition of the non-convex function (the neural network) into a set of linear functions. The preimage (input set) for a target output set with regard to a neural network f is characterized as a union of polytopes, where the mapping functions are completely linear on each subregion.

a) Exact preimage: The exact preimage generation method [26] complements the forward analysis methods to reason about the inputs that lead to target outputs. The algorithm computes the exact preimage by relying on two elementary properties: (1) preimage of the composite functions is the reversed composition of preimages for each layer, i.e., $(f^{(L)} \circ \cdots \circ f^{(1)})^{-1} = (f^{(1)})^{-1} \circ \cdots \circ (f^{(L)})^{-1}$, and (2) preimage of a union set can be built up from the preimages of each subset in the union, i.e., $f^{-1}(\cup_j S_j) = \cup_j f^{-1}(s_j)$. This method assumes that the output set, e.g., a safe region, can be formulated as a polytope (intersection of half-planes) $\{y \in \mathbb{R}^m | Ay - b \leq 0\}$. It then propagates the polytope backwards through the layers.

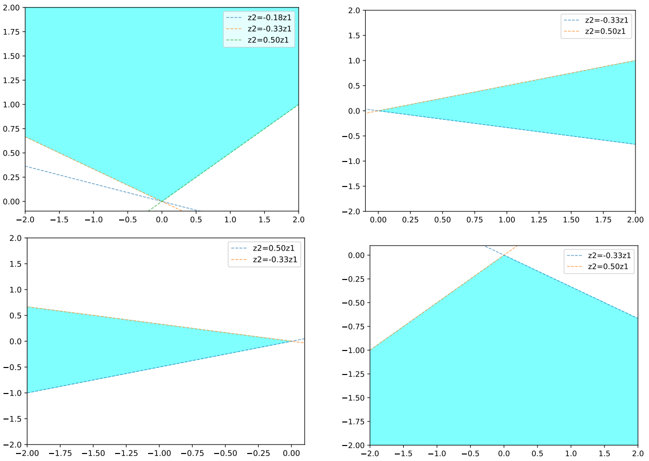

Fig. 6: Preimage polytopes by exact method.

For linear layers, the preimage is computed by applying the linear operations corresponding to the layer. Suppose we have a linear mapping in the form of $y = Wz + a$, then the preimage of the output polytope under this linear operation can be formulated as $\{z \in \mathbb{R}^{n_{L-1}} | AWz + (Aa - b) \leq 0\}$. For nonlinear layers, the algorithm restricts the backward propagation to a subset where the activation pattern of the ReLU neurons is fixed. Let $s(z)$ denote the activation status vector of the nonlinear neurons where $s(z)_j = 1$ if $z_j \geq 0$ and $s(z)_j = 0$ otherwise. A diagonal matrix $diag(s(z))$ is introduced to restrict to a fixed activation pattern, on which only linear computation is required to compute the preimage subset. The exact preimage can then be computed by taking the union of each partition (preimage property (2)).

$$\begin{aligned}
&ReLU^{-1}(\{y \in \mathbb{R}^m | Ay - b \leq 0\}) \\
&= \bigcup_{s \in \{0,1\}^{n_i}} \{z \in \mathbb{R}^{n_i} | Adiag(s)z - b \leq 0, -diag(s)z \leq 0, \\
&\qquad diag(1-s)z \leq 0\}
\end{aligned}$$

Example 4. *In this example, we consider the same verification problem as in Example 2 and 3, but from the backward perspective. Preimage analysis aims to investigate whether the input region* $[-1, 1] \times [-1, 1]$*, which is expected to result in decision* y_1*, fails the safety check. We first formulate the target output region as a polytope. Since we only have two labels, the output constraint is, therefore, a single half-plane encoded as* $\{y \in \mathbb{R}^2 | y_1 - y_2 \geq 0\}$*. We then proceed to compute the preimage of the target polytope under the linear mapping (from the* 2^{nd} *hidden layer to the output layer), of which the result is* $\{(z_3, z_4) \in \mathbb{R}^2 \mid 3z_3 + z_4 \geq 0\}$*. Next,* *preimage computation for ReLU starts with partitioning the neuron vector space $\mathbb{R}^2$ into 2^2 sets where, for each subset, the status of nonlinear neurons is fixed and preimage computation proceeds similarly to the linear mapping. The partition leads to four result polytopes.*

Figure 6 shows the result of four preimage polytopes derived in the two-dimensional space (z_1, z_2). As an example, the preimage polytope derived corresponding to the partition where both neurons are active is (upper left of Figure 6):

$$\{z^{(1)} \in \mathbb{R}^2 \ : A^{(1)} z^{(1)} \geq 0\} \quad \textit{where}$$
$$A^{(1)} = \begin{bmatrix} 2 & 11 \\ 1 & 3 \\ -1 & 2 \end{bmatrix}, \quad z^{(1)} = \begin{pmatrix} z_1 \\ z_2 \end{pmatrix}$$

The other three polytopes are derived in the same way. The four preimage polytopes are then partitioned further into 16 polytopes to characterize the exact preimage of the input layer. Note that the combination of the four polytopes actually covers the hidden vector space $[-2, 2] \times [-2, 2]$, and the resulting preimage polytopes on the input layer cover the region $[-1, 1] \times [-1, 1]$, which certifies that the correct decision is taken for the entire region under investigation.

b) SyReNN: SyReNN is proposed in [47] to compute the symbolic representation of a neural network so as to understand and analyze its behaviours. It targets *low-dimensional* input subspaces and computes their exact symbolic partitioning, on which the mapping function is completely linear. This methodological design is also referred to as neural network decomposition. We classify it as a backward analysis method, as this method provides a symbolic representation in the input space. SyReNN focuses on neural networks with piecewise-linear activation functions. This restriction enables a precise characterisation of the input space X as a finite set of polytopes $\{X_1, \cdots, X_n\}$. Within each input polytope X_i, the neural network is equivalent to a linear function. By means of such a symbolic representation, safety verification is reduced to checking whether the vertices of every bounded convex polytope X_i satisfy the output property.

To compute the symbolic decomposition on the input domain, this algorithm starts with the trivial partition X and derives the linear partitions layer by layer. Given the partition hyperplanes of the nonlinear layer i, e.g., $z_1 = 0, z_2 = 0, \cdots, z_{n_i} = 0$ with n_i ReLUs, and the symbolic representation $\hat{f}_{i-1}$ (a set of polytopes) computed until layer $i-1$, $\hat{f}_i$ is computed by recursively partitioning the current polytopes based on the newly-added hyperplanes. For example, given a polytope Z_{i-1}, if an orthant boundary (e.g., hyperplane $z_i = 0$) is hit when traversing the boundary of Z_{i-1}, then Z_{i-1} is further partition into $Z_{i-1,1}$ and $Z_{i-1,2}$ which lie on the opposite sides of the hyperplane. This procedure terminates until all resulting polytopes lie within a completely linear region of the neural network f.

2) Approximate methods: Exact methods for preimage analysis suffer from exponential complexity in the worst case. Similarly to the development of incomplete verifiers, preimage approximation techniques begin to emerge by leveraging different approximation (relaxation) techniques. They compute a symbolic approximation of the preimages to bypass the intractability of computing exact preimage representations. Computational efficiency and scalability can be greatly improved with the sacrifice of precision.

a) Symbolic interpolation: Symbolic interpolation [48] has been used for program verification and SMT solving. To compute provable preimage approximations, [27] leverages interpolants, especially those with simple structures, and computes preimages from the output space through hidden layers to the input space. The generated approximations can then be applied to reason about the properties of the neural network itself. For example, in the case that a desired property (a target output set) Y should be satisfied when starting from a certain input set X, an under-approximation $\underline{X}$ of the preimage for Y can be computed. Then the property can be verified by checking whether $\underline{X} \rightarrow X$ holds.

[48] proposes an algorithm to compute the preimage approximation by iterating backwards through the layers. It encodes the neural network as constraints in the theory of *quantifier-free linear rational arithmetic* (QFLRA) and requires the output set to be encoded as a Boolean combination of atoms in the form of half-spaces. Suppose we now focus on deriving preimage over-approximations of the target output set Y. The algorithm starts by computing the (overapproximated) set of inputs to the last layer, denoted as $p_L^{f,Y}$, which leads to the output set Y, i.e., $f^{(L)}(p_L^{f,Y}) \models Y$. The algorithm then iteratively computes preimages of the other layers that satisfy $p_i^{f,Y} = \{z \mid f^{(i)}(z) \models p_{i+1}^{f,Y}\}$. This procedure leverages sampling techniques to construct a set of points mapped to the complement of Y, which are used to tighten the over-approximations. The algorithm relies on Craig's Interpolation theorem to guarantee the existence of an (over- and under-) approximation. It also leverages the bound propagation framework to compute a bounded domain on each layer, which speeds up the interpolation condition checking.

b) Inverse bounding: [28] points out two important applications based on preimage analysis: safety verification for dynamical systems and out-of-distribution input detection. Motivated by these use cases, an inverse bound propagation method is proposed to compute the over-approximation of the preimage. Bound propagation has been widely employed to build efficient verifiers in the forward direction (certified output bound computation). Compared with forward analysis, it is challenging to adopt bound propagation methods directly to compute tight intermediate bounds, and thus difficult to compute tight over-approximations. This is because, for the inverse problem, the constraints on the input are quite loose and even unbounded in some control applications. Simply applying the bound propagation procedure will not lead to useful intermediate bounds, which further impacts the tightness of the symbolic relaxation on nonlinear neurons.

Given this, an inverse propagation algorithm is proposed in [28] to compute a convex over-approximation of the preimage represented by a set of cutting planes. It first transforms

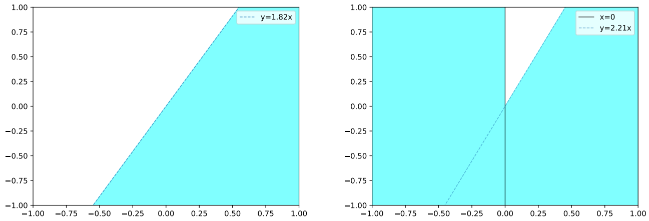

Fig. 7: Preimage approximation.

the preimage over-approximation problem to a constrained optimization problem over the preimage and further relaxes it to Lagrangian dual optimization. To tighten the preimage and intermediate bounds, they introduce a dual variable with respect to the output constraints and tighten these bounds iteratively, leveraging standard gradient ascent algorithm.

c) Preimage approximation: Motivated by the practical needs of global robustness analysis [49], [11], [21] and quantitative verification [50], [51], an anytime algorithm is proposed in [29] to compute provable preimage approximation. The generated preimage is further applied to verify quantitative properties of neural networks, which is defined by the relative proportion of the approximated preimage volume against the input domain under analysis, formally defined as follows.

Definition 3. *Given a neural network $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$, a measurable input set with non-zero measure (volume) $X \subseteq \mathbb{R}^n$, a measurable output set $Y \subseteq \mathbb{R}^m$, and a rational proportion $p \in [0, 1]$, the neural network satisfies the quantitative property (X, Y, p) if $\frac{\mathrm{vol}(f_X^{-1}(Y))}{\mathrm{vol}(X)} \geq p$.*

This approach targets safety properties that can be represented as polytopes and characterizes preimage under-approximation using a disjoint union of polytopes. To avoid the intractability of the exact preimage generation method, convex relaxation is used to derive sound under-approximations. However, one challenge is that the generated preimage under-approximation can be quite conservative when reasoning about properties in large input spaces with relaxation errors accumulated through each layer. To refine the preimage abstraction, a global branching method is introduced to derive tighter approximations on the input subregions. This procedure proposes a (sub-)domain search strategy prioritizing partitioning on most uncovered subregions and a greedy splitting rule leveraging GPU parallelization to achieve better per-iteration improvement. To further reduce the relaxation errors, this method formulates the approximation problem as an optimization problem on the preimage polytope volume. Then it proposes a differentiable relaxation to optimize bounding parameters using projected gradient descent.

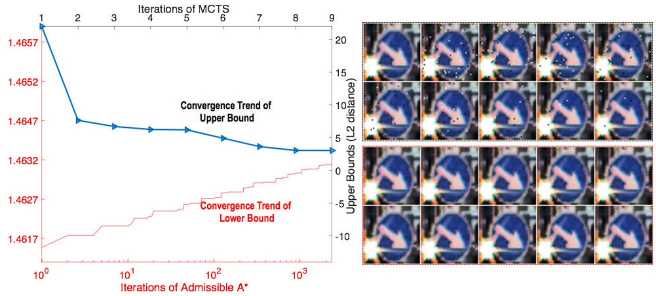

Fig. 8: Convergence of maximum safe radius computed using the game-based method for a traffic sign image from the GTSRB dataset originally classified as "keep right". Left: The convergence trends of the upper bound obtained with Monte Carlo Tree Search and the lower bound with Admissible A*. Right: unsafe images (top two rows) and certified safe images (bottom two rows). Figure taken from [10].

Example 5. *In this example, we demonstrate how to construct a provable preimage (under-)approximation for the target output region, and apply it to quantitative analysis of the verification problem shown in previous examples. Consider the quantitative property with input set $\phi_{\mathsf{pre}} = \{x \in \mathbb{R}^2 \mid x \in [-1, 1]^2\}$, output set $\phi_{\mathsf{post}} = \{y \in \mathbb{R}^2 \mid y_1 - y_2 \geq 0\}$, and quantitative proportion $p = 0.9$. We apply the preimage approximation algorithm to verify this property. Figure 7 presents the computed preimage before (left) and after one-iteration refinement (right). Note that the partition is performed w.r.t. input x_1, which results in two polytopes for the subregions. We compute the exact volume ratio of the refined under-approximation against the input set. The quantitative proportion reached with the refinement is 94.3%, which verifies the quantitative property.*

IV. Application Examples

In this section we provide a selection of experimental results and lessons learnt from applying formal verification and certification approaches described in the previous section to neural network models drawn from a range of classification problems. These include image and video recognition, automated decisions in finance and text classification. In addition to adversarial robustness of the models, we demonstrate certification of individual fairness of automated decisions and discuss robust explanations.

A. MSR-based Certification for Images and Videos

The game-based method [10] has been applied to analyse and certify the robustness of image classification models to adversarial perturbations with respect to the maximal safe radius, working with a range of feature extraction methods and distance metrics. Figure 8 shows a typical outcome of such analysis, with converging lower and upper MSR bounds for an image of a traffic sign for l_2 distance and features extracted from the latent representation computed by a convolutional neural network (CNN) model. It can be seen that the image is certified safe for adversarial perturbations of up to 1.463 in l_2 distance, which is some distance away from the best upper bound at approx. 3, but can be improved with more iterations since the method is anytime.

An extension of the game-based method was developed in [33] to provide MSR-based certification for videos, and

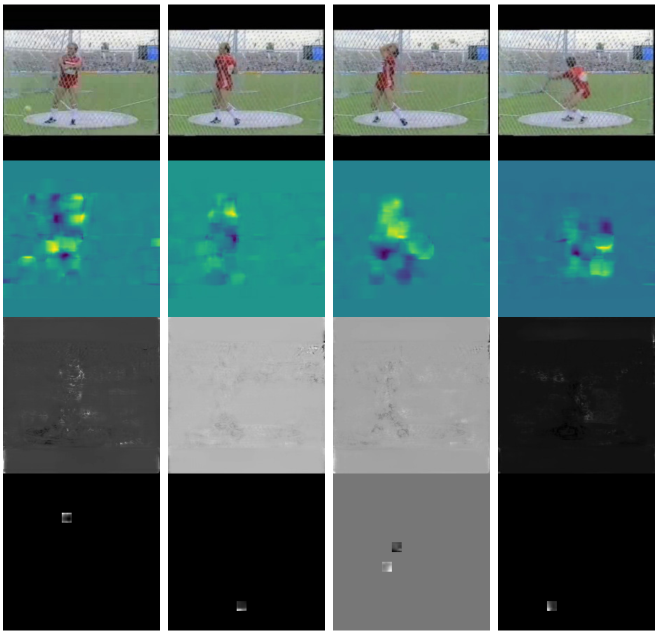

Fig. 9: Shown in top row are sampled frames of a HammerThrow video and the corresponding optical flows are in the 2nd row. Unsafe perturbations of flows are in 3rd row and safe in 4th. Figure taken from [33].

specifically for neural network models consisting of a CNN to perform feature extraction and a recurrent neural network (RNN) to process video frames. Adversarial perturbations were defined with respect to optical flow, and the algorithmic techniques involve tensor-based computation. Examples of safe and unsafe perturbations are shown in Figure 9, and convergence trends for lower and upper bounds similar to those in Figure 8 can be observed.

B. *Robustness of Language Models*

As an example of application of convex relaxation tools (variants of CROWN [34]), we mention the study of [52], which aims to assess the robustness of Natural Language Processing tasks (sentiment analysis and text classification) to word substitution. It was reported that standard fully connected (FC) and CNN models are very brittle to such perturbations, which may make their certification unworkable. [53] critiqued the appropriateness of the classical concept of adversarial robustness defined in terms of word substitution in the context of NLP models. It was observed in an empirical study that models trained to be robust in the classical sense, for example, trained using interval bound propagation (IBP), lack robustness to syntax/semantic manipulations. It was then argued in [53] that a *semantic* notion of robustness that better captures linguistic phenomena such as shallow negation and sarcasm is needed for language models, where a framework based on templates was developed for evaluation of semantic robustness.

C. *Robust Explanations for Language Models*

Explainability of language models was studied in [19], with a focus on robust optimal explanations that imply the model prediction. Figure 10 shows examples of high-quality robust optimal explanations (using the minimum length of explanation as the cost function). In contrast, heuristic explanations such as integrated gradients or Anchors my lack of robustness, but it is possible to repair non-robust Anchors explanations by minimally extending them, see Figure 11.

D. *Fairness Certification Using MILP*

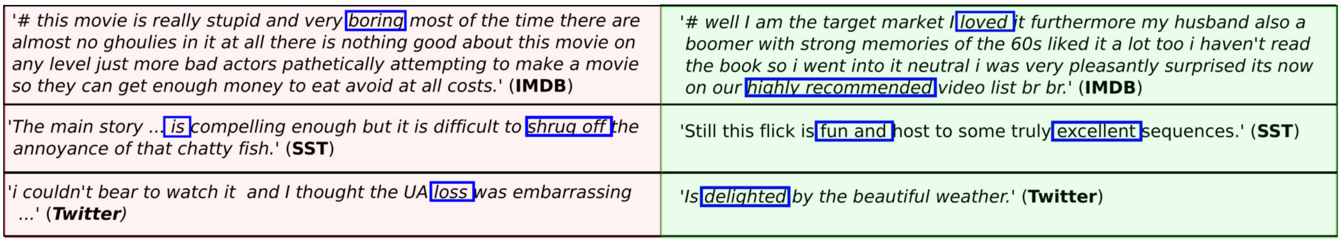
[54] developed methods for certification of individual fairness of automated decisions, defined, given a neural network and a similarity metric learnt from data, as requiring that the output difference between any pair of ϵ-similar individuals is bounded by a maximum decision tolerance $\delta \geq 0$. Working with a range of similarity metrics, including Mahalanobis distance, a MILP-based method was developed not only to compute certified bounds on individual fairness, but also to train certifiably fair models. The computed certified bounds δ_* are plotted in Figure 12 for the Adult and the Crime benchmarks. Each heat map depicts the variation of δ_* as a function of ϵ and the NN architecture. It can be observed that increasing ϵ correlates with an increase in the values for δ_*, as higher values of ϵ allow for greater feature changes.

V. Future Challenges

Formal verification and certification of neural network models has made steady progress in recent years, with several tools released to the community and an established tool competition [4]. Nevertheless, considerable scientific and methodological progress is needed before these tools are adopted by developers. Below we outline a number of research challenges.

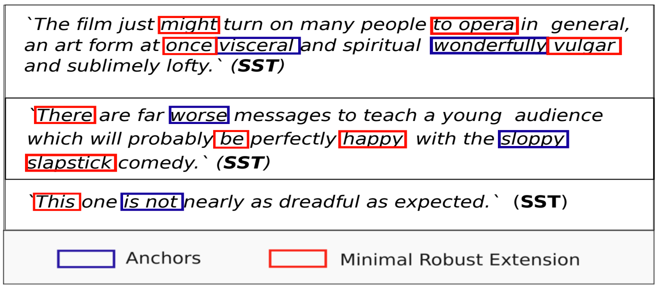
a) Beyond ℓ_p-norm robustness: The vast majority of robustness evaluation frameworks consider bounded ℓ_p-norm perturbations. While these suffice as proxies for minor visual image perturbations, real-world tasks rely on similarity measures, for example cosine similarity for word embeddings or Mahalanobis distance for images. It is desirable to define measures and certification algorithms for semantic robustness, which considers such similarity measures as first class citizens, and works with perturbations that reflect visual or geometric aspects characteristic of the application, such as object movement or lighting conditions. More generally, robustness evaluation frameworks for more complex properties induced by the use cases will be needed.

b) Beyond supervised robustness: Existing robustness formulations focus on the supervised learning setting. However, collecting and labelling large datasets that are necessary to ensure the high robustness performance needed in safety-critical applications is costly and may not be feasible for use cases such as autonomous driving. Instead, it is desirable to formulate robustness measures and evaluation frameworks directly in some appropriate semi-supervised, or even unsupervised, setting, where the definition of robustness needs to focus on the quality of the learned representations rather than



'# this movie is really stupid and very boring most of the time there are almost no ghoulies in it at all there is nothing good about this movie on any level just more bad actors pathetically attempting to make a movie so they can get enough money to eat avoid at all costs.' (**IMDB**)	'# well I am the target market I loved it furthermore my husband also a boomer with strong memories of the 60s liked it a lot too i haven't read the book so i went into it neutral i was very pleasantly surprised its now on our highly recommended video list br br.' (**IMDB**)
'The main story ... is compelling enough but it is difficult to shrug off the annoyance of that chatty fish.' (**SST**)	'Still this flick is fun and host to some truly excellent sequences.' (**SST**)
'i couldn't bear to watch it and I thought the UA loss was embarrassing ...' (***Twitter***)	'Is delighted by the beautiful weather.' (**Twitter**)

Fig. 10: Optimal robust explanations (highlighted in blue) for IMDB, SST and Twitter datasets (all the texts are correctly classified). Figure taken from [19].



`The film just might turn on many people to opera in general, an art form at once visceral and spiritual wonderfully vulgar and sublimely lofty.` (***SST***)

`There are far worse messages to teach a young audience which will probably be perfectly happy with the sloppy slapstick comedy.` (***SST***)

`This one is not nearly as dreadful as expected.` (**SST**)

□ Anchors □ Minimal Robust Extension

Fig. 11: Examples of Anchors explanations (in blue) along with the minimal extension required to make them robust (in red). Figure taken from [19].

classification (prediction) because of the lack of labels. This may involve working with similarity measures such as Mahalanobis distance and will be challenging both theoretically and computationally to achieve provable robustness guarantees.

c) Scalability in network width and depth: Despite much progress, the scalability of robustness certification and evaluation frameworks remains limited to low-dimensional models. In order to apply certification to realistic use cases (such as object detection) will necessitate significant improvements with respect to input dimensionality and network depth, as well as the types of activation functions that can be handled.

d) Efficiency and precision trade-off: Robustness certifications and evaluation involves a variety of methods, including exact, approximate and statistical. While exact methods offer completeness, trading off exact precision for approximate bounding results in more efficient any time methods, and completeness can be recovered by combining fast approximate methods such as convex relaxation with branch-and-bound computation. Statistical methods provide estimates of robustness that may be unsound but fast and, in many cases, sufficient for the application being considered.

e) Compositionality and modularity of AI systems: Certification tools that have been developed to date are monolithic, which matches the monolithic structure of the vast majority of neural network models. Yet, similarly to safety-critical systems, it is anticipated that better structuring of models and tools is likely to improve their reliability and maintainability. Therefore, modularity, compositionality and, in particular, assume-guarantee compositional frameworks, are desirable future directions.

f) Calibrating uncertainty: It is recognised that deterministic neural networks can be overconfident in their decisions, and instead a variant known as Bayesian neural networks (BNNs), which admits a distribution over the weights and provides outputs in the form of the posterior distribution, is preferred, as it allows for a principled means to return an uncertainty measure alongside the network output. BNN certification methodologies are much more complex than for deterministic NNs, and still in early stages of development, including uncertainty quantification [55], computing lower bounds on safety probability [56] and certifiable adversarial robustness [57]. Unfortunately, the methods do not scale beyond small networks and standard Bayesian inference tends to underestimate uncertainty.

g) Robust learning: A drawback of certification as presented in this paper is that it pertains to trained models, and if the model fails certification, it is not clear how it can be repaired, and expensive retraining may be needed. A natural question then arises as to whether one can learn a model that is guaranteed to be robust. Building on the positive and negative theoretical results in the case of robust learning against evasion attacks [58], [59], [60], [61], it would be interesting to generalise these results to neural network models and development of implementable frameworks that can provide provable guarantees on robustness.

VI. Conclusion

We have provided a brief overview of formal verification approaches that can be employed to certify neural network models at test time, to train certifiably robust or fair models, and to provide meaningful explanations for network predictions. The methods can be categorised into forward and backward analysis, and involve techniques such as search, bound propagation, constraint solving and abstract interpretation. Both forward and backward analysis have the potential to support more complex verification properties, which have been little explored to date. Empirical results obtained on a range of standard benchmarks show that neural network models are often brittle to adversarial perturbations, but verification approaches can be used to strengthen their robustness and compute certification guarantees, thus improving trustworthiness of AI decisions.

Multiple Criteria Decision Aiding by Constructive Preference Learning (Keynote Lecture – Extended Abstract)

Roman Słowiński*†
*Poznań University of Technology, Poland
†Systems Research Institute, Polish Academy of Sciences, Poland

The notion of preference is relevant across a variety of scientific disciplines, including economics and social sciences, operational research and decision sciences, artificial intelligence, psychology, and philosophy. Preferences provide a means for specifying desires in a declarative and intelligible way, a key element for the effective representation of knowledge and reasoning respecting the value systems of Decision Makers (DMs) [1].

Recognizing the preferences of DMs is also crucial for multi-criteria decision aiding. We present a constructive preference learning methodology, called robust ordinal regression (ROR) [2]. This methodology links operational research (OR) with artificial intelligence (AI), and as such, it confirms the current trend in mutual relations between OR and AI [3].

The lecture starts from an observation that the dominance relation established in the set of alternatives evaluated on multiple attributes (criteria, or voters, or states of the nature) is the only objective information that stems from the formulation of a multiple attribute decision problem (ordinal classification, or ranking, or choice – with multiobjective optimization being a particular case). While it permits to eliminate many irrelevant (i.e., dominated) alternatives, it leaves many alternatives incomparable. This situation may be addressed by taking into account preferences of the DM. Therefore, decision aiding methods require some preference information exhibiting a value system of a single or multiple DMs.

In ROR, the preference information has the form of decision examples. They may either be provided by the DM on a set of real or hypothetical alternatives, or may come from observation of DM's past decisions. This information is used to build a preference model, which is then applied on a non-dominated set of alternatives to arrive at a recommendation presented to the DM(s).

In practical decision aiding, the process composed of preference elicitation, preference modeling, and DM's analysis of a recommendation, loops until the DM (or a group of DMs) accepts the recommendation or decides to change the problem setting. Such an interactive process is called constructive preference learning. We describe this process for three types of preference models:

1) utility functions,
2) outranking relations, and
3) sets of monotonic decision rules.

The case of a hierarchical structure of the set of criteria will be discussed [4], and the transparency and explainability features required from preference learning will be discussed on the example of interactive multiobjective optimization [5].

***Abstract*—In this paper, we consider the problem of prediction of Radio Link Failures (RLF) in flying ad hoc networks (FANETs). Many environmental factors that influence the quality of radio wave propagation are dynamic, and thus, drones must continually learn and update their radio link quality prediction model while they operate online.**

Online machine learning algorithms can be used to build adaptive RLF predictors without requiring a pre-deployment effort. To predict the RLF, we use an online machine learning algorithm and information gathering by message-passing from the neighbors. We propose an algorithm called *ML-Net* (Machine Learning and Network algorithm) to predict RLF. To the best of our knowledge, the combination of online machine learning algorithms together with the message-passing algorithm has not been used before. The proposed methodology outperforms the state-of-the-art online machine learning algorithms.

***Index Terms*—Online learning, RLF prediction, UAV.**

I. Introduction

UNMANNED aerial vehicles (UAVs), also known as drones or flying robots, have gained significant attention in various real-life applications. The flying ad hoc network (FANET) is established to leverage high-speed communications. However, due to the high mobility of UAVs in FANETs, the network topology may continuously change, making it challenging to establish end-to-end connections. Radio Link Failure (RLF) prediction can help UAVs handle this issue and improve FANET performance to ensure continuous service availability. Accurate prediction of radio link failures (RLF) is critical for ensuring reliable communications in flying ad hoc networks (FANETs). However, link prediction remains challenging due to the dynamic topology and unpredictable mobility patterns in FANETs. Nodes can move in and out of communication range rapidly, leading to frequent link disruptions. The ability to accurately predict impending link failures can enable proactive mitigation strategies. For example, drones could switch to more reliable links ahead of time to prevent packet loss and service interruptions. Link prediction also allows optimizing routing by avoiding unstable links that are about to fail. Furthermore, timely knowledge of upcoming link losses enables adapting transmission parameters to maintain connectivity. The development of link prediction techniques tailored to the FANET environment is therefore essential for efficient network operation and robust aeronautical communications. Machine learning holds promise for developing adaptive, data-driven predictors that can operate in real-time based on local interactions. This motivates our exploration of online learning combined with message passing for high-accuracy RLF prediction in FANETs.

Two essential characteristics should be present in RLF predictors. First, adaptivity is critical since an RLF predictor must cope with quality fluctuations over time, especially for FANET. Second, plug-and-play is crucial since RLF predictors should be applied without requiring any predeployment effort, which might not be feasible for all deployment scenarios, even if the effort is reduced. Online machine learning algorithms can be used to build RLF predictors that are adaptive without requiring predeployment effort.

Most current machine learning approaches are limited to the traditional batch setting, where data is provided in advance to the training process. Model selection and meta-parameter optimization can rely on the full set of data, and training can assume that the data and its underlying structure are static. In contrast, online machine learning involves continuous model adaptation based on constantly arriving data. The underlying distribution of the data, which changes over time, presents some primary challenges and difficulties in the dynamic environment. Old data can become irrelevant or even detrimental to model the current concept. Online machine learning [3] exhibits great potential for performance improvement with the sequential arrival of data and superiority over offline learning, including real-time predictions and lower memory requirements.

This paper explores the possibility of using online machine learning algorithms together with local information gathering by messages to predict RLF. Each drone uses only its local information and information gathered from its neighbor. Specifically, the main contributions of this paper are as follows.

1) Motivated by the characteristics of RLF predictors mentioned above, we propose a link failure prediction model *ML-Net*, which combines the online machine learning algorithm with a message-passing algorithm.
2) To the best of our knowledge, we pioneer the use of the online machine learning method combined with the message-passing algorithm for RLF prediction.
3) We conduct simulations to analyze the performance of the *ML-Net*. We compare the proposed solution with state-of-the-art techniques and perform an analysis of simulation results. The analysis shows that the proposed approach *ML-Net* achieves better performance than the state-of-the-art methods.

The remainder of this paper is organized as follows. Section II discusses recent related studies. Section III describes the theoretical model used to define our problem. The details of the proposed approach are described in Section IV. In Section V, we describe all aspects of the evaluation setup and simulation results. Finally, we summarize our paper with conclusions and suggestions for future research in Section VI.

II. Related Work

In this study, we propose the use of online machine learning algorithms combined with message-passing approach for predicting Radio Link Failure (RLF) in communication networks. Several recent studies on RLF suggest using online machine learning algorithms for prediction.

In [1], the authors studied the link quality prediction for wireless mesh networks. They performed a performance analysis of four state-of-the-art algorithms for link quality prediction and proposed a new hybrid online algorithm for link quality prediction based on this analysis.

The authors of [7] presented an adaptive link estimator (TALENT) that uses online learning. They argued that TALENT adapts to network dynamics better than statically trained models without the need for advance data collection for training the model before deployment in a real system. The solutions follows the performance of the autoencoders very closely with a tiny margin on very bad, very good and intermediate link quality classes.

The study [8] introduced a framework to reduce energy and network capacity overhead expenses by incorporating active learning to selectively label only a portion of the samples from the data stream. The framework also uses incremental training batches to conserve labeling resources and updates the batches using change detection and forgetting mechanisms to mitigate concept drift. Experimental results showed that the framework reduces label queries by up to 21.5% and prediction error by up to 9% after periods of concept drift.

As a part of their work in [12], the authors looked at the problem of predicting channel quality between vehicles in terms of path loss, which shows strong fluctuations over time due to the highly dynamic nature of vehicular environments. They proposed a framework for a data-driven path loss prediction model that combines the changepoint detection method and online learning. The evaluation of the proposed framework was done using real-world datasets.

Machine learning methods were used in [10] to predict the short-term evolution of link quality for switching to a better link for data transmission. The problem was modeled as a game of prediction based on experts' advice, using the Link-Quality Indicator (LQI) metric. A decision-maker predicts the LQI values, called a forecaster, who receives advice from several experts. To predict values close to actual LQI values, the forecaster can learn how to adapt its strategy. As a general model, the proposed learning and prediction model can be easily adapted to different link-quality metrics or prediction methods.

In summary, some recent works have used online machine-learning algorithms to predict RLF and took into consideration the adaptability issue, see [2]. Based on these previous studies, we propose the use of a novel method based on online machine learning with a combination of neighbor information gathering by a message-passing solution.

III. System Model and Problem Formulation

We consider a set of n UAVs (denoted as S) that are deployed arbitrarily in a given area and may be located in any position in $\mathbb{R}^3$. The network imposed on S is connected.

We assume that the transmission power of all nodes is fixed. We denote the transmission power of node i at time t as P_i^t. The set of nodes i's neighbors at time t depends on the current positions and channel gain. Based on [13], we can approximate the path loss on link ij as follows:

$$L_{ij}^t = -10\log_{10} G_l \left(\frac{\lambda}{4\pi d^t}\right)^2, \tag{1}$$

where G_l is the product of the transmitter and receiver antenna field radiation patterns of LOS transmissions, d^t is the distance between a transmitter and its corresponding receiver at time t, and λ is the operating wavelength. Thus, the path loss is related to the transmission distance when transmitting radio signals over a specific channel through a specific antenna.

Let N_i^t be the set of neighbors of node i at time t. Formally, N_i^t is defined as:

$$N_i^t = \{j \in S \setminus i | L_{ij}^t \geq \theta\}, \tag{2}$$

where θ is a predefined parameter of the network.

A network is defined as a directed graph $G^t = (S, E^t)$, where node $i \in S$ has a directed edge (link) to each of its neighbors according to Equation 2. The edge set E^t is the union of all directed edges among the nodes in time t, $E^t = \bigcup_{i \in S} E_i^t$.

At each timestamp t, when node i receives a message from node j, node i collects a set x_t of metrics (features) that describe the communication with node j at time t. Node i adds x_t to a multivariate time series that represents features of communication with node j, denoting this multivariate time series as $X_{ij}^t = \{x_1, \ldots, x_t\}$.

Thus, each edge $e^t_{ij} \in E^t$ has a multivariate time series associated with it, X^t_{ij}. In addition, e^t_{ij} has an associated binary class variable $v^t_{ij} \in \{1, -1\}$, representing the existence (1) or failure (-1) of the edge.

Now we can formally define our problem. Given the current X^t_{ij}, we wish to determine whether the edge e_{ij} will fail or not in the following timestamp (namely, at $t + 1$).

IV. *ML-Net*

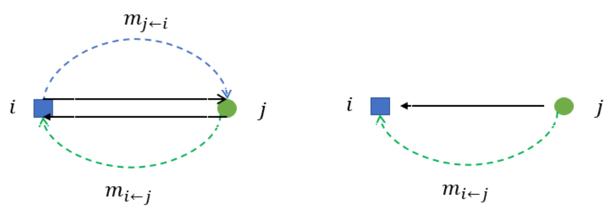
In this section, we describe the proposed *ML-Net* approach. We combine the machine online learning algorithm with the network structure algorithm to cope with RLF prediction in the next timestamp. We suggest using the expression $S(X^t_{ij}, m^t_{i\leftarrow j})$ which approximates the probability that the edge e^t_{ij} will fall in the next timestamp.

$$S(X^t_{ij}, m^t_{i\leftarrow j}) = \begin{cases} \alpha \hat{Pr}(v^{t+1}_{ij} = -1|X^t_{ij}) + (1-\alpha) m^t_{i\leftarrow j}, & \text{Message from node } j \text{ was received} \\ \hat{Pr}(v^{t+1}_{ij} = -1|X^t_{ij}), & \text{otherwise} \end{cases} \tag{3}$$

where $0 \leq \alpha \leq 1$, $m^t_{i\leftarrow j}$ is the message sent by j to i including the belief of node j about v^t_{ji}, and $\hat{Pr}(v^{t+1}_{ij} = -1|X^t_{ij})$ is the probability that edge e_{ij} will fail in timestamp $t+1$ given multivariate time series X^t_{ij}. We use on the shelf online machine learning algorithm to calculate $\hat{Pr}(v^{t+1}_{ij} = -1|X^t_{ij})$ (in Section V-A we will broadly describe the proposed algorithms).

$$m^t_{i\leftarrow j} = \begin{cases} \alpha \hat{Pr}(v^{t+1}_{ji} = -1|X^t_{ji}) + (1-\alpha) m^t_{j\leftarrow i}, & \text{Message from node } j \text{ was received} \\ \hat{Pr}(v^{t+1}_{ji} = -1|X^t_{ji}), & \text{otherwise} \end{cases} \tag{4}$$

Due to the fact that the $G^t = (S, E^t)$ is a directed graph, then the following scenario may occur: the edge $e^t_{i,j}$ exists but the edge $e^t_{j,i}$ does not exist. In this scenario, $m^t_{i\leftarrow j}$ may arrive but $m^t_{j\leftarrow i}$ cannot arrive. In Figure 1 we can see an example of this scenario.



a) Edges e_{ij} and e_{ji} exist

b) Edge e_{ij} exists

Fig. 1: Directed edges.

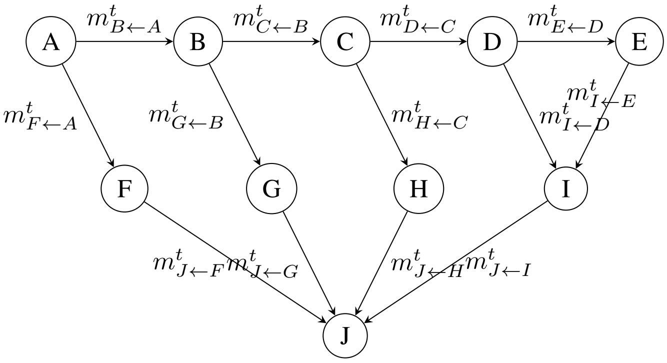


Fig. 2: Illustration of Message-Passing Algorithm

Figure 2 showcases a random graph with 10 nodes (A-J), representing entities in a system. The directed edges between nodes symbolize the flow of messages, demonstrating the operation of the message-passing algorithm. The labels on the arrows, m^t_{ij}, represent the messages passed from node i to node j at time t. This graph serves as a visual representation of the algorithm's functioning in a system with multiple interacting components.

Algorithm 1 ML-Net Algorithm

```
Input: Node $i$, current time $t$, set of neighbors $N^t_i$, link features $X^t_{ij}$
Output: Link failure prediction $S(X^t_{ij}, m^{t\leftarrow j}_i)$
Hyperparameters: $\alpha$
for $j \in N^t_i$ do
    if $msg_received(j, t)$ then
        $m^{t\leftarrow j}_i = \alpha \hat{P}(v^{t+1}_{ij} = -1|X^t_{ij}) + (1-\alpha) m^{t\leftarrow i}_j$
    else
        $m^{t\leftarrow j}_i = \hat{P}(v^{t+1}_{ij} = -1|X^t_{ij})$
    end if
    $S(X^t_{ij}, m^{t\leftarrow j}_i) = \alpha \hat{P}(v^{t+1}_{ij} = -1|X^t_{ij}) + (1-\alpha) m^{t\leftarrow j}_i$
end for
return $S(X^t_{ij}, m^{t\leftarrow j}_i)$
```

The ML-Net algorithm shows the key steps for combining online machine learning with message passing to predict link failures. For each neighbor j, node i first checks if a message was received from j at time t. If so, i updates its belief about the $i \rightarrow j$ link failing using both its own prediction and j's belief from the message. This allows propagating information through the network. If no message is received, i relies only on its own link prediction. Finally, the algorithm returns the combined prediction score S for each link $i \rightarrow j$ based on the updated beliefs. This demonstrates how ML-Net leverages both local online learning models and information exchange with neighbors to achieve accurate real-time RLF prediction in dynamic FANET environments.

A. *Notations*

The notations used in this paper are summarized in Table I. Also, Table I contains further notation defined below in the paper.

Symbol	Meaning
S	Set of drones
L_{ij}^t	Path loss between receiver j and transmitter i
n	Size of set S, $n = \|S\|$
$\mathcal{K}$	The set of sources and destination in the network
$G^t = (S, E^t)$	Directed graph that represents the network in timestamp t
X_{ij}^t	multivariate time series associated with measures from link ij
P_i	The transmission power
v_{ij}^t	Binary variable represented the link failure between node i to j in time t
e_{ij}^t	Edge between node i to j in time t
$m_{i \leftarrow j}^t$	Message sent by j to i (contains v_{ji}^t)

TABLE I: Summary of notations used in this paper

V. Experimental Setup

Simulation is the most reliable and cost-effective approach to examining the performance of real-world problems. For performance evaluation of the proposed technique, OMNET++ [15] is used as the primary tool for FANET environment generation and routing protocol implementation. This section describes the data generation process. Let $\mathcal{K}$ represent the set of the source and destination pairs within the network that should communicate.

We simulated the network for $|S| = 20$ and for $|\mathcal{K}| = 3$. In Figure 3 we can see an example of a network with 20 UAV's and $|\mathcal{K}| = 3$.

The routing protocol we chose to use is AODV (Ad-Hoc On-Demand Distance Vector) [14]. This protocol is designed for wireless and mobile ad hoc networks and has been broadly adopted for FANETs. Next, we present the schemes for comparison and the evaluation metrics.

A. Schemes for Comparison

In the following, we briefly describe the state-of-the-art online machine learning algorithms and their hyperparameters used in this paper to compare with *ML-Net*. These algorithms were selected as the comparison baseline solutions due to their advanced nature.

1) The Extremely Fast Decision Tree (EFDT) [9]: EFDT constructs a tree incrementally. The EFDT seeks to select and deploy a split as soon as it is confident the split is useful and then revisits that decision, replacing the split if it becomes evident that a better split is available. The EFDT learns rapidly from a stationary distribution, and eventually, it learns the asymptotic batch tree if the distribution from which the data are drawn is stationary. We chose a EFDT with the following hyperparameters: grace period of 200 and split confidence of $1e^{-7}$.

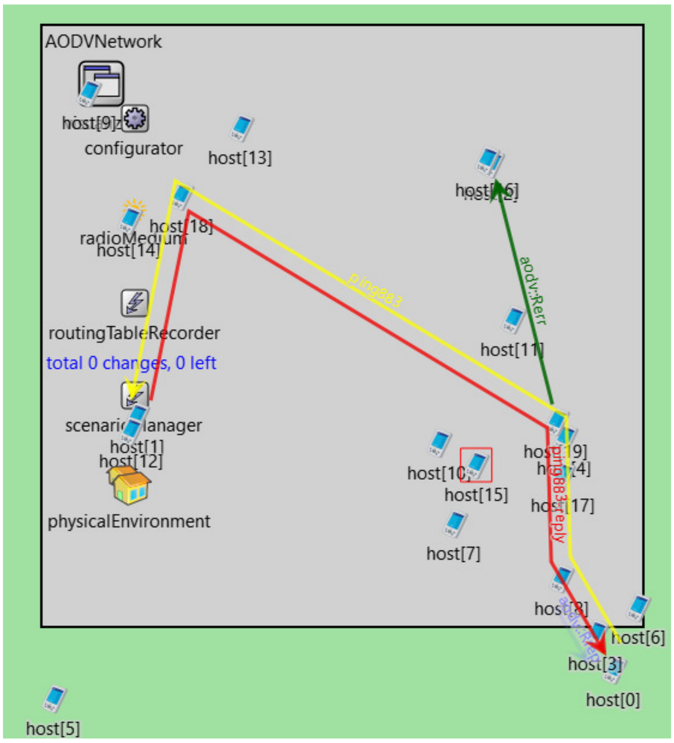

Fig. 3: Example of network with 20 nodes and 3 pairs of source and destination.

2) Adaptive Random Forest (ARF) [4]: ARF algorithm for the classification of evolving data streams enables the Random Forests algorithm for evolving data stream learning. There are effective resampling methods and flexible operators in ARF that can cope with different types of concept drifts without requiring complex optimizations for different data sets. We chose a ARF with the following hyperparameters: grace period of 50, lambda is 6, max features are 3, split confidence of 0.01, and tie threshold of 0.05.

3) Hoeffding Tree Classifier (HTC) [6]: This method involves determining an upper bound for the learner's loss based on the number of examples used in each step of the algorithm. In this algorithm, the number of examples required for each step is minimized while ensuring the model performance is not significantly different from the one obtained from an infinite dataset. We chose a HTC with the following hyperparameters: grace period of 200, min samples reevaluate of 20, split confidence of $1e^{-7}$, and tie threshold of 0.05.

4) Streaming Random Patches Classifier (SRPC) [5]: The Streaming Random Patches algorithm is a machine learning technique that involves randomly selecting subsets or ”patches” of data from a continuous stream of input. These patches are used to train and update a model iteratively over time, allowing the model to adapt and learn from new incoming data.

B. Evaluation Metric

We use the following performance metrics to evaluate the performance of different machine learning algorithms:

1) Precision: The ratio of the number of true positives over the total number classified as positive. In the context of our problem, it is the ratio of correctly predicted link failures versus the total number of link failures predicted. The precision value is computed as follows:

$$P = \frac{T_P}{T_P + F_P}, \tag{5}$$

where P is the precision value, T_P is the number of "true positives," and F_P is the number of "false positives."

2) Recall: The ratio of the number of data points associated with link faults correctly classified over the total the number of data points associated with link faults that have occurred. The recall value is given by

$$R = \frac{T_P}{T_P + F_N} \tag{6}$$

3) F_1-Score: The F_1-Score is the harmonic average of the precision and recall values. It takes a value in $[0, 1]$. Higher the value of F_1-Score, the better the performance of the machine learning technique. It is computed as follows:

$$F_1 = \frac{2P \cdot R}{P + R} \tag{7}$$

4) Cohen's kappa- κ : Cohen's kappa measures the agreement between two raters who each classify N items into C mutually exclusive categories the Cohen's kappa formula can be written as:

$$\kappa = \frac{2(T_P \cdot T_N - F_N \cdot F_P)}{(T_P + F_P) \cdot (F_P + T_N) + (T_P + F_N) \cdot (F_N + T_N)} \tag{8}$$

C. Features

This section provides an exploratory data analysis of key features in the communication system. Visualizations are utilized to understand feature distributions and relationships in the data.

1) **Time**: This feature represents the elapsed time since the start of the simulation or experiment. It captures the dynamics of the communication system over time.
2) **IdTransmitter**: This categorical feature identifies the transmitter for each signal received. It allows the model to capture any specific characteristics related to individual transmitters.
3) **64-QAM SNR**: These features represent the Signal-to-Noise Ratio (SNR) for the 64-level Quadrature Amplitude Modulation (64-QAM) scheme. SNR is a measure of signal quality, with higher values generally indicating better quality.
4) **64-QAM BER**: These features represent the Bit Error Rate (BER) for 64-QAM. BER is another measure of signal quality, with lower values indicating fewer errors and therefore better quality.

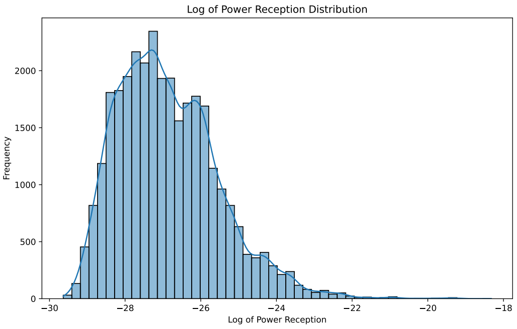

Fig. 4: Distribution of Log Received Power

5) **powR**: This feature represents the power of the received signal. It is a critical factor in communication systems, as a stronger received signal usually implies a better communication link.
6) **angle_between**: This feature represents the angle between the transmitter and receiver. The relative orientation between these devices can affect the signal strength and thus the link quality.
7) **Link**: This is the target variable that we want to predict. It is a binary variable representing the quality of the communication link, with '1' indicating a good link and '0' indicating a bad link. This allows us to frame the problem as a binary classification task.

These features provide a comprehensive description of each signal reception event, capturing information about the transmitter, signal quality, received signal power, and relative device orientation. This enables construction complex models to predict the communication link quality.

Figure 4 shows the histogram that presents the distribution of the logarithm of the received Power Reception. The x-axis shows the log power values, and the y-axis shows the frequency. The kernel density estimate smooth line approximates the probability density function.

The log transformation handles skewed data by making the distribution more symmetric. The log-transformed power distribution appears Gaussian, concentrated around -26.

The KDE peak indicates the most frequent log power value. The distribution spread provides insights into power variability. This transformation can help modeling techniques assume normality.

Figure 5 is a histogram that shows the distribution of angles between transmitters and receivers. The x-axis represents the angle from 0 to 180 degrees. The y-axis represents the frequency. This reveals common orientations in the simulation.

The overlaid Kernel Density Estimate (KDE) approximates the distribution. It assists in identifying shape characteristics like peaks. These insights are key to understanding angle variability and its potential impact on system performance.

The heatmap presented in Figure 6 illustrates feature correlations. Each cell shows the correlation coefficient between feature pairs. Cool colors indicate negative correlations. Warm

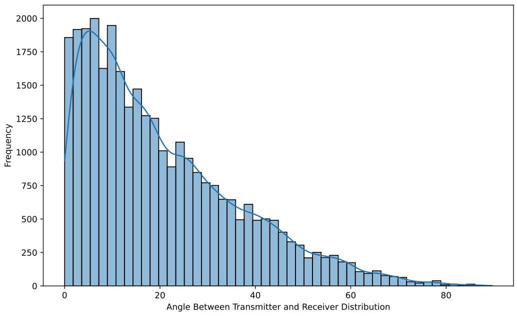

Fig. 5: Distribution of Transmitter-Receiver Angle

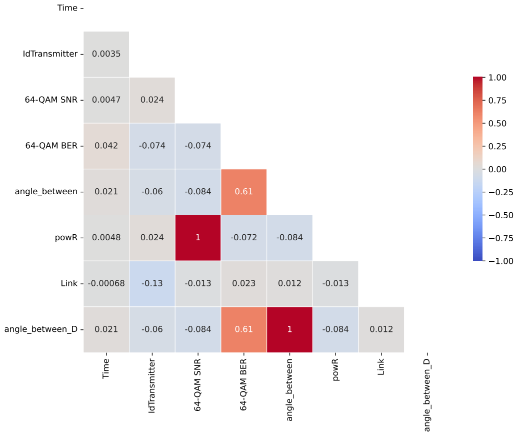

Fig. 6: Correlation Matrix

colors indicate positive correlations. Neutral colors indicate minimal correlation.

This visualization identifies relationships between features. It assists in feature selection by highlighting potential redundancies.

D. Evaluation and Numerical Results

We evaluate the proposed method using data collected from simulations implemented in OMNET++ [15]. As part of our simulation, we randomly deployed 20 drones and randomly selected three pairs of source destinations from these drones as shown in Figure 3 for an example. The drones run the AODV routing protocol.

Each node participating in communication extracts the following parameters (features) when receiving a message from its neighbor: reception power, transmission power, SINR, modulation, location, and orientation. Features collection does not require particular messages. Simulation runs for 3000 seconds, during which the link failure is collected.

Table II summarizes the parameters used by us in the simulation.

We first used the schemes from Section V-A to predict RLF so that we could compare our method with their performance. The compression mechanism is implemented using [11]. We calculate $\hat{Pr}(v_{ij}^{t+1} = -1|X_{ij}^{t})$ using all the schemes for comparison, estimate the RLF by Eq. 3, and provide the performance for each of the cases.

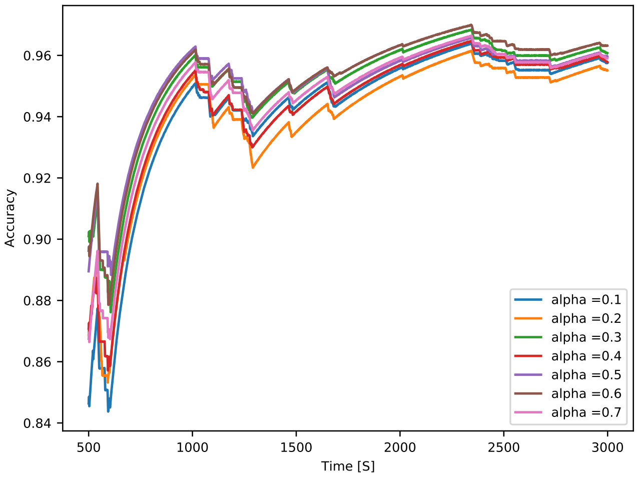

Fig. 7: α selection for *ML-Net*

Figure 7 shows the performance of *ML-Net* as a function of α. The x-axis represents the time of the simulation, and the y-axis represents the accuracy of the RLF prediction. As we can learn from the figure, the accuracy of the RLF prediction generally increases as we increase the value of α. This is because a larger value of α gives more weight to the node's own information and less to its neighbor's information. We can also see that when α is very small, the algorithm is overly influenced by the neighbors' information, and the predictions may not be accurate enough. On the other hand, when α is very large, the algorithm may not be able to adapt quickly to changes in the network topology due to a lack of influence from the neighbors' information. Based on Figure 7, we chose the alpha value to be 0.6, as it strikes a balance between the node's own information and its neighbor's information and achieves the best accuracy value.

Parameter	**Value**
Number of drones	20
Simulation Playground Size	800 $\times$ 800 m^2
Bandwidth	2MHz
σ	10^{-3}
Power	1.4mW
λ	10dB
SINR threshold	4dB
α	0.6
Speed	$\mathcal{N}(200, 0.001) mps$

TABLE II: Simulation Configuration

We provide a detailed explanation of the performance analysis of *ML-Net* with different online learning algorithms in calculating $\hat{Pr}(v^{t+1}ji = -1|X^{t}ji)$. To evaluate the performance of our proposed approach, we compare it with other

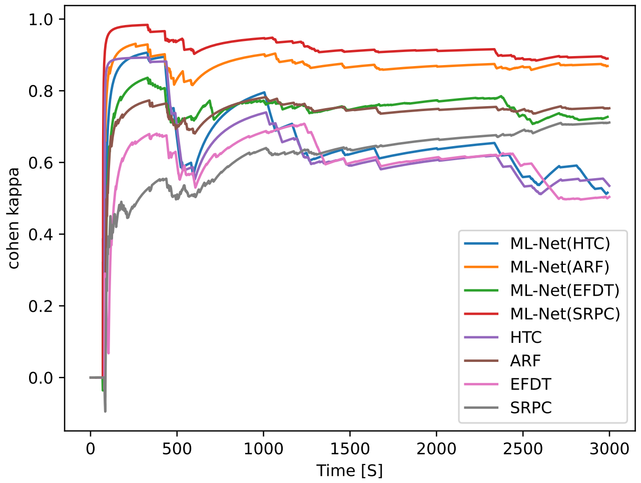

Fig. 8: κ achieved by schemes for comparison versus *ML-Net*

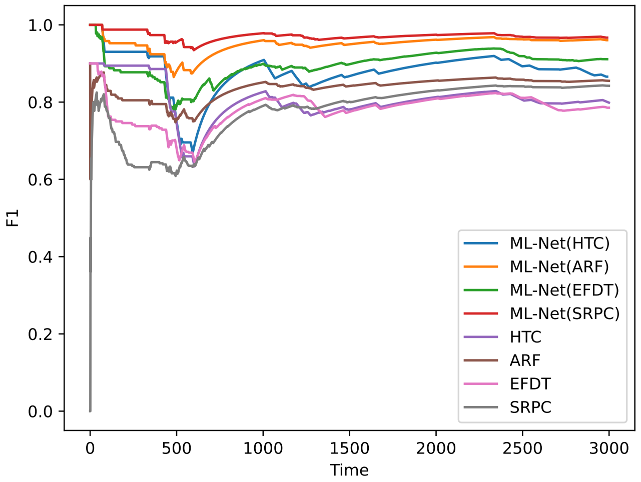

Fig. 9: F_1

existing schemes (see subsection V-A). The evaluation is based on several performance metrics, including precision, recall, accuracy, Cohen's kappa, and F_1.

Figures 9, 10, 11 and 12 demonstrate the performance of *ML-Net* with different online learning algorithms in calculating $\hat{Pr}(v^{t+1}ji = -1|X^tji)$. We observe that the proposed method outperforms the comparison schemes, regardless of the online learning algorithm used. This indicates that our approach is not dependent on the specific online learning algorithm utilized to calculate $\hat{Pr}(v^{t+1}ji = -1|X^tji)$.

Specifically, the evaluation was carried out using several performance metrics. Precision refers to the fraction of correctly identified negative instances among all the predicted negative instances. The recall is the fraction of correctly identified negative instances among all the actual negative instances. Accuracy refers to the fraction of correctly predicted instances among all the instances. Cohen's kappa is a statistical measure of inter-rater agreement between two raters for categorical items. Variable F_1 is the harmonic mean of precision and recall.

The results of the performance analysis are depicted in the figures mentioned above. The results show that the proposed approach outperforms the comparison schemes in terms of all the performance metrics evaluated. Therefore, we can conclude that *ML-Net* is an effective method for calculating $\hat{Pr}(v^{t+1}ji = -1|X^tji)$ in an online learning setting.

To summarize, we see that *ML-Net* outperforms, for each of the evaluation metrics, the previously known scheme that achieves the best performance for this metric.

VI. Conclusions

This paper addresses the critical issue of Radio Link Failures in FANETs, which stands as a significant challenge requiring innovative solution. We propose a novel approach that combines online machine learning algorithms with message-passing, a technique that has not been explored in this context before. Our proposed solution, known as *ML-Net*, significantly outperforms the best existing competitors across all evaluation metrics, indicating the immense potential of this approach in addressing real-time prediction challenges in communication networks.

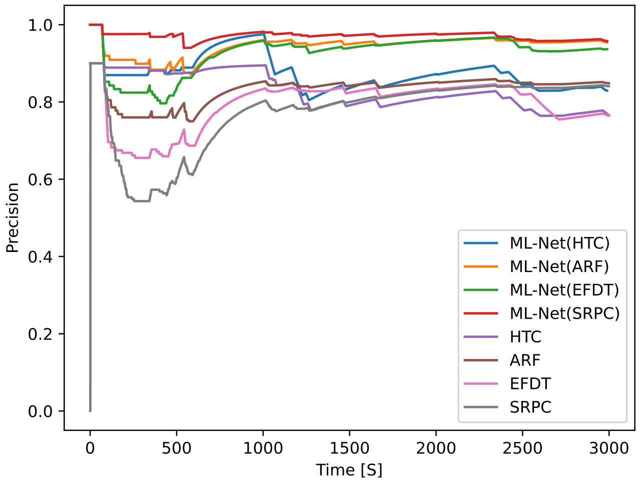

Fig. 10: Precision achieved by schemes for comparison vs. *ML-Net*

Our obtained results are highly promising and suggest that this novel combination of online learning algorithms and message-passing algorithms has the potential to revolutionize the field of FANETs and pave the way for more effective and efficient communication networks in the future. Also, it would be interesting to analyze analytically the influence of parameter α.

***Abstract*—Multipath TCP (MPTCP) has been widely used as an efficient way for communication in many applications. Data centers, smartphones, and network operators use MPTCP to balance the traffic in a network efficiently. MPTCP is an extension of TCP (Transmission Control Protocol), which provides multiple paths, leading to higher throughput and low latency. Although MPTCP has shown better performance than TCP in many applications, it has its own challenges. The network can become congested due to heavy traffic in the multiple paths (subflows) if the subflow rates are not determined correctly. Moreover, communication latency can occur if the packets are not scheduled correctly between the subflows. This paper reviews techniques to solve the above-mentioned problems based on two main approaches; non data-driven (classical) and data-driven (Machine Learning) approaches. This paper compares these two approaches and highlights their strengths and weaknesses with a view to motivating future researchers in this exciting area of machine learning for communications. This paper also provides details on the simulation of MPTCP and its implementations in real environments.**

***Index Terms*—Multipath TCP, congestion control, scheduling, deep reinforcement learning, machine learning**

I. Introduction

COMMUNICATION is key in many domains, such as defense, hospitality, technology, and space. In telecommunications, packet switching is a method of grouping data in smaller packets for faster communication [1]. One of the earliest packet-switched networks started with the Advanced Research Projects Agency Network (ARPANET) [2] in the United States, which is also called the forerunner of the Internet. Today, the Internet has expanded and now consists of a set of protocols for global communications. Basically, a protocol is a set of rules that the sender and receiver must agree on to communicate with each other. The two well-known Transport layer protocols are User Datagram Protocol (UDP) [3] and Transmission Control Protocol (TCP). UDP does not need any handshaking, which means the receiver does not send any acknowledgment to the sender when it receives a message. UDP thus leads to faster communication.

TCP [4] provides more consistent communication by considering handshaking between the sender and receiver. With millions of devices connected to the Internet, there is a demand for faster communication, but TCP fails to meet that need. It's because of TCP's congestion control algorithm, which decreases the throughput (message delivery rate) in response to the loss of packets in the network. Also, the handshaking of TCP increases the time necessary for a packet to travel, resulting in higher latency. Keeping in mind these problems, Multipath TCP (MPTCP) has been introduced by the Internet Engineering Task Force (IETF) [5] to use multiple paths effectively and efficiently between the sender and receiver.

TCP connections can experience packet losses or connection drops, resulting in a poor user experience [6]. MPTCP can use multiple TCP connections, known as subflows, in parallel to overcome TCP's limitations. One of the main goals of MPTCP is to control congestion and maintain traffic flows. Another focus of MPTCP is scheduling the packets over different subflows to send packets with the smallest round-trip time (RTT) [7], which is the time taken to send a data packet to the destination and receive an acknowledgment from the receiver. There are a set of traditional techniques such as Dynamic-Window Coupling (DWC) [8], Opportunistic Linked Increases Algorithm (OLIA) [9], Balanced linked adaptation (BALIA) [10], and Adaptive and Efficient Packet Scheduler (AEPS) [11] that control congestion or simultaneously schedule packets over multiple paths in MPTCP.

Since the standardization of MPTCP, a lot of classical approaches have been proposed to improve the performance of the network in terms of throughput and latency, but most of them perform poorly in highly dynamic networks. Recently, *data-driven* approaches, which are mostly based on Deep Reinforcement Learning, perform much better in dynamic networks because of their ability to learn the network conditions. To the best of our knowledge, there have been only a few proposals on controlling congestion while scheduling packets using deep reinforcement learning-based approaches. Although some methods have been proposed to control congestion, those works have not focused on reducing RTT. Some researchers have proposed schedulers to reduce latency, but they did not consider achieving high throughput.

One of the biggest benefits of using MPTCP is its capacity to use all the available subflows and boost the network's throughput. However, to achieve high goodput, a scheduling strategy is important. Scheduling in MPTCP distributes packets over different subflows based on the smallest RTT. Schedulers using classical approaches, like [12]–[14], increased the throughput but failed to adapt to the dynamic nature of a real-world network. They were tested using simulation, which, of course, does not emulate the real-world scenario. Machine Learning and Reinforcement Learning models have improved the above drawbacks as they can learn from past experience and they are more robust to the dynamic nature of real-world networks; However, machine learning techniques are usually slower than classical approaches and need a huge dataset to train the models [15]–[17].

A. Contributions

The *objective* of this paper is to provide a brief overview of the existing work on MPTCP, including both classical and machine learning-based approaches. We discuss how previous researchers have addressed MPTCP challenges and summarized their solutions. Previous works have reviewed the existing congestion control and scheduling techniques for MPTCP [7], [18]–[21]. Among those works, some review papers have focused on either congestion control of MPTCP or only the scheduling of MPTCP, while others have reviewed only the existing work on MPTCP establishment. There are also some works that have mentioned both congestion control and scheduling but have not focused much on the scheduling-based works of MPTCP. The *contributions* of this paper are as follows:

- Discuss the difference between the traditional TCP and MPTCP communication protocols.
- Discuss in detail both the congestion control and the packet scheduling problems separately.
- Comparison between the performance of ML-based and classical algorithms in terms of controlling congestion and packet scheduling.
- Summarize basic concepts in MPTCP, including the establishment of MPTCP in real-world platforms and simulators.
- Highlights advantages and limitations of previous works that can help the readers investigate future improvements on MPTCP.

The rest of our paper is organized as follows; Section II describes the terminologies in communication and deep reinforcement learning. Section III compares TCP and MPTCP. Sections IV and V describe previous works on congestion control and scheduling of MPTCP, respectively. Section VI focuses on the performance of both congestion control and packet scheduling. MPTCP implementations in the kernel and NS-3 are described in Section VII. Lastly, in Section VIII, we conclude our survey by discussing future works in MPTCP congestion control and scheduling.

II. Background & Terminologies

A. Overview of TCP

TCP is a connection-oriented communication standard that computer applications use to communicate over a network. It is a packet transfer protocol in the Transport Layer [22] of the TCP model. TCP uses only one dedicated path for packet transfer. Though TCP guarantees data integrity of the packets, it has to face packet loss, delay and other problems which are discussed in Section III. Also, network congestion is another major problem in TCP which is discussed briefly later. Section II-B summarizes some concepts in TCP which would be in common with MPTCP and they are also used in congestion control.

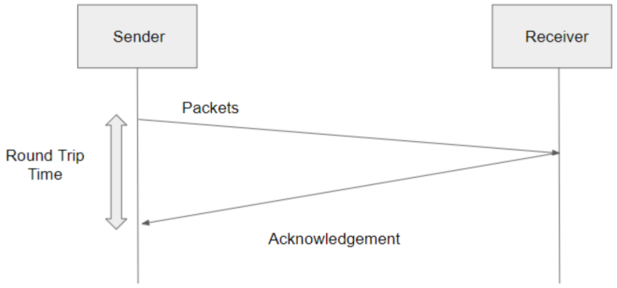

Fig. 1. Illustration of the RTT of a packet from the sender to the receiver.

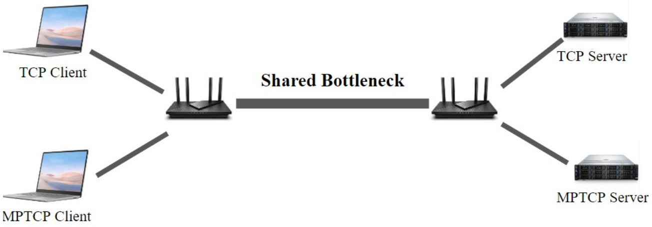

Fig. 2. Illustration of shared bottleneck scenario in a network [23].

B. Some Concepts in TCP

- **Round Trip Time (RTT):** The time required to send a packet from the client to the server, and the time it takes for the server to receive an acknowledgment about receiving the packet is known as the round trip time (RTT). Reducing the round trip time is a primary focus of MPTCP. Figure 1 illustrates the meaning of RTT.
- **Throughput vs Goodput:** Throughput refers to the total number of packets transferred to the destination within a fixed time frame. On the other hand, Goodput is the number of meaningful packets that are delivered to the destination within a given time frame.
- **Low Latency vs High Latency:** Latency refers to the amount of time required to send a packet from source to destination and back again. Low latency is always preferable.

- **Congestion Window (CWND):** The congestion window decides the number of bytes or how many packets will be sent at a given time. Depending on the larger congestion window size, the throughput will also be maximized. Congestion window size has been determined by the slow start and congestion avoidance phases of TCP which will be discussed in the next part.
- **Bottleneck vs Shared Bottleneck:** Bottleneck occurs when there is not enough network capacity in a connection to handle the current volume of traffic. On the other hand, when a bottleneck link is shared between multiple subflows, it is referred as a shared bottleneck which is useful for maximizing the throughput. Figure 2 illustrates the concept of a shared bottleneck scenario.

C. Congestion Control in TCP

TCP's congestion control mechanism has three phases; (1) slow start phase; (2) congestion avoidance phase; and (3) congestion detection phase. The basic difference between these three phases is the rate of increase in the congestion window size.

- **Slow Start Phase:** Slow start phase works as a part of the congestion control algorithm in TCP by controlling the amount of data flow in a network. When a network becomes congested from excessive data in the network, the slow start phase chokes the traffic by limiting the congestion window size. In the slow start phase, the sender sends a packet that contains its initial congestion window, and the client responds with its maximum buffer size after receiving the packet. If the sender gets the acknowledgment from the receiver, the number of packets to be sent to the receiver is doubled. This procedure continues until no acknowledgment is received. The acknowledgment may not be received for two reasons: if congestion occurs or the window limit of the client is reached.
- **Congestion Avoidance Phase- Additive Increase:** The congestion avoidance phase starts when the congestion window size of the TCP reaches a threshold in the slow start phase. In this phase, the size of the congestion window increases linearly. To elaborate, assume the congestion window size at time t is 20 and all the packets have been transmitted successfully, then the congestion window size at time $t+1$ will be 21.
- **Congestion Detection Phase- Multiplicative Decrease:** If congestion occurs in the slow start phase or congestion avoidance phase, the congestion window size is decreased. This is called the multiplicative decrease phase, where TCP follows an exponential reduction of the congestion window. The additive increase and multiplicative decrease phases of the congestion avoidance and detection phases are referred to as Additive Increase Multiplicative Decrease (AIMD). An example of AIMD is shown in Figure 3.

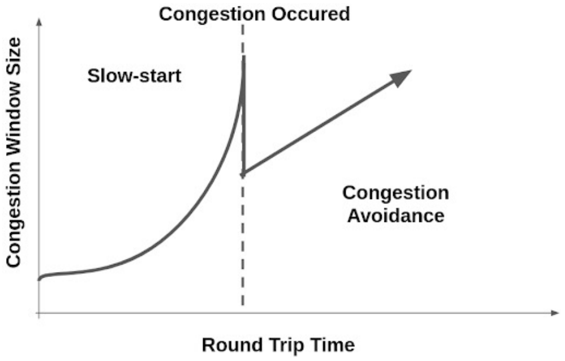

Fig. 3. Change in the congestion window in AIMD algorithm when a packet loss is encountered.

D. Overview of MPTCP

As opposed to TCP, which solely considers one path to transfer data, MPTCP is a transport layer protocol that allows the transfer of packets along multiple paths between the sender and the receiver. This helps the network increase its load capacity, thereby transferring a larger number of packets compared to TCP. The paths in MPTCP are called subflows. When one or more of the subflows fails to send a packet, it can flow through other subflows, leading to a fault-tolerant network. MPTCP is used in several areas of communication where there is a need for high throughput and very low latency during packet transfer. MPTCP is used in different applications such as online streaming, networking, gaming industries, VPNs. Figure 4 depicts the use of MPTCP where a cellphone may use either one of the subflows from two subflows to get connected to the server: one is the Wifi, and another subflow is the 5G network. The following section explains the procedure for establishing the MPTCP communication.

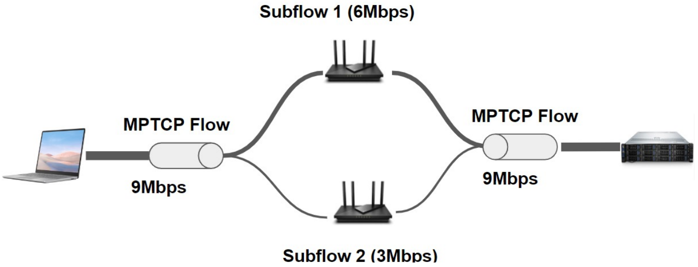

Fig. 4. Overview of MPTCP

.

1) Establishment of MPTCP Connection: The establishment of MPTCP between a sender and the receiver has two stages; In the first step a single flow is established. This phase is similar to TCP. Then, subsequent subflows are created. In the first stage, the sender and the receiver use one subflow to set up the MPTCP connection between them by sharing randomly generated keys. This lays the foundation for creating further paths between the sender and the receiver. Figure 5 shows the establishment of an MPTCP connection using all subflows.

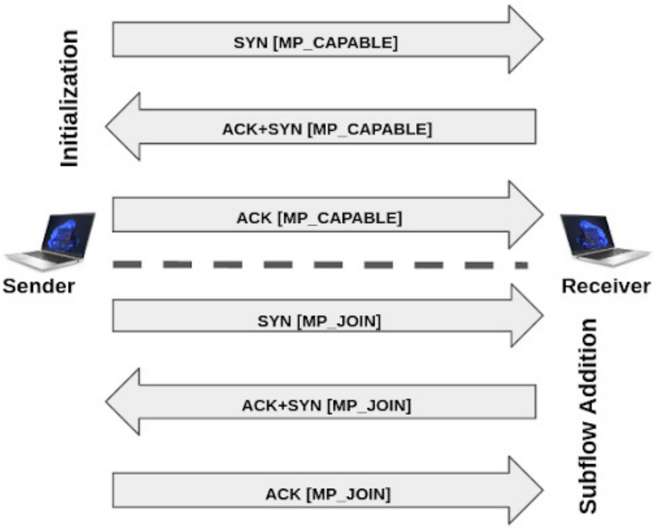

Fig. 5. Establishment of an MPTCP connection.

In MPTCP, after the establishment of the initial handshake as in TCP, the subsequent subflows are also handshaked [24]. MPTCP follows three-way handshaking consisting of SYN (synchronize), ACK+SYN and ACK (acknowledge). In the SYN packet, the sender shares its own token and a random nonce (number). Here the token is the hash value of the key using some cryptographic function which can be calculated in the initial phase with the keys exchanged in that phase. Subsequently, in the SYN+ACK packet, the receiver creates an HMAC (Hash-based message authentication code), the receiver's token and its nonce.

The option MP_CAPABLE is used to check whether the remote host is MPTCP enabled in the initial subflow. The option MP_JOIN is used in the additional subflow establishment to associate with MPTCP connections. Lastly, the sender responds with its HMAC in the ACK packet. [24]

E. Overview of Machine Learning Concepts used in Congestion Control in MPTCP

1) RNN and LSTM: RNN (Recurrent Neural Network) is one kind of neural network that passes the output from the previous steps to the next steps. RNN consists of the input layer, hidden layers, and the output layer. Its hidden state remembers the previous information to predict the next output. RNN works well in terms of correlation, while LSTM (Long Short-Term Memory) not only connects the correlation but also focuses on the context of the information. LSTM is an artificial neural network that follows feedback connections and stores previous information to predict the next one. It is a modified version of the RNN that solves the vanishing gradient problem [25] and can easily process longer sequences. LSTM has an input gate, an output gate and a forget gate. The Input Gate takes an input and vectorizes the input value. The forget Gate is responsible for forgetting unnecessary information, while the output gate generates the output. This helps the framework keep the necessary information and forget the unnecessary ones. Figure 6 shows the different components of an LSTM and compares with RNN. The LSTM-based framework is very popular to create Deep Reinforcement Learning-based congestion control system for MPTCP [26], [27].

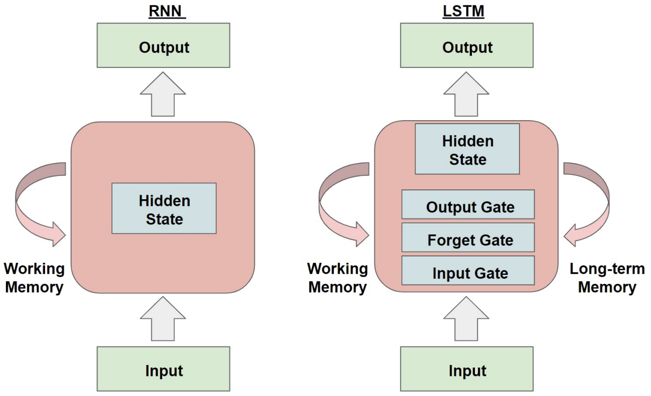

Fig. 6. Architecture of RNN (left) vs LSTM (right).

2) Reinforcement Learning and Deep Q-Learning (DQN): A Markov model [28] consists of a tuple $(s, a, r(s, a))$, where s is the current state vector, a is the vector of actions an agent takes, and R is the reward or the feedback the environment provides for the agent, given the current state and action. In a Markov Decision Process, the agent makes a set of actions, called policy, to maximize its expected reward. The function $Q(s, a)$ defines the optimal (*i.e.*, maximum) expected reward the agent can get, given the current state s and action a. Evaluating Q is important to plan for the optimal policy. Due to the stochastic nature of many environments and agents, calculating the exact value of Q is usually not possible. Instead, the agent learns Q values from its experience; this is called Q-learning, a type of reinforcement learning.

DQN Reinforcement Learning (DRL) uses a deep neural network (DNN) to learn/estimate the Q function. The deep neural network could be RNN, LSTM, CNN etc. In contrast, a traditional Q estimation (e.g., Temporal Difference (TD) learning [29]), is usually a memory table that stores all the previous records of the different steps that have been taken, along with their rewards which is not scalable for an environment with large size of space and actions, or when the action/state space is continuous. Deep-RL has been used in communication for learning the communication strategy between multiple agents. DRL is also used in MPTCP implementation to control congestion and schedule packets to maximize throughput and get low latency. In MPTCP communication network, the state can be throughput, sending rate, RTT, and loss of packets; actions should be increasing/decreasing congestion window size and reward is the measurement of either good or bad performance of the network, based on the state and action.

3) Actor-critic model: An actor-critic has two major components: an actor and a critic. An actor takes the state of the current environment and determines the best action that needs to be taken, depending on that state. Whereas the critic works for the evaluation role by taking the environment state with actions and returning a score/reward (*e.g.,* Q) to decide how good is that action for that state. Determining the best action depends on the Q score, which is calculated separately in the critic network. An actor-critic learning technique learns both a policy function and a value function at the same time. The value function aids in enhancing the value function's training procedures, while the policy function instructs on how to make decisions.

4) Transformers and Self-Attention: The transformer is an encoder-decoder model and has been used in many applications [30]. Self attention follows the encoder part of transformers and can be used in many communication applications such as congestion control [27], or scheduling packets for MPTCP. In natural language processing or machine translation, self-attention for a particular word measures the dependency of that word on the other words; more relevant words have a higher value in self-attention, and loosely connected words have lower values [31], [32]. This concept is brought into the area of communication and subflows. Here the words have been replaced by the subflows. In MPTCP, self-attention checks the dependency of a subflow with the other subflows by assigning different weights to the states of the other subflows. Here the states of the subflows may refer as RTT, packet loss, packet delay, and throughput [27].

III. Traditional TCP vs Multipath TCP

In this section, we discuss some major challenges in network communication, how MPTCP and TCP address them in different situations, including the comparison of MPTCP and TCP performance.

A. Packet Loss

Packet loss happens in a network when a packet fails to reach the receiver. Packet loss in a network indicates network congestion, disruption, or even a complete loss of connection. When a TCP connection encounters a packet loss, it considers a sign of network congestion and, therefore, halves the size of the congestion window and the threshold value; hence the throughput decreases. However, MPTCP is more robust in such cases; whenever it sees one of the subflows having packet loss, it reduces the congestion window of that subflow, while the other subflows remain intact. This was experimentally tested [33] where TCP and MPTCP transmission performances were compared using WiFi and LTE. In this real-world experiment, 750 individuals from 16 nations utilized a crowd-sourced smartphone application for 180 days. Deng et al. [33] compared MPTCP and TCP performance via WiFi or LTE from 20 different places across seven cities in the United States. The fastest link of normal TCP exceeds MPTCP performance for short flows. In this scenario, MPTCP fails to select an appropriate communication path to reduce transmission time for a small amount of data; hence, the packet loss increases for MPTCP. However, TCP experiences greater packet loss than MPTCP in log-distance communication experiments.

B. Packet Delay

Packet delay in a network is the time taken to transfer a packet of data from sender to receiver. The packet delay is highly affected by the number of routers or switches in the route, the nature of the path the packet follows, and the congestion in that path. The vulnerability of packet delay in both TCP and MPTCP scenarios can be described by one communication example. If a computer is connected via both wireless and wired connections, it may communicate with servers using TCP or MPTCP. In terms of TCP, if the connection is established over the wireless connection, it will have a greater overall delay than MPTCP. Wireless connection experiences high packet loss as opposed to the wired connection which leads to higher latency [34].

MPTCP has the choice to choose either a wired or wireless connection, it may transfer the packets via the wired connection if it experiences major packet delay through a wireless connection. Raiciu et al. [35] have compared the performance of MPTCP and TCP-based on the packet delays in different network topologies. Their findings reveal that MPTCP can achieve 90 percent bandwidth utilization and low overall packet delay when the number of subflows is two and eight in the VL2 [36] and FatTree network [37] topologies, respectively. The result also showed that MPTCP not only increases the bandwidth but also increases the robustness to network changes by lowering the packet delay.

C. Out-of-Order Packets

In TCP, a message is divided into multiple parts, known as packets. Each of these packets is given a unique number known as the sequence number. When these packets reach the receiver, it uses the sequence number to put them in order to retrieve the message. If these orders are not maintained during transmission, the delivery is called out-of-order delivery of packets. UDP is notorious for these deliveries as it does not consider any handshaking when each packet is received. But in TCP, the next packet is not sent until it gets the acknowledgment from the previous packet. If it gets a time out or negative acknowledgement (NACK) [38], the packets are sent again; therefore, out-of-order delivery is rare in TCP. However, in MPTCP, there is a high chance of out-of-order delivery of packets as they use different subflows with different delays. Therefore, scheduling is one of the most challenging tasks in MPTCP, and a lot of work has been done to address this issue. Yang et al. [39] have mentioned a situation where the jitter can happen for transferring data in MPTCP. They tackled this issue using an innovative traditional scheduling process named Delay Aware Packet Scheduling technique to remove the jitter in the packets. Han et al. [17] used a queue to keep redundant packets that may get lost.

D. Round Trip Time

Round Trip Time (RTT) has been discussed in section II. Chen et al. [40] have compared the performances of TCP and MPTCP over WiFi and cellular networks where the authors compared the RTTs of the transmission protocols. They conducted two sets of experiments; in the first experiment, they used small-sized files, and in the second, large-sized files were used. In the first experiment, the file size varied from 8KB to 32MB. When WiFi is the default route, there is no discernible gain in MPTCP download performance over TCP. For small file downloads (such as 64 KB), the single route via WiFi delivers the optimum speed. However, a single LTE (Long-Term Evolution) [1] channel becomes the optimum option for relatively longer traffic flows. MPTCP outperforms TCP for larger files.

IV. Congestion Control of MPTCP

Congestion control is a concept of controlling congestion in a network and could happen in both TCP and MPTCP. Congestion occurs when there is too much data that needs to be sent through a network. Congestion control regulates the flow of data packets into the network, allowing for efficient use of a shared network infrastructure and preventing congestion collapse. In TCP, where there is only one subflow, the network is easily congested.

Different types of algorithms have been proposed to improve the congestion in TCP networks, such as TCP Cubic [41], TCP Vegas [42], and TCP Reno [42]. MPTCP provides several subflows, which results in a reduction of congestion. MPTCP has been designed to address the congestion issue, while still having the traffic flowing like a single-path TCP. A naive implementation of CC in a multipath setting would be using regular TCP congestion control for each subflow; however, it is not efficient as MPTCP which uses multiple concurrent TCP connections. Having a congestion control that manages the packet flows on subflows concurrently seems more efficient. For this purpose, many methods have been proposed to improve congestion in MPTCP. Congestion control algorithms for MPTCP are classified as classical and machine learning approaches which will be discussed in the following subsections.

A. Classical Congestion Control Approaches

Most of the existing congestion control algorithms in MPTCP setting focus on the Congestion-Avoidance (CA) phase that solely considers long flow transmissions and does not focus much on the slow start phase. The congestion avoidance phase prevents a network from being overflooded by data such that it discards packets with low priority to be delivered, and the rate of transmission rises linearly over time. Another approach is to focus on Slow Start. The Slow Start phase limits the quantity of data to be sent over a network to avoid congestion. However, it causes exponential growth of the congestion window in the uncoupled Slow-Start (SS) phase, leading to buffer overflow from burst data. In terms of solving the mentioned problems, Yang et al. [43] have proposed a Throughput Consistency Congestion Control (TCCC) algorithm which consists of both Coupled Slow-Start (CSS) and Aggressive Congestion Avoidance (ACA). The usage of CSS prevents packet loss brought on by large data bursts and ACA works on getting fair bandwidth which is shared in congestion avoidance. Their proposed framework enhances transmission efficiency. However, the CSS algorithm only plays a part in the initial slow start phase of MPTCP. As the subflows of MPTCP belong to different phases in congestion control (see Section II-C), the CSS algorithm needs much extra consideration, which makes congestion control more challenging in MPTCP [43].

Traditional AIMD used in TCP shows poor performance adaptation in terms of network state-changing situations in MPTCP. Gilad et al. [44], have presented a method named MPCC that uses online learning. Their implementation has been performed in Linux kernel and the method has been tested on different network conditions and many different network topologies. In terms of improving the implementation, their analysis needs to be reached beyond parallel link networks. As further research, they have mentioned about boosting the performance for short flows and solving the bandwidth mismatch problems on network paths.

An energy-aware based congestion control algorithm (ecMTCP) has been developed by Le et al. [12] where the method distributes traffic between the most crowded and least crowded paths, as well as across paths with different energy costs, to achieve load balancing and energy savings. For simulation purposes, they used NS-2 simulator [45], and their design mechanisms can work on getting higher throughput in terms of both TCP and MPTCP flows. The main goal was to shift the traffic to less energy-intensive and less crowded paths. Cao et al. [13] proposed weighted Vegas (wVegas), a delay-based congestion control scheme for MPTCP. This algorithm has detected the packet queuing delay of each path and ultimately has decreased the packet load of congested subflows by increasing the load of the less congested one. This framework performed traffic shifting which can cause less packet losses and provide better traffic balance in subflows. Cao et al. used NS-3 simulator [46] to conduct the simulation and build a Network Utility Maximization Model by proposing an approximate iterative algorithm to reach their aim of controlling congestion.

Ji et. al [14] mentioned that existing multipath congestion control algorithms are unable to quickly adjust to dynamic traffic due to the heterogeneous Quality of Service (QoS). QoS refers the technologies that work on a network to manage traffic and enhance performance by reducing packet loss, delay, and latency in a network. It may lead to poor performance in certain network environments. To mitigate these issues, firstly, the authors have noticed the performance constraints of the most recent multipath congestion control algorithms through vast experimentation. Then, they used a unique control policy optimization phase referred to an adaptive QoS-aware multipath congestion management system that can quickly adapt to network changes. Their method uses the Random Forest Regressing (RFR) [47] method to carry out QoS-specific utility function optimization to adapt and encourage the improvement of the selected performance metric. They

[1] wireless broadband communication standard came before 4G network

conducted the implementation in Linux kernel and showed their work outperformed most of the multipath congestion control methods such as wVegas [13], Opportunistic Linked Increases Algorithm (OLIA) [9], Balanced Linked Adaptation (BALIA) [10].

Singh et al. [48] improved the Opportunistic Linked Increases Algorithm [9] and Dynamic-Window Coupling (DWC) [8]. The authors provided a mechanism to reduce the overall packet reordering delay and focused on the buffer size in the receiver side. Their proposed work showed good performance in terms of various bottleneck scenarios.

Hassayoun et al. [8] proposed a multipath congestion control scheme called Dynamic-Window Coupling (DWC) to obtain higher throughput to each end-to-end multiple paths. The authors also detected shared bottlenecks by monitoring loss and delay signals, and then grouped their congestion control mechanism over all subflows that shared a common bottleneck. Detecting the bottleneck for network conditions and regrouping the subflows in terms of the same bottlenecks leads to higher throughput. They also introduced subflow sets, a concept for enabling subflows to smoothly switch between independent and shared bottleneck-based congestion control. The algorithm has been implemented in NS-2 simulator. As future research, the authors introduced the possibility of including ”memory” into the detection method for detecting the previous subflow groupings.

Ferlin et al. [49] have mentioned that increasing the bandwidth of multiple links and getting higher throughput will be impossible if two or more paths do not share a bottleneck. They found out the nonshared bottleneck paths of the coupled congestion control for links, they referred to it as a penalty, and to overcome it, they implemented shared bottleneck detection (SBD) algorithm for MPTCP. This work can balance congestion and throughput. Their observation has shown that in the case of non-shared bottleneck scenario, the maximum throughput can be achieved up to 40% with two subflows. Also, the throughput gain increased by above 100% when the number of subflows increased to five. Their implementation has been performed in Linux kernel and for emulation purposes, they have also used CORE network emulator [50].

B. Machine Learning Approaches for Congestion Control in MPTCP

Though lots of work have been done in classical-based approaches for congestion control of MPTCP. But for controlling congestion, classical-based approaches focus solely on different types of congestion indicators (*i.e.*, packet loss or RTT). In the case of classical-based approaches, the decision-making process totally depends on these unpredictable factors, which leads to poor performance. Whereas ML-based approaches aim to provide decisions based on experience, and can adapt well to any network situation. Thus, ML-based approaches outperform classical-based methods [51].

In reality, networks are dynamic, and the state of the network changes frequently. Due to that, MPTCP performs poorly in many practical situations as MPTCP has to adapt in new network states. Zhuang et al. [52], introduced a Reinforcement Learning technology that can learn the best route to send TCP packets such that the throughput has been maximized. They proposed a simple algorithm for controlling multipath congestion, where congestion control has been approached as a multi-armed bandit [53] issue based on online learning (MP-OL), which allowed flexible and adaptive transmission rate adjustments for each subflow with good performance.

In [26], the authors proposed a Deep Reinforcement Learning (DRL)-based framework to control congestion where a single DRL agent has been utilized to perform congestion control for all MPTCP flows to maximize the total utility. Figure 7 illustrates the concept of DRL for MPTCP congestion control. They implemented the MPTCP in the Linux kernel and used an LSTM-based neural network under a DRL framework to develop a representation for all active flows. Their work was the first work where the authors incorporated the LSTM-based representation network into an actor-critic architecture for controlling congestion which used the deterministic policy gradient [54] to train the critic, actor, and LSTM networks.

He et al. [27] worked on increasing/decreasing the sending rates of packets in response to congestion, where each DRL agent can control the congestion window size of each subflow. Their proposed DRL-based MPTCP framework also included self-attention, which has been used to check the dependencies of one subflow with the weighted sum of other subflows. They compared their work with DRL-CC [26] and showed their method outperforms DRL-CC.

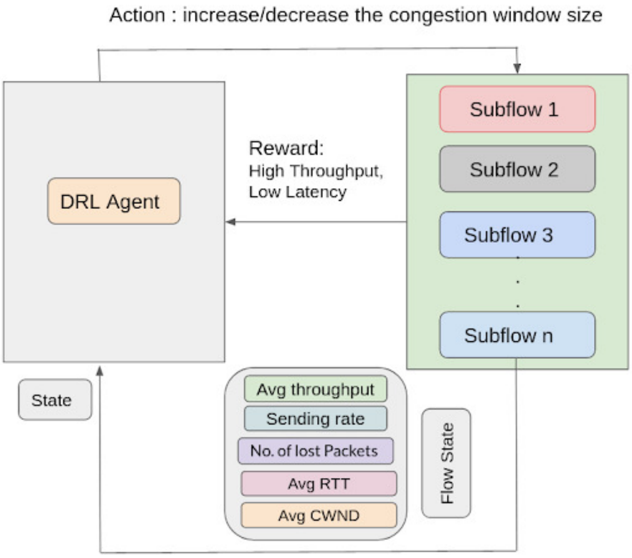

Fig. 7. Subflows are controlled by a DRL agent.

Li et al. [55] proposed a method called SmartCC which can learn a set of congestion rules for observing the environments and taking actions to adjust the congestion window size of each subflow. For the MPTCP implementation task, the authors used the NS-3 simulator.

The Internet of Deep Space Things, or IoDST, offered communication services for mission spacecraft that send video data. To improve TCP throughput and stream playback, Ha et al. [15] designed a congestion control framework for MPTCP, which can be used for data streaming transmission. Their proposed Q-learning and Deep Q-Network (DQN)-based congestion control scheme calculated the ideal congestion window for data transfer in IoDST conversations.

Xu et al. [56] proposed the SGIN-based High-Speed Railway (HSR) scenario with MPTCP. Space-ground integrated networks (SGINs) has been referred to as promising network architecture that provides seamless, high-rate, and reliable data transmission with incredibly wide coverage. By utilizing MPTCP in the SGIN, simultaneous data transfer over terrestrial and satellite networks has been made possible. However, due to MPTCP's current congestion control (CC) mechanisms, it's difficult to know the difference between negative effects (like packet loss and/or increased round-trip time) brought on by congestion and those brought on by handovers. This may lead to severe performance degradation in the SGIN-based HSR scenario, where handover may occur frequently. To solve it, a DRL-based novel approach has been proposed to improve the goodput which outperformed other state-of-the-art algorithms.

Xu et al. [57] presented a DRL-based novel framework for traffic engineering that can make decisions under the guidance of actor-critic networks. In their work, the state consisted of two components, such as the throughput and the delay of each communication session. On the other hand, the action has been defined as the solution to Traffic Engineering (TE) problems. The authors used the NS-3 simulator, and the reward of the model was the sum of the output from the utility function for an entire communication session. The utility function was a function of the throughput and delay of the network, which depicted how the network can perform. In the paper, each session had 20 iterations. In each iteration, the agent sent its actions to the environment and recorded the value from the utility function before updating the reward value. While they considered only one DRL agent (*i.e.*, decision maker) in their framework, adding multiple agents can be considered to further improve the performance.

Pokhrel et al. [58] introduced a transfer learning-based MPTCP framework for Industrial IoT, where the neighboring machines can collaborate to learn from each other. In their approach, when a new DRL system controlling the IoT network joins the environment, it can use the idea of transfer learning. [2] NS-3 was used to simulate the algorithm. Their model has been proven theoretically and needs further research to determine its performance in a real-world situation.

V. Scheduling of MPTCP

Scheduling of MPTCP decides the amount of data that needs to be scheduled to different subflows based on getting the higher performance (high throughput, low latency, less packet loss) in MPTCP. In this section, different classical and ML-based approaches have been discussed which can be used to schedule packets in MPTCP.

A. Classical Approaches for Scheduling in MPTCP

Hwang et al. [59] dealt with the problem of scheduling small-length packets. However, the authors mentioned MPTCP is usually advantageous for long-lived flows, and it performs worse than single-path TCP when the flow size is tiny (*e.g.*, hundreds of KiloBytes). In this scenario, the quickest method is preferable since latency is far more critical than network bandwidth with such tiny data deliveries. The regular MPTCP packet scheduler may pick a slow path if the fast path's congestion window is unavailable, resulting in a delayed flow completion time.

To address this issue, Hwang et al. [59] suggested a novel MPTCP packet scheduler that momentarily blocks the slow path when the latency difference between the slow and fast paths is considerable, allowing the tiny quantity of data to be delivered swiftly via the fast path. The authors used the method to find the subflow with the lowest RTT regardless of the availability of the congestion window, and then they used the existing Lowest-RTT-First policy [60] to choose the optimal subflow. They then returned the best one if the difference between the best subflow RTT and the minimum RTT is less than a certain threshold. They picked 100ms for threshold delay when testing 3G and WiFi networks in this paper.

Chaturvedi et al. [11] analyzed different existing schedulers and identified some current outstanding concerns, such as head-of-line (HoL) blocking and out-of-order packet delivery. HoL blocking may occur when a single data packets queue may wait to be transmitted and the packet at the head of the line may not be able to move ahead due to congestion [61]. These problems reduce MPTCP performance and to mitigate the issues, the authors have presented an adaptive and efficient packet scheduler (AEPS). This novel MPTCP packet scheduler not only addresses these concerns but also offers high throughput with a short completion time by using the capacity of all available pathways. AEPS can send data packets to the receiver in the order they were received, and its performance is unaffected by the size of the receiver buffer, or the size of the data being transmitted. The AEPS has been developed with three objectives: (1) packets should arrive to the receiver buffer; (2) all pathways' bandwidth should be used; and (3) completion time should be as short as possible. According to the authors, the first condition assisted AEPS in resolving the HoL blocking and received window-limiting issues by sending packets to the receiver buffer in sequence. The second condition summed the bandwidth of each interface (path) by using all accessible pathways to the MPTCP source, which also helped to enhance throughput. The third criterion aided in choosing the routing for each packet so that the total network completion time can be minimized.

Dong et al. [62] thoroughly compared existing scheduling algorithms and guided the development of new scheduling algorithms in 5G. The authors examined the influence of several

[2] Transfer learning uses a previously trained model as the foundation for a new model on a different task.

network parameters, such as RTT, buffer size, and file size, on the performance of current extensively used scheduling algorithms over a wide range of network circumstances. The paper compares the Lowest-RTT-First [60], Delay-aware packet scheduler (DAPS) [63], Out-of-order transmission for in-order arrival scheduler (OTIAS) [64] and Blocking estimation-based MPTCP scheduler (BLEST) scheduling [65] algorithms. The number of timeouts and flow completion time are compared in the path heterogeneity test. The results showed Lowest-RTT-First has the most timeouts, while the BLEST has the fewest. BLEST surpasses other algorithms in varying buffer size outcomes, followed by OTIAS and DAPS. Since BLEST can dynamically predict whether head-of-line blocking will occur and hence minimizes the quantity of out-of-order packets. In the different file size tests, BLEST and LowRTT perform better than DAPS, and OTIAS outperforms BLEST.

Le et al. [66] tackled the problem of out-of-order delivery in MPTCP. Because of the diverse nature of latency and bandwidth on each channel, the out-of-order packet issue becomes severe for MPTCP. To solve this issue, the authors presented the forward-delay-based packet scheduling (FDPS) method for MPTCP. The technique is divided into two parts: predicting the forward delay differences across pathways and picking data to send through a path when the congestion window is available.

B. Machine Learning Approaches for scheduling in MPTCP

In recent times, many ML-based approaches have been proposed to improve the scheduling mechanism of MPTCP. Though classical approaches achieve good performance in terms of scheduling in MPTCP, ML-based approaches also show promising result and becomes popular in terms of getting higher throughput with lower latency than non-ML methods.

Wu et al. [16] applied a learning-based technique to schedule packets in the different paths of an MPTCP. The authors have presented FALCON, a learning-based multipath scheduler that can adapt to changing network circumstances quickly and correctly using meta-learning. The meta-learning algorithm comprises two parts: offline training and online training parts. The online learning module captures the network-changing conditions whereas the offline learning module takes the experience(data) from the online module and divides the experience into different groups depending on the network conditions.

Han et al. [17] used the technique of redundancy of packets to reduce packet loss by suggesting EdAR (Experience-driven Adaptive Redundant packet scheduler). In the face of dramatic network environment changes, EdAR enables dynamically scheduling redundant packets using an experience-driven learning-based strategy for multipath performance enhancement. To allow accurate learning and prediction, a Deep Reinforcement Learning (DRL) agent-based framework has been created that learns both the network environment and the optimal course of action. EdAR has two transmission modes: standard transmission and redundant transmission. Standard transmission follows the regular data transition. Regarding the redundancy transmission, there is a buffer called redundant buffer. The redundant buffer holds packets that have already been transmitted but have yet to be acknowledged. If a new packet is transmitted from the send buffer on a subflow, it is copied to the redundant buffer. If a packet in the redundant buffer is not sent out or acknowledged, it is deleted from the redundant buffer. Silva et al. [67], used linear regression [68] to predict throughput and latency in MPTCP subflows, and proposed Artificial Neural Network [69]-based linear classifier to choose the best subflow which can provide better performance in MPTCP scheduler. They implemented their work in NS-3 simulator.

VI. Congestion Control and Scheduling of MPTCP

Few works have been done focusing on congestion control and scheduling the packets of MPTCP at the same time. Those works get higher throughput and lower latency in terms of performance evaluation. Though further research regarding congestion control with packet scheduling is needed to be done. This section reviews classical and machine learning approaches that have been done in this domain.

A. Classical Approaches on both Congestion Control and Scheduling of MPTCP

Wei et al. [23] proposed a model that gets higher throughput when the networks do not go through a shared bottleneck. Their work had two outcomes: (1) When no congestion would occur, their method has been able to get higher throughput than a single TCP. (2) When there is congestion in the network, their method has at least the same throughput as TCP. Their method also measured how severe or minor the congestion is in the network. They have introduced both SB-CC (Shared Bottleneck-based Congestion Control Scheme) and SB-FPS (Shared Bottleneck-based Forward Prediction packet Scheduling scheme), where SB-CC can detect shared bottlenecks and estimate the congestion degree of all subflows. SB-FPS can perfectly schedule data in shared bottleneck and can also distribute data according to the congestion window size of each subflows. For implementing MPTCP, they used the Linux kernel and achieved higher throughput.

B. Machine Learning Approaches on both Congestion Control and Scheduling of MPTCP

Pokhrel et al. [71] have introduced the Deep Q learning (DQL)-based method to control congestion and schedule packets for MPTCP. Their proposed DQL framework has utilized the LSTM-based recurrent neural network where in their framework the Q function provided the logarithm value of goodput for the previous iteration. Here, the policy function was the actor-critic of two LSTMs and the value function was the reward. They considered RTT, throughput, and sending rate as the state. Depending on the state, their model provided action on whether window size needed to be increased or decreased and what changes can be taken in the schedule of packets for the subflows. In their work, the reward was the

TABLE I
Performance measurement of reviewed papers for Congestion Control and Packet Scheduling in MPTCP.

Approaches	**Paper**	***Feature***	***Strength***	***Limitations***	***Implementation***

summation of all the Q functions for all subflows. Similar to other RL algorithms, the optimal decision was learned to maximize the reward. They have made their MPTCP implementation in the Linux kernel and achieved low delays with maximum goodput.

VII. Implementation of MPTCP

In this section, we describe different ways of implementing MPTCP either in real hardware (kernel) or in simulator and list some of the works for each type of implementation as the reader's reference. Previously, NS-2 simulator has been used for implementing MPTCP [8], [72]. Now, most of the recent works have focused on implementing MPTCP in the Linux kernel after enabling MPTCP in the operating system or using the NS-3 simulator. Very few works implemented MPTCP on the CORE emulator.

A. Simulation

Chihani et al. [73] implemented MPTCP in the NS-3 simulator and introduced a new protocol that worked better in various network conditions. They compared different packet reordering systems and analyzed that their implementations will be necessary for further MPTCP performance analysis in terms of controlling congestion. Nadeem et al. [74] worked on introducing three path managers; default, ndiffports, and fullmesh to create an MPTCP patch for implementing MPTCP in the NS-3 development version. While the default patch has not made any new subflows, fullmesh made a mesh of whole new subflows towards the feasible pairs of IP addresses; ndiffports introduced subflows in between the same IP pair with the help of distinct source and destination. It showed better results in terms of getting higher throughput and less flow completion time than prior works. Coudron et al. [75] proposed MPTCP implementations in NS-3 to handle network traffic. They also compared their algorithm with previous work implemented in NS-3 and Kernel. Table I lists some other MPTCP implementations in NS-2, NS-3 and CORE simulator with the aim of congestion control or schedule packets or perform both congestion control and packet scheduling for MPTCP.

B. Real Hardware (kernel)

Network simulators sometimes fail to depict the original network conditions, as the real-world network is highly dynamic; the breaking of links and the creation of new links are spontaneous. Therefore, the evaluation of MPTCP on real-world networks using Linux kernels shows a much bigger picture of its strengths and weaknesses. In the work [76], the authors have implemented MPTCP in a Linux kernel to study if each subflow has a different scheduler and then how the different subflows of an MPTCP may dispute bottleneck links with conventional single-path TCP. They tested LIA, OLIA, BALIA and wVegas on Linux kernel implementation of MPTCP and evaluated the throughput, latency, etc., on real-world networks. Zannettou et al. [24] used the kernel implementation of MPTCP to show their MPTCP-aware scheduling performs better than random hashing of packets to subflows which is generally used. They used the FatTree [77] and Jellyfish [78] topologies to conduct their experiments. FatTree is a highly structured topology used in data centers to obtain the highest throughput cost-effectively, while Jellyfish is the most commonly used randomly structured topology which can support more hosts than the FatTree, while keeping almost the same throughput. The commercial application for MPTCP support is available online [79].

VIII. Conclusion

This paper focuses on two crucial concepts in MPTCP - congestion control and scheduling. The study shows how the most recent works fulfill the previous work gaps and mitigate the above two MPTCP issues using different classical and ML-based approaches. Our study also presents the advantages and limitations of current works and encourages the researchers to continue further improvements in this domain. As in every communication sector MPTCP establishes a tremendous role, it is necessary to improve the performance of MPTCP, and our paper can be beneficial for the readers to have an extensive knowledge of MPTCP performance issues and can use it for proposing new algorithms.

Abstract Approach to Entropy and Co-Entropy in Measurable and Probability Spaces Invited Lecture—Extended Abstract

Gianpiero Cattaneo*
* Retired from Department of Informatics, Systems and Communications
University of Milano–Bicocca, Italy

THE talk is divided in following parts.

(Pa1) First of all, the talk is based on the *Universe* $\mathcal{U} := (\mathbb{N}, \mathcal{P}(\mathbb{N}))$, consisting of the set of natural integers $\mathbb{N}$ and its power set $\mathcal{P}(\mathbb{N})$. Elements $a \in \mathbb{N}$ are interpreted as *micro-states* of the system and subsets $A \subseteq \mathcal{P}(\mathbb{N})$ of the universe are interpreted as *events* which can be tested on it. The first part concerns the abstract approach to *measure distributions of total measure* $M > 0$, as non negative sequences of integer numbers $\widehat{m} := (m_1, m_2, \dots, m_M)$, i.e., with any $0 \leq m_j \in \mathbb{N}$, and satisfying the condition $\sum_{j=1}^{\infty} m_j = M$. These measure distributions can also be interpreted as *physical macro-states* of the system and their collection will be denoted as $\mathcal{MD}_M$.

From any M-measure distribution $\vec{m}$ it is induced, in a standard way, the *probability distribution* $\vec{p} := (p_1 = m_1/M, p_2 = m_2/M, \dots, p_M = p_M/M)$, where any $p_j := m_j/M \geq 0$ and $\sum_{j=1}^{M} p_j = 1$ (from which it follows that $p_j \in [0, 1]$, according to the usual definition of probability). Based on these basic notions, the following important definitions are then introduced:

a) The *entropy* associate to a M-measure distribution $\vec{m}$ is defined as $H(\vec{m}) := \log M - \frac{1}{M} \sum_j m_j \log m_j$ (from which it follows the standard Shannon entropy $H(\vec{p}) = -\sum_j p_j \log p_j$).

b) The *co-entropy* (i.e., *complementary* entropy) of $\vec{m}$ is defined as $K(\vec{m}) := \frac{1}{M} \sum_j m_j \log m_j$ (from which it follows $K(\vec{p}) = \sum_j p_j \log(M \cdot p_j)$).

Now, once introduced the *total entropy* as $E(\vec{m}) := H(\vec{m}) + K(\vec{m})$, it is easy to prove the *total entropy conservation principle*: $\forall \vec{m}$, $E(\vec{m}) = \log M$ (resp., $\forall \vec{p}$, $E(\vec{p}) := H(\vec{p}) + K(\vec{p}) = \log M$), quantity *always* equal to the constant $\log M$, i.e., invariant with respect to the considered measure distribution $\vec{m}$ (resp., to the considered probability distribution $\vec{p}$).

(Pa2) In the context of the *concrete Universe*, the second part is dedicated to the partition $\pi(\mathbb{N}) = \{A_1, A_2, \dots, A_K\}$ ($K \leq M$) of the universe $\mathbb{N}$, formed by the so-called *blocks* A_j, and generating the equivalence relation $\equiv$ on $\mathbb{N}$:

let $a_r, a_s \in \mathbb{N}$, then $a_r \equiv a_s$ iff $\exists A \in \pi(\mathbb{N})$: $a_r \in A$ and $a_s \in A$.

The partition $\pi(\mathbb{N})$ determines the measure distribution:

$$\vec{m}(\pi(\mathbb{N})) = \big(m(A_1) = |A_1|, \\ m(A_2) = |A_2|, \dots, m(A_K) = |A_K|\big),$$

of total measure $m(\pi(X)) := \sum_{j=1}^{K} m(A_j) = \sum_{j=1}^{K} |A_j| = M$; with corresponding entropy and co-entropy.

But in some sense, the present part (Pa2) constitutes a point of connection between the abstract content of point (Pa1) and the concrete part which constitutes the fundamental content of the next point (Pa3).

(Pa3) The collection $\mathcal{MD}_M$ of all measure distributions was the subject of a long research conducted together with French collaborators many years ago entitled *Ice Pile Models*. Brylawski in a paper published od Discrete Mathematics (1973) investigated from a pure algebraic point of view the collection $\mathcal{IP}_M$ of M-uples of non-negative integers $\alpha := (a_1, a_2, \dots, a_M)$, called *integer partitions*, satisfying the further condition of being *non-increasing*: $\forall i$, $a_{i-1} \geq a_i$. Trivially, $\mathcal{IP}_M \subseteq \mathcal{MD}_M$. This collection has a lattice structure with respect to a lattice order $\leq$, called *dominance*, with minimum element $\mathbf{0} := (M, 0, \dots, 0)$ and maximum element $\mathbf{1} := (1, 1, \dots, 1)$, i.e., $\forall \alpha \in \mathcal{IP}_M$, $\mathbf{0} \leq \alpha \leq \mathbf{1}$. On the lattice $\mathcal{IP}_M$ Brylawski introduces the definition of *elementary transition* as the binary relationship: $\alpha \to \beta$ iff $\alpha \lneqq \beta$ and $\exists \gamma$: $\alpha \leq \gamma \leq \beta$, then either $\gamma = \alpha$ or $\gamma = \beta$. On the standard configuration space $\mathcal{IP}_M$ of Brylawski, we interpret the component of place i of the configuration α as a column of a_i grains that can move from left to right. The most interesting result is the following

Theorem – *The configuration transition $\alpha \to \alpha'$ in the space $\mathcal{IP}_M$ occurs iff one of the only two cases occurs: (1) The* vertical *evolution rule (VR) which solves jumps in the configuration of two units. Formally,*

$$\textit{let } \; a_{j-1} \geq a_j + 2, \quad \textit{then}$$
$$(a_{j-1}, a_j, a_{j+1}) \xrightarrow{(VR)} (a_{j-1} - 1, a_j + 1, a_{j+1})$$

(2) the horizontal evolution rule (HR) in which a grain can slip from column $j-1$ to column j according to the following local behaviour

$$\textit{let } a_{j-1}-1=a_j, \quad \textit{then}$$
$$(a_{j-1},a_j,a_{j+1}) \xrightarrow{(HR)} (a_{j-1}-1,a_j+1,a_{j+1})$$

But, the Ice Pile model has been defined by Goles–Kiwi (1993) just as the structure based on the Brylawski lattice equipped with the two local evolution rules (VR) and (HR). Furthermore, from another point of view, since the two local rules involve neighborhoods of the center a_i of radius 1, they define a one-dimensional *Elementary Cellular Automata*. In any case, whatever the point of view adopted, the application of the two rules (HR) and (VR) determine a discrete time dynamical system since it is possible to consider all the dynamic evolutions $\gamma : \mathbb{N} \mapsto \mathcal{IP}_M$ of initial state $\mathbf{0}$ of the kind $\mathbf{0} \to \alpha(1) \to \alpha(2) \to \ldots \to \alpha(t) \to \ldots$, which by a Theorem converges after a finite number t_f of time steps to the unique final equilibrium configuration $\ldots \to \alpha(t_f) = \mathbf{1}$.

The important point is that if to any configuration $\alpha(t)$ of a trajectory γ one calculates the corresponding entropy $H(\alpha(t))$ one obtains the strictly increasing chain of positive numbers $0 = H(\mathbf{0}) < H(\alpha(1)) < H(\alpha(2)) < \ldots < H(\alpha(t)) < \ldots < H(\mathbf{1})$ and, also important result, if any transition $\alpha(t) \to \alpha(t+1)$ is the result of a parallel application of the (VR) rule to $\alpha(t)$, then the dynamical evolution is unique. It is an open problem to prove some similar result in the case of the Ice Pile parallel dynamical evolution.

(Pa4) The forth part is dedicated to the exposition of those theories which are a concrete application of the abstract treatment made in point (Pa1) of entropy in measurable spaces:

(1) the *Pawlak rough set theory* as mathematical approach to imperfect knowledge, with its application to information systems, based on a non-empty set X of objects forming the Universe of the discourse, a non-empty set Att of attributes, and a function $F : X \times Att \mapsto val$ assigning to any pair $(x,a) \in X \times Att$ consisting of an object x and an attribute a a value $F(x,a) \in val$. Fixed a collection $\mathcal{A} := \{a_1, a_2, \ldots, a_N\}$ from the set of all attributes Att, two objects x_1 and x_2 are considered *indistinguishable* with respect to $\mathcal{A}$ iff $F(x_1,a) = F(x_2,a)$ for every attribute $a \in \mathcal{A}$. Trivially, this binary relation of indistinguishability is an equivalence relation on the set of all objects X, inducing a partition $\pi_{\mathcal{A}}(X)$ of the universe X, and so all the results of part (Pa2) can be applied to the present case of rough set theory;

(2) the *Zadeh fuzzy set theory*, as distributive lattice equipped with a (unique) Kleene negation connective. The De Luca–Termini approach to fuzzy set as distributive lattice equipped with a (unique) Brouwer, or intuitionistic, negation connective has been successively introduced. Based on these two (non intersecting) approaches, it is then defined the Brouwer–Zadeh (BZ) distributive lattice structure equipped with both the Zadeh and the Brouwer negation connectives, where rough sets constitute its crisp part (without however capturing all the applicative richness exposed in point (1)).

(3) the *conservative self–reversible logical gates*. Conservative logic is a model of computation whose principal aim is to compute with zero dissipation of internal Shannon entropy. This goal is reached by basing the model upon reversible and conservative primitives, for example Fredkin and Toffoli gates, which reflect physical principles such as the *reversibility* of microscopic dynamical laws and the *conservation* of certain physical quantities, such as the entropy of the physical system used to perform the computations.

Finally, a standard procedure for embedding non-reversible logical gates into reversible–conservative logical ones is exposed.

Towards reliable rule mining about code smells: The McPython approach

***Index Terms*—Rule mining, code smell, McPython, Python, domain specific languages**

Problem

CODE smell is a risky pattern in code that can lead, in the future, to problems with code maintenance. One of the approaches to identifying smells in the code is metric-based smell detection. A classic example is the *God Class* smell which can be detected by using three metrics (see, e.g., [1], [2], [3]):

- Weighted Method Count (WMC – sum of McCabe's complexity of all methods in the analysed class),
- Tight Class Cohesion (TCC – relative number of directly connected methods within the analysed class), and
- Access to Foreign Data (ATFD – number of classes containing attributes referenced by the analysed class directly or via get/set methods).

To make a decision (smelly / not smelly), computed metrics are compared against predefined thresholds. So, the quality of smell detection depends not only on a set of chosen metrics, but also on their thresholds.

Unfortunately, the quality of the existing smell detectors is still not satisfactory (cf. [4]) and there is a need for more research in the area. One of the issues worth investigation is the impact of a set of code smells on severity of the detriment caused by them. To conduct this research in a clear and reproducible way one needs an appropriate workbench (a critical review of the literature in the area is presented in [5]).

The proposed workbench

In this paper, it is postulated that empirical research on smell detectors should be based on (1) precise definitions of the analysed smells, and (2) smell detection rules (including metric thresholds) should be mined from software repositories using machine learning (ML).

The overall architecture of the proposed workbench is illustrated in Fig. 1. Given a code repository, a code smell detector identifies all smelly classes while the issue detector identifies troublesome classes (e.g., defective classes - here one can use an idea proposed by Śliwerski *et al.* in [6]). The reports generated by both detectors are consolidated to produce a decision table (the decision table of Fig. 1 refers to the *God Class* smell with three thresholds, _WMC, _TCC, and _ATFD, corresponding to the three metrics mentioned earlier). Given a decision table, one can use e.g. C4.5 algorithm to get a decision tree (see [7] or [8]). Another option is to apply rough-set approach (see e.g., [9]).

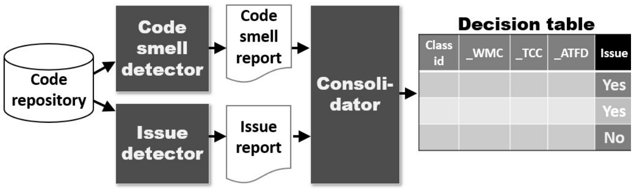

Fig. 1. Architecture of the proposed workbench.

The McPython language

For defining metric-based code smells we propose a domain-specific language, McPython (Meta Code in Python). Its notation is based on Python. Description of a smell detector consists of three parts: code model, smell definitions, and query.

Code model defines all the code attributes needed for detection of a given smell (it corresponds to view model in the 3-layer model of code proposed in [10]). Those attributes are provided by another program, code modeller, and code model just defines what is needed from the code modeller. As McPython is focused on object-oriented languages, there are four categories of entities represented in each model, namely: classes, their attributes, methods, and their parameters. An example of code model is presented in the first part of Listing 1. Each code entity has a number of attributes along with their JSON types (*nat* is an extra type denoting natural numbers and it is a subset of *int*). Each description of entity category starts with the `ent` keyword and ends with a double colon (::).

A smell definition is a Python-like function returning a Boolean value. It is accompanied by a set of auxiliary functions (some of them can be imported). The second part of Listing 1 contains a function named `GodClass` defining the *God Class* smell and an auxiliary function `WMC`. The `GodClass` function uses three special parameters called *thresholds*: `_WMC`, `_TCC`, and `_ATFD`. A threshold represents an upper/lower bound on some metric. It is declared in a separate line, its name begins with an underscore ('_') and is preceded with the `thr` keyword.

Smell definitions can refer to attributes specified in the code model and they can contain mathematical symbols such as summation ($\sum$) or quantifiers($\forall$, $\exists$). On the other hand there are some restrictions imposed on McPython code:

Listing 1. God Class detector in McPython.

```
--- Model:
ent class:
    name:    string,   # class’s name
    methods: list,     # method ids
ent method:
    name: string,  # method’s name
    McCABE: nat :: # cyclomatic complx.
--- Smells:
import TCC, ATFD
def WMC(c: class):
    return ∑ m ∈ c.methods: m.McCABE::
thr _WMC
thr _TCC
thr _ATFD
def GodClass(c: class):
    return WMC(c) ⩾ _WMC ∧
           TCC(c) < _TCC ∧ ATFD > _ATFD
--- Query:
_WMC  ∈ [45, 47]
_TCC  ∈ [0.4, 0.3, 0.2]
_ATFD ∈ [4, 6]
select c.name for c ∈ class \
              where GodClass(c)
```

- each variable is assigned a value only once;
- there are no compound statements like `while` or `if`.

Parameters of McPython functions can have types assigned to them. Those types are categories of code entities, e.g., `class` or `method`.

The third part of code in McPython is a `query`. It starts with specifying the values of the thresholds one is interested in. Then comes the `select` clause which resembles the one known from SQL. The result of the query is a report showing the requested attributes of all the code entities matching the query for all the possible combinations of the values of thresholds.

Implementation remarks

McPython definition of a smell detector is encoded in Unicode what makes all the mathematical symbols easily available. When McPython code is ready one has:

- to translate it to Python 3, and
- to generate a model of the analysed code (smell detector expects on the input a code model, not the code itself).

The process is illustrated in Fig. 2. An advantage of running smell detector on a code model instead of the code itself is possibility of using the same definition of a code smell on repositories written in different programming language, provided that one has a code modeller for a given language.

Current version of McPython translator is written in Python 3 (Python accepts Unicode as an input). Model of the analysed code is implemented as a list of all its entities (position of an entity on the list serves as its identifier) and it is read with the library function `json.loads`. McPython constructs concerning operations over sets, e.g., a universal quantifier ($\forall$) or summation ($\sum$), are translated as calls to an appropriate function (definitions of those functions are added to the generated code). Those functions have two parameters: a set of code entities (represented by their identifiers) and a condition or expression that is evaluated for each element of a given set (here lambda expressions of Python proved very useful).

Code modeller for the Python language (cf. Fig. 2) is built with the help of Python’s `ast` module and the `NodeVisitor` class contained in it. First all class nodes of a given abstract syntax tree are visited and then their method are analysed. The collected data are stored as an array of dictionaries and transformed into JSON with the `dumps` function of the `json` module.

Combination of Fuzzy Sets and Rough Sets for Machine Learning Purposes (Tutorial – Extended Abstract)

Chris Cornelis, Henri Bollaert
Computational Web Intelligence,
Department of Applied Mathematics, Computer Science and Statistics,
Ghent University, Belgium

FUZZY set theory (Zadeh [22], 1965) is a popular AI tool designed to model and process vague information. Specifically, it is based on the idea that membership to a given concept, or logical truthhood of a given proposition, can be a matter of degree. On the other hand, rough set theory (Pawlak [14], 1982) was proposed as a way to handle potentially inconsistent data inside information systems. In Pawlak's original proposal, this is achieved by providing a lower and upper approximation of a concept, using the equivalence classes of an indiscernibility relation as building blocks.

Noting the highly complementary characteristics of fuzzy sets and rough sets, Dubois and Prade [7] proposed the first working definition of a fuzzy rough set, and thus paved the way for a flourishing hybrid theory with numerous theoretical [8] and practical [18] advances.

In this tutorial, we will explain how fuzzy rough sets may be successfully applied to a variety of machine learning problems. After a brief discussion of how the hybridization between fuzzy sets and rough sets may be achieved, including an extension based on ordered weighted average operators (see e.g. [1], [4]–[6]), we will focus on the following practical applications:

1) Fuzzy-rough nearest neighbor (FRNN) classification [10], [11], [21], along with its adaptations for imbalanced datasets [15], [19] and multi-label datasets [20]
2) Fuzzy-rough feature selection (FRFS) [2], [3]
3) Fuzzy-rough instance selection (FRIS) [9] and Fuzzy-rough prototype selection (FRPS) [16], [17]

We will also demonstrate software implementations of all of these algorithms in the Python library fuzzy-rough-learn [12], [13].

***Abstract*—The aim of this tutorial is to present a brief overview of the theory of rough sets from the perspective of its mathematical foundations, history of development as well as connections with other branches of mathematics and informatics. The content concerns both the theoretical and practical aspects of applications. The above mentioned target of the tutorial will be covered in two parts. In the first part we would aim to present the introduction to rough sets and the second part will focus on the connections with other branches of mathematics and informatics.**

I. Introduction to Rough Sets

THE THEORY of rough sets, pioneered by Z. Pawlak in 1982 [1], [2], provides a way to formalize imprecise concepts with respect to a given set of attributes. Let us think of a data table, where the rows represent descriptions of the objects from a universe U with respect to a set of (conditional) attributes A, and each column of the data table corresponds to an attribute of A. Each such description is usually known as *information signature* of an object with respect to the set of attributes A, and it can be represented as a vector of values over A. Formally, one can think of a pair (U, A) where for each $a \in A$ and $u \in U$, $a(u)$ denotes the value of the object u for the attribute a in a relevant value set. In rough set literature such a pair is known as *information system* or *information table*. Moreover, an information system along with a designated attribute d for decision, say $(U, A \cup \{d\})$ is called a *decision system*.

Now, given an information system, with respect to any subset X of A the whole data table can be clustered into equivalence classes of objects where each equivalence class contains all those objects from the universe which have the same values with respect to each attribute of X. Thus from (U, A) we obtain a pair (U, R) where R is the respective equivalence relation, usually known as *indistinguishability relation*. In rough set literature (U, R) is known as *approximation space*. A subset $S \subseteq U$, may be called a concept, can be either definable in terms of the union of some equivalence classes, or may fall in the overlapping zone of a few equivalence classes; in the latter case the concept is regarded as imprecise with respect to the considered set of attributes. So, given any set of objects S one can describe the intention of S in terms of rough approximation operators. The lower approximation of S picks up those equivalence classes which are completely contained within S, and thus gives a flavour of 'certainty zone for the concept'. On the other hand, the upper approximation of S selects those equivalence classes which have non-empty intersection with S, and this corresponds to a 'possibility zone for the concept'.

With this mathematical foundation the development of rough set theory goes further to address many useful aspects of data mining. For example, suppose there are two decision classes representing positive and negative decision for the attribute d (i.e., subsets of U representing $d = 1$ and $d = 0$ respectively). Now if these decision classes are not definable in a straightforward manner, one may require to characterize them using rough set approximations. In this presentation, we will try to present some of such aspects which have practical uses in the context of data mining. A few such issues are listed below.

1) To describe a data table in terms of comprehensible rules so that using those rules unseen test examples can be effectively classified.
2) To find out a smaller set of attributes, a *reduct* in RST terminology, that can faithfully classify the decision classes as it is presented with respect to the whole set of attributes.
3) To handle a decision system where two indistinguishable objects may have different decision values.
4) To design decision valuations describing different aspects of decision making by aggregating available information of the training objects (i.e., already available objects).
5) To check similar aspects of decision making when the available data is not clustered into disjoint equivalence classes as the underlying notion of indistinguishability can be based on a relation which is weaker than an equivalence relation, such as a similarity relation.

II. Connection with other branches of mathematics and informatics

Due to its simplicity and effectiveness, the concept of approximations has found applications in various fields, establishing connections with several branches of mathematics and computer science right from its inception. Over the years, we have observed a substantial accumulation of results, which we can only provide a high-level summary of.

A. Mathematics

The main contributions relate to logic and topology, with multiple connections also existing in algebra and graph theory.

a) Logics: Rough sets are associated with modal logics. Indeed, given the standard syntax of the modal system S5, a semantics can be provided by the indiscernibility relation used as the modal accessibility relation. In this manner, the lower and upper approximations coincide with the logic operators of necessity and possibility [3]. It is evident that for rough sets based on weaker forms of relations, there corresponds weaker modal logics. Additionally, by interpreting the lower approximation as positive (or true), the complement of the upper approximation as negative (or false) and the remaining elements of the universe as unknown a correspondence with three-valued logics can be established [4]. Finally, a complete logical framework based on a distinct notion of truth, namely *rough truth*, has been defined where both syntax and semantics are "rough" [5].

b) Topology and Algebra: The lower and upper approximations behave like a topological interior and closure operator on a Boolean algebra. Several links between various types of topological operators and models of rough sets have been established [6]. Moving to a more abstract context, a hierarchy of topological operators can be defined on a lattice structure, each corresponding to a different model based on various generalizations of rough sets [7]. Many authors have taken further steps toward abstraction by defining the approximations in different types of algebraic structures, such as rings and groups.

c) Graph Theory: The connection with graph theory can be interpreted in at least two ways. Firstly, by relating ideas from rough sets to those on graph theory. One significant result in this setting is the equivalence between computing reducts and computing minimal transversal on hypergraphs. The latter is a well-known problem and algorithms that solve it in incremental polynomial time exist [8]. Another approach, consists in applying rough-set ideas to graph theory, such as attempting to define approximations or reducts on graphs.

B. Computer Science

We highlight the main contributions of rough sets to Artificial Intelligence and Theoretical Computer Science.

a) Knowledge Representation: Of course, the first link with computer science and artificial intelligence concerns the ability of rough sets to represent and handle uncertainty due to the granularity of the universe. Particularly fruitful in this domain has been the connection with other tools to manage different forms of uncertainty, mainly fuzzy sets [9] and belief functions [10].

b) Machine Learning and Data Mining: From an application stanpoint, the main contribution of Rough sets is in Machine Learning and Data Mining, where they have been used in several tasks [11]. In particular, in Machine Learning their success can be seen in feature selection and classification by means of reducts and decision rules and in clustering where the idea of approximations has been applied to obtain new soft clustering methods. In Data Mining, a major contribution is the use of rough sets to perform *approximate queries* in relational databases by means of standard SQL statements, this approach also lead to a successful industrial application [12].

c) Theoretical Computer Science: The concept of entropy has been used to evaluate the uncertainty of a given information table with an equivalence relation. Extended approaches to missing values and generalized relation has also been provided [13] as well as applications in computing approximate reducts [14]. Another connection with TCS concerns the use of rough sets in dealing with uncertainty in discrete dynamical systems, such as cellular automata, reaction systems and Petri nets [15].

THE theory of rough sets [1] is a powerful mathematical framework for handling imprecise or uncertain information in data analysis and decision-making. At its core, rough set theory introduces the concept of decision reducts [2], which are subsets of attributes or features that preserve the essential information needed to make accurate decisions while eliminating redundant or irrelevant information. By identifying ensembles of decision reducts [3], analysts can simplify complex datasets, improve classification accuracy, and gain valuable insights from noisy or incomplete data [4]. These appealing characteristics make rough sets a valuable tool in various fields, including machine learning, data mining, and expert systems [5].

There have been proposed many extensions to the notion of decision reducts, such as approximate decision reducts [6], dynamic decision reducts [7], DAARs [8], decision bireducts [9], and many others. The key objective of most of them was to prevent the inclusion of illusionary dependencies between attributes and decision values to the reducts. A lot of research was also committed to the problem of algorithms for the efficient computation of diverse reduct sets [10]. This topic is particularly important from the perspective of practical applications of the rough set theory [11].

In this tutorial, we focus on the latter aspect of the decision reduct-related research. We discuss various, both, well-known and relatively new algorithms, and consider their specific advantages. We explain in detail selected implementation aspects that are crucial for the efficient computation of many types of decision reducts. We also overview and demonstrate libraries in popular programming languages that allow easy computation of reducts on real-world datasets, including *RoughSets* library for R [12] and a novel Python language library *scikit-rough*[1] [11]. Finally, we share the results of a study aiming at the comparison of the computational efficiency of various reduct algorithms.

***Abstract*—The increasing prevalence of diabetes, particularly in Saudi Arabia, calls for effective self-management tools to monitor blood sugar levels, such as Continuous Glucose Monitors. These are medical devices that can be used to track the glucose levels of people without a fingerstick blood sample. However, the adoption of IoT-enabled Continuous Glucose Monitors (IoT-CGM) can be challenging due to the use of new technology. This study proposes the Intention to Adopt IoT-enabled Continuous Glucose Monitors (IAI-CGM) a framework, which incorporates practical, technological, and user behaviour considerations based on the Technology Acceptance Model (TAM). The study defines 8 hypotheses that are analysed using structural equation modelling. Data was collected; from 873 type 1 diabetes patients (T1DM) from Saudi Arabia. The model predicts the significant impact of all factors on adoption intent except technology -related self-efficacy (TRSE), enabling the assessment of Saudi T1DM patients for IoT-CGM readiness. Furthermore, the framework's novelty may serve as inspiration for developing comparable frameworks for wearable or attached health monitoring devices in patients with other illnesses and in other geographical locations.**

***Index Terms*—IAI-CGM, TIDM, Internet of Things, Continuous Glucose Monitors, Adoption Intention, Technology Acceptance Model.**

I. INTRODUCTION

THE RISING prevalence of diabetes in Saudi Arabia can be attributed to the Westernized food and sedentary lifestyle prevalent in the country. A quarter of Saudi adults are expected to develop diabetes by 2030, with over half of Saudis over the age of 30 having diabetes or being at risk [1]. The solution to this issue lies in patients taking control of their healthcare and self-managing their blood sugar levels [2]. However, patients often lack the ability to follow physicians' advice on self-care management, necessitating the use of sophisticated technology. The emergence of innovative wearable technology has created an opportunity for the creation of a wireless body area network that could monitor healthcare delivery, including diabetes self-management [3]. To standardize IoT-enabled Continuous Glucose Monitoring (CGM) devices in Saudi Arabian primary care institutions, the country must undertake an in-depth analysis and publication on IoT in its healthcare system.

This study aims to measure patient preparation and willingness to use a CGM in primary diabetes care settings in Saudi Arabia to promote patient autonomy. The research will involve conducting a literature review to determine the extent to which intelligent technologies have permeated the Saudi healthcare system. It will also use the Technology Acceptance Model (TAM) to measure patient autonomy readiness towards IoT adoption by surveying people with type-1 diabetes. The study's scope and objectives include a quantitative analysis of diabetic patients in Saudi Arabia regarding their preparedness for autonomy. With resource constraints and significant health management risks facing emerging nations, research in this field is vital. In addition, the study aims to fill a research gap by examining Saudi Arabia's digital transformation efforts and readiness for IoT in healthcare [4]. The study's results will contribute to advancing IoT-enabled CGM adoption and primary diabetes self-management in Saudi Arabia, helping the country meet its digital transformation goals by 2030 [5].

II. THEORETICAL BACKGROUND

A. *Role of CGM in T1DM Primary Care*

Continuous Glucose Monitoring (CGM) is crucial for primary care in managing Type 1 diabetes. It enables patients to respond to their readings and maintain safe blood sugar levels, leading to increased self-management care [6]. CGMs provide continual feedback on blood sugar levels, encouraging patients to take their medication as recommended, thereby improving glucose levels.

However, in Saudi Arabia, poor drug compliance is a significant issue, with inadequate education and urban lifestyles being the main factors [7].

To improve technology tolerance among low-income and urban patients, IoT-CGM deployment requires patient health literacy improvement [8]. When primary care institutions provide self-management instruction and follow-up, it can help reduce patients' blood glucose levels. Self-management increases patients' health-related motivation, autonomy, and competence, but its effectiveness requires educating patients about their responsibilities in controlling T1DM. Encouraging patient autonomy helps doctors regulate blood glucose levels. This implies that with the help of health education provided to the patients could increase the sense of responsibilities to control T1DM disease themselves with self-empowerment [9]. The study concludes that IoT-CGMs might improve patient autonomy, but their adoption is uncertain, and adoption issues need to be addressed [10].

B. *IoT-CGM Adoption Concerns*

The use of Internet of Things continuous glucose monitoring (IoT-CGM) devices has been shown to provide numerous benefits to diabetics, such as improved long-term complication management [11]. However, despite the advancements in accuracy and dependability, these devices have not been widely adopted, with most diabetics still relying on the traditional method of drawing blood from a fingertip to measure their blood glucose levels. The slow uptake of IoT-CGM can be attributed to various factors, such as initial concerns about the devices' lack of accuracy [12], patients' unawareness of the advantages they offer, and sociopsychological and economic barriers to adoption.

Studies have shown that proper use of CGM devices, advice from medical professionals, and acting on CGM alarms can significantly reduce long-term difficulties in diabetic patients [13], [14]. The study by Gia et al. [15] provided evidence that proper guidance from health professional can help to reduce the long-term complications from 75 percent to 40 percent in the accuracy of CGM.

However, without a technology acceptance model (TAM) study, it is difficult to determine whether patients nationwide will adhere to the recommendations and continue to benefit from long-term complication management. Furthermore, wearable smart gadgets, including IoT-CGM, are still in their infancy, and persuading developing nations to adopt them will require work.

However, according to Rodbard [16], still there are only 8 percent to 17 percent of T1DM patients using CGM devices. Although, it is evidenced by the study [17], that the overall size of IoT healthcare sector expected to reach up as a 2 trillion US dollar industry by 2025. Despite this prediction fancy prediction still the adoption rate is very low.

Another study by Ayanlande et al. [18] elaborates that acceptability of CMG devices is also hinge on the patient's socio-psychological aspect, along with the affordability of patients and the healthcare system of the region where they reside. Another study provides that the availability is dependent on the scope of the service to meet minimum requirements [19]. Furthermore, another study [20], discussed the development of HIT enabled patient care that empowers patient and provides them with self-management capabilities, with the end goal that health matters such as diabetes patient care does not go poorly managed.

Saudi Arabia, a wealthy nation with an unequal income distribution, has only recently started using IoT-CGM. Its patient population is diverse, including those who have already adopted IoT-CGM, those who have heard of it but are hesitant to use it, and those who have never heard of it. Therefore, research on IoT-CGM adoption in Saudi Arabia includes many controversies.

To address the slow uptake of IoT-CGM, a new paradigm for adoption using the theoretical foundations of the technology acceptance model is proposed. The TAM considers factors such as sociopsychological, economic, and healthcare infrastructure determinants of acceptance, affordability, accessibility, and satisfaction with the service's breadth. However, there is a dearth of knowledge on the usage of healthcare technology that is unique to type 1 diabetes mellitus (T1DM), which is a health issue that should not be handled carelessly [21].

Making IoT-CGM more widely used in Saudi Arabia and other nations is a major issue, and the first stage in achieving the criteria set for improving healthcare quality in Saudi Arabia is understanding the viability of adoption. The literature on continuous glucose monitoring for diabetes with the Internet of Things is voluminous, but most studies have focused on the advantages of self-management, its effectiveness, and an analysis of the variables that influence the slow uptake of medical technology.

Therefore, determining the adoption characteristics of T1DM patients and providing a framework for adoption specific to them constitute the initial stages. Wearable smart devices offer the most appropriate solutions, but patients are not required to utilize them, and health factors and technological adoption scales are not always taken into consideration. Thus, providing a framework for IoT-CGM adoption that is specific to T1DM patients is crucial. The proposed structure provides theoretical underpinnings for this framework and a clear picture of a nation's present adaptability.

The authors proposed the Intention to Adopt IoT-enabled Continuous Glucose Monitors (IAI-CGM) framework in [4]. Based on this framework, the study aims to identify factors affecting adoption to analyse the readiness and willingness of primary diabetes T1DM patients, particularly in Saudi Arabia, to use (IoT-CGM) technology. The framework has strong predictive capabilities for assessing the adoption of Internet of Things-enabled Continuous Glucose Monitors (IoT-CGMs) used for monitoring blood glucose levels. The factors of the proposed framework include Perceived Reliability (PR), Perceived Usefulness (PU), Ease of Use (EU), Information Overload (IO), Technology Related Self-Efficacy (TRSE), Attitude (AT), Intention to Use (IT), and

Visibility of Body Change (VBC) as designed by Borges and Kubiak's [22].

II. RESEARCH METHODOLOGY

This study aims to investigate the factors that influence the adoption of IoT-CGM devices by T1DM patients in Saudi Arabia. The study used an online survey to collect quantitative data from participants. Qualtrics was used for survey creation and administration, while Microsoft OneDrive was utilized for data storage. In addition, IBM SPSS was used for data analysis.

The survey questions were grounded in the theoretical framework of the study, which identified usability, technology, and user behaviour as the primary drivers of adoption intention. The study sample size was calculated based on a confidence level of 95% and a confidence interval of 5%; the total population is 11,662 of T1DM, and based on the statistics provided by [2], at least 372 responses we are required. Therefore, an accurate total sample of 873 was collected from the T1DM patients from King Khalid Hospital Saudi Arabia and Najran region.

There are three categories of human factors that influence patients' decisions to embrace continuous glucose monitoring devices that are enabled by the Internet of Things: those that are purely theoretical, those that pertain to technology, and those that pertain to user behaviour. Perceived reliability, perceived utility, and simplicity of use are three of the metrics used to assess the practical factors of a product's performance. The technological factors are measured by the innovation orientation and the technology-related self-efficacy measures, while the user behavioural factors are measured by the attitude, intention to use, and the visibility of body change factors.

The study took ethical measures to protect the interests of all those involved, making sure participants knew that taking the survey was completely optional and that they could stop at any time without consequences or explanations. Participants were also made aware that their data would not be sold or otherwise distributed to outside parties and were assured complete privacy. The study did not seek individual information in the questionnaires, and participants were instructed not to provide any identifying information in the survey. In the case of a participant's comment warranting a quotation, a unique numeric identity would be issued instead. Data collection methods and research instruments were approved by Institutional Review Board (IRB) in Saudi Arabia, Ministry of Health; King Khaled Najran Hospital (KKNH) by assigning IRB registration number with KACST, KSA: H-11-N-081; IRB Log Number 2022-01E.

The survey questionnaire was developed based on the findings of a previous study [22]. The theoretical framework of this study provides the foundation for the survey. The survey consists of questions that allow for assigning values to each variable. This is done using a 5-point Likert scale system, where 1 indicates "Strongly disagree", and 5 indicates "strongly agree".

IV. RESULTS

In a quantitative study, selecting an appropriate sample size is critical to ensure reliable and transferable results while eliminating bias. The sampling strategy employed in this study followed scientific principles and focused on patients with Type 1 diabetes at King Khaled Najran Hospital and the Najran region in Saudi Arabia. The survey was administered online using Qualtrics, with data immediately entered into a database. Outliers are exceptional data points that fall outside of the norm and can result from typos, poor wording of questionnaires, or data input errors. Univariate outliers stand out in only one way, while multivariate outliers have multiple scores that deviate from the norm [23]. The frequency distribution test and other normality tests can help detect outliers [24]. The research variables in this study had z-scores of less than 3.29 and a standard deviation range of 0.708 to 1.302, indicating no extreme values among the outliers.

A. *Data Analysis and Confirmatory Factor Analysis (CFA)*

Confirming the theoretical structure of variables is a crucial part of CFA analysis. It involves conducting one-dimensionality, reliability, divergent, and convergent validity tests. Researchers can determine whether to adopt a theory based on these results. To establish relationships in SEM, researchers should perform CFA on all latent variables, with a minimum latent concept loading of 0.60 for the assessment items measured by one-dimensionality [25]. CFA findings are founded on nine different latent constructs. A few examples of these constructs are technology-related self-efficacy (TRSE), information overload (IO), perceived reliability (PR), perceived usefulness (PU), ease of use (EU), attitude (AT), intention to use (IT), visibility of body change (VBC), and intention to adopt (AI).

TABLE I
RELIABILITY AND CONSTRUCT VALIDITY

Constructs	Cronbach (above 0.7)	CR	AVE	MSV
TRSE	.756	0.763	0.521	0.274
IO	.772	0.776	0.537	0.383
PR	.842	0.844	0.643	0.127
PU	.821	0.848	0.652	0.475
EU	.821	0.835	0.629	0.241
AT	.773	0.785	0.553	0.441
IT	.786	0.790	0.557	0.475
VBC	.856	.0.868	0.623	0.397

B. *Measures of the Model Validity*

To ensure construct validity and composite reliability, Cronbach's alpha and Composite Reliability (C.R.) values were used before hypothesis testing. The present study used Cronbach's alpha with a cut-off value of 0.70, and another study suggests cut-off values of 0.60 for C.R. and 0.70 for Cronbach's alpha [26]. The reliability scores in Table I are greater than 0.70. Both Cronbach's alpha and C.R. were used to examine internal consistency, showing the convergent and discriminant validity and reliability of findings and comparing it with cut-off-points [27]. The results indicate that all variables are free from measurement error. Assessment for consistency refers to measurements on the same point on two different scales, assuming that an instrument can assess a similar context over time. Cronbach's alpha is considered the initial step to ensure reliability. The present study uses Cronbach's alpha and Composite reliability to test instrument reliability. The study used average variance extracted (AVE) to identify variation in latent variables caused by random measurement errors, with a cut-off value of 0.50 or greater. AVE values were between 0.537 to 0.644. Discriminant validity was achieved through the maximum shared squared variance (MSV), Fornell-Larcker test, and average shared squared variance (ASV), with AVE for each construct higher than MSV [28]. The CFA assessment of the model showed that both convergent and discriminant validity met the fitness criteria.

TABLE II
DESCRIPTIVE ANALYSIS AND FACTORS LOADINGS FOR ITEMS

Measure	Chi-square (CMIN) / Degrees of freedom (D.F.)	Comparative fit index (CFI)	Standardized root mean square residual (SRMR)	Root mean square error of approximation (RMSEA)	Normed Fit Index (NFI)
Estimate	4.380	0.913	0.054	0.062	0.901
Threshold	Between 1 and 5	> 0.90	< 0.08	< 0.08	> 0.90
Interpretation	Good fit	Good fit	Good fit	Good fit	Good fit

C. Model Good Fit

The study involved 873 participants, and the observed results for the fitness of the model indicated that all observed statistical values were under the cut-off threshold as given (CMIN/DF = 4.380, CFI = 0.913, SRMR = 0.054, RMSEA = 0.062, NFI = 0.901). Therefore, no issue was observed about the good fit of the model. The results are shown in Table II.

D. Discriminant Validity

Table III illustrated that there were no problems regarding discriminant validity, as the square roots of the AVEs' "diagonal line" showed values greater than the values below the diagonal, as demonstrated below. The findings suggest that the CFA model's evaluation was valid with respect to both convergent and discriminant validity criteria.

TABLE III
DISCRIMINANT VALIDITY

	TRSE	IO	PR	PU	EU	AT	IT	VBC	AI
TRSE	**0.722**								
IO	-0.249	**0.733**							
PR	-0.066	0.356	**0.802**

E. Structural Equation Model

In order to test the hypotheses of the study Structural Equation Modelling (SEM) was used to investigate the interrelationship between latent and observed variables via the software AMOS version 28. The SEM approach is widely used in various research fields, such as psychology, behavioural studies and education. In order to ensure the accuracy of the data, a confirmatory factor analysis was conducted to assess the validity of the collected data. The SEM model includes both structural and measurement models. Therefore, the AVE score in the convergent validity test should be greater than 0.5, indicating a good model fit [27].

All factors caused a significant change in the dependent factors except hypothesis 5, where TRSE does not have a significant effect on the intention to adopt IoT-CGM. The present study discusses critical factors related to the intention to adopt IoT-CGM.

Results clearly indicate significant differences from previous findings, which may be attributable to regional or cultural differences in corporate climate or at the individual level. After getting empirical evidence based on structural equation modelling, it was observed in Table IV that Perceived Reliability (PR) has a significant positive influence on intention to adopt IoT-CGM (β = 0.154 along with p-value < 0.001). Similarly, perceived usefulness (PU) has a significant positive influence on the intention to adopt IoT-CGM (β = 0.251 along with p-value < 0.001). Next, it was observed that Ease of Use (EU) has a significant positive influence on intention to adopt IoT-CGM (β = 0.077 along with p-value < 0.001). Similarly, information overload (IO) has a significant negative influence on the intention to adopt

TABLE IV
REGRESSION WEIGHTS FOR PATH COEFFICIENTS AND ITS SIGNIFICANCE

IoT-CGM (β = -0.128, along with p < 0.001). On the one hand, Technology Related Self-Efficacy (TRSE) does not have a significant influence on the intention to adopt IoT-CGM (beta = -0.017 along with p-value > 0.05). Furthermore, attitude (AT) positively influences Adoption Intention (AI), β value =.194 along with p < 0.05). Next, results show that intention to use (IT) positively influences intention to adopt IoT-CGM, with β value = 0.171 along with p < 0.05). Results further indicate that visibility of body change (VBC) has a significant negative impact on intention to adopt IoT-CGM along with β = -0.153 and p-value < 0.05. Based on overall results, it is observed that all independent variables cause a significant change in intention to adopt IoT-CGM except TRSE, as it did not cause a significant change in the intention to adopt IoT-CGM. One reason could be the mistrust that makes people reject IoT-CGM. So, the intention to not use IoT-CGM is correlated with a lack of knowledge, little desire to learn and doubt related to the technology or its adoption.

F. Descriptive Statistics

Descriptive results Table V shows that in the survey, there were 440 Male (50.4%), and 433 females (49.6%). 36.7% of participants were within the age group of 18-25, 37.1 % of participants were within the age group 26-35, participants from the age group of 36 to 45 were 22.0 %; and participants from the age group of 46 to 60 were only 3.9 %, and there were only 3 participants or (0.30 %) older than 60. The majority, 43.5%, were reported to have a bachelor's degree, 29.1% had secondary school education and Ph.D. degree holders only accounted for 0.5%. Furthermore, only 2.1% had only completed primary school, while 18.3% had diplomas, 2.7% had master's degrees, and 3.8% had only completed elementary school education.

TABLE V
SAMPLE CHARACTERISTICS (N = 873)

		Frequency	**Percentage**			**Frequency**	**Percentage**
Gender	**Male**	440	50.4%	**Education level**	**Primary School**	18	2.1%
	Female	433	49.6%		**Elementary School**	33	3.8%
Ages	**18-25**	320	36.7%		**Secondary school or less**	254	29.1%
	26-35	324	37.1%		**Diploma**	160	18.3%
	36-45	192	22.0%		**Bachelor degree**	380	43.5%
	46-60	34	3.9%		**Master degree**	24	2.7%
	60+	3	0.3%		**Doctorate degree**	4	0.5%

V. DISCUSSION

The study provided an updated framework based on empirical findings on Internet of Things-enabled Continuous Glucose Monitoring (IoT-CGM), which empowers type 1 diabetics. The results from Table IV. The approach illustrated how several factors affect patients' inclinations to use internet-enabled continuous glucose monitoring. The dimensions of human factors that affect the patients' intentions to adopt IoT-enabled continuous glucose monitoring devices are grouped into three factors.

Practical factors: These are the first set of factors that influences the adoption of IoT-CGM.

The study found that perceived reliability was a significant factor that affected the adoption of IoT-CGM [29]. Similarly, empirical results from the present study show that perceived reliability (PR) has a significant positive influence on intention to adopt IoT-CGM along with β = 0.154 and p-value < 0.001. Therefore, there are 0.154 units of positive change in IAI-CGM when PR changes by 1 unit. Another study revealed that customers' feelings regarding new technology were positively correlated with their faith in the gadget's accuracy [30]. Trust was found to be the most crucial attribute while communicating with doctors.

The perceived usefulness of IoT-CGMs improves behavioural intention. User satisfaction with continuous glucose monitors (CGMs) may be affected by aspects, including the availability of trend and graph glucose readings and the ability of CGMs to compensate automatically for glucose level swings in real-time [31]. The present study also observed that perceived usefulness (PU) is a significant factor that positively influences intention to adopt IoT-CGM along β = 0.251 and p-value < 0.001. Furthermore, it shows 0.251 units change in IAI-CGM due to PU.

Ease of use (EU) is an essential practical factor in the practical factor when adopting a product. Furthermore, the simplicity of use is a critical factor that influences early computer adopters' behavioural intentions [31]. Similarly, the present study also observes that Ease of Use (EU) has a significant positive influence on IAI-CGM with β = 0.077 along with a p-value < 0.001. However, there is a positive influence of the EU on IAI-CGM.

Technological factors: These are the second set of factors that affects the adoption of IoT-CGM.

Information overload is one of the critical technological factors. Tansey et al. [31] have suggested that an excessive number of features in CGMs can lead to information overload for users. Although real-time glucose readings in IoT-CGMs may be an attractive feature but a constant influx of information can also be burdensome for users, potentially resulting in a negative response to the technology. Similarly, it was observed in the empirical results that information overload (IO) has a significant negative influence on intention to adopt IoT-CGM along with β = -0.128 and $p < 0.001$. However, the presence of an overload feature in IAI-CGM can have a negative impact on user adoption, as users may become overwhelmed by the excess information provided.

Technological self-efficacy [4] is characterized as type 1 diabetes patients' perception of their capability to utilize IoT-enabled continuous glucose monitors and their ability to trust new technology. Apart from expectations and the ability to trust, there could also be the issue of technology and the lack of knowledge and know-how to use the technology, which might be the reason for the low adoption rate causing the insignificant relationship of TRSE with the intention to adopt [32] Similarly, results show that Technology Related Self-Efficacy (TRSE) does not have a significant influence on the intention to adopt IoT-CGM beta = - 0.017 along with p-value > 0.05.

User behavioural factors: These are the third set of factors that affects the adoption of IoT-CGM.

Users' views on technology are measured in this factor. Technology perception is also reflected in consumers' mental processes, which shows intention to use [33]. Empirical results also show that intention to use positively influences IAI-CGM, β value =.171, along with $p < 0.05$. Patients' perspectives of how others view them also influences their technology choices. The patients' scheduled activities were based on their attitudes and personal values [34]. A person's behavioural intention also depend on how much they value their own attitudes and the societal norms around them. Similarly, empirical results show that attitude (AT) positively influences Adoption Intention (AI), β value =.194 along with $p < 0.05$. Furthermore, visibility of body change (VBC) is found to have negative influence on the Adoption Intention (AI), β value =-.153 along with $p < 0.05$.

The present study discusses critical factors related to intention to adopt IoT-CGM. Empirical findings with some differences may be attributable to regional or cultural perspectives. However, adoption of IAI-CGM framework may subject to cultural and individual differences that need to be addressed before adopting this framework.

The Updated framework that is presented below In Fig.2, that can be used to determine the adoption intention of IoT-CGMs and has been termed the Intention to Adopt IoT-enabled CGM (IAI-CGM) framework. This framework has been proposed to determine the adoption intention based on the practical factors of using IoT-CGMs, the technological factors of using IoT-CGMs, and factors regarding user behavioural factors. PR, PU, and EU are all practical factors that increases the adoption intention among users. IO and TRSE are technological factors. IO decreases adoption intention, and TRSE has an insignificant effect on adoption intention. User behavioural factors are AT, IT, and VBC. AT and IT factors increase adoption intention, while VBC decreases adoption intention.

Fig2: The Updated IAI-CGM Framework

A. *Implications*

This study analyzed the factors affecting the adoption of Internet of things-enabled continuous glucose monitors among Saudi users. The authors used an integrated research methodology that incorporated the TAM and other factors to examine the perceived reliability and utility of the monitors, as well as user behavioural and technological factors (see Fig 2 The Updated IAI-CGM Framework). The study found that an individual's perceived reliability of continuous glucose monitoring and its utility were the most important factors affecting adoption. Physical changes in the body negatively impacted adoption, and technology-related self-efficacy did not affect adoption intention. The study also revealed that Saudi Arabians were skeptical of government hospitals and their ability to train them in wearable technologies. This study provides valuable insights into the adoption of IoT-enabled continuous glucose monitors and can aid in future research in this area.

VI. CONCLUSION

In this study, we constructed the Updated framework (IAI-CGM) to identify critical factors that influence the adoption of (IoT-CGM). We present the theoretical background by way of a literature review that outlines previous empirical findings related to type 1 diabetic patients using IoT-CGM from King Khalid Hospital Saudi Arabia and the Najran region. Then, our updated framework (IAI-CGM) is based on investigating three main categories of factors, including practical factors, technological factors, and user behavioural factors.

Among the practical factors, PR, PU, and EU are identified as drivers that increase adoption intention among users. However, with the technological factors, only IO influenced adoption intention, while TRSE was found to have an insignificant impact on adoption intention. Finally, user behavioural factors AT, IT, and VBC are also relevant. Both AT and IT increase adoption intention, while VBC has the opposite effect. Results are intended to provide valuable insight into the main factors that influence type 1 diabetic patients to adopt IoT-CGM in Saudi Arabia.

The study was conducted on Saudi Arabian citizens with type 1 diabetes, and the findings revealed new avenues for future research. The study recommends that future research should focus on specific areas, such as software development models and process structure models, to better understand the factors that contribute to acceptance and the hurdles that must be overcome. This research emphasizes the importance of addressing adoption challenges to improve healthcare delivery.

The future work will involve testing the IAI-CGM framework using qualitative approach based on 15 semi-structured interviews. The study will be conducted on T1DM patients admitted in diabetes primary care stage. The patients will be recruited from King Khalid Hospital, located in Najran, Saudi Arabia. Based on the qualitative results, the model will have the potential to be further improved. Qualitative results will help to identify other critical factors for adoption intention (AI) for IAI-CGM framework.

ACKNOWLEDGEMENT

The authors extend their appreciation to the Directorate General of Health Affairs in Najran. We would like to express our gratitude to Najran Research Department, King Khalid Hospital Najran and Diabetes and Endocrine Centre. Finally, we would like to express our heartfelt appreciation to all participants for their time and effort.

***Abstract*—Context: predicting the number of defects in a defect backlog in a given time horizon can help allocate project resources and organize software development. Goal: to compare the accuracy of three defect backlog prediction methods in the context of large open-source (OSS) projects, i.e., ARIMA, Exponential Smoothing (ETS), and the state-of-the-art method developed at Ericsson AB (MS). Method: we perform a simulation study on a sample of 20 open-source projects to compare the prediction accuracy of the methods. Also, we use the Naïve prediction method as a baseline for sanity check. We use statistical inference tests and effect size coefficients to compare the prediction errors. Results: ARIMA, ETS, and MS were more accurate than the Naïve method. Also, the prediction errors were statistically lower for ETS than for MS (however, the effect size was negligible). Conclusions: ETS seems slightly more accurate than MS when predicting defect backlog size of OSS projects.**

I. Introduction

DEFECT backlog is the collection of all project defect reports that need to be handled. The size of this collection changes over time. The problem of monitoring defect backlogs is important in all modern software development organizations. In agile software development, it is important to correctly prioritize defects to continuously deliver business value. Also, especially in large organizations, the assignment of developers and testers to projects is often done dynamically, on demand. When a situation in a project demands more human resources for quality improvements, developers shift their focus from feature implementations to defect removal [2]. Because of these dynamic changes, knowing in advance that a project may require more human resources in the following week is valuable information for the managers, developers, testers, and other project stakeholders.

In particular, the managers need to know defect backlogs for the coming weeks. Therefore defect prediction models that forecast the number of defects that will need to be handled in a given time horizon are needed. There have been multiple studies on designing such models in industrial contexts [3], [4], [5], [6]. One of the successful studies on defect backlog prediction was conducted at Ericsson by Staron and Meding [3]. They proposed an autoregressive model (MS) that is based on the moving average and predicts defect backlog size within a weekly horizon. Although the MS model turned out to be very accurate at Ericsson, there are several other state-of-the-art autoregressive models for time series forecasting that have not been tried out for defect-backlog predictions. Two of them are Autoregressive integrated moving average (ARIMA) [7] and Exponential Smoothing (ETS) [8], [9], which are the two most widely used approaches to time series forecasting [10].

Although most of the previous studies on defect prediction were based on open-source software (OSS) datasets, the studies on defect backlog predictions in Ericsson have not been replicated in the OSS context. The flow of OSS projects differs from the flow of their industrial counterparts, however, they are often larger in terms of the number of involved contributors. Predicting the number of defects in a backlog is not easy due to uncertainties in identifying all the defects. The dynamic nature of software development, with its changing requirements and iterative cycles, adds to the complexity. Moreover, the accuracy of predictions can be affected by the quality and relevance of historical data used for analysis. Most existing methods rely on data from classical repositories like NASA and PROMISE, which may have limitations. Lastly, current predictive models may not consider all the contextual factors and unique project characteristics that impact defect discovery.

The goal of this study is to design defect-backlog prediction models based on the ARIMA and ETS methods and validate their accuracy in the context of large OSS projects. We use the state-of-the-art MS model developed at Ericsson [3] as a baseline for comparison since it has been reported as an accurate defect backlog prediction model validated in an industrial setting.

The structure of this paper is as follows. Section II provides a brief overview of the ARIMA and ETS methods, while Section III discusses the related work. Section IV describes the research methodology of our study. The results are presented

This work was supported by the Poznan University of Technology within the project 0311/SBAD/0738. Some of the paper's contents come from the corresponding author's master thesis [1].

and discussed in Section V. Finally, Section VI summarizes the main findings of our study.

II. Background

A. Defect Backlog

In many software projects, defects that need to be resolved are collected in defect backlogs. There are many defect-tracking tools on the market (e.g., Bugzilla, Jira, ReQtest). This kind of software helps the entire team and managers to get a view of how many defects remain in the software and what they are. To help developers work on the project, the defects in the backlog can be ordered according to priority. Often each issue includes additional information which differs between projects. If the software is regularly tested the size of the defect backlog changes over time. The number of defects that have been reported in a specific period of time is called *defect inflow*. Similarly, the number of defects that have been resolved in that period is referred to as *defect outflow*. The defect backlog size change within a given period of time (for the sake of this study, a week) is the difference between its inflow and outflow.

B. Autoregressive Integrated Moving Average

ARIMA stands for Autoregressive Integrated Moving Average. As the name suggests, it combines two time-series techniques, namely, the Autoregressive model and Moving Average.

ARIMA requires the time series to be stationary. The values of stationary time series do not depend on time. Thus, if we can see a trend or seasonality in time series, it means that it is non-stationary—its value depends on the time. Non-stationary time series have to be first transformed into stationary time series by using the differencing operation. The differenced time series is calculated as changes between subsequent observations [10]—see Equation 1. The differencing operation can be repeated multiple times if the obtained time series is still non-stationary.

$$y_t^{'} = y_t - y_{t-1} \tag{1}$$

where:
$y_t^{'}$ - value of the differenced series at time t,
y_t - value of the original series at time t,
y_{t-1} - value of the original series at time $t-1$.

The Autoregressive model is based on multiple linear regression. What distinguished it from other linear regression models is that it predicts the outcome variable (y) using past values as predictor variables (x). This approach assumes that there is some correlation between subsequent values in a time series (autocorrelation). The Autoregressive model is defined by Equation 2 [10].

$$y_t = c + \phi_1 y_{t-1} + \phi_2 y_{t-2} + ... + \phi_p y_{t-p} + \epsilon_t \tag{2}$$

where:
c - constant value,
ϕ - model parameter,
ϵ_t - error,
p - order of the model.

The p value in Equation 2 is called *the order* of the Autoregressive model. It determines how many past values will be considered to calculate the outcome. The autoregressive model of order p can be referred to as AR(p).

The Moving Average model calculates the outcome variable as a linear combination of past forecast errors. The formula of the model is presented in Equation 3 [10].

$$y_t = c + \epsilon_t + \theta_1 \epsilon_{t-1} + \theta_2 \epsilon_{t-2} + ... + \theta_q \epsilon_{t-q} \tag{3}$$

where:
c - constant value,
θ - model parameter,
ϵ - forecast error,
q - order of the model.

It shows that the value of y_t can be considered as a weighted moving average of the past forecast errors. The model order value q determines how many past forecast errors will influence the outcome. The moving average model of order q can be referenced as MA(q).

The equation of a non-seasonal ARIMA model presented in Equation 4 shows that it combines components of autoregressive and moving average models, which are lagged values and lagged errors.

$$y_t^{'} = c + \phi_1 y_{t-1}^{'} + ... + \phi_p y_{t-p}^{'} + \theta_1 \epsilon_{t-1} + ... + \theta_q \epsilon_{t-q} + \epsilon_t \tag{4}$$

where:
$y_t^{'}$ - differenced series.
The outcome of the model is a differenced series. To get the actual predicted values time series need to be integrated. Integrating is the reverse of differencing. The transformation aims to add the trend or seasonality which were previously removed.

The non-seasonal ARIMA model is characterized by 3 parameters:

- p - order of autoregression part,
- d - degree of involved differencing,
- q - order of moving average part.

The model of some specific parameters can be referenced as ARIMA(p, d, q).

We use the ARIMA implementation provided by the R forecast package [11]. The function `auto.arima()` estimates the model parameters by analyzing the training data.

C. Exponential Smoothing

The general idea behind Exponential Smoothing (ETS) forecasting methods is that predicted values are weighted averages of past observations. The weight which is associated with the observation depends on how old the observation is. Thus, the oldest observations will have a smaller impact on the outcome than the recent ones.

The simplest version of the exponential smoothing method, called Simple Exponential Smoothing, is expressed by Equation 5 [10]. The application of this version of the method is limited to the data with no clear trend or seasonality.

$$\hat{y}_{T+1} = \alpha y_T + \alpha(1-\alpha)y_{T-1} + \alpha(1-\alpha)^2 y_{T-2} + ... \quad (5)$$

where:

- $0 \geq \alpha \leq 1$ is smoothing parameter.

The smoothing parameter regulates how the weights change with the change in the distance of observation. If α is small, more weight is given to the observations from the past. If it is large, more weight is associated with the recent observations.

Equation 5 [10] can be described in the component form as presented in Equation 6.

$$\begin{aligned} \text{Forecast Equation} \quad & \hat{y}_{t+h} = l_t \\ \text{Smoothing Equation} \quad & l_t = \alpha y_t + (1-\alpha)l_{t-1} \end{aligned} \quad (6)$$

where:

- h - number of steps to forecast,
- l - level component.

A single component is called level (smoothed value) l_t of the series at time t. From the forecast equation, we can see that the predicted value at time $t+1$ is the level of the time series at time t. Replacing the level component in the smoothing equation according to the relation $\hat{y}_{t+h} = l_t$ leads to the exponential smoothing form presented in Equation 5 [10].

To extend the application of the simple exponential smoothing method for data with trend, an additional component has been added to the equations. The extended method's name is Holt's linear trend method and is expressed by 3 equations presented in Equation 7 [10].

$$\begin{aligned} \text{Forecast Equation} \quad & \hat{y}_{t+h} = l_t + hb_t \\ \text{Level Equation} \quad & l_t = \alpha y_t + (1-\alpha)(l_{t-1} + b_{t-1}) \\ \text{Trend Equation} \quad & b_t = \beta^*(l_t - l_{t-1}) + (1-\beta^*)b_{t-1} \end{aligned} \quad (7)$$

where:

- b - the estimate of the trend,
- β^* - smoothing parameter for the trend, $0 \geq \beta^* \leq 1$.

The trend (slope) forecast function is no longer flat as it was in the case of Simple Exponential Smoothing. However, this method is still not especially useful because of the fact that the trend is constant. The method assumes that the outcome values always increase or decrease in the same way. Thus, an additional parameter called damping parameter has been introduced to deal with that. Because of this modification, the trend can be flattened in the future. The form of the method which includes the damping parameter is expressed by Equation 8. As we can see with damping parameter $\phi = 1$, the method is the same as Holt's linear method presented in Formula 7.

$$\begin{aligned} \text{Forecast Equation} \quad & \hat{y}_{t+h} = l_t + (\phi + \phi^2 + ... + \phi^h)b_t \\ \text{Level Equation} \quad & l_t = \alpha y_t + (1-\alpha)(l_{t-1} + \phi b_{t-1}) \\ \text{Trend Equation} \quad & b_t = \beta^*(l_t - l_{t-1}) + (1-\beta^*)\phi b_{t-1} \end{aligned} \quad (8)$$

where:

- ϕ - damping parameter, $0 \geq \phi \leq 1$.

Holt's method can be extended with the seasonal component. This version is called Holt-Winters' seasonal method. There are two versions of the method: additive and multiplicative. The additive method is suitable for the series with constant seasonal variations. On the other hand, the multiplicative method is preferred when the variations change in proportion to the series. The component form of Holt-Winters' additive method is expressed by Formula 9 [10].

$$\begin{aligned} \text{Forecast Equation} \quad & \hat{y}_{t+h} = l_t + hb_t + s_{t+h-m(k+1)} \\ \text{Level Equation} \quad & l_t = \alpha(y_t - s_{t-m}) \\ & \quad + (1-\alpha)(l_{t-1} + b_{t-1}) \\ \text{Trend Equation} \quad & b_t = \beta^*(l_t - l_{t-1}) + (1-\beta^*)b_{t-1} \\ \text{Seasonal Equation} \quad & s_t = \gamma(y_t - l_{t-1} - b_{t-1}) \\ & \quad + (1-\gamma)s_{t-m} \end{aligned} \quad (9)$$

where:

- m - number of seasons in a year,
- k - integer part of $(h-1)/m$,
- γ - smoothing parameter for the seasonality, $0 \geq \gamma \leq 1-\alpha$.

  The component form of Holt's-Winters' multiplicative method is expressed by formulas 10.

$$\begin{aligned} \text{Forecast Equation} \quad & \hat{y}_{t+h} = l_t + hb_t + s_{t+h-m(k+1)} \\ \text{Level Equation} \quad & l_t = \alpha\frac{y_t}{s_{t-m}} + (1-\alpha)(l_{t-1} + b_{t-1}) \\ \text{Trend Equation} \quad & b_t = \beta^*(l_t - l_{t-1}) + (1-\beta^*)b_{t-1} \\ \text{Seasonal Equation} \quad & s_t = \gamma\frac{y_t}{l_{t-1} - b_{t-1}} + (1-\gamma)s_{t-m} \end{aligned} \quad (10)$$

The difference between those two versions of Holt-Winters' method is how they express the seasonal component and then take it into account. In the additive method, it is expressed in absolute terms and then is seasonally subtracted from the series. In contrast to this in the multiplicative method, the seasonal component is expressed in relative terms and then the series is seasonally divided by it.

There are 9 different exponential smoothing methods. Those presented so far are examples of different combinations of components. Each method is defined by the type of trend and seasonal components.

The types of trend components are:

- None (N),
- Additive (A),
- Additive damped (A_d) .

The types of seasonal components are:

- None (N),
- Additive (A_d),
- Multiplicative (M).

Each exponential smoothing method can be labeled with two letters which refer to the type of trend and seasonal components. Table I presents the classification of exponential smoothing methods.

TABLE I: Classification of exponential smoothing methods.

Trend component	Seasonal Component		
	None (N)	Additive (A)	Multiplicative (M)
None (N)	(N, N)	(N, A)	(N, M)
Additive (A)	(A, N)	(A, A)	(A, M)
Additive damped (A_d)	(A_d, N)	(A_d, A)	(A_d, M)

For each of the 9 presented methods, there are two models differing in the way of expressing the errors. The first model with additive errors and the second one with multiplicative errors. For each method, the forecast points of two different models are the same. However, they generate different prediction intervals. To make the distinction the classification in Table I is extended by the third letter. Every exponential smoothing model is labeled with three letters as ETS(Error, Trend, Seasonal). Thus, the model that includes additive error, none trend component, and multiplicative seasonal component would be denoted as ETS(A, N, M).

We use the ETS implementation provided by the R forecast package [11]. The function `ets()` estimates the model parameters by analyzing the training data.

III. Related Work

A. Software Reliability Growth Models

Software Reliability Growth Models are equations used to model the growth of software reliability using defect inflow data gathered during the development process. Researchers use SRGMs to make defects forecasting. The side effect of predicting defects themselves is the knowledge about the number of defects in defect backlog. Using this relationship and applying SRGMs to predict the size of the defect backlog is a popular technique [12]. There is no standard way of selecting the most appropriate SRGMs for given defect data. There are studies that reveal the best-fitted models for reliability in some types of projects. In [6] researchers investigated the distribution of defect inflow in automotive domain projects which could aid in finding the best-fitting SRGMs. This work presents that selecting the appropriate model is the most challenging part of the forecast. There are more than 100 SRGMs.

B. Linear Regression

Linear regression modeling was also applied to the problem of defect backlog prediction. The examples of independent variables which are used in the regression models are [13]:

- program metrics (such as program size, number of variables),
- number of defects found in the earlier phase,
- testing time,
- design methodology.

Yu, Shen, and Dunsmore [13] investigated the correlation between those variables and the number of defects that remain in the software. They discovered the strongest relationship between a number of defects identified during earlier phases of development and those discovered later.

C. Defect Backlog Prediction at Ericsson AB

A research program executed at Ericsson AB company resulted in a few studies on defect backlog predictions. In the first study [4], Software Reliability Growth Models were designed to defect inflow prediction after release. The results were not satisfying. Defects profile described by the model significantly deviated from the profile of defects in the studied project.

In the follow-up study on defect inflow predictions in a large-size software project [5], the prediction accuracy of different methods (e.g., multivariate linear regression or method which used the moving average of defect inflow) was compared. Table II presents average prediction errors depending on number of predictor variables and the used method. To evaluate the accuracy of methods they used the Mean Magnitude of Relative Error (MMRE). The error of none of the evaluated methods was good enough to reach the required accuracy level by the organization.

TABLE II: Extract of prediction accuracy in a large-size project for 1-week interval [5].

Model	Type of model	MMRE (%)
Project milestone progress	Multivariate linear regression + PCA over milestone progress	52
2 weeks moving average	Moving average	34
3 weeks moving average	Moving average	38
Test progress – best statistical models	Multivariate linear regression + PCA over test progress	58
Test progress – statistics and expert combined	Multivariate linear regression over test progress (variables chosen by experts)	28
Expert estimations	Expert estimates based on historical data	375

To improve prediction accuracy researchers from Ericsson decided to conduct a more detailed study on medium-size project [3]. This time they evaluated the prediction accuracy of three methods:

- Multivariate linear regression,
- Analogy-based prediction,
- Expert estimations.

Seven variables identified as most influential on defect inflow were chosen from a set of over 50 and used to construct a multivariate linear regression model. For analogy-based prediction, researchers collected an analogy database (projects that they found the most similar to the one that they were working on). The variables used for calculating similarity were [3]:

- the number of test cases planned in integration testing 4 weeks before the predicted week,
- the number of test cases executed in integration testing 4 weeks before the predicted week.

Also, they decided to enrich analogy-based predictions by involving experts and asking them to choose variables that they found the most influential on defect inflow and assign them weights.

In the following study at Ericsson AB [3], the problem was reframed to predict defect backlog size instead of predicting defect inflow. A new method was proposed by Meding and Staron (MS) that relied on the moving average of defect inflow and defect outflow and the previous backlog size (see Equation 11). The proposed model allowed for predicting defect backlog size with the highest accuracy (MMRE of 16%) compared to the previous studies.

$$db(i) = db(i-1)\frac{di(i-1)+di(i-2)+di(i-3)}{3} - \frac{do(i-1)+do(i-2)+do(i-3)}{3} \qquad (11)$$

where:

- db(x) - defect backlog in week x,
- di(x) - predicted defect inflow in week x,
- do(x) - predicted defect outflow in week x.

IV. Research Methodology

A. Research Goal and Questions

We perform a Simulation-Based-Study (SBS) [14] using the data from OSS projects to *compare the accuracy* of two new defect-backlog prediction models based on Autoregressive Integrated Moving Average (ARIMA) and Exponential Smoothing (ETS) with the state-of-the-art Meding-Staron model (MS). We formulate the following research questions:

- RQ1: *Are the MS, ARIMA, and ETS models more accurate than the Naïve prediction method?*
- RQ2: *Are ARIMA and/or ETS more accurate than the MS model when predicting the number of defects in defects backlogs of OSS projects?*

The question RQ1 could be considered a sanity test for the models. Shepperd and MacDonell [15] recommend performing such a test against "random guessing," however, we decided to use the so-called Naïve method instead of guessing. This method uses the actual observed values from the last week as the forecast for the next week. Although very simple, the Naïve method is reported to "work remarkably well for many economic and financial time series" [10]. Therefore, our sanity test is more demanding than the one proposed by Shepperd and MacDonell. However, for practical reasons, if a given model does not outperform the Naïve method, there is no point in considering it for real-life applications. The latter question (RQ2) is the central research question of this study. We compare the accuracy of the MS model, which according to the literature is the most accurate model for defect-backlog predictions with two models which are state-of-the-art in time-series predictions.

The replication package for this study is available on GitHub.[1]

B. Dataset

We collected defect backlogs from 20 Bugzilla instances of OSS projects managed by Apache Foundation, Eclipse, Mozilla Foundation, Linux, Open Office, and Libre Office. We selected only the projects that had a sufficiently long defect reporting period. The shortest defect-tracking period was 8 years (Libre Office Draw), while the longest was 22 years (Mozilla Core).

In the first step, we fetched defect reports from the *Bugzilla* service instances of OSS projects. The reports were grouped based on the dates when they were submitted or resolved and their severity level. By counting the number of defects submitted, resolved, or remaining in the backlog, we calculated defect backlog level (number of defect reports still opened at the end of the week), defect inflow (number of defects reported in a given week), and defect outflow (number of defects resolved in a given week) for every *week*.

The resulting dataset consisted of 20 defect backlogs presented in Table III. The beginning of each defect backlog is determined by the date of the first reports submitted to Bugzilla. The end of the bug tracking period is the same for all projects (01-01-2019). The average defect backlog size presented in Table IV ranges from 112 defects/week for Kernel Networking to 29,050 defects/week for Mozilla Core.

TABLE III: Dataset of OSS projects under study.

Open Office Draw	30-10-2000 - 01-01-2019
Apache Ant	11-09-2000 - 01-01-2019
Apache Apache2	15-01-2001 - 01-01-2019
Libre Office Writer	15-01-2001 - 01-01-2019
Libre Office Calc	08-10-2010 - 01-01-2019
Libre Office Draw	15-01-2011 - 01-01-2019

While visualizing the change in defect backlogs over time, we observed a suspicious phenomenon of rapid, significant drops in the number of defects in the backlog. We perceive them as anomalies that could result from "cleaning" processes of Bugzilla instances from irrelevant defect reports. Figure 1 presents an example of defect backlog level change over time in the Open Office Draw project with at least two sudden major drops in the number of defects around weeks 650 and 860, which are unlikely to be caused by the real defect fixing activities. Unfortunately, such drops are unexpected and poorly predicted by the considered prediction methods. On

Libre Office Calc	1,816.79
Libre Office Draw	370.36

the contrary, they have a less visible impact on the prediction errors made by the Naïve method since the error is present only for a single week following such a drop.

To mitigate the effect of sudden drops in the level of the backlog, we decided to split the defect backlogs based on the presence of unexpected drops in the number of defects. The process of dividing backlogs into fragments was the same for all projects and started with differencing the defect backlog level which result is presented in Figure 2. The peaks in the differenced time-series plot correspond to the sudden falls in backlog level from Figure 1. To consistently determine the weeks for which there are sudden decreases in the backlog level and to set the boundaries between fragments in those weeks, the 99.5 percentile of the difference in the backlog between successive weeks was calculated. For instance, Open Office Draw backlog was divided into 5 fragments presented in Figure 3. The final prediction error of a given method for a divided backlog is counted as the average of errors for individual fragments.

C. Predictions And Accuracy Evaluation

We performed training and accuracy evaluation for each individual defect backlog. We used data from all the previous weeks to train the ARIMA and ETS models and predict the number of defects in the backlog for the following week. We based the accuracy evaluation on Absolute Error calculated according to Equation 12 and calculated Mean Absolute Error (MAE) for each backlog.

$$AE = |actual\, value - predicted\, value| \tag{12}$$

We also calculated a variant of standardized accuracy measure (SA_m) [15] that shows a relative improvement in accuracy in comparison to the Naïve method, which was calculated according to Equation 13.

$$SA_m = (1 - \frac{MAE_m}{MAE_n}) * 100\% \tag{13}$$

where:
– $\mathrm{MAE_m}$ - Mean Absolute Error for the method m,
– $\mathrm{MAE_n}$ - Mean Absolute Error for Naïve method.

We used a non-parametric Wilcoxon signed-rank test to compare AE between prediction models with significance level $\alpha = 0.05$ and Cliff's δ effect-size coefficient to quantify the strength of the observed difference. Cliff's δ evaluates how often the values of one set are larger than the ones from the second set. The thresholds used for Cliff's δ coefficient interpretation proposed by Kitchenham et al. [16] are as follows: δ < 0.112 – negligible, 0.112 $\geq \delta$ < 0.276 – small, 0.276 $\geq \delta$ < 0.428 – medium, and $\delta \geq$ 0.428 – large.

We also calculate the number needed to treat (NNT = δ^{-1}) measure, which is commonly used in the field of medical science. NNT indicates how many patients need to be treated with a drug to heal one patient and is the measure of the medicine's effectiveness. The lowest the NNT value the fastest we achieve the improvement. In the context of this study, NNT could be interpreted as the number of weeks one would have to use a given prediction method A instead of method B to observe improvement in the accuracy for at least one week. We also calculated the average NNT to aggregate information from all the projects.

V. Results And Discussion

Mean prediction errors for the three considered methods and the Naïve method are presented in Table V, while the mean errors transformed to standardized accuracy measures (SA_m) are presented in Table VI.

ARIMA, ETS, and MS predicted backlog sizes with mean errors lower than the Naïve method for most of the projects (mean SA equal to ca. 17.1%, 17.7%, and 10.3%, respectively). However, there were three projects for which the Naïve method performed better than all three other methods. The effect size and the results of Wilcoxon signed-rank tests for comparison between AE (intra-project level) for the considered models and the naive one are presented in Table VII. For every of the considered models that were at least 10 projects for which a statistically significant difference in the central tendency of AE was detected. The effect size was at least "small" for nearly half of the projects, i.e., 10/20 (ARIMA vs. Naïve), 9/20 (ETS vs. Naïve), and 11/20 (MS vs. Naïve). That translates to NNT at the levels of 8 weeks for ARIMA, 14 weeks for ETS, and 36 weeks for MS. Finally, we performed Wilcoxon signed-rank test at the level of MAE (dataset level). In all three cases, the difference in the central tendency for MAE between considered models and the Naïve method turned out to be statically significant. **Therefore, we conclude that all of the considered methods outperform the Naïve method (RQ1).**

In the next step, we compared the accuracy of the state-of-the-art MS method and two methods proposed in this paper that are based on ARIMA and ETS. As it follows from Table V the lowest mean MAE was observed for ETS (16.36) and ARIMA (16.70), however, the mean MAE for MS was only ca. 5% higher (17.28) than the one observed for ETS. It is also visible that the methods perform consistently for all projects, i.e., there are no methods that would visibly outperform other methods on a single project. Also, as it follows from Table VIII, only for 3-4 projects the observed difference in the central tendency for AE (intra-project level) could be considered statistically significant. Also, the effect size could be interpreted as "negligible" for comparing AE for all the projects that translated to NNT at the level of 68 for ARIMA vs. MS and 32 ETS vs. MS. However, statistical inference at the dataset level regarding central tendency in MAE resulted in rejecting the null hypothesis for comparison between ETS and MS methods. **Therefore, we conclude that**

all the considered methods are good candidates to be used for predicting defect backlog size for OSS projects—with a slight preference towards ETS (RQ2). Taking into account NNT, statistically, one shall see improvement in defect prediction for at least one week after applying ETS for 32 weeks instead of MS.

A. Threats to Validity

We address the threats to validity in the manner as described by Wohlin et al. [17] and de França et al. [14].

a) Construct validity: The main construct validity threat concerns the process of cleaning the data. Each backlog was divided into fragments in places of sudden falls in the number of defects. The rule of determining the sudden falls was the same for all backlogs. It assumes a division point between weeks for which the difference in the number of defects in the backlog was more than 99.5 percentile of the differences between successive weeks from the backlog. It resulted that all backlogs being divided, even those in which the aggressive declines have not really taken place.

b) Internal validity: There exists a threat to the internal validity of this study regarding the validity of reported defects. For OSS projects, all users can report defects to Bugzilla. The new reports may be duplicates or not be real defects. We cannot control who makes reports and what they are. Because of that, the size of some defect backlogs is extremely large.

c) External validity: The main threat to the external validity of our results is the fact that we applied the defect backlog prediction methods only to a selected sample of well-established OSS projects that maintain public Bugzilla instances. We do not know whether our results would also apply to smaller OSS projects, however, there is a question of whether such projects would benefit from defect backlog predictions. Also, we limited our study to OSS projects only, therefore, we would be careful in generalizing the findings to industrial projects since the ways of working differ visibly between the OSS and industrial settings. Even when it comes to OSS projects themselves, we have to be aware that the process could be less stable in time than it is for the industry (e.g., the number of contributors involved, the number of commits they produce, or the number of defects they fix can vary in time). Also, we used the 1-week prediction horizon after the previous studies in Ericsson AB, however, we cannot claim based on our results that the methods will behave the same way if a longer prediction horizon is needed by a given OSS community.

d) Conclusion validity: The main threat to conclusion validity regards performing multiple statistical inference tests while drawing some of the conclusions (statistical inference tests at intra-project and dataset levels). We set the local significance level α to 0.05, however, the true, global significance level would be much higher. Still, the outcomes of the statistical inference tests were only one of a few sources of information that we used to draw the conclusions, therefore, the impact of rejecting a true null hypothesis would have a minor impact on the final conclusions.

VI. Conclusions and Future direction

In this paper, we evaluated three defect backlog prediction methods in the context of open-source projects, i.e., the state-of-the-art Meding-Staron model (MS) and two new models based on Autoregressive Integrated Moving Average (ARIMA) and Exponential Smoothing (ETS) time-series forecasting methods.

We compared the accuracy of these methods on the dataset consisting of defect backlog histories of 20 large open-source projects (ranging from 8 to 22 years). In the first step, we performed a sanity check by comparing the accuracy of these methods with the accuracy of the so-called Naïve method, which predicts a defect backlog size in the following week to be the same as the one observed in the current week. All three methods outperformed the Naïve method by ca. 10% to 17.7% (the largest improvement was observed for the ETS method). The observed differences in mean absolute errors (MAE) were statistically significant for all the methods. With respect to effect size, one would have to use these methods instead the Naïve one for 8 to 36 weeks to, statistically, notice improvement in defect backlog predictions for at least one week.

Exponential Smoothing (ETS) provided slightly more accurate defect backlog size predictions than the state-of-the-art MS method (by ca. 5%) and the prediction method based on ARIMA (by ca. 2%). If one decides to use the ETS-based defect backlog prediction method instead of the MS method should statistically, notice an improvement in defect backlog predictions for at least one week after using it for 32 weeks.

Therefore, the main contributions of our study to the body of knowledge are as follows:

- we provided some new observations regarding the state-of-the-art Meding-Staron model (MS) by evaluating its accuracy in the open source context (in addition to the previous studies in Ericsson). Based on the results of this and the previous studies on that method, we can conclude that it is suitable for defect backlog size prediction in both industrial and open-source settings.
- we proposed two new defect backlog size prediction methods based on the state-of-the-art time series forecasting methods ARIMA and ETS, which perform slightly better (especially ETS) than the MS method in the open source context.
- all the considered defect backlog prediction models based on autoregression (ARIMA, ETS, and MS) are very accurate when estimating defect backlog levels in OSS. Taking into account that the mean size of the defect backlogs for the considered OSS project ranged from ca. 112 to 29,000 defect reports and the mean absolute error for the ETS model ranged from ca. 2 to 85 defects, the relative error for that model was at the level of 0.13% to 2.28% (with respect to the average backlog size of a project).

As future research directions, we plan to investigate the accuracy of artificial neural network-based time-series prediction models (e.g., LSTMs, GRU) for defect backlog predictions. We would also like to validate the proposed models based on ARIMA and ETS based on historical data from industrial projects.

***Abstract*—Artificial Intelligence (AI) represents a highly investigated area of study at present and has already become an indispensable component within an extensive range of business models and applications. One major downside of current supervised AI approaches lies in the need of numerous annotated data points to train the models. Self-supervised learning (SSL) circumvents the need for annotation, by creating supervision signals such as labels from the data itself, rather than requiring experts for this task. Current approaches mainly include the use of generative methods such as autoencoders and joint embedding architectures to fulfil this task. Recent works present comparable results to supervised learning in downstream scenarios such as classification after SSL-pretraining. To achieve this, typically modifications are required to suit the approach for the exact downstream task. Yet, current review works haven't paid too much attention to the practical implications of using SSL. Thus, we investigated and implemented popular SSL approaches, suitable for downstream tasks such as classification, from an initial collection of more than 400 papers. We evaluate a selection of these approaches under real-world dataset conditions, and in direct comparison to the supervised learning scenario. We discuss SSL's potential to take up with supervised learning, as well as the influence of the right training methods. Furthermore, we also introduce future directions for SSL research, as well as current limitations in real-world applications.**

I. Introduction

SELF-supervised learning (SSL) has recently gained massive attention as a promising new learning paradigm in the machine learning world. The main advantage over supervised learning lies in SSL's capability to reduce the amount of required prior work of data scientists by avoiding manual annotation. Recent work has shown that state-of-the-art results can be achieved in downstream tasks, when using SSL as a pretraining method. This includes classification scenarios, as well as clustering.

Especially for medical and industry applications, where annotations can only be created by highly trained, rarely available experts, this can possibly be a game-changer in bringing Artificial Intelligence (AI) to a wider mass of companies. Currently, however, SSL methods are typically evaluated on large image datasets such as ImageNet [1], which compare poorly to real-world data. The problem is that ImageNet and comparable datasets consist of well-balanced, well-curated and giant data collections. Real-world datasets, especially in the industry and medical sector, on the other hand, typically only feature a few 1000 to 10000 samples which contain systematic label noise, defective images and imbalanced data. Additionally, such datasets often contain obvious data properties and fine-granular ones, whereas the latter ones need to be represented by the SSL-extracted features. Popular SSL methods currently are only proven to work correctly if balanced data [2] and large batch sizes are used [3]. For datasets and tasks under real-world conditions, this is often unfeasible and thus, the applicability and required modifications of SSL remain unclear.

We thus reviewed the literature to find the most important approaches for SSL in computer vision and summarize their basic functions, as well as possible modifications. We focused on practical implications of the presented approaches and investigated possible application fields of different algorithmic groups and their modifications. Additionally, we compared the performance of SSL models and their supervised pendants. For this, we evaluated the models using two datasets composed of MNIST and Oxford-Flower+IIT-Pet data [4], [5], [6] with little dataset size and different complexities of problems to address, thus, with conditions that hold for real-world applications as well.

To retrieve an extensive and representative collection of SSL-approaches, various databases were queried, using the system as described in Bramer et al. [7]. We identified appropriate journals and conferences for the topic and selected appropriate search engines that contain these. Several well-recognized journals such as the "IEEE Transactions on Pattern Analysis and Machine Intelligence" cover the scope of our work. We selected 20 of the best-ranked journals that cover our scope and picked an initial database according to the best availability of these journals. Among other choices, such as Cabi, Inspec and Web of Science, EBSCO had the best availability and thus was selected. The EBSCO academic search premier contains more than 3000 peer reviewed journals. In addition, we used the IEEE database directly, as well as Google Scholar, to also include popular conference proceedings such as the MICCAI, CVPR and NeurIPS, as well as publishers like ACM Digital Library and less popular journals. EBSCO is also preferred because it offers the use of thesauri terms, which are useful for filtering the search results. From an initial collection of 1792 samples, we finally extracted 42 articles to be considered for our comparative study. The detailed literature selection process is shown in Fig. 1.

II. Related Work

Various works have been proposed in the past that demonstrate impressively the value of SSL for clustering and classification tasks. Generally, two major approaches with five possible modification types can be found in the literature, among preliminary, less generalizable works. Fig. 2 provides an overview of SSL and its configuration possibilities.

Autoencoders (AEs) are the possibly most prominent architecture, and already gained attention for several years. The core principle is simple: Input data (i.e., images) is processed using a CNN encoder and a feature vector (:= embedding or latent) is created. Afterwards, the inverted CNN is used as a decoder to reconstruct the input. The supervision signal is then generated from the distance of the generated and input image. Thus, an optimization can be done, whereas reconstruction will improve with more meaningful latents that capture significant properties of the input data. A first application of this architecture was denoising, as proposed by Vincent et al. [8], followed by variants that make use of Gaussian inference [9] and additional classification tasks, called adversarial learning [10]. Even though AEs can achieve remarkable results for, e.g., clustering with smaller and simple image datasets (such as the MNIST dataset), they have known limitations when working with more complex data.

Thus, another class of SSL algorithms, joint embedding architectures (JEA), have gained attention recently. In JEA, the input will be processed using at least two CNNs (whereas weights may be shared), sent through a bottleneck to reduce dimensions, and then passed through a projection head, which is typically a fully connected network. As for the AE, backpropagation is the last step in JEA training. JEA uses a contrastive loss function [11] or an entropy-based function [12] that keeps the vectors of augmented and non-augmented image versions consistent. Very early works of Noroozi et al. [13] show that suitable SSL signals for JEA may be easy and intuitive to implement, e.g., by splitting or solving jigsaw puzzles. Even though such works didn't directly combine latents, and thus technically aren't JEAs, they share the idea and can be seen as close relatives of JEA. As the model needs to understand contextual information before solving the task, representative features will be learned as a side effect. Similar results can be achieved using image rotation [14], pseudo-classification [15] or combining multiple augmentations [11]. JEA's representative feature extraction capabilities can even improve if historical examples are used from a memory bank [16].

The major groups of AE and JEA can be divided further according to the following six modification types:

- Input variations: Input data is directly modified before being processed.
- Backbone variations: Other architectures than a single CNN are used.
- Latent variations: The features created by the bottleneck are processed in a parallel or preceding path to projection/decoding.
- Projection variations: A more sophisticated model than, e.g., an MLP is used as projection head.
- Temporal component: Time-dependent information is captured.

The following sections contain information about AE and JEA basic and modified approaches.

A. AE with Input Variations

The proposed basic principle of the AE as of Vincent et al. [8], as well as the ones of Kingma et al. and Makhzani et al. [9], [10], may be modified such that the input is preprocessed in a certain way, before feeding it to the AE. Such modifications may include augmentations, such as stretching, rotation and jitter, that will or will not be part of the target image. That way, the training can be guided to pay particular attention, or ignore certain properties of the input data, and thus to learn more robust features. This can be of value, e.g., in single-cell cytometric imaging, where AEs may be vulnerable to trivial features such as cell rotation [17]. Generally, an AE approach with input variations is seemingly mostly feasible, if obvious data properties should be ignored, as the typical application of this architecture often comes with little to no knowledge about important input data properties. This is not

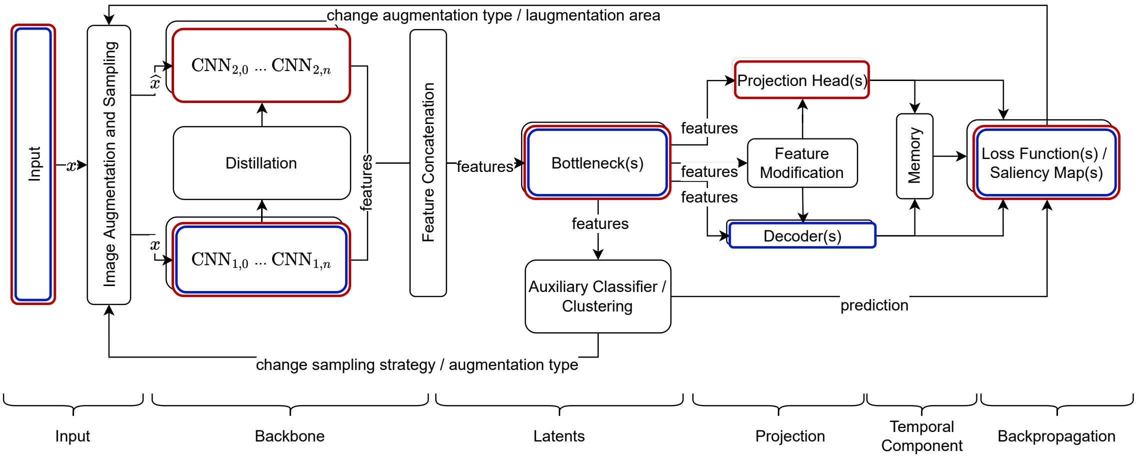

Fig. 2: Overview of the discovered SSL training elements and their respective order. The default configurations for JEA (red) and AE (blue) are marked. Note that not all elements are necessarily used.

only limited to examples in the research field of life sciences. Another application in the industry context could, e.g., be the extraction of different features than build-part size in 3D-print classification. As the build-parts are printed layer after layer and hence their size differs throughout the print job, the most simple property is to learn exactly this varying size. This will, however, have almost no implications for, e.g., quality measurements. Using augmentations such as scaling and stretching, particular attention for anomalies can likely be created that enables extracting more meaningful latents that, e.g., correlate with the print quality.

B. AE with Backbone Variations

Another approach to increase the AE's performance lies in changing the encoder backbone from a simple CNN to a more sophisticated architecture. This includes using multiple backbone branches, or an encoder ensemble, whereas each model receives different input (i.e., augmented versions of the original). Furthermore, features from different model depths can be concatenated as the latent, to consider different morphological complexities in the vector representations. By modifying the backbone that way, a better weighting of global and local features may be achieved [18], as well as multiple views that carry different information may be considered for feature extraction, e.g., as in the case of analysing spectral bands in hyperspectral imaging (HSI) classification [19]. The concept can also be adapted to applications that leverage information, e.g., from audio and text data. Even though this variant may cause the trained models to be significantly more memory-intensive or slower, their feature extraction capabilities also may improve remarkably, when compared to a basic AE.

C. AE with Latent / Loss Variations

Similar to the approach of Makhzani et al. [10] the learning signal can be supported by not only formulating the cost functions as a reconstruction problem, but rather adding an auxiliary learning signal, such as the adversarial problem. Recent work shows that different learning signals than the adversarial discriminator, such as clustering, may be of value to assist the training process. They are included as a multi-loss cost function. Possible applications include the direct consideration of the extracted features clustering probabilities, e.g., in tasks where clustering of different cell lines is the goal [20]. Popular approaches to achieve better clustering capabilities include the use of Gaussian mixtures rather than a single Gaussian for the feature space [21]. The advantage of this modification is that it successfully extracts more robust features and thus is more suited against data distribution drift and noise. Typical application fields could also lie in life-science imaging, where artefacts are likely to arise and confuse trained models.

D. JEA with Backbone Variations

In contrast to the generative AE models, JEA enables one to train without the need for image generation. State-of-the-art results have recently been achieved in different downstream tasks of models pretrained with JEA. There are, however, applications, where the standard architecture needs to be modified analogous to the generative AE methods.

A first approach is to change the backbone or combine multiple architectures. The influence of different backbone models has been shown by Guerin et al. [22], who conclude that different architectures have different strengths/target domains and thus combining them helps to increase model performance. They use multiple pretrained architectures to perform clustering using JULE [23].

Another variant of backbone modifications is the use of Vision Transformers (ViTs) that could be shown to achieve comparable or even better results than CNNs that process images as a whole, while also, e.g., offering better properties when it comes to interpretability (c.f. [24]). They are thus a promising alternative to, e.g., residual networks [25]. In contrast to convolutional networks, ViTs show better properties regarding the weighting of local and global features, which can be advantageous in imaging domains that require context for each object, such as polarimetric synthetic aperture radar image classification [26]. For applications such as remote sensing imaging, where images are inherently very similar even though they may show different objects (e.g., a town house vs. a barn), ViTs also can be combined with knowledge distillation [27]. The imposed teacher vs. student asymmetry then improves fine-granular feature extraction capabilities. The distillation approach furthermore offers the possibility to reduce the network's parameters within the student model, and thus to decrease memory usage and processing times. JEAs backbone may also be modified, when multiple domains need to be unified, e.g., 2D and 3D images [28], or if special downstream tasks such as object detection are the training target [29].

E. JEA with Latent Variations

Directly modifying the latents may be of value to enable the model to, e.g., perform fine-grained clustering. This includes rearranging, normalization and regularization of the latents before processing them with the projection head and triggering the backpropagation. Additionally, created latents may also be used, to generate an auxiliary training signal that improves properties such as drift-resistance. This can be of interest, e.g., where slight changes between images have no meaning as in the case of scene classification, and thus the model needs to be robust against changes in poses, part configurations, as well as to relative motion between objects, and scene structures. Possible methods to implement such latent variations are spatial assembly [30] or the use of adversarial training for resistance against perturbations [31]. The use of an adversaria task also allows adapting JEA for image hashing problems [32].

Recent works as Masked Siamese Networks (MSN) or Joint Embedding Predictive Architectures (JEPA) randomly mask parts of the latents [33], [34], to simulate masking of the input images while maintaining asymmetry between, e.g., a student and teacher network. That way, the JEA scenario can be used with significantly less computation time, as no computation expensive augmentations need to be performed.

Modifications to, and further auxiliary processing of latents is advantageous where slight image changes have a significant impact on the data domain they refer to. This can, e.g., be the case in quality control, where small deviations from the standard can have a significant impact on product quality, in representation learning scenarios or in security applications.

F. JEA with Projection Variations

After latents have been extracted by the backbone, features typically are projected to a fixed-size vector, e.g., using fully connected layer and average pooling. Different methods allow for improving this projection compatible to later downstream applications such as clustering. For medical imaging, typically images need to be split into patches, and thus separate modules need to be created, that keep features consistent through the global image scope [35]. Furthermore, clustering capabilities of the extracted features may be improved, by assigning the features to cluster prototypes according to an optimal transport problem [36], which advantageously also avoids trivial solutions (mode collapse). Thus, using different projections heads, one can not only control the level of granularity in information extraction, but also adapt the model to special application scenarios, as in the case of histopathological whole-slide-imaging.

G. JEA with Temporal Component

In many scenarios, important information is time-dependent and thus can't be extracted from a single data point. Therefore, additional components need to be integrated, such that the model can capture the time-information. This can also enable a model to be suitable for streaming scenarios. Including temporal information can be done using distillation procedures [37], or memory bank approaches [38]. While distillation has the advantage of imposing asymmetry, which helps to find more robust features, memory banks can reduce the calculation efforts in terms of GPU-usage. Integrating a temporal component into the JEA learning setup further extends the possible application scope, e.g., to include quality monitoring, where slight data distribution changes are expected and need to be captured by the model to represent all data classes correctly [39]. This modification is, however, more of interest for time-series or video-based scenarios, than for imaging.

H. Preliminary Works

In addition to the presented groups and subgroups, further approaches have been discovered that show preliminary results or, as of now, fail to achieve state-of-the-art results on real-world data. They are presented for completeness here. Modifications to the default JEA scenario may also include recoupling of the model's output, e.g., by leveraging the Grad-Cam approach for sharpening the area of interest in the input image [40]. To ensure a higher probability of finding a global minimum during CNN parameter optimization, dropout is known as a useful measure, especially as it helps to avoid over-fitting. Thus, advanced dropout methods such as biologically inspired ones [41] may be a good choice to add to the JEA or AE model. The right choice of pre-text tasks also heavily influences the training. Thus, popular works often investigate how different augmentations contribute to the training results [42]. Other approaches show that methods typically used in JEA, such as the one of He et al. [43], are also of value for AEs. Examples include the mapping of AE features to dictionaries rather than simple keeping them for further processing [44] or combining AE and JEA architectures [45]. In special cases, selecting specific training variants, such as evolutionary [46] or sparse kernel network training, as well as solutions inspired by biological processes such as associative learning [47] may be of value to the JEA pipeline as well. A promising approach for future SSL directions lies in the usage of energy-based models (EBMs). These models may be capable of more fine-granular analysis of data distributions, and are thus in the focus of various visionary works, such as the one of Yann LeCun

[48]. Restricted Boltzmann Machines are one very rudimentary implementation of such EBMs and have been studied in the literature, even though their capabilities in computer vision are very limited, as they model the data distribution, which is rarely feasible for images of a real-world size [49], [50]. Similar as with RBMs, self-organizing maps [51] are a popular choice, especially in life sciences and genetics, but have come unfashionable due to their poor scalability.

III. Qualitative and Quantitative Model Evaluation

To get a more profound understanding of the similarities and differences of SSL vs. supervised training, we analysed the observations and findings, and collected implications for SSL's applicability to real-world problems. We compared eleven different models, as depicted in Table I using three of the classes taken from the MNIST dataset, as well as various thousands images of cats, dogs, and flowers taken from the Oxford IIT-PET and Oxford IIT-Flower dataset. Note that each custom data set contains an obvious task and a more challenging task, as well as a slightly imbalanced data amount between the classes (e.g., more flowers than pets). For the MNIST data set, these are the separation of the digit four from eight and zero, and the separation of the similar digits zero and eight itself. Analogous, the Oxford-based data needs to be categorized into flowers and pets, as well as cats and dogs. The parameters for each training have been optimized in a grid search. For the qualitative analysis, the extracted latents were further reduced using a principal component analysis (PCA) and inspected. Similar results could be achieved for all models, except for the model using spatial transformations, as it struggled in finding a suitable solution. Fig. 3 shows the results of the highest accuracy models, as referred in Table II, for the MNIST dataset. It's evident that both models captured expressive filters and can successfully separate all the three digit types. The features extracted with the baseline model (SimCLR), however, seemed to use the latent space more efficiently, as they are denser. For the remaining models except the one with spatial transforms, distinguishable classes could be observed as well, while clusters were more entangled than in the presented examples.

TABLE I: Overview of implemented approaches and the subcategories. We implemented the particular methods as suggested in the referenced literature.

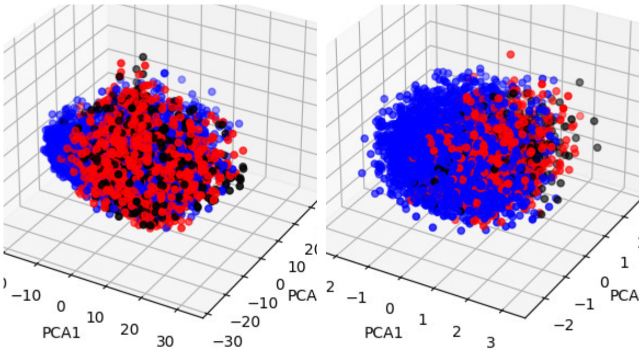
(a) AE with clustering. (b) SimCLR.

Fig. 3: Features of a selection of MNIST samples (red – 0, black – 4, blue – 8), when converted to a three-dimensional space using the PCA.

For the Oxford datasets, qualitative results could be found to be worse than the ones for the MNIST dataset. This was not surprising, given the fact that the data contains far more complex objects. As shown in Fig. 4, the significant difference of flowers vs. pets could generally be recognized in the latent space's clusters, while the pets' features themselves yield only strongly entangled clusters. It's noteworthy to say that further compression through PCA possibly amplified the entangling, especially in the case of SimCLR. The remaining approaches showed similar behaviour for the Oxford datasets' qualitative analysis. The main difference was the amount of entangling.

From the qualitative analysis, three major observations could be made about SSL's capabilities. First, more complex datasets very likely require a higher number of samples, to guarantee finding a minimum on the error surface during training. Furthermore, fine-granular distinction of different data point classes, such as "cat" and "dog", may be challenging for both the AE and JEA setup. In addition, no significant difference between AE and SSL models could be observed in qualitative analysis, opposing to the results presented in further sections of this paper. The differences among the reviewed



(a) AE with clustering. (b) SimCLR.

Fig. 4: Features of a selection of Oxford-Pets+Oxford-Flowers samples (red – cat, black – dog, blue – flower). In contrast to the MNIST data, the fine-grained task couldn't be solved.

modification types were investigated deeper, by evaluating model linear classification performance on the dataset's test cohorts, after pretraining with SSL. For the MNIST dataset, similar to the qualitative results, all approaches, except the spatial transforms, achieved results comparable to state-of-the-art models. The spatial transforms likely fail to achieve a good result, as the learned augmentations do not contribute to finding similar vector representations in the JEA setups. This effect is similar to the one observed by Li et al. [42] who conclude that only certain augmentation techniques are suited for their training task.

Overall, the AE with auxiliary (i.e., clustering) task performed best, in terms of absolute accuracy, with 99.87% (c.f. Table II). The JEA approaches achieved similarly good results, whereas SwAV even had the highest improvement compared to the supervised pendant of 1.37%. The results of the quantitative performance analysis thus matched the ones of the qualitative analysis. As the MNIST dataset could even be learned by linear machine learning models such as support vector machines, this finding can only be seen as proof of concept for the implemented approaches. For the Oxford data, more differences could be observed among different models. The previously top-performing AE with clustering only achieved a poor accuracy of 49.44% (c.f. Table II). Further investigation strongly suggested that the model failed to learn a meaningful distribution to generate data, thus the clustering loss was blocking the training, rather than helping, by creating confusing samples. Generally, the generative AE approaches performed worse than the JEA ones. This is likely because data complexity was too high for the small number of samples. As this is an unavoidable condition for numerous practical scenarios, generative AE approaches showed a systematic weakness here.

TABLE II: ΔAcc. (Accuracy – Supervised Accuracy) of different models on the MNIST and Oxford datasets, within a 5-fold cross-validation downstream test, when trained using SSL and in a supervised fashion.

Dataset	Approach	Acc. (%)	ΔAcc. (ppt.)	$\frac{t \cdot s^{-1}}{epoch}$
MNIST	AE baseline	99.46	0.03	29
	AE + clustering	**99.87**	1.29	36
	AE + ensemble	91.89	-6.87	87
	AE + input variations	99.31	1.21	153
	JEA + distillation	87.82	-8.65	47
	JEA + spatial transforms	50.44	-46.43	66
	SimCLR	99.72	1.36	58
	JEPA	91.45	-6.22	30
	MSN	93.21	-5.12	103
	SwAV	97.40	**1.37**	90
	Dino	90.36	-9.20	260
Oxford	AE Baseline	49.44	-20.26	17
	AE + clustering	55.82	-16.25	17
	AE + ensemble	56.27	-24.98	32
	AE + input variations	59.01	-21.1	46
	JEA + distillation	62.02	**-7.43**	21
	JEA + spatial transforms	34.32	-44.48	25
	SimCLR	**72.80**	-8.44	36
	JEPA	57.50	-24.19	17
	MSN	56.30	-25.39	58
	SwAV	55.40	-26.29	39
	Dino	61.90	-8.00	65

Among the JEA approaches, surprisingly, the baseline model performed best, with 72.80% accuracy. It's noteworthy to say that JEPA and MSN, however, took the shortest training time, as they already showed stable results after a few ten epochs. JEPA also had the fastest processing time per epoch. The distillation scenario showed the least difference to the supervised pendant, but similar to the generative AE approaches, the dataset size was possibly too small. The ViT-based Dino model likely suffers from the same problem. For the SwAV model, loss froze at an early stage of the training, at around epoch 50. This indicates that only a trivial solution was found in swapped prediction problem. Thus, training loss failed to converge to the global minimum. The effect could be compensated slightly by using a buffer to collect multiple batches, which increased the batches' variability, before solving the swapped prediction problem. The results were, however, inferior. The SimCLR approach, overall, could be found to work reasonably well, when compared to the supervised pendant. This also aligns with the findings of Zhong et al. [54].

The results on the Oxford datasets, opposing to the ones of the MNIST data, showed that systematic problems occurred for all the presented approaches, given a higher complexity of the data. Thus, the confusion matrices of the models we're examined, to see what the limitations are. Table III shows the result for the AE with clustering task, which was performing best on the MNIST dataset, and the JEA baseline. The AE with clustering model achieved a correct classification of flowers against the pets of 91%. For the more challenging part of distinguishing the pets themselves as cats, or respectively dogs, the model, however, performed only slightly better than a random classifier. The JEA Baseline provides better results with TP rates of 47, 77 and 95% for cats, dogs, and flowers. Similar to the AE, the less challenging task was solved remarkably well, while the dog vs. cat problem was characterized by a strong overfitting to the dog class.

TABLE III: Confusion matrix of the AE with latent variations and the JEA baseline on the Oxford-Flower+IIIT-Pet dataset.

	AE with clustering			SimCLR		
Pred / True	Cat	Dog	Flower	Cat	Dog	Flower
Cat	0.23	**0.45**	0.31	**0.47**	0.24	0.29
Dog	0.16	**0.53**	0.31	0.07	**0.77**	0.17
Flower	0.03	0.06	**0.91**	0.01	0.04	**0.95**

As the training data only contained a few thousand images per class, the low data amount, in contrast to results created on the ImageNet dataset, seemed to be a limitation for all approaches. It's also noticeable that even more sophisticated JEA approaches generated worse solutions, as the results of the remaining models aligned with the ones of the clustering AE. An explanation for this may be that the dataset provided too few inputs to solve the optimization problem for a sufficient number of parameters, given the relatively small dataset size. This was especially the case for multi-loss training such as Dino, SwAV and JEA with distillation. The problem is likely caused by the non-contrastive loss-term. For example, in the clustering-based approaches (clustering AE and SwAV), the optimization of the clustering problem is only possible, if the batches are large enough at each step and have enough variability between the epochs. As this is not necessarily the case using a small dataset, the clustering-loss part will hinder training and eventually cause convergence to a suboptimal or trivial solution. Analogously, the second loss term of Dino and plain distillation do not contribute positively to the training. The AEs with ensemble and input variations showed improvements, when compared to the AE baseline, but couldn't keep up with the more capable JEA.

IV. Future Perspectives for SSL

From our results, we conclude that SSL can open new perspectives for future AI research. Even though the validated architectures failed to solve the most fine-grained task without specific modifications (i.e., separating pets and flowers of the Oxford data), various practical applications can be found in the literature that serve as a proof-of-concept for adapting SSL in industry and medical applications. In most of the cases identified in the literature, at least SSL-pretraining was helpful to extract more robust features or even such ones, that supervised learning was missing.

Future work should concentrate on facilitating the implementation of SSL in practice. Additionally, it should be investigated, how SSL can help in curating and understanding data, rather than simply using it as a tool to pretrain a model. Figure 5 shows such a scenario. After initially processing the unlabelled data, latents get annotated by an expert. To decrease the annotation burden, suggestions for annotation can be made by group selection of latents or labelling closest neighbours. That way, a larger dataset could be annotated using only a few examples. For uncertain latents, e.g., those that show similar logits for all pseudo classes, concepts such as active learning may be used for sampling. This way, experts could focus on conceptual work and result validation, rather than on searching for significant/anomalous data. Such a tool could bring major improvements to scenarios such as clinical applications, where initial annotation will likely result in subjective bias, or in scenarios where a-priori annotation is unfeasible due to the data set size.

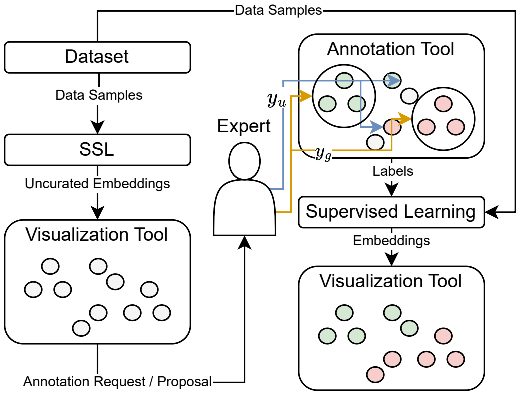


Fig. 5: SSL as a tool for data annotation.

V. Conclusions

In this work, we presented a comparative overview of current SSL methods. We conclude that SSL is a promising method to change the paradigms of machine learning, even though none of the approaches yet achieves identical or better performance than the supervised pendant on more complex datasets. The models solved less challenging tasks without problems, and showed promising initial results for more challenging tasks. Overall, they provided good baseline results that suggest SSL may be capable of achieving or surpassing performance of supervised training.

Regarding the training setups, we acknowledge that grid search may be a suboptimal choice to get optimal accuracies, especially as models with fewer hyperparameters benefit more from grid search than more complex ones due to search complexity. The performance results thus can only be seen as an indicator for certain characteristics of SSL approaches.

In addition to presenting the reviewed work, we performed an experimental validation using a selection of approaches. From the qualitative analysis, we conclude that all models generally capture important information from the data. The models, however, failed to solve the more challenging task. The latter finding is supported by the results of the performance analysis. Among all approaches, JEA methods outperformed generative (AE) ones. The SimCLR approach even showed a rudimentary solution to the challenging task of separating cats from dogs.

The biggest problem for all the models still seemed to be related to small dataset size. This may be the most significant weakness of SSL, as this condition typically can't be compensated. Additionally, many hyperparameters such as temperature [11], patch size (in case of using ViTs) or batch size need to be examined when using SSL (c.f. [3]). Especially the fact that approaches such as SimCLR, SwAV, MSN and JEPA require gigantic batch sizes of more than 1000 images, unnecessarily limits SSL applicability as multi-GPU clusters will be needed for calculation, with a data set of according size. In practice, this means a high technical burden to implement such a solution. Therefore, future research should focus on small-dataset SSL, that also works under real-world conditions, rather than focusing on ImageNet benchmarks. Additionally, more effort should be spent to understand structural differences between supervised and SSL models, and the exact effects leading to this behaviour.

***Abstract*—Global financial scandals have demonstrated the harmful impact of creative accounting, a practice where managers creatively manipulate financial reports to conceal a company's actual performance and influence stakeholders' decision-making. Studies showed that Saudi-listed companies use it in preparing financial statements. Despite posing a significant risk to the Saudi financial market, detecting it using ordinary auditing procedures remains challenging. Big data analytics has provided practical applications in auditing, and recently, the employment of Deep Learning in fraud detection has delivered remarkably accurate results. Still, limited research has considered it in detecting creative accounting. This study proposes a novel framework using a hybrid learning approach. It suggests training on a simulated dataset of financial statements prepared (i.e., deliberately manipulated) based on financial statements available in the literature for supervised learning. It is then tested on real-world financial reports from the Saudi Open Data and Saudi Statistics. Our framework contributes to the literature with a new governing approach to limit creative accounting and improve financial reporting quality.**

***Index Terms*—Creative Accounting, Big Data, Deep Learning.**

I. Introduction

CREATIVE accounting (CA) practices have negatively affected the financial reporting quality and disturbed the trust in the information extracted from financial statements. The issue with CA is that it does not necessarily violate the International Financial Reporting Standards (IFRS), yet it has the same severe consequences as Financial Statement Fraud (FSF) [1]. Besides, CA is more enigmatic and almost impossible to detect using traditional auditing techniques. Some studies consider CA and Earnings Management (EM) as FSF, while others identify the thin line between them [1]. Another harmful practice that could be identified along CA and FSF is Window Dressing (WD), where managers invest in the freedom of interpretation area to manipulate the presentation of reports. The term 'creative' gives a positive impression about the practice whereas, in reality, this practice has been considered to be the primary cause behind many financial scandals such as Enron, WorldCom, in the U.S., and Parmalat, Royal Ahold, and Vivendi Universal in Europe [2][3][4][5][6][7][8]. These incidents confirm that account manipulation is designed to gain a temporary benefit, eventually leading to financial scandals and substantial losses. In Saudi Arabia, cases of CA exist and, according to the literature, employ the same accounting techniques for similar reasons. Considering the proposition that less efficient markets tend to have greater tolerance to manipulations, the weak-form efficiency of the Saudi stock market Tadawul, as proved by [9], indicates the high possibility of manipulations. Many studies have investigated the practice in the region, but non include real-time case studies [10][11] [12][13]. The results of these studies agreed that financial statements do not represent the true and fair position of a company, although being approved by auditing procedures.

However, big data analytics and AI models are currently employed in different business sectors. Many models and techniques have been developed and validated to replace or supplement traditional accounting and auditing procedures. In our context, the literature is rich with significant contributions in FSF detection using data mining and machine learning ML. The availability of data types like financial (FIN) and non-financial (N-FIN) and the possibility to include these data types in advanced intelligent models motivated researchers to develop many applications that meet business needs. Indeed, detecting CA using traditional techniques (e.g., accrual-based detection) requires non-public, inaccessible, and time-consuming data to reach [14]. On the other hand, the literature is rich with examples of Machine Learning (ML) and Deep Learning (DL) models that can learn from publicly available FIN and N-FIN data and produce predictions and results with high accuracy.

The use of big data analytics made it possible to include N-FIN data and aggregate accounting data with other sectors' data. Consequently, accounting results are now more accurate and credible [15]. Moreover, big accounting firms are adopting server-based platforms that support auditors by implementing real-time financial data collected directly from clients. For example, in April 2022, *PwC* announced the use of a new cloud-based auditing platform named *Aura* that provides many services powered by advanced analytics. These capabilities motivate us to further add to the capacity

IEEE Catalog Number: CFP2385N-ART ©2023, PTI

and efficiency of these analytical tools for enhanced detection procedures.

This study aims to overcome the misrepresentation of information in financial reports in Saudi Arabia and improve financial reporting quality by proposing a framework for the Creative Accounting Detection Model (CADM). The model suggests the employment of a Hybrid Deep Learning (HDL) that implements Artificial Neural Network (ANN), Recurrent Neural Network (RNN) and Long Short-term Memory (LSTM). It uses FIN and N-FIN data related to selected Saudi-listed companies in different sectors. CADM introduces a new approach to evaluate published financial information more accurately and limit CA. It will also create new insights into the quality of financial statements and indicate the extent to which these practices are incorporated.

II. Research Background

A. Overview of CA

CA is a term to describe the accounting procedures used to present an enhanced image of an enterprise that misleads users [16]. The word '*creative*' means using new expertly invented ways of preparing accounts [6] to make the company more appealing to stakeholders without committing fraud. The practice is considered legal within IFRS but deviates from its goal and spirit as it operates in the grey area between legitimacy (in the context of IFRS) and fraud. As in *Fig 1.*, CA can exceed the regulations and become fraudulent, yet in this case easier to detect.

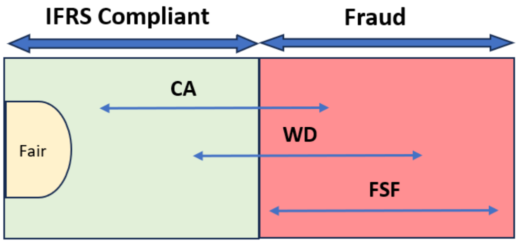

Fig 1. Financial Accounting and Its Relationship with IFRS

The quality of financial reporting (measured by different methods such as discretionary accruals, accounting conservatism, and asymmetry of information [17]) is significantly affected by CA practices [18]. On the international scale, more financial problems have been discussed in the literature [19], such as low liquidity, tightening credit conditions, and price volatility. However, the literature has no particular definition for the practice [20]. Yet the most recent definition by [6] described these practices as follows:" *They are the methods which deviate from the rules and regulations, it is an excessive complication and use of innovative ways to visualise income, assets, and liabilities, it is an innovative and aggressive way of reporting financial statements, it is a systematic misrepresentation of the true and fair financial statements*." It can be concluded that any accounting procedure meant to present non-realistic financial information is a form of CA.

B. CA Incentives

Incentives differ according to the business type and size. The reason for a manager in a private company to engage in this practice is different from the reason for a manager in a public company since the practice has different impacts on various parties, and sometimes more than one party in the same incident. Regardless of all the different impacts, incentives have been initiated from the Agency Problem (AP). Accordingly, we classify the incentives based on three main areas of primary impacts: internal affairs, stock market, and third-party's decisions., as shown in Table I. Whether these incentives existed from personal, organisational, or political backgrounds, they ultimately motivated report preparers individually or in groups to engage in the CA practice.

Table I.
Classification of Creative Accounting Incentives

Incentive impact	Examples	Studies
Internal affairs	Share options, personal satisfaction, job security	[1]
	Remuneration and management compensation (bonuses)	[56], [57], [58],
	Political costs (tax and zakat), lawsuits	[59], [56]
Stock market	Stock prices, Information asymmetries conflict	[60], [61], [62]
	Debt covenants	[58], [63]
Third party's decision	Financial forecasts	[64], [61], [65]
	Political costs (tax and zakat), lawsuits	[59], [56]

C. CA Techniques

The financial report preparation involves many techniques that can be innovatively different from one firm to another. There are rules and policies for these techniques, yet managers apply the approach that fulfils their personal or institutional interests. However, CA techniques can be categorised regarding the report type being prepared [21], the accounting area operating in [12][22], the accounting items being used [23], and the type of creativity being applied [24]. This study categorises CA techniques using two layers: the relative accounting area, as in [12], and the accounting items, as in [23]. Table II shows accounting techniques categorised by both approaches and highlights the techniques applied in this study.

D. CA Detection

The recognition of CA practices as a crime is quite an argument [19] [2] [6] [21]. Therefore, big data analytics studies were limited to FSF detection [25][26] and FSF prediction models [27]. Earlier FSF detection models, like the M-score model [28], were mainly quantitative depending on numerical FIN data. In contrast, recent models are qualitative intelligent models (i.e., ML models) that have proved to outperform the

TABLE II.
CA TECHNIQUES

Area	Accounting items	Technique
Classification	Extraordinary items	Including ordinary items
	Contingent liabilities	Misclassifying contingent liabilities
	Cost	Capitalization of costs
Disclosure	Financing	Off-balance-sheet financing
		Pre-acquisition write-down
	Cashflow	Reporting for cashflow
	Special Purpose Entities	Deferred considerations
	Accounting choice	Failure to justify accounting choice
	Pension fund	Failure to disclose
Timing	Revenue	Revenue recognition
	Accruals	Overvaluing/ undervaluing
Estimation	Intangible assets	Overestimating intangible assets
	Currency	Currency mismatching
	Assets and liabilities	Misreported assets and liabilities

earlier models [29][30][31] [32]. As revealed by [33], fraud detection has the highest percentage (39.4%) of published studies in the Journal of Emerging Technologies in Accounting *JETA*.

Since the speed of uncovering FSF can limit its consequences [8], the need to find faster and more accurate models is becoming essential. Unfortunately, the literature has no research on detecting CA as an IFSR practice using big data analytics as far as this study. Due to the ambiguous nature of the practice and the sophisticated historical actions involved, no specific financial ratios or traditional mathematical model can accurately detect it. However, FSF prediction scenarios can be considered in our proposal for many reasons. First, FSF prediction models use historical FSs (i.e., time-series dataset) labelled as fraudulent to learn from and reflect which variables can be used to classify the case. This can help predict future fraud or financial distress. Presuming that CA practices eventually lead to FSF (e.g., Enron started using SPEs legally, then it became 'increasingly doubtful' over time [1]), CA detection has similar domain characteristics of predicting FSF. It can be adapted to detect further activities that don't exceed IFRS limits. Another reason is that both procedures aim to prevent future fraud and provide alerting flags that don't normally appear to stakeholders in their usual financial information reviews.

E. The case of Saudi Arabia

According to the ACEF occupational fraud report in 2022, Saudi Arabia was the second-highest number of occupational fraud cases in the middle east [34]. Many studies investigated the problem in Saudi-listed companies. Most of these studies were quantitative, as opinions from accounting academics and professionals were gathered and analysed for a better understanding of the incentives and techniques [35][36][4][37][13]. Still, some studies were empirical papers focused on one business type [11][35] or one business size [36][13], applying a detection model with successful results. However, the application of big data and ML in the Saudi business research domain was focused on marketing[38] and finance[39] but never on accounting. On the other hand, accounting professionals have been using ML models, especially in some audit procedures has been employed in accounting firms. Apart from The Big Four[1], although these platforms guarantee efficiency for both the client and the auditing firm itself, they are not used due to cost and technical training limitations.

Recently, Saudi Arabia has been through several economic transformation steps that influenced the governing materials of accounting. An instance of these steps is joining the World Trade Organization (WTO) and adopting the International Financial Reporting Standards (IFRS) [40]. In addition, during the last 20 years, the Kingdom has established new institutions to regulate businesses and control the Saudi stock market. Some of these institutions were specifically designed to fulfil an essential Saudi vision for the future: *Vision 2030*[2] [41]. An instance of these institutions is the Saudi Data and Artificial Intelligence Authority (SADAIA), which has provided many valuable services and facilities for market and academic research. It is a helpful attempt to support the effort to improve financial reporting and leverage the Saudi business environment with innovative technologies through adequate investment in the country's prospects.

III. BIG DATA IN ACCOUNTING AND AUDITING

The accounting literature is rich with innovative analytical models that have the potential to enrich the accounting environment, develop accounting regulations and reduce the profession's defects [42]. The JETA has 51.5% of its publications between 2005-2015 on data analytics [33]. Moreover, 13% of published research on emerging technologies in the accounting domain was about big data analytics [43]. Although studies address the limitation in the literature regarding the use of big data in accounting [44][45], there exists a consensus that

[1] A term used to refer to the 4 big accounting firms: PwC, KPMG, EY, and Deloitte.

[2] https://www.vision2030.gov.sa/

ML algorithms in big data used in accounting research are growing remarkably [46], providing new services to the business environment that are never possible before. Further, standardising accounting data through new unified formats like XBRL and secure data structures like Blockchain added promising opportunities for efficient research and improved accounting outcomes.

By professional means, accounting and auditing embrace big data analytics in different procedures. The Big 4 are investing heavily in data analytics and artificial intelligence [47] and promoting embracing big data technologies. For instance, the recent adaptation of the *Halo* online platform by *PwC* implemented the inclusion of whole population analysis, which outperforms the sampling techniques that are usually used in auditing procedures along with many recalculations and risk assessment tools (e.g., journal entry testing and general ledger analysis) that become possible by its enhanced connectivity and high server-based processing capabilities. Moreover, regulatory agencies' results have been enhanced by incorporating non-financial data as a supplement to the traditional financial data in their systems (e.g., the UK government's tax authority uses different sources of data from the internet, social media, land registry records, international tax authorities, and banks [48]).

The research on the application of big data in accounting (summarised in TABLE III) is more focused on auditing. The analytical nature of auditing procedures made it more likely to benefit from these applications. Many ML frameworks were used in the research giving insightful results. Each framework used different models, datasets, and features for multiple objectives. However, recent studies in this domain used a subfield of ML, namely DL. It is recently trending in every field, particularly in accounting research, because of its potential to learn from massive amounts of data. ML and DL models can be used parallelly to build a model with improved capabilities, as in Hybrid Learning (HL). They can also be combined, and the output of one model is the input for the second, and that is called Ensembled Learning (EL) as in [49][29]. Accordingly, the training process of CADM uses an HL approach for enhanced performance. Training is performed in two stages: the feature extraction stage and the CA detection stage. Therefore, the CADM framework is designed to apply an HL approach for its suitability to our proposal. The following section will briefly describe the CADM framework and models used.

TABLE III.
BIG DATA IN FSF RESEARCH

Method	Model	Dataset/ sources	Objective	Study	Year
Data Mining	LR NN (BP) DT	Data related to fraud factors based on the fraud triangle (incentive, opportunity, attitude)	Detecting FSF	[51]	2015
	DT, SVM, K-NN, RS	FSs	Predict audit opinion	[66]	2021

IV. CADM Proposed Framework

This study considers previous FSF detection and prediction research in designing the CADM framework. The peculiarity of our detecting model is found in the DL models' hybrid nature and the datasets originality. Another critical point of distinction is our innovative learning process design. FSF prediction models are built using real publicly available FRs that regulators have recognised as fraudulent, whereas no labelled CA incidents are open to learning from. Consequently, this study intends to simulate manipulated accounting datasets to learn from and then test the model on real-time Saudi FSs that are publicly available.

A. *Datasets and Data Sources*

Datasets are divided into two groups: training data and test data. Training data is a simulated dataset of FSs prepared (i.e., deliberately manipulated) based on pre-FSF statements available in the literature for supervised learning. The second data set is a real-world FRs chosen from the Saudi Open Data Portal and Saudi Statistics Authority (for price history and market information), companies' websites (for reports on corporate governance information, marketing information, discretionary disclosures, and investments), corporation social media accounts, Saudi Press Agency, Zakat, Tax and Customs Authority (ZATCA) (for historical levels of compliance), and Capital Market Authority (CMA) (for observations and statistics about the company). Both training and testing datasets consist of two types of data: FIN and N-FIN, from relevant sources, as shown in Table IV. As CA evolves, the datasets will be time-series datasets of Saudi-listed companies for 2012-2022. Finally, we know the usefulness of including audio and video data types like GPS and CCTV recordings, yet we postpone their inclusion for future work.

Table IV.
Data Types and Sources

Source	Data (examples)	
	FIN	**N-FIN**
Annual Report	Financial statements, Enumerations.	Changes in Corporate Structure, Enumerations, Board Meetings, Auditor reports.
CMA	Market Values, Performance, Asset Quality Index.	Insider dealing reports, Actual Assurance.
ZATCA	Tax Compliance, Zakat Compliance.	Regulations Changes, Tax Compliance, Zakat Compliance.
Media	Business Analytics.	Lawsuits, Mergers and Acquisitions.

B. *Variables*

The data types and sources described above mean that features will be scattered between multiple types of datasets. We will select variables from prior FSF studies and test them to validate their inclusion. Researchers have tested many FIN features, such as indices and financial ratios, and N-FIN features, such as changes in the board, market-adjusted stock returns, governance measures, economic changes, and changes in regulations. Other N-FIN features can be included according to their availability in Saudi sources, such as board meetings, meeting minutes, and meeting content, as tested in [26]. As shown in Table IV., FIN and N-FIN features selection will follow the criteria in [50], [49], and [51] accordingly. For any AI model to be accurate, variables should be limited[52], though this study proposes to test extended obtainable variables and exclude some in the exploration process if needed.

C. *Modeling and Testing Methodology*

As shown in *Fig 2*, our proposed framework consists of multiple steps. First, data collection starts by accessing open Saudi databases to gather information about listed companies and then gathering FRs from available sources. Second, in the data pre-processing stage, we set up a wide selection of variables to be included (based on available datasets), and then they will be limited while training. Third, feature extraction will be performed using ML models. Then, the feature selection process that gives the best results will be chosen. Finally, we will use some DL models, such as RNN and LSTM, for training. Finally, we test the model on a real-time group dataset described in the following section.

D. *Deep Learning DL*

DL is a subfield of ML that can learn patterns and structures that reside in data and find relations in data. Many models are used in DL, but the most used models are deep belief networks DBN and convolutional neural network CNN [53], but they perform successfully for image recognition problems. Since our dataset design needs a model that can handle sequential interconnected data, we propose using ANN that can take such features as the LSTM can. In the CADM framework, we suggest using ANN and RNN to train our model using the simulated dataset. We will also recommend using LSTM for the improved performance of CADM.

E. *Long short-Term Memory LSTM*

LSTM is a type of RNN that can handle time-series datasets and include previous states in the calculation. It is commonly used in DL application research in finance, like stock price predictions and portfolio management [54]. It can remember short-term and long-term values, which makes it useful in sequential data [55]. *Fig 3* shows LSTM unit has three types of gates that regulate input. The unit receives an input and a previous state, then calculates the output and updates the memory state. This type of network is needed to train the model due to the nature of the time-series datasets we use. We argue that

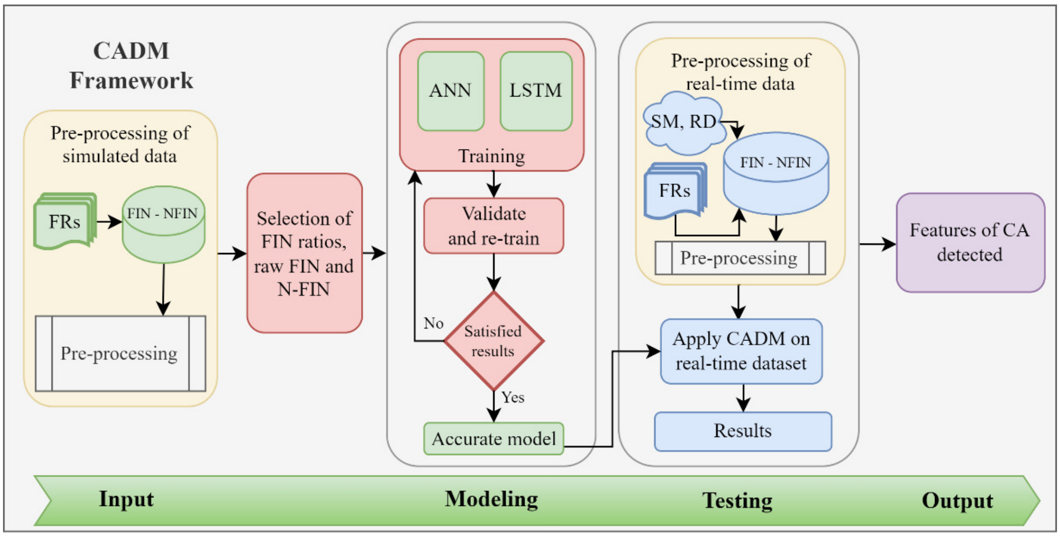

Fig 2. CADM Proposed Framework

CA techniques evolve, and the probability of detecting them increases significantly when considering changes over time.

Fig 3. LSTM Structure

F. *Python and Hadoop*

Python has many efficient packages to use when dealing with big data. Our framework suggests the use of *Python* on the *Hadoop* platform. *Hadoop* is a distributed file system that scales up thousands of computers to store, process, and control big data operations. Since we plan to train a rather complex model, *Hadoop* with *Apache Spark* integration will be used as it can run distributed programs (e.g., using the *MapReduce* method) in the most reliable, error-tolerable, scalable, and portable way.

V. Conclusion

CA is proven to be harmful, and the consequences exceed the long-lasting financial and reputational damage for corporations and their CEOs, to national-level consequences like a country-wide lower level of financial market participation [8]. This paper aims to protect the Saudi financial market from the negative impacts of CA and offer stakeholders an opportunity to depend on enhanced sources of financial information for better decision-making. We introduced the framework of a new analytical model CADM that inspects the features available to detect CA used in preparing FRs. We suggested the inclusion of FIN data and N-FIN in the learning and testing stages through two DL models: ANN and LSTM. We also suggested two sources of the dataset that represent a sample of Saudi-listed companies from different sectors for a period of 10 years.

VI. Limitations and Future Work

This research is part of ongoing research on big data applications in CA. Accessibility and availability of applicable datasets remain a challenge. However, open-source Saudi platforms like SDAIA, CMA Open Data, and ZATCA Open Data are expected to provide the required dataset size to train and test our model. Additionally, the implementation and testing stages of the CADM framework may encounter some pre-processing restrictions in the translation and standardisation stages. Yet, there is a reasonable chance that most FIN data are already standardised, given that Saudi companies are obligated to publish their FSs in XBRL format. Moreover, we are preparing a short survey designed for independent auditors in Saudi Arabia to validate the suitability and accessibility of our selected variables before starting the data collection process. The next stage's outcomes are expected to unveil new insights and contribute to the existing accounting and big data literature.

***Abstract*—This paper delves into the realm of community detection in network science and graph theory with the overarching objective of unraveling the underlying structures between nodes within a network. In this pursuit, we put forth a novel and comprehensive approach to ascertain the optimal solution to maximizing the renowned community quality metric known as Max-Min Modularity. Through a series of experiments encompassing diverse case studies, we substantiate the efficacy and validity of our proposed approach, further bolstering its credibility.**

***Index Terms*—Graph partitioning, community detection, mathematical programming, exact method**

I. Introduction and Related Work

In COMPLEX networks, nodes usually divide into several subsets sharing common characteristics and relationships, forming *communities*. The discovery and analysis of these structures hold paramount importance in computer science, particularly within the network domain and graph theory. Identifying cohesive and interconnected groups of nodes enables a deeper understanding of complex systems, facilitating insights into structural patterns, functional modules, and underlying relationships. The ability to detect network communities owes immense value and applications in networked systems, such as Social Network Analysis [1], [2], Biological Networks [3], Cosmological Networks [4], WEB analysis [5], Distributed Computing [6], Signal Processing [7], and Data Clustering [8]. It enables us to uncover hierarchical structures, predict missing links, and enhance network resilience.

More concretely, a network can be represented as a graph $G = (V, E)$, where V is the set of vertices and E is the set of edges. A community within the network can be seen as a subset of vertices $C \subseteq V$, characterized by a dense connection of edges among the nodes within the subset and a sparse connection of edges with other subsets; see Fig. 1. In this regard, the community detection problem can be defined as partitioning V into a set of communities $\mathbf{C} = \{C_1, C_2, \ldots, C_k\}$ that often entails optimizing a specific *quality measure* that quantifies the excellence of a community. A wide array of quality measures has been proposed in the literature, encompassing both *connectivity-based* and *topology-based* metrics [9].

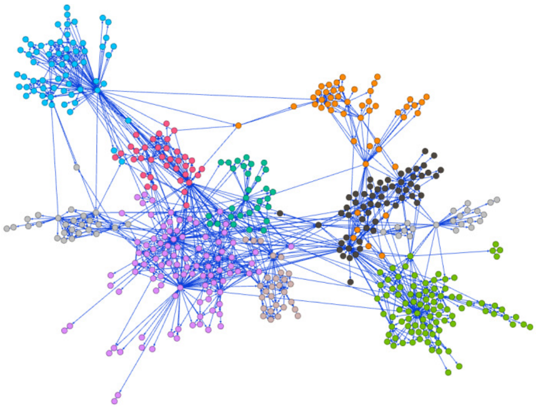

Fig. 1: Illustration of a network and its communities as subsets of vertices with densely connected nodes within each subset and sparser connections to nodes outside the batch.

For example, in [10], a dynamic connectivity-based metric is introduced to assess the quality of a community C by computing the ratio between the sum of the radius of C and the number of edges exiting C, divided by the number of edges with both endpoints belonging to C. The radius, a measure showcasing the size and compactness of the function, plays a crucial role in this evaluation. The authors of [10] also devised a two-stage heuristic algorithm to identify high-quality communities by minimizing the proposed metric. The initial stage of the algorithm, which is particularly crucial for our research, intelligently identifies an initial set of remarkably high-quality communities. This will be followed by a revising phase aimed at refining and enhancing the quality of the communities. The contributions in [10] properly highlight the significance of connectivity-based metrics in assessing community quality.

On the other hand, topological metrics have also gained considerable attention in the field of community detection. Notably, *Modularity*, introduced by Newman [11], stands out as one of the most widely recognized and extensively utilized measures in this regard. For a network G containing n vertices and m edges, the Modularity (Q) of a given partitioning $\mathbf{C}$ is mathematically defined as follows:

This research was supported by the Austrian Science Fund (FWF) project DMAC (grant no. P32431).

* Also affiliated with TU Wien, Embedded Computing Systems Group. *Email: aferdowsi@ecs.tuwien.ac.at.*

$$Q(\mathbf{C}) = \frac{1}{2m} \sum_{i,j \in V} [a_{ij} - \frac{d_i d_j}{2m}] \sigma(i,j) \tag{1}$$

where $A = (a_{ij})$ is the adjacency matrix of G with a_{ij} sets to one if an edge exists between node i and node j, and zero otherwise. d_i represents the degree of node i and is defined as the sum of all entries in the i-th row of the adjacency matrix. Moreover, $\sigma(i,j)$ is one if i and j are in the same community and zero otherwise.

Simply put, Modularity quantifies the number of edges within a community minus the expected number of such edges leading to the fact that communities with higher Modularity values have better quality. Therefore, maximizing Modularity results in identifying high-quality communities within a network.

Nevertheless, despite the widespread use of Modularity, it has been known to have certain limitations (see [12], [9] for more details). Notably, Modularity only takes into account the existing edges of the network, meaning it solely evaluates the goodness of a community based on its fit with the observed edges, while it fails to consider disconnected nodes (absent edges) within the same community. This is indeed a drawback since the disconnection of nodes does not inherently imply an absence of underlying relations between them. To overcome this limitation, an extension of Modularity called *Max-Min Modularity* [13] has been developed, which improves the accuracy of the measure by penalizing Modularity when disconnected nodes are present in the same community. In Max-Min Modularity, an additional zero-one relation matrix $U = (u_{ij})$ is introduced, which defines the relationship between pairs of disconnected nodes in the network. The value of u_{ij} is one if disconnected nodes i and j are *related* and zero otherwise. This extension acknowledges the significance of indirect connections between disconnected nodes by penalizing the Modularity measure only when unrelated nodes coexist within a community. In a more abstract sense, consider a complemented graph $G' = (V, E')$, where E' contains an edge between every pair of disconnected nodes in G that are unrelated. In other words, an edge exists between nodes i and j in G' if there is no such edge in G, and u_{ij} is zero. Let $A' = (a'_{ij})$ be the adjacency matrix of G', and d'_i be the degree of node i in G'. Additionally, let m' be the number of edges in G'. The Max-Min Modularity (Q_{MM}) of a given partition $\mathbf{C}$ of V is defined as follows:

$$Q_{MM}(\mathbf{C}) = \sum_{i,j \in V} [\frac{1}{2m}(a_{ij} - \frac{d_i d_j}{2m}) - \frac{1}{2m'}(a'_{ij} - \frac{d'_i d'_j}{2m'})] \sigma(i,j) \tag{2}$$

We refer to the problem of partitioning a network with respect to maximizing the Max-Min Modularity as the *Max-Min Modularity Maximization* problem.

Chen et al. [13] proposed a hierarchical clustering algorithm, similar to what Newman [11] had offered for the classical Modularity Maximization Problem, that approximately greedily optimizes Max-Min Modularity. In addition to the suboptimal precision of the final community detection results obtained through the heuristic approach, the primary drawback of their method lies in its reliance on a user-defined relation matrix rather than a systematic approach. This dependency on subjective input introduces the potential for misinterpretations, biases, and erroneous human decisions, which can lead to significant issues. Relying on a user-defined matrix not only increases the likelihood of errors but also lacks the robustness and objectivity provided by a systematic and automated procedure.

Furthermore, since it is known that solving the Max-Min Modularity Maximization problem is computationally challenging, as it is proven to be NP-hard, most of the approaches for solving it rely on heuristic methods. [13]. There exist, of course, methods focusing more on exact techniques, such as the approach presented in [14], in which the authors successfully formulated the Max-Min Modularity Maximization problem as an *integer programming* model and proposed an equivalent sub-problem that simplified the overall formulation. This streamlined approach facilitated the efficient solving of the model's linear relaxation and provided a systematic means of defining the relation matrix. They further employed a local search strategy to convert the fractional solutions to integer ones that led to obtaining a set of communities. Nevertheless, despite their outstanding breakthrough in the modeling and the solution approach, the error caused by the rounding approach prevents us from obtaining an optimal solution, which is indeed crucial in scenarios where precise analysis is required. This underscores the need for alternative methods that can provide more accurate results.

Main contribution:

(1) Building upon the integer programming modeling discussed in [14], we present an alternative integer model for the Max-Min Modularity Maximization problem that offers a significant reduction in the number of variables and constraints. This streamlined model enhances computational efficiency while maintaining the same optimization capabilities. The equivalence of the proposed model and the original formulation proved in Theorem 1, affirms that both models yield the same set of optimal solutions.

(2) Inspired by the prominent algorithm proposed in [10], we devise a methodology to generate an initial feasible solution for the formulated model. By employing a row generation technique in combination with the branch and bound method and leveraging the powerful CPLEX[1] solver, we efficiently and optimally solve the model. This comprehensive approach enables the detection of a set of (near) optimal communities whose efficacy and effectiveness become apparent in the experiments done.

The structure of this paper unfolds as follows: In Section II, we delve into modeling an effective integer programming formulation for the Max-Min Modularity Maximization problem, followed by an insightful theoretical exploration of how

[1] CPLEX is a powerful optimization software package developed by IBM that employs advanced algorithms to solve linear programming, mixed-integer programming, and quadratic programming problems efficiently.

to simplify the model. Subsequently, Section III outlines our devised approach for acquiring an intelligent initial feasible solution and employing a row/column generation technique to solve the model optimally. Finally, Section IV is dedicated to showcasing the experimental results, providing a comprehensive analysis of the outcomes.

II. Mathematical modeling

Let the binary variable x_{ij} indicate if nodes i and j belong to the same community or not; the value of x_{ij} is zero if nodes i and j belong to the same community, and one otherwise. Let $I_{all} = \{(i,j) \in V^2 \mid i < j\}$; and $q_{ij} = a_{ij} - \frac{d_i d_j}{2m}$, for each $(i,j) \in I_{all}$. As described in [15], the Modularity Maximization problem can be formulated in terms of the following integer linear program.

$$\max \quad \frac{1}{m} \sum_{(i,j)\in I_{all}} q_{ij}(1-x_{ij}) \qquad \text{(IP-M)}$$

$$x_{ij} + x_{jk} - x_{ik} \geq 0 \qquad \forall i<j<k \qquad (3)$$

$$x_{ij} - x_{jk} + x_{ik} \geq 0 \qquad \forall i<j<k \qquad (4)$$

$$-x_{ij} + x_{jk} + x_{ik} \geq 0 \qquad \forall i<j<k \qquad (5)$$

$$x_{ij} \in \{0,1\} \qquad \forall (i,j) \in I_{all} \qquad (6)$$

Constraints (3)-(5) guarantee that if i and j are in the same community and j and k are in the same community, then so are i and k. We refer to the relaxation of (IP-M), obtained by replacing the constraints $x_{ij} \in \{0,1\}$ by $x_{ij} \in [0,1]$, as (LP-M).

Now to turn our attention to the Max-Min Modularity Maximization problem, we first recap the systematic and precise approach provided in [14] for defining the relation matrix governed by an optimal fractional solution x^* to the linear programming problem (LP-M). Considerably crucial is that x^* can be efficiently obtained in polynomial time using various algorithms such as the row and column generation algorithm introduced by [16]. It is also important to note that x^* gives rise to a metric known as the LP distance on the graph G. In this context, x^*_{ij} can be interpreted as the "distance" between nodes i and j, and notably, the constraints (3)-(5) guarantee the fulfillment of the triangle inequality for any nodes $i,j,k \in V$ in the induced metric. Evidently, the larger the LP distance between two nodes, the less related those nodes are. This observation, along with the fact that the Modularity Maximization problem can be effectively formulated for weighted graphs as demonstrated by [17], serves as motivation to define the relation matrix and the corresponding complemented (weighted) graph G' utilizing the LP distance rather than using user knowledge.

In this framework, we define the relation matrix $A' = (a'_{ij})$ (and consequently G', with (a'_{ij}) representing the weight of the edge between nodes i and j in G'), as follows:

$$a'_{ij} = \begin{cases} x^*_{ij} & \text{if } a_{ij} = 0 \text{ and } j > i \\ x^*_{ji} & \text{if } a_{ij} = 0 \text{ and } i > j \\ 0 & \text{otherwise} \end{cases} \qquad (7)$$

Consequently, given a matrix $A' = (a'_{ij})$, the Max-Min Modularity Maximization problem can be formulated as the following integer programming problem. Let $c_{ij} = \frac{q_{ij}}{m} - \frac{q'_{ij}}{m'}$, where $q'_{ij} = a'_{ij} - \frac{d'_i d'_j}{2m'}$, $d'_i = \sum_{l=1}^{n} a'_{il}$, and $m' = \sum_{(i,j)\in I_{all}} a'_{ij}$ for each $(i,j) \in I_{all}$.

$$\max \quad \sum_{(i,j)\in I_{all}} c_{ij}(1-x_{ij}) \qquad \text{(IP-MM)}$$

$$x_{ij} + x_{jk} - x_{ik} \geq 0 \qquad \forall i<j<k \qquad (8)$$

$$x_{ij} - x_{jk} + x_{ik} \geq 0 \qquad \forall i<j<k \qquad (9)$$

$$-x_{ij} + x_{jk} + x_{ik} \geq 0 \qquad \forall i<j<k \qquad (10)$$

$$x_{ij} \in \{0,1\} \qquad \forall (i,j) \in I_{all} \qquad (11)$$

The very first thing to note, however, is that solving (IP-MM) falls in the class of NP-hard problems, making it challenging to be optimally solved. Consequently, we came to investigate whether it is possible to simplify (IP-MM) while maintaining the same set of optimal solutions. To achieve this objective, we have obtained the subsequent conceptual insights derived from the notion of row generation: The following lemma demonstrates that the optimal solution remains unaffected when only focusing on variables x_{ij} with $c_{ij} > 0$, and the subsequent theorem establishes that the optimal solution to (IPs-MM) without constraints involving x_{ij} where $c_{ij} \leq 0$ is equivalent to the optimal solution to (IP-MM).

Lemma 1: If a binary variable x_{ij} satisfies the constraints (8), (9), and (10), then it is sufficient to consider only the variables x_{ij} for which $c_{ij} > 0$ in the objective function (IP-MM).

Proof. Suppose we have a binary variable x_{ij} that satisfies the constraints (8), (9), and (10). We will show that if $c_{ij} \leq 0$, then x_{ij} will not affect the optimal solution of the objective function (IP-MM). Let us consider the term $c_{ij}(1-x_{ij})$ in the objective function (IP-MM). If $c_{ij} \leq 0$, then regardless of the value of x_{ij} (0 or 1), the term $c_{ij}(1-x_{ij})$ will be non-positive. Thus, including x_{ij} in the objective function with $c_{ij} \leq 0$ does not contribute to maximizing the objective. On the other hand, if $c_{ij} > 0$, including x_{ij} in the objective function can potentially increase the objective value by setting x_{ij} to 0 (i.e., nodes i and j belong to the same community) since $c_{ij}(1-0) = c_{ij}$. Therefore, it is sufficient to consider only the variables x_{ij} for which $c_{ij} > 0$ in the objective function (IP-MM). □

Theorem 1: For the given integer programming problem, if we exclude the constraints involving variables x_{ij} where $c_{ij} \leq 0$, the optimal solution of the modified problem remains the same as the original problem.

Proof. Let us assume that we have an optimal solution to the original (IP-MM) model, which satisfies all the constraints including those involving variables x_{ij} where $c_{ij} \leq 0$. We will show that by excluding these constraints, we can still obtain the same optimal solution. If x_{ij} satisfies the constraints (8), (9), and (10), its value will not change when we exclude the constraints involving $c_{ij} \leq 0$. The reason is that these constraints do not impose any restrictions on x_{ij}; they only provide additional information. Removing them does not alter the feasible region. Furthermore, since $c_{ij} \leq 0$, excluding these constraints means that the corresponding term $c_{ij}(1 - x_{ij})$ is non-positive and does not contribute to the objective function. Therefore, the objective value remains unchanged. Consequently, the optimal solution for the modified problem without constraints involving x_{ij} where $c_{ij} \leq 0$ is the same as the optimal solution for the original problem. This concludes the proof of the theorem. □

Having these considered, one can simplify (IP-MM) by considering only the variables x_{ij} where $c_{ij} > 0$ in the objective function. We can express this modified model as follows:

$$\max \sum_{(i,j)\in I_{pos}} c_{ij}(1 - x_{ij}), \tag{12}$$

where I_{pos} is the set of all pairs $(i, j) \in I_{all}$ for which $c_{ij} > 0$. We still need to ensure that the constraints (8), (9), and (10) hold for the selected variables. To achieve this, we introduce new binary variables y_{ijk} for all $i < j < k$ such that:

$$y_{ijk} = \begin{cases} 1 & \text{if } x_{ij} + x_{jk} - x_{ik} \geq 0 \\ 0 & \text{otherwise} \end{cases} \tag{13}$$

By introducing these variables, we can replace the constraints (8), (9), and (10) with the following constraint:

$$x_{ij} + x_{jk} - x_{ik} \geq 0 \quad \forall i < j < k \text{ s.t. } (i, j) \in I_{pos} \tag{14}$$

Finally, we include the binary variable definitions:

$$x_{ij} \in \{0, 1\} \qquad \forall (i, j) \in I_{pos} \tag{15}$$

$$y_{ijk} \in \{0, 1\} \qquad \forall i < j < k \text{ s.t. } (i, j) \in I_{pos} \tag{16}$$

Gathering all together, we get an equivalent sparse model for (IP-MM) as follows:

$$\max \sum_{(i,j)\in I_{pos}} c_{ij}(1 - x_{ij}) \tag{IPs-MM}$$

$$x_{ij} + x_{jk} - x_{ik} \geq 0 \qquad \forall i < j < k \text{ s.t. } (i, j) \in I_{pos} \tag{17}$$

$$x_{ij} \in \{0, 1\} \qquad (i, j) \in I_{pos} \tag{18}$$

$$y_{ijk} \in \{0, 1\} \qquad \forall i < j < k \text{ s.t. } (i, j) \in I_{pos} \tag{19}$$

Highly encouraging is that (IPs-MM) has considerably fewer constraints and variables compared to the original (IP-MM) model but preserves the same set of optimal solutions.

III. Solution Approach

Despite (IPs-MM) providing us with a considerably simpler integer modeling than (IP-MM), it could still remain unlikely to obtain the optimal solution, particularly when dealing with average to large-scale networks. Undoubtedly, one possible way to speed up the branch and bound technique using the CPLEX solver is to feed it with a reasonably good initial solution. Starting with a smart choice among the feasible solution space has turned out to improve performance immensely. In this vein, we came to take advantage of the heuristic two-stage community detection algorithm introduced in [10]. Considerably relevant to our research is the first stage of the algorithm's authority to swiftly find a collection of initial communities with excellent quality w.r.t. optimizing a connectivity-based criterion they established.

In this procedure, the degree of a node and its set of neighbors are defined naturally. Additionally, the inner and outer edges of a community C, denoted as E_C^{in} and E_C^{out}, respectively, represent the edges with both endpoints and one endpoint within C. Let $\alpha \in \{1, \ldots, diameter(G)\}$ be an integer and define $P_\alpha \subseteq V$ as a sequence of nodes arranged in descending order according to their degrees, provided they are all at least α steps away from each other. P_α is referred to as the *influential nodes* of G with respect to α. The distance between a vertex $j \notin C$ and the community C is then determined as the length of the shortest path from j to the influential node of C. The radius of a community C, denoted by $r(C)$, is the maximum distance from its influential node to other vertices within the community.

Subsequently, the authors of [10] proposed a measure to compute the quality of a community C:

$$q(C) = \frac{|E_C^{out}| + r(C)}{|E_C^{in}|}. \tag{20}$$

Furthermore, given a set of communities $\mathbb{C} = \{C_1, \ldots, C_k\}$, the quality of the partition $\mathbb{C}$ is defined as follow:

$$q_G^{\mathbb{C}} = \sum_{C\in\mathbb{C}} q(C). \tag{21}$$

Having everything considered, we can now summarize the procedure of determining an appropriate set of initial communities in the following manner:

- Repeat the procedure below for all α between 2 and $diameter(G)$ and pick $\mathbb{C}_\alpha$ with the minimum $q_G^{\mathbb{C}_\alpha}$ as the best initial set of communities.
  - Establish P_α as defined above.
  - Let each $p \in P_\alpha$ initially designate a sole community, leading to a set of $|P_\alpha|$ communities $\mathbb{C}_\alpha = \{C_1, \ldots, C_{|P_\alpha|}\}$.
  - Assign every $v \notin \mathbb{C}_\alpha$ to its closest community until all nodes belong to a community.

An essential insight of this approach revolves around the idea of ensuring a meaningful spatial distribution of the influential nodes of the network, striking a balance between proximity to facilitate cohesive communities and sufficient distance to avoid interference. To achieve this, the notion of $\alpha-$far nodes is introduced to serve as a criterion to evaluate the distance between potential influential vertices. By leveraging this parameter, one can successfully identify the best set of influential nodes capable of bunching and leading their surrounding vertices.

Now, by putting everything together, we devise the following tractable procedure for optimally solving (IPs-MM):

- Start with the initial communities obtained with the method explained above and employ the following row generation technique:

1) Consider (IPs-MM) without any constraints.
2) Use the CPLEX solver and apply the branch and bound technique to obtain an optimal solution x^* to (IPs-MM).
3) Verify whether all constraints of (IPs-MM) are satisfied by x^*. If not, add the violated ones to the model and go to (2).

IV. Computational results

Within this section, we conduct a comprehensive performance evaluation of our proposed methodology. To maintain fairness, we take into account exactly the set of 12 networks used in [14]. These networks, outlined in Table I, are among the recognized and commonly utilized real-world networks utilized in this context, and each of them possesses a corresponding ground truth, representing the optimal community structures. Hence, it becomes convenient to evaluate the effectiveness of a community detection algorithm by quantifying the similarities between the algorithmically derived communities and the ground truth. To facilitate this evaluation, we employ the widely acknowledged performance metric NMI (*Normalized Mutual Information*).

A. Normalized Mutual Information (NMI)

NMI, as described in [29], is a widely recognized and established metric for evaluating the similarity between clusters. However, it can effectively measure the agreement between the optimal communities and those discovered by an algorithm. Consider a network G with n nodes, where $\mathcal{C}(\mathcal{A}) = C_1, \dots, C_k$ represents the communities obtained by algorithm $\mathcal{A}$, and $\mathcal{C}' = C'_1, \dots, C'_{k'}$ denotes the ground truth communities. The NMI value corresponding to the algorithm $\mathcal{A}$ can be computed as follows

$$NMI(\mathcal{A}) = \frac{-2\sum_{x=1}^{|\mathcal{C}|}\sum_{y=1}^{|\mathcal{C}'|}\frac{|C_x \cap C'_y|}{n} log(\frac{n|C_x \cap C'_y|)}{|C_x||C'_y|})}{\sum_{x=1}^{|\mathcal{C}|}\frac{C_x}{n} log(\frac{C_x}{n}) + \sum_{y=1}^{|\mathcal{C}'|}\frac{C'_y}{n} log(\frac{C'_y}{n})} \quad (22)$$

When the detected communities perfectly align with the ground truth, NMI attains its maximum value of one. Conversely, if the two sets exhibit no similarity, the NMI score is zero. In general, a higher NMI value indicates a more accurate and effective discovery of community structures.

B. Experiments

In what follows, we present a thorough evaluation demonstrating our proposed method's superiority in achieving high-quality communities over several competing algorithms. All the experiments are conducted on a computer system with a processor *Intel(R) Core i9-12900KF @ 3.2GHz, 16.6 Core(s)* and *128 GB* of *RAM*. Algorithms are implemented with C++, and CPLEX optimizer 12.9 is used for solving linear programming.

Fig. 2 delivers the comparisons by evaluating communities that are discovered based on the following cases:

- Our method (the blue curve): Obtaining the communities by optimally solving (IPs-MM) with the proposed method consisting of a row and column generation procedure.
- Method proposed in [14] (the red diagram): Solving the linear relaxation model of (IP-MM) via a row and column generation technique and applying a local search manner rounding procedure for obtaining the communities.
- Max-Min Modularity, proposed in [13] (green diagram): Using a user-defined relation matrix and applying a hierarchical heuristic algorithm for maximizing the Max-Min Modularity.

It is evident to conclude the promising outperformance of our proposed community detection method. In particular, the considerable gap between the blue and red curves clearly shows the advancement of using an exact method rather than relying on just heuristic approaches. While the technique in [14] took into account optimally solving the liner relaxation version of the (IP-MM), their proposed local search-based rounding procedure for obtaining the solution to (IP-MM) causes a significant error. The lever provided by the simpler model (IPs-MM), which was proven to be equivalent to (IP-MM), enabled us to seek an optimal solution to the model and, therefore, discover high-quality communities considerably better than those in [14]. This dominance could be more pronounced when noticing that the communities obtained in [14] were superior to a wide range of other algorithms.

Herein, for the sake of more visualization, Fig. 3 displays the schematic representations of the *Erdos collaboration* and *C. elegans* networks, along with the communities identified by the proposed algorithm.

Furthermore, to strengthen the assessment of our algorithm, we also decided to examine its execution time, for which we came to follow twofold perspectives: first, to determine how solving (IPs-MM) instead of (IP-MM) could enhance time complexity, and second, to compare the execution time of our model with that of the integer programming model proposed in [14] for the Max-Min Modularity Maximization problem. Fig. 4 illustrates the results of these comparisons.

Our proposed row and column generation technique, coupled with the intelligently determined initial solution, resulted in a significant speed improvement when optimally solving (IPs-MM), surpassing the performance of solving (IP-MM).

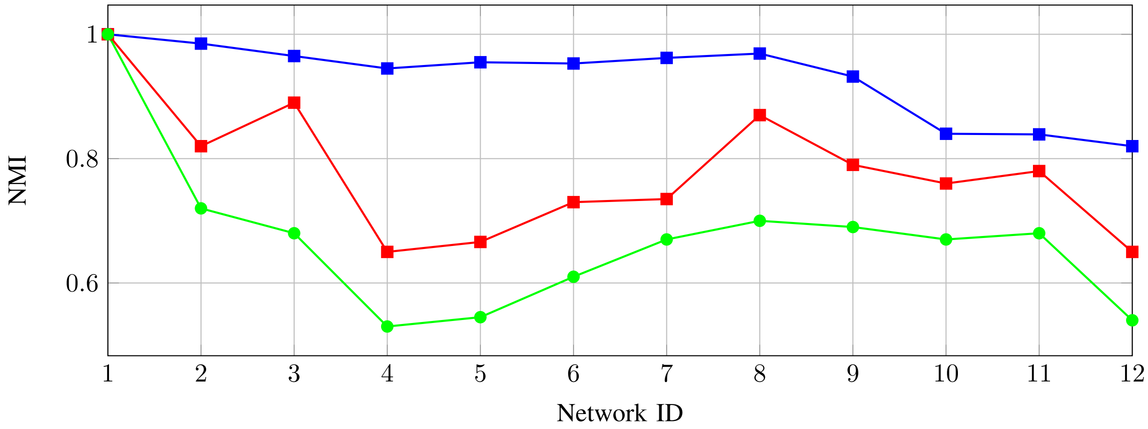

Fig. 2: Comparison between NMI values achieved by (i) blue curve: our method, (ii) red curve: method in [14], and (iii) green curve: the conventional Max-Min modularity.

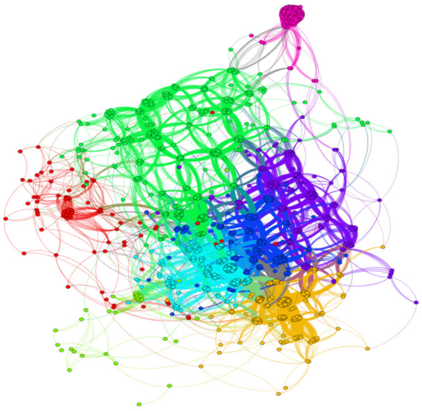
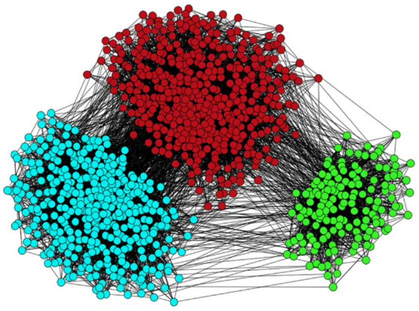


(a) Erdos collaboration network



(b) C. Elegans network

Fig. 3: Two networks from Table I and their detected communities using the proposed algorithm.

This highlights the substantial impact of our simplified model and solution approach. Furthermore, our method demonstrated faster execution compared to solving the equivalent integer formulation of the sub-problem for the Max-Min Modularity Maximization problem proposed in [14], which further validates the efficiency of our simplification. As could be naturally expected due to the NP-hardness nature of the problem, our model performs slower than when solving the LP relaxation version of the model in [14] plus using the rounding algorithm. Nevertheless, the inaccurate results obtained in [14] reveal its untrustworthy against this work's proposed model.

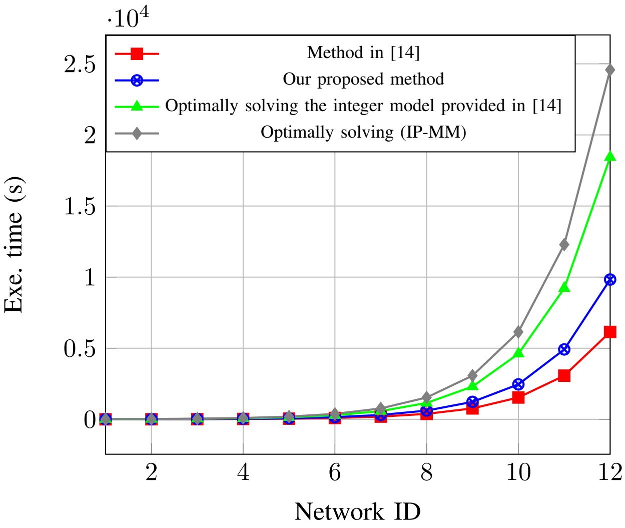


Fig. 4: The time elapsed (in terms of seconds) for solving different methods.

We complete this section by highlighting that even though the method presented in [14] can yield promising community structures in large-scale networks, for situations where accuracy is paramount, exact methods become significantly crucial. In such cases, the proposed method in this work can provide substantial assistance.

V. Conclusion

In this study, we addressed the Max-Min Modularity Maximization problem, a widely recognized metric for community evaluation. To enhance the problem's solution efficiency, we proposed an integer programming model that exhibits a reduced number of variables and constraints while preserving the same set of optimal solutions as the original model. By incorporating a row and column generation technique guided by an intelligently determined initial feasible solution, we were able to achieve optimal solutions in a remarkably efficient manner. The resulting solution provided us with a set of communities that exhibit notable similarities with the optimal community structures, indicating the effectiveness of our approach. This not only improved the overall quality of the obtained communities but also demonstrated the advantages of our model in terms of computational time.

***Abstract*—We consider a single-server queueing system with multiple customer types having bounded processing times in which users are scheduled according to the Shortest Remaining Processing Time (SRPT) discipline, with First In First Out (FIFO) as the tie-breaker. We assume that the processing times of jobs arriving in the system are bounded. We use probabilistic methods to find, under typical heavy traffic assumptions, a suitable approximation of the workload and queue length processes after a long time has passed and show that these processes are divided among the customer classes according to specific proportions, depending on their arrival rates and distributions of initial service times. Our results are confirmed by simulations.**

***Index terms*—Queueing systems, shortest remaining processing time, heavy traffic, diffusion approximations, multiple customer classes.**

I. Introduction

THE SHORTEST Remaining Processing Time (SRPT) service protocol assigns preemptive priority to the task with the smallest residual service time. It started gaining interest after Schrage had proved in [24] that it minimized the number of jobs in a single-server system. SRPT is also well known in queueing theory for minimizing the mean response time (Schrage and Miller [18]). Since then, its properties have been widely studied. Schreiber provides a summary of early work on SRPT in [25]. More recent research of this protocol includes investigating fairness (e.g., Wierman and Harchol-Balter [27]) or tail behavior (Núñez-Queija [19], Nuyens and Zwart [20]). In [12], Gromoll, Kruk and Puha prove, under typical heavy traffic assumptions, a diffusion limit theorem for a measure-valued state descriptor. Another approach, approximating SRPT by the Earliest Deadline First (EDF), leads to the same result (with a slight loss of generality) in [16]. The follow-up research on this topic includes obtaining diffusion limits under nonstandard spatial scaling by Puha [23] and limits for queues with heavy tailed service time distributions by Banerjee, Budhiraja and Puha in [4]. Moreover, Atar, Biswas, Kaspi and Ramanan presented in [3] a unified framework for analyzing single server queueing systems under various service protocols, including SRPT.

Some authors discussed the possibility of implementing the SRPT policy in practice. The main factor impeding it is its unfairness, which could potentially lead to a few tasks having much greater response times (so-called "starving"). However, it has been noted in many works that large jobs are only negligibly penalized at most. For example, Agrawal, Bansal, Harchol-Balter and Schroeder in [1] and [2] propose a method of improving the performance of Web servers by implementing SRPT-based scheduling. Another study by Harchol-Balter and Schroeder ([14]) presents the possibility of a great improvement of the performance of a Web server by changing the traditional fair scheduling policy to SRPT. There are also more recent papers concerning this topic. For example, [6] describes a way of improving the default Linux scheduler by using the existing CFS (Completely Fair Scheduler) and FIFO schedulers to approximate SRPT.

Recent studies suggest that the SRPT protocol performs well in the case of multiserver systems with a single queue. Grosof, Scully and Harchol-Balter proved in [13] that the mean response in the M/G/k queue under the SRPT discipline is asymptotically optimal in the heavy-traffic limit. Dong and Ibrahim ([8]) considered the multiserver M/G/k+G queue with impatient customers with the SRPT protocol and showed that in this setting, SRPT asymptotically maximizes the system throughput among all scheduling disciplines. However, it was also shown that the SRPT protocol can behave suboptimally in multiclass queueing networks to the extent of rendering the queueing system unstable ([7]).

Another related field of research involves studying resource sharing networks under the SRPT service discipline. In [10], [11], a notion of minimality, related to maximizing the corresponding cumulative transmission time with respect to jobs with residual service time not greater than a given threshold, was introduced and it was shown that SRPT is minimal in this sense. Moreover, in [11], another optimality criterion, local edge minimality, was proposed and it was proved that it characterizes a certain subclass of SRPT disciplines, named strong SRPT protocols.

This paper focuses on a single-server queueing system with multiple customer classes. Previous research on this topic includes the work of Peterson ([21]) concerning heavy-traffic limit theorems for queueing networks with multiple customers classes divided into two types: high-priority ones having a preemptive priority over low-priority ones, with customers within each of these types served according to the FIFO policy. In [17], Kruk and Sokołowska establish a fluid limit theorem for a single-server queueing model with K classes of customers, served according to the SRPT protocol, with FIFO used as the tie-breaker.

In this paper, we extend the analysis of [12] and prove a diffusion limit theorem for a multidimensional measure-valued state descriptor $\mathcal{Z}(t)$ defined in Section II, under usual heavy traffic assumptions. More precisely, we first describe a stochastic model for a single-server queuing system with multiple customer classes. We focus on the case of bounded service times of jobs arriving in the system. In order to obtain a diffusion limit, we consider a sequence of such models and apply diffusion scaling as in (1) to follow. We make typical heavy traffic assumptions, as detailed in Section III. The main results of this paper are Theorems 1 and 2. They enable us to easily obtain results for the corresponding workload and queue length processes. This method gives us a way to approximately predict the proportions between the workloads (and queue lengths) of the customer classes in the long run.

The paper is organized as follows. In the second section, we present the mathematical model of the queueing system outlined above and introduce stochastic processes describing its state. In the third section, we introduce a sequence of such models and describe the necessary assumptions. In Sections IV and V, we state and prove the main theorems of this paper. In Section VI, we provide a brief overview of computer simulations illustrating our results.

A. Notation

Let $\mathbb{N}$ denote the set of positive integers, let $\mathbb{R}$ denote the set of real numbers and let $\mathbb{R}_+ = [0, +\infty)$. For $a, b \in \mathbb{R}$, we write $a \vee b$ ($a \wedge b$) for the maximum (minimum) of a and b and $\lfloor a \rfloor$ for the largest integer not greater than a. By convention, a sum over the empty set of indices equals zero. The sets (a, b), $[a, b)$ and $(a, b]$ are empty for $a, b \in [0, \infty]$ with $a \geq b$. The Borel σ-field on $\mathbb{R}_+$ will be denoted by $\mathcal{B}(\mathbb{R}_+)$. For $B \in \mathcal{B}(\mathbb{R}_+)$, we denote the indicator of the set B by $\mathbb{I}_B$. We also define the function $\chi(x) = x,\ x \in \mathbb{R}_+$. For a function $g : \mathbb{R}_+ \to \mathbb{R}$ and $T > 0$, let $\|g\|_T = \sup\{|g(t)| : 0 \leq t \leq T\}$ and $\|g\|_\infty = \sup\{|g(t)| : t \geq 0\}$.

For a vector $a = (a_1, ..., a_K)$, with either real or measure-valued elements, by a_Σ we denote $\sum_{i=1}^K a_i$, unless stated otherwise, where it is a weighted sum. The same notation is used for vector-valued processes.

Let $\mathbf{M}$ denote the set of finite, nonnegative measures on $\mathcal{B}(\mathbb{R}_+)$. When $\mu \in \mathbf{M}$ and $a, b \in \mathbb{R}_+ \cup \{+\infty\}$, we will simply write $\mu(a, b)$, $\mu[a, b)$, $\mu(a, b]$ instead of $\mu((a, b))$, $\mu([a, b))$, $\mu((a, b])$, respectively. Moreover, we will write $\mu(x)$ instead of $\mu(\{x\})$ to denote the measure of a single-element set $\{x\}$. For $\xi \in \mathbf{M}$ and a Borel measurable function $g : \mathbb{R}_+ \to \mathbb{R}$ that is integrable with respect to ξ, define $\langle g, \xi \rangle = \int_{\mathbb{R}_+} g(x)\xi(dx)$.

The set $\mathbf{M}$ is endowed with the weak topology, that is, for $\xi_n, \xi \in \mathbf{M}$, we have $\xi_n \xrightarrow{w} \xi$ if and only if $\langle g, \xi_n \rangle \to \langle g, \xi \rangle$ as $n \to \infty$ for all bounded, continuous real functions g on $\mathbb{R}_+$. With this topology, $\mathbf{M}$ is a Polish space ([22]). We denote the zero measure in $\mathbf{M}$ by $\mathbf{0}$ and the measure in $\mathbf{M}$ that puts one unit of mass at a point $x \in \mathbb{R}_+$ by δ_x. For $x \in \mathbb{R}_+$, the measure δ_x^+ is δ_x if $x > 0$ and $\mathbf{0}$ otherwise. Let $\mathbf{M}_0$ denote the set of those elements of $\mathbf{M}$ that do not charge the origin and have a finite first moment.

We use " $\overset{d}{=}$ " for equality in distribution, " $\xrightarrow{fd}$ " to denote the convergence of finite-dimensional distributions of stochastic processes and " $\Rightarrow$ " to denote convergence in distribution of random elements of a metric space. All stochastic processes used in this paper are assumed to have paths that are right continuous with finite left limits (r.c.l.l.). For a Polish space $\mathcal{S}$, we denote by $\mathbf{D}([0, \infty), \mathcal{S})$ the space of r.c.l.l. functions from $[0, \infty)$ into $\mathcal{S}$, endowed with the Skorohod J_1 metric d ([9]). If $\mathcal{S} = \mathbb{R}$, we write $\mathbf{D}[0, \infty)$ instead of $\mathbf{D}([0, \infty), \mathbb{R})$. For $x \in \mathbf{D}([0, \infty), \mathbb{R}^n)$ and $t > 0$, define $x(t-) = \lim_{s \to t^-} x(s)$.

II. Stochastic model for an SRPT queue

The queueing model considered here consists of one server and K job types. Let $\mathcal{K} = \{1, ..., K\}$. The stochastic model involves a random initial condition $(\mathcal{Z}(0), S^x, x > 0)$, describing the system at time zero, together with a measure-valued state descriptor $\mathcal{Z} = (\mathcal{Z}_k, k \in \mathcal{K})$ specifying the time evolution of the system.

A. Initial condition

The initial condition for each class $k \in \mathcal{K}$ consists of the number $Z_k(0)$ of class k jobs in the queue at time zero, the initial service time for each class k job, and the functions describing the order in which the initial jobs with the same initial service time complete service.

Assume that $Z_k(0)$ is a nonnegative integer-valued and finite almost surely random variable for each $k \in \mathcal{K}$. Initial service times for each class k are given by the sequence $\{\tilde{v}_k^j\}_{j \in \mathbb{N}}$ of strictly positive, finite random variables. The initial job with service time $\tilde{v}_k^j, j \leq Z_k(0)$, is called job j for class k. The state of the system will be described by a counting measure with unit masses at the service times of the jobs present in the system. More formally, for $k \in \mathcal{K}$ we define the initial random measure $\mathcal{Z}_k(0) \in \mathbf{M}$ by

$$\mathcal{Z}_k(0) = \sum_{j=1}^{Z_k(0)} \delta_{\tilde{v}_k^j}.$$

Let $\mathcal{Z}(0) = (\mathcal{Z}_1(0), ..., \mathcal{Z}_K(0))$.

For every $x > 0$ the number of initial jobs with initial service time x that are served to completion once t units of time have been devoted to their service is $\lfloor t/x \rfloor \wedge \sum_{k \in \mathcal{K}} \mathcal{Z}_k(0)(x)$. Here we introduce processes $S_k^x,\ k \in \mathcal{K}$, that dictate how much service is allocated across classes. In particular, let $S_k^x(t)$ be the number of initial class k jobs with initial service time x that have left the system by the time that the server has devoted t units of time solely to serving jobs with this initial service time. We assume that the random functions $S_k^x(t)$ satisfy the following consistency conditions:

1) $S_k^x(0) = 0$,

2) $S^x_k(t)$ is nondecreasing and

$$S^x_k(t) = \mathcal{Z}_k(0)(x),\ t \geq x\mathcal{Z}_\Sigma(0)(x),\ k \in \mathcal{K},$$

3) we have

$$\sum_{k\in\mathcal{K}} S^x_k(t) = \lfloor t/x \rfloor \wedge \mathcal{Z}_\Sigma(0)(x).$$

The system $(\mathcal{Z}(0), S^x, x > 0)$, where $S^x = (S^x_1, ..., S^x_K)$, will be called the initial condition.

B. Stochastic primitives

Let E_k be the exogenous arrival process for class $k \in \mathcal{K}$. For $t \geq 0$, $E_k(t)$ is the number of class k arrivals to the system in the time interval $(0, t]$. For each k it is a (possibly delayed) renewal process with rate $\alpha_k > 0$ such that the interarrival times have standard deviation $a_k \geq 0$. Let $E(t) = (E_1(t), ..., E_K(t))$, $\alpha = (\alpha_1, ..., \alpha_K)$ and $a = (a_1, ..., a_K)$. In particular, α_Σ is the total arrival rate. For $t \geq 0$ and $k \in \mathcal{K}$ let $A_k(t) = Z_k(0) + E_k(t)$ and $A(t) = (A_1(t), ..., A_K(t))$. Then job j of class k arrives at time $T^j_k = \inf\{t \geq 0 : A_k(t) \geq j\}$. For $k \in \mathcal{K}$ and $j \in \mathbb{N}$ a random variable v^j_k represents the service time of the $(Z_k(0) + j)$th job of class k. We assume that the random variables $\{v^j_k\}_{j\in\mathbb{N}}$ are strictly positive and form an independent and identically distributed sequence with common distribution ν_k on $\mathbb{R}_+$ for each $k \in \mathcal{K}$. For $k \in \mathcal{K}$ let the sequences $\{v^j_k\}_{j\in\mathbb{N}}$ be mutually independent. Assuming that the mean $\langle\chi, \nu_k\rangle > 0$ and the standard deviation $b_k = \sqrt{\langle\chi^2, \nu_k\rangle - \langle\chi, \nu_k\rangle^2} \geq 0$ we define $\beta_k = \langle\chi, \nu_k\rangle^{-1}$ for each class. We put $\nu = (\nu_1, ..., \nu_K)$. Define $p_k = \alpha_k/\alpha_\Sigma,\ k \in \mathcal{K}$. Then $\nu_\Sigma = \sum_{k\in\mathcal{K}} p_k\nu_k$ is a mixture of service time distributions. It may be thought of as the distribution of the initial service time of a randomly chosen customer. Let $\rho = \alpha_\Sigma\langle\chi, \nu_\Sigma\rangle$ be the traffic intensity.

It will be convenient to combine the stochastic primitives for job classes into measure-valued load processes

$$\mathcal{V}_k(t) = \sum_{j=1}^{E_k(t)} \delta_{v^j_k},\ t \geq 0,\ k \in \mathcal{K},$$

and $\mathcal{V}(t) = (\mathcal{V}_1(t), ..., \mathcal{V}_K(t))$. Then for each $k \in \mathcal{K}$, $\mathcal{V}_k \in \mathbf{D}([0,\infty), \mathbf{M})$, since $E_k \in \mathbf{D}([0,\infty), \mathbb{R}_+)$.

C. Basic performance processes, service protocol

For $j \in \mathbb{N},\ k \in \mathcal{K}$ and $t \geq T^j_k$ let $w^j_k(t)$ denote the residual service time of job j in class k at time t. Thus, w^j_k decreases at rate one when the job j of class k is in service and is constant otherwise. In particular, w^j_k is identically equal to zero after the departure of the job j from the system.

Customers are served using the SRPT service protocol, which gives preemptive priority to the job with the shortest residual service time. In case of a tie, FIFO is used as a tie-breaking rule. When both the service times and the arrival times of two or more jobs are the same, we break the tie in an arbitrary manner.

The state of the system at time t will be described by a K-dimensional vector of counting measures with unit masses at the residual service times of the jobs of each class still present in the system. More formally, for $t \geq 0$ and $k \in \mathcal{K}$, the state descriptor of class k is defined as follows:

$$\mathcal{Z}_k(t) = \sum_{j=1}^{A_k(t)} \delta^+_{w^j_k(t)}.$$

Put $\mathcal{Z}(t) = (\mathcal{Z}_1(t), ..., \mathcal{Z}_K(t))$. For $t \geq 0$ and $k \in \mathcal{K}$, we define the workload of class k by $W_k(t) = \langle\chi, \mathcal{Z}_k(t)\rangle$ and $W(t) = (W_1(t), ..., W_K(t))$. Let $Q_k(t) = \langle 1, \mathcal{Z}_k(t)\rangle$ denote the number of customers of class $k \in \mathcal{K}$ present in the system at time t and define $Q(t) = (Q_1(t), ..., Q_K(t))$.

III. Diffusion limit

We define a sequence of systems to which the diffusion scaling is applied. Let $\mathcal{R}$ be a sequence of positive real numbers increasing to infinity. Consider an $\mathcal{R}$-indexed sequence of stochastic models, each defined as in Section II. For each $r \in \mathcal{R}$ there is an initial condition $(\mathcal{Z}^r(0), S^{r,x}, x > 0)$, stochastic primitives E^r_k and $\{v^{r,j}_k\}_{j\in\mathbb{N}}$ with parameters $\alpha^r_k, a^r_k, \nu^r_k, \beta^r_k$, b^r_k, p^r_k and ρ^r, for each class $k \in \mathcal{K}$. We also have arrival processes A^r with arrival times $\{T^{r,j}_k\}_{j\in\mathbb{N}},\ k \in \mathcal{K}$ a state descriptor $\mathcal{Z}^r$ and processes W^r, Q^r. The stochastic elements of each model are defined on a probability space $(\Omega^r, \mathcal{F}^r, \mathbf{P}^r)$ with expectation operator $\mathbb{E}^r$.

A diffusion scaling is applied to each model in the $\mathcal{R}$-indexed sequence as follows. For each $r \in \mathcal{R}$ and $t \geq 0$, let

$$\begin{aligned}
\hat{E}^r(t) &= \frac{1}{r}(E^r(r^2t) - r^2t\alpha^r),\\
\hat{\mathcal{Z}}^r(t) &= \frac{1}{r}\mathcal{Z}^r(r^2t),\\
\hat{W}^r(t) &= \frac{1}{r}W^r(r^2t),\\
\hat{Q}^r(t) &= \frac{1}{r}Q^r(r^2t),\\
\hat{\mathcal{V}}^r(t) &= \frac{1}{r}\left(\mathcal{V}^r(r^2t) - r^2t\alpha^r\nu^r\right).
\end{aligned} \tag{1}$$

A fluid scaling is applied to functions $S^{r,x}$. For each $r \in \mathcal{R}$, $x > 0$ and $t \geq 0$, let

$$\bar{S}^{r,x}(t) = \frac{1}{r}S^{r,x}(rt).$$

Let $\alpha = (\alpha_1, ..., \alpha_K) \in (0, +\infty)^K$, $a = (a_1, ..., a_K) \in (0, +\infty)^K$ and define $\alpha(t) = \alpha t,\ t \geq 0$. Let $\nu = (\nu_1, ..., \nu_K)$ be a vector of probability measures on $\mathbb{R}_+$ such that for each $k \in \mathcal{K}$

$$\nu_k(0) = 0, \qquad \langle\chi, \nu_k\rangle = \frac{1}{\alpha_k}, \qquad 0 < \langle\chi^2, \nu_k\rangle < \infty.$$

We make the following asymptotic assumptions for the sequence of stochastic primitives. Assume that as $r \to \infty$,

$$\alpha^r \to \alpha, \qquad a^r \to a, \qquad \hat{E}^r \Rightarrow E^*, \tag{2}$$

where E^* is a K-dimensional Brownian motion starting from zero with drift zero and covariance matrix $\Sigma = [\sigma_{ij}]$ such that

$\sigma_{kk} = a_k^2 \alpha_k^3,\ k \in \{1, ..., K\}$. In particular, if the coordinate processes of E^* are independent, then $\sigma_{ij} = 0,\ i \neq j$. Put

$$b_k = \sqrt{\langle \chi^2, \nu_k \rangle - \langle \chi, \nu_k \rangle^2},\ k \in \mathcal{K},$$

and $b = (b_1, ..., b_K)$. In addition, assume the heavy traffic condition that for some $\gamma \in \mathbb{R}$

$$\lim_{r \to \infty} r(1 - \rho^r) = \gamma. \tag{3}$$

For the sequence of service time distributions, we assume that $\nu^r = \nu$, i.e., ν^r does not depend on r. Then $\beta^r = \beta$, $p_k^r \to p_k := \frac{\alpha_k}{\alpha_\Sigma}$ as $r \to \infty$, where α is given by (2), $\rho^r \to 1$ as $r \to \infty$ and $b^r = b$. Define

$$x^* = \sup\{x \in \mathbb{R}_+ : \alpha_\Sigma \langle \chi \mathbb{I}_{[0,x]}, \nu_\Sigma \rangle < 1\}.$$

We assume that $x^* < \infty$.

For the sequence of diffusion scaled initial conditions $\{(\mathcal{Z}^r(0), S^{r,x}, x > 0)\}_{r>0}$ we assume that as $r \to \infty$

$$\hat{W}_\Sigma^r(0) \Rightarrow W_0^*, \tag{4}$$

where W_0^* is some random variable. It is well known ([15]) that from (2), (3), (4), the fact that service time distributions ν^r do not depend on r and that SRPT is a work conserving discipline, it follows that as $r \to \infty$

$$\hat{W}_\Sigma^r \Rightarrow W_\Sigma^*, \tag{5}$$

where W_Σ^* is a reflected Brownian motion with initial value $W_\Sigma^*(0) \overset{d}{=} W_0^*$ with drift $-\gamma$ and variance $(a_\Sigma^2 + b_\Sigma^2)\alpha_\Sigma$ per unit time. It can be shown ([12]) that if $x^* < \infty$ then $\hat{Q}_\Sigma^r \Rightarrow Q_\Sigma^* := \frac{W_\Sigma^*}{x^*}$.

Before we proceed, we state a standard result, as presented in [12].

Proposition 1. *For each* $r \in \mathcal{R}$, *let* $\{x_k^r\}_{k=1}^\infty$ *be an independent and identically distributed sequence of nonnegative random variables on a probability space* $(\Omega^r, \mathcal{F}^r, \mathbf{P}^r)$ *with finite mean* μ^r *and standard deviation* σ^r, *independent of a (possibly delayed) rate* $\alpha^r > 0$ *renewal process* B^r *such that the standard deviation of the interarrival times equals* $a^r \geq 0$. *Assume that* $\hat{B}^r \Rightarrow B^*$ *as* $r \to \infty$, *where*

$$\hat{B}^r(t) = \frac{1}{r}\left(B^r(r^2 t) - r^2 t \alpha^r\right),\ t \geq 0,$$

and B^* *is a one-dimensional Brownian motion starting from zero with drift zero and variance* $a^2\alpha^3$ *per unit time. Suppose that for some finite nonnegative constants* μ, σ, *and positive* α, a *we have that* $\mu^r \to \mu$, $\sigma^r \to \sigma$, $\alpha^r \to \alpha$ *and* $a^r \to a$ *as* $r \to \infty$. *Further assume that for each* $\varepsilon > 0$,

$$\lim_{r \to \infty} \mathbb{E}^r\left((x_1^r - \mu^r)^2 \mathbb{I}_{[|x_1^r - \mu^r| > r\varepsilon]}\right) = 0.$$

For $r \in \mathcal{R},\ n \in \mathbb{N}$ *and* $t \geq 0$, *let*

$$X^r(n) = \sum_{k=1}^n x_k^r \text{ and } \hat{X}^r(t) = \frac{X^r(\lfloor r^2 t \rfloor) - \lfloor r^2 t \rfloor \mu^r}{r}.$$

Then, as $r \to \infty$, $(\hat{B}^r, \hat{X}^r) \Rightarrow (B^*, X^*)$, *where* X^* *is a Brownian motion starting from zero with drift zero and variance* σ^2 *per unit time, independent of* B^*. *Furthermore, as* $r \to \infty$,

$$\hat{Y}^r(\cdot) \Rightarrow X^*(\alpha(\cdot)) + \mu B^*(\cdot),$$

where for each $r \in \mathcal{R}$ *and* $t \geq 0$,

$$\hat{Y}^r(t) = \frac{X^r(B^r(r^2 t)) - r^2 t \alpha^r \mu^r}{r},$$

and $\alpha(t) = \alpha t$.

IV. The case of $\nu_\Sigma(x^*) > 0$

The results in this section require all the assumptions made in Section 3. To simplify the notation, we will write S_k^r and $\bar{S}_k^r$ instead of S_k^{r,x^*} and $\bar{S}_k^{r,x^*}$ and similarly S^r and $\bar{S}^r$ instead of S^{r,x^*} and $\bar{S}^{r,x^*}$.

Theorem 1. *Let* $x^* < \infty,\ \nu_\Sigma(x^*) > 0$. *Assume that as* $r \to \infty$

$$\left(\hat{\mathcal{Z}}^r(0), \bar{S}^r, \hat{W}_\Sigma^r(0)\right) \Rightarrow (\mathcal{Z}^*(0), D, W_0^*) \tag{6}$$

in $\mathbf{M}^K \times (\mathbf{D}[0,\infty))^K \times \mathbb{R}$, *where*

$$\mathcal{Z}^*(0) = \left(\frac{p_k \nu_k(x^*)}{\nu_\Sigma(x^*)} \frac{W_0^*}{x^*} \delta_{x^*}, k = 1, ..., K\right) \tag{7}$$

and

$$D(t) = \left(\frac{p_k \nu_k(x^*)}{\nu_\Sigma(x^*)} \frac{t \wedge W_0^*}{x^*}, k = 1, ..., K\right),\ t \geq 0. \tag{8}$$

Then

$$\left(\hat{\mathcal{Z}}_k^r, k = 1, ..., K\right) \Rightarrow \left(p_k \frac{\nu_k(x^*)}{\nu_\Sigma(x^*)} \frac{W_\Sigma^*}{x^*} \delta_{x^*}, k = 1, ..., K\right). \tag{9}$$

A. Proof of Theorem 1

The general idea of the proof of Theorem 1 is to first show that in the diffusion limits all jobs with service times less than x^* are prioritized so that their corresponding workload and queue length processes vanish. This implies that the processes $\hat{\mathcal{Z}}_\Sigma^r$ converge weakly to a multiple of δ_{x^*}. Then we use functional limit theorems and the fact that FIFO is the tie-breaking rule to prove that in the diffusion limit the queue lengths and the workloads of job classes are divided according to the proportions in the statement of the theorem. In the proof, we follow the ideas of Peterson [21], with customers having the residual service times not less than x^* regarded as the low priority (L) ones with necessary modifications. The most important difference is that in [21] the priority of a job cannot change. In our setting however, the priority of a job can change from low to high (H). It happens every time a job with service time x^* receives some service and hence its residual service time is decreased. Consequently, our problem requires a somewhat more careful approach, described below in more detail.

1) Additional notation: For $k \in \mathcal{K}$, $r \in \mathcal{R}$ and $t \geq 0$ denote

$$V_k^r(t) = \langle \chi, \mathcal{V}_k^r(t) \rangle, \quad \hat{V}_k^r(t) = \langle \chi, \hat{\mathcal{V}}_k^r(t) \rangle,$$

$$\begin{aligned}
V_{k,H}^r(t) &= \langle \chi \mathbb{I}_{[0,x^*)}, \mathcal{V}_k^r(t) \rangle, \\
Q_{k,H}^r(t) &= \langle \mathbb{I}_{[0,x^*)}, \mathcal{Z}_k^r(t) \rangle, \\
W_{k,H}^r(t) &= \langle \chi \mathbb{I}_{[0,x^*)}, \mathcal{Z}_k^r(t) \rangle, \\
\hat{V}_{k,H}^r(t) &= \langle \chi \mathbb{I}_{[0,x^*)}, \hat{\mathcal{V}}_k^r(t) \rangle, \\
\hat{Q}_{k,H}^r(t) &= \langle \mathbb{I}_{[0,x^*)}, \hat{\mathcal{Z}}_k^r(t) \rangle, \\
\hat{W}_{k,H}^r(t) &= \langle \chi \mathbb{I}_{[0,x^*)}, \hat{\mathcal{Z}}_k^r(t) \rangle
\end{aligned}$$

and

$$\begin{aligned}
V_{k,L}^r(t) &= V_k^r(t) - V_{k,H}^r(t), \quad W_{k,L}^r(t) = W_k^r(t) - W_{k,H}^r(t), \\
\hat{V}_{k,L}^r(t) &= \hat{V}_k^r(t) - \hat{V}_{k,H}^r(t), \quad \hat{W}_{k,L}^r(t) = \hat{W}_k^r(t) - \hat{W}_{k,H}^r(t).
\end{aligned}$$

In general, subscript "H" stands for high priority jobs, i.e. jobs with residual processing times strictly lower than x^* and subscript "L" indicates low priority jobs, i.e. those with residual service times greater than or equal to x^*.

Recall that in our notation

$$\begin{aligned}
E_\Sigma^r(t) &= \sum_{k \in \mathcal{K}} E_k^r(t), \quad \hat{E}_\Sigma^r(t) = \sum_{k \in \mathcal{K}} \hat{E}_k^r(t), \\
E_\Sigma^*(t) &= \sum_{k \in \mathcal{K}} E_k^*(t), \quad W_\Sigma^r(t) = \sum_{k \in \mathcal{K}} W_k^r(t),
\end{aligned}$$

and similarly,

$$\begin{aligned}
Q_{\Sigma,H}^r(t) &= \langle \mathbb{I}_{[0,x^*)}, \mathcal{Z}_\Sigma^r(t) \rangle, \ \hat{Q}_{\Sigma,H}^r(t) = \langle \mathbb{I}_{[0,x^*)}, \hat{\mathcal{Z}}_\Sigma^r(t) \rangle, \\
W_{\Sigma,H}^r(t) &= \langle \chi \mathbb{I}_{[0,x^*)}, \mathcal{Z}_\Sigma^r(t) \rangle, \ \hat{W}_{\Sigma,H}^r(t) = \langle \chi \mathbb{I}_{[0,x^*)}, \hat{\mathcal{Z}}_\Sigma^r(t) \rangle, \\
W_{\Sigma,L}^r(t) &= W_\Sigma^r(t) - W_{\Sigma,H}^r(t), \ \hat{W}_{\Sigma,L}^r(t) = \hat{W}_\Sigma^r(t) - \hat{W}_{\Sigma,H}^r(t).
\end{aligned}$$

Let $L^r(t)$ denote the number of units of service dedicated to jobs with initial service times equal to x^* by time $t \geq 0$ in the r-th system. Observe for future reference that $S_k^r(L^r(t))$ is the number of fully served initial class k jobs with initial service time x^* by time t in the r-th system.

2) Concentration of the mass at x^*: We will first show that

$$\hat{Q}_{\Sigma,H}^r \Rightarrow 0, \ r \to \infty. \tag{10}$$

Observe that (10) implies

$$\hat{W}_{\Sigma,H}^r \Rightarrow 0, \ r \to \infty \tag{11}$$

since

$$\hat{W}_{\Sigma,H}^r \leq x^* \hat{Q}_{\Sigma,H}^r. \tag{12}$$

For $r \in \mathcal{R}$ and $t \geq 0$, let

$$\tau^r(t) = \sup\{s \in [0,t] : \hat{Q}_{\Sigma,H}^r(s) = 0\},$$

which equals zero by definition if

$$\{s \in [0,t] : \hat{Q}_{\Sigma,H}^r(s) = 0\} = \varnothing.$$

Then for $r \in \mathcal{R}$ and $t \geq 0$

$$\begin{aligned}
\hat{Q}_{\Sigma,H}^r(t) &\leq \hat{Q}_{\Sigma,H}^r(\tau^r(t)) + \frac{1}{r}\left(E_\Sigma^r(r^2 t) - E_\Sigma^r(r^2\tau^r(t)) + 1\right) \\
&= \hat{Q}_{\Sigma,H}^r(\tau^r(t)) + \hat{E}_\Sigma^r(t) - \hat{E}_\Sigma^r(\tau^r(t)) + \frac{1}{r} + r(t - \tau^r(t))\alpha_\Sigma^r.
\end{aligned}$$

Indeed, the inequality above follows from the fact that clearly $\tau^r(t) \leq t$, so we can bound the (diffusion scaled) number of high priority customers in the system at time t from above by an analogous number of customers at time $\tau^r(t)$ increased by the number of external arrivals in this time interval. The addition of 1 on the right-hand side of the inequality is needed because of a possibility that there is no job with service time less than x^* at time $r^2\tau^r(t)$ in the system and a job with service time x^* is chosen for processing at this time, which immediately increases the number of jobs with residual processing times less than x^* by 1.

First we find an upper bound on $\hat{Q}_{\Sigma,H}^r(\tau^r(t))$. Fix $r \in \mathcal{R}$ and $t \geq 0$. If $\tau^r(t) = 0$, then $\hat{Q}_{\Sigma,H}^r(\tau^r(t)) = \hat{Q}_{\Sigma,H}^r(0)$. Otherwise, $\tau^r(t) > 0$. If $\hat{Q}_{\Sigma,H}^r(\tau^r(t)) = 0$, then any nonnegative upper bound suffices, so we can also assume that $\hat{Q}_{\Sigma,H}^r(\tau^r(t)) > 0$. Then $\hat{Q}_{\Sigma,H}^r(\tau^r(t)-) = 0$ and $\hat{Q}_{\Sigma,H}^r(\tau^r(t)) > 0$. Therefore in the rth system at time $\tau^r(t)$ the exogeneous arrival process has a jump. This means that $\hat{Q}_{\Sigma,H}^r(\tau^r(t)) \leq \hat{E}_\Sigma^r(\tau^r(t)) - \hat{E}_\Sigma^r(\tau^r(t)-)$. Combining the bounds for $\tau^r(t) = 0$ or $\tau^r(t) > 0$ gives

$$\hat{Q}_{\Sigma,H}^r(\tau^r(t)) \leq \hat{Q}_{\Sigma,H}^r(0) + \hat{E}_\Sigma^r(\tau^r(t)) - \hat{E}_\Sigma^r(\tau^r(t)-),$$

where by convention $\hat{E}_\Sigma^r(0-) = \hat{E}_\Sigma^r(0) = 0$. Hence

$$\hat{Q}_{\Sigma,H}^r(t) \leq \hat{Q}_{\Sigma,H}^r(0) + \hat{E}_\Sigma^r(t) - \hat{E}_\Sigma^r(\tau^r(t)-) + \frac{1}{r} + r(t - \tau^r(t))\alpha_\Sigma^r. \tag{13}$$

For $r \in \mathcal{R}$ and $t \geq 0$ let $\theta^r(t) = t - \tau^r(t)$ and $\tilde{\theta}^r(t) = \theta^r(t) + \frac{1}{r^2}$. For now, suppose that

$$r\theta^r \Rightarrow 0. \tag{14}$$

Then, it follows from (14) that as $r \to \infty$,

$$\theta^r \Rightarrow 0 \quad \text{and} \quad \tilde{\theta}^r \Rightarrow 0. \tag{15}$$

Fix $r \in \mathcal{R}$ and $t \geq 0$. By (1), we have

$$\hat{E}_\Sigma^r(t) - \hat{E}_\Sigma^r(\tau^r(t)-) = \hat{E}_\Sigma^r(t) - \frac{1}{r} E_\Sigma^r(r^2\tau^r(t)-) + r\tau^r(t)\alpha_\Sigma^r$$

which, together with the fact that the process E_Σ^r is nondecreasing, implies

$$\begin{aligned}
\hat{E}_\Sigma^r(t) - \hat{E}_\Sigma^r(\tau^r(t)) &\leq \hat{E}_\Sigma^r(t) - \hat{E}_\Sigma^r(\tau^r(t)-) \\
&\leq \hat{E}_\Sigma^r(t) - \hat{E}_\Sigma^r\left(\left(\tau^r(t) - \frac{1}{r^2}\right)^+\right) + \frac{\alpha_\Sigma^r}{r}.
\end{aligned}$$

Therefore,

$$\begin{aligned}
\hat{E}_\Sigma^r(t) - \hat{E}_\Sigma^r(t - \theta^r(t)) &\leq \hat{E}_\Sigma^r(t) - \hat{E}_\Sigma^r(\tau^r(t)-) \\
&\leq \hat{E}_\Sigma^r(t) - \hat{E}_\Sigma^r\left(\left(t - \tilde{\theta}^r(t)\right)^+\right) + \frac{\alpha_\Sigma^r}{r}.
\end{aligned}$$

By (2), (15) and the fact that E^*_Σ is continuous almost surely, we obtain (see [5], Section 17) that for $t \geq 0$ as $r \to \infty$

$$\hat{E}^r_\Sigma(t) - \hat{E}^r_\Sigma(t - \theta^r(t)) \Rightarrow 0$$

and

$$\hat{E}^r_\Sigma(t) - \hat{E}^r_\Sigma\left((t - \tilde{\theta}^r(t))^+\right) + \frac{\alpha^r_\Sigma}{r} \Rightarrow 0.$$

Hence, as $r \to \infty$

$$\hat{E}^r_\Sigma(t) - \hat{E}^r_\Sigma(\tau^r(t)-) \Rightarrow 0. \tag{16}$$

Since the space $\mathbf{M}^K \times (\mathbf{D}[0,\infty))^K \times \mathbb{R}$ is separable, we can apply the Skorohod representation theorem ([5], Theorem 6.7) and assume that all the random elements in (6)-(8) are defined on a common probability space $(\Omega, \mathcal{F}, \mathbf{P})$, on which as $r \to \infty$

$$\left(\hat{\mathcal{Z}}^r(0), \bar{S}^r, \hat{W}^r_\Sigma(0)\right)(\omega) \to (\mathcal{Z}^*(0), D, W^*_0)(\omega) \tag{17}$$

in $\mathbf{M}^K \times (\mathbf{D}[0,\infty))^K \times \mathbb{R}$ for almost every $\omega \in \Omega$. Fix such an ω. In this paragraph, all the random elements under consideration are evaluated at this ω. Observe that from the consistency conditions for functions S^x_k listed in Section II-A it follows that, for a given r, $\bar{S}^r_k(t) = \hat{\mathcal{Z}}_k(0)(x^*)$ for $t \geq x^*\hat{\mathcal{Z}}^r_\Sigma(0)(x^*)$. By (17), there exists a finite constant C such that $\hat{\mathcal{Z}}^r_\Sigma(0)(x^*) \leq C$ for all $r \in \mathcal{R}$. This means that all the functions $\bar{S}^r_k$ as well as the functions D_k are constant on $[Cx^*, \infty)$. In this case, convergence in the Skorohod topology to a continuous limit implies convergence in the uniform topology as well ([5], Section 12). Hence, by (17) as $r \to \infty$

$$|\hat{\mathcal{Z}}^r_\Sigma(0)(x^*) - \mathcal{Z}^*_\Sigma(0)(x^*)| = \left| \left\| \sum_{k\in\mathcal{K}} \bar{S}^r_k \right\|_\infty - \left\| \sum_{k\in\mathcal{K}} D_k \right\|_\infty \right| \tag{18}$$

$$\leq \left\| \sum_{k\in\mathcal{K}} \bar{S}^r_k - \sum_{k\in\mathcal{K}} D_k \right\|_\infty \to 0.$$

This, together with (6), (7), (17), gives us

$$\hat{Q}^r_{\Sigma,H}(0) = \langle \mathbb{I}_{[0,x^*)}, \hat{\mathcal{Z}}^r_\Sigma(0)\rangle \Rightarrow \langle \mathbb{I}_{[0,x^*)}, \mathcal{Z}^*_\Sigma(0)\rangle = 0, \ r \to \infty, \tag{19}$$

which in turn, together with (2), (13), (14), (16) implies (10).

Therefore it remains to prove (14). For each $r \in \mathcal{R}$ and $t \geq 0$, we examine the behavior of $W^r_{\Sigma,H}$ on time intervals of the form $(r^2\tau^r(t), r^2t]$ to derive an expression that relates $\hat{W}^r_{\Sigma,H}(t)$ and $\theta^r(t)$. In particular, since for each $r \in \mathcal{R}$ and $t \geq 0$, $Q^r_{\Sigma,H}(s) \neq 0$ for all $s \in (r^2\tau^r(t), r^2t]$ and the service discipline is SRPT, it follows that for each $r \in \mathcal{R}$ and $t \geq 0$,

$$\begin{aligned} W^r_{\Sigma,H}(r^2t) \leq\ & W^r_{\Sigma,H}(r^2\tau^r(t)) + V^r_{\Sigma,H}(r^2t) - V^r_{\Sigma,H}(r^2\tau^r(t)) \\ & + x^* - r^2(t - \tau^r(t)). \end{aligned}$$

Again, the addition of x^* on the right-hand side of the inequality is needed because of a possibility that there are only jobs with service time greater than or equal to x^* at time $r^2\tau^r(t)$ in the queue.

By applying diffusion scaling and rearranging, we obtain for $r \in \mathcal{R}$ and $t \geq 0$

$$\begin{aligned} \hat{W}^r_{\Sigma,H}(t) \leq\ & \hat{W}^r_{\Sigma,H}(\tau^r(t)) + \hat{V}^r_{\Sigma,H}(t) - \hat{V}^r_{\Sigma,H}(\tau^r(t)) + \frac{x^*}{r} \\ & + (\alpha^r_\Sigma\langle\chi\mathbb{I}_{[0,x^*)}, \nu_\Sigma\rangle - 1)r\theta^r(t). \end{aligned}$$

Using the same line of reasoning that gave rise to (13), for $r \in \mathcal{R}$ and $t \geq 0$,

$$\begin{aligned} \hat{W}^r_{\Sigma,H}(t) \leq\ & \hat{W}^r_{\Sigma,H}(0) + \hat{V}^r_{\Sigma,H}(t) - \hat{V}^r_{\Sigma,H}(\tau^r(t)-) + \frac{x^*}{r} \\ & + (\alpha^r_\Sigma\langle\chi\mathbb{I}_{[0,x^*)}, \nu_\Sigma\rangle - 1)r\theta^r(t). \end{aligned}$$

Since $\hat{W}^r_{\Sigma,H}(t) \geq 0$ for all $r \in \mathcal{R}$ and $t \geq 0$, it follows that for such r and t

$$\begin{aligned} (1 - \alpha^r_\Sigma\langle\chi\mathbb{I}_{[0,x^*)}, \nu_\Sigma\rangle)r\theta^r(t) \leq\ & \hat{W}^r_{\Sigma,H}(0) + \hat{V}^r_{\Sigma,H}(t) \\ & - \hat{V}^r_{\Sigma,H}(\tau^r(t)-) + \frac{x^*}{r}. \end{aligned} \tag{20}$$

By (2) and the theorem assumption, we have that

$$\lim_{r\to\infty}\left(1 - \alpha^r_\Sigma\langle\chi\mathbb{I}_{[0,x^*)}, \nu_\Sigma\rangle\right) = 1 - \alpha_\Sigma\langle\chi\mathbb{I}_{[0,x^*)}, \nu_\Sigma\rangle > 0. \tag{21}$$

Hence, for r sufficiently large, $\left(1 - \alpha^r_\Sigma\langle\chi\mathbb{I}_{[0,x^*)}, \nu_\Sigma\rangle\right)\theta^r \geq 0$ for all $t \geq 0$. Using Proposition 1, one can prove (see [12]) that

$$\hat{V}^r_{\Sigma,H} \Rightarrow V^*_{\Sigma,H}, \ r \to \infty, \tag{22}$$

where $V^*_{\Sigma,H}$ is a Brownian motion starting from zero with zero drift and finite variance per unit time. Then (17) and (20)-(22) together imply that $\theta^r \Rightarrow 0$, $r \to \infty$. By the same line of reasoning that gave rise to (16), we have that for $t \geq 0$

$$\hat{V}^r_{\Sigma,H}(t) - \hat{V}^r_{\Sigma,H}(\tau^r(t)-) \Rightarrow 0.$$

By using this, (6), (7), (12) and (19)-(21) we obtain (14).

3) Proportional breakdown: For $r \in \mathcal{R}$ let $\sigma^r(t)$ be the time of arrival to the rth system of the job with service time x^* which most recently completed service before time t (if none has yet completed we define it as 0). Let $\bar{\sigma}^r(t) = \frac{1}{r^2}\sigma^r(r^2t)$, $t \geq 0$. We will now prove that $\bar{\sigma}^r \Rightarrow e$, where $e(t) = t$ for $t \geq 0$. For $t \geq 0$ we have

$$\begin{aligned} W^r_{\Sigma,L}(t) \geq\ & V^r_{\Sigma,L}(t) - V^r_{\Sigma,L}(\sigma^r(t)) - u^r(t) \\ & + x^*\left(\mathcal{Z}^r_\Sigma(0)(x^*) - S^r_\Sigma(L^r(t))\right), \end{aligned} \tag{23}$$

where $u^r(t)$ denotes the partial service (if any) that has been performed in the time interval $[\sigma^r(t), t)$ on the next job with service time x^*. Recall that $S^r_\Sigma(L^r(t))$ is the number of fully served initial jobs with initial service time x^* by time t in the rth system, so the last term is the workload of initial low priority jobs still present in the system at time t. The fact that (23) holds is a consequence of the FIFO discipline among the jobs with the same residual service time. Notice that $u^r(t) \leq x^*$. On the other hand, we also have that for $t \geq 0$

$$\begin{aligned} W^r_{\Sigma,L}(t) \leq\ & V^r_{\Sigma,L}(t) - V^r_{\Sigma,L}(\sigma^r(t)-) - u^r(t) \\ & + x^*\left(\mathcal{Z}^r_\Sigma(0)(x^*) - S^r_\Sigma(L^r(t))\right) + \langle\chi\mathbb{I}_{(x^*,\infty)}, \mathcal{Z}^r_\Sigma(0)\rangle, \end{aligned} \tag{24}$$

where $V^r_{\Sigma,L}(0-) = V^r_{\Sigma,L}(0) = 0$ by convention. The last term in (24) takes into account possible initial jobs with processing times greater than x^*. Under the diffusion scaling $\hat{W}^r_{\Sigma,L}(t) = \frac{1}{r}W^r_{\Sigma,L}(r^2t)$ we have $\hat{W}^r_{\Sigma,L} = \hat{W}^r_{\Sigma} - \hat{W}^r_{\Sigma,H}$ and by (5) and (11),

$$\hat{W}^r_{\Sigma,L} \Rightarrow W^*_{\Sigma}. \qquad (25)$$

Under the diffusion scaling, since $\mathcal{Z}^r_{\Sigma}(0)(x^*) - S^r_{\Sigma}(L^r(t)) \geq 0$, (23) yields for $t \geq 0$

$$\begin{aligned}\hat{W}^r_{\Sigma,L}(t) \geq \hat{V}^r_{\Sigma,L}(t) - \hat{V}^r_{\Sigma,L}(\bar{\sigma}^r(t)) - \frac{1}{r}u^r(r^2t)\\ + r\alpha^r_{\Sigma}\nu_{\Sigma}(x^*)(t - \bar{\sigma}^r(t)). \qquad (26)\end{aligned}$$

Since $\sigma^r(t) \leq t$, (26) gives us after rearranging

$$\begin{aligned}0 \leq t - \bar{\sigma}^r(t) \leq \frac{1}{r\alpha^r_{\Sigma}\nu_{\Sigma}(x^*)}\Big(\hat{W}^r_{\Sigma,L}(t)\\ -\hat{V}^r_{\Sigma,L}(t) + \hat{V}^r_{\Sigma,L}(\bar{\sigma}^r(t)) + \frac{1}{r}u^r(r^2t)\Big). \qquad (27)\end{aligned}$$

Let $T > 0$. Since convergence in the Skorohod topology to a continuous limit implies convergence in the uniform topology, we have $\|\hat{W}^r_{\Sigma,L}\|_T \Rightarrow \|\hat{W}^*_{\Sigma}\|_T$. For $t \in [0,T]$, we can bound $\hat{V}^r_{\Sigma,L}(\bar{\sigma}^r(t))$ by $\|\hat{V}^r_{\Sigma,L}\|_T$, so (27) after taking norms gives

$$\|t - \bar{\sigma}^r(t)\|_T \leq \frac{1}{r\alpha^r_{\Sigma}\nu_{\Sigma}(x^*)}\left(\|\hat{W}^r_{\Sigma,L}\|_T + 2\|\hat{V}^r_{\Sigma,L}\|_T + \frac{x^*}{r}\right).$$

Define the continuous functions $h_r : \mathbb{R} \to \mathbb{R}$ and $h : \mathbb{R} \to \mathbb{R}$ by $h_r(x) = \frac{x}{r}$ and $h(x) = 0, x \in \mathbb{R}$. Then, by Theorem 2.7 of [5], $h_r(\|\hat{W}^r_{\Sigma,L}\|_T + 2\|\hat{V}^r_{\Sigma,L}\|_T + \frac{x^*}{r}) \Rightarrow h(\|\hat{W}^*_{\Sigma}\|_T + 2\|\hat{V}^*_{\Sigma,L}\|_T) = 0$. Thus the right hand side above converges in probability to zero, which in turn implies that $\bar{\sigma}^r \Rightarrow e$ by Theorem 3.1 of [5].

For $t \geq 0$, let

$$I^r(t) := x^*\left(\hat{\mathcal{Z}}^r_{\Sigma}(0)(x^*) - \bar{S}^r_{\Sigma}(\bar{L}^r(rt))\right) + r\alpha^r_{\Sigma}\nu_{\Sigma}(x^*)(t - \bar{\sigma}^r(t)),$$

where $\bar{L}^r(t) = \frac{1}{r}L^r(rt)$. From (23)-(24) we have that

$$I^r(t) \leq \hat{W}^r_{\Sigma,L}(t) - \hat{V}^r_{\Sigma,L}(t) + \hat{V}^r_{\Sigma,L}(\bar{\sigma}^r(t)) + \frac{1}{r}u^r(r^2t), \qquad (28)$$

$$\begin{aligned}I^r(t) \geq \hat{W}^r_{\Sigma,L}(t) - \hat{V}^r_{\Sigma,L}(t) + \hat{V}^r_{\Sigma,L}(\bar{\sigma}^r(t)-) + \frac{1}{r}u^r(r^2t)\\ - \langle \chi\mathbb{I}_{(x^*,\infty)}, \hat{\mathcal{Z}}^r_{\Sigma}(0)\rangle. \qquad (29)\end{aligned}$$

Notice that

$$\langle \chi\mathbb{I}_{(x^*,\infty)}, \hat{\mathcal{Z}}^r_{\Sigma}(0)\rangle \Rightarrow 0, \; r \to \infty. \qquad (30)$$

Indeed,

$$\hat{W}^r_{\Sigma}(0) = \langle \chi\mathbb{I}_{[0,x^*]}, \hat{\mathcal{Z}}^r_{\Sigma}(0)\rangle + \langle \chi\mathbb{I}_{(x^*,\infty)}, \hat{\mathcal{Z}}^r_{\Sigma}(0)\rangle.$$

By (7) and (18), $\langle \chi\mathbb{I}_{[0,x^*]}, \hat{\mathcal{Z}}^r_{\Sigma}(0)\rangle \Rightarrow W^*_0$, so, taking (4) into account, we see that (30) must hold.

Using Proposition 1, one can prove (see [12]) that

$$\hat{V}^r_{\Sigma,L} \Rightarrow V^*_{\Sigma,L}, \; r \to \infty, \qquad (31)$$

where $V^*_{\Sigma,L}$ is a Brownian motion starting from zero with zero drift and finite variance per unit time. From (28)-(29), using (25), (30)-(31), the fact that $\bar{\sigma}^r \Rightarrow e$ and the Random Time Change Theorem ([5], Theorem 14.4) we have that

$$I^r \Rightarrow W^*_{\Sigma}. \qquad (32)$$

We can now obtain the desired breakdown for the workload processes. For $t \geq 0, k \in \mathcal{K}$ we have the following inequalities, analogous to (23)-(24):

$$\begin{aligned}W^r_{k,L}(t) \leq V^r_{k,L}(t) - V^r_{k,L}(\sigma^r(t)-) - u^r_k(t)\\ + x^*\left(\mathcal{Z}^r_k(0)(x^*) - S^r_k(L^r(t))\right) + \langle \chi\mathbb{I}_{(x^*,\infty)}, \mathcal{Z}^r_k(0)\rangle, \qquad (33)\end{aligned}$$

$$\begin{aligned}W^r_{k,L}(t) \geq V^r_{k,L}(t) - V^r_{k,L}(\sigma^r(t)) - u^r_k(t)\\ + x^*\left(\mathcal{Z}^r_k(0)(x^*) - S^r_k(L^r(t))\right), \qquad (34)\end{aligned}$$

where $u^r_k(t)$ denotes the partial service (if any) that has been performed in the time interval $[\sigma^r(t), t)$ on the next job of class k with service time x^*. Notice that $u^r_k(t) \leq x^*$ for all $k \in \mathcal{K}$.

Under diffusion scaling, (33) yields

$$\begin{aligned}\hat{W}^r_{k,L}(t) \leq \hat{V}^r_{k,L}(t) - \hat{V}^r_{k,L}(\bar{\sigma}^r(t)-) - \frac{1}{r}u^r_k(r^2t)\\ + x^*\left(\hat{\mathcal{Z}}^r_k(0)(x^*) - \bar{S}^r_k(\bar{L}^r(rt))\right) \qquad (35)\\ + r\alpha^r_k\nu_k(x^*)(t - \bar{\sigma}^r(t)) + \langle \chi\mathbb{I}_{(x^*,\infty)}, \hat{\mathcal{Z}}^r_k(0)\rangle\end{aligned}$$

and (34) yields

$$\begin{aligned}\hat{W}^r_{k,L}(t) \geq \hat{V}^r_{k,L}(t) - \hat{V}^r_{k,L}(\bar{\sigma}^r(t)) - \frac{1}{r}u^r_k(r^2t)\\ + x^*\left(\hat{\mathcal{Z}}^r_k(0)(x^*) - \bar{S}^r_k(\bar{L}^r(rt))\right) \qquad (36)\\ + r\alpha^r_k\nu_k(x^*)(t - \bar{\sigma}^r(t))\end{aligned}$$

for $t \geq 0, \; k \in \mathcal{K}$. Since $\mathcal{Z}^r_k \leq \mathcal{Z}^r_{\Sigma}$ and χ is nonnegative, from (30) we have that as $r \to \infty$

$$\langle \chi\mathbb{I}_{(x^*,\infty)}, \hat{\mathcal{Z}}^r_k(0)\rangle \Rightarrow 0. \qquad (37)$$

Suppose that for each $k \in \mathcal{K}$, $r \in \mathcal{R}$

$$\begin{aligned}I^r_k(t) := x^*\left(\hat{\mathcal{Z}}^r_k(0)(x^*) - \bar{S}^r_k(\bar{L}^r(rt))\right) + r\alpha^r_k\nu_k(x^*)(t - \bar{\sigma}^r(t))\\ \Rightarrow \frac{\alpha_k\nu_k(x^*)}{\alpha_{\Sigma}\nu_{\Sigma}(x^*)}W^*_{\Sigma}(t). \qquad (38)\end{aligned}$$

Using this, (35)-(37), the fact that $\bar{\sigma}^r \Rightarrow e$ and the Random Time Change Theorem, we can write that

$$\hat{W}^r_{k,L} \Rightarrow \frac{\alpha_k\nu_k(x^*)}{\alpha_{\Sigma}\nu_{\Sigma}(x^*)}W^*_{\Sigma} = p_k\frac{\nu_k(x^*)}{\nu_{\Sigma}(x^*)}W^*_{\Sigma}. \qquad (39)$$

From Section IV-A2 and (30) it follows that $\hat{\mathcal{Z}}^r_{\Sigma} \Rightarrow \frac{W^*_{\Sigma}}{x^*}\delta_{x^*}$. Taking this into account gives us (9). Therefore it remains to prove (38).

Recall from (2) that $\alpha^r \to \alpha$ as $r \to \infty$ and that by the Skorohod representation theorem we may assume that all the random elements in (6)-(8) are defined on a common probability space $(\Omega, \mathcal{F}, \mathbf{P})$ such that (17) holds for almost every $\omega \in \Omega$. In what follows, all the random elements are evaluated at such an ω. Using an analogous line of reasoning as the one that led us to (18) we obtain that, as $r \to \infty$,

$$|\hat{\mathcal{Z}}_k^r(0)(x^*) - \mathcal{Z}_k^*(0)(x^*)| \to 0 \tag{40}$$

and, similarly,

$$\sup_{t \geq 0} |\bar{S}_k^r(t) - D_k(t)| \to 0. \tag{41}$$

Observe that

$$I_k^r - \frac{\alpha_k \nu_k(x^*)}{\alpha_\Sigma \nu_\Sigma(x^*)} I^r = x^* \left(\hat{\mathcal{Z}}_k^r(0)(x^*) - \frac{\alpha_k \nu_k(x^*)}{\alpha_\Sigma \nu_\Sigma(x^*)} \hat{\mathcal{Z}}_\Sigma^r(0)(x^*) + \frac{\alpha_k \nu_k(x^*)}{\alpha_\Sigma \nu_\Sigma(x^*)} \bar{S}_\Sigma^r(\bar{L}^r(rt)) - \bar{S}_k^r(\bar{L}^r(rt)) \right).$$

By (7),

$$\mathcal{Z}_k^*(0)(x^*) = \frac{\alpha_k \nu_k(x^*)}{\alpha_\Sigma \nu_\Sigma(x^*)} \frac{W_0^*}{x^*} = \frac{\alpha_k \nu_k(x^*)}{\alpha_\Sigma \nu_\Sigma(x^*)} \mathcal{Z}_\Sigma^*(0)(x^*),$$

so by (40),

$$\left| \hat{\mathcal{Z}}_k^r(0)(x^*) - \frac{\alpha_k \nu_k(x^*)}{\alpha_\Sigma \nu_\Sigma(x^*)} \hat{\mathcal{Z}}_\Sigma^r(0)(x^*) \right| \to 0$$

as $r \to \infty$. Similarly, by (8) and (41)

$$\sup_{t \geq 0} \left| \bar{S}_k^r(\bar{L}^r(rt)) - \frac{\alpha_k \nu_k(x^*)}{\alpha_\Sigma \nu_\Sigma(x^*)} \bar{S}_\Sigma^r(\bar{L}^r(rt)) \right| \to 0$$

as $r \to \infty$, which implies that the limits as $r \to \infty$ of I_k^r and $\frac{\alpha_k \nu_k(x^*)}{\alpha_\Sigma \nu_\Sigma(x^*)} I^r$ coincide and, by (32), proves (38).

V. The case of $\nu_\Sigma(x^*) = 0$

In this case we take a seemingly different approach. We start from modeling an exogeneous arrival process E_Σ common for all jobs. When a job arrives at the system, we randomly assign it to a class $1, ..., K$ with probabilities $p_1, ..., p_K$ correspondingly[1]. We also assume that there are no customers in the system at time 0. This is described more formally below.

Let $(\Omega, \mathcal{F}, \mathbf{P})$ be the probability space on which the stochastic elements of the model are defined. Let E_Σ be the exogenous arrival process, i.e. for $t \geq 0$, $E_\Sigma(t)$ is the number of arrivals to the system in the time interval $(0, t]$. It is a delayed renewal process with rate $\alpha_\Sigma > 0$ such that the interarrival times have standard deviation $a_\Sigma \geq 0$. Then job j arrives at time $T^j = \inf\{t \geq 0 : E_\Sigma(t) \geq j\}$.

Let $\{\varphi_i\}_{i \in \mathbb{N}}$ be i.i.d. random vectors, independent of E_Σ such that for each i $\varphi_i = (\varphi_{i,1}, ..., \varphi_{i,K})$, where $\varphi_{i,k} = 1$ if job i belongs to class k and $\varphi_{i,k} = 0$ otherwise. We assume that $\mathbf{P}(\varphi_i = e_k) = p_k$, where e_k is the kth unit vector in $\mathbb{R}^K$ and $p_k \in (0,1)$ for each $k \in \mathcal{K}$, $\sum_{k \in \mathcal{K}} p_k = 1$. Put $p = (p_1, ..., p_K)$. Let $\Phi(n) = (\Phi_1(n), ..., \Phi_K(n)) = \sum_{i=1}^n \varphi_i$. In words, $\Phi_k(n)$ is the number of class k jobs among the first n jobs which arrived in the system. We can now define $E_k(t) = \Phi_k(E_\Sigma(t))$, $k \in \mathcal{K}$, $t \geq 0$ and $E(t) = (E_1(t), ..., E_K(t))$. Put $\alpha_k = p_k \alpha_\Sigma$, $k \in \mathcal{K}$ and $\alpha = (\alpha_1, ..., \alpha_K)$. We define the processes $\mathcal{Z}$, W, Q and $\mathcal{V}$ analogously as in Section II. We assume that $\mathcal{Z}_k(0) = \mathbf{0}$ for each $k \in \mathcal{K}$.

Let v_i represent the initial service time of the ith job in the system. We assume that $(\varphi_i, v_i)_{i \geq 1}$ are i.i.d. random vectors independent of E and that ν_k is the conditional distribution of v_i under the condition of $\varphi_i = e_k$, $k \in \mathcal{K}$. We put $\nu_\Sigma = \sum_{k \in \mathcal{K}} p_k \nu_k$. For $j \in \mathbb{N}$, $k \in \mathcal{K}$ and $t \geq T^j$ let $w^j(t)$ denote the residual service time of job j at time t. As before, the SRPT protocol is used.

We apply diffusion scaling for a sequence of systems similarly as in Section III. Let $\mathcal{R}$ be a sequence of positive numbers increasing to infinity. Consider an $\mathcal{R}$-indexed sequence of stochastic models presented in the previous paragraph. For each $r \in \mathcal{R}$, there are stochastic primitives E_Σ^r, $\{\varphi_i^r\}_{i \in \mathbb{N}}$, Φ_k^r, E^r, $\{v_i^r\}_{i \in \mathbb{N}}$ with parameters $\alpha^r, a_\Sigma^r, p_k^r, \nu_k^r$. The stochastic elements of each model are defined on a probability space $(\Omega^r, \mathcal{F}^r, \mathbf{P}^r)$ with expectation operator $\mathbb{E}^r$ and variance operator Var^r. We also have arrival times $\{T^{r,j}\}_{j \in \mathbb{N}}$, a state descriptor $\mathcal{Z}^r$ and processes $W^r, Q^r, \mathcal{V}^r$.

A diffusion scaling is applied to each model in the $\mathcal{R}$-indexed sequence as in (1). Furthermore, for each $r \in \mathcal{R}$ and $t \geq 0$, let

$$\hat{\Phi}^r(t) = \frac{1}{r}(\Phi^r(\lfloor r^2 t \rfloor) - \lfloor r^2 t p^r \rfloor).$$

Let $\alpha_\Sigma, a_\Sigma \in (0, +\infty)$ and define $\alpha_\Sigma(t) = \alpha_\Sigma t$, $t \geq 0$, $p = (p_1, ..., p_k) \in (0,1)^K$, $\sum_{k \in \mathcal{K}} p_k = 1$. We make the following asymptotic assumptions for the sequence of stochastic primitives. Assume that as $r \to \infty$,

$$\alpha_\Sigma^r \to \alpha_\Sigma, \qquad a_\Sigma^r \to a_\Sigma, \qquad p^r \to p, \qquad \hat{E}_\Sigma^r \Rightarrow E_\Sigma^*, \tag{42}$$

where E_Σ^* is a Brownian motion starting from zero with drift zero and variance $a_\Sigma^2 \alpha_\Sigma^3$ per unit time. Moreover, we assume that $\nu^r = \nu$, i.e., ν^r does not depend on r.

We will now determine the limits of processes $\hat{\Phi}^r$ and $\hat{E}^r$ as $r \to \infty$. We first apply Proposition 1 to the processes $\hat{\Phi}^r = \left(\hat{\Phi}_k^r, r = 1, ..., K\right)$. Fix $k \in \mathcal{K}$. For each $r \in \mathbb{R}$, $\{\varphi_{i,k}^r\}_{i \in \mathbb{N}}$ are independent Bernoulli distributed random variables such that $\mathbf{P}^r(\varphi_{i,k}^r = 1) = p_k^r$. Hence $\mathbb{E}^r \varphi_{i,k}^r = p_k^r$ and $\mathrm{Var}^r\ \varphi_{i,k}^r = p_k^r(1 - p_k^r)$. Using the fact that $p_k^r \to p_k$ and Proposition 1, we obtain

$$\frac{1}{r} \left(\sum_{i=1}^{\lfloor r^2 t \rfloor} \varphi_{i,k} - \lfloor r^2 t \rfloor p_k \right) \Rightarrow \Phi_k^*, \ r \to \infty, \tag{43}$$

where Φ_k^* is a Brownian motion starting from zero with drift zero and variance $p_k(1 - p_k)$ per unit time. By using the Cramer-Wold device, multidimensional central limit theorem and Prohorov theorem, we can generalize this to joint convergence $\hat{\Phi}^r \Rightarrow \Phi^*$, where Φ^* is a K-dimensional Brownian motion starting from 0 with drift 0 and covariance matrix $C = [c_{ij}]_{i,j}$ such that $c_{ii} = p_i(1 - p_i)$, $c_{i,j} = -p_i p_j$ for $i \neq j$ (cf. [26], proof of Theorem 4.3.5). Moreover, this convergence is joint with (42) and Φ^* is independent of E_Σ^*.

[1] As we will see, this is a special case of the approach considered in Sections 1-4, with the exogeneous arrival process E having dependent coordinates.

Now we use Proposition 1 again to obtain the limit of the process $\hat{E}^r = \left(\hat{E}^r_k, r = 1, ..., K\right)$. Fix $k \in \mathcal{K}$. Observe that

$$\hat{E}^r_k(t) = \frac{\Phi^r_k\left(E^r_\Sigma(r^2t)\right) - r^2t\alpha^r_\Sigma p^r_k}{r}.$$

Therefore, by Proposition 1, $\hat{E}^r_k \Rightarrow E^*_k$, where $E^*_k(t) = \Phi^*_k(\alpha_\Sigma t) + p_k E^*_\Sigma(t), t \geq 0$. Note that E^*_k is a Brownian motion starting from 0 with drift 0 and variance per unit time $\alpha_\Sigma p_k(1-p_k)+p_k^2\alpha_\Sigma^3 a_\Sigma^2$. Therefore, by an analogous argument as in the previous paragraph, we obtain joint convergence $\hat{E}^r \Rightarrow E^*$, where $E^*(t) = \Phi^*(\alpha_\Sigma t) + pE^*_\Sigma(t), t \geq 0$. Note that E^* is a K-dimensional Brownian motion starting from 0 with drift 0 and covariance matrix $D = [d_{ij}]_{i,j}$ such that $d_{ii} = p_i^2 a_\Sigma^2\alpha_\Sigma^3 + \alpha_\Sigma^2 p_i(1-p_i)$, $d_{ij} = \mathrm{Cov}(\Phi^*_i(\alpha_\Sigma) + p_i E^*_\Sigma(1), \Phi^*_j(\alpha_\Sigma) + p_j E^*_\Sigma(1)) = p_i p_j a_\Sigma^2 \alpha_\Sigma^3 - \alpha_\Sigma^2 p_i p_j$, $i \neq j$.

Before we proceed, we present a general property of the SRPT protocol, which will be used in the following proofs.

Lemma 1. *Consider a single-server queueing system with customers served according to the SRPT protocol. Let $t \geq 0$ and let i, j be two jobs present in the system at time t with initial processing times v_i, v_j and residual processing times $w_i(t), w_j(t)$ respectively. Then the intervals $(w_i(t), v_i)$ and $(w_j(t), v_j)$ are disjoint.*

Proof. Suppose that $(w_i(t), v_i) \cap (w_j(t), v_j) \neq \varnothing$. First, consider the case when neither of the intervals is a subset of the other. Without loss of generality we may assume that $w_i(t) \leq w_j(t) < v_i \leq v_j$, thus $(w_i(t), v_i) \cap (w_j(t), v_j) = (w_j(t), v_i)$. This means that the job j, even though its initial processing time was not less than v_i, was partially served so that its residual processing time is lower than the initial processing time of the job i. Since the system uses the SRPT protocol, this is possible only when $v_i = v_j$ or when i arrived after j. In the first case, the start of the processing immediately breaks the tie so i cannot be partially processed before j gets fully serviced, thus $w_i(t) = v_i$ and therefore this case is impossible. In the second case, let t_1 be the time of the arrival of the job i. If $w_j(t_1) > v_i$, then for any $t \geq t_1$ the job j could only be chosen for processing after i had been fully serviced, which means that this case is impossible. If $w_j(t_1) \leq v_i$, then for any $t \geq t_1$ the job i could only be chosen for processing after j is fully serviced, which means that this case is impossible as well.

Finally, consider the case when one of the intervals is a subset of the other. Without loss of generality we can assume that $w_j(t) \leq w_i(t) < v_i \leq v_j$. Arguing as above, we can obtain that this is also impossible. This leads to a contradiction, therefore the intervals $(w_i(t), v_i)$ and $(w_j(t), v_j)$ are disjoint. □

We are now ready to formulate the main theorem in the case under consideration.

Theorem 2. *Let $x^* < \infty$, $\nu_\Sigma(x^*) = 0$. Assume that for every $k \in \mathcal{K}$ the limit*

$$\gamma_k = \lim_{x \uparrow x^*} f_k(x), \tag{44}$$

where f_k is the Radon–Nikodym derivative of the measure ν_k with respect to ν_Σ, exists. Under the assumptions of this section, we have that, as $r \to \infty$,

$$\left(\hat{\mathcal{Z}}^r_k, k = 1, ..., K\right) \overset{fd}{\to} \left(p_k\gamma_k \frac{W^*_\Sigma}{x^*}\delta_{x^*}, k = 1, ..., K\right). \tag{45}$$

Proof (somewhat heuritstic). We first show that

$$\hat{\mathcal{Z}}^r_\Sigma \Rightarrow \frac{W^*_\Sigma}{x^*}\delta_{x^*},\ r \to \infty. \tag{46}$$

and that, for any $x \in (0, x^*)$

$$\left\langle \mathbb{I}_{[0,x)}, \hat{\mathcal{Z}}^r_\Sigma(t) \right\rangle \Rightarrow 0, \quad \left\langle \chi\mathbb{I}_{[0,x)}, \hat{\mathcal{Z}}^r_\Sigma(t) \right\rangle \Rightarrow 0,\ r \to \infty. \tag{47}$$

This is done similarly as in the first part of the proof of Theorem 1.

Fix $t > 0$ and $\varepsilon > 0$. Let $\{i^r_j\}_j$ be the sequence of jobs present in the system r and having residual processing time in $(x^* - \varepsilon, x^*]$ at time t, i.e. such that $w^r_{i_j}(t) > x^* - \varepsilon$. In what follows, we will simply write i_j instead of i^r_j when the system in question can be inferred from the context. Let $n^r(t)$ be the number of such jobs (of all classes) in the rth system at time t. Notice that

$$\sum_{j=1}^{n^r(t)} v^r_{i_j} \geq W^r_\Sigma(t) - \left\langle \chi\mathbb{I}_{[0,x^*-\varepsilon]}, \mathcal{Z}^r_\Sigma(t) \right\rangle. \tag{48}$$

We claim that

$$\sum_{j=1}^{n^r(t)} v^r_{i_j} \leq W^r_\Sigma(t) - \left\langle \chi\mathbb{I}_{[0,x^*-\varepsilon]}, \mathcal{Z}^r_\Sigma(t) \right\rangle + \varepsilon. \tag{49}$$

Indeed, by Lemma 1, the intervals of the form $(w^r_{i_j}(t), v^r_{i_j})$ are pairwise disjoint. All of these intervals are contained in $(x^* - \varepsilon, x^*]$ by the definition of the sequence $\{i^r_j\}_j$, therefore the sum of their lengths cannot exceed ε.

By (5) and (47)-(49) we obtain that as $r \to \infty$[2]

$$\frac{1}{r}\sum_{j=1}^{n^r(r^2t)} v^r_{i_j} \Rightarrow W^*_\Sigma(t). \tag{50}$$

Observe that for $r \in \mathcal{R}$ and almost every (with respect to ν_Σ) $x \in (x^* - \varepsilon, x^*)$

$$\begin{aligned} &\mathbf{P}^r(\varphi^r_i = e_k | v^r_i = x) \\ &= \frac{\mathbf{P}^r(\varphi^r_i = e_k)}{\mathbf{P}^r(v^r_i = x)} \cdot \mathbf{P}^r(v^r_i = x | \varphi^r_i = e_k) \\ &= p^r_k f_k(x). \end{aligned} \tag{51}$$

Consider the sequence $\{v^r_{i_j}\varphi^r_{i_j,k}\}_j$. Obviously $\varphi^r_{i_j,k} = 1$ if the job i^r_j belongs to the class k and $\varphi^r_{i_j,k} = 0$ otherwise. Similarly as before we can show that the limits of $\hat{W}^r_k(t)$ and $\frac{1}{r}\sum_{j=1}^{n^r(r^2t)} v^r_{i_j}\varphi^r_{i_j,k}$ coincide. By (47) and the fact that $Q^r_\Sigma(t) = n^r(t) + \left\langle \mathbb{I}_{[0,x^*-\varepsilon]}, \mathcal{Z}^r_\Sigma(t) \right\rangle$ we obtain that as $r \to \infty$

$$\hat{n}^r(t) := \frac{1}{r}n^r(r^2t) \Rightarrow Q^*_\Sigma(t) = \frac{W^*_\Sigma(t)}{x^*}. \tag{52}$$

[2] In the context of diffusion scaling, we define the sequence $\{i_j\}_j$ for time r^2t instead of t.

If $n^r(r^2t)$ is of the order less than r, then by (47)-(48) and the bound $v_i \leq x^*$ for all i, $\hat{W}^r_\Sigma(t)$ is asymptotically negligible. On the other hand, if $n^r(r^2t)$ is large, using the law of large numbers, we get,

$$\frac{1}{n^r(r^2t)}\sum_{j=1}^{n^r(r^2t)} v^r_{i_j}\varphi^r_{i_j,k} \approx \frac{1}{n^r(r^2t)}\sum_{j=1}^{n^r(r^2t)} \mathbb{E}^r\left(v^r_{i_j}\varphi^r_{i_j,k}\right) \tag{53}$$

and by (51), (44),

$$\begin{aligned}\mathbb{E}^r\left(v^r_{i_j}\varphi^r_{i_j,k}\right) &= \int_{x^*-\varepsilon}^{x^*} u\mathbf{P}^r(\varphi^r_{i_j} = e_k | v^r_i = u)dF^r_j(u) \quad (54)\\ &= p^r_k\int_{x^*-\varepsilon}^{x^*} uf_k(u)dF^r_j(u)\\ &= p^r_k(\gamma_k + o(1))(x^* + O(\varepsilon)),\end{aligned}$$

where F^r_j is the distribution function of $v^r_{i_j}$ and $O(\varepsilon) \in [-\varepsilon, 0]$. Therefore, from (52)-(54) and (42) it follows that, as $r \to \infty$, any weak limiting distribution of a subsequence of the sequence

$$\frac{1}{r}\sum_{j=1}^{n^r(r^2t)} v^r_{i_j}\varphi^r_{i_j,k} = \frac{\hat{n}^r(r^2t)}{n^r(r^2t)}\sum_{j=1}^{n^r(r^2t)} v^r_{i_j}\varphi^r_{i_j,k}$$

is stochastically bounded from below by the distribution of

$$p_k\frac{W^*_\Sigma}{x^*}(\gamma_k(x^*-\varepsilon) + o(1))$$

and stochastically bounded from above by the distribution of

$$p_kW^*_\Sigma(\gamma_k + o(1)).$$

By letting $\varepsilon \downarrow 0$ and taking (46), (50) into account we obtain the desired breakdown and convergence of one-dimensional distributions. It is easy to extend this result to convergence of finite-dimensional distributions.

□

VI. Simulations

In this section we present the results of our computer simulations. We simulated the system described in Section II with two user classes. The times between arrivals of jobs of each class are exponentially distributed with parameters α_1, α_2 correspondingly.

We first consider the case when $\nu_\Sigma(x^*) > 0$. We assume that $\alpha_1 = 0.25$, $\alpha_2 = 1.25$. Hence $\alpha_\Sigma = 1.5$. The initial service times of the first class take the values $0.5, 1, 1.5$ with equal probabilities and the initial service times of the second class take the values $0.2, 0.3, 0.4, 0.6, 1.5$ with equal probabilities. Then we have $x^* = 1.5$, $\rho = 1$, $p_1 = 1/6$, $p_2 = 5/6$, $\nu_\Sigma(1.5) = 2/9$ and $p_1\nu_1(1.5)/\nu_\Sigma(1.5) = 1/4$. We assume that there are no customers in the system at time 0. The results of the simulation in this case are shown in Fig. 1.

Let us add an initial condition consisting of 25 jobs in each of two classes, with the same service time distributions as jobs arriving in the system in the corresponding class. Notice that their workloads are not even approximately distributed according to the asymptotic proportions stated in Theorem 1. The results are shown in Figure 2.

Now, let us change the initial condition. It still consists of 25 jobs in each class, but their processing times are distributed uniformly on $[0, 3]$, which is even further from the assumptions on the initial condition in Theorem 1. The results are shown in Fig. 3.

Now let us consider the case when $\nu_\Sigma(x^*) = 0$. Assume that $\alpha_1 = 1$, $\alpha_2 = 0.6$. Then $\alpha_\Sigma = 1.6$. The initial service times are uniformly distributed in the interval $[0, 1]$ and $[2/3, 1]$ correspondingly. This gives us $x^* = 1$, $\rho = 1$, $p_1 = 0.625$, $p_2 = 0.375$, $\gamma_1 = 4/7$ and $p_1\gamma_1 = 5/14 \approx 0.357$. We assume that there are no customers in the system at time 0. The results are shown in Fig. 4.

We add an initial condition consisting of 25 jobs in each of two classes, with the same service time distributions as jobs arriving in the system in the corresponding class. The results are shown in Fig. 5.

Let us summarize the results. In Fig. 1 we can observe in the left chart that the proportion of workload of class 1 to the total workload in the system stabilizes at $p_1\nu_1\left(\frac{3}{2}\right)/\nu_\Sigma\left(\frac{3}{2}\right) = 1/4$ after a long time has passed, which confirms that Theorem 1 holds true. Moreover, we can notice that the blue graph in the right chart illustrating the predicted workload of class 1 obtained by applying Theorem 1 “lies close” to the red graph presenting the actual workload of class 1. The prediction at a given time is more accurate, if there are more tasks in the system at this time.

Adding an initial condition in the simulation in Fig. 2 does not noticeably change the situation, even though at time 0 a large amount of workload is not distributed between the two classes according to the proportions required by the assumptions in Theorem 1. We can also observe less instability in the left chart, since with such a number of initial tasks the queue lengths remains at higher levels, where the proportions are more stable. However, in Fig. 3 we can see that an initial condition consisting of tasks greatly different from those arriving in the system results in a notably slower convergence. While the decreasing trend is still visible in the left chart, it is very small in magnitude and in the simulated time horizon the system did not manage to stabilize. Therefore, applying Theorem 1 to predict the proportion of class 1 workload to the total workload in the system gives us an inaccurate approximation and the assumptions for the initial conditions cannot be omitted.

In Fig. 4-5 we can see that if $\nu(x^*) = 0$, we also obtain similar results as above and can make analogous observations. This indicates that Theorem 2 (and even its generalized form, without assuming a zero initial condition) holds true.

VII. Conclusion

In this paper, we have proved a diffusion limit theorem for the measure-valued state descriptor for a single-server queuing system with multiple job classes and bounded processing times of arriving jobs. In particular, we have shown that, under suitable assumptions, the workload and the queue length in the

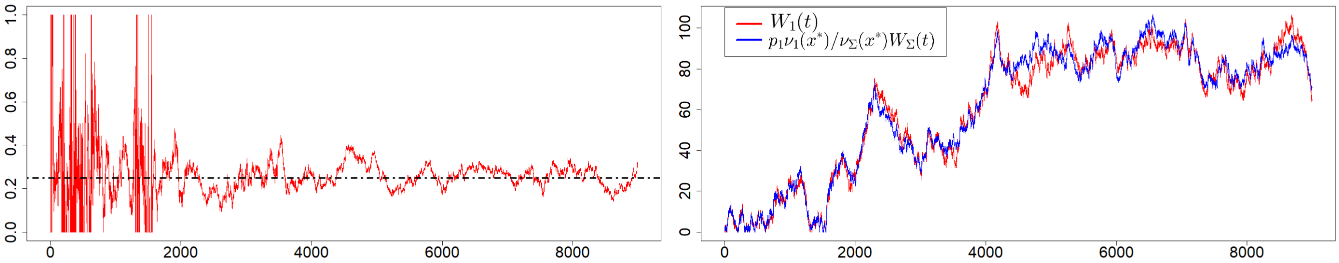

Fig. 1. Simulation in the case of $x^* < \infty, \nu_\Sigma(x^*) > 0$. The left chart illustrates the proportion of workload of class 1 to the total workload in the system as a function of time. The right chart presents the predicted workload of class 1 obtained as a result of applying Theorem 1 (blue) and the actual workload of class 1 (red).

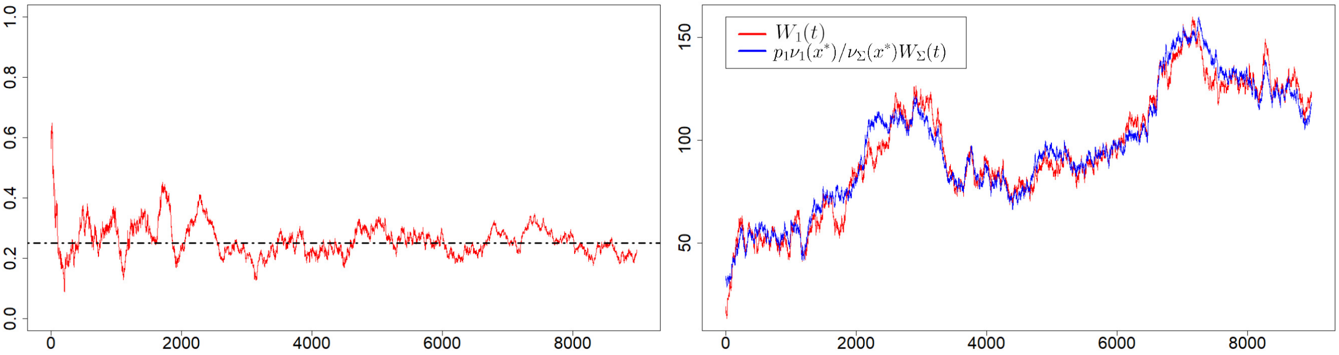

Fig. 2. Simulation in the case of $x^* < \infty, \nu_\Sigma(x^*) > 0$ with a non-zero initial condition. The interpretations of charts is the same as in Fig. 1.

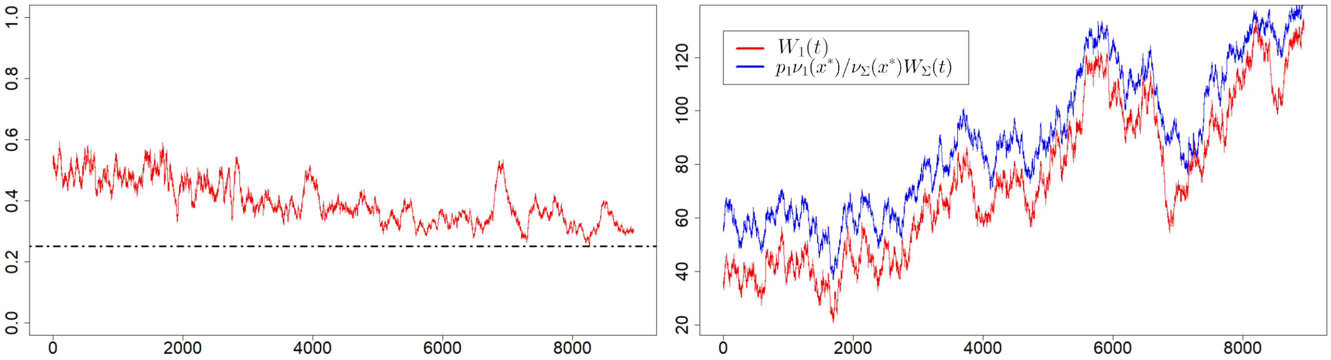

Fig. 3. Simulation in the case of $x^* < \infty, \nu_\Sigma(x^*) > 0$ with a different initial condition.

diffusion limit are divided between these classes according to specific proportions. This result can be applied in practice – it can be used to approximate proportions between workloads of different classes in the long run. The simulations presented in the last section indicate that it should be possible to further generalize Theorem 2 by removing the zero initial condition requirement.

***Abstract*—The Planning and Scheduling (PS) problem plays a vital role in several domains, such as economics, military, management, finance, and games, where finding the optimal plan and schedule to achieve specific goals is essential. In this article, we present a Genetic Algorithm for the Planning and Scheduling (GAPS) problem in the StarCraft II Build Order Optimization problem (SC2 BO) context – as it signifies that modern strategy games present a more challenging environment than classical planning problems. We evaluate the performance of GAPS and compare it with state-of-the-art methods. Experimental results provide valuable insight into the effectiveness of GA in the context of the PS Problem under various configurations, notably in the context of Lamarckianism and the Baldwin Effect. Ultimately, this research enhances the understanding of GA application for the PS problem, offering notable insights regarding GA performance and potential for future work.**

I. Introduction

A *PLANNING* problem involves creating a series of strategic steps to achieve a specific goal. It often encapsulates order and conditions under which various actions must be performed while simultaneously factoring uncertainty, resources, and goals of a given problem instance. *Scheduling* is a decision-making process that manages the allocation of resources over time. Its primary objective is to optimize specific performance metrics, typically total completion time, often called *makespan*. Therefore, planning and scheduling problems could be described as determining the optimal sequence of actions to achieve specific goals in the most time and resource-efficient manner. Despite a long history of research into these problems, the need for solutions persists due to the consistent emergence of new challenges and their increasing complexity. Planning and scheduling apply to diverse real-world applications, including manufacturing, pathfinding, logistics, management, space exploration, telecommunications, economics and games (i.e. economic or computer ones).

This article aims to solve the planning and scheduling problem in the context of the economic development aspect in the StarCraft II (SC2) strategy game, in this area known as *Build Order Planing*.

In the following sections, we will provide the state-of-the-art analysis (Sec.II), define the exact problem (Sec.III), and present the proposed approach (Sec.III) and experimental results (Sec.IV) that describe the application of Genetic Algorithm (GA) to *Build Order Planing*. The last sections of the paper consist of conclusions (Sec.V) and future works (Sec.VI).

II. Related Work

A. Build Order-Planning

As described in the [5], Build Order Planning or Build Order (BO) optimization is a class of Automated Planning problems that arise in a video game genre called real-time-strategy (RTS). It is a process of finding the sequence (order) of actions to be made by the player to achieve a specific goal in the shortest makespan. This goal depends on the exact scenario and larger strategy, but it can be associated with creating a certain number of military units or gathering the precise amount of resources. Individual RTS games differ, but the basics are mostly similar. The player performs a series of actions like collecting resources, developing a base, and training military units, all in order to gain an advantage over the opponent and finally defeat him. Mentioned actions can be divided into two groups: strategical level actions (*macro*) and tactical level actions (*micro*). In this paper, we discuss a sequence of the macro actions only - called Build Order.

In the context of the SC2 game, simple build-order solutions, such as a quick attack with a small number of military units, may be countered easily by building defensive structures whose overall cost is lower compared to the cost of the attack. Therefore, engagement benefits the defending side. On the other hand, a defensive stance is disadvantageous against economic development, as it will overtake the defending player in the long term. Finally, development focus can be easily countered by an aggressive strategy (known as 'early rush'), which closes the cycle. Based on this stone-paper-scissors-like dynamic, both players can change their focus during a game to gain an advantage against the opponent. Selecting goals and switching them in-game time is a separate subject that can be described by a high-level strategy Artificial Intelligence (AI) system as described in [1]. We can imagine it as a sort of manager that dictates the overall strategy goal, however, the problem of determining the plan for achieving this goal in the most efficient manner is the subject of the presented research.

RTS games are interesting application domains for AI researchers because of the huge state spaces and concurrent actions. The most common instance of BO application in games is StarCraft (published by Blizzard Entertainment), a popular RTS game with over 10 million copies sold. StarCraft has received over 50 industry awards, including over 20 "Game of the Year" awards. It is considered the so-called e-sports game, as each player has the same chances at the beginning, does not contain random elements, and the result depends solely on the player's skill. As StarCraft (and its sequel - StartCraft II) is the most commonly used case, multiple other RTS games are known for the importance of early game build order. Such games as Age of Empires or Company of Heroes are worth mentioning. For the all mentioned real-time games, an important factor is the speed of action execution and fast reaction time. However, this is not an essential aspect of defining the BO problem. Turn-based games also make a good example.

BO-solving methods can be used to support players or design demanding opponents for games. It can also help with game balancing and exploit detection. For instance, when there are several civilizations (or races) to choose from, they should compete on a similar level. The existence of a specific action sequence that makes a civilization significantly stronger than the others is considered a product defect. The ability to simulate and detect it at an early stage of development is a significant improvement compared to the process of lengthy manual tests common in the game-development industry.

Authors of the [6] suggest that historically studied economic games such as Prisoner's Dilemma (where tit-for-tat derives) or Cournot Production games are far more streamlined in comparison to modern RTS games. In a broader look at this application, simulations of systems implemented in games refer to economic mechanisms known from the real world. An exemplary generalization can be interpreted as the optimization of the company's development strategy or even the investment strategy, where subsequent decisions depend on the results of previously taken steps. To support this assumption, Cobb-Douglas (CD) model presented in [14], has been applied by Webel et al. in [6] to the modern RTS game StarCraft: Brood War, where worker units gather resources, build infrastructure, and eventually lead to the construction of combat units. The winner of the game is the last one with a standing structure.

As suggested in [1], BO is an instance of a temporal planning problem. Temporal planning recognizes that actions take a certain amount of time to execute and acknowledges that multiple actions can occur concurrently under specific circumstances. For example, certain actions may have specific temporal requirements, such as waiting for a resource to become available or ensuring that one action finishes before another can start. By treating BO as a temporal planning problem, the planning process becomes more realistic and aligned with real-world scenarios than in the classical planning approach, which is streamlined, instantaneous, and does not consider actions interacting with each other.

To further emphasize treating planning in RTS games as a formal problem, Buro et al. in [1] present a study on the optimization of build order strategies in real-time strategy (RTS) games, highlighting the potential of using the Planning Domain Definition Language (PDDL) for modeling these problems. PDDL presented in [8] is a language utilized in automated planning competitions to standardize the description of planning domains and problems, enabling diverse planners to compete against each other. The authors of [1] also discuss the issue of concurrent execution and propose efficient mechanisms for ordering actions within the build order domain of RTS games. However, it is worth noting that even the most recent version of PDDL does not support object creation or deletion, which is essential in RTS games where object creation plays a vital role. While it is possible to simulate them implicitly within the language, it signifies that modern strategy games present a more challenging environment than classical planning problems.

Wei et al. in [3] were the first to address the BO problem as Planning and Scheduling problem with Producer/Consumer constraints. This attempt to mathematically model and approximate the BO problem is further supported by Blackford et al. article [5] about build order optimization in a multi-objective approach.

B. Methods

Several approaches to solving planning and scheduling problems exist in the literature, such as Ant Colony Optimization [13], Graph Search [5, 2], Stochastic Search [11], Evolutionary Algorithm [4, 2] and Machine Learning [9, 3].

Churchill et al. in [5] introduced a depth-first branch-and-bound algorithm (BnB) to address initial build orders in StarCraft. The authors implemented a tree search, with the root representing the initial game state, and conducted a depth-first exploration to identify an optimal solution. This solution aims to meet the goal within the shortest possible makespan. While it is possible to validate found build orders in the game environment, this approach is time- and resource-intensive. To address this challenge, the authors suggested developing a StarCraft economic simulator to measure the value of build orders effectively.

El-Nabarawy et al. in [11] implemented a Monte Carlo Tree Search (MCTS) based on a StarCraft mini-game called BuildMarines the goal is to find build orders that can provide players with a larger amount of Marines military units in a fixed amount of time. Both methods have significantly lower action space, and although they may be effectively applied to smaller problems, they differ from the efficiency and speed of evolutionary algorithms and machine learning techniques. The comparison of these methods has been described in the experiments section to support this claim further.

In the context of Evolutionary Algorithms (EA), Justesen et al. in [2] has successfully implemented the evolutionary-based method of Continual Online Evolutionary Planning (COEP) for build order optimization. The goal was to create a game agent that can, in-game time, find build orders that counter opponents' movements, also utilizing the BO simulator for evaluation. The fitness function is based on a heuristic that can describe how desirable founded BO is. Heuristic values short-term rewards higher than long-term rewards, which are very important in game planning agents because long-term build orders can provide the agents with optimal strategy and powerful armies, which are easier to counter by opponents.

Blackford et al. implement a multi-objective evolutionary algorithm (MOEA) detailed in their work [4] for the Total Annihilation RTS game. The multi-objective approach is advantageous because solutions evolve to satisfy different goals, and the algorithm does not find just one solution but a set of different solutions, each potentially providing different strategic advantages.

Another significant implementation of a machine learning-based game agent was achieved in the form of AlphaStar [9] for StarCraft II. This sophisticated AI has the capability to generate valid build orders dynamically during gameplay.

Liu et al. in their work [10] used a reinforcement learning technique to create a low-cost StarCraft II agent and suggested that on a larger scale, this technique could create a better agent using fewer resources. Although machine learning-based methods show immense potential in solving BO problems, they require considerable resources and time to develop a functioning model and, once created based on a problem, cannot be easily applied to another similar problem. Conversely, Genetic Algorithms (GA) only necessitate game data and a build order evaluation method to produce valid build orders. It makes GA a more universally applicable solution for these types of problems. GA can also be deployed within build orders for game balancing, which is a complex problem.

For the above reasons, we implement the Genetic Algorithm in our research. As for reference methods, we propose those mentioned earlier, specifically the ones proposed by Justesen et al. as cited in [2], the COEP method configuration (COEPc), and the method proposed by Blackford et al. in [4], MOEA method configuration (MOEAc). In addition, we will present an application of the Genetic Algorithm in comparison to approaches based on Branch and bound (BnB) and Monte Carlo Tree Search (MCTS) methods, as cited in [5, 11].

III. Problem Definition and proposed Method

A. Planning and Scheduling Problem Definition

We generalize the SC2 BO problem using Planning and Scheduling (PS) problem with Producer/Consumer constraints based on [4] work.

The planning aspect of the problem involves determining which actions need to be performed to achieve a certain goal G. The scheduling aspect, on the other hand, describes the timing of action execution with consideration to available resources R and minimizing the overall completion time of all actions $a \in A$, called makespan. Solution $s \in SP$ where SP is a solution space could be described by a vector of actions a as follows:

$$s = [a_0, a_1, ..., a_{n-1}] \tag{1}$$

where n is the solution size. The solution s changes the initial game state S^a into desired state of S^x (see Eq.2).

$$S^a \xrightarrow{a_0} S^b \xrightarrow{a_1} ... \xrightarrow{a_{n-1}} S^x \tag{2}$$

Every considered action a_x has a set of certain prerequisite conditions of execution. These prerequisites are described by resources $r \in R$. Wei et al. in [3] for the PS problem, distinguish two categories: Consumable, Renewable; and four types of resources: Consume, Produce, Borrow, and Require.

- **Consumable**
  - Consume - action can consume a specific amount of resources, for example, the cost of creating a wall (structure) in SC2 is: 100 gold, and 50 wood, so the action of making a wall would consume 100 gold and 50 wood.
  - Produce - action usually after completion provides a game environment with some kind of good (produces it). This good can be a soldier, building, research, or any other environmental element that changes the game state, but generally, we can define it as some kind of resource.
- **Renewable**
  - Borrow - action can borrow certain resources during execution time, for example in SC2 game, the action of creating a Zealot army unit needs to use Gateway building, Gateway can produce only one unit at a time, so it is borrowed by action to create Zealot action.
  - Require - a type of resource that multiple actions at the same time might require. For example, action mine coal borrows one miner and requires the mine to execute. However, in mine multiple miners can work so the resource is shared and now borrowed.

Note that given resources can belong to two or more types. For example, the SC2 Gateway building can be borrowed and produced. The list of resources associated with an action can be defined as a_R. For instance, in the action of creating a military unit a, a_R consists of consuming 100 gold and borrowing barracks for the production of the unit as follows: $a_R = \{100\ gold, barracks, null, military\, unit\}$

B. Constraints

To consider the build order a *feasible* solution, it is imperative that the set of constraints C is satisfied, which also limits SP.

Cumulative Producer/Consumer constraint refers to Consumable resources. It requires that when two actions are planned to occur simultaneously, the combined resources they need should not exceed the available quantity of those resources. For example, creating two Zealots (units) at the same time requires 200 crystals, 2 Gateways, and 4 supply consumption. Constraint can be expressed as:

$$\forall_{a \in s}\ a_R^t \leq T^t \tag{3}$$

where s is solution, a_R^t are resources required by the a action in time t and T is the total amount of resources available in time t.

Disjunctive constraint refers to borrowed resources, it states that for a pair of actions competing for execution at the same time. The constraint is satisfied when these actions do not overlap, and thereby the integrity of the system process is maintained. Constraint can be expressed as:

$$\forall_{(i,j)\in s^2, i\neq j}\ (i_{end} \leq j_{start}) \vee (j_{end} \leq i_{start}) \tag{4}$$

where pair $(i,j) \in s^2$ is every pair of two different actions that can be extracted from s. As a_{start} and a_{end}, we describe the start and end time of executing action a, respectively.

Exist constraint refers to Required resources. It states that certain resources must exist in order for action to execute. An example of an existing constraint in the context of SC2 could be Stalker army unit which we can not build until we build Cybernetics Core building. Constraint can be expressed as:

$$\forall_{a\in s}\forall_{r\in \text{exist}(a_R)}\ a_{start} \leq t \leq a_{end} \wedge r \in T^t \tag{5}$$

where $exist(a_R)$ is a subset of action a resource set a_R that contains only resources which must exist in order to execute action a. Resource r is not consumed.

According to the above definition, the problem could be defined as:
Given: $< G, R, C, A, S^a >$,
interpreted as follows. To find: Solution s that fulfills goal G in the shortest possible makespan, starting from state S^a, using resources R, considering only actions present in A, satisfying all constraints C.

C. SC2 BO problem as PS problem

SC2 is a strategic game that allows players to embody one of three distinct races, each differing in units, structures, and strategies. For our research purposes, we have selected the Protoss race, an advanced, alien-like race within the game. We denote the initial state S^a as a typical SC2 start state for the Protoss race, which includes the following resources: 50 crystals, 1 Nexus, 12 Probes, and a supply capacity of 15. Probes function as worker units that accumulate crystals at the Nexus base. These Probes have the capability to construct buildings, such as the Pylon, which not only increases the supply capacity but also permits the construction of more specialized buildings within its energy field. One such building is the Gateway, which facilitates the creation of basic military units, like the Zealot. In this context, we categorize actions like creating a Probe, constructing a Pylon or Gateway, or building a Zealot as macro actions, which is typical for SC2 BO. While we take into account all possible macro actions of Protoss race in our research, we will not delve into each one individually due to their sheer number.
To present SC2 BO as the PS Problem, the set of metrics $m \in M$ should be defined as follows:

- m^0 - total completion time,
- m^1 - total build cost of workers,
- m^2 - total build cost of the army,
- m^3 - total research cost,
- m^4 - total cost of defensive buildings.

The goal G within the SC2 BO context is represented as an *objective vector* $O = [m^1, m^2, m^3, m^4]$ comprising non-negative integer value. Assigning values on the vector positions defines exact scenarios. Each value within this vector can range from 0 to the maximum possible value of each metric m. However, m^0 is the total completion time of all actions in solution s extracted after BO simulation, which will be discussed later.

Based on each metric defined in vector O, we can divide the action space A into four distinct subsets, each containing actions that contribute solely to one specific objective metric value. This arrangement allows the given method to utilize every action in the game during the optimization process.

To address the scheduling aspect of the issue, we adopt a model based on the rule that each action is executed as swiftly as possible, under the condition of all prerequisites are met. For instance, if the task involves constructing two Zealots, this task will be executed concurrently if a sufficient amount of resources is available. It is the responsibility of the method to order actions in such a way that the arrangement is optimal in the context of the addressed rule. This model is adopted by a SC2 game simulator that conducts BO simulations. To acknowledge the need for the delay before executing certain actions, we propose *None* action, which will force a delay for the next action execution by a fixed amount of seconds.

The given definition allows the construction of solution $s \in SP$ (alternatively referred to as BO), where SP is the solution space, described by an ordered list of integers, each of which maps to a specific BO action in SC2 (an example presented in Figure 1).

In this paper, we engage with the complete action space of the Protoss race, which comprises 59 actions plus one additional *None* action. Each race in the game encapsulates actions space A of around 60 actions. In the case of the Protoss race, which we choose as the base for our research, the initial game state permits the execution of four possible actions. Notably, certain actions can expand the list of potential actions, making the explicit determination of the solution space a considerable challenge. Nevertheless, it's possible to estimate the entire set of potential genotypes by utilizing the length of the build order. This concept can be formally encapsulated in the following equation:

$$x = a^n \tag{6}$$

Here, n represents the size of the build order, a stands for the total size of the action space, and x signifies the complete number of genotypes – a similar representation is presented in [12]. For a comprehensive problem definition, particularly within the context of a BO problem, we need to define the size of the build order solution n. We will address size n in Sec.IV-B.

Finally, we define the evaluation function E, which value is to be minimized by the optimization method, as a function of end state S^x and objective vector O provided by simulator

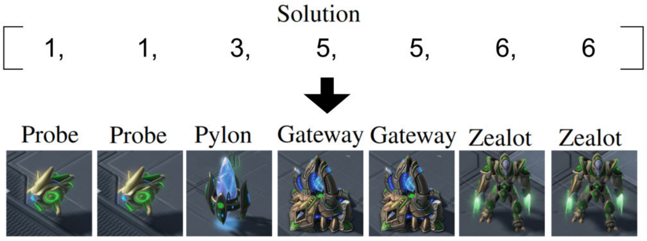

Fig. 1. The example solution – genotype (i.e. solution) presented as list of integer is mapped to list of SC2 actions

from all actions a in a given solution s. If the solution does not fulfill the objective described by the objective vector, we add a penalty for every metric m objective that is not fulfilled. E can be presented as the formula:

$$E(S^x, O) = S^{x^{m^0}} + \sum_{m \in M, m \neq m^0} max(0, O^m - S^{x^m}) \quad (7)$$

where $m \in M$ is metric, O is objective vector and S^{x^m} is end game state metric m acquired by simulation. The goal value of metric m, which is part of objective vector O can be formulated as O^m. As $S^{x^{m^0}}$ we understand the game end state time metric m^0 value. The $max(a, b)$ function represents the maximum of a and b. For example, for a given objective vector:
$O = \{m^1 = 0, m^2 = 200, m^3 = 0, m^4 = 0\}$
and end state S^x:
$\{m^0 = 120, m^1 = 800, m^2 = 100, m^3 = 100, m^4 = 0\}$
is evaluated as follows:

$$\begin{aligned} E(S^x, O) &= 120 + max(0, 0 - 800) + max(0, 200 - 100) \\ &\quad + max(0, 0 - 100) + max(0, 0 - 0) \\ &= 120 + 0 + 100 + 0 + 0 \\ &= 220 \end{aligned}$$

The mechanism for extracting metric values from S^x is built upon the simulation detailed in the following section.

D. Build Order Simulator

The BO simulator is a program inspired by previous state-of-the-art implementations. It takes input parameters such as the input game state S^a, action space A, build order s, and provides the Genetic Algorithm (GA) with the output game state S^x. The output is described by solutions s in-game execution time and end state metrics S^{x^M} values. The simulator focuses only on the BO aspect of the SC2 game and does not simulate enemy players.

The program simulates every second of the game in a loop until every action in the build order is completed or timeout is reached. During the simulation, we execute actions, often concurrently. Once an action is executed, we add the provided resource to the game state. We extract metrics from the provided game state S^n for the E function when the simulation ends. The simulator loops through BO and tries to execute the current action in each time frame. If it cannot, it just skips to another time frame, so during the evolution process, we have to ensure that every build order in the population is valid.

The simulation ends with a timeout if the build order is invalid, meaning it is impossible to execute based on game rules. However, in the proposed implementation, timeout never occurs, and the simulator validates correct solutions.

Build order completion is not a deterministic process, but it can be approximated by one. For instance, the time to build a Pylon can vary based on the place we want to build it. Nevertheless, this time is often similar, so it could be approximated by a fixed amount of time. For every action that needs to significantly change the location of execution, such as creating a new Nexus base, additional time is needed for travel.

E. Genetic Algorithm for Planning and Scheduling (GAPS)

We attempt to solve Planning and Scheduling (PS) problem on the example of the StarCraft II Build Order Optimization (SC2 BO) problem using a Genetic Algorithm (see **Algorithm 1**). GA is advantageous for exploring expansive solution spaces and strategy games encapsulating complex, deterministic environments, providing an ideal ground for conducting research in this field. Therefore we name our method Genetic Algorithm for Planning and Scheduling (GAPS). We propose a straightforward solution generation method that creates valid length solutions n based on an action tree. In this tree, state S^a is the root. From there, one action is selected randomly from the list of possible options, which transitions the system to the next state. This process is repeated, updating the list of possible actions based on the actual state until the size of the created solution equals n. After initialization, each created solution is evaluated and sorted based on fitness. To evaluate build order, we employ function E as previously described. We search for optimal configuration of the rest of the operators like selection, crossover, mutation, and repair in experiments (Sec.IV).

In the context of GA, Lamarckianism gives that an individual can modify their genotype in response to their environment and subsequently pass this change on to their offspring. In contrast, the Baldwin Effect posits that individuals can make non-genetic (phenotypic) changes over their lifetime in response to their environment. Those that successfully adapt in this way are more likely to survive and reproduce. Over time, genetic changes supporting these phenotypic adaptations could become more prevalent in the population, leading to the genetic assimilation of learned traits. Applying Lamarckianism to a fixed-length Build Order (BO) is challenging, requiring solutions to be repaired without altering its length. We provide the pseudocode of our base repair function, which eliminates actions that cannot be executed (see **Algorithm 2**). We then incorporate the Lamarckian approach by filling in missing actions with a 'None' action and overriding the genotype.

We implement the Baldwin Effect by repairing and evaluating a copy of the genotype, leaving the original genotype unchanged in the population.

Algorithm 1 GAPS

```
Require: $gameState$, $actionSpace$, $solution$, $populationSize$, $generations$, $solutionSize$, $crossoverRate$, $mutationProb$
Initialize $population \leftarrow generatePopulation(...)$
for $i$ = 0 to $generations - 1$ do
    $sort(population)$
    $best = population[0]$
    Initialize $children$ as an empty list
    $children.append(best)$
    for $i$ = 0 to $populationSize - 1$ do
        $parent1$, $parent2$
        $selection(population, parent1, parent2)$;
        if $underProbabilityThreshold(crossoverRate)$ then
            $child \leftarrow crossover(parent1, parent2)$
        end if
        if $underProbabilityThreshold(mutationProb)$ then
            $child \leftarrow mutate(child)$
        end if
        $repairedSolution \leftarrow repair(child)$;
        $fitness \leftarrow evaluate(repairedSolution)$;
        $children.append(child)$
    end for
    $populaton \leftarrow children$
end for
return $population[0]$
```

Algorithm 2 Repair Algorithm

```
Require: $gameState$, $actionSpace$, $solution$
Initialize $resultBuildOrder$ as an empty list
for $i$ = 0 to $solution.buildOrderSize - 1$ do
    $action \leftarrow solution.buildOrder[i]$
    if $isActionPossible(gameState, actionSpace, action)$ then
        $resultBuildOrder.append(action)$
    end if
end for
return $resultBuildOrder$
```

IV. Experiments

In this section, all research experiments are presented to answer four research questions:

- **RQ1** - How do different genetic operators (crossover, mutation) influence the evolution process? ($a30case$)
- **RQ2** - How does GA configuration (budget, selection, crossover rate, mutation probability) influence the evolution process? ($allcases$)
- **RQ3** - How effective is GA using Lamarckianism in comparison to Baldwin Effect? ($allcases$)
- **RQ4** - How effective selected GA configuration based on previous experiments is in comparison to some state-of-the-art setups in the context of all test cases? ($allcases$)

The following sections present details and results of developed experiments to answer the above research questions.

A. Test cases

We prepared three objective scenarios for enriching experiments: $aggressive$, $balanced$, and $development$. Each scenario is divided into three problem sizes: 30, 60, and 150, where problem size describes how long action sequences we want to examine. For 9 cases, we propose objective vectors $O = [m^1, m^2, m^3, m^4]$. In the $aggressive$ scenario, the goal is to gain as much army value as soon as possible, the development scenario aims to create a strong economy, and the balanced scenario is a mix of economy, army, research, and defense; we propose values of each O based on game experience. This approach allows us to examine the algorithm's behavior in response to varying types of problems in the context of different levels of complexity.

Based on our knowledge of the game and previous manual experiments, we propose setting budgets for all examined methods corresponding to three problem sizes. Additionally, we use a short code to name each case; for instance, an aggressive problem of size 30 is labeled $a30$. The case $a30$ will serve as the base case. For the $a30$ case, we define $O = [0, 2000, 0, 0]$, meaning that, given a maximum of 30 actions, a selected method needs to identify a build order that yields an army value of 2000 in the shortest possible makespan (see Tab.I on p.7).

For testing procedures in tuning/general experiments, as default *a30* scenario is used. For methods comparison, all test cases are used.

B. Setup

All experiments were done using the computer with AMD EPYC 7H12 64-Core Processor, Ubuntu operating system, and C++20. Because of the non-determinism nature of GA, for every configuration, we repeat the experiment 10 or 30 times, depending on the experiment.

For each case scenario, we propose to examine three different solution sizes described by $n = sum(O) * 1.5\%$. For example, in the case of $a30$ we examine population sizes 60, 90, and 150. We can define the number of generations as $number\, of\, generations$ = $budget/population\, size$. Therefore we have specific problem sizes for each scenario with defined budgets. For each problem size, we have three population size/generations proportions constrained by budget. For example, in the aggressive scenario for problem size 30, we have three population size/generations proportions: 60/750, 90/500, and 150/300.

We conduct crossover/mutation experiments incorporating three standard crossovers: one-point crossover, two-point crossover, and uniform crossover. We also examine three different mutations: random, bit flip, and mixed mutation presented in COEPc. For our configuration experiment, we validate three distinct population sizes/generations proportions within a specified budget across all nine scenarios, using

TABLE I
TEST CASES – SCENARIOS

Genotype size	**Budget**	**Aggressive**	**Balanced**	**Development**
30	45000	$a30\ O = [0, 2000, 0, 0]$	$b30\ O = [1100, 1000, 250, 150]$	$d30\ O = [1500, 200, 0, 0]$
60	150000	$a60\ O = [0, 4000, 0, 0]$	$b60\ O = [2000, 1000, 400, 300]$	$d60\ O = [2200, 400, 0, 0]$
150	750000	$a150\ O = [0, 10000, 0, 0]$	$b150\ O = [3300, 1000, 250, 150]$	$d150\ O = [5500, 0, 0, 0]$

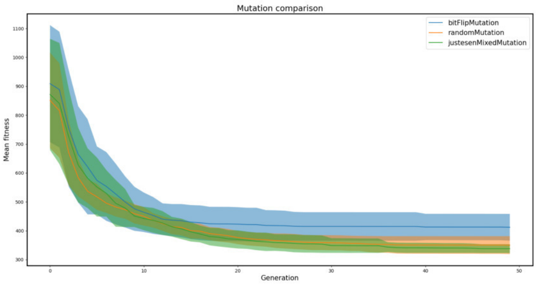

Fig. 2. Mutation comparison for $a30$

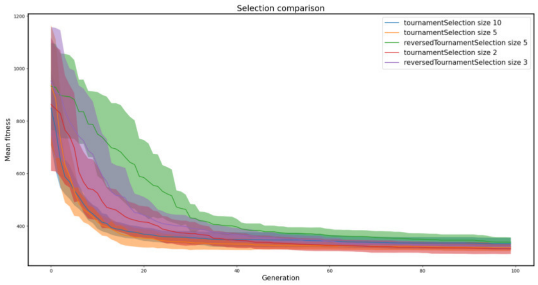

Fig. 3. Selection results for $a30$

TABLE II
MUTATION COMPARISON $a30$

Mutation type	mean	std_dev
Bit Flip	409.9	46.8
Mixed	314.3	19.2
Random	329.2	20.7

TABLE III
SELECTION COMPARISON TYPE $a30$ REPEATS

Tournament size	mean	std_dev
reversed 5	315.1	14.51
reversed 3	298.4	14.31
2	305.5	17.69
5	309.0	17.25
10	315.1	14.51

various tournament selection sizes, crossover rates, and mutation probabilities. It is important to note that mutation probability refers to the chance of applying a mutation that alters precisely one gene in the genotype, an approach inspired by state-of-the-art implementations. In addition to the standard configuration experiment, we investigate a further variant: a reverse tournament of size n that selects a parent randomly based on the $n-1$ best candidates and thus considerably lowers selection pressure.

Once we establish the GAPS configuration (GAPSc), we explore it in the context of Lamarckianism and the Baldwin Effect.

Finally, we compare GAPSc with BnB and MCTS as well as COEPc and MOEAc for a state-of-the-art comparison. State-of-the-art GA-based methods configurations:

- COEPc - random selection (best 25%), two-point crossover (crossover rate 100%), mixed mutation (probability 50%), Baldwin Effect-based repair,
- MOEAc - tournament selection (size 2), one-point crossover (crossover rate 90%), bit flip mutation (probability 100%), Baldwin Effect-based repair.

C. How does crossover/mutation influence GAPS effectiveness? – **RQ1**

The experiments with genetic operators (i.e. crossover and mutation) showed that although chosen crossover does not have much impact on the evolution, mutation can be quite vital (see Tab.II and Fig.2). The best mutation proved to be presented in COEP mixed mutation, which encapsulated four different mutations where each can be applied to created offspring. It helps enrich population exploitation of solution space, improving evolution quality.

D. How to configure the GAPS? – **RQ2**

In the initial stage of experiments, the configuration experiment proved the insignificance of validated population sizes.

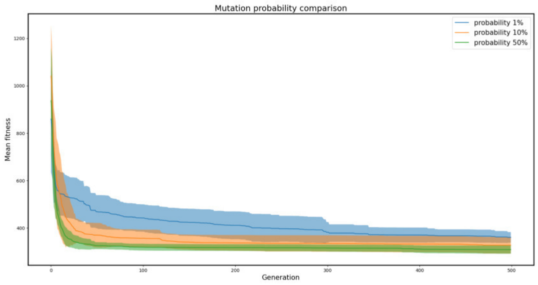

Fig. 4. Mutation probability comparison ($a30$)

TABLE IV
MUTATION PROBABILITY COMPARISON FOR $a30$, BEST FITNESS FOR 10 REPEATS

Mutation probability	mean	std_dev
1%	360.5	22.3
10%	327.5	35.1
50%	309.0	17.2

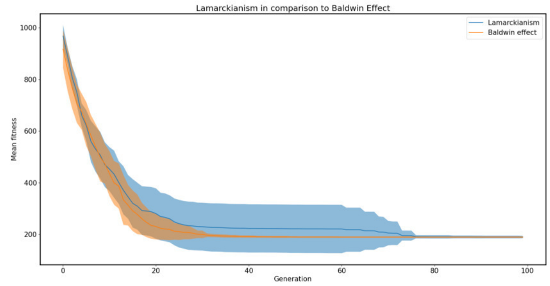

Fig. 5. Lamarckianism in comparison to Baldwin Effect for $d60$

TABLE VI
COMPARISON RESULTS OF BNB, MCTS AND GAPS FOR $a30$, BEST FITNESSES FROM 30 REPEATS

Method	mean	std_dev
GAPS	318.7	32.8
BnB	1933	*0.0*
MCTS	1827.3	43.1

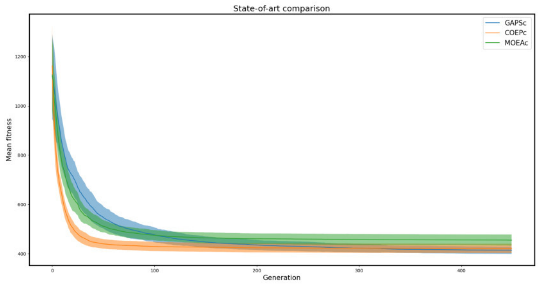

Fig. 6. Comparison results for GA for $b150$

It could be suggested that we search too few configurations to show a significant difference. However, this gives us valuable information about the evolution process.
The selection/crossover rate/mutation probability experiment provided us with the best configuration for the next experiments, which proved to be reversed tournament selection with size 3, crossover rate = 40%, and mutation probability = 50% – see Tab.III with Fig.3. and Tab.IV with Fig.4. Based on experimental results, we can define the best-found configuration of GAPS (GAPSc): random correct solutions generation, tournament selection (size 5), one-point crossover (crossover rate 30%), mixed mutation (probability 50%), and Baldwin Effect-based repair.

E. Lamarckianism in comparison to Baldwin Effect – **RQ3**

Results of GAPS in the context of Lamarckianism and the Baldwin Effect varies based on the scenario. At times, one outperforms the other. However, generally speaking, the Baldwin Effect tends to be the more stable choice (see Tab.V and Fig. 5).

F. State-of-the-art setups comparison – **RQ4**

Experimental results showed that BnB and MCTS methods could not find any solutions for any scenarios under a given budget because they cannot search for solutions of defined sizes (ex. 30). Therefore to extract some solutions, we compare them by giving the task of finding a solution with the most military units in a given budget and then comparing these solutions to the solution found by GA in $a30$ case (see Tab.VI). The experiment shows that under a budget of 45000, associated with a problem of size 30, BnB can find an optimal solution for acquiring 200 army value. MCTS, on the other hand, can find a suboptimal solution that can provide 300 army value. In comparison, for the same budget, GAPS is able to find a solution that achieves the given goal of 2000 army value on average in 318.7 in-game seconds.

TABLE V
LAMARCKIANISM IN COMPARISON TO BALDWIN EFFECT FOR $d60$, BEST FITNESSES FROM 30 REPEATS

Repair type	mean	std_dev
Lamarckianism	187.8	2.7
Baldwin Effect	188.9	1.9

The results from the GA-based experiments reveal interesting insights (see Table VII and Figure 6). These suggest that our GAPS configuration (GAPSc) often discovers superior solutions in smaller, $aggressive$ cases. Conversely, COEPc tends to generate better solutions in larger, more $balanced$ cases. The outcomes for $development$ cases are quite similar.

The explanation for this might be rooted in the specifications of the distinct scenario. $Aggressive$ cases typically require highly optimized solutions with a specific order of action execution. In contrast, $development$ cases permit a wider range of solutions, all yielding similar results.

G. Comparison to known build order

We conduct a final experiment in which we take a well-rated Stalker rush build order from a website that stores the best Sc2 build orders. We simulate this order, extract metrics, and then input those metrics as an objective vector for our implementation to check if GAPS can find a similar build order. The experiment reveals that while the website build order takes 221 in-game seconds, our method only requires 205 seconds to produce a build order described by the same objective vector. Although using the same actions, the solution provided by GAPS completely reorders them in a manner

TABLE VII
COMPARISON RESULTS FOR GA FOR ALL SCENARIOS

	GAPSc		**COEPc [2]**		**MOEAc [4]**	
Case	mean	std_dev	mean	std_dev	mean	std_dev
a30	**302.17**	11.34	306.83	20.27	356.63	37.29
b30	258.2	10.15	**251.26**	10.78	320.033	32.22
d30	**187.23**	2.06	**187.83**	2.29	207.03	39.16
a60	**409.3**	16.21	420.23	19.55	452.467	22.57
b60	318.5	14.5	**309.36**	7.99	373.36	27.17
d60	**246.57**	3.55	**245.2**	4.99	262.2	10.71
a150	731.0	9.1	**707.7**	20.25	785.9	20.96
b150	561.27	18.62	**534.56**	15.37	644.3	39.93
d150	**1422.13**	1.2	**1422.87**	1.83	**1422.83**	1.84

that allows a significant number of actions to be executed concurrently.

V. CONCLUSION

This study offers several key conclusions regarding applying and optimizing GAPS for planning and scheduling problems in the context of the game StarCraft II.

Mutation operators significantly impact the evolutionary process. The mixed mutation strategy described in [2] provided the best results, enhancing the population's ability to exploit the solution space and thereby improving the quality of evolution.

Search for optimal GAPS configuration, including population size, number of generations, selection, crossover rate, and mutation probability, reveals that population size and number of generations did not significantly impact the experiment results. The best-founded configuration proved to be: reversed tournament selection of size 3, one-point crossover with crossover probability of 40% as well as mixed mutation [2] with mutation probability of 50%.

The results were scenario-dependent when comparing Lamarckianism and the Baldwin Effect in GA. The Baldwin Effect emerged as a more stable choice across different problem sizes and scenarios. This stability is primarily due to the Baldwin Effect's ability to balance exploration and exploitation in the solution space, reducing the risk of premature convergence to suboptimal solutions.

In contrast to other state-of-the-art configurations, GAPSc demonstrated proficiency in smaller, aggressive cases where precision and optimization were vital. Conversely, COEPc prevailed in larger, balanced cases where flexibility and a range of solutions were advantageous. Therefore, careful consideration of case characteristics is crucial when deciding the most appropriate method to apply. In doing so, we can utilize the strengths of each method, ensuring optimal outcomes.

The final experiment underscored the potential of GA in optimizing game strategies. In comparison to a highly-rated Stalker rush build order from a renowned strategy website, the GA generated a similar build order in fewer in-game seconds, showcasing its potential to create efficient and competitive game strategies. The time difference (16sec.) might cause a significant difference at the very beginning of the high-ranked match.

In conclusion, the findings of this study underscore the effectiveness and potential of Genetic Algorithms in tackling complex planning and scheduling problems, similar to StarCraft II Build Order Optimization. Furthermore, they provide a foundation for future exploration and optimization in this domain.

VI. FUTURE WORKS

Several promising future research directions exist for enhancing the Genetic Algorithm applied to BO.

Firstly, the development of more sophisticated objective metrics could be beneficial. Such metrics would encapsulate the tactical nuances of each unit in the game, providing a richer representation of the problem domain within the evolutionary process. This enhancement could lead to solutions that better reflect the complex dynamics of the game.

A natural extension of this is the application of a multi-objective Genetic Algorithm. It would enable the simultaneous optimization of several objective functions, providing a more comprehensive optimization that considers the nature of planning and scheduling problems.

Using surrogate models, also known as meta-models, could help accelerate the evaluation process within the GA. These models, built based on existing evaluation data, can provide fast, approximate evaluations, significantly speeding up the evolutionary process.

Exploring different approaches could also increase the effectiveness. One promising method that aligns well with the nature of Genetic Algorithms in the context of presented results is Extreme Optimization (EO). This technique focuses on the most complex components of a solution and attempts to improve them. Thus, it could be particularly effective in complex environments like those encountered in StarCraft II, where optimizing numerous suboptimal solutions is necessary. Combining GA with EO could lead to a more efficient search process. While GA excels at exploring a broad solution space, adding EO allows it to focus more specifically on the areas that need the most improvement, leading to more exploitation of the solutions space and enhancing effectiveness.

Integrating GA with a high-level agent could validate its performance and potentially create a powerful StarCraft II bot. This agent could use the GA-generated solutions as part of its decision-making process, while the feedback from the agent's performance could further inform and refine the evolutionary process.

GAPS can be extended to numerous domains, such as economics, and military simulations, due to its inherent flexibility and adaptability. In the economic field, GAPS can be applied to optimize portfolio management, improve supply chain efficiency, and refine resource allocation plans in large-scale projects, effectively scheduling investments over time to maximize returns while minimizing risk. Similarly, in military simulations, GAPS can optimize strategies for defense and offense, logistics, troop deployment, and disaster response by assessing multiple scenarios accordingly.

The potential directions for enhancing the presented GA are vast and multidimensional, ranging from more nuanced objective functions to hybrid techniques and high-level agent integration. These could all contribute to a more robust, efficient, and capable GA for tackling the complex problem of game planning and scheduling.

Finally, more advanced simulations or games can be examined, to verify how the increased number of resource management options affects the results. It could include a higher number of resources, a resources trade/exchange system with a simple demand/supply mechanism, and soft constraints based on the simulation-specific rules. Those extensions can bring the environment significantly closer to real-world scenarios. Another interesting, yet challenging aspect to simulate is risk management. In both game and economic environments multiple players compete with each other, thus long-term and error-prone plans can be replaced by less efficient but safer strategies. It is related to the previously mentioned multi-objective optimization as the risk exposure might be one of the minimized objectives.

***Abstract*—Enterprise systems are inherently complex and maintaining their full, up-to-date overview poses a serious challenge to the enterprise architects' teams. This problem encourages the search for automated means of discovering knowledge about such systems. An important aspect of this knowledge is understanding the data that are processed by applications and their relationships. In our previous work, we used application logs of an enterprise system to derive knowledge about the interactions taking place between applications. In this paper, we further explore logs to discover correspondence between data processed by different applications. Our contribution is the following: we propose a method for discovering relationships between data using log analysis, we validate our method against a benchmark system AcmeAir and we validate our method against a real-life system running at Nordea Bank.**

I. Introduction

LARGE enterprises, especially those with a long history of operation, face the challenge of modernizing their processes and adapting them to the changing environment. One of the key, and often the most challenging, aspects of such adaptation is the modernization of the enterprise's IT infrastructure. This is usually a complex endeavor, that includes exiting legacy systems, reorganizing the architecture, and harmonizing the data usage across the enterprise system. Each of these activities requires the enterprise architects team to have a good understanding of the existing IT infrastructure constituting the enterprise system, including the processes, applications participating in them, and the data being processed.

In [1] we proposed a method for discovering the knowledge about the interactions between applications in an enterprise system based on the analysis of application logs. We chose this type of analysis as the basis for our method due to some interesting properties of logs. Firstly, logging is a common practice present in IT from its very beginning, meaning that both legacy and modern applications are expected to create some sort of log (a trace of the actions executed by an application). Secondly, logs contain rich information, which blends the working application's technical and business aspects. Lastly, log entries tend to be kept up-to-date with the executed application code. All of these properties make application logs a perfect candidate for deriving the actual knowledge about various aspects of the enterprise system in an automated way.

In this paper, we further explore the potential of application log analysis in terms of supplying enterprise architects with valuable information about the enterprise system. This time, we focus on the data processed by applications. We try to find correspondence between data processed by different applications, which can be treated as good candidates for reconstructing relationships between data models used by different applications of the system. This information can be valuable in many aspects – it allows for the "detection" of pieces of information used by various applications, it allows for explaining information from legacy applications by finding its correspondence to information in modern (well-documented) applications, and it allows for attaching some business meaning to information by utilizing the business part of log entries. Our work fits in the domain model extraction area of the landscape of automated log analysis proposed by the authors of [2]. Other research in this area includes ontology discovery with process mining [3], search query categorization into a predefined taxonomy using search log analysis [4], or learning expert knowledge on applying security rules based on security log [5]. Our contribution to the body of knowledge is three-fold:

- we propose a method for automated discovery of relationships between data processed by applications, using textual analysis of the log content,
- we validate our method on the benchmark system AcmeAir [6],
- we validate our method on a real-life system running at Nordea Bank.

The rest of the paper is organized as follows. In Section II, we present a formal statement of the problem. Section III describes the proposed method of log analysis. In section IV, we introduce the two datasets used for the evaluation of our method and we define the evaluation criteria. In Section V, we compare our method with alternative approaches and describe the related work. We present the conclusions and plans for future work in Section VI.

This work was supported by the Gdańsk University of Technology and Nordea Bank

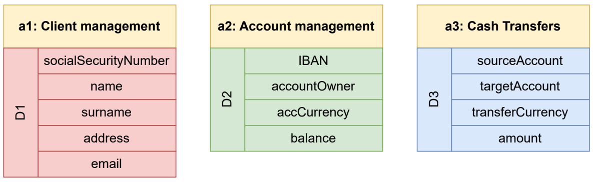

Fig. 1. An example of a fragment of an enterprise system S from the banking domain, related to the execution of cash transfers. The yellow color denotes different applications constituting the system. Red, green, and blue colors denote the data attributes processed by each of the applications.

II. Problem Statement

Let enterprise system S consists of a set of applications $A = \{a_1, \ldots, a_n\}$. Let each application $a_i \in A$ process some data represented by a set of data attributes $D^i = \{d_1^i, \ldots, d_{k^i}^i\}$. For each data attribute $d_k^i \in D^i$, we denote the set of potential values that the attribute can take by $V(i, k)$.

A fragment of an example enterprise system with applications and respective data attributes is presented in Fig. 1. The presented fragment is related to the processing of cash transfers in a bank and consists of three applications - managing clients, managing accounts, and cash transfer execution.

For any two data attributes d_k^i, d_l^j, we define their level of similarity using the Jaccard index

$$J(d_k^i, d_l^j) = \frac{|V(i,k) \cap V(j,l)|}{|V(i,k) \cup V(j,l)|} \tag{1}$$

We define a data relationship graph $G(S) = (U, E)$ as an undirected graph, where E is the set of edges consisting of all pairs of related data attributes d_k^i, d_l^j, and U is the respective set of vertices. An example of such a graph is presented in Fig. 2.

Let $L(a_i) = (l_1^i, \ldots, l_{k^i}^i)$ denote the log of application $a_i \in A$, represented by a tuple of log entries.

We define the problem of discovering data relationships as follows. Having a set of application logs $L = \{L(a_1), \ldots, L(a_n)\}$, find approximate graph $G^{'} = (U^{'}, E^{'})$.

III. Proposed Method

A. Method Overview

We propose a method that treats a log as a text. Such an approach has several benefits. It does not require any arbitrary assumptions to be made about the log content, which results in a broader scope of the method's usability. It also does not require additional preprocessing of the log, apart from unifying the log format across applications. Our method does not require any knowledge of the underlying data attributes for each application – they are discovered from the log automatically. Fig. 3 presents an overview of the steps that our method consists of.

Our method is parameterized by the following hyperparameters:

- N – the maximum length of n-gram embedding of a token,
- ies – inner embedding similarity threshold,

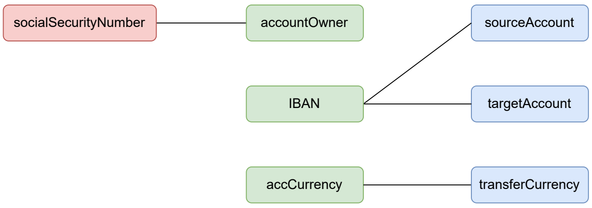

Fig. 2. A data relationship graph for the example system presented in Fig. 1. Edges represent relationships between data attributes from different applications. The coloring of nodes matches the coloring in Fig. 1.

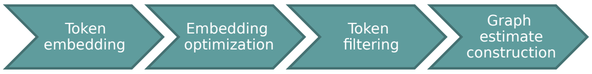

Fig. 3. Overview of data relationship discovery method.

- oes – outer embedding similarity threshold,
- mt – minimum number of tokens sharing the same embedding that is required for the embedding to be considered,
- ml – minimum length for a token to be considered valid.

The following subsections describe each of the steps in detail.

B. Token Embedding

We process the log of each application $a \in A$ separately. For each log entry, we extract a list of tokens using the regular expression $[@.A-Za-z0-9\_]+$. For each token in the log entry and each $k \in \{1, \ldots, N\}$, we create its embedding as a k-gram of words [7] preceding the given token in the log line. Such an approach means that the same token can have multiple embeddings for a given value of k, depending on the context (consisting of k preceding tokens). An example of such embeddings is presented in Fig. 4. It can be noticed that "NRT", "destPort" and "miles" tokens have different embeddings for both log lines due to different neighbor tokens in each of the lines.

For each value of k and for each unique embedding e, we maintain the set of all tokens sharing this embedding within the $L(a)$, which we denote as $Emb^a(e, k)$. We denote the set of all k-gram embeddings within a as Emb_k^a, and the set of

all embeddings within $L(a)$ as $Emb^a = \bigcup_{k \in \{1,\ldots,N\}} Emb^a_k$. Fig. 5 shows groups of tokens sharing the same embedding.

For given k-gram embedding e consisting of tokens $(t_k, t_{k-1}, \ldots, t_1)$ and $l < k$, we define an l-cut operation on e, denoted as $e|l$, as follows: $e|l = (t_l, t_{l-1}, \ldots, t_1)$.

C. Embedding Optimization

The result of the previous step is ambiguous – the same groups of tokens are represented with multiple embeddings, for different values of $k \in \{1, \ldots, N\}$. To remove this ambiguity, we search for the highest value of k such that k-gram embedding of the groups of tokens represents them better than $k+1$-gram embedding. The longer the embedding, the more precisely it describes the represented tokens.

We start with the set of initial embeddings E that consists of all 1-gram embeddings. For each 2-gram embedding e, we then take the set of all tokens that it represents $Emb^a(e, 2)$. We compare this set with the set of all tokens represented as 1-cut of e, using the Jaccard index. If the index value is above the ies threshold, we substitute the $e|1$ embedding in E with e. We repeat this procedure for longer k-grams until $k = N$, each time comparing the k-gram embedding with its k-1-cut. In the end, the set E contains all the embeddings for log $L(a)$ after optimization, which we denote as $OEmb^a$. Fig. 6 shows the two consecutive steps of the optimization process.

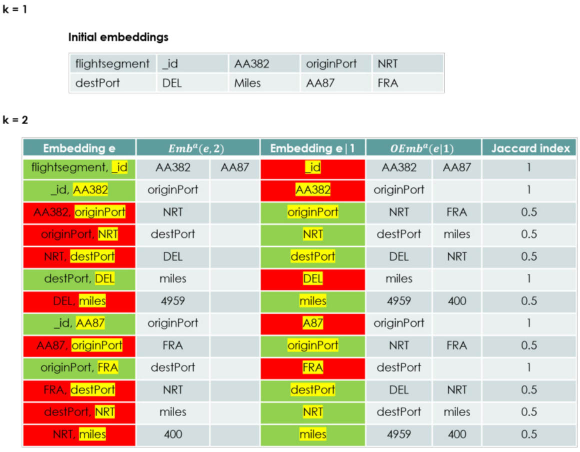
$OEmb^a(e)$ denotes the set of tokens represented by embedding e within log $L(a)$. The above algorithm ensures that there is only one embedding (one value of k) that represents a given set of tokens. Fig. 7 presents the example outcome of the optimization process.

D. Token Filtering

We further optimize the set of embeddings. For each application log $L(a)$ and each embedding $e \in OEmb^a$:

- we discard e if $|OEmb^a(e)| < mt$,
- we define the filtered set of tokens, such that $\forall_{e \in OEmb} FEmb^a(e) = \{t \in OEmb^a(e) | length(t) \geq ml\}$.

$FEmb^a(e)$ denotes the final set of tokens represented by the embedding e within application log $L(a)$, while $FEmb^a$ represents the set of all final embeddings for application a,



k = 1

and $FEmb = \bigcup_{a \in A} FEmb^a$ is a set of all embeddings in the system.

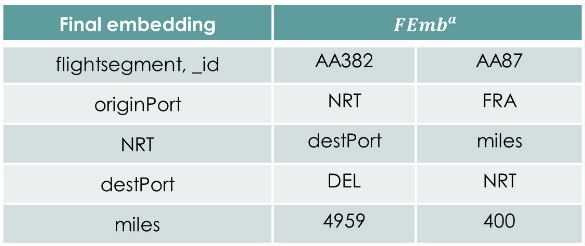
The first optimization removes embeddings that represent only a few tokens. Such embeddings are interpreted as representations of static parts of the log entry, which are of less interest in terms of data relationship discovery. The second optimization removes short tokens, which decreases the chance of discovering accidental relationships.

E. Graph Estimate Construction

We calculate a distance matrix between all $FEmb$ embeddings using the Jaccard index as the distance measure:

$$\forall_{e_1, e_2 \in FEmb, e_1 \neq e_2} dist(e_1, e_2) = \frac{|FEmb(e_1) \cap FEmb(e_2)|}{|FEmb(e_1) \cup FEmb(e_2)|} \tag{2}$$

We filter pairs of embeddings based on their distance, using oes as the threshold, above which the embedding relationship is considered strong enough and should be retained. The retained embedding pairs form the edges of our approximate graph $G^{'}$ and respective embeddings become the vertices of the graph. Fig. 9 presents an example distance matrix



Final embedding	$FEmb^a$

for the final embeddings presented in Fig. 8. The respective graph estimate is shown in Fig. 10, which shows a detected relationship between *originPort* and *destPort* data attributes.

IV. Method Evaluation

A. Dataset Overview

We evaluate our method using two datasets:

- AcmeAir – a dataset allowing us to assess the accuracy of our method on a benchmark system, that we have full knowledge about,
- NDEASET2 – a dataset from a real-life enterprise system running at Nordea Bank.

Both datasets are described in detail in subsequent sections.

B. Benchmark Dataset

AcmeAir [6] is an open-source implementation of a fictitious flight reservation system that is commonly used as a benchmark system [8]. It consists of a web application and several restful web services that contribute entries to a common log file. AcmeAir provides very limited documentation that allows deriving only the data model (Fig. 11).

The AcmeAir documentation does not provide a component diagram but limits itself only to listing backend services with their responsibilities:

- BookingService - creating new bookings and canceling existing bookings for a given customer,
- CustomerService - creating and updating customer information, managing the customer's session,
- FlightService - allowing users for searching for flights by airports and/or departure dates and searching for flight segments.

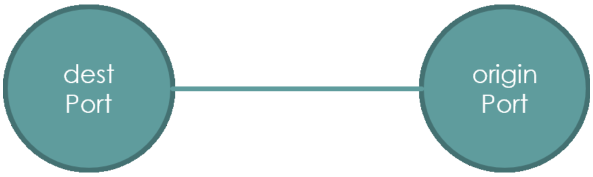

Fig. 10. Graph estimate for the set of final embeddings and oes threshold of 0.25.

However, based on the analysis of the system's source code, we have reconstructed missing elements of the component model, which are presented in Fig. 12.

All AcmeAir components put their log entries into a common log file in a standardized manner. Each log entry produced by AcmeAir consists of the following elements (see Fig. 13 for a log sample):

- Timestamp – date and time of creating the log entry,
- Logging level – either DEBUG or INFO,
- Source – the name of the component that created the entry,
- Content – logged message.

In our analysis, we use logs produced by a fork of AcmeAir [9] which extends the logging to cover HTTP requests/responses issued within AcmeAir. We use the AcmeAir driver – a built-in simulator of user interactions with the system – to generate a log file used in further analysis. The workload is generated in a multi-threaded manner. We use five threads to simulate concurrent actions taken by users of the web application. It is important to note that although the log is generated in a multithreaded way, log entries do not contain any information allowing one to identify a thread within which specific entries are logged. We use a log fragment of 1000000 lines (file size: 314MB). We have found that larger log fragments do not introduce more information as the patterns appearing in the log keep repeating.

As part of log preprocessing, we performed the following transformations to the log:

- we transform the content into a CSV format to be aligned with our real-life dataset. Each log entry is described by *timestamp*, *source*, and *message*.
- For the log entries where HTTP request/responses are logged, we derive the source from the HTTP endpoint. Such an approach better reflects the actual relationship between the data and the service that processes them.

Both the original and the preprocessed logs are available in [9].

C. Real-life Dataset

We used a log dataset NDEASET2 from a real-life system deployed at Nordea Bank, which we refer to as NDEASYS. As compared to the NDEASET1 dataset described in our previous work [1], NDEASET2 covers a full working week of the NDEASYS. The total size of the dataset is larger by an order of magnitude (95GB). It covers one more application and one additional process (daily reporting). We followed the same rules for removing bias as described in [1] to ensure proper diversity of the dataset, which include:

- team diversity – applications built by teams of different sizes, experiences, locations,

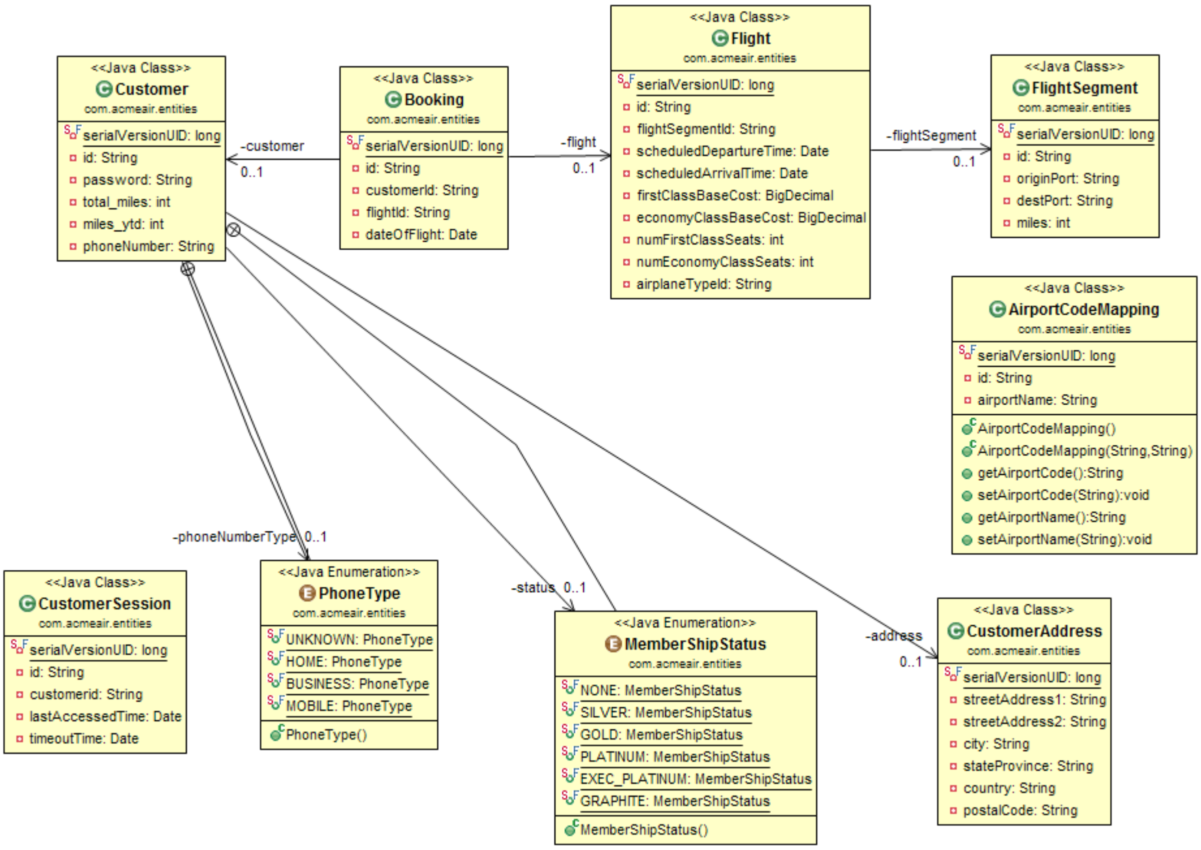

Fig. 11. Class diagram of AcmeAir system available in its documentation.

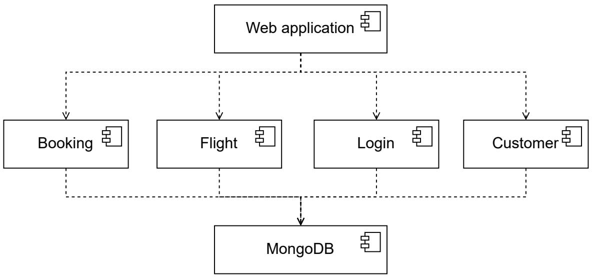

Fig. 12. Component model of AcmeAir.

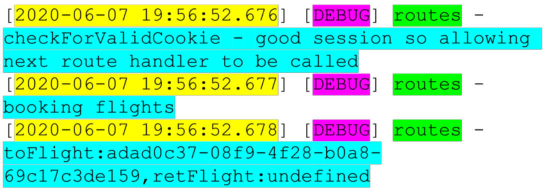

```
[2020-06-07 19:56:52.676] [DEBUG] routes -
checkForValidCookie - good session so allowing
next route handler to be called
[2020-06-07 19:56:52.677] [DEBUG] routes -
booking flights
[2020-06-07 19:56:52.678] [DEBUG] routes -

69c17c3de159,retFlight:undefined
```

Fig. 13. An AcmeAir log sample. Yellow color denotes the timestamp, magenta – the logging level, green - the source of the log entry, and cyan – the message.

- application diversity – we included dedicated business applications, purely technical components, and shared service platforms (e.g., storage or communication services),
- time diversity – applications built in different periods,
- integration diversity – applications communicating using different interfaces and exchange formats.

The bias of the dataset related to logs being collected within the same company is mitigated by the fact that Nordea does not enforce any strict rules for log creation and log content for non-regulatory logging.

The fragment of the architecture of the NDEASYS that contributes to the creation of logs within NDEASET2 is shown in Fig. 14. Applications B and D are both providing data of the same type to A, but using different formats. Application A enriches the received data with data from applications C, E, and F. The final result is aggregated as part of the daily reporting and the aggregated data are provided to application G.

Table I describes the characteristics of the NDEASYS2 dataset. As part of the log preprocessing, we unify all of the logs in the dataset to a common CSV format with timestamp, source, and message columns, which match the format of the AcmeAir logs that we use as a benchmark. Fig. 15 presents an anonymized example of log entries in NDEASET2.

```

Fig. 15. Example of one log entry from NDEASET2. Yellow color denotes the timestamp, green –the source application, and cyan –the message.

D. Evaluation Criteria

For each dataset, we use evaluation criteria suitable to the level of knowledge about the system that the dataset is based on. For AcmeAir, we can assume full knowledge about the system and its data model due to its simplicity and open-source nature. Based on the data model presented in Fig. 9, we construct the reference data relationships graph shown in Fig. 16, which serves as our ground truth. Arrows are introduced for clarity only. They denote the direction of the relationship and are not taken into consideration during method evaluation. Vertical lanes represent different services depicted in Fig. 10. Nodes within a lane represent data attributes managed by a given service. Each node is described by an attribute and entity it belongs to (e.g. *Customer* is an entity and *id* – is its attribute). Edges of the graph represent relationships between data attributes. Only the attributes that are related to one another are presented in the graph.

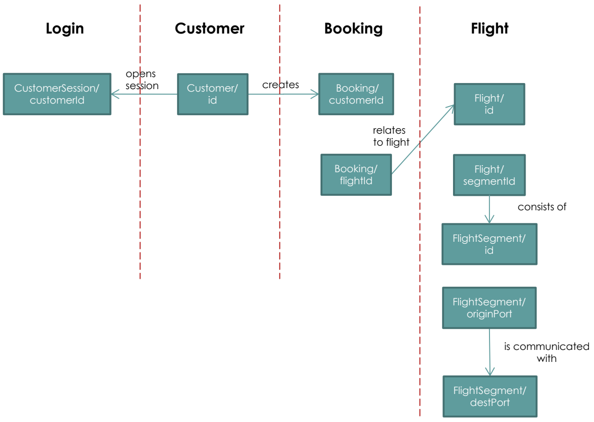

Fig. 16. Graph of data relationships in AcmeAir system, serving as our ground truth.

We use the F1 score of the set of graph edges to determine the accuracy of our method for the AcmeAir dataset.

For the NDEASET2 dataset, we are unable to construct a reference graph. However, our knowledge of the NDEASYS system allows us to assess, whether or not the discovered relationship is correct. Therefore, for this dataset, we use only the precision of the discovered set of edges as the measure of our method's accuracy.

E. Benchmark Results

To be able to compare the outcome of our method with the ground truth presented in Fig. 16, we need to perform two types of mapping:

- mapping of discovered data attributes to the data attributes from Fig. 11 (details of mapping are presented

TABLE II
MAPPING OF DATA ATTRIBUTES BETWEEN THE ACMEAIR LOG AND THE REFERENCE DATA RELATIONSHIP GRAPH

Log		**Reference data relationship graph**	
Service	**Discovered** attribute	**Entity**	**Attribute**
Booking	returnbookingid	Booking	id
	departbookingid	Booking	id

	_id	FlightSegment	id
	destport	FlightSegment	destPort
	originport	FlightSegment	originPort

in Table II),

- mapping of the denormalized data model present in the logs to a normalized model present in Fig. 11.

The latter mapping is necessary because the information in the logs of individual services represents some part of the view of the overall schema of the application. Additionally, the information in logs overlaps between the logs of different services.

It is expected that logs contain more information than only related to data schemas, thus the resulting data relationship graph will be richer (having more nodes and edges) than the reference graph from Fig. 16. To provide a fair assessment of our method, we first present the results on a subgraph limited to the set of nodes from Fig. 16. Then we discuss separately the rest of the graph.

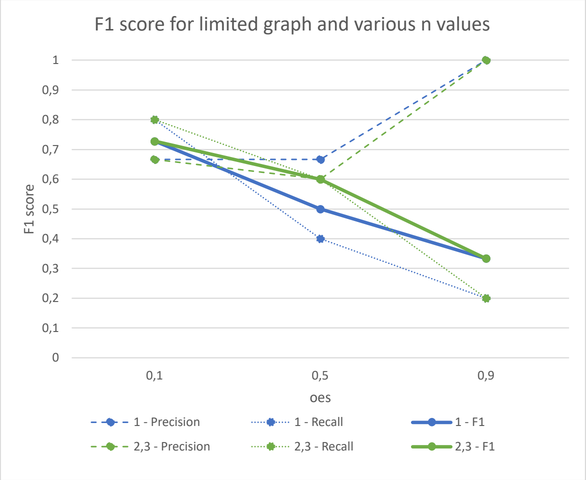

Fig. 17. The results of our method were measured by the F1 score. Colors denote the outcome for different values of n. Dashed lines represent precision, dotted – recall, and solid – F1 measure. The horizontal axis represents different values of the oes meta-parameter.

Fig. 17 Shows the results of our method for the limited graph under different values of meta-parameters. It can be observed that for $n = 2$ and $n = 3$, the results are the same, and the n meta-parameter, in general, does not have a key influence on the overall score. A much more significant parameter is oes, which determines the perception of similarity between data attributes. The best F1 score of 0,72 was reached for the oes value of 0.1. We interpret such a low value as our method needing an argument to exclude a relationship (low level of similarity). This follows the intuition that, even though two attributes are closely corresponding to one another, they do not have to share the same values across the whole log. It is more probable that the set of shared values would be rather small because of a different set of services being triggered depending on the processes executed in the system.

An example of a graph generated by our method is shown in Fig. 18. The thick edges denote data relationships that match the reference data relationship graph from Fig. 16. We can see that the generated graph is much richer in information and our method gives a couple of interesting insights into the underlying data schemas. Firstly, it shows the potential of detecting unknown relationships based on data. An example is a relationship between *CustomerSession/customerId* and *Booking/customerId* which was detected based on matching values that both attributes take. An interesting part of the graph is a complete subgraph under Web service, whose nodes represent airport names. The fact that these attributes were extracted and are connected means that these values must frequently occur next to one another in logs. It is the case since when a flight is booked, origin and destination airports are logged in a single log entry. The fact that these attributes form a complete subgraph is the effect of the low cardinality of the set of airports. Combined with the automated

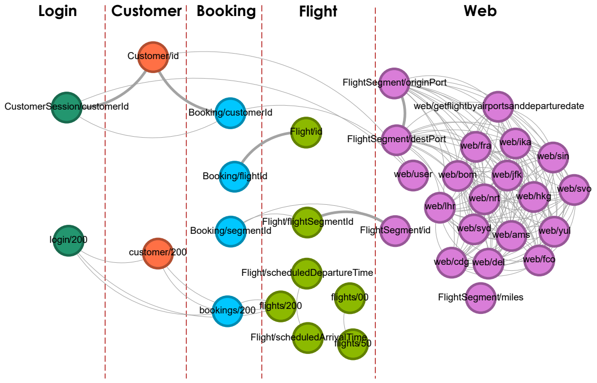

Fig. 18. A data relationship graph was generated for n=3, ies=0.9, and oes=0.1. Vertical lanes denote services depicted in Fig. 12. Nodes within a lane represent data attributes discovered in the log of a given service. Thick edges represent data relationships that match the reference relationship graph in Fig. 16.

TABLE III
CHARACTERISTICS OF THE NDEASYS2 DATASET

n	Discovered data attribute (n-gram embedding)
2	booking, byuser
2	flightsegment, _id
3	customer, by, user
3	flights, by, user

generation of the AcmeAir log sample, this resulted in all the origin/destination airport combinations being exhausted. It shows that our method is susceptible to the identification of false relationships for data of low cardinality. This is normally addressed in our method by choosing only long enough tokens (ml meta-parameter of our method). For the AcmeAir dataset, however, the minimum token length was set to 3 to utilize the airport data as a means of detecting other relationships.

In Fig. 18 it can be observed that the graph contains nodes representing data attributes that are not present in the original model in Fig. 11, e.g. *web/user* or *web/getflightsbyairportanddeparturedate*. These attributes come from the analysis of log entries that do not directly log the whole data entity but are representants of typical observation-point logging used by developers [10]. Such attributes are valuable since they provide an additional semantic context to interpret other attributes. In the case of *web/user*, we can interpret that a customer is a user of the system.

The graph presented in Fig. 18 is created after performing the attribute mapping described at the beginning of the section. The full set of results achieved by our method for various meta-parameters is available in [9] in the GEXF format. However, it is interesting to analyze raw data attributes. Table III presents a sample extract of raw attributes represented by n-grams for $n \in \{2, 3\}$. The set of tokens constituting the n-gram can also be viewed as a semantic context, which can be used for the refinement of the generated graph in the future.

Our method has also identified some false positives – numeric nodes that represent an accidental correlation of data that should be treated as noise. Filtering out this noise is one of the challenges for our future work.

F. Real-life System Results

Our method has been executed against a log of the real-life system running at Nordea Bank - NDEASYS. We used the following meta-parameters to get the best results:

- $N = 4$,
- $ies = 0.9$,
- $oes = 0.1$,
- $mt = 10$,
- $ml = 5$.

Since, due to the size of the domain, it is hard to obtain the full ground truth, we focused on identifying falsely discovered data relationships. The edges of the resulting graph were validated using our domain knowledge. Our method achieved a precision of 0.98 on NDEASET2.

We performed an additional validation of the achieved results based on the analysis of data flows within NDEASYS. Based on Fig. 14, it is expected that data relationships are found between applications B, G, A, and F, which represent the main data flow. The discovered data relationships are aligned with the diagram in Fig. 14. For every edge of the architecture graph, there is at least one discovered data attribute relationship between the two applications.

Also, other properties of our method revealed on the AcmeAir dataset were confirmed:

- larger values of N tend to introduce an additional semantic context to the data relationship graph,
- observation-point logging entries introduce a domain nomenclature that puts other discovered attributes into a concrete context.

While promising, these results still need to be validated especially in terms of the recall and F1 measures. The size of the data and the big number of discovered relationships do not allow us to present an anonymized visualization of the retrieved graph, analogous to Fig. 18.

G. Threats to Validity

Internal threats to validity include the construction of the NDEASET2 dataset and the level of detail of logs. We tried to mitigate both threats by choosing applications that provided a decent level of diversity. We find team diversity especially important, as it ensures log entries are created by developers from different teams, potentially following different standards. Also, the application diversity (different types of applications included in the dataset) is meant to increase the overall representativeness of the dataset. As for the quality of logs, we will cover its influence on our method's results in our future work.

The biggest external threat to validity is the dataset from Nordea Bank, which might not be representative of the whole bank and enterprise systems in general. This threat might come from the specific dataset that was chosen for research but also from potential formal or informal rules regarding logging practices enforced by Nordea. We tried to mitigate this threat by applying our method to a benchmark system, which is however much simpler than an average enterprise application, both business and technical-wise. In the future, we will try to find other datasets to further mitigate these threats. It is worth noting that although publicly available datasets are very beneficial for the validation of our method and the general reproducibility of research, they will never be close to the size and complexity of real-life enterprise systems. Therefore, apart from selecting open-source datasets, we will seek further datasets inside Nordea Bank to retain real-world validation for our research.

The threat to construct validity is an insufficient measure of the quality of our method for the NDEASET2 dataset (we are using only precision, not using recall, and not being able to construct the reference graph). Construction of the reference graph for NDEASYS is one of the goals of our future work.

Conclusion validity is threatened by data attributes with low cardinality of values (e.g. currency symbols in the banking industry or airport codes in the flight booking domain). Such data attributes can be falsely considered as related just because of a high chance of them getting the same values. Another threat to conclusion validity is the low level of detail of logs can result in relationships between data attributes not being detected.

V. Related Work

Discovering relationships between data is a topic studied by schema matching discipline [11]. This domain is very broad and uses several techniques, including matching strings, matching words in certain languages, matching graphs, or using ontologies representing knowledge in certain fields. The goal of traditional schema matching is to match elements between two schemas given as input. The authors of [12] and [13] study a more general case where the number of schemas to be matched is greater than two. Finding similarities in attribute values (called duplicates) is the basis of the method proposed in [14]. The authors perform schema matching based on a small number of matching values in two schemas. [15] proposes a method for matching knowledge graphs. The authors split the process into schema-level and instance-level matching. In the first phase, matching is performed using only schema information, while in the second phase, the result is further refined by matching the values that schema attributes take. All of the approaches in the schema matching domain assume full knowledge of the individual schemas being matched. What is in the area of interest is only finding the correspondence between the attributes of the schemas. This is a significant difference compared to our method, which needs to discover both the schemas and their corresponding attributes.

Semantic data type discovery is a field of research that focuses on assigning types that have well-defined meanings to schema attributes. As compared to regular type detection (e.g. whether an attribute is a string, int, or boolean), semantic types hold much more information (e.g. postal code, surname, country) and as such could be used to match attributes of different schemas. [16] introduces *Sherlock*, a supervised-learning approach to semantic type detection. It uses the VisNet dataset to train a classifier that detects one of the 78 semantic types defined in the *T2Dv2Gold Standard* dataset. The authors of [17] propose the *SATO* algorithm, which extends *Sherlock* by incorporating the concept of context. Data attributes are matched not only based on the values they take but also based on the neighbor attributes in the same schema. Such an approach allows to properly classify semantic types for attributes with a low number of samples. Both [17] and [18] rely on model training for a given dataset which contrasts with the unsupervised approach we take to derive data relationships. [18] describes *RaF-STD*, an unsupervised learning approach to semantic type detection. The authors exploit triples of schema attributes that share common values and iteratively introduce higher-level virtual attributes representing the notion of similarity. This method does not require any prior knowledge of the source schemas but requires the existence of such schemas, which we do not assume in our method.

Automated log analysis is a field of research that focuses on the extraction of data from logs in an automated fashion. The authors of [2] split this field based on the type of knowledge being extracted. According to this classification, domain model extraction is a field that is somewhat relevant to data attribute discovery. [19] presents a method for discovering an ontology based on event logs and process mining techniques. The method is validated using a dataset of stack overflow posts and proved to generate a valid ontology in a computer science domain. The use of an event log requires intensive log preprocessing, which is not the case with our method, which operates on raw application logs, with very little preprocessing to unify log format across applications.

Log template generation is a field of research that aims in finding patterns in lines of log files as part of a log analysis task. Typically such patterns split a log line into static and variable parts, which could be used to discover data attributes in our method. [20] and [21] are two common methods for discovering log patterns. According to [1], both of these methods do not cope well with log lines of variable length (e.g. XML document being logged), which can be a typical case of logging entry/exit data. The authors of [10] classify such log entries under the observation-point logging category and show it is one of the most common types of log entries. [1] proposes an *SLT* method for log template generation, which is well-suited for handling log entries of variable length but the result is coarse-grained – it does not provide any information on the position of the variable parts within a log line. Our method for data relationship discovery uses the context of neighbor tokens to detect data attributes, so the position of the variable tokens within a log entry is essential.

Word embedding is a sub-field of natural language processing that aims in representing words in some text corpus as multi-dimensional vectors. This corresponds to the initial phases of our method, where we perform the embedding of tokens of a log line. [22] and [23] are the two most popular methods for word embedding. For both, there is a large set of pre-trained models over text corpora in various languages. However, their usability to log analysis is limited. Firstly, they require training of the model on a particular text corpus, as the model is specific to the logs being analyzed. Secondly, the set of words in log corpora is infinite due to information like unique identifiers being commonly logged.

The method for discovering interactions between applications described in [1] shares similar ideas to the method described in this paper. It looks for rare tokens in various applications' logs and uses the findings to justify the hypothesis of the existence of a relationship between applications. The main difference between [1] and this paper is that [1] is focused on detecting the relationships between applications, while this paper focuses on detecting relationships between data attributes. For this purpose, we are looking not only at the rare but also the more frequent tokens. Discovery of a relationship of more frequent tokens (e.g. currency codes) in two applications cannot be treated as a good justification for the existence of a dependency (data exchange) between the applications. Therefore the method presented in this paper cannot be considered a generalization of the method described in [1]. These methods are rather complementary and the identification of relationships in data can be used to refine the set of interactions discovered by [1].

VI. Conclusions and Future Work

In this paper, we proposed an unsupervised method for the automated discovery of data relationships in an enterprise system. We validated our method on a synthetic and real-world dataset. In both cases, it proved to be a useful tool for obtaining an overview of the data processed by applications within an enterprise system. For the real-world dataset, the method has successfully detected correspondences between data attributes in different applications, which can have multiple uses - failure diagnosis, schema discovery, or schema mapping, to name a few.

In the future, we will extend the method to take advantage of additional information – locality of log entries, data attributes described by n-grams with higher values of n, and semantics hidden in the observation-point logging entries. We will further analyze the retrieved relationship graphs for the NDEASET2 dataset and work on establishing the ground truth for NDEASYS to validate the recall and F1 measures. We will also combine the proposed method for data relationship discovery with the method of interaction discovery [1] to form a comprehensive approach for discovering knowledge about an enterprise system based on automated log analysis.

Acknowledgment

This paper was written in cooperation with the Nordea Bank which provided the log dataset and an overview of the systems that were subject to this study.

***Abstract*—The increased digitalization of the economy and society has triggered drastic changes in companies and confronted them with enormous challenges. The consulting industry is also strongly affected by this digital transformation. In an exploratory study, we examined digitalization's impact on management consultancies in Germany and their use of digital technologies. In our article, we provide insights into which digital technologies are considered to be important for the different phases of consulting and how digitalization affects the work of management consultants. From the perspective of such consultants, we discuss the technologies currently in use and offer an outlook on their future importance based on an online survey. Our results reveal that many business consultancies already rely heavily on digitalization and use a variety of digital technologies in all phases of the consulting process. Although business consultancies currently use well-established technologies, they remain aware of the growing importance of modern technologies for the future of consulting services.**

***Index Terms*—Digitalization, Digital technology, Consulting, Business consultancy**

I. Introduction

TODAY more than ever, society as a whole is undergoing a rapidly evolving digital transformation. Government institutions, households, enterprises, and their interactions are all changing due to the increased prevalence and rapid growth of digital technologies. Especially for enterprises, it has never been more important to be able to rely on a deep understanding of information technologies (IT) in general and of digital innovation in particular. The persistently high level of dynamism in everyday business today shows that constant changes and adaptations in response, including ones due to digitalization, will be the rule, not the exception, in the future economy. Worldwide digital networking, the automation of individual or even all business processes, and the restructuring of existing business models are just a few of the wide-ranging effects of digitalization. Indeed, the consequences of digitalization are omnipresent, as is the question of whether such changes should be viewed as positive or negative [1]–[4]. In either case, nearly all companies will have to pursue increased digital transformation, at least to some extent, in order to remain competitive in the (global) market [5].

Digitalization is partly of unprecedented importance owing to the COVID-19 pandemic, which delivered an unparalleled shock of uncertainty across all state borders and industries. Nationwide store closures, contact restrictions, and mandatory home offices forced companies to use contactless distribution channels and to facilitate remote work. Those developments drove a push toward digitalization as numerous processes in companies had to be digitalized and as companies themselves had to prove their resilience [6], [7].

One industry especially challenged by uncertainty during the COVID-19 pandemic was the consulting industry. As reported by the German Association of Management Consultancies—that is, the BDU (https://www.bdu.de/en)—the revenue growth of business consultancies collapsed in 2020 for the first time since 2010. The pandemic also dramatically altered the working methods of consultants. Guided by the motto of "New Work," the BDU reported massive contact restrictions and significant changes in workplace and working time models [8]. To be sure, business consultancies had to radically reorient themselves to meet the challenges of the COVID-19 pandemic.

At the same time, the pandemic, sometimes hailed as an accelerator of digital transformation, clarified that companies should and indeed were seizing the moment as a launchpad for not only digital transformation but also structural change. However, even before the pandemic, consulting companies faced the same challenges associated with digitalization that other companies faced as well. New competitors, new demands from customers seeking to professionalize their own digitalization [9], new requirements imposed by digitalization in providing consulting services, and the need for new skills and know-how on the part of consulting companies all confronted the classic people-oriented business of consulting with the need for changes in service provision, just as in other industries. In that light, "business as usual" was not a valid business strategy for many consulting companies even before the COVID-19 pandemic and became especially impractical due to the pandemic. Instead, the consulting industry has had to increasingly implement digital technologies in the various phases of the consulting process and, in turn, deal with emerging opportunities and innovations. In that context, the question thus arises as to what extent business consultancies are already using digital technologies. Therefore, to gain insight into how relevant digitalization already is and how much more relevant it will become in the consulting industry, we sought to survey the current and future significance of digitalization. We also wanted to investigate the general perception of digitalization among consultants in a bid to provide a basic picture of their opinions regarding digitalization. Beyond that, to gain comprehensive insight into business consultancies, we aimed to examine the current and future significance of digital technologies and trends for consultants.

To those ends, we developed a study using an online questionnaire to evaluate the status quo of the use of digital technologies in business consultancies in Germany, which we chose to examine due to our cultural background. The research question for our study was:

To what extent do business consultancies in Germany use digital technologies?

In response to that question, in this article we present selected results of our study. Following this section addressing our motivation for the study, we provide a short theoretical background before describing our study's design and our method of data collection. Afterward, we present and discuss selected results in light of our research question. The article closes with a summary of the main results and an outlook for future research in the field.

II. Theoretical Background: Business Consultancies

Business consultancies can be characterized in light of their consulting focus. In our study, we classified consultancies with reference to the BDU's classification, which divides the market for consulting into four classic fields [8]:

- Strategy consulting
- IT consulting
- Organization and process consulting
- Human resources consulting

To begin, strategy consulting is considered to be the most demanding field of consulting. Not only does it occur exclusively within the top management of companies, but the topics also concern the core of all corporate activities—that is, the corporate strategy [10]. The goal of a consultant in strategy consulting is to help the client to define long-term goals and develop a course of action to achieve the corporate strategy. Achieving that goal involves analyzing the current business situation, identifying opportunities and challenges, and developing a tailored strategy [11].

By comparison, IT consulting addresses the widest variety of consulting topics of all four classic fields of consulting. The topics range from the creation of business-critical individual software and the implementation of standard software and web-based applications to system integration and the optimization of IT architectures and infrastructure [11].

Next, organization and process consulting builds on the concepts of strategy consulting. By contrast, however, consultants work at the operational level, and contact between the client company and the consultancy usually occurs not within top management but mostly in middle and lower management [11]. Organization and process consulting deals with the optimization of organizational structures and processes within a company. Its goal is to improve the efficiency, effectiveness, and agility of the company by reviewing and, if necessary, adapting its business processes [12].

Last, human resources consulting focuses on both the managers and employees of a company. Among other activities, it involves the promotion of professional and social skills, usually facilitated in training courses [12].

No matter the field, a key factor of success for business consultancies is the consulting approach that they adopt. At base, successful consulting requires an understanding of the consulting process. In the literature, the consulting process is described in various procedure models, which differ less in their content than in the number of phases conceived as being part of the process. Barchewitz and Armbrüster [13] have described the consulting process in a three-phase model involving planning, realization, and control. Bodenstein and Herget [14], by contrast, have presented a four-phase process model involving conception, contract design, implementation, and conclusion. In our study, we followed the procedure model developed by Seifert [15], which comprises six phases:

- Acquisition
- Project preparation
- Problem analysis
- Problem-solving
- Implementation
- Post-processing

First, acquisition forms the basis of the consulting process, because in that phase a business consultancy seeks to win an order from a client [15]. A general exchange of information also occurs, after which the business consultancy submits a bid for the project order. Once the consultancy has received the order, a consultancy contract is negotiated between the parties [11].

Second, in project preparation, the project team is defined, the team's members are given access to all relevant systems, and further organizational arrangements are made [15].

Third, problem analysis focuses on gathering, deepening, and evaluating information. During that phase, the current situation is analyzed, and a formulation to meet the project's objective is finalized [11].

Fourth, problem-solving is the core phase of a consulting project [11]. Therein, a strategy for realizing a solution to the problem is presented. To that purpose, different alternative solutions are designed, evaluated, and presented to the client, who subsequently selects one of them to pursue [15].

Fifth, during implementation, the selected solution is implemented. The process is carefully planned to ensure successful implementation, and, afterward, the results are reviewed, and, if necessary, then the solution is optimized [14].

Sixth and last, post-processing considers both the client and the consultancy. On the client's side, the phase involves the conclusion of the project, including the achievement of the project's objectives. On the consultancy's side, it entails the preparation of documentation, assessments, and results for reuse [15].

III. Data Collection

Our research question was designed to afford access to initial insights into how consulting firms view and use digital technologies. To gain such insights, we adopted an exploratory approach in our study, which we conceive as being a starting point for more in-depth research in the future. For that reason, we make no claim regarding the representativeness of participants in the study.

Questionnaire Design

Overall, our questionnaire included 20 questions, divided into seven blocks of questions:

- General information about the participants
- Importance of digitalization
- Importance of digital technologies
- Degree of digitalization
- Importance of the business model
- Use of digital technologies
- Perception of digitalization and future trends

General information about the participants: In the first block of questions, participants were asked four fact-focused questions as a means to later categorize them in data analysis. Question 1 inquired into the number of employees in the participants' companies, the responses to which were used to classify the companies into micro, small, medium, and large companies. Question 2 asked participants about the area of consulting in which they were most active. Last, Questions 3 and 4 addressed the participants' professional experience by inquiring into the number of years spent in the profession and the number of client and consulting projects undertaken.

Importance of digitalization: The second block of questions, containing Questions 5–8, addressed the current and future importance of digitalization, along with its importance during the COVID-19 pandemic. To that end, participants were asked to indicate digitalization's importance for themselves as consultants in Question 5 and for their company in Question 7. In between, Question 6 asked for an assessment of digitalization's expected importance in the next five years from the participant's perspective. Last, Question 8 inquired into how digitalization's importance has changed from the company's perspective since the pandemic.

Importance of digital technologies: In the third block of questions, Questions 9 and 12 sought to determine the importance of digital technologies and trends in business consulting. To that purpose, a list of 14 digital technologies was created with reference to the literature. To ensure consistency in understanding, potentially unfamiliar technologies were briefly explained. Meanwhile, Questions 10 and 11 asked participants about the importance of those technologies during the COVID-19 pandemic. Those questions allowed us to determine both the current state of digital technologies in business consultancies and the most significant technologies for the consultants during the COVID-19 pandemic.

Degree of digitalization: In the fourth block of questions, Question 13 asked participants to select one of four statements that best describes the current level of digitalization in their respective companies.

Importance of the business model: The fifth block of questions consisted of Question 14, which asked about the COVID-19 pandemic's impact on the company's business model.

Use of digital technologies: To gain more granular insight, the first question of the sixth block of questions, Question 15, asked the consultants to rate their current use of digital technologies during the different phases of the consulting process. Afterward, Question 16 asked them to rate their expected use of digital technologies in the next five years, and Question 17 asked them to select the technologies that they use in each phase of the consulting process.

Perception of digitalization and future trends: The intention of the seventh and final block of questions was to determine how the participants perceived digitalization at present and in the future. To that end, Questions 18 and 19 asked participants to evaluate specific opportunities by responding to different statements. The questions were intended to capture the participants' opinions on digital technologies. Last, Question 20 inquired into the participant's personal attitude toward digitalization.

Data Collection

As a result of several pretests with various researchers of the Technical University of Central Hesse and different practitioners, the questionnaire was improved. The general aim of the pretests was to assess the questionnaire's instructions as well as the individual questions for comprehensibility and errors.

Next, mostly using email, we invited consultants to participate in our study. To that end, we contacted all business consultancies that were members of the BDU at the time of data collection, and their responses were our primary source for contact information. The emails were sent between January 15 and February 15, 2023. We also shared the link to the online questionnaire on business platforms such as LinkedIn (www.linkedin.com) and XING (www.xing.com) and with personal contacts in our business networks.

When the survey period ended, the online questionnaire had been completed 291 times. Of those 291 questionnaires, 187 had been completed in full. Before data analysis, those 187 questionnaires were checked for plausibility, with special attention to whether any pattern in the answers might suggest that the participant had only clicked through the questionnaire at random. As a result, we had to exclude only one data set, meaning that 186 data sets were analyzed for the results presented in the following section.

IV. Selected Results

Participants' General Characteristics

To be able to differentiate responses along the lines of company size, the business consultancies were grouped according to the number of employees. Table I provides an overview of the respective company sizes.

Table I.
Participant structure by number of employees (n=186)

Number of employees	Absolute frequency	Relative frequency
1–10	47	25.3%
11–49	30	16.1%
50–249	19	10.2%
>250	90	48.4%

Table I shows that 47 consultants from micro-enterprises and 30 from small enterprises participated in the survey. The smallest group of participants, totaling 19, was represented by medium-sized companies, whereas the largest proportion of participants, totaling 90, came from large companies.

The distribution of participants across the different fields of consulting (see Section 2) was highly heterogeneous. Because Question 2 allowed multiple answers, the 186 participants gave a total of 245 answers. The most represented field was organization and process consulting, with 78 responses, followed by IT consulting with 70, strategy consulting with 44, and human resources consulting with 36. Added to that, 17 participants selected the answer option “Other.”

Concerning the experience of the participants in terms of their years spent working as consultants, Table II shows that 105 participants had up to 10 years of work experience and that 81 had at least 10 years of work experience.

Table II.
Participants by years of work experience (n=186)

Years of work experience	Absolute frequency	Relative frequency
<1	5	2.7%
1–5	66	35.5%
6–10	34	18.3%
11–15	20	10.8%
16–20	20	10.8%
21–25	18	9.7%
26–30	13	7.0%
31–35	4	2.2%
36–40	6	3.2%
> 40	0	0%

The participants' professional experience with consulting projects was also queried. Whereas only 11 consultants had previously worked on 1–3 projects, 43 had been involved in 4–9 projects, 37 in 10–19 projects, 20 in 20–29 projects, and 17 in 30–39 projects. In the largest group, 58 participants had been involved in more than 40 projects.

Digitalization: General Aspects

The participants were also asked to assess the current role of digitalization in their day-to-day work. For a detailed look at their responses, Figure 1 shows how participants with up to 10 years of professional experience responded versus participants with more than 10 years of professional experience. On the one hand, participants with up to 10 years of professional experience attributed “medium significance” and “high significance” to digitalization in their day-to-day work in nearly equal measure, at rates of 44.8% and 48.6% respectively. By contrast, only 6.7% participants selected “low significance.” On the other hand, 63.0% of participants with more than 10 years of professional experience characterized digitalization as having “high significance” in their daily work, whereas 30.9% of them selected “medium significance” and another 6.2% selected “low significance.” Remarkably, none of the participants selected “no significance” to answer the question. It is therefore clear that digitalization was perceived as playing a greater role in the day-to-day work of consultants with more than 10 years of professional experience than for ones with up to 10 years of such experience.

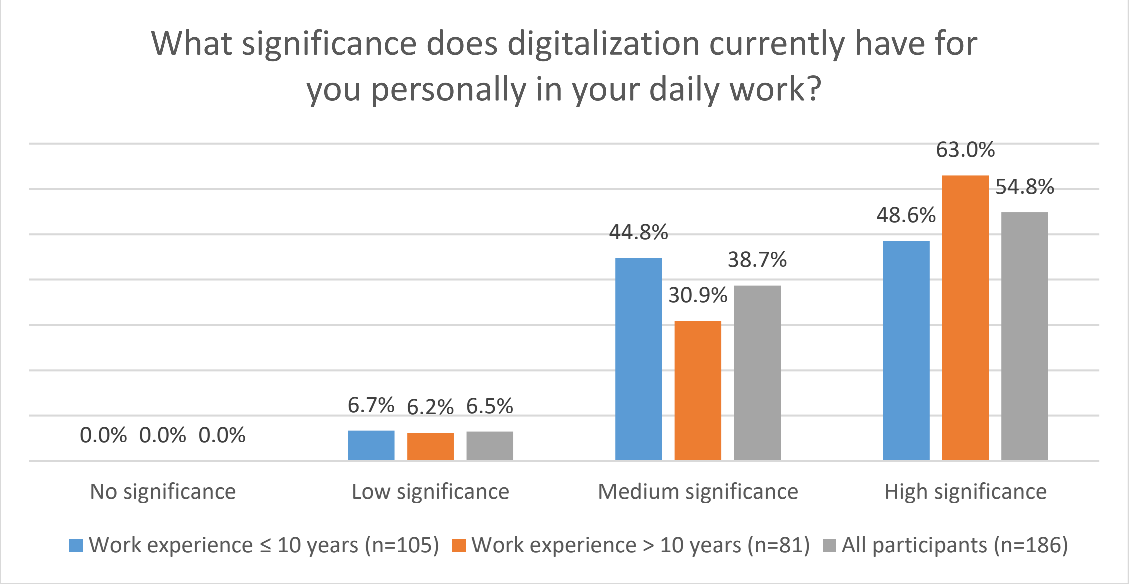

Fig 1. Significance of digitalization for consultants according to work experience (n=186; relative frequency)

Regarding digitalization in general, the participants were additionally asked to assess the level of digitalization in their consultancies by choosing one of the following levels:

- **Level 1:** We predominantly rely on consulting processes in which our consultants work together with the customer on-site. Technologies such as chat, video-conferencing, and other digital collaboration tools are rarely used in projects.
- **Level 2:** We carry out projects in which our consultants and customers work together at separate locations. However, most of our projects are based on on-site, face-to-face interaction.
- **Level 3:** Digital technologies are an integral part of our business model. We specifically manage the personal deployment of consultants on-site and no longer include it in every project.
- **Level 4:** Our business model is based predominantly on digital technologies. Consultants work on-site with clients only in particularly critical phases and in regard to particularly complex problems.

Given those four statements, only 22 of the 186 participants selected Level 4 to characterize digitalization at their companies. By contrast, 83 selected Level 3, 68 selected Level 2, and, least frequently, 13 selected Level 1.

To present the level of digitalization in greater detail, Figure 2 depicts the level of digitalization of the business consultancies by company size. As shown, 18.9% of large companies were characterized as having Level 4 digitalization, followed by 10.5% of medium-sized companies. Micro-enterprises accounted for the largest share of Level 1 digitalization, at 12.8%, while small companies had the second-largest share, at 10.0%. Those results clearly show that larger companies seem to have a higher level of digitalization than smaller companies.

Turning to the perception of digitalization, we asked participants whether they perceived digitalization primarily as a threat to or as an opportunity for their companies. Figure 3 provides a breakdown of their answers based on company size. The top bar of the graph shows the overall results, which indicates that 113 participants perceived digitalization in their companies “clearly as an opportunity” and 61 as “more like an opportunity.” The remaining 12 participants perceived digitalization in their companies as both an opportunity and a threat (i.e., “opportunity/threat”). Notably, none of the participants selected the answer options “more like a threat” or “clearly as a threat.” The other four bars in the graph show the evaluation by company size. Of the 90 participants from large companies, 56 perceived digitalization at their companies “clearly as an opportunity,” 29 as “more like an opportunity,” and 5 as “parts/parts.” The picture sharpens for medium-sized companies; of those 19 consultants, 17 perceived digitalization in their companies “clearly as an opportunity” and 2 as “more like an opportunity.” Thus, medium-sized companies had the highest proportion of participants who selected “clearly as an opportunity.” The 30 participants from small companies also only selected two answer options; 19 selected “clearly as an opportunity,” while 11 selected “more like an opportunity.” By contrast, of the 47 participants in micro-enterprises, 21 chose “clearly as an opportunity,” 19 chose “more like an opportunity,” and 7 chose “parts/parts.”

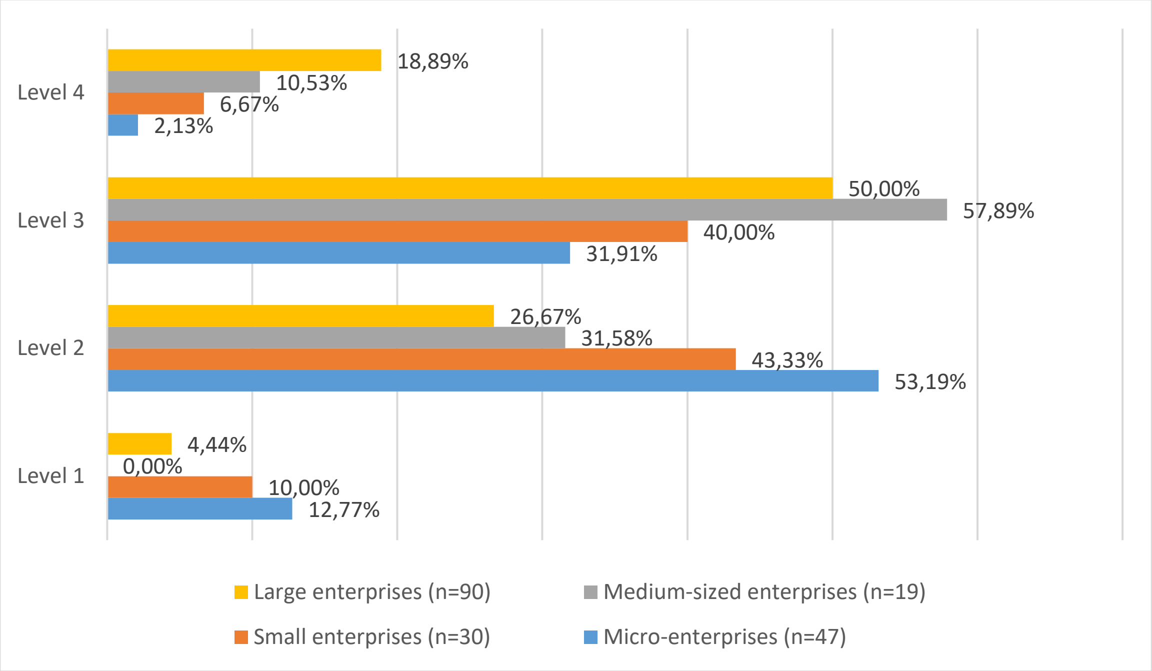

Fig 2. Level of digitalization by company size (relative frequency)

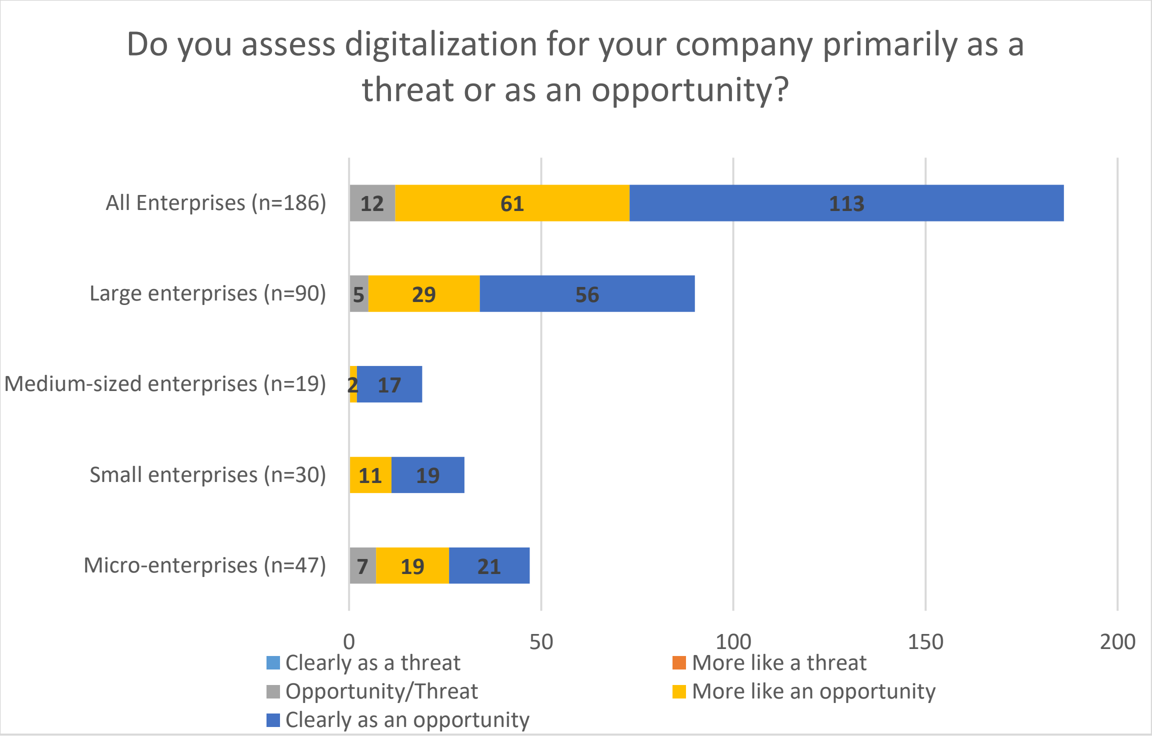

Fig 3. Perception of digitalization (n=186; absolute frequency)

Use of Digital Technologies

This section presents the results of our analysis of the data from questions concerning the use of digital technologies in business consultancies.

To begin, focusing on the current and future significance of digital technologies in business consultancies, participants were asked to assess the current significance of 14 specific technologies. They were next asked to assess the importance of those technologies for their consultancies in the next five years. To evaluate those data, the verbalized answers were coded and recorded as arithmetic mean values. The following coding was chosen:

- 1 = *no importance*
- 2 = *low importance*
- 3 = *medium importance*
- 4 = *great importance*

Table III provides an overview of the results. Because not every participant assessed every technology, the table also provides the number of participants who assessed the particular technology.

TABLE III.
SIGNIFICANCE OF DIGITAL TECHNOLOGIES (N=186; MULTIPLE ANSWERS POSSIBLE)

Digital technology	Current significance (arithmetic mean)	Future significance (arithmetic mean)
Knowledge management systems (n=180)	2.96	3.38
Virtual marketplace for consultants and customers (n=180)	2.96	2.99
Social media (n=180)	2.18	3.29
Self-service consulting (n=175)	2.05	2.98
Open community and expert platforms (n=171)	2.32	3.01
Mobile computing (n=171)	3.54	3.81
Artificial intelligence (n=182)	2.66	3.62
Document management systems (n=181)	2.99	3.34
Data/process mining (n=171)	2.52	3.47
Crowdsourced consulting (n=170)	2.05	2.96
Cloud computing (n=180)	3.29	3.69
Chats (n=183)	3.22	3.31
Big data analytics (n=176)	2.52	3.55
Audio/video-conferencing (n=186)	3.72	3.75

As Table III shows, audio/video-conferencing was viewed as being the most important digital technology, with a mean value of 3.72 out of 4.00. In second place was mobile computing, with a mean of 3.54, followed by cloud computing, with a mean of 3.29. The importance of the mean values becomes particularly clear when looking at the technologies in the lower ranks. Social media came in third lowest place, with a mean value of 2.18, followed by crowdsourced consulting and self-service consulting as lowest in ranking, each with a mean of 2.05.

The difference between the arithmetic means of “Current significance” and “Future significance” indicates which digital technologies may become the focus of consulting firms in the next five years. The third-largest difference was 0.96 for artificial intelligence technology, closely followed by social media, with a difference of 1.01. The largest difference, 1.03, was with big data analytics.

Next, participants were asked to indicate the current and anticipated future use of digital technologies in their consulting process. Again, the arithmetic mean was used for evaluation. To that end, the verbalized answers were coded as follows:

- 1 = *no use*
- 2 = *very little use*
- 3 = *low use*
- 4 = *medium use*
- 5 = *high use*
- 6 = *very high use*

Figure 4 shows the participants’ evaluation of the current and anticipated future use of the technologies in the consulting process undertaken by their respective business consultancies. The figure readily clarifies that the anticipated future use of digital technologies in all phases of the consulting process was rated higher than the current use.

To gain a comprehensive view of the current use of digital technologies in the consulting process, participants had the opportunity to assign the 14 listed technologies to the individual phases of the process and could select multiple response options. Table IV provides an overview of the results. When the numbers of the various technologies per phase were totaled, digital technologies emerged as being used most frequently in problem analysis, followed by problem-solving and project preparation. Implementation ranked fourth, followed by acquisition. Last, post-processing was reported to involve the fewest digital technologies. Altogether, the results suggest that the diversity of digital technologies used is most often greatest in the middle phases of the consulting process.

Regarding the use of digital technologies in the different fields of consulting, participants in IT consulting selected different digital technologies most frequently in all six phases of the consulting process, closely followed by participants in organization and process consulting. Participants in strategy consulting reported using nearly half as many different digital technologies as in IT consulting or organization and process consulting. Meanwhile, participants in human resources consulting reported using the fewest different digital technologies.

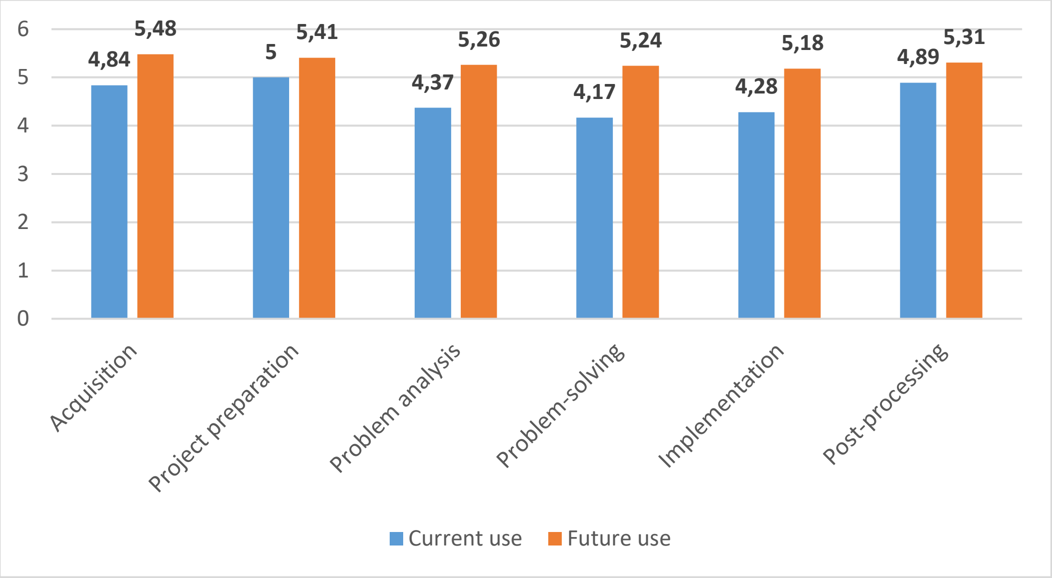

Fig 4. Use of digital technologies (n=182; arithmetic mean)

TABLE IV.
DIGITAL TECHNOLOGIES PER PHASE OF THE CONSULTING PROCESS (N=186; ABSOLUTE FREQUENCY, MULTIPLE ANSWERS POSSIBLE)

	Acquisition	**Project preparation**	**Problem analysis**	**Problem-solving**	**Implementation**	**Post-processing**
Knowledge management systems	66	133	121	125	95	100
Virtual marketplace for consultants and customers	92	36	35	39	27	18
Social media	144	24	21	23	18	20
Self-service consulting	11	29	92	37	23	13
Open community and expert platforms	68	37	41	62	29	16
Mobile computing	123	139	143	140	138	131
Artificial intelligence	19	28	77	78	56	18
Document management systems	92	124	115	117	113	122
Data/process mining	16	32	102	79	35	17
Crowdsourced consulting	17	31	42	62	30	29
Cloud computing	72	118	120	118	116	100
Chats	90	136	126	124	116	112
Big data analytics	20	26	111	67	30	15
Audio/video-conferencing	106	166	143	135	128	143

Last, Table V provides an overview of the participants' opinions on five statements regarding the use of digital technologies. For each statement, the arithmetic mean was again calculated, and the verbalized scale was coded as follows:

- 1 = *strongly disagree*
- 2 = *somewhat disagree*
- 3 = *parts/parts*
- 4 = *somewhat agree*
- 5 = *strongly agree*

Table V shows that the statement "By using digital technologies, the work–life balance in the consulting industry is improved" was only partly agreed with, with a mean value of 3.71. By contrast, the statement "By using digital technologies, there is an increase in the efficiency of consulting" had the highest level of agreement of the five statements, with an mean of 4.3. The lowest level of agreement, with a mean of 2.82, was achieved by the statement "By using digital technologies, the quality of the result delivered to the customer is improved." The statement, "By using digital technologies, new customers and markets can be addressed," was agreed to by significantly more participants, with a mean value of 4.25. The rating of the remaining statement, "By using digital technologies, a differentiation from competitors is made possible," had a mean value of 3.82. Based on the five mean scores, it can be concluded that the participants were more likely to agree than disagree with the statements.

TABLE V.
OPINIONS ON THE USE OF DIGITAL TECHNOLOGIES (N=186; ABSOLUTE FREQUENCY AND ARITHMETIC MEAN)

By using digital technologies...						
Statement	**Strongly agree**	**Somewhat agree**	**Parts/parts**	**Somewhat disagree**	**Strongly disagree**	**Arithmetic mean**
...a differentiation from competitors is made possible. (n=181)	64	56	31	24	6	3.82
...new customers and markets can be addressed. (n=182)	89	60	24	8	1	4.25
...the quality of the result delivered to the customer is improved. (n=186)	48	72	54	10	2	2.82
...there is an increase in the efficiency of consulting. (n=186)	85	77	19	4	1	4.3
...the work–life balance in the consulting industry is improved. (n=184)	49	65	42	23	5	3.71

V.Conclusion, Limitations, and Directions for Future Research

The results of our analysis suggest that consultants currently consider digitalization as to be of medium to high importance in their business consultancies. Taking into account their work experience, digitalization seems slightly more important for more experienced consultants than for less experienced ones. In terms of the four classic fields of consulting that we considered in our study, digitalization currently seems to be most important in strategy consulting and human resources consulting. No matter the field—indeed, overall—digitalization is not perceived as being exclusively a threat (vs. an opportunity). In fact, for 60.1% of consultants, digitalization is clearly perceived as an opportunity and for 32.8% is perceived as being at least somewhat of an opportunity. Therefore, digitalization is seen in an almost entirely positive light by consultants. On top of that, consultants perceive an opportunity to increase efficiency in the consulting process by using digital technologies and believe that the technologies will allow new markets and customers to be reached.

From the consultants' perspective, traditional technologies such as audio- and video-conferencing, mobile computing, and cloud computing are currently the most important for their business consultancies. By contrast, analytical tools are used only sporadically but increasingly more often in larger companies. Beyond that, technologies such as self-service consulting, virtual marketplaces for customers and consultants, and crowdsourced consulting are rarely used. According to the participants, established technologies will continue to play the most important role in their business consultancies in the next five years. Nevertheless, they also expect the use of analytical tools and social media to increase in importance. From their perspective, digital technologies in general will play an important part in developing future business consultancies, and their use stands to have a major impact on the efficient delivery of good consulting services in the future.

Within the concrete phases of the consulting process, the fewest technologies are used during acquisition and post-processing. By contrast, technologies are increasingly used from the phrases of preparation to implementation. From the consultants' perspective, the use of technologies in all phases of the consulting process will increase in the future; even so, they expect priority use after acquisition and before post-processing. Within the individual phases, established technologies are preferred and used the most frequently. Social media, by comparison, is primarily used in acquisition, and analytical tools are used especially during problem analysis. However, a clear change in the technologies used within the phases was not observed despite the existence of social media and virtual marketplaces.

In sum, it can be stated that business consultancies clearly see the benefits of digitalization and of using digital technologies. Nevertheless, they continue to rely on more established technologies. In response to that tendency, future research needs to produce a more detailed, diversified view of the use of different digital technologies. That need is especially evident considering the potential impact of widely discussed generative AI tools such as ChatGPT. On that count, qualitative studies should be conducted in individual fields of consulting and with more specific consideration of company size, especially the size of the companies using the consulting service, to further pinpoint the importance of digital technologies for the consulting process in general and for its respective phases. Future research should also analyze the use of digital technologies with reference to the different types of consulting projects, including logistics projects, IT/digitalization projects, and human resources projects, in order to identify and highlight differences. Last, we recommend investigating barriers to and challenges in using digital technologies in business consultancies and how they can be minimized.

As most empirical studies, ours was limited in multiple ways. Due to our approach, our results possess limited statistical generalizability. However, the method applied allowed us to identify important details and obtain initial insights into the experience of business consultants, which was the chief focus of our study. Another limitation was that the participants' origins were limited to German business consultancies. Because German-specific trends could have influenced the results, the results reflect the situation in one country only.

***Abstract*—In their transition to smart cities, an increasing number of cities are pursuing strategies to improve efficiency of transport. One strategy is to achieve smart mobility, for which cities implement intelligent transport systems (ITS). Simultaneously, municipalities recognize their responsibility for creating a sustainable environment for citizens in the face of challenges like overpopulation, land shortage, and climate change. Interestingly, many ITS initiatives mainly focus on technical outcomes and overlook their impact on sustainability despite its key benefit for smart mobility. To fill this gap, we develop a framework for assessing the sustainability impact of ITS initiatives in this paper. We analyze the Sustainable Development Goals (SDGs) defined by the United Nations and relate them to various concepts of ITS to derive our framework. Thereby, our work bridges two fundamental perspectives for further research and supports decision-makers in choosing ITS initiatives that contribute to both smart mobility and sustainability.**

***Index Terms*—smart city, smart mobility, smart traffic management, intelligent transport systems, sustainability**

I. Introduction

SMART mobility can be viewed as a comprehensive and collective term encompassing various data-driven concepts for maneuvering individuals, groups of people or objects in one or multiple geographies and influences our present and future [1]. Considering the complex challenges of the current decade, such as overpopulation, demographic change, globalization, space shortage, and dense traffic, cities aim to stay attractive to their citizens and provide a livable environment [2], [3]. With over 50% of the global population living in urban areas, their citizens can especially profit from the opportunities of smart traffic management and the management of high traffic volume in congested environments [4]. Simultaneously, the environmental and social challenges driven by climate change raise the need for municipalities to take responsibility and counteract the negative influences on their citizens. Consequently, more cities aim to use the advances of digitalization to create value for smart and sustainable mobility of citizens [5]–[8]. Some researchers even point out that cities cannot become smart without being sustainable, making sustainability an important factor in smart city projects [9].

Intelligent transport systems (ITS) provide a set of technical applications and aim to provide innovative services for different modes of transport and traffic management [1], [10], [11]. They empower citizens to make better decisions regarding their mobility and enable safer and better-coordinated transport networks. Since road traffic is responsible for about 65% of the CO2 emissions in cities and is likely to increase in the future, ITS promise to mitigate the negative effects of traffic on the environment [12]. However, while sustainability is a key factor in smart mobility initiatives, many ITS projects are still mainly focused on technical criteria and measures and do not seem to analyze their impact on sustainability [13]–[15].

Therefore, we target the intersection of sustainability and ITS in this paper. We analyze the Sustainable Development Goals (SDGs) defined by the United Nations (UN) to determine which goals, targets, and indicators have implications for the development of ITS in the context of smart mobility towards a sustainable smart city. Specifically, we explore different perspectives on ITS and relate them to the SDGs to answer the following question:

> Which Sustainable Development Goals, targets, and indicators are relevant for assessing the sustainability of intelligent transport systems?

To answer this question, we review the relevant literature and combine it with international agreements and resolutions to derive a framework for measuring the effectiveness of ITS strategies on sustainability. Therefore, the paper is structured as follows. First, we define the term intelligent transport systems and set it into the context of smart cities and sustainability. We then develop our framework based on the literature and describe the implications for further research and practice.

With our research, we contribute to the research fields of sustainable smart cities and mobility while also providing practical implications for sustainable ITS. With our findings, we want to inspire municipal decision-makers and technical leaders to consider sustainability factors to build data-driven solutions that leave a positive impact on society and nature. In fact, we are currently facing this specific challenge in a project for data-driven traffic management funded by the German Federal Ministry for Digital and Transport. Hence, we want to share our approach to support other cities considering or planning ITS projects.

II. Related Literature

A. Smart Cities and Smart Mobility

With the trend of urbanization and population growth, cities become increasingly populated while space and resources are limited. Urban areas will face challenges in meeting the needs of their growing number of citizens in many sectors, such as housing, transportation, energy systems, education, and healthcare, which leads to the need for sustainable development [16]. The concept of smart cities has been evolving in the last decade and aims to enhance quality of life in urban areas by using the opportunities of information and communication technologies (ICT), hardware, algorithms, and data to create a positive impact on life in cities [7].

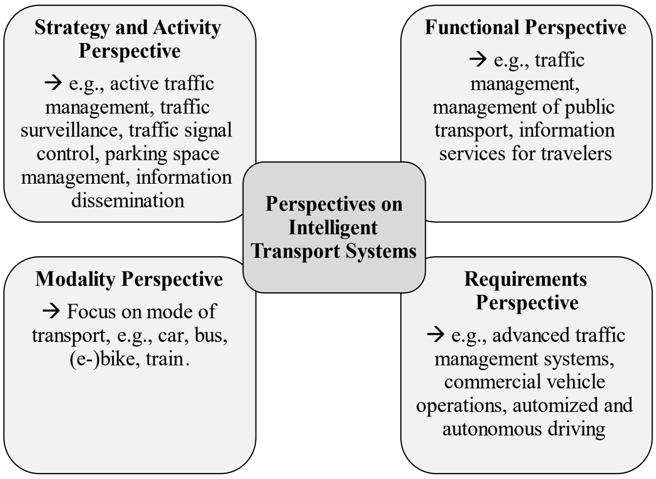
Smart cities are characterized by the six areas *smart economy, smart people, smart governance, smart environment, smart living,* and *smart mobility,* which are all interlinked [17]. Smart mobility is an especially relevant building block of smart cities. The improvement of mobility with technical advances can save resources, increase efficiency, and provide accessibility [4]. More specifically, smart mobility is defined as "a set of coordinated actions addressed at improving the efficiency, the effectiveness and the environmental sustainability in cities," which is characterized by transport and the use of information and communication technology [6]. It further consists of local accessibility, (inter-)national accessibility, availability of ICT infrastructure, and sustainable, innovative and safe transport systems [17]. Smart mobility has direct implications for fulfilling the Sustainable Development Goals defined by the United Nations and will contribute to the future of city planning and logistics [18]. However, research still shows gaps regarding the consideration of potential sustainability factors that directly affect citizens, e.g., air quality [19]. The field of smart mobility therefore leaves high potential for future research for more sustainable cities.

B. Smart Traffic Management and Intelligent Transport Systems

A variety of terms is employed to denote the technical applications, data-driven services, and conceptual advances for data-driven traffic management; the most frequently used terms are intelligent transport systems, smart traffic management, transport/travel demand management, and smart mobility management. Though not completely congruent, these terms exhibit a high semantic overlap and are used interchangeably. In this paper, we consistently use the term intelligent transport systems (ITS) since it has been researched for more than two decades now [20] and is used by the United Nations and European Parliament [11].

ITS are defined as all technical solutions and construction concepts related to traffic [1]. The United Nations Economic Commission for Europe (UNECE) further describes them as "a set of procedures, systems and devices that enable (a) improvements in the mobility of people and transportation of passengers and goods, through the collection, communication, processing and distribution of information and (b) the acquisition of feedback on experience and a quantification of the results gathered" [21]. The European Parliament defines ITS in a slightly more generalized manner as communication systems to provide services related to different modes of transport and traffic management which supports a safer, more coordinated, and smarter use of transport networks for users [11]. All definitions, however, have the target of technology-based and data-driven traffic management in common that aims to improve mobility. ITS further consist of various tools based on information and communication technology and support the concept of smart mobility [10]. Examples for specific applications are traffic light control systems or analytical tools that influence transport management.

In addition to various definitions, several perspectives on ITS focus on different means and needs. In Fig. 1, we summarize four of the most prominent perspectives and definitions and in the following describe them in more detail for a broad understanding of the concept.



Strategy and Activity Perspective
→ e.g., active traffic management, traffic surveillance, traffic signal control, parking space management, information dissemination
Functional Perspective
→ e.g., traffic management, management of public transport, information services for travelers
Perspectives on Intelligent Transport Systems
Modality Perspective
→ Focus on mode of transport, e.g., car, bus, (e-)bike, train.
Requirements Perspective
→ e.g., advanced traffic management systems, commercial vehicle operations, automized and autonomous driving

Fig. 1. Perspectives on intelligent transport systems, own illustration derived from [1], [10], [21], [22], [23]

The strategy and activity perspective on ITS [22], [23] is defined by the U.S. Department of Transportation and provides the broadest and most granular perspective. It is focused on ITS strategies and details them into activities. Depending on the publication, 16 to 26 related activities are defined. The strategies and sample activities are:

- Traffic management and operations (e.g., traffic surveillance, traffic signal control, speed and intersection warning systems, bicycle and pedestrian crossing enhancements),
- Road weather management operations (e.g., road weather information systems, winter roadway operations),
- Maintenance and construction management (e.g., coordination activities for construction management, work zone management),
- Incident and energy management (e.g., emergency management, emergency vehicle routing), and
- Public transportation management (e.g., electronic fare collection and integration, multimodal travel connections, transit surveillance).

The functional perspective [10] on ITS describes functions of ITS like management or information provision, consisting of:

- Traffic management,
- Management of public transport,
- Management of cargo transport and fleet of vehicles,
- Traffic safety management and monitoring systems for violation of regulations,
- Management of road incidents and emergency services,
- Information services for travelers and electronic payment services, and
- Electronic systems for collecting tolls for road use.

Some of these functions also overlap with the activities from the strategy and activity perspective, which shows that there is no clear separation of the different perspectives. According to this definition, ITS operation is particularly focused on information collection from different systems, processing of this information, and the provision of related recommendations.

The requirements perspective [1] focuses on requirements profiles and specific technical systems. Again, there are overlaps to both the strategic and functional perspectives. The related systems are:

- Advanced Traffic Management (ATMS),
- Advanced Traveler Information (ATIS),
- Advanced Vehicle Control (AVCS),
- Commercial Vehicle Operations (CVO),
- Advanced Public Transportation (APTS),
- Rural Transportation (ARTS),
- Automized and Autonomous Driving,
- Intelligent Traffic Data (Smart Traffic), and
- Vehicle Networks (Connected Vehicles).

These systems have a direct impact on activities such as emergency management, information management, or innovation management.

While the previous perspectives provide a more generic view, ITS can also be categorized according to the modes of transport they address. That leads to the modality perspective [1], comprising:

- (Motor) car traffic,
- Public transport (bus, train, city train, subway),
- (e-)Bike,
- Motorcycle,
- Plane, or
- Vessel.

The modal split is especially important in relation to sustainable solutions. However, in contrast to the previous ones, this perspective does not present activities or strategies. In summary, every perspective provides a slightly different view on ITS while they have a focus on more efficient, safe, and sustainable intelligent traffic management and the consideration of the modal split in common.

C. Sustainable Development Goals

In 2015 the United Nations formally acknowledged the need for transformative change towards sustainability and defined 17 goals for sustainable development (SDG). The resulting resolution defines sustainability as "meeting the needs of the present without compromising the ability of future generations to meet their own needs" by considering environmental concerns, social aspects, and economic development [16]. Therefore, sustainability encourages growth and technological progress by focusing on people's needs while also making sure that choices in the present do not exhaust resources needed in the future.

All 17 goals are interdependent, and they are defined by 169 targets overall. The progress for achieving these targets can be tracked by 231 unique indicators (ibid). The goals are set to be achieved by 2030 and have universal relevance, as they have been aligned between all 191 UN member nations and thus represent a collective understanding of sustainability.

Many of these goals build an important foundation for the progress towards smart mobility. The application of traffic-related technology and smart services in cities reflects the original idea of smart mobility. However, smart mobility also calls for a balance of technology with the needs of citizens that are reflected by the sustainability factors [24]. Recent research shows that there is high potential for analyzing the contribution of smart cities to achieve sustainable development [25] and some researchers even go as far as to point out that cities cannot become smart without being sustainable, making sustainability an important factor in smart city projects [26]. Further, researchers have covered ICT adoption for sustainable development in the industry context, highlighting the link between ICT and sustainability [27].

The presented literature shows that sustainability is important for smart mobility in smart cities. Therefore, we aim to provide a framework of the important SDGs that relate to ITS in order to be able to assess related projects and support decision-making in smart mobility initiatives.

III. Methods

In the previous chapter, we showed the need for ITS that are not only smart but also sustainable. However, to our knowledge, there is no framework that would help researchers and decision-makers assess whether and how smart traffic management measures contribute to sustainability. Therefore, we dedicate this research to analyzing the various perspectives on ITS and bringing them into the context of the SDGs. To answer our research question, we combine the Sustainable Development Goals, their targets, and related indicators in a framework that shows the sustainability factors ITS can influence. Based on the relevant literature on sustainability, smart mobility, and ITS, we conduct conceptual development in our study. Besides scientific literature, we also include international agreements and recommendations into the development for several reasons: First, UN resolutions can be seen as universally relevant because 191 states from the world community have committed to their achievement. Recommendations by the UNECE are similarly relevant and, while not legally binding, provide a more detailed view than the resolutions. Second, we aim to ground our framework on existing work while developing a new concept through the combination of several perspectives. A literature exploration can provide different views and serve as a foundation for developing a unified understanding. Third, the combination of scientific literature with international agreements allows for both rigorous and relevant contributions. The detailed process of the framework development is described in the following chapter.

IV. Framework Development

A. Overview

In the following, we describe the process of our framework development in detail and explain how we combined the SDGs with perspectives from ITS, filtered and refined them across different stages, and finally brought them together for a central view. Fig. 2 summarizes this process and shows how both strands are first considered individually and then merged into the final framework.

B. Determination of Relevant Sustainable Development Goals

To determine the relevant SDGs for our framework and their relation to ITS, we searched for key terms in the resolutions A/RES/70/1 as the original 2030 Agenda for Sustainable Development and A/RES/71/313, which additionally contains the later-adopted indicators to the goals [16], [28]. We started out with all 17 goals, 169 targets, and 231 indicators (248 indicators including duplicates) and filtered them according to the terms in Table 1. We determined the terms according to the perspectives of ITS described in the previous chapter and used collective terms, e.g., "transport," for all related terms. We further added terms that focus on cities since we used them as the application context of our study. Additionally, we added the pollution perspective as a result of traffic and as one goal of ITS. The detailed rationale behind the terms can also be found in Table 1.

The resulting set contained 8 goals, 16 targets, and 16 indicators. We then eliminated two further targets and five indicators. First, we ruled out target 14.1 because it is related to marine pollution, which falls outside the scope of our framework that focuses on traffic on land. We also excluded two indicators that contained the term "urban" as a description for the measurement process and therefore did not apply in terms of content (indicators 1.1.1., 4.5.1, 11.6.1). Finally, we also excluded goal 12.c and indicator 12.c.1 because they are re-

TABLE I.
FILTER TERMS FOR SUSTAINABLE DEVELOPMENT GOALS, TARGETS, AND INDICATORS

Term	Rationale
"traffic", "transport"	Direct relation to the traffic component of ITS
"air", "pollution", "air pollution", "greenhouse gas", "emission(s)"	Direct relation to the consequences of (motorized) traffic and traffic density as well as the goal of ITS to mitigate the effects on the environment with data-driven systems and technology
"urbanization", "urban", "urban planning", "city", "cities"	Application context of a (smart) city
"fuel", "fossil fuel"	Resources for motorized traffic that is the dominant form of traffic in cities
"car", "bike", "bicycle", "public transport", "train", "pedestrian", "walk(ing)"	Relation to modes of transport on land that are part of ITS

lated to subsidies that are not decided on the level of municipalities and therefore not in the scope of ITS in the context of smart cities. Afterward, we added the superordinated targets or goals related to targets or indicators since they would not apply to the search terms. Hence, we did not add indicators to related targets when they did not apply to the criteria, leaving some indicators blank. From these constraints remained 8 goals, 14 targets, and 11 indicators that we applied to different perspectives on ITS and that can be found in the matrix in Table 2.

C. Determination of Intelligent Transport System Perspectives

After the preselection of relevant SDGs, we determined the relevant ITS dimensions. As presented in the literature review, there are multiple perspectives of ITS that overlap and align in some parts but still provide different views and concepts. In general, we opted for the definition by the UNECE which contains the aspects of improvements in the mobility of people, transportation of passengers and goods, the collection, communication, processing, and distribution of information as well as the acquisition of feedback on experience and quantification of the gathered results. Based on this definition, we aimed to equally consider all four perspectives on ITS that we derived from literature and presented in Fig. 1. We decided against choosing only one of the perspectives in order to include SDGs that are relevant but do not relate to all perspectives. By using several perspectives, we further aim for more transparency, a broader view, and stability in the evaluation to assess the SDGs for developing our final framework.

D. Combination of SDGs and ITS

After filtering the relevant SDGs and determining the ITS perspectives, we combined both dimensions in a matrix (Table 2). On the Y-axis (e.g., in the rows), we entered the Sustainable Development Goals together with the related targets and indicators. We chose a hierarchical view to represent goals, targets, and indicators in an accessible way. On the X-axis (e.g., in the columns), we added the four perspectives on ITS. We then analyzed how measures of each of the ITS perspectives could contribute to the sustainability targets and indicators. We used the resulting intersections to record the results of our analysis. Perspectives that directly contributed to a target or indicator were marked with "XX" in the related row. Perspectives with a more indirect relation were marked with only one "X" to indicate a lower relevance.

After analyzing each relation, we summarized the findings in a central framework (Table 3). We summed up the labels that indicate each relevance per row to determine whether a target or indicator is primarily or secondarily impacted by ITS. We considered targets and indicators that were marked as relevant ("XX") in relation to all ITS perspectives as primarily impacted by ITS and indicators that were either marked as less relevant ("X") or relevant for less than all four perspectives, as secondarily impacted.

E. Final Framework

From the analysis performed, we were able to determine six main sustainability indicators and eight targets that relate to a total of six Sustainable Development Goals and are primarily influenced by ITS. The remaining five indicators and five targets can be influenced by ITS but probably with lower intensity. Therefore, they were marked as indirectly influenced. The final framework is displayed in Table III.

While SDG 11, "Sustainable Cities and Communities," is the most represented goal in the framework with the highest number of related targets and indicators, the other goals are equally relevant. Our framework especially highlights goals that do not relate directly to traffic, like SDG 7, "Affordable and Clean Energy," or SDG 6, "Clean Water and Sanitation."

Our framework provides an overall view of the most important SDGs as a recommendation for researchers and practitioners to consider in the development process of intelligent transport systems. It further stresses that there is not only one perspective on sustainability and that ITS solutions could target sustainability in multiple areas. Some measures might also contribute to multiple SDGs at the same time, e.g., targeting indicator 9.4.1, "CO2 emission per unit of value added," might also have a positive impact on indicator 13.2.2, "Total greenhouse gas emissions per year," due to the general reduction of emissions.

While it might not be possible to consider every factor equally, it serves as a starting point to create awareness of sustainability targets and indicators in the context of ITS. The framework can be used by researchers, but especially but practitioners, to reflect upon projects and initiatives related to intelligent transport systems and sustainability. We recommend using it as a checklist to determine, whether at least one of the goals, targets or indicators is addressed with the planned initiative. The framework is best used in the planning phase of new ITS projects to determine possible sustainability goals, targets, and indicators that might play a role in the projects. Throughout initiatives, it can then help in making the general assessment of the contribution to sustainability of the solutions more transparent.

V. Limitations And Implications

While we aim for a broad and deep analysis in the creation of our framework, we would like to address some weaknesses in the approach and potential for future work. First, one challenge of a literature review is to include both relevant and novel literature as well as consider established "basic" literature. Despite our diligence in the selection process, we cannot claim to have a complete overview. Further, we recognize that other researchers might choose different publications. Additionally, the selection of the four perspectives on ITS might be influenced by subjective perception. As discussed in the literature review, there are many different terms for and perspectives on ITS. One reason might be the interdisciplinary character of ITS where different perspectives from traffic engineering, traffic planning, business administration, and information systems intersect. We see potential for future work in the attempt to find one definition of ITS that includes all perspectives in order to establish a common transdisciplinary understanding.

Second, the inclusion and exclusion criteria of the relevant Sustainable Development Goals were chosen with the application context in mind but are nevertheless subjective and offer room for discussion. Applying different search terms might lead to a different result set and might influence the final matrix. Further, there might be additional SDGs that do not have a direct relation to ITS but might still be considered when developing such systems. For example, SDG target 16.7 calls for ensuring responsive, inclusive, participatory, and representative decision-making at all levels. From a more social perspective, inclusive decision-making in the process of choosing and developing ITS measures, e.g., by including citizens, could contribute to this target as well. While we do not consider the development process of the applications or social factors in our analysis, our framework is easily adjustable and could include these factors in the future or be enhanced for projects with special emphasis on these dimensions.

Third, we recognize that the assessment of each SDG in relation to ITS might be subjective. We conducted the assessment to the best of our knowledge and based it on the descriptions of each SDG, target, and goal. However, other researchers might have rated the criteria differently. In future work, the rating could be enhanced with more expertise by including more researchers.

Fourth, our framework shows the criteria for assessing ITS from a qualitative perspective but does not provide quantitative measurement criteria. The UN does provide some implications for measurement in its definition of indicators. However, they are on a rather high level and need to be adjusted to and detailed for the specific context. Therefore, we suggest a follow-up study on developing a specific measurement for assessing ITS quantitatively.

VI. Conclusion

In this paper, we described the need for more sustainable actions in the mobility sector and pointed out that previous ITS projects and research seemed to lack the consideration of sustainability factors. We further argued that municipalities have a particular responsibility towards sustainability due to their position as decision-makers for their citizens. We developed a framework that considers both different ITS perspectives and sustainability factors and determined which Sustainable Development Goals, targets, and indicators are relevant for the assessment of the sustainability of intelligent transport systems and should be considered when developing ITS strategies.

To summarize, our framework supports decision-makers in municipalities with an approach to assess their selected or planned ITS initiatives regarding sustainability factors. This could help to make more conscious decisions towards a higher quality of living in cities and contribute to the economy, society, and nature at the same time. Hence, we call for a municipal traffic management that is not only smart but also sustainable to contribute to a livable future.

TABLE II.
ASSESSMENT MATRIX OF SDGS IN RELATION TO ITS

Sustainable Development Goals, targets and indicators			**ITS Perspectives**			
SDG	**SDG Target**	**SDG Indicator**	**STR**	**FNC**	**REQ**	**MOD**
Goal 3: Good Health and Well-Being	3.6 Halve the number of global deaths and injuries from road traffic accidents	3.6.1 Death rate due to road traffic injuries	XX	XX	XX	XX
	3.9 Substantially reduce number of deaths and illnesses from hazardous chemicals and pollution and contamination	3.9.1 Mortality rate attributed to household and ambient air pollution	XX	XX	XX	XX
Goal 6: Clean Water and Sanitation	6.3 Improve water quality by reducing pollution, eliminating dumping and minimizing release of hazardous chemicals and materials	-	XX	XX	XX	XX
Goal 7: Affordable and Clean Energy	7.1 Ensure universal access to affordable, reliable and modern energy services	7.1.2 Proportion of population with primary reliance on clean fuels and technology	XX	XX	XX	XX
Goal 9: Industry, Innovation and Infrastructure	9.4 Upgrade infrastructure and retrofit industries to make them sustainable, with increased resource-use efficiency and greater adoption of clean and environmentally sound technologies and industrial processes	9.4.1 CO2 emission per unit of value added	XX	XX	XX	XX
Goal 11: Sustainable Cities and Communities	11.2 Provide access to safe, affordable, accessible and sustainable transport systems for all, improving road safety, notably by expanding public transport	11.2.1 Proportion of population that has convenient access to public transport, by sex, age and persons with disabilities	XX	XX	XX	XX
	11.3 Enhance inclusive and sustainable urbanization and capacity for participatory, integrated and sustainable human settlement planning and management	11.3.2 Proportion of cities with a direct participation structure of civil society in urban planning and management		XX		
	11.6 Reduce the adverse per capita environmental impact of cities; special attention to air quality	11.6.2 Annual mean levels of fine particulate matter (e.g. PM2.5 and PM10) in cities (population weighted)	XX	XX	XX	XX
	11.7 Provide universal access to safe, inclusive, and accessible green and public spaces	11.7.1 Average share of the built-up area of cities that is open space for public use for all, by sex, age, and persons with disabilities				XX
	11.a Support positive economic, social and environmental links between urban, peri-urban, and rural areas by strengthening development planning	11.a.1 Number of countries that have national urban policies or regional development plans that respond to population dynamics and ensure balanced territorial development			XX	
	11.b Increase the number of cities/settlements adopting and implementing policies and plans towards inclusion, resource efficiency, mitigation, and adaptation to climate change, etc.	-	XX	XX	XX	XX
Goal 12: Responsible Consumption and Production	12.4 Environmentally sound management of chemicals and all wastes and reduce their release to air, water and soil	-	XX	XX	XX	XX
Goal 13: Climate Action	13.2 Integrate climate change measures into national policies, strategies and planning	13.2.2 Total greenhouse gas emissions per year	X	X	X	X
Goal 16: Peace, Justice and strong Institutions	16.1 Significantly reduce all forms of violence and related death rates everywhere	16.1.4 Proportion of population that feel safe walking alone around the area they live after dark	XX	X		X

***Abstract*—Modern manufacturing systems collect a huge amount of data which gives an opportunity to apply various Machine Learning (ML) techniques. The focus of this paper is on the detection of anomalous behavior in industrial manufacturing systems by considering the temporal nature of the manufacturing process. Long Short-Term Memory (LSTM) networks are applied on a publicly available dataset called Modular Ice-cream factory Dataset on Anomalies in Sensors (MIDAS), which is created using a simulation of a modular manufacturing system for ice cream production. Two different problems are addressed: anomaly detection and anomaly classification. LSTM performance is analysed in terms of accuracy, execution time, and memory consumption and compared with non-time-series ML algorithms including Logistic Regression, Decision Tree, Random Forest, and Multi-Layer Perceptron. The experiments demonstrate the importance of considering the temporal nature of the manufacturing process in detecting anomalous behavior and the superiority in accuracy of LSTM over non-time-series ML algorithms. Additionally, runtime adaptation of the predictions produced by LSTM is proposed to enhance its applicability in a real system.**

***Index Terms*—anomaly detection, anomaly classification, machine learning, deep learning, LSTM, sensor data, manufacturing systems**

I. Introduction

MODERN manufacturing systems have hundreds of sensors that record a huge amount of data, which provides an opportunity to use data science to improve the performance of manufacturing processes [1]. Valuable information and knowledge can be extracted from these data using different techniques, such as machine learning algorithms, statistical analysis methods, data visualization techniques, etc. [2]. One very important aspect that can be addressed is the detection of anomalous behavior in the manufacturing system. Abnormal process behavior is a major problem that can cause a decrease in the quality of a product or a complete process failure that results in the direct loss of a huge amount of money and raw material. The process may fail due to malfunctioning equipment, poor maintenance, external hacker attack, etc. All components and sensors in the system must be continuously monitored, and prompt actions should be provided if any deviations from normal behavior are identified.

This paper aims to detect anomalous behavior in industrial manufacturing systems by considering the temporal nature of the manufacturing process. This temporal nature can be presented by time-series data, which can be easily obtained from any manufacturing system. The time-series is a collection of observations made chronologically, characterized by large data size and high dimensionality [3]. In this paper, the time-series Machine Learning (ML) algorithm, more specifically, Long Short-Term Memory (LSTM) network, is applied on a synthetically generated dataset called Modular Ice-cream factory Dataset on Anomalies in Sensors (MIDAS) [4], which was created using a simulation of a modular manufacturing system for ice cream production. Two different problems are addressed: Anomaly Detection (AD) and Anomaly Classification (AC).

The main contributions of the paper can be summarized as follows:

- an analysis of the LSTM performance (in terms of accuracy, execution time, and memory consumption) in a new data set on manufacturing systems for AD and AC,

[§] Equal contribution

- a comparison in performance between LSTM performance and non-time-series ML algorithms,
- runtime adaptation of the predictions produced by LSTM to enhance its applicability in a real system.

The rest of the paper has been divided into the following sections. Section II provides a description of related research. A background on deep learning and more specifically on LSTM is provided in Section III. The experimental setup, and the results and discussion for the conducted experiments are given in Sections IV and V, respectively. The conclusion and the future work wrap up the paper in Section VI.

II. Related Work

Detecting anomalies in time-series data using ML techniques has recently piqued the interest of many researchers and has been the subject of several studies. Time-series data can be found in various application domains such as smart manufacturing, health monitoring, cyber security, and smart energy management [5]. The data source and its application can have a significant impact on the efficacy of different AD approaches. Moreover, to select an appropriate approach, data characteristics should be also considered, such as label availability and data volume. Several surveys exist that study techniques for AD with respect to different application domains [6], [7], [8]. The focus of the work presented in this paper is to detect anomalies in industrial systems through the analysis of data from multiple sensors.

Identifying patterns or deviations in industrial sensors can be done using various techniques such as statistical analysis, simple ML algorithms, and deep learning. Simple ML methods often utilize classical techniques to model the distribution of time-series data. The authors in [9] used One-Class Support Vector Machine (OC-SVM) and extended Kalman filter for real-time sensor AD in connected automated vehicle sensors. Their proposed method combines model-based signal filtering and ML technique to detect anomalous sensor readings and/or malicious cyber attacks. In [10], the authors used multivariate linear regression and Gaussian mixture models to detect anomalies in the reading sensor values from engine-based machines. They create a model from the correct behavior of the system based on sensor values such as fuel usage, engine load, and oil pressure to gauge and identify specific failures in the machine by comparing the received data with the normal model.

In recent years, deep learning models have shown promising results in time-series modeling [11]. The deep learning ability to automatically learn complex patterns from huge amounts of data makes it suitable for time-series AD. In the application of deep learning on time-series data, there are three clear approaches that can be seen in the literature.

The first approach is to use LSTM. In [12], an automated approach to detecting anomalies using a supervised LSTM and statistical analysis is introduced. This study uses an LSTM neural network to predict non-robust statistical properties and robust ones. This model identifies anomalies in time-series data by combining statistical analysis with a supervised LSTM neural network. In [13], a supervised LSTM-based model is introduced to detect abnormal data generated by mechanical equipment. The model extracts spatial features from the visual representation of the signal's frequency spectrum over time using a convolutional model and detects anomalies using a residual LSTM. In [14], authors introduced an LSTM-based real-time AD algorithm for time-series that can tolerate minor pattern changes. This algorithm automatically calculates the detection threshold based on changes in the data pattern. They employed two LSTM models, each with a distinct threshold. The first threshold is derived by taking into account all data points, whereas the second threshold is determined by taking into account those data points that are considered normal. Two LSTM models work in parallel, where one LSTM model finds single-point anomalies, while the other detects anomalous based on the long-term threshold.

The second approach combines an autoencoder with LSTM for unsupervised/semi-supervised problem-solving. In [15], an LSTM-based scheme is proposed for multi-sensor AD. It uses normal data to train an encoder-decoder model, which reconstructs normal data with minimal error. Anomalies are detected by measuring reconstruction error and likelihood. In [16], a model using autoencoders and residual error detects anomalies in sound sensor data for complex machines, aiding early maintenance planning. [14] introduces an LSTM-based real-time AD algorithm for time-series, adjusting the detection threshold based on pattern changes. Two LSTM models work together for single-point and long-term AD. In [17], a stacked autoencoder connects gated neural networks and LSTMs for short-term and long-term AD in discrete manufacturing. Authors in [18] characterized multi-sensor time series with a deep convolutional autoencoder model. They used a non-linear bidirectional LSTM and linear auto-regressive model for prediction. Multi-Scale Convolutional Recurrent Encoder-Decoder (MSCRED) framework proposed in [19], where they used convolutional recurrent encoder-decoder for detection and diagnosis in multivariate time series data. In this framework, the spatial information is encoded into signature matrices using a convolutional encoder, while the temporal information is modeled using an attention-based ConvLSTM. In [20], the authors proposed the Multivariate Time-series Anomaly Detection via Graph Attention Network (MTAD-GAT) framework, which treats each univariate time series as an individual feature and includes a feature-oriented graph attention layer and a time-oriented graph attention layer to detect the complex dependencies of multivariate time series. Furthermore, to find anomalies, it computes the inference score of forecasting-based model prediction reconstruction-based model predictions. Variational Autoencoder Generation Adversarial Networks (LSTM-based VAE-GAN) method proposed in [21] which uses Generative Adversarial Networks (GAN) for time series AD to monitor the equipment sates. This method trains the encoder, the generator and the discriminator with LSTM models and detects anomalies based on reconstruction error and discrimination results. Corizzo et al. [22] presented an AD model that leverages spatial awareness through a stacked autoencoder architecture. The proposed method utilizes spatial autocorrelation patterns generated by the autoencoder during the distinctive encoding phase to detect anomalies based on distance measures. The authors evaluated the effectiveness of their algorithm using geo-distributed data collected from renewable energy plants.

The final approach is to use a Convolutional Neural Network (CNN). In [23] a fault detection and diagnosis model using a CNN in semiconductor manufacturing is proposed. The authors applied windowing techniques to deal with variable-length multiple time-series data and trained CNNs to detect anomalies in the quality of electric wafers. This model is equipped with a mechanism to identify the contribution of each sensor on anomalies to provide traceable information for fault diagnosis. The work presented in [24] proposes a new deep learning architecture for supervised AD on multi-sensor data using a combination of CNN and Recurrent Neural Networks (RNN). This architecture is proposed to detect anomalies in elevators with different sensors in terms of type and count. They used individual CNN networks for each sensor as a first layer to extract features. This layer eliminates the need for preprocessing and provides architecture design flexibility for the next layers. The next layer of this architecture aggregates these features using LSTM or RNN networks using the windowing technique, where each window can model part of the time-series. The work presented in [25] proposed an algorithm based on CNN and Spectral Residual (SR) to improve the performance of AD on public datasets and Microsoft production data. They converted time series data with the SR model and then used visual saliency detection for AD in time series.

The main difference between this paper and all the above mentioned papers is that this paper focuses on the application of basic LSTM approach to detect and classify anomalies in analog sensors data from a manufacturing environment and compares that approach with different non-time-series ML algorithms.

III. Long Short-term Memory Recurrent Neural Network

A. Artificial Neural Network

Artificial Neural Network (ANN) [26], [11] is an ML algorithm inspired by the human brain. Artificial neurons are organized into layers (input layer, one or more hidden layers, and output layer), where the output of one layer is used as input to the next layer. An example of ANN architecture can be seen in Fig. 1. The layers are interconnected with connections that have parameters called weights. The output of each layer is calculated as follows

$$\overline{O}_{layer_i} = activation((W_{layer_i})^T \times \overline{O}_{layer_{i-1}} + \overline{B}_{layer_i}) \qquad (1)$$

where $O_{layer_{i-1}}$ is the output of the previous layer (if i is the first layer, then $O_{layer_{i-1}}$ is equal to the input values X), $(W_{layer_i})^T$ is the transpose of the weights that connect layer i and layer $(i-1)$ and B_{layer_i} are random weights that are not multiplied by any input. Finally, an activation function transforms the output into a different range. There are different activation functions as sigmoid, tanh, softmax, ReLU, LeakyReLU, etc. [26]. Three activation functions that are used in the paper are: sigmoid (Eq. (2)), tanh (Eq. (3)) and softmax (Eq. (4)). The sigmoid activation function transforms the data into $(0,1)$ interval, while tanh transforms it to $(-1,1)$. The softmax activation function is only used for the output layer and it does not normalize the output where the values are in the $(0,1)$ range and the summation of all values is equal to 1.

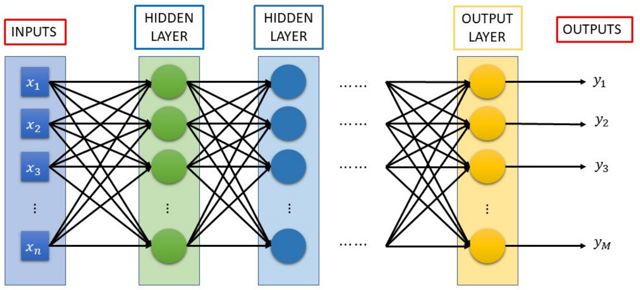

Fig. 1: Artificial Neural Network

$$sigmoid(x) = \sigma(x) = \frac{1}{1+e^{-x}} \qquad (2)$$

$$tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}} \qquad (3)$$

$$softmax(x)_j = \frac{e^{x_j}}{\sum_{k=1}^{K} e^{x_k}} \qquad (4)$$

The goal of the ANN training process is to adjust its weights (black connections in Fig. 1) to fit the objectives. This is done using the backpropagation algorithm [27], [11]. Once the weights are trained, the ANN is ready to be used.

B. Recurrent Neural Network

Recurrent Neural Networks (RNN) is a type of Artificial Neural Network that takes into consideration time-series data. In order to compute the output at time t, the calculations made in $t-1$ are used. Fig. 2 shows an example of RNN, and how it uses the different time steps. To be more specific, the equations that compute the output for time step t ($\overline{Y}(t)$) are as follows

$$\overline{Y}(t) = activation((W_y)^T \times \overline{S}(t)) \qquad (5)$$

$$\overline{S}(t) = activation((W_x)^T \times \overline{X}(t) + (W_s)^T \times \overline{S}(t-1)) \qquad (6)$$

where W_y, W_s, W_x are weight matrices for the connection between the hidden layer and the output layer, the hidden layer connected to itself, and the connection between the input layer and the hidden layer, respectively. Additionally, $\overline{X}$ and $\overline{S}$ are vectors that represent the input and the output of the hidden layer, respectively.

Unfortunately, RNN has a problem, called grading vanishing problem, when training with backpropagation algorithm [26]. For this reason, a more advanced type of network is needed.

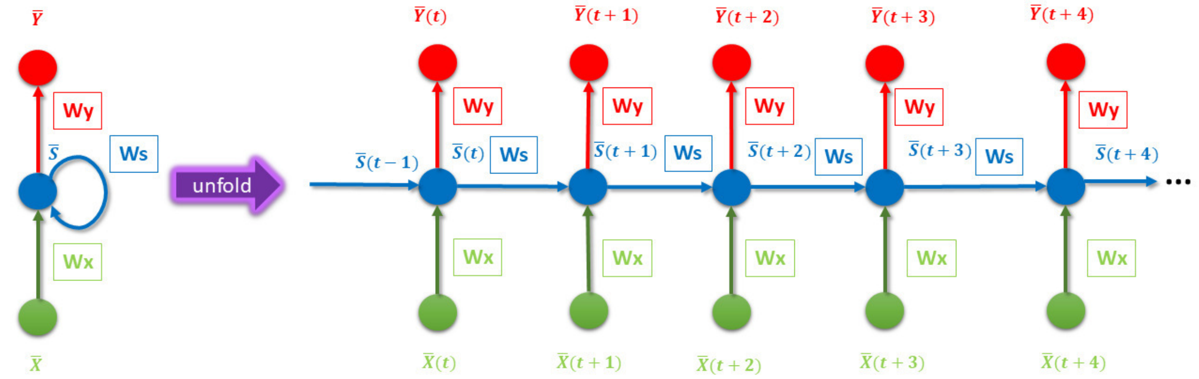

Fig. 2: Recurrent Neural Network in its fold and unfolded version.

C. Long-Short Term Memory Neural Network

Long-short Term Memory (LSTM) neurons are presented to solve the grading vanishing problem. Each of this units is composed of:

- Two memories:
  - **Long-term memory (*LTM*)** which passes the information that has been used for a long period of time to the current time step. Additionally, thanks to this memory, the gradient vanishing problem is solved.
  - **Short-term memory (*STM*)** which saves the information that has been used in the previous time step.
- Four different areas (gates):
  - **Forget gate** which finds information that can be discarded. It is calculated as follows:

$$\overline{F}(t) = \sigma((W_f)^T \times [\overline{X}(t), \overline{STM}(t-1)] + \overline{B}_f) \qquad (7)$$

    where W_f represents the weights of the forget gate, $\overline{X}$ the input information, $\overline{STM}$ the short-term memory, t the time step and $[\overline{a}, \overline{b}]$ the concatenation of the vector a with the vector b.
  - **Input gate** which finds information that is relevant $(\overline{R}(t))$ and needs to be modified into the LTM, and weights the values based on their importance $(\overline{I}(t))$ into the [-1,1] range. The calculations are as follows:

$$\overline{R}(t) = \sigma((W_r)^T \times [\overline{X}(t), \overline{STM}(t-1)] + \overline{B}_r) \qquad (8)$$

$$\overline{I}(t) = tanh((W_i)^T \times [\overline{X}(t), \overline{STM}(t-1)] + \overline{B}_i) \qquad (9)$$

    where W_r and W_i are the weights used to calculate the relevance and the importance, respectively. In the same way, $\overline{B_r}$ and B_i represent the biases used to calculate the relevance and the importance, respectively.
  - **Update gate** which modifies LTM by adding the information found in the input gate. Additionally, LTM needs to be modified by $\overline{F}$ calculated in Eq. (7). The LTM vector $(\overline{LTM})$ for the current time step t is calculated as follows:

$$\overline{LTM}(t) = \overline{LTM}(t-1) \times \overline{F}(t) + \overline{R}(t) \times \overline{I}(t) \qquad (10)$$

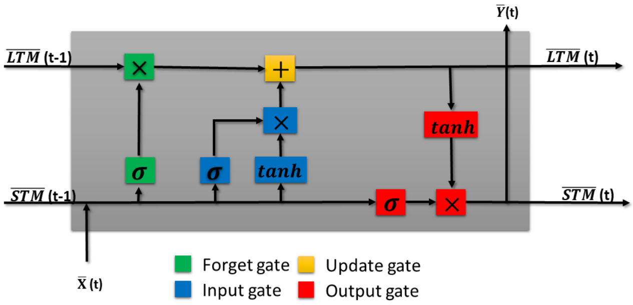

Fig. 3: Long-Short term memory unit. STM and LTM stand for Short-Term Memory and Long-Term Memory, respectively, where t indicates the time step.

  - **Output gate** which calculates the final output that depends on the input information, the output used in the previous time step and the LTM that is previously modified. It is calculated as follows:

$$\overline{Y}(t) = \overline{STM}(t) = \sigma((W_y)^T \times [\overline{X}(t), \overline{STM}(t-1)] + \overline{B}_y) \times tanh(\overline{LSTM}(t)) \qquad (11)$$

    where W_y is the weight matrix used in the use gate, while $\overline{B}_y$ is the bias used on the same gate.

The complex units explained above are used to replace the simple units in the hidden layer of RNN (blue circles in Fig. 2). An overview of the entire LSTM unit is given in Fig. 3.

IV. Experiments

A. Dataset Description

The experiments presented in this paper are conducted on a publicly available dataset called MIDAS[1], which is created using a modular manufacturing simulation environment, where an ice cream making process is simulated [4]. The simulated system is composed of 6 interconnected modules, and each module has various analog and digital sensors [28], [29]. To

[1] https://github.com/vujicictijana/MIDAS/

create MIDAS dataset, three different types of anomalies in analog sensors were injected during the simulation process, and each of them represents modifying the value in a different way: freeze value, step change and ramp change. From the moment of anomaly injection, the actual sensor value was replaced by a modified value until the end of the current run, which means that the simulation behavior was changed from that point since the controllers have access to the wrong values. In this way, different scenarios were simulated, from malfunctioning sensors to external intrusions. The anomalies were injected into the 8 different analog sensors, one sensor at a time.

One run of the system represents a full ice cream making process according to the given recipe, from mixing all the ingredients to producing the ice cream cones as the final product. All runs in the dataset are generated using the same recipe and they are completely independent of each other. The dataset contains a separate csv file for each of 1000 runs, where 258 runs represent normal behavior and 742 runs contains anomalies. There are three different types of anomalies: Freeze value (24.9% of total runs), Step change (24.% of total runs) and Ramp change (24.6% of total runs). The dataset is divided into 500 run for training, 100 for validation and 400 runs for testing data.

Each run has around 36000 instances and one instance represents system state at a certain time point, which results in 36,124,859 instances in the entire dataset. Each instance has 60 columns, including ordinal number of instance within one run, all sensor readings for all modules, and information about anomaly injection. If the instance contains an anomaly the anomaly type, sensor where the anomaly was injected, and actual sensor value are provided. The dataset is well balanced since the percentage of anomalous instances is 50.33%, and approximately one third of anomalous instances belongs to each type of anomaly.

B. Dataset preprocessing

During the dataset preprocessing phase, the following steps were conducted:

- Output variable was defined - The “Anomaly” column is used as the output variable. This column contains 4 different values (- for no anomaly, Step, Ramp, and Freeze) that were encoded to numbers from 0 to 3, in the given order.
- Input variables were defined - All sensor readings for all modules were used as input variables, except the ones that have the same value in the entire dataset, which resulted in 38 input variables.
- Input variables were normalized - All input variables are binary values or real numbers. Binary values remained unchanged and real numbers were normalized in the range [0, 1] using the Min-Max normalization technique.
- Numeric values were transformed to float32 - By default, the columns in the dataset have float64 as a data type. To prevent memory overflow, the data type of the normalized numbers was changed from float64 to float32, with a negligible effect on the results of the LSTM.
- Sliding window approach was applied - In order to generate time-series data for LSTM a sliding window approach was applied. The experiments were conducted with different window sizes and the windows were generated only within a run. Additionally, only the output in the last time step was consider as an output for AD/AC.

C. Experimental settings

Two different problems were addressed: Anomaly Detection (AD) and Anomaly Classification (AC) of abnormal time points on multivariate temporal data using supervised ML algorithms.

All experiments were performed in a MacBook Pro 2019 2.6GHz, Intel Core i7, 16 GB RAM. Python programming language and Tensorflow[2] [30] ML library were used to implement the experiments. The experiments were performed with 500-100-400 runs for training, validation and testing, respectively.

All experiments were conducted with all input variables that were selected during the preprocessing phase (full data), but also with the reduced number of input variables (reduced data). For the experiments with the reduced number of input variables only variables that contain sensor readings for sensors in which the anomalies were injected are considered (8 variables). During all experiments the time and memory consumption was recorded with a goal to analyse how demanding the resulting LSTM is. Each experiment was repeated 5 times and the average results are presented.

Four different experiments have been carried out:

1) *Study of hyper-parameters in LSTM for AD and AC* - The validation set was used to find the best combination of hyper-parameters in LSTM: number of hidden neurons and number of epochs. Values 1, 2, 5, 10 and 20 were tested for both parameters, for both AD and AC. Additionally, two different activation functions were tested for AD (Sigmoid and Softmax), while Softmax activation function was used for AC.
2) *Study of window sizes in LSTM for AD and AC* - The validation set was used to find the best window size with the best combination of hyper-parameters from the first experiment. The window sizes that were tested include 1, 2, 5, 10, and 20 for both AD and AC. The maximal number was selected to cover all time steps within half of a second.
3) *LSTM performance for AD and AC* - LSTM was trained with the best combination of the hyper-parameters from the first experiment and the best window size from the second experiment and tested with the testing data.
4) *Runtime adaptation of LSTM prediction* - Since the resulting LSTM will be applied in a simulator of a modular manufacturing system, it is needed to prevent false negative and false positive alarms as much as

[2] https://www.tensorflow.org/

possible. After it is certain that an anomaly has occurred, the alarm should be on until the run ends or until someone checks the systems. This means that all the remaining time points until the end of that run should be considered as anomalous. To achieve this, runtime adaption of current prediction (y_i) was implemented by checking the previous predictions and changing it according to Eq. 12. Different amount of past time points that are considered ($t \in \{10, 20, 30 \ldots 3000\}$) and different rates of points that have to be predicted as anomalies ($r \in \{1, 2, \ldots 9\}$) were tested on validation set. Before the moment when certainty is achieved, predictions will be considered false positive if less than 10% of predictions in the previous period are predicted as anomalies, so the final prediction will be normal behaviour. All adaptions are made considering only data from the specific run.

$$y_i = \begin{cases} 1 & \text{if } \exists_{k \leq i} \sum_{j=k-t-1}^{k} y_j = \frac{t}{r} \\ 0 & \text{otherwise, if } \sum_{j=i-t-1}^{i} y_j < \frac{t}{10} \\ y_i & \text{otherwise} \end{cases} \tag{12}$$

V. Results and Discussion

A. Study of hyper-parameters in LSTM for AD and AC

The performance of LSTM with different combinations of hyper-parameters on the validation set is presented in Fig. 4 for AD and in Fig. 5 for AC. It can be noticed that the accuracy of LSTM is higher as the number of epochs increases, for both AD and AC, which is expected because the longer training process enables LSTM to fit better to the data. The same happens if the number of hidden neurons is increased, which means that the LSTM can better generalize the model. However, increasing from 10 to 20, for both epochs and hidden neurons, does not bring a big improvement.

With respect to the activation function in the output layer for AD, it can seen how the use of softmax gives improvements in all cases except when there is one neuron in the hidden layer. This is normal since having two neurons in the output layer helps generalize better than having only a single unit.

Finally, if considering using all the input variables or only the variables where anomalies were injected, it can be noticed that using all available information gives benefits to the proposed model, which means that other variables in the process are also affected by the anomalies.

Taking into consideration all of the above statements it was decided to use softmax as an activation function for the output layer for AD, and 10 as the number of hidden neurons and the number of epochs for all problems. The selected combination did not have the absolute highest accuracy, however, the results are very similar with the best combination. This option is selected because it makes the model more efficient in terms of time and memory. Although the results using the full data are better, the experiments in the following sections are conducted using both options.

TABLE I: Accuracy of LSTM on validation set for different window sizes for AD and AC with all and reduced input variables

Problem Window	AD		AC	
	full	reduced	full	reduced
1	84.01	82.72	68.81	68.29
2	86.75	85.21	69.58	69.51
5	87.45	86.73	69.74	69.89
10	88.06	86.07	71.27	69.01
20	**88.51**	**86.92**	**71.52**	**70.55**

B. Study of window sizes in LSTM for AD and AC

The best combination from the previous section is used to train LSTM with different window sizes and the results are presented in Table I. As expected, as the window size increases the accuracy of LSTM is higher, since the model considers more time steps back in time. It can be observed that the improvement is around 1 percentage point in almost all cases for full data in AD for window sizes 1, 2 and 5. The differences from window size 5 to 10 and 10 to 20 are around 0.5 percentage points. On the other hand, on full data for AC, the improvement is only big when comparing window size 1 to window size 2 (around 3 percentage points). Then, for the rest of the window sizes the accuracy remains stable. If the reduced data are considered, a similar behavior can be noticed for both AD and AC.

If the results between window size 1 (which considers only a single time step) and window size 20 (which considers half a second of the manufacturing process) are considered, the improvement can be noticed in all cases varying from 2.2 to 4.5 percentage points. This clearly shows the benefit of considering time-series when making a predictions.

C. LSTM performance for AD and AC

The window size that achieved the best performance on the validation set (Table I) was used to measure the LSTM performance on the test set. The accuracy of LSTM and the comparison with non-time-series ML algorithms is presented in Table II, for both AD and AC. The non-time-series ML algorithms that were considered include: Logistic Regression (LR), Decision Tree (DT), Random Forest (RF), and Multi-Layer Perceptron (MLP). The parameters used for these algorithms can be found in paper [4].

It can be observed that LSTM has the highest accuracy, obtaining a better performance than the best non-time-series algorithm (MLP) by 2.7 and 0.12 percentage points for AD and AC, respectively. This again proves that considering the previous data can help detect anomalous behavior. Additionally, it can be noticed that LSTM that uses reduced data also has higher accuracy than all non-time-series algorithms for AD, while it is better than all of them and almost equal to MLP for AC. This means that historical information can bring more benefits than using data from all sensors without considering the temporal nature of the process.

Problem / Algorithm	AD	AC
LR	64.60	51.42
DT	69.97	56.53
RF	75.07	62.49
MLP	82.36	70.73
LSTM (full data)	**85.06**	**70.85**
LSTM (reduced data)	84.49	69.89

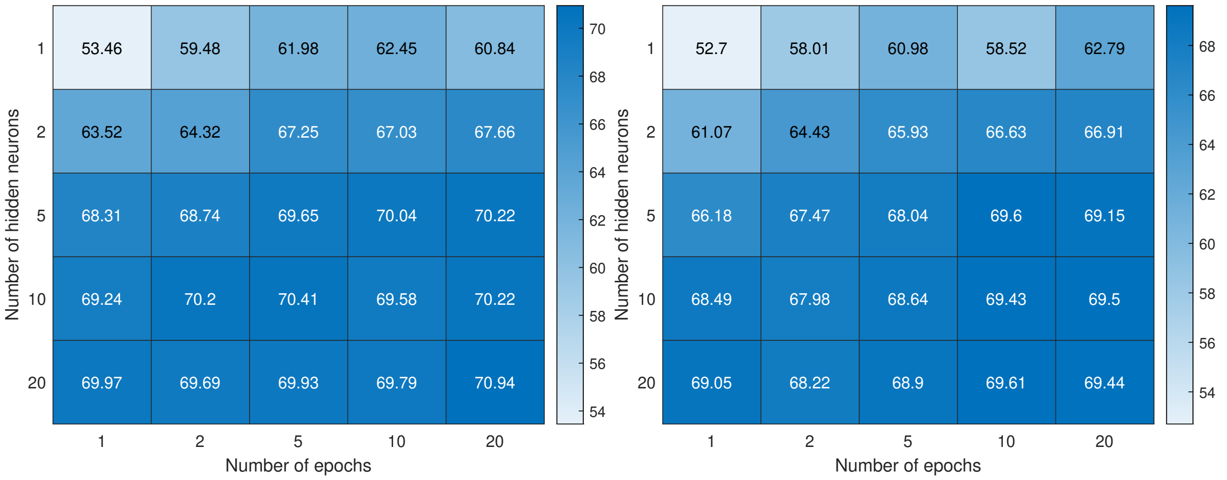
D. Runtime adaptation of LSTM prediction

The performance of LSTM on validation set after making a runtime adaption of the predictions is shown in Figure 6. It can be observed that the best results were achieved if all the previous time points ($r = 1$) in the selected period are predicted as anomalous. The best results were achieved when the amount of previous time points was 390. This means that the system needs around 8 seconds of continues positive predictions to be certain that an anomaly happened. Additionally, it can be noticed that after the selected number of time points (t) the accuracy is stabilized. Comparing all considered combinations, they have the same trend. However, with smaller number of required ones, the system needs more time to be certain about the anomaly, which results in lower overall accuracy.

After applying real-time adaption on the testing set, the overall accuracy of the model improved in average 1.8 percentage points, resulting in overall average accuracy of 86.9%. The actual performance of the runtime adaptation is showed in Fig. 7. It can be noticed that by adding the runtime adaption some of the wrong predictions were successfully fixed (some of the false positive and negative alarms were prevented).

E. Time and memory consumption

An important aspect to consider is the time that LSTM requires to create the model, as well as the time that is needed to apply the model to detect/classify the anomalies in a real-time environment. Firstly, a comparison between model training and testing time depending on the window size and



(a) Softmax activation function with full data

(b) Softmax activation function with reduced data

Fig. 5: Hyper-parameters selection for LSTM network for AC - Heatmaps with accuracies of LSTM on the validation set

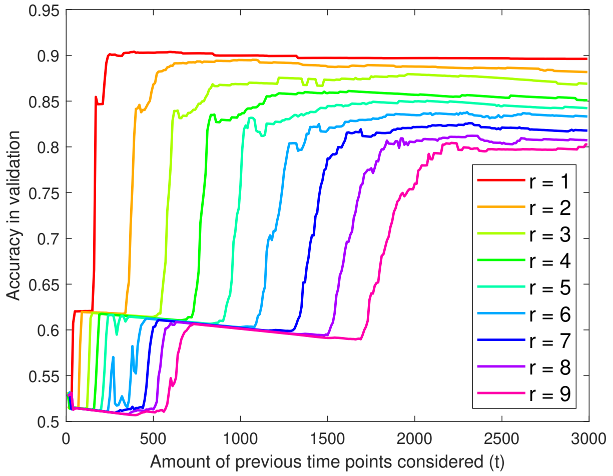


Fig. 6: Accuracy of adapted LSTM on validation set for different combinations of amount of previous time points considered (t) and the rate of anomalous predictions (r)

the amount of data (full data and reduced data) is given in Fig. 8. It can be observed how the time increases linearly for training (Fig. 8a), except when the full data with window size 20 is used. The main reason for this increase in time is that the RAM memory is not large enough to allocate the whole dataset, so the computer is forced to use the hard-drive to load the data. Secondly, if the testing time is considered (Fig. 8b), it can be noticed that all models with all window sizes would be able to run on a real-time system. The time between data readings within the system is equal to 25 ms, which is much higher than the slowest LSTM model that was evaluated (which requires less than 0.05 ms).

Additionally, the time used by LSTM and the non-time-series ML algorithm are compared with respect to training and testing time (Table III). Using LSTM requires more time than the non-time-series ML algorithms for both training and testing, which is expected since the LSTM uses more data points within every example. When focusing only on the testing time, it can seen that the LSTM is 84 times slower than non-time-series version of ANN (MLP) for AD, while it is 39 times slower for AC.

TABLE III: Average time of LSTM for training on entire training set and testing of one single case and comparison with non-time-series ML algorithms

Problem / Algorithm	AD		AC	
	Train (s)	**Test (ms)**	**Train (s)**	**Test (ms)**
LR	889.06	0.00032	4520.92	0.00027
DT	415.44	0.00048	447.42	0.00063
RF	1493.27	0.00432	2197.63	0.00576
MLP	11362.16	0.00052	17925.70	0.00110
LSTM (full data)	45367.63	0.04386	61860.21	0.04328
LSTM (reduced data)	3028.62	0.04475	4702.19	0.04509

Finally, the memory used by the training data, for both full and reduced data, is given in Fig. 9. It can be seen that the required memory increases linearly, however, with the full data from the window size 10, the dataset requires more memory than the amount of memory available in the RAM. This also proves that the limit of RAM is the reason why time increases exponentially after window size 10 (as shown in Fig. 8a).

VI. Conclusions and Future Work

In this paper, LSTM is applied to detect and classify anomalies in the manufacturing system. Experiments were conducted on the synthetically generated dataset called MIDAS that contains various anomalies in analog sensors data during ice cream making process and realistically represents a manufacturing process. The results showed that considering time-series nature of the data is beneficial for the accuracy of both detection and classification of anomalies. The LSTM had better performance than all non-time-series ML algorithms

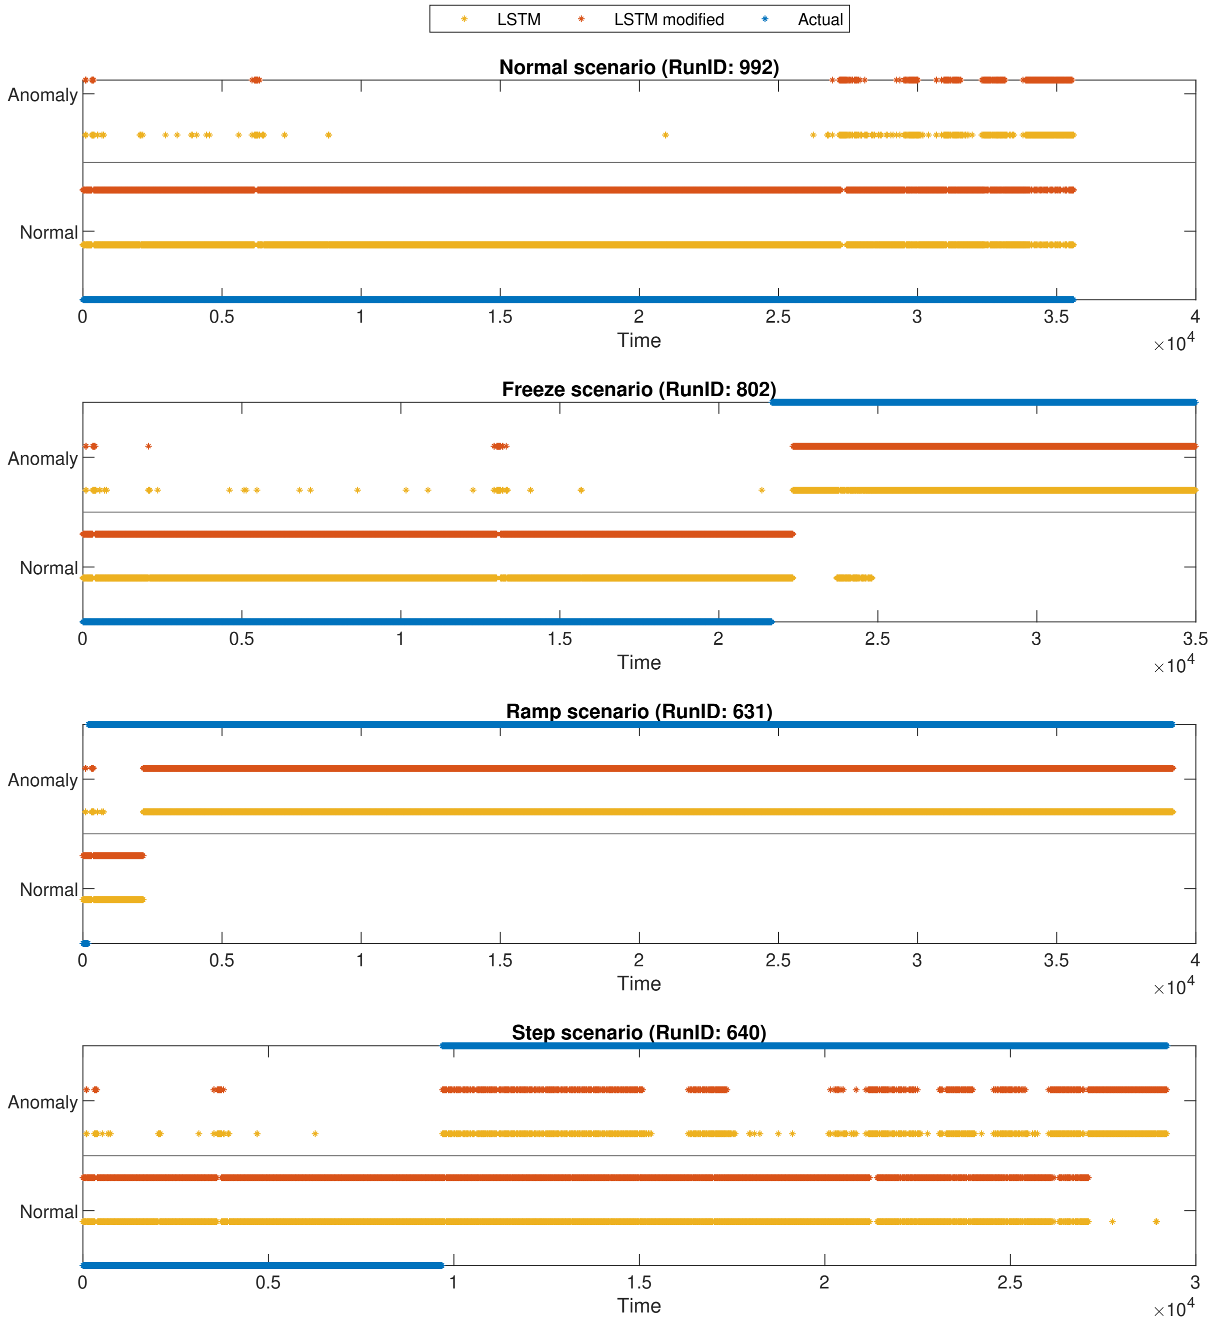

Fig. 7: Predictions of LSTM and LSTM after runtime adaptation (LSTM modified) for 4 full scenarios from the testing set for anomaly detection. Every time-point prediction is plotted.

it was compared with. On the other hand, it is more time consuming, but it can still run on a real-time system. Furthermore, the predictions generated by LSTM were adapted during runtime, with a goal to improve its performance and applicability in real systems.

As a future work, we plan to integrate the proposed model in the simulation environment that is used to generate MIDAS dataset. Additionally, we plan to develop a federated learning approach for LSTM that will be able to distribute the AI on different system levels.

***Abstract*—In this research paper, we propose a novel approach to digital circuit design using XOR-based decomposition. The proposed technique utilizes XOR gates as a fundamental building block for decomposing complex Boolean functions into simpler forms, leading to more efficient and compact digital circuits. We demonstrate the effectiveness of our approach in two different contexts: memory-based logic synthesis and reversible logic synthesis. In particular, we demonstrate that the proposed technique can efficiently reduce the number of input variables, which is a crucial task when using memories in the design. Obtained results prove that the XOR-based approach can efficiently complement variable reduction and dimensionality reduction algorithms. Furthermore, we show its application in generating the XOR-AND-XOR form of a reversible function and demonstrate how to combine it with another technique, i.e., a functional decomposition for reversible logic synthesis.**

I. Introduction

LOGIC synthesis is a very important process that enables efficient design and implementation of complex digital circuits. Its importance continues to grow since the complexity and performance demands of digital circuits are still increasing. In recent years, a specific type of logic synthesis, i.e., memory-based synthesis has gained attention from researchers, leading to the development of numerous algorithms and techniques in this field, making it a promising approach for the design of modern electronic systems. Especially logic synthesis of incompletely specified Boolean functions was deeply analyzed.

This technique approaches the design of digital circuits from a different perspective than traditional logic synthesis methods. Instead of focusing solely on Boolean logic gates and their interconnections, memory-based logic synthesis incorporates memories, such as static random-access memory (SRAM) and read-only memory (ROM), as fundamental building blocks in the design process. Due to that, this approach can improve the performance, area, and power consumption of digital circuits.

Lately, a synthesis of specific functions, called index generation functions [6], [9], [13], gained significant interest due to the practical applications of their implementations in network hardware, e.g., in telecommunication and cybersecurity.

Due to the properties of index generation functions, typically fewer variables than initial N variables can be used to represent those functions. It is important, especially in memory-based logic synthesis [11], where the memory size strongly depends on the number of input variables.

In the literature, the application of linear (i.e., XOR-based) decomposition in index generation functions minimization was widely investigated. However, XOR-based logic synthesis is a relatively new approach to a digital circuit design that leverages the properties of the exclusive OR (XOR) gate as a fundamental building block. It is worth noticing that this approach can often exploit the symmetries of Boolean functions, leading to more efficient circuits.

This approach implements a function as a composition of linear and general functions. The layer of XOR gates implements the first one, while the second one is typically implemented using memory (RAM/ROM). A typical decomposition scheme is presented in Fig. 1. Variable reduction is an optional step that reduces the number of variables, i.e. it removes those variables that can be removed without loss of any information. The outputs of this algorithm become the inputs to a linear function algorithm. This algorithm finds P reduction equations that use XOR combinations of subsets of the input variables. In the end, the general function is implemented using $2^P Q$ memory bits, where Q denotes the number of output variables.

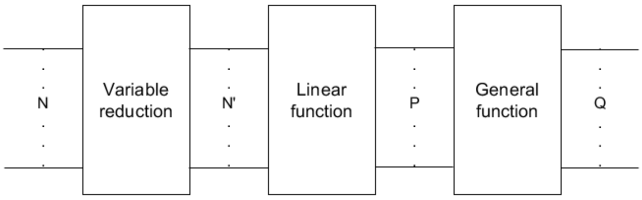

Fig. 1: The linear decomposition scheme.

Similar approaches, i.e. reduction of a number of variables (or dimensionality reduction) and implementation of a reduced general function, are used in other fields, e.g. in reversible logic synthesis [2] and data mining [3]. Especially the first field is a promising research area due to its potential to improve the energy efficiency of digital circuits. Work on the potential of the exposition of an XOR relationship in the logic synthesis of boolean functions has also been carried out. For example, Czajkowski and Brown [5] showed that it leads to significant resource savings for MCNC (Microelectronics Center of North Carolina) benchmark functions.

In this paper, we analyze how the XOR-based method used previously in index generation functions minimization [6] can be generalized and applied to any function represented using binary input vectors. We present the whole algorithm and show its usefulness using standard benchmark functions. We also present how the proposed approach can be used in the fields mentioned above. In particular, lately, the novel form called XORAX (XOR-AND-XOR) was proposed [2] to represent a function. This form can ease the reversible synthesis of some functions. In this paper, we show that the XOR-based decomposition can be used to perform the first step of XORAX form generation. We also prove that the proposed method can be used to improve the results obtained using a functional decomposition [10].

II. Preliminaries

A. Basic notation

Let N denote the number of input variables, and K denote the number of rows in a function truth table. Notice that $K = 2^N$ for completely specified Boolean functions.

To present an algorithm of XOR-based decomposition, we introduce a concept of discernibility set. It will be denoted as $C_{p,q}$, where p and q ($p, q \in \{1, 2, \ldots, K\}, p < q$) are indexes of vectors of $\{0, 1\}^N$, such that $F(p) \neq F(q)$, where $F(p)$ is the output value for row number p in a function truth table. We define discernibility set as follows:

$$C_{p,q} = \{x \in X : x(p) \neq x(q)\}, \tag{1}$$

where X denotes the set of input variables.

In particular, $C_{p,q}$ represents input variables where vectors number p and q differ. For example, in Table I the first and third vectors differ on variable x_2. Thus, $C_{1,3} = \{x_2\}$.

TABLE I: An example function.

idx	x_1	x_2	x_3	$F(X)$
1	0	0	0	0
2	0	0	1	0
3	0	1	0	1
4	0	1	1	1
5	1	0	0	1
6	1	0	1	1
7	1	1	0	0
8	1	1	1	0

Notice that for any index generation function, the condition $F(p) \neq F(q)$ is true for every possible pair of values p and q since the output values are unique consecutive integer values. This observation simplifies computations for such functions. However, it leads to higher memory consumption since many more $C_{p,q}$ sets might be generated.

The collection of all $C_{p,q}$ will be denoted as RC, i.e.

$$RC = \{C_{p,q} : p, q \in \{1, 2, \ldots, K\}, p < q\}. \tag{2}$$

Its complement, i.e., collection of all sets that are not present in the RC, will be denoted as $COM(RC)$. Additionally, the complement limited to r-element sets will be denoted as $COM(RC^r)$. The discernibility sets for all possible values of p and q can be represented using the discernibility matrix.

Example 2.1: Consider the example function ($N = 3, O = 1, K = 8$) presented in Table I. All calculated C_{pq} sets for this function (i.e., RC) are presented in Table II. Notice that pairs of p and q values such that $F(p) = F(q)$ were omitted in the calculation (e.g. $C_{1,2}$ is not present since the value for both the first and second rows equals zero). Based on the calculated sets, we get

$$RC^1 = \{\{x_1\}, \{x_2\}\},$$

$$RC^2 = \{\{x_1, x_3\}, \{x_2, x_3\}\},$$

$$RC^3 = \emptyset.$$

Therefore, we get the following complements:

$$COM(RC^1) = \{\{x_3\}\},$$

$$COM(RC^2) = \{\{x_1, x_2\}\},$$

$$COM(RC^3) = \{\{x_1, x_2, x_3\}\}.$$

TABLE II: $C_{p,q}$ sets for the example function

p, q	$C_{p,q}$	p, q	$C_{p,q}$
1,3	$\{x_2\}$	3,7	$\{x_1\}$
1,4	$\{x_2, x_3\}$	3,8	$\{x_1, x_3\}$
1,5	$\{x_1\}$	4,7	$\{x_1, x_3\}$
1,6	$\{x_1, x_3\}$	4,8	$\{x_1\}$
2,3	$\{x_2, x_3\}$	5,7	$\{x_2\}$
2,4	$\{x_2\}$	5,8	$\{x_2, x_3\}$
2,5	$\{x_1, x_3\}$	6,7	$\{x_2, x_3\}$
2,6	$\{x_1\}$	6,8	$\{x_2\}$

Since we check whether $F(p) \neq F(q)$, the proposed approach can be applied also to functions that do not return only 0 or 1. In particular, both multiple-output functions and functions with multiple-valued output can be decomposed using the same technique as long as input vectors are represented as binary vectors.

Example 2.2: Consider the function presented in Table III. It represents the following mapping: $F : \{0, 1\}^6 \to \{1, 2, 3\}$. Using the same approach as in Example 2.1, we get the RC presented in Table IV.

TABLE III: An example with multiple-valued output.

idx	x_1	x_2	x_3	x_4	x_5	x_6	$F(X)$
1	1	0	0	0	0	0	1
2	0	1	1	1	1	0	1
3	0	0	1	0	0	1	2
4	1	0	1	1	1	1	2
5	0	1	0	0	1	0	3
6	0	1	0	0	0	0	3

B. Memory-based logic synthesis

Memory-based logic synthesis plays an important role in embedded systems, which often rely heavily on memory for storing and processing data. For example, nonvolatile Read Only Memories (ROMs) are used to store some fixed data used in a design, or to implement a truth table or a state machine.

TABLE IV: $C_{p,q}$ sets for the example function

p,q	$C_{p,q}$	p,q	$C_{p,q}$
1,3	$\{x_1, x_3, x_6\}$	2,5	$\{x_3, x_4\}$
1,4	$\{x_3, x_4, x_5, x_6\}$	2,6	$\{x_3, x_4, x_5\}$
1,5	$\{x_1, x_2, x_5\}$	3,5	$\{x_2, x_3, x_5, x_6\}$
1,6	$\{x_1, x_2\}$	3,6	$\{x_2, x_3, x_6\}$
2,3	$\{x_2, x_4, x_5, x_6\}$	4,5	$\{x_1, x_2, x_3, x_4, x_6\}$
2,4	$\{x_1, x_2, x_6\}$	4,6	$\{x_1, x_2, x_3, x_4, x_5, x_6\}$

This technique helps to optimize the design of digital circuits that interface with memory.

In modern embedded systems, Field-Programmable Gate Arrays (FPGAs) are used very often due to the wide range of applications, including signal processing, video processing, networking, and data storage. The fundamental building blocks used to implement a digital circuit described typically using a hardware description language, are Look-Up Tables (LUTs). A LUT is a small, programmable memory block that can store a truth table, which implements a Boolean function. The number of inputs to a LUT can vary depending on the FPGA architecture, but in modern devices equals typically 4 to 6. Additionally, FPGAs very often contain memories.

The main goal of memory-based logic synthesis [11] is to minimize the memory usage of the design. The typical approach is to use functional decomposition to divide a function into smaller subfunctions that can be efficiently implemented using memories or LUTs. Additionally, a variable reduction [3] is often used to remove redundant information from a function. However, this technique fails for some functions [6], or the number of variables can be further minimized. For example, the XOR-based decomposition reduces the number of variables by using the additional layer of XOR gates.

C. Reversible logic synthesis

Reversible logic synthesis is a process of designing circuits that can run both forward and backwards, meaning that can perform both computation and its inverse. In order to do so, the circuit has to have the same number of input and output variables and the implemented function must be a bijection (i.e., the input values can be uniquely determined from the output values and vice versa). In this process, the main goal is to minimize the number of gates required to implement a function.

In order to unify the approach for the comparison of different reversible logic synthesis methods, several gate libraries are used. The smallest complete set of gates, proposed in [14] and called the NCT gate library, contains three gates: NOT, CNOT and Toffoli gates. Any reversible function can be implemented using a combination of those three gates.

The first gate is a one-bit gate that performs the logical negation operation. The second gate is a two-bit gate, meaning it has two input signals and two output signals, which implements the following mapping $(x, y) \rightarrow (x, x \oplus y)$, where $\oplus$ denotes the XOR function. The Toffoli gate is a three-bit gate with two control bits and a single target bit. It implements the following mapping $(x, y, z) \rightarrow (x, y, xy \oplus z)$.

The NCT library is commonly used in the design of reversible circuits due to its simplicity and efficiency. However, it can be extended to include some additional gates, such as SWAP and Fredkin gates (NCTSF library) or multiply-controlled gates (GT and GT&GF libraries). Reversible circuits are implemented as a cascade of those reversible logic gates.

There are several significant applications of reversible logic synthesis. Due to the asymptotic zero power dissipation achievable by reversible computation [1], it can be used in low-power computing, making them an attractive option for mobile devices, wearables, and Internet of Things (IoT) devices. Reversible circuits are also important in quantum computing since quantum algorithms require reversible logic gates for their implementation. Reversible logic synthesis might be also useful in optical computing and DNA computing.

III. XOR-based decomposition

The existence of the XOR-based decomposition can be verified using a simple test [6], [9] : $x_i \oplus x_j$ is a decomposition function of F iff $\{x_i, x_j\} \in COM(RC^2)$. Similarly, pair of functions $x_i \oplus x_j$ and $x_j \oplus x_k$ is a decomposition function of F iff $\{x_i, x_j, x_k\} \in COM(RC^3)$, and so on.

Therefore, to find a decomposition function, we need to generate RC^r and look for a decomposition using the increasing value of r. In the result, we get:

$$F(x_1, x_2, \ldots, x_N) = G(y_1, y_2, \ldots, y_{N-1}). \qquad (3)$$

The first $N - r + 1$ inputs in the G function correspond to those inputs of the F function that are not used in a decomposition function. The last $r - 1$ inputs are obtained using a decomposition function, e.g. y_{N-1} might equal to $x_i \oplus x_j$ if a decomposition function for $r = 2$ is found.

Example 3.1: Consider again the function F from our previous example (Example 2.1). Notice that both $COM(RC^2)$ and $COM(RC^3)$ are not empty. Therefore, two possible decompositions are:

1) $y_1 = x_3$ and $y_2 = x_1 \oplus x_2$,
2) $y_1 = x_1 \oplus x_2$ and $y_2 = x_2 \oplus x_3$.

In the first case, we get

$$F(x_1, x_2, x_3) = G(x_3, x_1 \oplus x_2),$$

while in the second case we get

$$F(x_1, x_2, x_3) = G(x_1 \oplus x_2, x_2 \oplus x_3).$$

In both cases, the number of variables was reduced by one. Truth tables for both cases are presented in Table V. Notice that the number of rows is also reduced (from 8 to 4). The first column shows the row numbers from the original truth table to which the newly generated value corresponds.

The same approach can be applied to the function from Example 2.2. Based on the RC we know that $x_1 \oplus x_3$ is a decomposition function, since $\{x_1, x_3\} \notin RC \Rightarrow \{x_1, x_3\} \in COM(RC^2)$. Therefore, we get:

$$y_1 = x_2,\ y_2 = x_4,\ y_3 = x_5,\ y_4 = x_6,\ y_5 = x_1 \oplus x_3.$$

TABLE V: The example function after decomposition.

(a) Function after decomposition number 1.

$idxs$	y_1	y_2	$G(Y)$
1, 7	0	0	0
3, 5	0	1	1
2, 8	1	0	0
4, 6	1	1	1

(b) Function after decomposition number 2.

$idxs$	y_1	y_2	$G(Y)$
1, 8	0	0	0
2, 7	0	1	0
4, 5	1	0	1
3, 6	1	1	1

Algorithm 1 Finding decomposition

```
$labels \leftarrow [\{i\} : i \in \{1, 2, \ldots, N\}]$
$dm, bins \leftarrow$ Algorithm_2()
while $True$ do
    $dec \leftarrow$ Algorithm_3($dm, bins$)
    if $dec$ is $None$ then
        break
    end if
    $dm \leftarrow$ Algorithm_4($dm, dec$)
    $labels \leftarrow$ Algorithm_5($labels, dec$)
end while
return $labels$
```

Algorithm 2 Generation of discernibility matrix

```
1:  $dm \leftarrow \emptyset$
2:  for $p \leftarrow 1$ to $K - 1$ do
3:      for $q \leftarrow p + 1$ to $K$ do
4:          if $F(p) \neq F(q)$ then
5:              $dm = dm \cup (v_p \oplus v_q)$
6:          end if
7:      end for
8:  end for
9:  $bins \leftarrow split\_to\_bins(dm)$
10: return $dm, bins$
```

Algorithm 3 Finding decomposition (single iteration)

```
1:  for $a \leftarrow 2$ to $N$ do
2:      if $|B_a| = \binom{n}{a}$ then
3:          continue
4:      else if $|B_a| = 0$ then
5:          return $\{x_i : i \in \{1, 2, \ldots, a\}\}$
6:      end if
7:      for $comb \in combinations(n, a)$ do
8:          if $\neg \exists v \in B_a : \forall c \in comb : v(c) = 1$ then
9:              return $\{x_i : i \in comb\}$
10:         end if
11:     end for
12: end for
13: return $None$
```

The complete algorithm is presented as Algorithm 1. Firstly, Algorithm 2 is used to generate a discernibility matrix. Array *labels* is used to represent the current form of a function. Based on that the Algorithm 3 is used to find a decomposition. If a decomposition is found, we need to modify the matrix (Algorithm 4) and labels (Algorithm 5, where Δ denotes the symmetric difference of two sets).

The proposed algorithm uses the discernibility matrix to find a possible representation of an input function using XOR gates. This matrix represents all generated $C_{p,q}$ sets for all possible pairs p and q ($p < q$). In Algorithm 2 a pseudocode for matrix generation is presented. Notice that in the 5th line, we check whether the value of the function differs between rows number p and q. If so, the value of the XOR operation of those rows is added to the matrix. An added row has ones on those positions where vectors number p and q differ, i.e. the $C_{p,q}$ set. In order to reduce the computational complexity of the whole algorithm, we analyze RC^r using the increasing value of r. Therefore, the rows from the matrix are divided into bins, based on their size, i.e. bin B_i represents RC^i. Furthermore, repeating values from each bin are removed.

The process of multilevel function minimization consists of iteration of the basic decomposition steps, presented as Algorithm 3. To speed up computation, we start each iteration by checking whether $|B_a| = \binom{n}{a}$ or $|B_a| = 0$. In the first case, $RC^a = \emptyset$. Thus, it is impossible to find a decomposition for that value of a. On the other hand, in the second case $C^a = \emptyset$. Thus, we can simply return $\{x_i : i \in \{1, 2, \ldots, a\}\}$. The found decomposition (lines 7-11) is represented as a vector. Indexes of bits set to 1 in this vector represent input variables that will be used to minimize an input function. For example, $comb = (11000)$ shows that XOR of the first and second input variables is a decomposition function of F, i.e.

$$F = G(x_3, x_4, x_5, x_1 \oplus x_2).$$

Notice that in this approach we return the first found function. Such an approach is called First-Fit [6]. Other approaches to selecting decomposition functions were proposed in the literature. However, the described one is the fastest and provides good results in terms of the solution quality (i.e., the number of variables). On the other hand, it generates slightly worse results for specific functions, e.g. *M-out-of-N* coders.

For example, if *comb* $= (11000)$, then we get the following content of *labels*: $[\{3\}, \{4\}, \{5\}, \{1, 2\}]$ that represents the function G mentioned above. Notice that found decomposition function (i.e., using variables x_1 and x_2) is used as the last input to the new representation, while the other input variables come before it. Therefore, the algorithm will more likely find a decomposition using input variables that have not been used in the previous iterations. In the result, the compound degree (i.e., the number of inputs to the XOR operation) of each variable y_i might be similar.

Since the number of $C_{p,q}$ sets strongly depends on the value of K, the proposed approach is very efficient especially if $K \ll 2^N$.

The described approach treats the value of a function as a single output. However, a multi-output logic function

$$F : B^N \rightarrow B^Q, \tag{4}$$

Algorithm 4 Modification of discernibility matrix

```
$jdx \leftarrow 1$
for $idx \leftarrow 1$ to $N$ do
    if $idx \notin dec$ then
        $new\_dm[:, jdx] = dm[:, idx]$
        $jdx \leftarrow jdx + 1$
    end if
end for
for $idx \leftarrow 1$ to $|dec| - 1$ do
    $col1 \leftarrow dm[:, dec[idx]]$
    $col2 \leftarrow dm[:, dec[idx + 1]]$
    $new\_dm[:, jdx] = col1 \oplus col2$
    $jdx \leftarrow jdx + 1$
end for
return $new\_dm$
```

Algorithm 5 Modification of labels

```
$new\_labels \leftarrow \emptyset$
for $idx \leftarrow 1$ to $|labels|$ do
    if $x_{idx} \notin dec$ then
        $new\_labels \leftarrow new\_labels \cup labels[idx]$
    end if
end for
for $idx \leftarrow 1$ to $|dec| - 1$ do
    $l1 \leftarrow labels[dec[idx]]$
    $l2 \leftarrow labels[dec[idx + 1]]$
    $new\_labels \leftarrow new\_labels \cup (l1 \Delta l2)$
end for
return $new\_labels$
```

Algorithm 6 Finding decomposition for each output

```
$res \leftarrow \emptyset$
for $i \leftarrow 1$ to $Q$ do
    $res = res \cup$ Algorithm_1$(X, Y[:, i])$
end for
return $res$
```

where $B = \{0, 1\}$ can be implemented using XOR-based decomposition to each output variable separately. Recall that we denote by Q the number of output variables. The proposed approach is presented as Algorithm 6. In that case, the final result is a composition of found decompositions, where each function returns a single bit value.

IV. Application in memory-based logic synthesis

In this paper, we applied the proposed approach to some well-known functions. The obtained results are presented in Table VI. The variable reduction algorithm was applied to all analyzed functions, and the total number of reducts and the size of the shortest one are both presented in the table. Each reduct was then used as an input function to our linear decomposition algorithm. For each function, we show how many decompositions with the specified value of output variables (P) were found. *xor5* function is presented here to prove that described method correctly finds decomposition with a single multi-input XOR gate.

In the table, the Δ_1 and Δ_2 columns display the reduction factor in memory usage. The reduction factor is calculated using two different scenarios. The first formula, which is calculated using the following equation:

$$\Delta_1 = 2^{N-P} \tag{5}$$

compares the memory usage of the implementation from an input function to the implementation using XOR-gate decomposition. The second formula, which is calculated using the following equation:

$$\Delta_2 = 2^{N'-P} \tag{6}$$

compares the memory usage obtained after variable reduction to the final implementation, where N' is the size of the shortest reduct. In both formulas, the smallest value of P obtained for a function is used. For example, $\Delta_1 = 2$ means that memory usage is halved compared to the direct implementation (i.e., without using a decomposition algorithm).

The proposed approach can not directly operate on *don't care* terms, since it relies on the XOR operation. Typically, such terms can be ignored, set to 0 or set to 1. For *add6* and *clpl* function, we set each *don't care* term to 0. For *9sym* function, we add rows to make it a complete function and analyzed all possible values of *don't care* terms.

As already mentioned, memory-based logic synthesis was often used in the implementation of index generation functions. a well-known example of such a function consists of ten 40-bit vectors [12] and a unique consecutive integer value from 1 to 10 is assigned for every vector. In this paper, we denote this function as *igf40*. Using the variable reduction algorithm [3], it is possible to find more than 2200 reducts with $N' = 4$, and more than 100k in total ($N' \in \{4, 5, 6, 7\}$). In this paper, we applied the described approach to all those functions after variable reduction. For example, in Table VIIa, we present a function after variable reduction, where $N' = 5$. In Table VIIb we present that function after linear decomposition, where $y_4 = x_4 \oplus x_{32}$ and $P = 4$. In the end, the number of variables was minimized to 4 for more than 99% of reducts.

The most striking observation to emerge from the results is that the proposed approach lead to significant memory usage minimization. It is because obtained values of P are smaller than both the number of input variables N and the sizes of the shortest reducts.

When Algorithm 1 fails for some functions, e.g. *rd53*, Algorithm 6 can be used. In that particular case, $N = 5$, $K = 32$, and $Q = 3$. Therefore, we can apply the proposed approach three times, each time focusing on a single output signal. This technique leads to decompositions with the following number of inputs: $P_1 = N = 5$, $P_2 = 4$, and $P_3 = 1$. In the end, the memory usage is minimized from $2^5 * 3 = 96$ bits to $2^5 + 2^4 + 2^1 = 50$ bits. Notice that the third function does not need to be implemented using memory, since the number of inputs after decomposition (i.e., P_3) equals 1.

The size of the memory required to implement a function is calculated as

$$MEM = 2^N * Q. \tag{7}$$

Furthermore, the size of a memory required after the application of Algorithm 6 equals

$$MEM' = \sum_{i=1}^{Q} 2^{P_i}. \tag{8}$$

The experimental results obtained using the multioutput approach are presented in Table VIII. The original memory size and the memory size after decomposition, using equations (7) and (8) respectively, were both presented. The function *igf40 {6,16,24,31}* is a function *igf40* after variable reduction, where $P = Q = 4$ and the values in the brackets are indexes of input variables left after the reduction. Thus, the memory size can not be further minimized using that approach. However, the multioutput approach leads to lower memory consumption. We also present a second reduct, where $N' = 5 \neq Q$. Similar results were obtained for other analyzed functions, leading to a significant minimization of memory usage ($MEM' < MEM$).

V. Application in reversible logic synthesis

Recently, a novel three-level XOR-AND-XOR form was proposed [2] to represent autosymmetric functions. It extends a popular Exclusive Sum of Products (ESOP) form (i.e., XOR-AND form) by adding an additional XOR level to the representation. Using that form, a reversible circuit implementing a function can be easily constructed.

The first XOR level is used to compute reduction equations. In particular, it reduces the number of input variables to a f_k function using XOR gates. Therefore, this step is crucial in this technique and influences the Quantum Cost of the circuit at most. Notice that this step is analogous to the approach described earlier in this paper. It corresponds to the scheme presented in 1, where the linear function corresponds to the reduction equations and the general function corresponds to the restriction function f_k. Therefore, XOR-based decomposition can be used to find reduction equations. Recall from Section II-C that those equations can be implemented using several CNOT gates if we find a decomposition function with the value of r limited to two.

Secondly, a f_k function is implemented using any logic minimization tool. Notice that $k = N - P$. For example, an ABC [4] tool can be used to synthesize a function. *&esop* function derives ESOP from an AND-Inverter graph AIG, and *&exorcism* performs heuristic ESOP minimization [8]. This representation can be then used to find a reversible circuit that implements a f_k.

The final step is used to perform *uncomputation*, meaning that the original value is being restored on those lines that were affected by the reduction equation. It can be achieved by adding the CNOT gates used in the first level in reverse order.

Example 5.1: Consider the following function in ESOP form:

$$ESOP(F) = x_1x_3 \oplus x_1x_4 \oplus x_2x_5 \oplus x_2x_6.$$

We apply the proposed approach to find reduction equations. In the first iteration of the algorithm, we get $x_3 \oplus x_4$ as a decomposition function (since all are smaller in lexicographic order two input functions are in RC^2). Therefore,

$$F(X) = G(x_1, x_2, x_5, x_6, x_3 \oplus x_4).$$

Applying the algorithm the second time, we get $x_5 \oplus x_6$. Since it leads to $COM(RC) = \emptyset$, the algorithm ends. In the end, we get the following reduction equations:

$$y_1 = x_1,\ y_2 = x_2,\ y_3 = x_3 \oplus x_4,\ y_4 = x_5 \oplus x_6.$$

In the result, we get the following ESOP representation of the restriction f_2 ($k = 6 - 4 = 2$):

$$ESOP(f_2) = y_1y_3 \oplus y_2y_4.$$

Thus, we get the following XORAX representation of F:

$$XORAX(F) = x_1(x_3 \oplus x_4) \oplus x_2(x_5 \oplus x_6).$$

It contains 6 literals and 2 products. Notice that the ESOP representation contains 8 literals and 4 products.

In Fig. 2 the obtained reversible circuit is presented. The first two CNOT gates are used to represent the reduction equations (i.e, $x_3 \oplus x_4$ and $x_5 \oplus x_6$). Next, two Toffoli gates represent the f_2 restriction based on its ESOP form. Finally, the last two CNOT gates recover the initial value of both x_4 and x_6 variables by applying XOR operations one more time. Four CNOT gates and two Toffoli gates are used in total. Therefore, the total Quantum Cost (QC) equals

$$QC = 4 * 1 + 2 * 5 = 14.$$

Notice that the straightforward implementation from an ESOP form requires four Toffoli gates, where each of them realizes the single product of two variables. Thus, its Quantum Cost equals 20.

The proposed approach can also be combined with a functional decomposition technique [10]. This method decomposes an input function into smaller irreversible functions that are connected, and the original function is preserved. The most important fact is that each function is smaller (in terms of the number of inputs), which makes it easier to synthesize. This technique was also used in memory-based logic synthesis to reduce memory consumption [7].

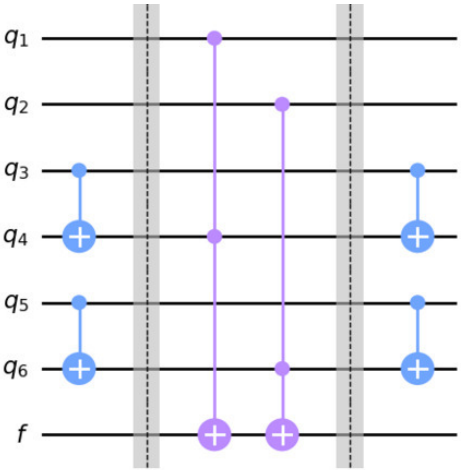

Fig. 2: Reversible circuit derived from a XORAX representation.

Each of the smaller functions is synthesized to get a reversible circuit and then combined into a single circuit. Because irreversible functions are implemented, a *garbage* output is introduced. In particular, the original value of the signal does not have to be restored on a line that was affected by reversible gates.

Example 5.2: Consider a function presented in Table IX. Using the ABC tool, we get a circuit, where Quantum Cost equals 120. Using functional decomposition it is possible, to divide this function into two functions (denoted G and H). The first function has three inputs (x_3, x_4, x_5) and one output (g). The second one has four inputs (x_1, x_2, x_6, g) and one output. The mapping between inputs and output for both functions can be found using a graph colouring method [7]. Truth tables for both functions are presented in Table X. Using the ABC tool, we get Quantum Cost 30 and 38 respectively, meaning 68 in total.

TABLE IX: An example function.

x_1	x_2	x_3	x_4	x_5	x_6	$F(X)$
0	0	0	0	0	0	1
0	1	0	0	1	0	1
0	1	0	1	1	0	0
0	0	1	0	0	1	0
0	0	1	1	0	1	0
1	0	1	1	0	0	0
0	1	0	0	0	0	0
1	0	1	0	0	0	1
0	1	0	1	0	0	0

Both functions can be decomposed using the XOR-based approach. For function G, we get $\{x_3, x_4, x_5\} \in COM(RC)$. Therefore,

$$y_1 = x_3 \oplus x_4,\ y_2 = x_4 \oplus x_5.$$

Linear function can be implemented using a single CNOT gate,

TABLE X: Functional decomposition of a function.

(a) Function G.

x_3	x_4	x_5	G
0	0	0	0
0	0	1	1
0	1	1	0
1	1	0	1
0	1	0	0
1	0	0	0

(b) Function H.

x_1	x_2	x_6	g	H
1	0	0	0	1
0	1	0	0	0
1	0	0	1	0
0	0	1	1	0
0	0	0	0	1
0	0	1	0	0
0	1	0	1	1

while the general function synthesized using the ABC tool has $QC = 6$.

For function H, we get $\{x_2, g\} \in COM(RC)$. Therefore,

$$y'_1 = x_1,\; y'_2 = x_6,\; y'_3 = x_2 \oplus g.$$

In that case, the linear function can be implemented using two CNOT gates. The general function synthesized using the ABC tool has $QC = 5$. In total, Quantum Cost was minimized from 68 to 14.

Interestingly, this specific input function can be directly decomposed using the proposed approach. In that case, after four iterations of Algorithm 1, we get:

$$y_1 = x_4 \oplus x_6,\; y_2 = x_1 \oplus x_2 \oplus x_3 \oplus x_5.$$

Those equations can be implemented using four CNOT gates (i.e., one for y_1 and three for y_2), while the general function has $QC = 6$, leading to $QC = 10$ in total.

VI. Conclusion

In this paper, we showed how XOR-based decomposition, which has been previously used in index generation functions synthesis, can be generalized and efficiently applied in memory-based and reversible logic synthesis. We provided a complete algorithm and used well-known benchmark functions to prove that it can provide significant minimization of memory usage. The presented results highlight the potential of this technique for memory-based logic synthesis. Furthermore, we showed that our algorithm can be easily combined with other techniques proposed in the literature to achieve promising results in reversible logic synthesis. Based on our research we believe that XOR-based decomposition might become a valuable tool for other researchers and practitioners.

***Abstract*—*Context:* Speech Emotion Recognition (SER) is a valuable technology that identifies human emotions from spoken language, enabling the development of context-aware and personalized intelligent systems. To protect user privacy, Federated Learning (FL) has been introduced, enabling local training of models on user devices. However, FL raises concerns about the potential exposure of sensitive information from local model parameters, which is especially critical in applications like SER that involve personal voice data. Local Differential Privacy (LDP) has prevented privacy leaks in image and video data. However, it encounters notable accuracy degradation when applied to speech data, especially in the presence of high noise levels. In this paper, we propose an approach called LDP-FL with CSS, which combines LDP with a novel client selection strategy (CSS). By leveraging CSS, we aim to improve the representatives of updates and mitigate the adverse effects of noise on SER accuracy while ensuring client privacy through LDP. Furthermore, we conducted model inversion attacks to evaluate the robustness of LDP-FL in preserving privacy. These attacks involved an adversary attempting to reconstruct individuals' voice samples using the output labels provided by the SER model. The evaluation results reveal that LDP-FL with CSS achieved an accuracy of 65-70%, which is 4% lower than the initial SER model accuracy. Furthermore, LDP-FL demonstrated exceptional resilience against model inversion attacks, outperforming the non-LDP method by a factor of 10. Overall, our analysis emphasizes the importance of achieving a balance between privacy and accuracy in accordance with the requirements of the SER application.**

***Index Terms*—Federated Learning, Privacy-preserving Mechanism, Differential Privacy, Speech Emotion Recognition**

I. Introduction

SPEECH Emotion Recognition (SER) is a cutting-edge technology that detects and interprets emotions conveyed through spoken language [1]. Its potential impact spans multiple sectors, including customer service, mental health, education, and entertainment [2], [3]. However, the traditional centralized SER model, which involves gathering user speech data and training a single model on a central server, poses privacy risks. Analyzing speech data can expose sensitive information like biometric identity, personality traits, location, emotional state, age, gender, and overall health [4]. To address these ethical and privacy concerns, regulation like the General Data Protection Regulation (GDPR) [5] has been implemented to safeguard personal data. Privacy must be a top priority when developing and implementing SER applications across various domains.

Federated learning (FL) has emerged as a promising solution to privacy concerns in various fields and applications [6]. FL maintains local data on end devices and trains ML models on local client devices without transferring raw data to a central server. This preserves data privacy and ensures compliance with regulations such as GDPR. For SER applications, the initial processing of speech data and training perform on clients' devices, and only local model parameters are sent to the central server for model aggregation [7].

However, FL faces new privacy concerns when it comes to transmitting local model parameters between clients and servers [8]. This is a significant concern because the transmission parameters can be exploited by third parties, enabling them to launch attacks that reconstruct raw speech data or features, thereby revealing sensitive information [9]. To address this issue, additional privacy mechanisms have been proposed together with FL to safeguard such applications.

One promising mechanism that has emerged is differential privacy (DP), which offers a potential solution to protect individual data points in certain cases. DP can be implemented in FL through two forms: local differential privacy (LDP) applied on the client side and global differential privacy (GDP) used on the server side [10]. LDP, a well-established technique, involves the addition of carefully calibrated noise to each client's model parameters before transmitting them to the central server [11], [12], [13].

Integrating LDP in FL for SER applications offers several benefits. It ensures the privacy and confidentiality of individual speech data, protecting sensitive information from unauthorized access and potential attacks. By introducing noise to the model parameters, LDP prevents the reconstruction of raw speech data or features by malicious third parties, thereby preserving users' privacy. Despite the promising potential of LDP in FL for SER applications, there is a noticeable lack of research published in reputable conferences or journals specifically addressing the utilization of LDP in this context. This gap highlights the need for further investigation and exploration to fully understand the effectiveness and practical implications of integrating LDP into FL for SER.

However, when applied to SER applications, LDP does not offer acceptable accuracy due to the adverse effects of adding noise to voice data, which can distort the audio signal [14]. Furthermore, adding noise to SER model parameters can affect the model's utility by distorting or misaligning the parameters, leading to errors in the model's output [15]. This compromise in accuracy is especially detrimental to most SER applications, which rely on precise results for industrial use [16]. Therefore, when developing LDP mechanisms in FL for SER, it is necessary to find a concrete solution that effectively mitigates the impact of noise on SER accuracy while still maintaining robust privacy protections.

This paper proposes a method, referred to as LDP-FL with CSS, which integrates LDP with a novel client selection strategy (CSS) to enhance privacy while preserving the acceptable accuracy of SER in the FL system. LDP is utilized to protect clients' speech datasets, while CSS is employed to minimize the negative impact of noise scaling on the model updates, resulting in more representative updates and improved accuracy.

Moreover, our study focuses on adapting the model inversion attack, initially developed for facial recognition models [17], for the SER model through appropriate configuration adjustments. This attack attempts to reconstruct speech features by considering the adversary's knowledge of a particular client's emotion label and their local SER model. The primary goal is to evaluate the effectiveness of the LDP method in safeguarding against such attacks within the FL setup. Finally, we comprehensively evaluated the LDP-FL with CSS approach, specifically focusing on assessing its alignment with SER requirements and analyzing the trade-off between accuracy and privacy.

The novel contributions of this paper can be summarized as follows:

- We introduce a novel approach that combines local differential privacy in federated learning (LDP-FL) with a client selection strategy (CSS) to enhance privacy while mitigating the impact of noise on SER accuracy.
- We implement model inversion attacks to assess the robustness of LDP-FL and determine its effectiveness in preserving privacy. These attacks involve an adversary attempt to reconstruct individuals' voice samples based on the output labels provided by the SER model.
- We conduct a comprehensive evaluation of the LDP-FL with CSS approach on public SER datasets, considering important parameters such as privacy budget, noise scale, failure probability, and clipping threshold value. Our evaluation focuses on assessing how well our method meets SER requirements and analyzing the balance between accuracy and privacy.

The rest of the paper is structured as follows. Section II covers background and related work on privacy-preserving FL and SER. A reference system description is provided in Section III, including the SER non-functional requirements, threat model, the proposed method, and implementation of the model inversion attack. Section IV presents the experimental results obtained using the proposed approach. Lastly, Section V concludes the paper and provides insights for future developments.

II. Background and Related Works

In this section, we will provide an overview of the background and related work on LDP mechanisms in FL. We will then discuss the use of FL for SER applications and its related work.

A. Privacy-preserving Federated Learning

FL protects user privacy by decentralizing data from the central server to edge devices; however, sharing information with servers (e.g., model weights) can pose privacy threats [8]. Since FL requires central servers and clients to exchange model update parameters, attackers with white-box access obtain the model, its architecture, weight parameters, and any hyperparameters needed for predictions. When using black-box scenarios, the adversary can observe only the outputs of the model on arbitrary inputs [9].

LDP has become an increasingly popular technique for privacy-preserving in FL [10]. LDP can prevent individual devices' data from being leaked to the central server during the model training process [11], [12]. This technique involves adding artificial noise to each model's updated parameters before sharing it with the central server. Recent work proposed a framework called NbAFL that utilized LDP and demonstrated its capability to meet DP requirements under different protection levels by appropriately adapting various variances of artificial noise [12]. Another study proposed LDP-based stochastic gradient descent (SGD) that guarantees a given LDP level by providing a noise variance limit after multiple rounds of weight updates using a tight composition theorem [13].

B. Speech Emotion Recognition using Federated Learning

SER technology aims to recognize and understand human emotions through speech. SER systems analyze the audio signals from human speech and use ML algorithms to detect patterns and classify the emotional states conveyed by the speech [2]. Building SER models requires significant amounts of data, including sensitive personal information such as speech signals and emotions. However, centralized storage of this data presents privacy risks. To mitigate these risks, FL is a promising solution that allows models to be trained collaboratively on decentralized devices without the need to transfer raw data [7].

The paper [18] introduces an FL-based approach for building a private decentralized SER model. The proposed method utilizes data-efficient federated self-training to train SER models with minimal on-device labelled samples. However, the proposed method only relies on the FL framework as a privacy-preserving technique and does not consider any

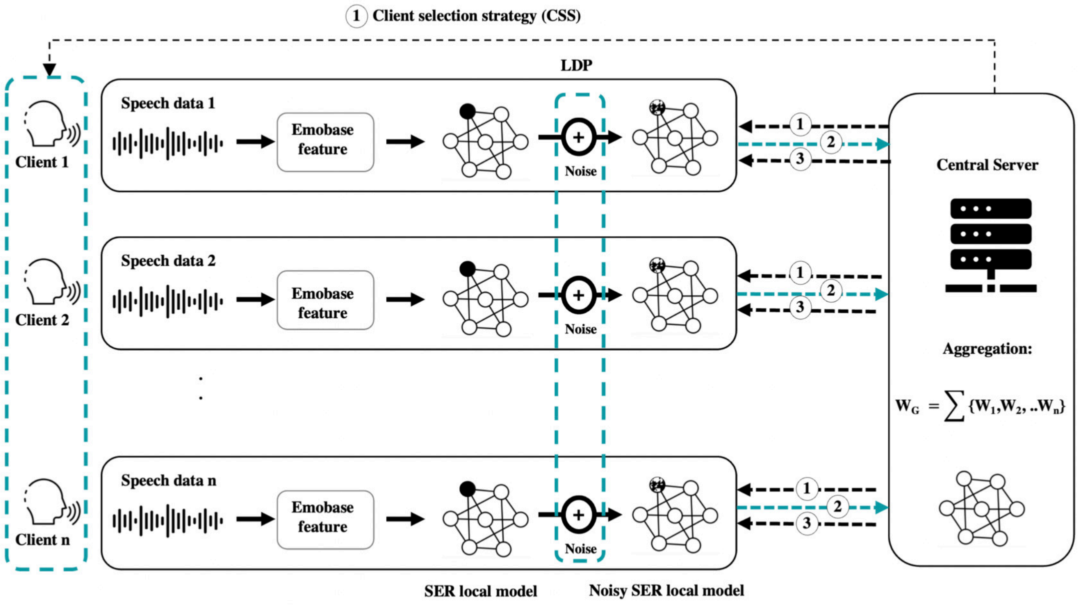

Fig. 1: An overall overview of LDP-FL with CSS for SER application.

threat models from clients or servers in FL, nor does it consider any other privacy-preserving techniques. Similarly, another work [19] proposes a federated adversarial learning framework to protect both data and deep neural networks in SER. The framework comprises an FL framework for data privacy and adversarial training during the training stage for model robustness. However, like the previous method, it only relies on the FL framework for privacy preservation and does not consider other privacy-preserving techniques in FL.

III. System Description

In this section, we will address the non-functional requirements of the SER application (III-A), discuss the associated threat model (III-B), present the proposed LDP-FL with CSS method (III-C) along with algorithms and details, and finally describe the model inversion attack for speech features using algorithms (III-D).

A. Non-functional Requirements of Speech Emotion Recognition Application

Non-functional requirements refer to the characteristics or qualities of a system that are related to its performance rather than its specific functionality. In the context of SER applications, important non-functional requirements include privacy and accuracy. Satisfying these requirements is critical to ensure user needs and expectations while complying with legal requirements. In this part, we provide a more detailed explanation and explain how we meet these requirements in the evaluation section IV.

1) *Privacy:*
   a) Personal speech data must be kept on local devices only [5].
   b) The central server or a potential eavesdropper must be not able to infer sensitive information from the local model parameters
2) *Accuracy:*
   a) The level of accuracy of SER applications must be kept high enough to identify the correct emotions from speech samples reliably. We can consider a baseline accuracy of a minimum 70% in detecting the four basic emotions - neutral, sad, happy, and angry [20].

It is important to highlight that those requirements can be highly interdependent. For instance, privacy-preserving approaches can have an impact on accuracy due to e.g. the distributed setup the usage of FL, applied noise of the LDP method, etc. Additionally, when implementing a SER in an FL setup, it has been demonstrated in reference [18] that there is a potential for a 0-5% accuracy drop.

B. Threat Model

In this paper, we assume the server follows the honest-but-curious (HBC) paradigm. Under this paradigm, the server is not malicious and adheres to the FL protocol, but may still possess a curiosity about the data or models of other clients [21]. While the individual client datasets are kept locally in FL, the intermediate parameter w_i needs to be shared with the server, which can potentially expose clients' private information, as evidenced by model inversion attacks. For instance, in [17], researchers demonstrated a model inversion attack capable of reconstructing images from a facial recognition system.

C. Proposed Method: LDP-FL with CSS

We present "LDP-FL With CSS," a novel approach that combines local differential privacy (LDP) and a client selection strategy (CSS) in federated learning to balance client privacy and the accuracy of the SER model. Our method addresses privacy requirement 1.a by processing and training clients' speech data locally on their devices within the FL setup. By leveraging LDP techniques, Gaussian noise is incorporated into the local updates before transmitting them to the central server. This implementation provides robust protection against the inference of sensitive information, thereby fulfilling the requirement of 1.b and mitigating potential risks in the threat model. To meet the accuracy requirements 2.a, we incorporate CSS, prioritizing clients with larger data pools and involving them in each training round. This strategy aims to mitigate the potential negative impact of LDP on accuracy while enhancing it to meet the desired accuracy levels.

Figure 1 outlines the proposed method, which consists of three main steps. Firstly, the server broadcasts the initialized global SER model and uses the CSS method to select clients for training. In the second step, the chosen clients analyze speech data, extracting Emobase features (explained in Sec. IV-A) and train their models. They also update their local model parameters using the global model. Privacy is ensured by applying the LDP method to each parameter before sharing them with the server. The clients then share the noisy model parameters with the server. In the third step, the server aggregates the received noisy local model parameters and returns the updated global model to the clients. We provide Algorithm 1 as a comprehensive outline of the LDP-FL with CSS approach. Subsequently, we will delve deeper into the concepts of LDP and CSS in the context of FL.

Algorithm 1: LDP-FL with CSS

```
   Input: Number of iterations: T, Number of selected
          clients: K, Local minibatch size: B, Initial
          global model: $w_0$, Learning rate: $\eta$, Clipping
          threshold: C, LDP parameters: $\epsilon$ and $\delta$
1  Initialization:
2  Initialize the global model parameters $w_0$
   for $t \leq T$ do
3      The server broadcasts current model $w_t$
4      K: Client Selection Strategy (CSS)
5      Clients-side:
       for $i \in 1, 2, ..., K$ do
6          for each batch $b \in B_i$ do
7              Compute gradient $g(b) \leftarrow \nabla_w L^i(w_t; b)$
8          Clip gradient $\overline{g}(b) \leftarrow g(b)/Max(1, \frac{\|g(b)\|}{C})$
9          Add Noise
           $\tilde{g_i} = \frac{1}{|B|}(\sum_{b \in B} \overline{g}(b) + N(0, \sigma^2 C^2 I)$
10         Share $\tilde{g_i}$ with server
11     Server-side:
12     Aggregate $\tilde{g} = \frac{1}{K}\sum_{i=1}^{K} \tilde{g_i}$
13     Global model update $w_{t+1} \leftarrow w_t - \eta.\tilde{g}$
```

1) Local Differential Privacy (LDP): LDP is defined under the setting where the user does not trust anyone (not even the central data collector) [11]. In this setting, users themselves apply a random perturbation to protect their privacy. Each user runs a random perturbation algorithm, denoted as M, on their data and shares the perturbed results with the aggregator or central server. In LDP, the privacy budget, denoted as ϵ, represents the amount of privacy protection desired, with a higher value of ϵ implying a lower level of privacy. While δ represents the probability that an LDP mechanism fails to provide the specified privacy guarantee. Here is a formal definition of LDP:

Definition 1 ((ϵ, δ)-LDP [22]): A randomized mechanism M satisfies (ϵ, δ)-LDP if and only if for any pairs of input values v and v' in the domain of M, and for any possible output $y \in$ S , it holds:

$$Pr[M(v) = y] \leq e^{\epsilon} Pr[M(v') = y] + \delta. \tag{1}$$

Theoretically, (ϵ, δ)-LDP means that a mechanism M achieves (ϵ, δ)-LDP with probability at least $1 - \delta$.

To implement the LDP mechanism in a FL setup, we followed the approach described in reference [23]. Specifically, we incorporated artificial Gaussian noise into the clients' model parameters. In order to ensure that the given noise distribution $Z \sim N(0, \sigma^2 C^2 I)$ preserves (ϵ, δ)-LDP, for any $\epsilon < cq^2 T$, $\delta > 0$, and T number of epoch, we choose noise scale $\sigma \geq c\frac{q\sqrt{Tlog(1/\delta)}}{\epsilon}$, where the constant c and sampling probability q. In this result, Z is the value of an additive noise for client gradient.

In Algorithm 1, during time slot t, each selected client $i \in k$ trains its local dataset by minimizing the loss function ∇L^i (lines 6-8). For each client, the gradient $g(b)$ is calculated for each $b \in B_i$. To limit the impact of each gradient $g(b)$, we apply clipping using the $\|L\|_2$ norm. Specifically, $g(b)$ is replaced by $g(b)/\max(1, \frac{\|g(b)\|_2}{C})$ where C is the clipping threshold (line 7). This clipping mechanism ensures that if the norm $\|g\|_2$ is less than or equal to C, the gradient g remains unchanged. However, if $\|g\|_2$ exceeds C, it is scaled down to have a norm of C, thereby controlling the contribution of large gradients.

After clipping the gradient, we compute the average of all gradients in set B and add a scaled Gaussian noise $Z \sim N(0, \sigma^2 C^2 I)$ to each client's gradient to achieve LDP in lines 9-10. The resulting noisy gradient $\tilde{g_i}$ is then shared with the server in line 11. On the server side, upon receiving the noisy gradients $\tilde{g_i}$ from the selected clients, the server performs the FedSGD algorithm by aggregating the gradients $\tilde{g} = \frac{1}{K}\sum_{i=1}^{K} \tilde{g_i}$. Subsequently, the global model is updated using $W_{t+1} \leftarrow W_t - \eta \cdot \tilde{g}$ and utilized for the next iteration in lines 13-14.

2) Clients Selection Strategy (CSS): To mitigate potential noise effects and uphold the initial accuracy of SER models in FL, we introduce a refined client selection strategy named

(CSS). Our proposed approach involves carefully selecting clients for FL training, employing two distinct criteria.

Algorithm 2: Clients Selection Strategy (CSS)

```
Input: Number of iterations: $T$, Clients list: $L$,
       Number of selected Clients: $K$
Output: List of selected clients
1 for $t \leq T$ do
2     Half of selection: $M = K/2$
3     $\mathcal{C}$ = sorted $L$ in descending order by sample size
4     Selected clients = $\mathcal{C}$ [:M]
5     Remaining clients = randomly select $\mathcal{C}$ [M:]
6 Return K = selected clients + remaining clients
```

Firstly, we select half of the clients from a larger pool of candidates based on their sample size. This criterion ensures that clients with larger local datasets are given preference. By incorporating larger local datasets, which are more likely to yield accurate and representative model updates, we aim to enhance the overall model accuracy. Secondly, to mitigate selection bias, the remaining half of the clients are randomly chosen. This random selection mechanism introduces an element of diversity and reduces the potential bias that could arise from selecting clients based solely on their sample size.

Algorithm 2 outlines the client selection strategy (CSS) method used in each training round of the overall Algorithm 1. Our method selects the top half of the clients based on their sample size, giving those clients with the largest sample sizes a higher probability of being chosen for each round of training (line 4). To reduce bias in client selection, we combine our proposed method with random selection for the remaining clients (line 5). We then combine the two sets of selected clients to obtain the final selection (line 6).

We ensure that there is no overlap between the two sets of selected clients to guarantee that each client is selected precisely once per training round. By employing the CSS approach, we strike a balance between leveraging large local datasets for training and maintaining diversity within the FL system. This methodology effectively minimizes noise effects and fosters the preservation of the initial model accuracy in SER models trained through FL.

D. Model Inversion Attack for Speech Emotion Recognition Models

A model inversion attack takes place when an adversary gains access to a model's output and potentially its parameters, aiming to infer sensitive training data. In our paper, we adjust the existing work conducted in the field of face recognition [17] and adapt it for speech emotion recognition by changing some configurations. In this scenario, we assume that the attacker possesses knowledge of a single emotion label, such as neutral, sad, happy, or angry, as well as the model used by the clients. The objective of the adversary is to reconstruct the speech data features associated with a specific client and the corresponding emotion label.

The target of model inversion attack in this case is the inversion of speech features, which represent high-level statistical characteristics of a client's speech. Each intensity value in the features corresponds to a floating-point value. In our attack scenarios, we assume that the attacker does not possess exact knowledge of the feature values they are trying to infer. We consider feature vectors with n components and four emotion label classes, and we model each emotion recognition classifier as a function $\tilde{f} : [0,1]^n \rightarrow [0,1]^4$. The output of the model is a probability vector, where each component represents the probability that the feature vector belongs to a specific emotion label. We use the notation $\tilde{f}_{\text{label}}(x)$ to refer to the ith component of the output corresponding to the emotion label. The Algorithm 3 provides a comprehensive outline of the model inversion attack specifically designed for speech emotion recognition models.

Algorithm 3: Model inversion attack for speech emotion recognition models

```
Input: Number of iteration: $T$, Best score: $\gamma$, Target
       model: $\tilde{f}$, Learning rate: $\eta$
Output: Related speech features to target label
$c = 1 - \tilde{f}_{label}(x)$
$x_0 \leftarrow 0$
for $t \leq T$ do
    $x_t \leftarrow \text{Process}(x_{t-1} - \eta \cdot \nabla c(x_{t-1}))$
    if $c(x_t) \geq \max(c(x_{t-1}), \ldots, c(x_{t-\beta}))$ then
        break
    if $c(x_t) \leq \gamma$ then
        break
return $[\arg\min_{x_t}(c(x_t)), \min_{x_t}(c(x_i))]$
```

The algorithm utilizes gradient descent to minimize a cost function involving the emotion recognition model $\tilde{f}$ for model inversion. Gradient descent iteratively updates a candidate solution by moving towards the negative gradient direction. The cost function, denoted as c, is defined based on $\tilde{f}$. The model inversion attacks employ gradient descent for a maximum of T iterations with a step size of η. After each iteration, the resulting feature vector is processed using a post-processing function called Process, which can apply various manipulations to the speech features, such as denoising and sharpening, depending on the specific attack. The descent terminates if the cost does not improve within β iterations or if the cost exceeds a threshold γ. In such cases, the best candidate is returned as a result.

IV. Experiment Results

In this section, we present an industrial use case and the simulation setting. We evaluate the impact of the LDP-FL method on SER accuracy, considering parameters like noise scale, failure probability, and clipping threshold. We analyze the effect of CSS on SER accuracy within the LDP-FL framework and investigate the robustness of LDP-FL against model inversion attacks. Finally, we discuss the crucial task of achieving the optimal balance between privacy levels and accuracy.

A. Usecase Description and Simulation Setting

DAIS[1] (Distributed Artificial Intelligent System) [24] is a pan-European project that aims to provide trustworthy connectivity and interoperability by combining the IoT with AI into a distributed edge system for industrial applications. The project includes industry-driven use cases in domains such as digital life, digital industry, and smart mobility. One of the important use cases in DAIS is SER which is deployed on TV recommendation systems. The goal is to accurately capture users' emotions and provide personalized movie recommendations, leading to higher levels of user satisfaction. Achieving this requires a distributed, efficient, private, and accurate SER application. This was one of the main motivations for exploring the potential of LDP-FL with CSS in SER.

As part of this study, we evaluated the proposed method on one of the most widely used SER datasets, namely CREMA-D [25]. CREMA-D is a data set of 7,442 original clips from 91 actors. These clips were from 48 male and 43 female actors between the ages of 20 and 74 coming from various races and ethnicities (African America, Asian, Caucasian, Hispanic, and Unspecified). Actors spoke from a selection of 12 sentences. The sentences were presented using one of six different emotions (Anger, Disgust, Fear, Happy, Neutral, and Sad) and four different emotion levels (Low, Medium, High, and Unspecified). To train the SER model, we chose the four most commonly occurring emotion labels (neutral, sad, happy, and angry) based on the possible emotions expressed in the sentences.

For speech processing and feature extraction, we generate the Emo-Base feature set using the OpenSMILE toolkit [26]. The Emo-Base feature set is a widely used set of features for SER tasks. These features are extracted from the speech signal and capture various acoustic characteristics of the signal that are associated with different emotions. The features are designed to be highly discriminative for emotion recognition and have been shown to achieve state-of-the-art performance in various SER tasks. After extracting the features, we utilized a multilayer perceptron (MLP) architecture for the SER model and trained it using the FedSGD algorithms. The model consists of two dense layers with layer sizes of [256, 128] and ReLU activation function, along with a 0.2 dropout rate. We set a local training batch size of 20 and a learning rate of 0.1 to accelerate convergence in the FedSGD algorithm.

For the FL training on the CREMA-D dataset, each speaker serves as a unique client since there are 91 distinct speakers in the dataset. We employed 80% of the data for local training at each client and reserved the remaining 20% for validation. To ensure the robustness of our approach, we conducted five experiments with different test folds, and we reported the average results of the five-fold experiments. The FL scenarios were conducted over 200 global training epochs. Our experiments were conducted on a Windows 10 Pro environment, featuring an Intel(R) Core(TM) i7 CPU @1.80GHz 1.99 GHz processor and 16.0 GB of RAM.

B. SER accuracy results across different parameters: noise scale, failure probability and clipping threshold

We conducted an analysis to assess the accuracy of SER in LDP-FL by examining the impact of various LDP parameters on accuracy. Our evaluation involved 50 randomly selected clients and 120 training epochs, as depicted in Figure 2. Specifically, we investigated the influence of the noise scale σ on accuracy (Figure 2(a)), the effect of varying failure probability δ on accuracy (Figure 2(b)), and the impact of the clipping threshold C on accuracy (Figure 2(c)).

The experimental results illustrated in Figure 2(a) indicate that the accuracy of LDP-FL gradually stabilizes with an increase in the number of training epochs, indicating convergence of the method. However, higher noise scales, such as $\sigma = 10$, can impede convergence due to the injection of larger amounts of noise during training, resulting in an unstable system. Figure 2(b) demonstrates that higher failure probabilities δ lead to faster convergence and higher accuracy but weaker privacy protection. Conversely, lower failure probabilities provide stronger privacy guarantees at the expense of reduced accuracy. For instance, a failure probability of $\delta = 10^{-3}$ achieved the highest accuracy while sacrificing some privacy for utility.

Our evaluation of LDP-FL's accuracy with different clipping thresholds showed that a threshold of 1.0 or 2.0 achieves high accuracy with fast convergence, as shown in Fig. 2(c). However, using a threshold beyond a certain point results in decreased accuracy due to excessive information loss during the clipping process. Hence, selecting the optimal clipping threshold is crucial to balance privacy preservation and model accuracy.

C. Effect of CSS on SER accuracy

To evaluate the effectiveness of LDP-FL with CSS for SER application, we conducted a comparative study between CSS and the commonly used random selection (RS) method in both LDP and non-LDP FL systems. Using parameters $\sigma = 1.0$, $C = 2$, $\delta = 10^{-5}$, and $K = 50$, we observed a significant improvement in accuracy from 60% to 70% when using CSS with LDP, as depicted in Figure 3 and meeting the accuracy requirements outlined in Section III-A. CSS proved to be an effective method for selecting clients, leading to more representative and larger datasets for training, resulting in more robust and accurate models. However, it is important to note that selecting clients with larger local datasets increases their exposure, potentially leading to data leakage. Therefore, a balance must be struck when employing CSS.

Interestingly, we observed that the choice of client selection method did not significantly impact the accuracy of non-LDP FL systems. This suggests that the accuracy improvement achieved by CSS is specific to the LDP-FL. Thus, adopting an

(a) (b) (c)

Fig. 2: Evaluation of the accuracy of the SER model using LDP-FL across different parameters: (a) noise scale σ, (b) failure probability δ, and (c) clipping threshold C.

TABLE I: MSE of reconstruction of speech features by model inversion attack in cases where FL has LDP or does not have LDP

Target model	**Clipping Threshold (C)**	**Mean Squared Error (MSE)**					
		LDP-FL					**Non-LDP-FL**
		$\sigma = 1$	$\sigma = 3$	$\sigma = 5$	$\sigma = 7$	$\sigma = 10$	-
Client SER model	C=1	0.971	1.189	19.830	45.132	157.640	1.02
	C=2	1.028	9.189	78.910	1139.474	5807.308	1.02
	C=4	1.886	344.000	8508.620	59164.757	572765.191	1.02

efficient client selection strategy like CSS can be a valuable technique to enhance the performance of LDP-FL and mitigate the potential negative impact of LDP on accuracy.

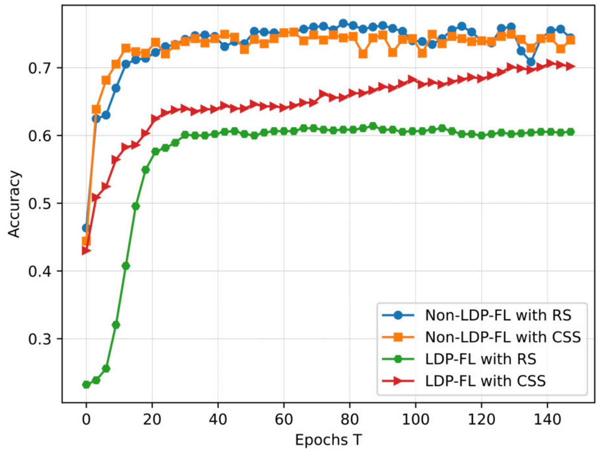

Fig. 3: Evaluation of different client selection methods based on accuracy.

D. Analyze the robustness of LDP-FL against model inversion attacks

We conducted a model inversion attack using the specified algorithms with the following settings: $T = 200$, $\eta = 0.1$, $\beta = 100$, and $\gamma = 0.99$. The attack was applied to two different settings in the system: LDP-FL with $C = [1, 2, 4]$ and $\delta = 10^{-5}$, and non-LDP in FL with $K = 7$. To ensure accurate results, we performed the attack on various client target models and target labels and reported the average outcomes.

The objective of model inversion attacks is to reconstruct the speech features of each client by exploiting the local SER model and its associated labels. To evaluate the effectiveness of these attacks on the FL system, we employed the Mean Squared Error (MSE) metric. The MSE was calculated by comparing the reconstructed speech features with the actual speech features of each specific client.

Table I illustrates the results obtained from the attack. When the noise scale σ was set to 1.0, the MSE values were similar for both LDP and non-LDP settings. However, as we increased the noise scale σ and the clipping threshold C, the MSE values significantly increased, indicating a decline in the attack effectiveness. These findings highlight the effectiveness of incorporating LDP as a robust privacy measure against model inversion attacks. Implementing LDP in the system significantly mitigates the risk posed by threat models and ensures compliance with the specified privacy requirements, particularly the 1.b privacy requirement. By introducing noise into the client models, the accuracy of predictions made by adversaries using these models is reduced, thereby impeding the reconstruction process of speech features associated with specific client labels.

E. Balancing privacy and accuracy

Achieving an optimal balance between privacy and accuracy is paramount when utilizing LDP for SER applications that require precise and accurate results. According to this reference [23], epsilon (ϵ) acts as a parameter that measures the level of privacy guarantee provided by the $(\epsilon, \delta) - LDP$

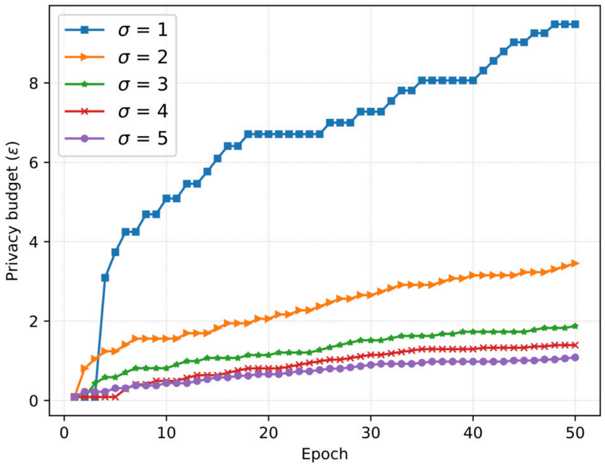

Fig. 4: With constant noise scale σ, changes in privacy budget (ϵ) with an increase in epochs

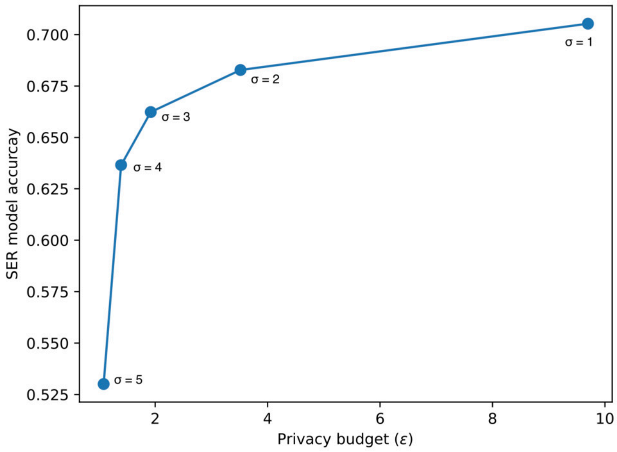

Fig. 5: An assessment of the accuracy of SER models based on privacy budgets and noise levels.

mechanism. It reflects the degree of privacy protection, with smaller epsilon values indicating stronger privacy guarantees. In our developed method, the value of ϵ is influenced by the number of epochs (T). Consequently, as the number of epochs increases, the value of ϵ changes, even when the noise scale remains constant. This association is illustrated in Figure 4.

In our evaluation of the LDP-FL with CSS mechanism for SER, we experimented with different noise scales σ, $k = 50$, failure probability parameter of $\delta = 10^{-5}$, clipping threshold $C = 2$ and a total of 50 epochs (T). The results, as illustrated in Figure 5 and Figure 4, revealed the following privacy levels and corresponding accuracy:

- For a noise scale of $\sigma = 5$, we achieved a privacy level of $(1.08, 10^{-5}) - LDP$, with an accuracy of approximately 54%.
- With a noise scale of $\sigma = 4$, we attained a privacy level of $(1.39, 10^{-5}) - LDP$, accompanied by an accuracy of around 64%.
- Employing a noise scale of $\sigma = 3$, we achieved a privacy level of $(1.92, 10^{-5}) - LDP$, while maintaining an accuracy of approximately 67%.
- A privacy level of $(3.51, 10^{-5}) - LDP$ was obtained by utilizing a noise scale of $\sigma = 2$, resulting in an accuracy of about 69%.
- Finally, with a noise scale of $\sigma = 1$, we achieved a privacy level of $(9.69, 10^{-5}) - LDP$, accompanied by an accuracy of roughly 70%.

Striking the right balance between privacy and accuracy is contingent upon specific system requirements. In the case of the SER application in the FL setup, where the specified acceptable accuracy range is 65-70% and privacy requirements are outlined in Section III-A, it is feasible to attain an acceptable level of privacy by utilizing a privacy parameter of $(1.92, 10^{-5})$-LDP, along with a noise scale of $\sigma = 3$, while maintaining the desired accuracy.

V. Conclusions and Future work

In this paper, we introduced LDP-FL with CSS, a novel approach for privacy-sensitive SER applications. Our objective is to ensure the privacy of clients' speech data while maintaining system accuracy. By combining LDP-FL and CSS, we mitigate the impact of noise scale on accuracy and improve it by selectively choosing clients based on their data size during each training round of FL. We evaluated our approach using the CREMA-D dataset. The evaluation results demonstrate that LDP-FL with CSS achieved an accuracy range of 65-70%, slightly lower than the initial SER model accuracy while maintaining a privacy level of $(1.92, 10^{-5})$-LDP. Our analysis highlights the importance of achieving a balance between privacy and accuracy, which aligns with the specific requirements of SER applications.

In the future, we plan to discuss personalized privacy with an adaptive noise scale of LDP mechanisms that are tailored to each client's privacy preference.

Abstract— **Starting from software development, Agile approaches are spreading across a broad range of industries and functions, with many great challenges. Mindset, as one of the crucial human factors of individuals in Agile, influences people's decision-making and affects every aspect of behavior and action. However, many organizations and teams face big challenges in achieving an Agile Mindset of their individuals. In addition to an often-unclear understanding of the Agile Mindset, various aspects of it such as success factors and indications are largely unknown, which makes it extremely difficult to establish an Agile Mindset. Motivated by this, our study aims to conduct a literature review by answering comprehensive research questions related to the Agile Mindset regarding publication demographics, importance, definitions, characteristics, elements, critical success factors, indicators, activities for development of Agile Mindset, and future directions of research.**

Keywords—Agility, Agile Mindset, systematic literature review, SLR, project management, Scrum.

I. Introduction

While Agile approaches have their native grounding in software development, today they are spreading across a broad range of industries and functions as well as research fields [1]. At the same time, organizations are facing great challenges in transitioning to Agile [1-5] and some of the transitioning attempts fail [1, 6], simply because of the actor's mindset involved in the process [1]. It is a reminder that regardless of tools, methods, or frameworks, the adoption of Agile comes down to the people who make up the organizations [2].

People have a special position in Agile transformations, compared to technology and process. Developers develop applications and systems mostly for people, and always with people. They design and shape technology and processes and are always one of the significant factors directly affecting their organizations and the success of projects [1, 5, 7]. They may cause serious problems. Weinberg [8] briefly states their key role: "No matter how it looks at first, it's always a people problem".

Even though social aspects are at least as important as technical skills [8] and the significance of people is obvious, human factors continue to be ignored by many organizations [1, 10, 11] and it presents a serious problem to them [12]. This issue is also reflected in the literature on Agile, which focuses on engineering perspectives, practices, and processes [13, 14, 15]. On the technical side, Agile teams are more often doing Agile rather than leading to being agile [14]. Issues related to people are usually missing from Agile adoption journeys [2].

Mindset, as one of the crucial human factors, influences people's behavior [16], decision-making [17], forms their way of thinking, beliefs, and attitudes [18], and thus, shapes the way organizations act [17]. It reflects a set of beliefs, assumptions, perceptions, norms, attitudes, and notions held by people [17, 19]. Individuals transfer their (agile) mindset to organizations, processes, and tools they create [20], which makes it a key factor to consider. Considering its significance, various research disciplines, ranging from psychology to information systems, are focused on the construct of mindset and its underlining key roles and its implications [6].

The mindset aspect becomes very important for Agile approaches as well, which put people at the center. Agile Mindset settles at the core of agility [22, 23] and without a change in mindset, targets cannot be met [24]. Agility can be viewed at different levels including individuals, teams, processes, tools, strategy, or culture. However, Agile Mindset has a special position compared to any specific methodology, process, system, platform, or organizational structure [25, 26]. Durbin and Niederman [27] state, "Following agile approaches requires the spirit of agile as well as the mechanics of following its 'rules'". When considering these two parts, the way to agility should start with establishing a proper and right Agile Mindset, the spirit of agility, instead of directly applying any Agile method [14, 28], because methods and practices can only lead to a shift in a degree of agility and they alone do not guarantee being agile [9, 14, 29]. Moreover, "without the right mindset, the methods are often adapted in an incorrect way and lose their purpose" [9]. To face this successfully, agile individuals require an Agile Mindset, beyond the given set of procedures, techniques, and rituals [30].

On account of this, organizations should go far beyond "doing Agile" and seek ways to "be agile" [14]. For Agile initiatives in information systems and beyond, it is required to live the core values, and principles of agility [9, 14], which may come with an Agile Mindset of individuals [9]. However, many organizations and teams fail to build an environment, which enables Agile Mindset development of the individuals [16, 31]. Even though organizations want to enable Agile Mindset development, Agile team members face several challenges in doing so, such as a continuous paradox of 'doing Agile' (trying to 'perfect' the adoption of their chosen packaged/ customized practices coming with Agile methods) versus 'being Agile' (continuously endeavoring to enhance their work, to handle uncertainty and for improvement) [3].

Hence, it is crucial to investigate the construct of Agile Mindset that has such importance in information systems and beyond and is furthermore concerned with high application challenges. However, until today, the research regarding this topic is still in its infancy. Motivated by this need, our study aims to conduct a literature review by addressing several issues related to Agile Mindset and to find answers to comprehensive research questions. In terms of the disciplines of the included studies, it was preferred to go beyond the software development that makes use of this construct intensely and gather information from every field in order to have a generalized representation of the construct and to nurture it with more inputs from a wide area.

The remainder of this paper is organized as follows. In Section 2, we describe the overview of the research design with research questions and the paper selection process. Section 3 delivers the results of the literature review along with discussions of our findings. In Section 4, we deliver conclusions and limitations of the study.

II. RESEARCH DESIGN

This research process has been undertaken as a Systematic Literature Review (SLR) based on the guidelines proposed by Kitchenham et al. [32]. The following section describes the implementation of this SLR.

The research process starts with defining research goals and questions. After defining search queries and searching in the Scopus and Web of Science (WoS) digital libraries, we gathered 1850 potentially relevant publications. For scanning the retrieved studies, we developed and applied inclusion/exclusion criteria and obtained a final pool of 19 sources. In addition, the references in the identified 19 studies were examined (backward snowballing) and one other related study was added. Finally, 21 studies in Table IV were identified. After extracting the data from the sources, the results of the SLR were analyzed and the findings were discussed. The remainder of the section concerns the research questions, publication selection process, and data extraction and synthesis.

A. Research Questions

This study aims to review studies that focus on Agile Mindset. Thus, we set the main goals related to our research 1) identify the studies which focus totally or partly on Agile Mindset and 2) analyze and synthesize the studies' relevant results. We raise and investigate the research questions (RQs) under two main groups: (1) Publication demographic-related RQs to identify developments regarding interest and relevance in research. And (2) contribution-related RQs. In the latter we summarize relevant insights regarding the Agile Mindset. We thereby started by investigating the relevance of the Agile Mindset for different outcomes (e.g. productivity or motivation) (RQ2.1). To build a common ground, we further searched for definitions and conceptualizations of the Agile Mindset (RQ2.2). To go even deeper, we reviewed for insights, what characteristics describe the nature of the Agile Mindset (e.g. stability, latency) (RQ.2.3) and provided elements, that build the Agile Mindset as a construct (e.g. openness, collaborative exchange) (RQ2.4). The following two research questions address insights, which are necessary for organizations to build effective surroundings for Agile Mindset development. We thereby searched for critical success factors (RQ2.5) and concrete activities to achieve Agile Mindset (RQ2.6). The Agile Mindset should be reflected in special behavior, which indicate its presence. Those behavioral indicators are summarized in RQ2.7. Finally, we conclude with future directions for research (RQ2.8). Finally, the RQs were identified as:

(1) Publication demographic-related RQs (RQ1) including country of authors, publication year, publication venue, authors' affiliation type, domain of study, and paper citation data.

(2) Contribution-related RQs (RQ2):

RQ2.1 What is the importance of Agile Mindset?

RQ2.2 What are the definitions of Agile Mindset?

RQ2.3 What are the characteristics of Agile Mindset?

RQ2.4 What are the elements of Agile Mindset?

RQ2.5 What are the critical success factors for Agile Mindset?

RQ2.6 What are the activities for developing Agile Mindset?

RQ2.7 What are the indicators of Agile Mindset?

RQ2.8 What are the future directions for Agile Mindset research?

B. Publication Selection Process

The search process was a manual search of peer-reviewed studies in the well-known digital libraries, Scopus and Web of Science (WoS), without any filter in the year range to gather a full overview. Based on the scope of this study, the search string was developed by following the SLR protocol in Table I [32]. We did not add a "population" related keyword in the string referring to the application area, which could be any discipline for our study, to access the largest possible set of the data. Regarding the search place, and taking our inclusion criteria IC2 (Table II) into account, we searched in meta-data and titles instead of the full text. Finally, the search strings were finally formed as in Table I.

TABLE I. SEARCH STRINGS AND LIBRARIES

Library	**Place**	**Search strings**	**Number of Initial Results**
Scopus	TITLE-ABS-KEY	TITLE-ABS-KEY ("be* of agil*" OR "be* agil*" OR "agile mindset" OR "agile mind set" OR "agile mind-set" OR "agile mind" OR "agile mental" OR "agile mentality" OR "mental agility" OR "agility mindset" OR "agility mind set" OR "agility mind-set" OR "agility mind" OR "agility mental" OR "agility mentality") OR TITLE (("be " OR being OR becom* OR bec ame) OR (mind* OR mental*) AND agil*) AND (LIMIT-TO (DOCTYPE , "cp") OR LIM IT-TO (DOCTYPE , "ar") OR LIMI T-TO (DOCTYPE , "ch")) AND (LIMIT-TO (LANGUAGE , "English"))	1641

Selected in Dictinct From Scopus and WoS			15
Snowballing			1
Total Selected			21

Based on the scope and context of our study, for the selection of papers, the following propositions of inclusion criteria (IC) and exclusion criteria (EC) in Table II were specified and applied to the papers. Every Agile practice, value, and principle is supposed to be theoretically and practically related to Agile Mindset. Considering this, the content was excluded if it was not explicitly related to Agile Mindset in the paper. For example, although it is known that one of the main elements in the journey to being agile is the mindset, if Agile Mindset was not mentioned explicitly by the study, then the contents of the study were not included.

During the application of inclusion/exclusion criteria, the papers were examined through their titles and, where necessary, abstracts in order to identify whether they were within our scope. If the abstracts were not sufficient to decide to include or exclude the papers, then, a scanning through the full texts of the papers was done to identify relevant ones. The studies for which inclusion and exclusion decisions could not be clearly made by the first author, a separate joint evaluation step with the second and third authors was conducted to reach consensus about the decisions.

The search process was conducted in June 2023. The initial list included duplicate records. A total number of 1850 of distinct peer-reviewed studies were returned after removing the duplicate ones. Three identified studies were the extended versions of their previous ones. In this case, only the extended versions were included. All papers were accessible by the authors when their full text was needed. We applied the exclusion criterion for papers not available in English by filtering, via the libraries' relevant feature allowing the elimination of non-English studies, and we also applied it via a manual investigation. Consequently, 21 papers were identified as shown in Table IV.

C. Data Extraction and Synthesis

The first researcher ran the data extraction and synthesis process that served to answer the research questions by applying detailed and thorough examinations of the relevant studies. The second author directed and consulted on the paper and the third author coordinated the research process.

A data collection form was designed, to record the relevant information from the identified studies. The collected information ranged from general information about each study such as author, title, year, venue, author affiliation, and author country, as well as specific information to answer the research questions. The relevant content items were captured and taken “as-is” from the studies and copied to the Excel file manually. In addition to this, the parts of the studies including the relevant data were highlighted in the original papers for any future reference. Thus, it was the authors' aim to have as little bias as possible, to comment on the original data and develop their research answers gradually. Once the data extraction was complete, they were synchronized and grouped into the relevant RQs manually. Thus, an interpretation for data analysis was limited since the actual extraction of data was conducted. Even so, for cases that were open to subjective evaluation in the interpretations of the extracted data, the first and second authors jointly evaluated the data until a consensus was reached for a common understanding.

TABLE II. INCLUSION CRITERIA AND EXCLUSION CRITERIA

ID	Criterion
IC1	Papers fully or partially focus on Agile Mindset
IC2	Papers in any field including software development, business management, human resource management, etc.
IC3	Conference, workshop, journal, or book-chapter papers
IC4	Papers in english language
EC1	Papers not involving the Agile Mindset as a research construct
EC2	Papers published in non-peer-reviewed sources such as thesis, web pages, workshop proposals, tutorials, panels, proceeding information, and books.
EC3	Papers not accessible by the authors
EC4	Duplicate studies
EC5	Extended papers
EC6	Articles not in English

D. Quality assessment

The entire process relied on a search procedure that called for explicit criteria to validate the quality of the selected candidate papers by ensuring each paper was of adequate standard [32]. Accordingly, a custom quality-assessment-criteria-list and item descriptions were established as shown in Table III.

Each paper was then assessed against this given set of questions by the first author. A manual inspection was done through the full-text investigation carried out to identify each selected paper’s quality assessment score.

We set a score weight based on two values: Satisfactory (1) and Not Satisfactory (0). Accordingly, the evaluations of the papers have been made based on the two predefined values to set their scores yielding a score maximum of three. It was decided that the studies with a score below one point would be eliminated. After applying the determined quality criteria, the quality scores of each study were satisfied; No studies existed lower than the threshold score and no elimination regarding the quality assessment was done. This was most likely due to the venue of publications being well-qualified and generally well-known.

TABLE III. CRITERIA FOR QUALITY ASSESSMENT

Criteria- Statement	Descriptions

QA1- Are the contributions of methods clear?	The clarity and robustness of the method applied in the study are satisfactory
QA2- Are outcomes as results clear?	Outcomes are clearly delivered and relevant to the method applied
QA3- Is the discussion on results clear?	Discussion of the results is satisfactory and based on the results objectively. Validity threats are delivered.

III. RESULTS AND DISCUSSION

We present the results and findings of this SLR study concerning the identified RQs. Table IV lists the identified studies along with their demographic information (Regarding RQ1).

According to the results, 52% (11/21) of the studies are conference papers (C) and 48% (10/21) are journal articles (J). In terms of venues for the selected 21 papers, there are 21 different venues. The conferences are in general well-known in their respective fields. The names of the journals are Sustainability, Human Resource Development International, International Business Review, International Journal of Information Systems and Project Management, International Journal of Managing Projects in Business, Journal of Advances in Management Research, Journal of Software: Evolution and Process, Research-Technology Management, Industrial and Organizational Psychology, and Technological Forecasting and Social Change. Considering the quality of journals and conferences, it can be deduced that qualified venues and researchers are interested in this subject.

The fact that there are more conference publications than journal articles may indicate that the field is developing. Publishing conference papers is in general easier than publishing journal papers, especially in developing topics. One more reason to have such a ratio for conference papers is related to the preference to communicate the research at a conference to get feedback on first insights, rather than in journals on such a developing topic. The journal publication process can be longer than the conference publication process in general. In addition, to find a place for Agile-related papers, there may have been a tendency for conferences that can be considered more flexible in scope compared to journals. Moreover, the fact that there are some conferences dedicated to Agile topics but there is a lack of (active) dedicated journals, may be another interpretation of this tendency.

TABLE IV: IDENTIFIED STUDIES

ID	Reference Number	Country	Year	Conference (C)/Journal (J)	Industry/ Academia/ Collaborative	Discipline	Citation Count	Citation Count Per Year
P1	[5]	Slovenia	2022	J	Academia	Human Resources	2	2
P2	[26]	Germany	2022	C	Collaborative	Project Management	0	0

P20	[46]	Denmark	2019	J	Industry	Enterprise Agility	78	19.5
P21	[21]	Germany	2020	J	Academia	Human Resources	26	8.7

In terms of the authors' affiliation types, 76% (16/21) of the papers are from academia, 19% (4/21) are from industry and academia collaboration, and 5% (1/21) are from industry. There is only one paper that has one sole author from the industry. It is obvious that the Agile Mindset issues attract the attention of the academic community more, a community that is more independent on Agile matters. This fact contradicts the common belief that Agile is mainly a practice-driven domain [40] and coincides with the view that Agile is commonly regarded as an object to sell [60]. This special case regarding the Agile Mindset poses an exception may be due to the fact that selling it cannot be feasible. A more non-profit-oriented and neutral part of the community may want to normalize and liberalize the Agile movement with the Agile Mindset publications.

The disciplines of the studies include information technology with seven papers at the top, General (with no specific domain stated) with six papers, Human Resource Management and Leadership with three papers, Project Management, Management, Enterprise Agility and Teaching and Education with one paper each. This distribution shows, again, Agile is popular in the Information Technology discipline, meanwhile, it has started to spread to other management areas as well.

Among the authors, Schoop M., Ozkan N., and Mordi A. have two papers in the list while other authors contribute with one paper. Only two papers have an international collaboration among their authors, including Turkey and the UK, and Germany and New Zealand as collaborating countries. The distribution of authors' countries is Germany (6), New Zealand (2), Sweden (2), Turkey (2), India (2), Netherlands (1), Israel (1), Italy (1), USA (1), UK (1), Switzerland (1), Slovenia (1), Poland (1), and Denmark (1). The reasons that separate Germany from other countries in this regard require further research. Like other Agile-related issues, European countries and Germany's positions stand out. Our study's outputs coincide with the bibliometrics study on Agile Software Development [15]. According to the study [15], the top two countries in terms of the number of Agile publications are the United States (257) and Germany (166). Thus, this remarkable position of Germany needs further investigation.

Figure 1 shows the number of papers per year. The acceleration in the paper numbers in recent years can be seen in the figure. The first published paper in the scope of our study [P17] is more about the effective and sustained usage of Agile methods rather than Agile Mindset, although it provides inputs for our study. The first paper focusing mainly on Agile Mindset, [P14], was published in 2014, 13 years later the Agile Manifesto was announced and 20 years later Scrum emerged.

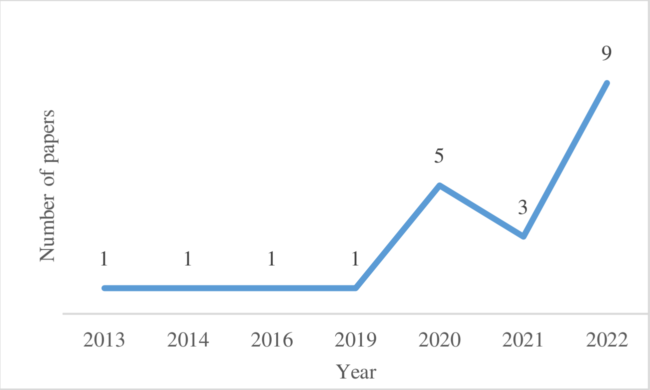

Fig. 1: Number of papers per year

With 287 total citations as shown in Table IV, the average citation count per publication is 13.6, the median of citation counts is 5, the h-index is 9, the i10-index is 7, and the i100-index is zero. There are studies that have received a high number of citations, as well as low numbers or none. The number of papers with at least one citation is 16 (76%). For the remaining 5 papers with zero citations yet, the average lifespan is almost one year (assuming all publications are published in the middle of the publication year). There is no paper published in 2021 or previous years with no citation. The studies that have never been cited seem to have a short lifespan.

Among the most influential papers include both journal and conference papers. With the highest citation count per year, [P20] and [P18] stand out. [P20] delivers the Agile transformation at LEGO Group. Eilers et al. [P18] focuses on Agile Mindset, discusses the construct and definitions of Agile Mindset and develop an instrument to measure it. Then, it investigates how Agile Mindset influences an organization's strategic agility and thus benefits its performance. This paper seems, to the authors, as one of the most comprehensive studies in the field focusing on Agile Mindset.

The remainder of this section was dedicated to RQ2 to address several dimensions including importance, definitions, characteristics, elements, critical success factors and indicators of Agile Mindset, ways to develop it, and future directions of research.

What is the importance of Agile Mindset? (RQ2.1)

The biggest issue when transitioning to an Agile organization is acquiring Agile Mindset by team members [27, 43, 44]. Many studies mention the key role of Agile Mindset and the necessity of internalizing it in order to succeed in various cases including the transition to agility [6, 14, 22, 41], effective and sustained usage of Agile approaches [34, 39], achievement of enterprise agility [6], effective teamwork [30], scaling Agile [6, 38], Agile team's productivity, responding to crises [16], onboarding for new-comers [42], helping team members in reducing negative behaviors [26], and having a proper culture, competitive advantage and project success [5, 26]. A team that does not adopt the Agile Mindset is likely to have less task responsibility, be disengaged, demotivated, and avoid challenges [16].

These studies show that Agile Mindset is important in many aspects. What is interesting is that, as far as we know, the number of papers focusing on deep understanding of Agile Mindset is highly limited.

What are the definitions of Agile Mindset? (RQ2.2)

We have found a very limited number of studies providing a definition of Agile Mindset. One study [6] states "Agile Mindset is a mindset based on the values and principles of the agile manifesto. It is underpinned by specific personal attributes on the individual level and an enabling environment on the organizational level... with the goal of achieving a state of being agile instead of merely doing agile." Another study states [30] "Agile team requires…a particular attitude, way of thinking and behavior of both the individuals and the entire team, a so-called 'Agile Mindset". Sathe and Panse [16] define Agile Mindset as "a way of thinking, that emphasizes collaboration among team members, and being adaptable to changing environments, to be a high-performing team." Study [21] produced an Agile Mindset definition derived from other studies: "the understanding of the workforce that agile behaviors are necessary for the organization to survive in a changing marketplace…a positive attitude toward learning and self-development, as well as a positive attitude toward change". Finally, [1, p.8] developed a definition of Agile Mindset: "An individual with a strongly developed AM [Agile Mindset] evaluates learning, exchanges with others, their own work organization, and value creation in terms of the customer in a highly positive way".

Regarding the main features of Agile Mindset, the most commonly used source is the Agile Manifesto [37], exemplified in the study of [6]. However, organizations should go beyond the ideas summarized in the manifesto [9], since the manifesto does not include a reference to mindset even though its values and principles contain a certain overlap with the Agile Mindset concepts [6, 34, 45]. Moreover, [34] proposes going beyond the manifesto and not solely relying on it for the Agile Mindset.

The definition by [30] resembles the general dictionary definition of a mindset: a mental and established set of attitudes, a cognitive understanding and interpretation of the environment, and a person's way of thinking and opinions [17, 47, 48]. To prove this, we just replaced the "Agile Mindset" definition with effectiveness or quality mindset. The definition still works for both (and possibly for many more). Another issue with previous Agile Mindset definitions is that people use different terms other than mindset to describe similar or identical construct, such as Agile culture [6].

Eilers et al. [1] provide in their work a sharp definition of an individual's Agile Mindset, which integrates previous definition approaches and synthesized them with new data. Consequently, in our study, we reached a similar Agile Mindset definition as compiled by [1]. While the definition of the term agility itself has no consistent, complete, precise, and agreed definition yet [49], it seems that it will take time to clarify the definitions of Agile Mindset from different perspectives and different levels. The current situation regarding the definitions of Agile Mindset implies a need for more studies on this topic and reinforces the findings of others; it remains unclear what Agile Mindset is on different levels and perspectives [1, 6, 9].

What are the Characteristics of Agile Mindset? (RQ2.3):

Agile Mindset is an abstract, vague, and latent (invisible) construct, thus, difficult to measure, even to observe, and demonstrate [P5, P6, P11, P15, P16], which makes the transformation and training of it the most difficult part [P6, P11]. Thus, it is hard to prove and show when the transformation and training of it is successful. This may cause both "sellers" and "buyers" of Agile to want to take less risk by acquiring "well-known" and "proven" products, such as Agile frameworks and tools, even though such aspects are on the "less valuable side" of the Agile Manifesto. Thus, Agile has penetrated the various sectors with relatively easy adoption of the "proven" products [50]. This abstract characteristic of Agile Mindset also brings a duality; its weakness comes with its strength [P15]. While it is vague and has a lack of prescriptive properties [P6, P15], it also presents a freedom and a "safe place" kept away from "Agile trading" for organizations.

Agile Mindset is a soft, dynamic, and intangible asset, resource, and capability and a kind of trigger that can influence various tangible assets of organizations [P11, P16, P18]. It is a prerequisite and starting point for a successful Agile transformation [P16]. It is inherently a psychological, socio-cultural, and human-related matter [P14, P15, P19]. Like other human-related assets, it presents complex interactions of social, cultural, and psychological perspectives of individuals with other people. This makes it challenging to understand, substitute, and emulate [P16]. The nature of it also creates challenges for organizations in terms of finding and developing their Agile Mindset as an individual endeavor [P8, P16].

The previous studies include a wide range of different behaviors, attitudes, and traits as elements of Agile Mindset. It seems that some of them appear to be specific forms of behavior (e.g. self-organization, self-managing, continually adapting, changing behavior, face-to-face conversations, mutual listening, not covering ups failures, continuous delivery, and so on). Such items that are more about the actual behavior can be results of Agile Mindset but are not elements of it. Agile Mindset in the mind of people is an intangible, invisible asset that influences various visible aspects [P11]. It is and should be a variation of "a way of thinking about things" [48] or "a person's way of thinking and their opinions" [47], not a way of doing in the apparent physical way.

What are the Elements of Agile Mindset? (RQ2.4):

We have found five main sources of studies identifying elements of Agile Mindset. One of these, [6] condensed 192 Agile Mindset elements into 27. Manen and van Vliet [22] identify factors that affect the expansion of Agile development in large organizations positively or negatively by using interviews. Those factors were then grouped into two categories: "Agile Mindset" and "Contextual Dependencies". Miler and Gaida [36] in their extended paper, focus on the elements of Agile Mindset and their importance to the effectiveness of Agile teams by reviewing the current literature and conducting interviews with experts, which results in 70 elements initially and 26 elements after applying their threshold criteria. Additionally, [16] mention two items covered by the current studies above; collaboration and focus on delivery. Finally, [1] identified four dimensions of Agile Mindset called a positive attitude towards learning spirit, collaborative exchange, customer co-creation, and empowered self-guidance and measured it on a scale of 20 items. Study [26] provides a list of Agile Mindset competencies for project leaders by conducting a semi-systematic literature review using a content analysis of current publications on the leadership role of project managers in Agile projects. Then, the identified competencies were rated by 40 respondents using a questionnaire.

We have found two more studies using the data from these primary studies. Ozkan and Gok [20] combine Agile Mindset elements from three primary studies [6, 22, 36], converged, categorized and examined their relationships. Secondly, [23] propose a training method to help trainers by focusing on the critical Agile Mindset elements based on the work of [6] that are grouped into ten topics.

After aligning Agile Mindset definitions, we need to identify and further extract Agile Mindset elements. "We need to know more about how these elements develop Agile Mindset and how they are connected with Agile Mindset" [1] and each other.

What are the Critical Success Factors for Agile Mindset? (RQ2.5):

The critical success factors for developing Agile Mindset are given in Table V and can be found in different levels in the environments of the individuals. According to the table, proper leadership and management mindset approaches are required to develop employees' Agile Mindset [P3, P16]. Agile talents should be supported to be proactive and resilient to cope with changing environments by having explorative activities such as creative ideas, risk-taking, and independent thinking [P3]. However, Agile Mindset should deal with both explorative and exploitative activities and attitudes of people [P3]. Agile teams are not completely free in their fields; they need monitoring and redirection from the management and strategy layers. This reminds us that agility is a matter of "how" that should serve a whole (what) and purposes, rather than being positioned or used in a way as to make room for unconscious acting. This inference is close to the expression that agility is a balancing act [51] in itself and with its environment.

Communication matters and continuous feedback systems are also crucial. Personal attitudes are the main driver for Agile Mindset, then, [P8] regards personal prerequisites of team members as a success factor and are a prerequisite for creating Agile Mindset. At the team level, Agile teams should have a common ground, understanding, norms, consensus, and team spirit as opposed to an "individualistic" mindset [P17]. Agile Mindset has a spirit supporting a continuous change in behavior, learning, and growth [P17].

TABLE V: CRITICAL SUCCESS FACTORS OF AGILE MINDSET

Critical Success Factors	Paper ID
A suitable leadership approach	P3
Building in-house agile talents by leaders	P3
Leadership behavior promoting employees' explorative activities	P3
Leaders facilitating employees to openly express their creative ideas, developing new competencies, and aiding in routine tasks	P3
A leadership approach where leaders provide clarity on employees' roles and responsibilities, communicate information timely and regularly, continuously provide feedback, set defined team goals, monitor their goal attainment, and promote entrepreneurial activities and innovative work behavior.	P3
Establishing a continued and consistent focus on value creation	P5
Personal prerequisites and attitudes of team members	P8
Having an open mind towards others and an Agile way of working	P8
Willingness to change	P8
Having a right management mindset	P16
Flexibility	P16
Becoming failure tolerant	P16
Having norms and consensus across different definitions	P17
Team spirit where team members display a strong sense of identification and commitment with the team as opposed to an "individualistic" mindset.	P17
A continuous change in behavior based on possibility thinking, learning, and growth	P17

What are the Activities for Developing Agile Mindset (RQ2.6):

Table VI shows the suggested actions from the identified studies about how to develop Agile Mindset. These items in total, partially, or in any form do not claim to be comprehensive, complete, or provide a method or framework to develop Agile Mindset, rather, list items from various sources.

According to the table, all stakeholders who want or will experience change, should know the reasons and value of change and should be involved in the transformation processes with a base of trust [P5, P7, P8, P16]. Although the change direction is recommended from the top-down by [P5], the change should be bi-directional and the two directions (from the top-down, from bottom-to-top) should be aligned. Managers should invest in training, building, and measuring their people/team/organization's Agile Mindset [P16]. Managers and Agile coaches should be role models for showing the Agile values [P8].

Organizations should take a holistic view of Agile implementations [P7] ranging from people aspects [P8] to tools [P5], from the individual level to the organizational level [P8]. As long as the trainings trigger behavioral transformation [P5, P16], they cannot go beyond being a weak start [P5]. In training, Serious Games can be used [P11] not only for teaching but also for learning for each individual. Highlighting the main features of Agile Mindset and in what way it differs from the mindset of a more traditional one is key to its internalization [P13]. A single teaching experience will not help. Teams should understand the vision and reasons behind the practices [P8]. After introducing and implementing the single Agile practice, some adjustments will be required according to need [P8]. During the transformation, combining existing elements into the current way of working can be used to facilitate a smooth and evolutionary process [P8].

Practices put aside, even Agile Mindset is not sufficient for being agile [P16]. As mentioned, the transformation of a mindset is challenging and takes considerable time. Therefore, it is crucial to be patient and give time to all entities involved in the transformation to mature [P7]. In this process, it is important to consider the context and unique nature of changing environments, let them fail, and try a new approach [P8]. The whole transformation process of the Agile Mindset should be meticulously followed by internal/external experts [P16, P19], and plans and progress should be monitored and measured [P13, P16]. Organizations should be aware of misconceptions and obstacles and remove them as soon as possible [P8].

TABLE VI: WAYS TO DEVELOP AGILE MINDSET

Ways to Develop Agile Mindset	Paper ID
The shift from top to bottom	P5
Integrate new tool use with Agile Mindset	P5
Establishing a continued and consistent focus on value creation throughout the development process consistent with Agile Mindset.	P5
Training sessions should be reinforced over time in a persistent manner until the mindset and practices become habitual	P5
Take a holistic view of Agile implementation	P7
Give time to mature	P7
Build trust	P7

Consider: (1) personal prerequisites and attitudes, (2) what the team has to provide for the collaboration with the coach, (3) problems on the team level, (4) the team's needs, and (5) what the team needs to learn.	P8
Consider the aspects related to the agile coach: (1) observing and understanding (the team), (2) activities of the coach, (3) making agile tangible, (4) perception of agile by the coach, and (5) experiences of the coach.	P8
Take care of (1) the collaboration between coach and management and (2) misconceptions and obstacles.	P8
Understand vision and reasons behind introducing an Agile way of working, get a brief theoretical training, including an explanation of why the respective practice is helpful and should be implemented, and start implementing single Agile practices, and adjust them.	P8
Integrate existing elements in the way of working to ease the transformation	P8
Observe teams to get an understanding of teams' dynamics, their current situation, and their way of working	P8
An Agile coach has to be a role model for showing Agile values	P8
Integrate teams into whole processes and listen to their ideas, concerns, and needs.	P8
Allow development teams to fail and to try something that may or may not work	P8
Serious Games can be used in training for Agile Mindset	P11
Find a basis on which to identify the main features of Agile Mindset and in what way it differs from traditional mindset	P13
Develop and plan a way of shifting Agile Mindset of a current team	P13
Measure the progress	P13
Build in advance resources that can be used at short notice	P16
Managers should invest in training, building, and measuring their organization's Agile Mindset	P16
Start by collaborating with expert institutions to train their managers to acquire an Agile Mindset	P16
Agile Mindset is not enough; organization must 'walk the talk'	P16
Place Agile Mindset Trainer roles	P19

Everything is influenced by people's mindset, even human-made artifacts such as tools, processes, and organizational structures. For instance, tools inherit a mindset from the person who produced them. Even such dummy entities should be aligned with the targeted Agile Mindset, which the organization desires for the individuals. We see such a need in the study of [P5] that proposes an integration of new tool use with an Agile Mindset and Agile resources management method which was suggested by [P16]. Agile practices should also be conduct with a proper mindset. 'Doing Agile' can be a step on the way towards fully embracing the Agile Mindset" [25, 52], but, starting blindly or only with Agile practices is not satisfactory; they alone do not guarantee being agile [9, 14, 29] and "without the right mindset, the methods are often adapted in a wrong way and lose their purpose" [9].

The findings indicate that Agile Mindset transformation, is a challenging, grueling, and long journey that requires patience and effort. It must focus on all dimensions of change, and in itself must be conducted in an agile way.

What are the Indicators of Agile Mindset? (RQ2.7):

When it comes to the indicators which reflect Agile Mindset in behaviors of people, we identified that those people collaborate with others [P4, P14] and use real-time planning [P1]. They behave with ownership, make decisions autonomously, and build connections between issues [P4]. They respond to changes [P4], focus on delivery [P4] and search for continuous improvements and new, unconventional, and better ways for organizations' management structures, methods, and systems [P14, P16], even when it is challenging [P16]. One of the fields that prove the existence of a strong Agile Mindset can be seen in flexible, quick, fluid, and successful resource management [P16]. Agile Mindset is indicated to be related to superior performance and higher innovativeness [P16]. While trustful interactions are a prerequisite and facilitating factor for the Agile Mindset, its presence is also an indicator of the Agile Mindset's existence [P14].

What are the Future Directions for Agile Mindset Researches? (RQ2.8):

Table VIII lists possible future work items extracted from the identified studies. While there are many studies investigating how the technical side of Agile can be agile, we see that reflections of them on the Agile Mindset need to be studied in the future. For instance, [P16] asserts that no study has examined how a mindset can be agile [at least until their work was conducted in the year 2022] or how it can be measured [P18].

While physical actions are observable, we need to find ways to observe and ensure that individuals are immersed in Agile Mindset [P5] and to remove the impediments which hinder achieving the Agile Mindset [P18]. Some personalities have more potential in terms of supporting Agile Mindset than others. Then, it would be interesting to combine research on Agile Mindset with research on personality, social aspects [P8], and experiences and maturity of practitioners [P19] to examine what type of organizations and people are able to utilize Agile Mindset more [P15]. Each unique individual, team, and organization should find an optimum level for their Agile Mindset by considering its tradeoffs and side effects. For instance, it can be interesting to research whether having an excessive Agile Mindset harms performance [P16], quality, or other aspects. We need to locate the responsibilities of Human Resource Management, Talent Development, other departments, and leaders in installing target-oriented initiatives and providing ways in which actors can develop their Agile Mindset [P18]. There is a need for valuable insights into Agile leaders' mindset and their effects on organizations [P18].

Agile Mindset should be integrated into a comprehensive network with other constructs [P18]. A satisfactory number of studies is missing in the literature to measure Agile Mindset [P18]. We also need more studies on how the state of having an Agile Mindset can be achieved at different levels starting from the individual level to the organizational level [P18, P19], by distinguishing differences between the perceived Agile Mindset at different organizational levels [P19].

Among the Agile Mindset elements, which of them are the most important and how and to what extent each element supports real agility and Agile Mindset can be sought [P8, P9] by categorizing them [P19]. Another research area can be what determines Agile Mindset and what organizational outcomes Agile Mindset and actors with Agile Mindset influence [P18, P19]. One of the interesting dimensions of the construct can be about time. Specifically, how the characteristic of the construct changes over time can be a matter of interest [P19].

TABLE VIII: FUTURE WORK ITEMS

Future Work Items	Paper ID
Are there ways to ensure that individuals are immersed in the Agile Mindset?	P5
Combining research on Agile mindset with research on personality and social aspects, for instance investigating what type of organizations and people are able to utilize Agile Mindset	P8, P15
What Agile elements are the most important and how and to what extent each element supports real agility and Agile Mindset?	P8, P9
Can an excessive Agile Mindset harm performance?	P16
Can Human Resource Management and Talent Development Departments install target-oriented initiatives and provide a framework in which actors can develop their Agile Mindset themselves?	P18
Investigating influences on Agile Mindset	P18
Investigating effects of managers' Agile Mindset on employees	P18
How actors with an Agile Mindset interact [with a specific subject]	P18
How managers with Agile Mindset empower their employees to develop their Agile Mindset	P18
Exploring nomological network of Agile Mindset, specific behaviors, and practices or social Agile practices	P18
How Agile Mindset improves other outcomes such as value to organizations	P18
Investigating impediments that hinder employees and teams to achieve Agile Mindset and transfer it into action	P18
Studying Agile Mindset on individual and organizational levels	P18, P19
Studying whether characteristics can be categorized and change over time	P19
Investigating whether there are differences in perception of mindset related to Agile experiences and maturity of practitioners	P19
Investigating whether there are differences between organizational levels in perceiving the Agile Mindset	P19

We point out that the Agile community and practitioners are aware that internalizing the Agile values and principles is key to being agile. However, it is remarkable that there has been very limited interest in Agile Mindset and the social aspects of agility [1], which is especially relevant for information systems as well organization studies. Even though Agile development is more about people and human factors from the onset [53], and people and human factors are an underlying foundation of agility as defined in the Agile Manifesto [54], the increased interest in Agile in the academic field is more on concrete entities such as practice, method, and frameworks. For instance, while there are plenty of cases investigating how practices can be agile, [17] asserts that no study has examined how a mindset can be agile [at least until their work was conducted in 2022] and studies are limited on how it can be measured [1]. In another instance, while our search with the keyword ("agile mindset" OR "agile mind set" OR "agile mind-set") brought 75 initial results in Scopus, the search in the same database within the same condition with the "Scrum" keyword brings 4,047 results (54 times of the former one). These, among others, indicate that Agile-related works focus on the practical, concrete, "easy-to-perceive" side of it.

On the "harder-to-implement side", Agile Mindset requires shifting to a whole new way of thinking, which manifests a challenge to unlearn old and traditional practices and to move towards new ones [55]. One of the other reasons for inhabiting the harder side to implement can be because Agile Mindset is a relatively hard-to-internalize-aspect of Agile in organizations [34, 35], and changing the mindset of employees and management seems to be more difficult than the mere implementation of Agile practices that is rather simple [9].

Gelmis et al. [34] state that because "these aspects are abstract, the transformation of a mindset is the most difficult part of the work and hard to prove and show; then, consultants do not prefer such a transformation [since the transition process can take several years and requires major resources] [35]. Rather, they prefer to transform only the concrete substances of the organizations. [50], [14], and [56] put forward that the industrialization effects driven by the Agile marketing and selling Agile™ products and "Fake Agile" to organizations have caused the overshadowing of Agile Mindset and prevented organizations to properly understand real and market-independent agility. Thus, Agile Mindset stays behind the "sold" practices because the market may want to sell "agility" for their economic interest [50]. This trading mostly ends with an illusion of "doing agile", which takes years to realize and overcome. It can also be seen with the first paper focusing mainly on Agile Mindset published in 2014, 13 years later the Agile Manifesto was announced and 20 years later Scrum emerged. We see a similar reflection of this case in agile trainings; the abstract nature of Agile Mindset leads to a limited study on explicit training for it [23]. Briefly stated, while there is an intense focus on the methods, the number of studies on the mindset part is very low [6, 20, 23], due to some reasons such as economic interests [57] and the abstract nature of it [23]. Consequently, many organizations fail to enable an Agile Mindset of the individuals [31].

However, an increasing number of researchers have started to focus on the internal aspects and human side of agility [1]. It seems that Agile Mindset aspects will be on the agenda of the organizations now and in the future [34]. This increasing interest of researchers in recent years can also be seen in our study results.

Even more, [34] foresees that the focus on the people side and having a proper Agile Mindset will be more important and the predefined practices will have relatively less place in the future. Similarly, [58] argues that after a while, Agile practices will be largely equalized for organizations, and organizations that make a difference will come to the fore with the people dimension. While the majority of organizations today prefer to focus on Agile frameworks, in the future, there can be some new frameworks tailored to each organization depending on organizational cultures and needs [34], which requires the intellectual capabilities of people's minds to make practices evolve more organically.

It is seen in our work that most of the excluded studies are satisfied by only mentioning the term Agile Mindset as a "fixed concept" without actual descriptions, details, explanations, or definitions. This case has also been witnessed by the study of [6] and [20]. Most of these publications investigate Agile Mindset either as a precondition or a relation to organizational culture [9]. When mentioned by some studies, Agile Mindset has been confined to being understood as only one category amongst many [59] or only a prerequisite for implementing Agile.

Regarding the RQ2, there are very limited resources especially involving definitions of Agile Mindset, its elements, methods to develop it, indicators, and the measurement of it. Inappropriate definitions lead to a variety of invalid measures [1]. Because of the missing consensus in existing Agile Mindset conceptualizations, an aligned comprehensive understanding of it must be conducted and conceptualizations from different perspectives and levels [1, 9]. Measuring instruments for this different conceptualization and progress on different levels are missing [1].

How can we decide the optimum level needed for Agile Mindset? What other capabilities should Agile Mindset be supported with? How can those who have a low Agile Mindset and those who have a high Agile Mindset work together? Or, do we need to have a common mindset understanding as stated by [35]? What are the effects of the tenets of Agile Mindset on agility? What are the relationships between a person's personality and Agile Mindset, which is currently absent from the academic literature?

With these and many more unanswered questions, it seems that there is a long way to go on this topic and that further studies should involve behavioral research, cognitive science, learning (rather than teaching), and other disciplines, to accelerate this relatively new concept.

IV. CONCLUSIONS AND LIMITATIONS

Although the importance of Agile Mindset is known by many studies and people, the construct interestingly seems to be underrated in the literature. Most of the studies involving the Agile Mindset term as a fixed term. For this reason, it seems necessary to further unbox the construct. To do so, it seems necessary to create projects to reflect the situation regarding Agile Mindset in practice. Although Agile Mindset is a new construct to study, it is recommended in the first stage to consider the studies that deal with the construct of mindset in general terms and to benefit from studies from multiple related disciplines.

Our study aims to deal with the important Agile Mindset construct comprehensively, using sources from many disciplines while doing this. We aim to open a door to this construct, which is worth researching in terms of practice and theory. In the future, we will study on the development and measurement of the Agile Mindset for individuals in organizations.

The procedures used in our study have limitations in several ways. Limitations of search terms and search engines can lead to an incomplete set of primary sources. It is possible that we may have missed some relevant studies as we did not include all possible libraries. In particular, we have missed the studies published in non-peer-reviewed resources. To minimize risks that may result from search engines process, we included two comprehensive academic databases and used a comprehensive search string developed through several iterative improvement processes. We recorded each paper that we found with its source in an Excel sheet. Therefore, we believe that an adequate and inclusive basis was established for this study.

Defining search terms in the source selection approach resulted in obtaining only the sources written in English and the peer-reviewed ones. However, the main issue regards whether the selected works represent all types of literature in the area of study. We ensure that the relevant studies collected in the study pool contained sufficient information to represent the entire related literature.

A single researcher extracted the data from the included studies. Also, the values of the quality assessment criteria are subjective but based on field experience. Moreover, the primary studies' results are context dependent and have thereby limited generalizability. However, when these processes were unclear a consensus session was applied with the second author. Additionally, the relevant data was taken as an actual extraction of terms from the identified studies and copied to the Excel file. To ensure the reliability of our study, the entire pool of the sources was analyzed carefully and the data were reviewed, extracted, and synthesized in iterations according to the research protocol and guideline applied.

***Abstract*—Translation from the national language into sign language is an extremely important area of research and practice, which aims to ensure communication between deaf or hard of hearing people and the hearing community. The article provides an overview of the most important research on sign language interpretation conducted in various research areas. The latest scientific and theoretical achievements were presented, which contribute to a better understanding of the subject of sign language translation and the improvement of the quality of translation services. Our main goal is to identify outstanding areas of interdisciplinary research related to sign language translation and to identify links between these studies conducted in different areas. The conclusions of the article aim to broaden the knowledge and awareness of sign language translation and to identify areas that require further research and development. The work is linked to a project related to the application of machine learning in increasing accessibility for deaf people.**

I. Introduction

SIGN language is an integral part of the lives of deaf people, enabling them to communicate, express their emotions and participate in society. Sign language interpreters are essential to ensure a balanced access to information and services for people with hearing impairments. Sign language interpreters play a key role in the transfer of information between deaf and hearing people, enabling full participation in various areas of social and professional life [1].

Sign language is a natural language that, like any other natural language, has its own grammar, vocabulary, and sentence structure [2]. There are many different sign languages in the world, each with its own unique characteristics. Therefore, translating from a national language into a sign language requires not only knowledge of the sign language, but also an understanding of the culture and social context of the people who use it. For this reason, the process of translating from the national language into a sign language is complicated and requires the interpreter not only to know both languages, but also to be able to interpret and translate the meaning. Sign language interpreters must consider not only the literal meaning of words, but also their connotations and cultural context. It is also important to skilfully use gestures, facial expressions and body movements to convey the speaker's emotions and intentions [3].

Increasing equal opportunities and participation of deaf people in society is important, therefore the need to develop solutions aimed at reducing the social exclusion of deaf people is the result of growing social awareness and legal obligations regarding equal access to services and information for all citizens. For this reason, research and development of solutions for automatic translation of natural language into sign language are of great importance to deaf people. Creating new solutions that automatically convert spoken language into sign language has great potential in removing communication barriers and enabling full participation of deaf people in various areas of social and professional life.

Research into automatic translation of natural language into sign language requires the use of advanced technologies such as artificial intelligence, machine learning and natural language processing. As a result, the development of such solutions contributes to technological progress and is also used in other fields, such as machine translation or speech recognition. The most important thing is that scientific research and creating solutions for automatic translation of natural language into sign language have a direct impact on improving the quality of life of deaf people. Eliminating communication barriers and enabling full participation in society contributes to greater equality and social inclusion for this community.

The aim of this article is to present an overview of research on sign language translation and to identify links between research conducted in various areas related to this field. Through our work, we aim to provide readers with a comprehensive view of contemporary research related to sign language interpretation, addressing a variety of aspects, such as translation efficiency, quality of interpreting services, technological support, and social and cultural contexts. Our work focuses on identifying common points and interconnections between research conducted in various areas that, having an interdisciplinary nature, relate to sign language translation. By analyzing these relationships, the article aims to develop understanding of the sign language translation process and on the potential benefits and challenges of an interdisciplinary approach to research in this field.

Our key goal is to implement the project of developing a virtual human figure presenting the content of public ad-

Topical area: Information Technology for Business and Society

ministration in Polish Sign Language. The project broadly aims to increase accessibility for deaf people – particularly those who use Polish Sign Language but do not understand Polish. It is a comprehensive solution in which it is necessary to prepare both a module for language translation and a corresponding avatar that is used to sign translated texts. To achieve this goal, it is necessary to familiarize yourself with the research and scientific and theoretical achievements in the field of sign language translation and their implications for translation practice. Although many of the analyzed studies are interdisciplinary in nature, one can distinguish the pursuit of scientists in specific directions. For this reason, we want to present our review of the work in the proposed research areas and encourage researchers to further research and development in the field of sign language interpretation. By identifying areas for further research and challenges, the article aims to stimulate conversations and innovations that will contribute to the continuous improvement of sign language services and the full participation of people with hearing impairments in society.

This article is organized as follows. The section I provides an introduction to the subject of this article. Section II provides an overview of related work on sign language interpretation methods. Section III describes a solution model that uses machine learning to automatically translate texts into Polish Sign Language. In the section IV, we present our proposed analysis of the literature review, where we indicate key research areas. In the sections VI, V and VII we present research into sign language translation broken down into the indicated areas. In the section IX, we present the results of identified links between research conducted in various areas. Finally, in the section X we conclude with general remarks about this work and indicate some directions for future research.

II. Related works

Traditional methods of obtaining information allow deaf people to become familiar with a very small percentage of digital information. In the context of the huge amount of material to be translated, it seems necessary to use semi-automatic and automatic tools to make at least some of it available in sign language on an ongoing basis [4]. Three basic barriers to automatic sign language translation have been distinguished, i.e. differences in modality, lack of a standard written form and a shortage of resources in the form of tools and technologies for translation as well as a limited number of sign language corpora [5]. In addition, the scope of sign language synthesis was defined by a detailed discussion of sign language dictionaries and repositories [6], [7]. A thorough review of the synthesis of sign language from the perspective of animation was also carried out, paying attention to the difference between the synthesis of single signs and the generation of full statements [7].

In some countries, public administrations are required to provide sign language interpretation for deaf people to enable them to fully enjoy public services. Translations are required to be available in places such as government offices, hospitals, schools and courts [8]. Public organizations must meet guidelines on the qualification and professionalism of sign language interpreters to ensure effective and accurate interpretation. The authors [9] focused on the criteria that public entities placed in virtual reality would have to meet, and pointed out that the appearance of avatars representing officials should be adequate to the situation of a fairly official nature. In [10], a framework of public values was developed that virtual advisors in offices should follow.

Many works indicate the interdisciplinary nature of the subject of sign language avatars and the great importance of non-manual signs, facial expressions and facial expressions, which is a great challenge for researchers dealing with the subject of sign language synthesis [11], [12]. The author [13] points to three interrelated threads, i.e. a linguistic approach to facial expressions that an avatar must have in order to convey a comprehensible message, computer graphics providing tools and technologies that are required to create avatars, and the third thread deals with the subject of sign language representation systems from the point of view of their ability to represent non-manual signs and facial expressions. The topic of non-manual signs, facial expressions and generating synthetic emotions was also addressed in works [3], [14]–[16]. Moreover, in [17], [18], a study of social trust in chat bots conducted was described. The study was based on theories of operators' trust in machines in industrial environments, showing that acceptance and trust can be related to the field in which the technology was introduced.

III. Project $Avatar2PJM$

The research is part of the $Avatar2PJM$ project (Project: Framework of an automatic translator into the Polish Sign Language using the avatar mechanism, The National Centre for Research and Development, GOSPOSTRATEG-IV/0002/2020). This project aims to develop a solution for translating speech from Polish into Polish Sign Language using avatar and artificial intelligence methods. The innovation of this solution lies in the inclusion of emotions and non-verbal elements in the visualisation of gestures.

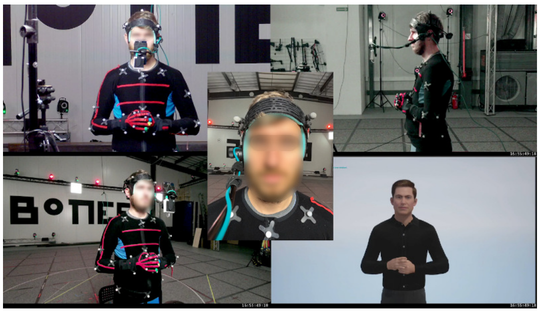

Fig. 1. MoCap recordings as part of the $Avatar2PJM$ project.

One of the key objectives of the project is to develop a method of translating Polish into Polish Sign Language using the avatar application control mechanism. A sign language avatar is a computer representation (animation) of linguistic phenomena. With appropriate reference material recorded in video form, it is possible to animate any described speech. To this end, Motion Capture (MoCap) sessions were conducted, which is a technique for capturing the actor's three-dimensional movements (see Fig. 1). Used in computer games, the MoCap technique imitates the natural movements of objects or people in a very realistic way to achieve a natural effect. In the case of sign language avatars, MoCap makes it possible to copy sign language signs and increase the understanding of the communicated content, since, from the animator's perspective, spoken sign language signs consist of geometric positions and movements.

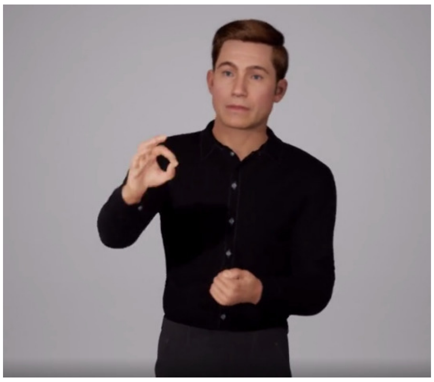

Fig. 2. Actual avatar prepared for testing the $Avatar2PJM$ project.

A sign language message consists of both sign language signs and various additional information, as what is physically expressed is the result of co-existing linguistic and extra-linguistic processes. In the process of creating computer-generated animations, the emotional context of the utterance is taken into account, as well as phenomena such as correct mouth movements or voiceless speech that occur during sign language communication. In particular, the sign language interpreter's facial expressions and the information they convey are important. Such elements are also important in the context of the data needed to develop the interpreting module. The material acquired during the MoCap session is used to feed the animation module and provide an input data set for the translation module based on machine learning methods. For this to be possible, it is necessary to subject the collection of recordings to an annotation process. The annotation process involves describing individual sign language sign elements at specific intervals. This includes sign units, lexical interpretations (lemmas, lexemes), as well as information concerning the non-manual elements of the sign. Since one of the key elements of annotation is the sign language interpreter's face, and this process is time-consuming, an attempt was made to explore the possibility of automatically recognising the interpreter's facial expressions. Automatic annotation would significantly improve and speed up the annotator's work. The article describes partial results of the research carried out in this field.

One of the expected outcomes of the project is pilot testing of selected online information services run by public administrations (the avatar used in the tests is presented in the Fig. 2). The widespread use of automatic translation mechanisms in public online systems is a constructive step towards improving the accessibility of digital public administration. In addition, the project team is investigating the professional potential of deaf people and their satisfaction with contact with public administration before and after the implementation of the virtual interpreter. This will identify the social and economic barriers that deaf people face in their contacts with the administration and in the labour market. The vocational potential of deaf people will also be explored, as well as methods of capturing data to maximise the effects of vocational activation. The results of the project will contribute to the sustainable elimination of barriers faced by users of Polish Sign Language.

IV. Proposed approach

When analyzing the current state of knowledge on the subject of sign language interpretation, one should pay attention to the interdisciplinarity of the subject of research, which combines various areas of knowledge in order to better understand this natural language of communication for the deaf. The interdisciplinarity of this research allows for a holistic approach to the issue of sign language translation. It requires collaboration between scientists and specialists in various fields to improve the translation process and develop new tools and strategies.

In order to provide a comprehensive view of contemporary research on sign language, we decided to analyze many scientific papers related to sign language translation, group them according to the nature of research, and then identify links between research conducted in different areas. To this end, we can identify three research areas related to sign language:

- the technological area where research focuses on developing and improving technological solutions related to sign language interpretation;
- the character animation area, where the proposed approaches relate to character animation for conveying information in sign language;
- the area of application, which presents solutions related to the use of automation in the field of providing information in sign language.

In the technological area, we want to classify works related to e.g. with translation into sign language, also in terms of the transition from the national language to the national sign language. In these works, researchers focus on developing innovative technological solutions for sign language translation. In this respect, classic methods can be distinguished, which include converting speech from the national language into sign language, often using motion capture techniques to generate animations. However, the development of artificial intelligence is also playing an increasingly important role, enabling the automatic translation of speech into sign language. In the technological area, research is focused on improving these methods and developing new tools and strategies that will improve the sign language translation process.

The character animation area focuses on ways to animate characters that convey information through sign language. Here too, motion capture techniques are often used to generate character animations that reflect flicker. It is also possible to create animations based on pre-recorded sequences performed by a lector. The aim of research in this area is to improve character animation techniques and search for new solutions that will allow even better transfer of information in sign language.

On the other hand, in the area of applications, research focuses on the use of automation in the transmission of information in sign language. Automation can be used in various contexts, for example in translation systems or online communication. The aim of the research is to improve these solutions so as to enable easier and more effective communication for deaf people using sign language.

In addition, there are many works related to with the analysis of accessibility [19], chaterbots [20], translations of sign languages [21] (e.g. from English (BSL) or American (ALS) to another sign language), or the development of applications related in some way to the implemented project [22]. Such a group in our research was named as other works and requires further analysis.

V. The technological area

The technological area is usually concerned with the translation of spoken language into sign language as input using text, sound or image. There are also studies on reverse translation, for example the solution described in [23], the system is able to recognize sign language poses and translate through avatars in the form of talking faces [24]. Many works also focus on the development of two-way communication by creating solutions that translate spoken languages into sign languages, and are able to recognize sign languages, as for example in works [8], [25], [26].

A. Recognition and translation of sign language into spoken languages

In the field of recognizing and translating sign language into spoken languages, we can distinguish the work [23] in which the authors proposed a solution for translating films with signers through a speaking avatar. This solution is able to generate videos with "talking faces" translating poses from sign language.

Another example is an AI-based novel approach to capturing and representing sign language [27]. A solution to the problem of unavailability of annotated sign language datasets is presented in the form of a crowdsourcing platform [28]. The authors [29] present an innovative approach to automatic sign language synthesis based on advances in the field of machine translation. A system has been proposed that is able to generate sign language videos from spoken language videos. Creating sequences of human poses is based on a combination of neural network-based machine translation (NMT) with motion graphs (MG). Kolejnym rozwiązaniem jest system rozpoznawania ruchu działający w czasie rzeczywistym z wykorzystaniem sygnału elektromiografii zaprezentowany w pracy [70]. Wyniki badań pokazały, że system może z dużą dokładnością rozpoznawać 20 znaczących i szeroko stosowanych ruchów ASL. Another solution is a real-time motion recognition system using the electromyography signal presented in [30]. Test results showed that the system could recognize 20 significant and widely used ASL movements with high accuracy.

B. Two-way communication

Recognition and translation of sign language into spoken languages and vice versa, i.e. two-way communication, is another important area of research related to sign language translation. Two-way communication is essential to ensure smooth interaction between deaf people using sign language and hearing people using spoken language.

The task of the European project [8] is to develop technology for automatic translation of sign languages into spoken languages and vice versa. The solution will be provided in the form of a mobile application for translation and communication. It focuses on several languages, i.e. English, Irish, Dutch and Spanish. In addition, the EXTOL project [25] was developed, which aims to develop the world's first system for translating British Sign Language into English and a functional machine translation system for any sign language. On the other hand, in [31] an automatic system for registering deaf patients was proposed, including a workstation with a computer, an RGB camera and a depth sensor (Kinect). Work related to sign language also applies to translations into Chinese. The proposed solution [26] is a framework-based framework for recognizing and generating Chinese Sign Language based on a recursive neural network. The algorithm has high accuracy in recognizing real and synthetic data, with reduced execution time.

C. Translation of spoken languages into sign languages

An important process among the aforementioned translations is the translation of spoken languages such as text, voice or film into sign languages. This is an important area of research and technological development that aims to facilitate communication between hearing people and deaf people who use sign language. This area includes paper [32] in which an Arabic sign language dictionary was developed using the HamNoSys notation and eSIGN editing software. Also presented is the SIGML sign language, where characters are presented using a 3D avatar, 3000 characters. The Mexican Sign Language avatar presented by the authors [33] was created based on a combination of natural language processing (NLP) techniques with the use of programming engines (Unity) to create animation. Using the structured language model of AZee, Paul's Avatar [34] was created, which is a hybrid system animated mainly with hand-made keyframes, and Kazoo's virtual avatar [35], which generates content from French to sign language.

On the basis of the results available in related literature, an analysis and evaluation of the Portuguese Sign Language (LIBRAS) translation system developed as part of the project was carried out in the context of generating signs and sentences considered ungrammatical by the Deaf community [36]. ProDeaf was developed as computer software for Portuguese Sign Language [4]. Translation takes place both from voice and from text to sign language. However, the proposed application is focused on one-way communication and is not able to translate sign language into text or sound.

On the other hand, for Hindi, a system was proposed that translates English text into Indian Sign Language (ISL) via a 3D avatar [37]. The basic component is an ISL parser that allows parsing sentences based on ISL grammar rules. The system does not use previously saved photos and videos, it displays representations of sentences and words in real time. The Indian Sign Language Dictionary [38], which is bilingual for both English and Hindi, uses the Hamburg notation system and markup language SIGML and the Web Graphics Library (WebGL) to animate 3D avatars. The presented dictionary has 2000 English words and 3286 Hindi words with 110 example sentences.

VI. The character animation area

Major sign language research focuses on the recognition and production of sign languages, as well as the improvement of sign language systems and tools. Research is focused on the development of advanced systems and tools that enable the generation of sign language animations [34], [39]. In this context, researchers are developing software that allows the creation of fluid gestures, facial expressions and body movements characteristic of sign language. For more authentic sign language animations, research is focused on developing motion capture techniques. Researchers are developing techniques that enable realistic facial expressions and emotional expression in sign language animation [40]. Improving the quality of animation and adding facial expressions contributes to better communication and understanding of the information conveyed [41].

A. Systems and tools in sign language animation

One of the proposed tools is Kazoo's virtual avatar [35], which generates content from French to sign language. This project offers the possibility of automatically animating a virtual avatar and content synthesis based on an abstract representation of the author's language model AZee. Paul's English Sign Language avatar was created using the AZee structured language model [34]. Developed at DePaul University by a team of scientists who are working on the avatar. The main goal is to create an avatar that would translate English to ASL in real time.

An interesting solution is a system that allows adding sign language translations in the form of a 3D avatar to digital mathematical educational materials [39]. Operation and construction of ASL System, which consists of 3 basic components: supporting the 3D model, supporting animations, supporting rendering. The SignGAN system [40] on the other hand, is a model for sign language production, a neural network-based translator between text and a synthesized skeletal pose, creating photorealistic sign language videos directly from spoken language. The proposed solution reduces the problems associated with motion blur.

B. Motion Capture Techniques for Sign Language Animation

Advanced motion capture, image processing, and virtualization techniques are often used to create a 3D avatar. An example is the avatar, which acts as a teacher of quite specific concepts in the field of electrical engineering in sign language [42] and the aforementioned Kazoo avatar [35] or Paul's avatar [34].

The key barriers to sign language generation, in particular differences in modality, lack of a standard written form and insufficient resources, are presented in paper [5]. The state of the art and challenges in presenting non-manual signs in avatar animation were also presented from the point of view of three areas, i.e. linguistic approach to facial expressions; Computer Graphics; sign language representation systems [13]. Solving the problem [27] of unavailability of annotated sign language datasets in the form of a crowdsourcing platform has been presented as a novel approach to capturing and representing sign language.

C. Efforts to improve the quality and realism as well as facial expression in sign language animation

Actions to improve the quality and realism of sign language animation are very important in order to better understand the information conveyed. For this reason, a new method [43] based on machine learning was proposed to automatically calculate three key values: selecting the location for inserting pauses, setting the differential speed of individual words, and setting the duration of pauses. In addition, in the years 2006 - 2014, models were worked on that combine language phenomena with specific facial movements in order to generate animations, and an infrastructure for animation synthesis using MPEG-4 facial animation parameters was developed [15].

On the basis of a review of existing lighting models and current progress and research efforts in the field of facial expression and facial expressions, an innovative technique was proposed [11] modifying the classic computer graphics techniques, which, according to the author, is the most efficient combination to present the smallest details. In addition to the automatic generation of complex facial expressions in 3D avatars, a new parametric model of facial expression synthesis using 3D avatars has been proposed [14].

VII. The area of application

The use of translation from the national language into sign language is especially important in situations where communication is necessary to understand and express thoughts, such as business meetings, school activities or conversations with a doctor. Thanks to appropriate translation, deaf people can actively participate in discussions, make decisions and express their views. The development of technologies, such as mobile applications or interactive screens, opens up new possibilities in the field of translation from the national language into the sign language. These innovations facilitate a faster and more precise translation process, thus enabling more effective communication between deaf and hearing people [44].

An important area of application for sign language avatars seems to be all issues related to meeting basic needs and ensuring proper functioning in various spheres of public and social life. Avatars should be used wherever access to information is crucial and it is not possible to employ a professional sign language interpreter. In particular, applications in the field of education, medicine and security and transport can be distinguished here.

A. Education Application

Automatic translation of natural language into sign language has the potential to improve the quality of education for deaf people. Access to translation tools enabling understanding of the content taught at school is invaluable for the intellectual and educational development of this group of people. The Mexican Sign Language Avatar, as a mobile application via a cloud server using NLP and automatic translation, will present limited content from a 4th grade primary Mexican history textbook in sign language [33].

In order to teach mathematics, an e-learning system was developed that was developed for Arab deaf sign language students using an Arabic Sign Language avatar [45], as well as a system for adding sign language translations in the form of a 3D avatar to digital math education materials [39]. A system facilitating independent learning of English Sign Language [46] has also been developed, in which the user has a graphical interface at his/her disposal. This system is based on a neural network that classifies signs flashed in the hand alphabet, recorded with a webcam.

Many efforts have been made in the field of education, e.g. in [47] a Turkish project was described, which presented the benefits of using 3D Avatar in the process of educating deaf children. For the experiment, an avatar was created and a test was performed using it to compare the educational effectiveness of the avatar with text-based learning tools. The results indicated that avatar-based tutoring was more effective in assessing a child's knowledge of certain words in sign language. In the field of education, dictionaries in English [34], Irish [48], Arabic [32] and Indian [37], [38] as well as Portuguese [42] dictionaries may also be considered.

B. Medical Application

The period of the pandemic significantly verified the accessibility of deaf people to medical care. Dutch researchers in [49], [50] studied the potential of automatic translation of text into sign language. Based on consultations with medical professionals, they built a corpus of the most frequently used expressions when diagnosing COVID. SIGML representation and JASignin avatar were used. Attention was drawn to the advantage of avatar over video translation in terms of flexibility and scaling. A definitely lower level of realism and difficulty of understanding was considered a disadvantage.

In a situation where physical well-being is at stake, patients are likely to feel more comfortable watching a human film than an animated avatar [51]. It was also found that users have greater acceptance of virtual advisors operating in general areas, e.g. answering questions in the field of waste management. However, in the case of more personal topics, e.g. parental support, they feel anxiety and distrust when the advisor is not a human but a virtual assistan [52], [53].

C. Security and transportation applications

In the area of ensuring safety, one of the examples of application can be the paper [54], which dealt with the subject of messages about disasters. The authors focus on voice notations that are widely used to transcribe video sequences in sign language. In the first steps, the authors created a corpus for disaster messages in Indian language to be presented by an avatar. In terms of character animation, two methods of Motion Capture and Video Tracing were investigated, for reasons of cost, it was decided to use Video Tracing, which creates 2D avatars. An avatar was created based on the video, the process of animating a 3D avatar based on a 2D video required a lot of effort and a lot of manual tweaking. The final generated corpus contained about 4,000 words on the subject of disasters and about 600 sentences. Several solutions have been identified to ensure smooth avatar movements during translation. However, collecting data on emotional expression and facial expressions remained a challenge during the work. Another example is the avatar of a machine translation system under development, built to translate Swiss Federal Railways' messages in real time [55]. The JASigning software was used to generate the avatar animations.

D. Public administration

Public administration is increasingly showing interest in AI technologies and their implementation. There are numerous publications showing all the research towards the acceptance of modern technologies and the way they are implemented, among others in offices [56], [57]. All actions taken in this direction and their results can be partly related to the implementation of sign language avatar technology. Sign language avatars should primarily be focused on ensuring accessibility to services, but they must also meet all other criteria and be appropriately adapted to the specific area of public administration [58].

For this purpose, a study of trust in virtual advisors in public administration was conducted [17] and the possibilities of using artificial intelligence techniques in public administration were discussed [59]. The methods of using modern technologies in employee training in the context of occupational health and safety were shown [60], and the advantages and potential threats in the use of virtual advisors in public administration were presented [61]. In the research on the introduction of virtual reality to public administration, the criteria that must be met were set, where an example is the appearance of avatars in offices [62], which should have a fairly official character [9], and a framework for public values was developed, which should include chat bots in public administration with examples of achievement [10]. In addition, research was conducted on the impact of implementing modern technologies in public administration in the context of changes in the relationship between employees and their tools, as well as changes in the ways of organizing work in the public sector [63].

The practical use of avatars was also reflected in the example of using avatars in libraries. Paper [64] presents the opportunities and possibilities of using spoken language in the avatar library. For the purpose of simulating crisis situations, the multi-agent multi-user architecture was used, which allows the use of virtual cities as environments for simulations with participants in the form of avatars [65].

E. General use

Works that are not strictly related to the application of research in one area can be indicated here as general application. The proposed solutions are often universal, and small transformations or refinements of parameters to a specific problem indicate their general applications. In the case of general applications, practical projects are most often created, such as applications, systems or other tools, but we also present here theoretical analyzes in the form of literature and systems reviews. An example of general applications may be a web application for generating sign language using the Kazoo virtual avatar [35]. This project is in progress, and the current version offers the ability to automatically animate a virtual avatar and synthesize content based on an abstract representation of the proprietary AZee language model. The same applies to the PE2LGP Animator tool [66], which was created as part of a wider project on the translation of Portuguese Sign Language. The tool allows users with no technical knowledge or animation experience to create LGP character animations for avatars using simple frame-by-frame poses [67].

Another project is a novel machine translation model [68] that translates English sentences into the Pakistani Sign Language equivalent. The system consists of an NLP pipeline and an external video rendering service for translated words based on avatars. In the aforementioned European Project [8], the task was to develop a technology for automatic translation of sign languages into spoken languages and vice versa. The solution will be provided in the form of a mobile application for translation and communication. It focuses on English Irish, Dutch, Spanish language. The Austrian project SIMAX [69] is being implemented as a semi-automatic system for interpreting into sign language. It is one of the most comprehensive systems and consists of several highly advanced ICT technologies. However, The benefits of using synthetic characters from the HamNoSys/SiGML notation instead of working with advanced and expensive motion capture technology were presented on the example of the eSIGN project [70]. It was a development of the ViSiCAST system, which was created as a new project.

VIII. The other works

In some of the analyzed works, it was not possible to indicate one main area of research, therefore we defined a group of other works. Our goal is to show that although much research is focused on one area, sign language research is interdisciplinary. Therefore, in this section we analyze papers providing an overview of solutions to various problems in the field of sign language interpretation.

The authors [36] developed a translation system for Portuguese Sign Language (LIBRAS) and presented research in the context of generating signs and sentences considered ungrammatical by the Deaf community [71]. However, in [67], various methods for finding the meaning of an unknown word in American Sign Language (ASL) were investigated. An overview of currently existing translation systems with their advantages and disadvantages as well as the approach they use is discussed in [4]. A new approach to the construction of sign languages has also been proposed, which significantly increases accuracy in translation. A systematic review of the literature [6] on the synthesis of sign language was carried out, in which dictionaries and repositories of sign languages were discussed in detail, emphasizing the importance of sign notation; translation systems and application areas [72]. Similarly, the authors of the paper [7] reviewed the synthesis of sign language from the perspective of animation, noting the difference between the synthesis of single signs and the generation of complete statements.

A review of existing sign language avatars in the context of details and facial expressions is presented in [11], [41]. An overview of modern techniques for generating facial expressions from the last 15 years was developed, based on 5 examples of avatar use in projects: HamNoSys-based, VComD, DePaul, SignCom, ClustLexical [16]. However, the authors [44] conducted research on the intelligibility of sign language avatars, in terms of methodology, it was proposed to combine a focus group with online research. In addition to determining the key aspects that the deaf community pays attention to in the avatar, it has been shown that the very conduct of research among the deaf community affects their positive perception of avatars [62]. The authors [73] developed a technique for automatically adding realism to animation without the need to manually animate details, and also identified issues related to avatar optimization that can reduce real-time rendering costs. It was also examined to what extent synthetically generated animations are understandable by the deaf community both in the form of skeletal visualizations and generated films [74]. The results show that the deaf community prefers synthetically realistic generated animations to skeletal visualization, it was pointed out that automatic methods of synthesis are not effective enough, the respondents had difficulties in recognizing some signs [75], [76].

Research [3], [12] focused on Irish Sign Language, where the impact of avatar facial expressions on better understanding and acceptance by the deaf community was analyzed and assessed. The reception of avatars' utterances with facial expressions enriched with 7 commonly accepted emotions was compared with the avatars' basic utterances. The results showed that the differences in understanding the content are small. In [27], however, the problem of unavailability of annotated sign language datasets in the form of a crowdsourcing platform was solved.

New challenges for sign language processing have also emerged, based on a discussion of the interdisciplinary nature and multidimensional approach based on Italian Sign Language [77], [78]. An overview of the most modern methods of interception, recognition, translation and representation in sign language, with an indication of their advantages and limitations, was made in [79]. In contrast, the authors [80] analyzed recent advances in the fields of deep learning recognition and production of sign language. The advantages, limitations and future directions for research are discussed, and key barriers to sign language generation such as differences in modality, lack of a standard written form, insufficient resources are presented [5].

IX. Results of literature review analysis

As part of the review of the literature on research on sign language, nearly several hundred scientific papers were reviewed. However, several dozen most closely related to the scope of work were selected for this study. A significant part of the works has been presented in the sections VI, V and VII, where they have been grouped according to the areas (character animation area, technological area and applications), with the exception that some works concern several areas. Such a situation is additionally presented in the figure 3 (together with other works), where all articles are in appropriate groups – it is possible to notice the permeability of works between the analyzed scopes of works.

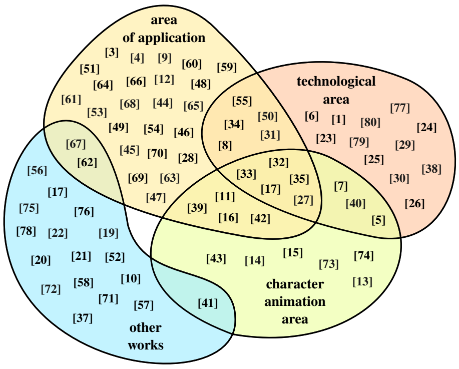

Fig. 3. Relationships between publications from different areas, based on the analyzed literature.

Over the dozens of analyzed works, it can be clearly seen that many of them concern only one area, but there are frequent connections between the application and technology or character animation. This means that there is a need to carry out scientific research combining the indicated areas.

Figure 4 presents boxplots for the number of publications by year and by area. It shows the current research related to the analyzed topic. As can be seen, the first articles were published in the years 2005 – 2008, since then the number of publications on sign language animation has increased significantly. The first quantile in the area related to animation and application is 2015, which is also a period of growth in publications in which there is a combination of sign language with technological possibilities. The median for most of the analyzed publications is 2019-2020. This shows that the analyzed subject matter is currently a very popular issue of research, application and development.

The observations resulting from the analysis of the drawing 3 also allow to justify the division adopted in this review of the current state of knowledge. It is important to thoroughly research both character animation and sign language applications, including - above all - from a technological point of view. The presentation of the multitude of works that have been analyzed requires an appropriate methodological approach. Hence the appropriate, original grouping of all works. On the other hand, the presentation of statistics related to publication dates (see fig. 4) is related to emphasizing the needs related to the discussed topic and its topicality. The needs are already visible on the example of similar works, which are related to e.g. with the analysis of accessibility for people with special needs and appear already in 2005. On the other hand, the topicality is indicated by a clear shift of the median and the third quantile to around 2020-2021 - primarily in the area of technology and character animation.

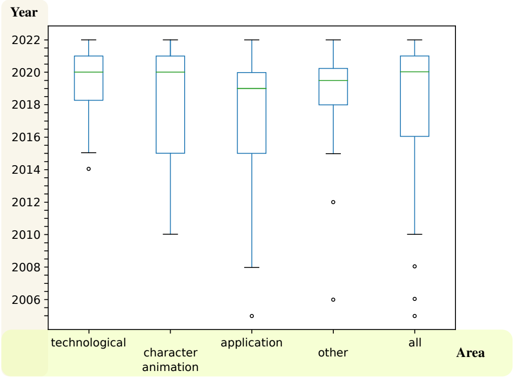

Fig. 4. Boxplots for the publication dates of the analyzed papers related to the subject of the project, in relation to the areas

X. Conclusions

This article focuses on the importance of national language to sign language translation as an important area of research and practice to enable communication between people with hearing impairments and the hearing community. The most important research on sign language interpretation conducted in various fields is reviewed. The article presents the latest scientific and theoretical achievements that contribute to a better understanding of this subject and the improvement of the quality of translation services.

The main aim of the article is to indicate the outstanding areas of interdisciplinary research related to sign language translation and to identify the links between these studies conducted in various fields. The authors try to broaden the knowledge and awareness of sign language interpretation, as well as identify areas that require further research and development.

The conclusions of the article aim to facilitate the improvement of interpretation practices and to promote further research and innovation in the field of sign language translation. This work is important to the hearing impaired community as it provides a better understanding of the communication needs of these people and inspires further efforts to improve the accessibility and effectiveness of sign language interpretation.

In conclusion, the subject of sign language animation is still quite a new and quite complicated field, because it combines many scientific disciplines, from linguistics to machine translation based on neural networks and advanced computer graphics. Today, professionals are collaborating and exploring many areas to develop acceptable and useful solutions to support deaf communities. Despite the great technological progress, the majority of works still discuss numerous challenges and barriers that must be faced in order to ensure full access to information that is so important for deaf people today. Ultimately, improving the quality of sign language interpretation services will contribute to strengthening the social inclusion and equality of people with hearing impairments, ensuring their full access to information and services in all spheres of life.

Acknowledgment

This research was funded by The framework of an automatic translator into the Polish Sign Language using the avatar mechanism, The National Centre for Research and Development, grant number GOSPOSTRATEG-IV/0002/2020.

***Abstract*—It is argued that for analysis of Positive Unlabeled (PU) data under Selected Completely At Random (SCAR) assumption it is fruitful to view the problem as fitting of misspecified model to the data. Namely, it is shown that the results on misspecified fit imply that in the case when posterior probability of the response is modelled by logistic regression, fitting the logistic regression to the observable PU data which *does not* follow this model, still yields the vector of estimated parameters approximately colinear with the true vector of parameters. This observation together with choosing the intercept of the classifier based on optimisation of analogue of F1 measure yields a classifier which performs on par or better than its competitors on several real data sets considered.**

I. Introduction

In the paper classification problem is analysed for partially observable data scenario for which in the case of some observations class indicators assigned to them (positive or negative in the case of binary classification) are unknown. More specifically, for positive and unlabeled data considered here, it is assumed that some observations from the positive class are labeled, whereas the rest of the observations (either positive or negative) are unlabeled. Such scenario is called Positive Unlabelled (PU) scenario. Thus in the PU setting the true binary class indicator $Y \in \{0,1\}$ is not observed directly but only through binary label S. One knows that if $S = 1$ (labelled case), Y has to be 1 (positive), but for $S = 0$ (unlabeled case) Y may be either 1 or 0 (positive or negative). Besides, each object is described by the vector of features x. This setup encompasses a legion of practical situations, in which effective inference methods about class indicator Y are sought. Examples include disease data (diagnosed patients with a specific disease detected, and patients yet to be diagnosed who may be ill or not), web pages preferences of a specific user (pages bookmarked as of interest and pages not yet viewed, thus of unknown interest) and ecological examples when environments are labeled provided a specific specimen inhabits them, and unlabeled, where this specimen has not been yet looked for). Such scenario is also relevant for survey data, when questions concerning socially reproachable behaviour may not be answered truthfully.

One of the popular approaches to learn from PU data is to impose certain parametric assumptions on distribution of (X, Y) as it commonly done in classical classification task together with some assumptions on labeling mechanism S. This is partly necessitated by the fact that in general situation the posterior distribution of Y as well as prior probability $P(Y = 1)$ is not identifiable. It is thus common to consider logistic type of dependence for the posterior distribution $P(Y = 1|X = x)$ and assume that censoring mechanism acts indiscriminately of x and is described only by the label frequency $c = P(S = 1|Y = 1)$ (SCAR assumption discussed below). Majority of learning approaches has been developed under such assumptions; see [1] for an extensive review of the proposed methods. Recently the JOINT method has been proposed in [11] which consists in minimisation of empirical risk for the observed data $(X_i, S_i), i = 1, \ldots, n$ with respect to parameter of logistic distribution *and* label frequency. JOINT method can be considered as a generic method with specific algorithms depending on optimisation technique used. The issue is delicate as it turns out that the empirical risk is *not* a convex function of its parameters and thus it may posess multiple local minima. In particular [11] used BFGS algorithm, whereas approach in [6] has been based on Minorization-Maximization (MM) technique. Among other methods important group consists of approaches based on weighted empirical risk minimisation in which weights of observations depend on labeling frequency c (see [1], section 5.3.2).

In the present contribution attention is called to the fact that in order to construct a reasonable classifier one can use a logistic model fitted to observable data $(X_i, S_i), i = 1, \ldots, n$ in order to recover the direction of the separating hyperplane and then shift it to the optimal position by maximising observable analogue of $F1$ score. In this approach the direction is obtained by minimising the misspecified *convex* empirical risk (equal to minus log-likelihood) for the observed data. The justification of the method is based on properties of misspecified logistic regression which are valid for PU model under SCAR condition considered here. It is argued that considering fitting parametric models to PU data as the misspecification problem gives new insights to the established properties and leads to new solutions. In particular, results on behaviour of estimators under misspecification (see e.g. [14], [12]) can be used to assess the performance of the naive classifier and its modifications.

II. Notions and auxiliary results

We first introduce basic notations. Let X be a multivariate random variable corresponding to feature vector, $Y \in \{0,1\}$ be a true class label and $S \in \{0,1\}$ an indicator of an example being labeled ($S=1$) or not ($S=0$). We consider X as a column vector and let $X = (1, \tilde{X}^T)^T \in R^{p+1}$, where the first coordinate of X corresponds to an intercept and coordinates of $\tilde{X}$ relate to p collected characteristics of an observation. We assume that there is some unknown distribution $P_{Y,X,S}$ such that (Y_i, X_i, S_i), $i = 1, \ldots, n$ are independent observations drawn from this distribution. Observed data consists of (X_i, S_i), $i = 1, \ldots, n$. This is the single sample scenario as opposed to case-control scenario when the samples from positive class and the general population are given. Only positive examples ($Y=1$) can be labeled, i.e. $P(S=1|X, Y=0) = 0$. Thus we know that $Y=1$ when $S=1$ but when $S=0$, Y can be either 1 or 0. Our primary aim is to construct a classifier which predicts Y class based on PU data. Note that this corresponds to a specific censored data problem as we only observe samples from distribution of (X,S), where $S=Y$ with a certain probability.

To this end we define binary posterior probability of $S=1$ given $X=x$ equal $s(x) = P(S=1|x)$ and propensity score function $e(x) = P(S=1|Y=1, X=x)$. In this paper we adopt Selected Completely At Random (SCAR) assumption which stipulates that $e(x)$ does not depend on x, thus $e(x) = P(S=1|Y=1) := c$, where c will stand for labeling frequency. This means that labeling is not influenced by feature vector x and in this case labeled data is a random sample (of a random size) from a positive class. This commonly adopted assumption is restrictive but it serves as an useful approximation especially in situations when the possibility of labeling bias is recognised and one tries to avoid it. We note that as we have $P(S=1, Y=0|X=x) = 0$ it holds

$$\begin{aligned} s(x) &= P(S=1|x) = P(S=1, Y=1|x) \\ &= P(S=1|Y=1,x)P(Y=1|x) \\ &= e(x) \times y(x) = c \times y(x), \qquad (1) \end{aligned}$$

where we let $y(x) = P(Y=1|X=x)$ denote posterior probability of class 1 and the last equality follows from SCAR assumption. We note that SCAR is equivalent to the property that S and X are conditionally independent given Y. We stress, however, that it is valid only when the label value is assigned with a fixed probability regardless of characteristics of an item. Under this assumption it is easy to see that $P_{X|S=1} = P_{X|Y=1}$ whereas $P_{X|S=0}$ is a mixture

$$P_{X|S=0} = \frac{\alpha - \alpha c}{1 - \alpha c} P_{X|Y=1} + \frac{1-\alpha}{1-\alpha c} P_{X|Y=0}$$

and $\alpha = P(Y=1)$ is a prior probability of $Y=1$. We also note that $c = P(S=1|Y=1) = P(S=1)/P(Y=1) = P(S=1)/\alpha$. We do not assume any previous knowledge of c (although it is frequently imposed see, e.g. [1]) and thus we only know that $0 < c \leq 1$.We will adopt an parametric model for posterior probability $y(x)$ assuming that Y is governed by logistic response:

$$y(x) = \frac{\exp(x^T\beta)}{1 + \exp(x^T\beta)} = \sigma(x^T\beta), \qquad (2)$$

where $\sigma(s) = \exp(s)/(1+\exp(s))$ is a logistic function, β^T stands for transposed column vector β and $\beta = (\beta_0, \beta_{-0}^T)^T \in R \times R^p$ is an unknown but fixed vector value. Thus in view of (1) and (2) we have

$$P(S=1|x) = c \times \sigma(x^T\beta).$$

III. Misspecified logistic modelling

Assume that (2) holds and consider naive approach when the logistic model is fitted to (X,S) data using Maximum Likelihood method i.e. we maximise a log-likelihood

$$\mathcal{L}_n(b) = \sum_{i=1}^n S_i \log\big(\sigma(X_i^T b)\big) + (1 - S_i)\log\big(1 - \sigma(X_i^T b)\big). \qquad (3)$$

Maximisation of $\mathcal{L}_n(\cdot)$ is a concave optimisation problem. Note that this is equivalent to assuming (erroneously) that all unlabeled observations belong to the negative class and thus misspecified logistic model is fitted to the data for which posterior probability is governed by (1). Obviously, one can write down the complete correct log-likelihood for $(X_i, S_i)_{i=1}^n$:

$$\tilde{\mathcal{L}}_n(b,c) = \sum_{i=1}^n S_i \log\big(c\sigma(X_i^T b)\big) + (1 - S_i)\log\big(1 - c\sigma(X_i^T b)\big) \qquad (4)$$

and maximise it wrt (b,c). Such method, named JOINT, has been proposed and investigated in [11]. However, finding global maximum of (4) is hindered by the fact that due to the presence of multiplicative constant c in the form of posterior probability $P(S=1|x)$ given in (1) log-likelihood $\tilde{\mathcal{L}}_n(b,c)$ is no longer concave wrt b, in contrast to $\mathcal{L}_n(b)$. There are some attempts to account for this, either by using Minorization-Maximization algorithm or modelling $\tilde{\mathcal{L}}_n(\cdot, c)$ as the difference of two concave functions ([13]).

Frequently, our aim is not to approximate (β, c) but to construct a classification rule based on training data $(X_i, S_i)_{i=1}^n$. For review of such methods see e.g. [1]. In such a case one can ask whether the classifier based on maximiser of $\mathcal{L}_n(b)$ can not be modified to yield approximation of Bayes classifier of Y. The answer is affirmative and it relies on the crucial observation that $\mathcal{L}_n(b)$ can be viewed as log-likelihood of misspecified logistic regression fitted to data corresponding to posterior probability $q(x^T\beta) = c \times \sigma(x^T\beta)$. This was noticed already in the context of estimation of β in [11] using Ruud's theorem [9] stated below, however its useful consequences have been never explored for PU classification. Here we try to fill this gap by showing that the naive classifier can be improved by adjusting its intercept, the step which has significant influence on its performance. Below we state Ruud's theorem [9] for a logistic loss, for the general statement see [8].

A. Colinearity under misspecification: general case

Assume that the distribution of random vector (X, S) is such that posterior probability $P(S = 1|X = x) = q(x^T\beta)$ for some unknown response function $q : R \to (0, 1)$ which is possibly different from logistic function. Let β^* be the maximiser of expected normalised log-likelihood in (3) for such distribution:

$$\begin{aligned} n^{-1}E_{(X,S)}\mathcal{L}_n(b) &= E_X\{q(x^T\beta)\log\sigma(x^Tb) \\ &+ (1 - q(x^T\beta))\log\big(1 - \sigma(x^Tb)\big)\} \end{aligned} \quad (5)$$

We note that β^* can be interpreted as the minimiser of the averaged Kullback-Leibler (KL) divergence between binary distribution $(q(X^T\beta), 1 - q(X^T\beta))$ and family of logistic models $\{\sigma(X^Tb)\}_{b\in R^{p+1}}$ (see [3] for the definition and properties of KL divergence) and thus corresponds to the Kullback-Leibler projection of the true distribution on this family. It also follows that β^* satisfies the following vector equality

$$EXq(X^T\beta) = EX\sigma(X^T\beta^*). \quad (6)$$

The obvious consequence of (6) is that when $q(s) \equiv \sigma(s)$ and the projection is unique, then $\beta^* = \beta$.
We say that X satisfies Linear Regressions Condition $(LRC(b))$ for vector $b \in R^{p+1}$ if

$$E(\tilde{X}|\tilde{b}^T\tilde{X} = w) = \gamma w + \gamma_0 \quad (7)$$

for some $\gamma = \gamma(\tilde{b}), \gamma_0 = \gamma_0(\tilde{b}) \in R^p$. We note that $LRC(b)$ condition is satisfied for the multivariate normal distribution for any $b \in R^{p+1}$ and, more generally, by the class of eliptically contoured distributions.

Theorem 1: [9] Assume that X satisfies $LRC(\beta)$ condition and moreover covariance matrix of $\Sigma_{\tilde{X}}$ of vector $\tilde{X}$ is strictly positive definite. Additionally, $P(Y = 1|X = x) = q_0(x^T\beta)$ for some unknown function q_0 and for some $\beta \in R^{p+1}$. Then minimiser β^* of (5) satisfies

$$\beta^*_{-0} = \eta\beta_{-0},$$

where $\beta = (\beta_0, \beta^T_{-0})^T$ and $\beta^* = (\beta^*_0, {\beta^*_{-0}}^T)^T$. Moreover, $\eta > 0$ provided that $\mathrm{Cov}(Y, X) > 0$ and $LRC(\beta^*)$ holds.

For the proof of the first part see e.g. [8]. The second part follows from normal equations (6) and the fact that vector γ in (7) equals $(\beta^T_{-0}\Sigma_{\tilde{X}}\beta_{-0})^{-1}\Sigma_{\tilde{X}}\beta_{-0}$.

Theorem above implies that under the stated conditions despite the misspecification of the fitted model we still retain colinearity of true parameter β and the vector β^* of its Kullback-Leibler projection when the first coordinate in both vectors corresponding to intercept is omitted. This has an obvious relevance in classification if one recalls that Bayes classifier when logistic model is valid equals under conditions of Theorem 1:

$$\begin{aligned} &\hat{Y}(X) = I\{(\tilde{X}^T\beta_{-0} + \beta_0 > 0\} \\ = \ &I\{\eta\tilde{X}^T\beta_{-0} + \eta\beta_0 > 0\} = I\{\tilde{X}^T\beta^*_{-0} + \eta\beta_0 > 0\} \end{aligned} \quad (8)$$

Thus the direction of the optimal separating hyperplane $\tilde{X}^T\beta_{-0} + \beta_0 = 0$ is given by projection β^*_{-0} which is easily estimable and only the intercept $\eta\beta_0$ needs to be recovered. Let $\hat{\beta}^*$ denote maximiser of (3). As Maximum Likelihood estimator $\hat{\beta}^*$ consistently estimates β^* under mild conditions (see [14]) one can use $\hat{\beta}^*_{-0}$ as the vector defining the direction of the separating hyperplane $w^Tx + w_0$ and then adjust its intercept appropriately.

B. Collinearity under misspecification: PU case

Consider now Positive Unlabeled data case and assume that posterior probability of Y given X is given by logistic model defined in (2). Then in the view of (1) when logistic model is fitted to (S, X), the model is misspecified as $P(S = 1|X = x) = c \times \sigma(^T\beta)$. However, under conditions of Theorem 1 we have $\beta^*_{-0} = \eta\beta_{-0}$ and moreover (6) yields

$$cEX\sigma(X^T\beta) = EX\sigma(\beta^*_0 + \eta\tilde{X}^T\beta_{-0}).$$

This shows how parameter η depends on labeling frequency c and distribution of $X^T\beta$. When X is multivariate normal this can be restated more explicitly.

Theorem 2: Assume that $X \sim N(0, \Sigma)$ and conditions of Theorem 1 are satisfied. (i) Then we have for any $j = 1, \ldots, p$:

$$\frac{\eta}{c} = \eta\frac{EX_j\sigma(\beta_0 + \tilde{X}^T\beta_{-0})}{EX_j\sigma(\beta^*_0 + \eta\tilde{X}^T\beta_{-0})} = \frac{E\sigma'(\beta_0 + \tilde{X}^T\beta_{-0})}{E\sigma'(\beta^*_0 + \eta\tilde{X}^T\beta_{-0})} \quad (9)$$

(ii) If $c \leq 1/2$ then $\beta^*_0 < 0$ for any β_0.

Proof. The first equality in (9) is just a consequence of (6) when j^{th} coordinate is considered. The second equality follows from Stein's lemma, which states that $\mathrm{Cov}(h(Z_1), Z_2) = Eh'(Z_1)\mathrm{Cov}(Z_1, Z_2)$ for bivariate normal vector (Z_1, Z_2). It implies that

$$\begin{aligned} &EX_j\sigma(\beta_0 + \tilde{X}^T\beta_{-0}) = \mathrm{Cov}(X_j, \sigma(\beta_0 + \tilde{X}^T\beta_{-0})) \\ = \ &E\sigma'(\beta_0 + \tilde{X}^T\beta_{-0})\mathrm{Cov}(X_j, \beta_0 + \tilde{X}^T\beta_{-0}) \end{aligned} \quad (10)$$

and, analogously

$$\begin{aligned} &EX_j\sigma(\beta^*_0 + \eta\tilde{X}^T\beta^*_{-0}) = \mathrm{Cov}(X_j, \sigma(\beta^*_0 + \tilde{X}^T\beta^*_{-0})) \\ = \ &E\sigma'(\beta^*_0 + \eta\tilde{X}^T\beta_{-0})\mathrm{Cov}(X_j, \beta^*_0 + \eta\tilde{X}^T\beta^*_{-0}). \end{aligned} \quad (11)$$

Applying normal equations again we obtain the second equality.
In order to prove (ii) note that for any symmetric univariate random variable Z we have

$$E\sigma(a + Z) < 1/2 \iff a < 0.$$

Indeed

$$E\sigma(a + Z) = 1 - E\sigma(-a - Z) = 1 - E\sigma(-a + Z),$$

where the second equation is due to symmetry of Z. This, and the fact that $\sigma(a+Z) < \sigma(-a+Z)$ is equivalent (due to monotonicity of $\sigma(\cdot)$) to $a < 0$ justify the claim. However, note that normal equations for the first coordinate being 1 imply that

$$E\sigma(\beta_0^* + \eta\tilde{X}^T\beta_{-0}) = cE\sigma(\beta_0 + \tilde{X}^T\beta_{-0}) < c \leq \frac{1}{2}$$

and thus $\beta_0^* < 0$.

Remark 3.1: Part (ii) explains why the naive classifier applied to (S, X) data will work poorly, especially for small c: its intercept is likely to be negative regardless the sign of the intercept $\eta\beta_0$ in (8). Thus it has to be modified to enhance the performance of naive classifier.

Remark 3.2: The case when no intercept is included in both the true and the fitted model has been considered in [11]. It is shown there that then $0 < \eta \leq c < 1$. Thus in this case coefficients of logistic model corresponding to genuine predictors are shrunk towards 0.

C. Choice of the intercept

We propose to choose the intercept $\widehat{w}_0$ of the separating hyperplane $\tilde{x}^T\hat{\beta}^*_{-0} + \widehat{w}_0 = 0$, where $\widehat{w}_0$ is an estimator of $\eta\beta_0$ (see (8)), by maximising the analogue of $F1$ measure on training data. We let, for a given classifier $\hat{Y} = \hat{Y}(X)$ learnt on the training data $\mathcal{D}^{train}$:

$$r = P(\hat{Y}(X) = 1|Y = 1) \qquad p = P(Y = 1|\hat{Y}(X) = 1)$$

be population recall and precision of $\hat{Y}$, respectively. Here, (X, Y) stands for unobservable random variable having distribution $P_{X,Y}$ which is independent of $\mathcal{D}^{train}$. We define $F1$ measure as their harmonic mean

$$F1 = \frac{r \times p}{(r + p)/2}. \tag{12}$$

Thus in order to have large $F1$ value, both the precision and recall should be large. We also note that simple derivation yields $F1 = 2 \times P(Y = 1, \hat{Y} = 1)/(P(Y = 1) + P(\hat{Y} = 1))$. Moreover, note that for PU data under SCAR we have that $P(\hat{Y}(X) = 1|Y = 1, \mathcal{D}^{train}) = P(\hat{Y}(X) = 1|S = 1, \mathcal{D}^{train})$ as $\hat{Y}(X)$ given $\mathcal{D}^{train}$ depends on X only and $P(X|Y = 1) = P(X|S = 1)$.

This means that the recall r can be easily estimated from (X, S) sample. The precision, however is unobservable, and thus we consider the following analogue of $F1$ introduced in [7], Section 4, (see also [10]) defined as

$$F1_{PU} = \frac{r \times p}{P(Y = 1)}. \tag{13}$$

$F1_{PU}$ is proportional to squared geometric mean of the precision and the recall i.e. Fowlkes-Mallows index [5]. Note that one obtains

$$\frac{P(Y = 1|\hat{Y}(X) = 1)}{P(Y = 1)} = \frac{P(\hat{Y}(X) = 1|Y = 1)}{P(\hat{Y}(X) = 1)}$$

which in terms of the precision and the recall means that $p = r \times P(Y = 1)/P(\hat{Y}(X) = 1)$ and thus

$$F1_{PU} = \frac{r^2}{P(\hat{Y}(X) = 1)}. \tag{14}$$

Let $\hat{Y}_z(x) = I\{\tilde{x}^T\hat{\beta}^*_{-0} + z > 0\}$, where $\hat{\beta}^*$ is maximiser of (3) and define $\widehat{F1}_{PU}(z)$ to be a sample analogue of $F1_{PU}$ for the classifier $\hat{Y}_z(X)$. We propose to choose $\widehat{w}_0$ as maximiser of

$$\widehat{w}_0 = \text{argmax}_z \widehat{F1}_{PU}(z) \tag{15}$$

We will call the classifier $\hat{Y}(x) = I\{\tilde{x}^T\hat{\beta}^*_{-0} + \widehat{w}_0 > 0\}$ the enhanced naive classifier. The pseudo-code for enhanced classifier is given in Algorithm 1. We show below when analysing its behaviour on real data sets that modification of the intercept of the naive classifier is crucial for its performance.

Algorithm 1 Enhanced naive classifier

```
Input: Observed data $(x_i, s_i)$, $i = 1, \ldots, n$.
Step 1: Obtain estimator $\hat{\beta}^* = (\hat{\beta}^*_0, \hat{\beta}^*_{-0})$ by fitting logistic regression to observed data $(x_i, s_i)$.
Step 2: Calculate intercept $\hat{w}_0$ as $\text{argmax}_z \widehat{F1}_{PU}(z)$.
Result: Parameters $(\hat{w}_0, \hat{\beta}^*_{-0})$ of the separating hyperplane.
```

IV. Numerical experiments

In the numerical experiments we have considered the following classifiers:

- Naive classifier based on fitting logistic regression model to (X, S) data called Naive and the classifier Enhanced proposed here;
- Classifiers based on JOINT and MM estimators discussed above;
- Weighted classifiers introduced in [1], Section 5.3.1 using two alternative estimators of c: proposed in [4] (denoted by e_1, p.214) and TIcE estimator introduced in [2]. For the discussion of both estimators of c see e.g. [6]. They will be called EN and TIcE classifiers, respectively.

The implementation of Enhanced estimator is given in github directory[1]. Maximisation of $\widehat{F1}_{PU}(z)$ in (15) is achieved by looking for maximal value among the values of this quantity, noting that numerators of numerator and denominator of the ratio defining it may change by ±1 when moving along ordered values of intercept for which predictions of considered classifiers change, i.e. values $z_i = \tilde{x}_i^T\hat{\beta}^*_{-0}$.

A. Synthetic data

In order to check how Ruud's theorem works in practice and the performance of the proposed classifier, we considered a simple synthetic example where vector of predictors $\tilde{X}$ has three-dimensional normal distribution with mean $m = (1, 1, -1)^T$, variances equal to 1 and covariances $Cov(X_1, X_2) = 0.2$, $Cov(X_1, X_3) = -0.2$ and

[1] https://github.com/MateuszPlatek/PU_Enhanced_Naive_Classifier

$Cov(X_2, X_3) = 0$. Thus X_1 is positively correlated with X_2 and negatively correlated with X_3. Moreover posterior probability of $Y = 1$ given $X = x$ is logistic with $\beta = (-1, -1, 1, 1)^T$. We investigated the angle between $\hat{\beta}_{-0}$ and β_{-0} for all considered estimators, the performance of corresponding classifiers for $c = 0.3, 0.6$ and several values of n ranging from 500 to 5000. The results are shown in Figure 1 situated at the end of the paper. The first row of the panel exhibits goodness of fit of the considered estimators measured by the mean differences of their angles and the angle of β_{-0}. It indicates that in concordance with Ruud's theorem the direction of β_{-0} is approximately recovered by direction of naive estimator $\hat{\beta}_{-0}$ for sample sizes larger than 1000 and the accuracy increases with increasing sample size. Moreover the accuracy of $\hat{\beta}_{-0}$ measured by mean difference of angles for naive, MM and JOINT estimators approximately coincides and is consistently better than that of EN and TIcE estimators. In terms of F1 measure shown in the second row the introduced enhanced naive classifier works consistently better than its competitors and in terms of Balanced Accuracy (defined as the average of the recall and the specificity; the third row) it is only outperformed by EN classifier for $c = 0.3$.

B. Real datasets

We have analysed performance of the estimators on six data sets from UCI directory with sample sizes ranging from around 300 to 30 000 and number of features from 3 to 166 (the main characteristics of the data sets are given in Table I). The figures show mean performance with the regard of F1 measure (Figure 2) and Balanced Accuracy (Figure 3), for values of c ranging from 0.1 to 0.9, based on 200 random splits of the data into training and testing subsamples. Standard errors for the mean are smaller than 0.01 in most cases for both F1 and BA measure with the only exception of F1 measure on `credit-a` and `diabetes` data set and the maximal value of SE is 0.026 for JOINT estimator on `credit-a`. Note that the results for the naive classifier are truncated from below in Figure 2: F1 measure for naive classifier is very low for $c \leq 0.5$ and approach 0 for c close to 0. The first immediate observation is that the change of the intercept estimator, which is the only difference between the naive classifier and its enhanced version, has a huge impact on its performance with regard to both considered measures.

F1 measure In all cases but one the enhanced classifier works better (data sets `musk, credit-a, diabetes, adult`) or on par (`banknote`) with JOINT and MM estimators. In the case of *spam* it works marginally worse than JOINT and MM. This is interesting, especially in comparison with MM estimator which requires much more computing effort. It also outperforms TIcE and EN estimators on three data sets: `banknote, musk` and `spam`. On `adult` data set enhanced classifier works better than EN and on par with TIcE. Its excellent performance on `musk` data set is worth pointing out. The performance of enhanced estimator deteriorates for small values of c, possibly due to loss of accuracy of $\widehat{F1}_{PU}$ (note that the denominator of (14) becomes smaller for smaller c).

Name	Size	Features	Fraction of positive observations
adult	32561	57	0.24
banknote	1372	4	0.44
credit-a	690	38	0.44
diabetes	768	8	0.35
musk	6598	166	0.15
spambase	4601	57	0.39

TABLE I: Analysed datasets and their statistics

Algorithm	Oracle	Enhanced	JOINT	MM	EN	TIcE
Time	0.05s	0.22s	0.23s	201s	0.66s	0.9s

TABLE II: Mean training time in seconds on the largest dataset adult with $c = 0.5$.

Balanced Accuracy The performance of enhanced estimator with respect of Balanced Accuracy is similar to that with respect to F1 measure.

We have also analysed training times of the considered classifiers. Table II shows the training times for the largest data set `adult`. In the case of Enhanced and JOINT classifiers the times are approximately the same and 2-3 times shorter that the times for EN and TiCE classifiers. The most computation intensive is MM classifier as it requires inner loop of convex optimisation for each iteration of $\hat{\beta}$.

V. Conclusion

We have studied a novel modification of naive classifier for Positive Unlabeled data under SCAR assumption. The classifier has strong theoretical underpinnings following from Ruud's theorem which are are established in Theorem 1. These indicate that the coefficients of logistic classifier corresponding to genuine predictors are consistently estimated based on observed (X, S) data and the estimation problem boils down to consistent estimator of the intercept. We have proposed such an estimator based on maximisation of observable analogue of $F1$ measure. Moreover, we have shown analysing real data sets that the resulting enhanced naive estimator is a promising alternative to classifiers based on parametric models of posterior probability (JOINT and MM classifier) as well as nonparametric ones (TIcE and EN classifiers). Future research may include finding alternatives to the proposed method of estimating the intercept as well as extension of the considered method to the situation when SCAR assumption is violated. In particular, note that when posterior probability $y(x)$ satisfies (2) and $e(x)$ is an *arbitrary* function of $y(x)$, posterior probability $s(x)$ of $S = 1$ given $X = x$ is a function of $x^T\beta$ and it corresponds to misspecified logistic model. Thus the conclusion of Theorem 1 applies also to this more general situation which as its special case includes probabilistic gap assumption when $e(x)$ is an increasing function of $y(x)$.

***Abstract*—Meta Automated Machine Learning (Meta AutoML) platforms support data scientists and domain experts by automating the ML model search. A Meta AutoML platform utilizes multiple AutoML solutions searching in parallel for their best ML model. Using multiple AutoML solutions requires a substantial amount of energy. While AutoML solutions utilize different training strategies to optimize their energy efficiency and ML model effectiveness, no research has yet addressed optimizing the Meta AutoML process. This paper presents a survey of 14 AutoML training strategies that can be applied to Meta AutoML. The survey categorizes these strategies by their broader goal, their advantage and Meta AutoML adaptability. This paper also introduces the concept of rule-based training strategies and a proof-of-concept implementation in the Meta AutoML platform OMA-ML. This concept is based on the blackboard architecture and uses a rule-based reasoner system to apply training strategies. Applying the training strategy “top-3” can save up to 70% of energy, while maintaining a similar ML model performance.**

I. Introduction

MACHINE LEARNING (ML) is an important subdomain of artificial intelligence (AI), allowing programs to make predictions using models based on previous observations [1]. Creating effective ML models requires substantial knowledge and experience in the field of ML. Data scientists are a group of experts possessing those foundations. Generating an ML model involves several tasks, including data analysis, data preparation, feature engineering, model selection, validation, learning curve analysis and hyperparameter optimization.

The research field of *Automated Machine Learning (AutoML)* emerged to support data scientists and domain experts (professionals in a domain like medicine) with these tasks. AutoML aims to automate the model selection and hyperparameter optimization process leading to higher efficiency, and potentially better results [2]. Finding the best model and its hyperparameter optimization for a given problem is also known as the Combine Algorithm Selection and Hyperparameter Optimization (CASH) problem [3]. An AutoML solution programmatically searches for an ML pipeline by solving the CASH problem [4]. More progressive AutoML solutions also perform data preparation, feature engineering, and validation, allowing for the creation of entire ML pipelines [5]. There are a growing number of AutoML solutions available [6] offering automated solutions for ML tasks belonging to supervised learning (e.g. Auto-WEKA [7]) and unsupervised learning (e.g. AutoCluster [8]). Although AutoML aims to be accessible to users with and without ML and programming expertise, only a few AutoML solutions are targeted at domain experts [6]. Furthermore, due to the wide range of AutoML solutions and their constraint to mainly support only one major ML library (e.g. Auto-Keras [9] supporting Keras[1]), finding the most effective ML method for a given use case requires a trial and error approach.

Meta Automated Machine Learning (Meta AutoML) [10] is a concept that addresses such issues by integrating multiple Automated Machine Learning solutions into one ensemble. During a training session, the AutoML solutions search for their best ML model in parallel. Some AutoML solutions may use different approaches to automatically optimize the model search [3]. This internal optimization aims to reduce the training time and increase the effectiveness of the final ML model. Within the research field of AutoML, a wide range of different optimization approaches exist [11] e.g. meta-learning [12], or early-stopping [13].

Running multiple AutoML solutions in parallel is energy-inefficient. Therefore, improving the energy-efficiency of the Meta AutoML process is an important goal. AI approaches that use vast amounts of computation power to increase their performance can be labelled as red AI [14]. Meta AutoML falls into this red AI category, as it uses a massive amount of computation power to operate multiple AutoML solutions in parallel. It is important to optimize the Meta AutoML process and move it towards green AI [14]. However, on the Meta AutoML level, there has been no research on improving efficiency.

A simple Meta AutoML training strategy to improve energy efficiency is the “top-3” strategy. This strategy performs two successive training sessions. The first training session uses all AutoML solutions with a reduced sample set and training time. The second training session utilizes the full sample set and the remaining training time. This session uses the 3 best performing AutoML solutions found during the first training session. We use the top-3 strategy to demonstrate and evaluate the approach presented in this paper.

IEEE Catalog Number: CFP2385N-ART ©2023, PTI

Topical area: Advanced Artificial Intelligence in Applications

The contributions of this paper are two-fold: (a) A survey of AutoML training strategies that can be applied to Meta AutoML; (b) A concept for a rule-based training strategy component for Meta AutoML and its prototypical implementation in the platform OMA-ML [6] as a proof-of-concept. This paper uses the prototypical implementation to evaluate the effectiveness of a selected training strategy, namely the top-3 strategy. The evaluation compares CO_2 emission equivalents produced by the entire Meta AutoML training and the ML model prediction performance with and without using the training strategy.

This paper is structured as follows. Section II presents related work. Section III shows the survey on training strategies. Section IV is the paper's core, introducing the concept of rule-based training strategies. Section V briefly indicates aspects of the prototypical implementation in the platform OMA-ML. Section VI evaluates the concept and prototypical implementation. Section VII concludes the paper and discusses future work.

II. Related Work

A number of surveys exist that focus on state-of-the-art research about AutoML [6][3][15][16][17][18][19]. These surveys focus on the algorithms and approaches used to solve the CASH problem. They also review individual AutoML solutions. However, only one survey [6] offers a broader survey of existing AutoML solutions. Furthermore, we are not aware of a survey on AutoML training strategies.

The next important aspect of research relates to AutoML training strategies. There are two different categories of AutoML strategies: strategies that are applied during preprocessing and strategies that are applied during training of an ML model. Some AutoML solutions preprocess the dataset only once; e.g., Autogluon infers the process from the initial dataset [20]. Others may use intricate data preprocessing approaches; e.g., TPOT uses genetic programming [21] to find the best preprocessing workflow. Additionally, some AutoML solutions apply strategies to the ML model training process, e.g. early stopping (e.g. H2O: AutoML [22]) which stops the fitting process of a ML model based on a user-defined termination criterion [13]. Another strategy is multi-fidelity (e.g. Auto-Pytorch [23]). This aims to optimize the ML model and hyperparameter search by training models using lower-fidelity (e.g. less time, computation, data) to determine the best configuration to run high-fidelity training [24]. AutoML solutions can implement frameworks like BOHB to use multi-fidelity optimization [25]. Finally, some AutoML solutions implement strategies such as meta-learning [26] to further improve their training by learning from previous ones. While early stopping and multi-fidelity training strategies are used by AutoML solutions, they are not limited to AutoML. Data scientists use the concept of applying optimization strategies to improve their manual search for the best ML model.

There exists a collection of foundation literature introducing different strategies to improve the ML training [27][28]. The literature provides different optimization strategies depending on the dataset and general ML training. There are scientific surveys that compare different approaches used to optimize the individual steps of preprocessing [29][30]. Additionally, there are publications that present new approaches to optimize or replace existing preprocessing approaches [31][32].

The concept of improving the efficiency of Meta AutoML via rule-based training strategies is novel. We are not aware of any publication dealing with this issue. Currently, we are aware of two Meta AutoML platforms: OMA-ML [6] and Ensemble Squared [33]. Both Meta AutoML platforms use a meta layer to administer the built-in AutoML solutions. This abstraction layer allows a user to leverage multiple AutoML solutions simultaneously, without requiring previous knowledge about individual AutoML solutions or data science.

Ensemble Square does not use training strategies to optimize its Meta AutoML process. It uses all supported AutoML solutions for every training session by default.

III. A Survey of ML Training Strategies

In this section we compare 14 training strategies from AutoML solutions regarding their applicability to Meta AutoML.

A. Methodology

The training strategies are evaluated using the following criteria:

- **Category** of the training strategy:
  - *Data cleaning*: Identification and correction of flaws in the data;
  - *Data transformation*: Changing the scaling or distribution of the data;
  - *Complexity reduction*: Reducing the feature or sample size to reduce complexity;
  - *Infrastructure*: Adjusting the available hardware and computation power;
  - *Spot checking*: Using trial training sessions to determine the most viable solution;
  - *Training observation*: Actively supervising the ML model performance during the fit process;
  - *Meta-learning*: Learning from past training sessions to improve future trainings.
- **ML process phase**: The phase during which the strategy is applied:
  - *Pre-processing*: The preprocessing phase occurs before the actual ML model training and focuses on preparing the dataset;
  - *Training*: The training phase where the ML models are fitted to the training data;
  - *Post-processing*: the phase after training proper;
  - *Meta-level*: The Meta-Level is not a phase as such but covers the entire process.
- **Advantage**: The benefits of applying the strategy:
  - *Effectiveness*: The ML model's effectiveness may increase;
  - *Efficiency*: The amount of computation power required by the training may decrease.

TABLE I
OVERVIEW OF AUTOML TRAINING STRATEGIES

Strategy	Category	ML process phase	Advantage	Feasibility	References
Handling outliers	Data cleaning	Preprocessing	Effectiveness	Yes	[27][34][29]
Imputing missing values	Data cleaning	Preprocessing	Effectiveness	Yes	[27][31][32]
Omitting redundant samples	Data cleaning	Preprocessing	Effectiveness, Efficiency	Yes	[27][35]
Data sampling	Data cleaning	Preprocessing	Efficiency	Yes	[27][36]
Text feature encoding	Data transformation	Preprocessing	Effectiveness	Yes	[37]
Numerical feature scaling	Data transformation	Preprocessing	Effectiveness	Yes	[38][39]
Feature extraction	Complexity reduction	Preprocessing	Effectiveness, Efficiency	Partial	[40][41]
Feature selection	Complexity reduction	Preprocessing	Effectiveness, Efficiency	Yes	[42][43][27]
Dimensionality reduction	Complexity reduction	Preprocessing	Effectiveness, Efficiency	Yes	[44][30][45]
Hardware optimization	Infrastructure	Training	Efficiency	Yes	
Multi-fidelity optimization	Spot checking	Training	Efficiency	Yes	[28][46][24]
Top 3 optimization	Spot checking	Training	Efficiency	Yes	
Early Stopping	Training observation	Training	Efficiency	Partial	[13]
Meta-learning	Meta-learning	Meta level	Effectiveness, Efficiency	Yes	[47]

- **Feasibility**: Can the strategy be applied to Meta AutoML:
  - *Yes*: Can be applied to Meta AutoML;
  - *Partial*: Can be partially applicable to Meta AutoML.
  - *No*: Cannot be applied to Meta AutoML.

B. Strategies

Table I gives an overview of the training strategies survey.

1) Data cleaning: Data cleaning aims to remove or repair dirty data within the dataset [27]. The following can be issues within a dataset:

- *Outliers*: A value is an outlier if it significantly deviates from the other values;
- *Missing values*: When no data is available for a feature in a sample;
- *Redundancy*: Identical samples present in a dataset.

a) Handling outliers: Detecting and handling outliers is one of the first steps of data cleaning. Outliers represent noise within data [27]. If outliers are improperly handled, they can decrease the prediction performance of the ML model [34]. Statistical methods can be used to automatically identify and handle outliers (e.g. interquartile range, standard deviation [29]). Some AutoML solutions (e.g. Pycaret[2]) offer support to handle outliers from datasets. Handling outliers may increase the effectiveness of ML models.

b) Imputing missing values: Imputing missing values is important. Missing values can negatively impact the quality and accuracy of ML models by introducing bias [27]. Statistical methods can automatically impute missing values (e.g. k-nearest-neighbor-based approaches [31], neural networks [32]). Some AutoML solutions (e.g. MLJAR[3]) implement automatic imputation of missing values. Handling missing values may increase the effectiveness of ML models, as the potential bias from missing values is not introduced.

c) Omitting redundant samples: Duplicated samples can introduce bias in the model. Identical samples can negatively impact the search time of the training session and the ML model's effectiveness. Statistical methods can automatically detect duplicate samples (e.g. probabilistic matching [35]). Removing duplicate samples may increase the effectiveness of the ML model by removing potential bias. It may also increase the training efficiency by reducing the size of the dataset.

d) Data sampling: Sampling can adjust the dataset size to the training configuration to allow the most effective training (e.g. limit time or computation power) [27]. By sampling the dataset the training efficiency may increase and the ML model performance may not be negatively impacted [27]. Some AutoML solutions (e.g. FLAML) apply sampling to adjust the dataset size on the training configuration (e.g. limited time and large sample set by applying e.g. holdout [36]).

2) Data transformation: Data transformation aims to change the type or distribution of the data in a dataset. This includes transforming data into a format an ML algorithm can process [27].

a) Text feature encoding: Text features often can not be processed by ML algorithms and require encoding [37]. Text features may be disregarded without proper encoding or lead to errors during the ML model training. When confronted with text features, three categories of encoding strategies exist:

- *Binary encoding*: encodes the textual values into binary values, e.g. yes/no;
- *Ordinal encoding*: encodes the textual values into a finite set of discrete values with a rank or ordering between them. e.g. low/medium/high;
- *Nominal encoding*: encodes the textual values into a finite set of discrete values with no relationship between them. e.g. married/single/widowed.

Some AutoML solutions (e.g. Autokeras [9]) automatically encode text features. Encoding text features may increase the

[2] https://github.com/pycaret/pycaret
[3] https://github.com/mljar/mljar-supervised

effectiveness of an ML model as it can consider those features while training instead of disregarding them.

b) Numerical feature scaling: Numerical features with a wide range of values may cause bias in the ML model. Some ML approaches are sensitive to the relative magnitude of features and may give more weight to features with larger values [38]. When confronted with numerical features displaying a wide range, two categories of scaling strategies can be applied:

- Normalization: This method resizes the data to a fixed value between 0 and 1;
- Standardization: This method resizes the data to have a median of 0 and a standard deviation of 1.

Some AutoML solutions (e.g. MLJAR) automatically scale numerical features using normalization or standardization functions. Scaling numerical features may increase the effectiveness of an ML model [39].

3) Complexity reduction: Complexity reduction aims to reduce the complexity of a dataset. The available methods can be divided into three categories:

- Feature extraction: Create new features from existing data that may have more meaningful information;
- Feature selection: Reduce the number of features by selecting the most relevant ones without changing the features themselves;
- Dimensionality reduction: Reduce the number of features by transforming the features into a lower dimensional space while preserving essential information.

a) Feature extraction: Feature extraction aims to create a subset of more meaningful features from the existing ones [40]. The construction of new features is highly specific to the data and data type of the dataset. Often, it is required to collaborate with domain experts who can group features correctly together. Automated feature engineering offers data scientists and AutoML solutions methods to automatically create candidate features derived from the original dataset e.g. Deep Feature Synthesis [41]. Using newly created features based on existing data may increase the performance of an ML model. Some AutoML solutions (e.g. MLJAR) apply automated feature engineering to create new and potentially more effective ML models. Multiple open-source libraries focus on automated feature engineering, e.g. Feature-engine[4]. Such tools can help data scientists quickly trial a wide range of different feature combinations. However, only a domain expert has the necessary understanding of the problem to determine the suitability of features.

b) Feature selection: Feature selection aims to reduce dataset complexity by removing non-useful features [42] and creating a feature subset that performs best under classification [43]. A dataset can contain irrelevant or noisy features (e.g. duplicated features) that may introduce bias into an ML model. By removing noisy features, the ML model's effectiveness and training efficiency may increase [27]. The existing methods can be classified into one of three categories:

- *Filter*: Filtering out undesirable features before learning by using heuristics based on the general data characteristics to evaluate the goodness of feature subsets;
- *Wrapper*: Methods that search the feature space for the best-performing subset. They assess the quality of features by training and evaluating a classifier with the subset;
- *Embedded*: Similarly to the wrapper method, the feature selection is performed during the learning process of the ML model.

Some AutoML solutions (e.g. MLJAR) apply automated feature selection to evaluate which feature is relevant for a given search.

c) Dimensionality reduction: Dimensionality reduction aims to reduce the dimensionality of the dataset. The number of features may be considered the dimensionality of the dataset. Dimensionality-reducing methods project the data into a lower-dimensional space that still preserves the most important properties of the original data. By reducing the complexity of the dataset the ML model's effectiveness and the training efficiency may increase. The existing methods can be divided into three categories:

- *Linear dimensionality reduction methods*: e.g. principal component analysis [44];
- *Non-linear dimensionality reduction methods*: e.g. multidimensional scaling [30];
- *Autoencoder methods*: e.g. using artificial neural networks [45].

C. Hardware optimization

Hardware optimization aims to choose the most suitable infrastructure for the task and use it in the most energy-efficient and resource-saving way possible. Optimizing the underlying hardware may reduce the amount of computation power invested during training by providing specialized hardware for ML. Another option is to limit the access to computation power to limit the used computation during training. Some AutoML solutions (e.g. MLJAR) can limit the maximum amount of RAM the solution uses.

D. Spot checking

Spot-checking aims to discover the approach that performs best for an ML task [28]. A spot-checking algorithm uses multiple trials to evaluate multiple ML algorithms on a given dataset to determine their performance. The spot-checking training aims to quickly assess the viability of a collection of ML models and decide which approach to use for further training.

a) Multi-fidelity optimization: The multi-fidelity strategy uses numerous training sessions with low-fidelity samples to evaluate the general trend of a system's behaviour, and a small number of high-fidelity samples to enhance the prediction accuracy in important regions [46]. Sequential multi-fidelity surrogate modelling is one multi-fidelity approach that limits the computational budget in addition to using low-fidelity

[4] https://feature-engine.trainindata.com/en/latest/

samples [24]. Some AutoML solutions (e.g. Auto-Pytorch) use multi-fidelity to improve their training.

b) Top-3 optimization: The top-3 strategy is a variation of the multi-fidelity strategy. The training is divided into two steps. The first is a pre-training with a low-fidelity configuration (limited data and time budget). After all candidates are trained, they are evaluated. The top 3 candidates are then trained with the full dataset and the remaining time. The benefit of top-3 is the increased efficiency of the training process, as only the best 3 ML models are fully trained. The top-3 strategy is not used by any existing AutoML solution, but it could be applied to AutoML.

1) Early-stopping: Early stopping is a strategy to intelligently terminate the training when a user-defined early stopping criterion is met. The standard early-stopping criterion is the loss on the validation set [13]. Some AutoML solutions (e.g. PyCaret) use early stopping to optimize training efficiency. On a Meta AutoML level, it is only partially possible to use early stopping. The main issue is that there is currently no interface available for Meta AutoML to extract the current status of the AutoML solution, except through text mining the console output. One issue with text mining is that some AutoML solutions produce limited or no relevant output during the training itself [6]. Additionally, no interface is available for the Meta AutoML process to halt the AutoML training. In most cases, the Meta AutoML could terminate the process using the underlying operating system, which leads to a complete loss of the ML model within the AutoML solution.

2) Meta-learning: Human domain experts derive knowledge from previous tasks by learning about the performance of ML algorithms. Meta-Learning mimics the perpetual process of "learning to learn" across similar tasks and transferring that prior knowledge to new tasks [47]. Some AutoML solutions (e.g. Auto-Sklearn) use meta-learning to form recommendations for ML algorithms and their configuration based on past training sessions. Meta-learning may increase training efficiency and the ML model effectiveness.

In the next section, we introduce a concept for implementing training strategies using a rule engine.

IV. A Concept for Rule-based Training Strategies

Before introducing the concept of rule-based training strategies, we define the optimization goals we aspire to achieve by applying training strategies:

- *Efficiency*: The energy consumption will be significantly reduced compared to a Meta AutoML training without applying a training strategy;
- *Effectiveness*: The ML model performance will not be significantly reduced.

The concept for achieving those goals uses a *blackboard architecture* [48]. The blackboard architecture is a problem-solving approach combining multiple specialized modules working collaboratively to solve a complex problem. The speech understanding system HEARSAY-II introduced and used this approach [49]. The blackboard architecture defines three components:

- *Blackboard*: a global data store that keeps the problem-solving state data;
- *Knowledge sources*: individual components with domain knowledge needed to solve a problem. Each component is represented as procedures, sets of rules or logic assertions and contributes information that will lead to a solution to the problem.
- *Controller*: A component that monitors the changes on the blackboard and decides what actions to take next. The controller decides on the order of invocation of the knowledge sources.

Fig. 1 shows a BPMN diagram [50] of the rule-based training strategies process. The process starts when a new Meta AutoML training is initiated.

A user initiates a new Meta AutoML training by configuring a new training within a Meta AutoML platform. A Meta AutoML platform is an application based on the Meta AutoML concept [10]. It unifies several AutoML solutions and allows the user to configure and start new training sessions without interacting with the AutoML solutions individually. One example of a Meta AutoML platform is OMA-ML [6]. The result of the user's training configuration is the *training configuration* data. For example, a training configuration could be represented as follows:

```
dataset : census_income.csv
task : tabular_classification
autoML_solutions_activated : [FLAML,
Autogluon, Autosklearn, TPOT, MLJAR,
AutoKeras, Pycaret, EvalML]
strategies_enabled : [top-3]
max_runtime : 60
```

In this example, the user configures the training for a tabular classification of the Census Income dataset [51] with a total runtime of 60 minutes. A total of 8 AutoML solutions are activated (FLAML, Autogluon, Autosklearn, TPOT, MLJAR, AutoKeras, Pycaret, EvalML) and one training strategy (top-3) is enabled.

When uploading new training data into the Meta AutoML platform, it is automatically analyzed. During this *dataset analysis*, the *analysis result* data is generated by extracting the properties of the *training data*. For example, the analysis result for the Census Income dataset could be as follows:

```
samples : 48000
features : 15
missing_values : none
duplicated_samples : 48
```

In this example, the Census Income dataset, is comprised of 48,000 samples and 15 features. It has no missing values and a total of 48 duplicated samples.

The training configuration and analysis result are added to the blackboard and represent the initial blackboard state data. The blackboard state data is the collection of the current state data of all the involved components and the current

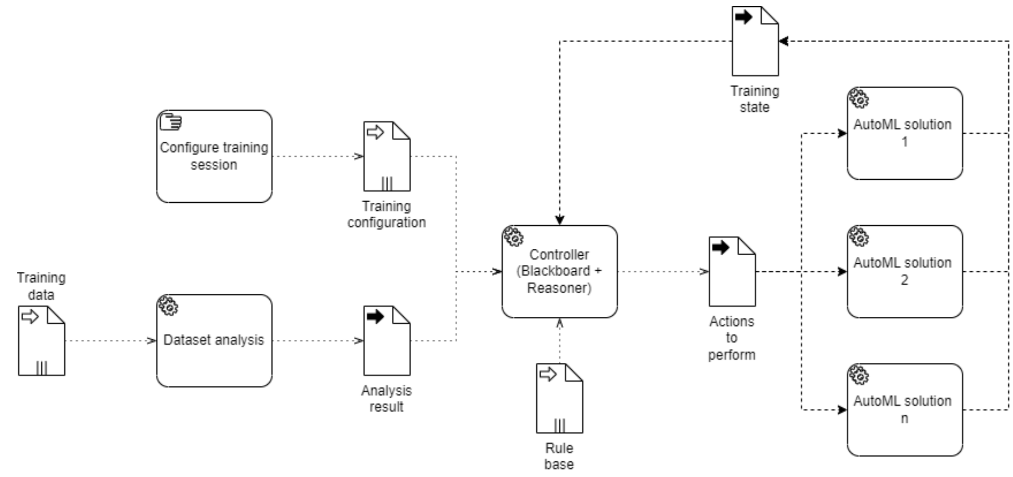

Fig. 1. Rule-based training strategies process as a BPMN diagram

training phase. When the blackboard is initialized the training phase is automatically set to 'preprocessing' and as the training progresses it is updated to 'training' and eventually to 'postprocessing'. For example, using the training configuration and analysis result from the previous examples, the initial blackboard state could be as follows:

```
phase: preprocessing
training_configuration:
    dataset : census_income.csv
    task : ...
analysis_result:
    samples : 48000
    features : ...
```

The blackboard and the reasoner component form together the *controller* module. The controller administers the Meta AutoML training process. It is responsible to advance the Meta AutoML training phase when the reasoner has no more rules to consider. During each phase, the reasoner will assess the *rule base* with the current blackboard state and execute matching rules. The rule base is a collection of all Meta AutoML training strategies supported by a Meta AutoML platform. A training strategy is composed of a condition and a collection of actions to perform if the condition matches. A training strategy is associated with one Meta AutoML training phase (see section III). For example, the definition of the top-3 strategy could be as follows:

```
if
phase == 'training' and
length(training_configuration.autoMl_
solutions_activated) > 3

then
do_top_3_training()
```

In this example, the condition for the top-3 strategy is that the Meta AutoML training phase is equal to 'training' and there are more than three AutoML solutions activated in the training configuration. If this is the case, the controller will execute the do_top_3_training function. During which, the controller instructs the *AutoML solutions* to begin the first training session. This initial training will use only 10% of the sample size, 10% of the max runtime and all activated AutoML solutions. For example, using the blackboard state from above, the *action to perform* by the top-3 strategy for the initial training could be represented as follows:

```
action : training
dataset : census_income.csv
task : tabular_classification
autoML_solutions_activated : [FLAML,
Autogluon, Autosklearn, TPOT, MLJAR,
AutoKeras, Pycaret, EvalML]
sample_size : 10%
max_runtime : 6
```

This action instructs the AutoML solution modules (FLAML, Autogluon, Autosklearn, TPOT, MLJAR, AutoKeras, Pycaret, EvalML) to perform tabular classification training, using 10% of the samples from the Census Income dataset, and a maximum runtime of 6 minutes.

During the training process, the AutoML solution modules notify the blackboard about their current *training state*. Each AutoML solution module represents the implementation of one AutoML solution used by the Meta AutoML platform. The training state represents information about the progression of the AutoML training process. For example, the information provided by the AutoML solution Autokeras during the initial training could be represented as follows:

```
AutoKeras:
    remaining_training_time : 2
    best_model_performance : 0.8
```

In this example, the remaining training time is 2 minutes, and the highest ML model performance is 80%. The ML model performance is measured using a standard ML metric for the current ML task. For example, the metric for tabular classification could be accuracy. This training state is updated throughout the AutoML solution training.

When the initial training for the top-3 strategy concludes, the controller evaluates the training state from all AutoML solutions and continues with the second training session using the complete sample set, the remaining 90% of the max runtime and the top-3 AutoML solutions from the preliminary training. For example, the final training state of the 8 AutoML solutions could be as follows:

```
FLAML:
    remaining_training_time : 0
    best_model_performance : 0.77
Autogluon:
    remaining_training_time : 0
    best_model_performance : 0.78
Autosklearn:
    remaining_training_time : 0
    best_model_performance : 0.87
TPOT:
    remaining_training_time : 0
    best_model_performance : 0.87
MLJAR:
    remaining_training_time : 0
    best_model_performance : 0.88
AutoKeras:
    remaining_training_time : 0
    best_model_performance : 0.92
Pycaret:
    remaining_training_time : 0
    best_model_performance : 0.95
EvalML:
    remaining_training_time : 0
    best_model_performance : 0.95
```

All AutoML solutions finished the preliminary training indicated by the remaining training time of 0. The controller based on the top-3 strategy decides that the best-performing AutoML solutions by best model performance are: AutoKeras, Pycaret and EvalML. The controller instructs these three AutoML solutions on further actions to perform. In this case, the action is to begin the second training using the remaining time and complete sample set. For example, the action to perform the second training could be as defined as follows:

```
action : training
dataset : census_income.csv
task : tabular_classification
autoML_solutions_activated : [AutoKeras,
Pycaret, EvalML]
sample_size : 1.0
max_runtime : 54
```

This action instructs the AutoML solutions AutoKeras, Pycaret and EvalML to perform a tabular classification training using the Census Income dataset with all the samples and a maximum runtime of 54 min.

As described above, the AutoML solution modules perform the training session and update their training state on the blackboard accordingly. When all three AutoML solutions conclude their training, the top-3 strategy ends. When the controller assesses that no more rules can be applied during this training, the Meta AutoML training concludes.

In the next section, we introduce the prototypical implementation of the rule-based training strategy within the OMA-ML platform.

V. Prototypical Implementation

The rule-based training strategy concept was implemented as a proof-of-concept in the Meta AutoML platform OMA-ML. OMA-ML is an open-source[5] platform providing users with a web application-based interface to configure the Meta AutoML training. Fig. 2 displays a screenshot of the training wizard used to configure the Meta AutoML training.

The training wizard displays the required and optional parameters for a Meta AutoML training. The minimal configuration OMA-ML requires comprises of the ML task (tabular classification), the target column (‘class’) and a maximum runtime (60 minutes).

For expert users, OMA-ML allows in-depth parametrization of the Meta AutoML training using optional parameters. The user may activate or deactivate individual ML libraries and associated AutoML solutions. For example, in Fig. 2 the following AutoML solutions are activated: Autogluon, Autosklearn, EvalML, FLAML, MLJAR, TPOT, Pycaret and Autokeras. Additionally, OMA-ML displays a collection of training strategies compatible with the current training configuration. For example, the top-3 strategy is available since more than 3 AutoML solutions are activated.

OMA-ML uses an ML ontology to display individual AutoML solution parameters. These are parameters AutoML solutions provide to fine-tune their search process. When the user clicks on the finish button, the Meta AutoML training begins.

The OMA-ML web application is developed in C# with the Blazor web framework[6]. OMA-ML follows a 3-layer architecture design. See Fig. 3 for an overview of the software architecture and technologies used.

The presentation layer is connected to the logic layer using a gRPC[7] interface. The logic layer is developed in Python based on the blackboard architecture. The Controller component uses the library rule-engine[8] to reason over the rule base. The library rule-engine provides a grammar to create general-purpose rule objects from a logical expression that can be applied to arbitrary objects. The Meta AutoML training strategies conditions are modelled using this grammar. The training strategies are implemented within a rule base

Enabled strategies: Ignore redundant samples, Split large datasets, ✓ Top 3 Models, Multi Fidelity

Parameter available for all AutoML solutions

metric: accuracy

Fig. 2. Screenshot of the OMA-ML training configuration wizard

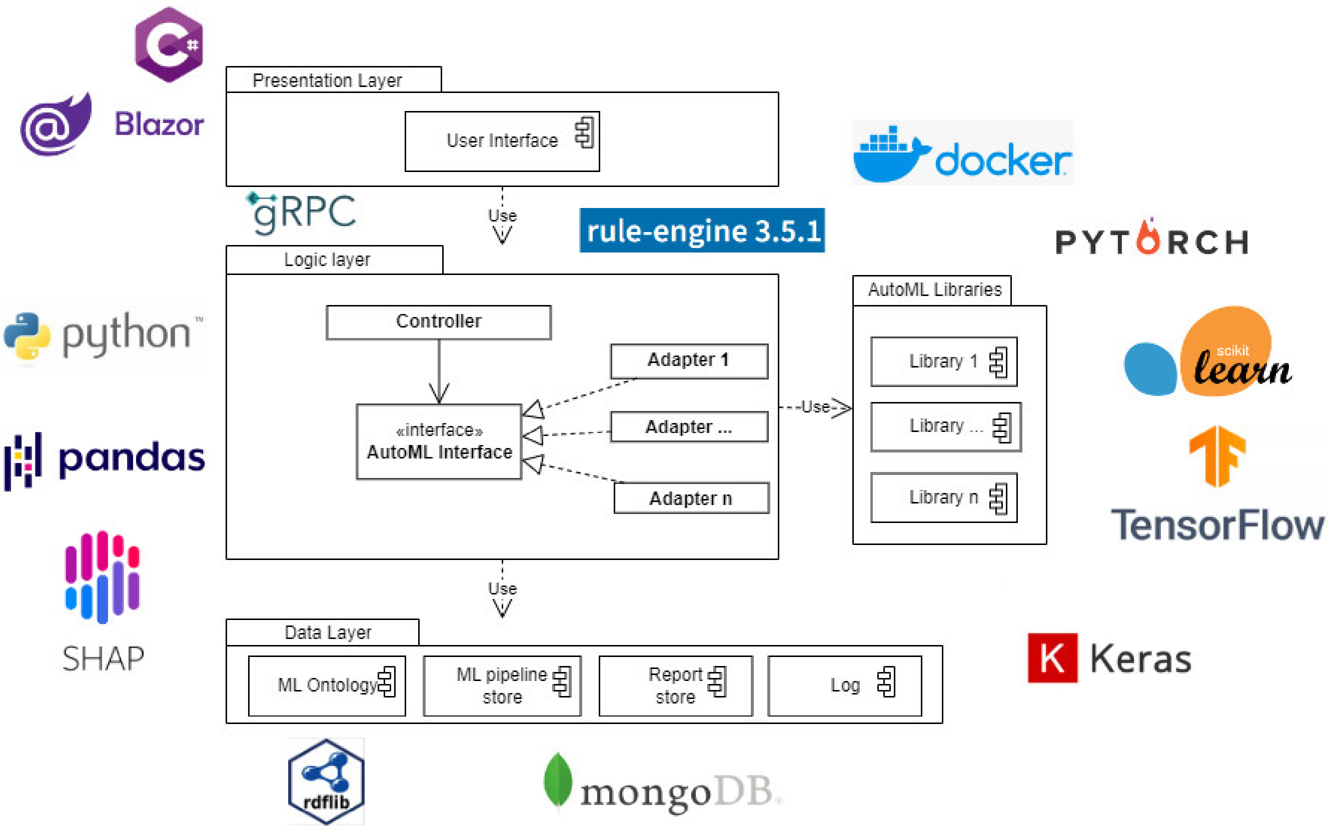

Fig. 3. OMA-ML software architecture and technologies (adapted from [6])

component. For example, the top-3 strategy implementation is as follows:

```
self.register_rule(
'training.top_3',
        Rule("phase == 'training'" and
        training_configuration['activated
        _auto_ml_solution'].length > 3,
        context=training_context),
        self.do_top_3
)
```

The register_rule functionality of the rule base permits rules to be registered. This method requires as parameters, the name, a condition in the rule-engine grammar and a function to execute when the condition matches. In the example above the top-3 strategy has:

- the name: 'training.top_3';
- the condition: the phase is training and the sum of all activated AutoML solutions must be greater than three;
- the function: 'do_top_3'.

Using the register_rule functionality, new training strategies can easily be added to the existing rule base. For example, the whole implementation of the top-3 strategy requires less than 50 lines of code. During a Meta AutoML training, the controller evaluates the rule base for any rule matching the state of the blackboard. Any matching rule invokes their respective function and interacts with the AutoML adapters. The AutoML adapters use the AutoML solutions (e.g. AutoKeras). They are based on the adapter-pattern and plug into the Controller, easing integration.

The logic layer uses the data layer to connect to various data stores. The ML ontology is located here and loaded using the Pyhton library RDFlib[9] into the Controller. SPARQL queries are used to interact with the ML ontology. Additionally, the document database MongoDB stores data generated by the Meta AutoML process. The ML pipelines generated by the AutoML adapters are saved in the ML pipeline store. Finally, any logs generated during the Meta AutoML training process are stored in a log storage.

VI. Evaluation

This section evaluates the concept and implementation of the rule-based training strategies within the Meta AutoML platform OMA-ML. By applying training strategies to Meta AutoML we aim to significantly reduce the energy consumption (efficiency) of the Meta AutoML process while avoiding a significant reduction in ML model performance (effectiveness). To evaluate these goals we compare two measures of quality:

- *Best ML model accuracy*: The highest accuracy of all the AutoML solutions found ML models;
- *Training CO_2-eq*: The sum of all the CO_2 equivalence produced by the AutoML solutions training.

To measure the CO_2 equivalence, the Python library codecarbon[10] was used. Codecarbon measures the amount of CO_2-eq emitted by the individual AutoML solutions. Codecarbon tracks the power consumption of the underlying computational infrastructure, measured in kilowatt-hours. This value is multiplied by the carbon intensity of the electricity consumed for the computation. The carbon intensity is calculated as a weighted average of the emissions of the different energy sources used to generate the used electricity (e.g. natural gas, coal, wind) in the respective country[11], here Germany.

During the course of the experiment, five datasets from the open-source AutoML benchmark by Gijsbers et al. [52] were used:

- *adult*[12]: This dataset contains samples of more than 48,000 individuals and their socioeconomic properties extracted from the Census database in 1994. This dataset is a binary classification and aims to predict if an individual earns over 50k a year;
- *amazon*[13]: This dataset contains samples of more than 32,000 resource requests with the associated Amazon employee meta information from 2010 and 2011. This dataset is a binary classification and aims to predict if access to a resource was approved;
- *sylvine*[14]: This dataset contains more than 5,000 numerical samples; there is no definition of the origin of the data of this dataset. This dataset is a binary classification;
- *credit-g* [15]: This dataset contains samples of 1,000 individuals, their economic properties and loan requests. This dataset is a binary classification and aims to predict the credit score of an individual;
- *kc1*[16]: This dataset contains samples of more than 2,000 software modules and their quality metrics. This dataset is a binary classification and aims to predict if a software module has a defect.

OMA-ML performed two training sessions with each dataset. During the first training session, no optimization strategy was activated. For the second training session, the top-3 optimization strategy was activated. After every training session, the best ML model performance by accuracy [53] was logged as well as the AutoML solution which produced this ML model. Finally, the total CO_2-eq was calculated by taking the total of all AutoML solutions training CO_2-eq.

The training sessions were performed on an AMD Ryzen 7 5800H @ 3.20 GHz CPU with 64GB of RAM. A result summary of all training sessions can be seen in Table II.

The Meta AutoML training sessions applying the top-3 optimization all display a significant saving in CO_2-eq. The difference ranges from 59% with the adult dataset to 70% with the sylvine dataset. The performance of the best ML model

TABLE II
EVALUATION SUMMARY

	Meta AutoML, no optimization			Meta AutoML, top-3 optimization			Comparision	
Dataset	**AutoML solution**	**accuracy**	**CO_2-eq [g]**	**AutoML solution**	**accuracy**	**CO_2-eq [g]**	**Difference accuracy**	**Saving CO_2-eq**
adult	FLAML	0.88	53.5	FLAML	0.87	22.1	-0.01	59%
amazon	Autogluon	0.95	45.8	Autogluon	0.95	16.6	0.00	64%
sylvine	Autosklearn	0.95	49.96	Autosklearn	0.95	15.0	0.00	70%
credit-g	FLAML	0.78	36.2	MLJAR	0.77	11.7	-0.01	68%
kc1	Autogluon	0.87	37.0	Autogluon	0.87	13.1	0.00	65%

is equal to or at worst one percentage point lower compared to the Meta AutoML training sessions without optimization. Additionally, the best AutoML solution is the same in both training sessions for four out of the five datasets. The only exception being the dataset credit-g, the best AutoML solution is FLAML in the training without optimization and MLJAR during the training with optimization. While FLAML did not produce the best ML model during the optimized training session, it was one of three AutoML solutions selected by the top-3 strategy to train a model in the second training session.

By using the top-3 training strategy it is possible to significantly (up to 70%) reduce the amount of CO_2-eq for a training session. While also achieving similar or slightly (1 percentage point) reduced results in the performance of the best ML model, the goals of this study can been regarded as achieved.

VII. Conclusion and Future Work

Meta AutoML provides users with or without data science knowledge access to automatically generated ML models. However, there is the major issue of massive computation power requirements for Meta AutoML. The concept of rule-based training strategies aims to optimize the energy efficiency and ML model effectiveness for Meta AutoML. The contribution of this paper is two fold. Firstly, we presented a survey of 14 AutoML training strategies, classifying them by their function category, ML phase, advantage and implementation feasibility for Meta AutoML. Most training strategies aim to optimize the dataset and only 3 strategies focus on the ML model fitting process. Twelve training strategies can be fully applied to the Meta AutoML process. The exception being the feature extraction and early-stopping strategy. While different approaches exist to automate feature extraction, only a domain expert can decide if the extracted features are relevant. Early stopping requires process information and an interface from the AutoML solutions to allow interaction by a Meta AutoML platform. Both of these are not supported by most AutoML solutions, making implementation of early stopping challenging. While AutoML solutions implement various training strategies already, on the Meta AutoML level however there has been no research on optimization using training strategies. The second contribution of this paper addresses this issue.

We presented the novel concept of rule-based training strategies. This concept uses the blackboard architecture to implement training strategies for Meta AutoML. This concept aims to significantly increase the efficiency of Meta AutoML by reducing the required computation power while not significantly reducing the best ML model performance. The Meta AutoML platform OMA-ML was used to implement a proof-of-concept. We evaluated the implementation by using the training strategy top-3. During the evaluation, five binary classification datasets were used. Using each dataset, two experiments were performed, one without an optimization strategy and one with the top-3 optimization strategy. Applying the top-3 optimization led to a saving of up to 70% CO_2-eq, with the best ML model having identical or slightly reduced performance (one percentage point).

The results show that rule-based training strategies can improve the Meta AutoML training efficiency significantly with only a slight reduction in ML model effectiveness. However, further evaluation is required. In future work, we aim to implement additional training strategies and perform extensive benchmark testing using a variety of ML tasks (e.g. regression, time series forecasting etc.) and various dataset types (e.g. texts, images, time series etc.).

***Abstract*—The paper presents a novel approach to investigating adversarial attacks on machine learning classification models operating on tabular data. The employed method involves using diagnostic parameters calculated on an approximated representation of a model under attack and analyzing differences in these diagnostic parameters over time. The hypothesis researched by the authors is that adversarial attack techniques, even if attempting a low-profile modification of input data, influence those diagnostic attributes in a statistically significant way. Thus, changes in diagnostic attributes can be used for detecting attack events. Three attack approaches on real-world datasets were investigated. The experiments confirm the approach as a promising technique to be further developed for detecting adversarial attacks.**

I. Introduction

THE widespread adoption of machine learning (ML) algorithms in various fields, such as healthcare, finance, transportation, and industry [1], has revolutionized the way we process and analyze vast amounts of data [2]. However, the rapid proliferation of ML applications has also raised operational security concerns, as malicious actors increasingly target these models with adversarial attacks to undermine their reliability and compromise their performance [3]. These attacks pose a significant threat to the integrity and trustworthiness of ML models, necessitating the development of robust detection and mitigation techniques to protect the systems from potential threats [4], [5].

The motivation for our work is rooted in the observed disparity between machine learning implementations, which primarily emphasize traditional quality characteristics, and the security-focused mindset held by stakeholders responsible for operational security in businesses that incorporate machine learning solutions reinforced by real-world examples of adversarial machine learning attacks [6]. This gap highlights the need for a more holistic approach to designing and deploying machine learning systems, taking into account not only their performance but also their resilience to adversarial attacks and other security challenges [7], [8].

Furthermore, we have found that the field of rough sets theory (RST) has not been thoroughly explored when it comes to its capability in attack detection. One of defining characteristics of RST is that it can be used to handle uncertainty and vagueness of data [9]. By approximating the decision boundaries of a classifier model, rough sets can be used to identify regions in the input space where adversarial perturbations are likely to occur [10]. By monitoring these regions, unusual deviations or patterns in input data can be flagged as potential adversarial attacks. This approach, if proved to be working, can not only provide a robust mechanism for detecting adversarial examples but also offer insights into the underlying structure of the data and its susceptibility to manipulations, thereby informing the design of more secure machine learning models. In this work, we want to test the usefulness of RST methods in practical security applications in the domain of adversarial machine learning prevention.

The end goal of our work is to create a robust black-box-based method that can be utilized in real-world scenarios for the detection and prevention of misclassification adversarial attacks on machine learning models, increasing the safety and trustworthiness of machine learning applications in everyday scenarios.

II. Related Work

A. Advesarial Machine Learning (AML)

Starting with the pioneering works of Szegedy et al. [11] and Goodfellow et al. [12], the topic of adversarial machine learning has entered the spotlight of the research community. Those works demonstrated that it is possible to influence the operation of machine learning models, most notably image-based classifiers, by adding limited amplitude (undetectable to the human eye) perturbances to original images, causing spectacular cases of misclassification of images.

Since the concept's inception, it has left the walls of academia, and real-world adversarial machine-learning attacks have been proven possible in various areas [13], [14].

There are several possible ways to classify the diverse world of AML attacks [3], [8], [15]. The classification of AML attacks is based on a different axis:

- Knowledge-based classification — distinguishes attacks based on the amount of knowledge an attacker has about the target model.
- Capability-Based Classification — considers the capabilities of the attacker and the stage of the machine learning pipeline targeted.

- Goal-Based Classification — differentiates attacks based on the attacker's objectives.

A point of note is that most of the published papers refer to attacks and defenses on image data [15]. Only in recent years, the interest in attacks and defense on tabular data processing models has increased [16].

B. AML detection

Complementary to works dedicated to increasing the robustness of models against adversarial machine learning, significant effort is put into the detection of attacks against ML models. These techniques are primarily designed to identify inputs that have been modified with the intent of misleading a machine-learning model.

Some detection strategies attempt to detect adversarial examples by identifying instances that significantly deviate from the distribution of normal instances. An example of such a technique, specific for adversarial attacks on image classification models, has been described in [17]. The detection technique presented therein hangs on the realization that adversarial images place abnormal emphasis on the lower-ranked principal components from principal component analysis (PCA), which allows adversarial examples to stand out after PCA whitening. Most recently, salience-based methods have been used to analyze adversarial examples for NLP models — based on an observation that salience tokens have a direct correlation with adversarial perturbations [18].

Another approach to the detection of adversarial perturbations is to train a separate classifier used to classify inputs as normal or adversarial. In [19], such an approach was implemented using neural network classifiers. The method has been proven to be useful for the detection of small adversarial perturbances in images (below the human-detection threshold). This auxiliary classifier can be integrated with the main model and can provide a reasonable level of adversarial threat detection [20].

An interesting approach for the detection of perturbed images has been presented in [21], where a method has been presented that detects adversarial examples by comparing the output of a discriminator of a generative adversarial network (GAN) trained on the dataset — with the realization that adversarial examples are scored lower by the discriminator part of the GAN.

III. Notions and definitions

A. Adversarial attack types used

In this work, we have tested our attack detection method against three known attack techniques: HopSkipJump, PermuteAttack, and ZOO. These attack methods were chosen based on three criteria: a thorough description of the attack methodology in an academic paper, its applicability to attacks on classifier models operating on tabular data, and the availability of its source code. While the choice of attack methods to be used in our work was arbitrary, it was considered to be proper for the preliminary attack detection method verification presented in this work.

1) HopSkipJump Attack: The HopSkipJump attack, also known as the Decision-Based Boundary attack, is an adversarial attack on machine learning models designed to generate adversarial examples by directly manipulating the input data to cause misclassifications while minimizing the perturbation to the original input [22].

It is an iterative, decision-based attack, meaning that it only requires access to the model's output decisions (e.g., classification labels) rather than full access to the model's internal workings or gradients. The attack algorithm consists of three main steps:

- Hop: Initialization of the adversarial example by searching for a starting point near the decision boundary of the model.
- Skip: Binary search along the line connecting the original input and the initialized adversarial example to find a point that lies closer to the decision boundary.
- Jump: Gradient-free optimization to further perturb the adversarial example while keeping it within a predefined perturbation budget.

2) Permute Attack: PermuteAttack, described in [23], is a counterfactual example generation method capable of handling tabular data including discrete and categorical variables. The method is based on gradient-free optimization genetic algorithm, that permutes randomly selected features making sure that resulting values are within ranges that are not outstanding for a given data set. As a result, it produces adversarial data points that are modified, as compared to the original data points, in a way that can elude some anomaly-detecting methods. Resulting adversarial examples can be also used for the analysis of the robustness of the attacked model.

3) Zeroth-Order Optimization (ZOO) Attack: The Zeroth Order Optimization (ZOO) attack is a black-box adversarial attack proposed by Chen et al. [24] The key idea behind the ZOO attack is to approximate gradients of the target model using zeroth-order (derivative-free) optimization methods, allowing the attacker to generate adversarial examples without direct access to the model's gradients or architecture. The ZOO attack steps:

- Approximate the gradients using zeroth-order optimization, such as the coordinate-wise finite-difference method or the spherical coordinate-based method.
- Compute the adversarial perturbation using the approximated gradients.
- Apply the perturbation to the original input, ensuring that the adversarial example remains within a predefined perturbation budget.

B. Diagnostic attributes

The whole workflow connected with model approximation and diagnostic attributes was originally described in work [25]. Here we just shortly call the main idea. This approach focuses on building a surrogate model for origin model predictions using the rough sets theory [26]. Based on discretized input data set we construct the ensemble of approximate reducts. The next step is to create a neighborhood for every instance in the diagnosed data set as a set of instances from the train data set that is similar to a given instance in the diagnosed data set. The defined neighborhood is a basis for calculating the diagnostic attributes listed below.

- Target consistency with approximations in neighborhood — measuring the consistency of the target of the diagnosed instance with the approximations from the neighborhood of this instance.
- Prediction consistency with targets in the neighborhood — measuring the consistency of the prediction of the diagnosed instance with the targets from the neighborhood of this instance.
- Target consistency with targets in neighborhood — measuring the consistency of the target of the diagnosed instance with the targets from the neighborhood of this instance.
- Targets and approximations inconsistency in neighborhood — measuring the inconsistency of targets and approximations in the neighborhood of diagnosed instance.
- Targets diversity in the neighborhood — measuring the diversity of targets in the neighborhood of diagnosed instance in comparison to the diversity of targets calculated on the whole diagnosed data set.
- Approximations diversity in the neighborhood — measuring the diversity of approximations in the neighborhood of diagnosed instance in comparison to the diversity of approximations calculated on the whole diagnosed data set.
- Uncertainty — the measure of uncertainty of prediction based on the approximations.
- Neighborhood size — the number of instances in the neighborhood of diagnosed instance.

We used the Kolmogorov-Smirnov (KS) test [27] to compare the distribution of diagnostic attributes. Additionally, the Wilcox signed rank test [28] for paired two samples was conducted. The first test compares the distance between distributions while the second measure only changes in the location parameter.

IV. Experiments and results

To evaluate proposed diagnostic attributes in attack detection we prepare benchmark data sets. From OpenML[1] we gathered 22 data sets with classification task. Each data set was split into train and diagnosed parts assuming that the diagnosed data set should consist of at least 100 observations. A list of data sets is placed in the appendix in Table IV.

For each data set, we fitted a logistic regression model, support vector machine, and XGBoost. Afterward, three adversarial attacks were conducted at the diagnosed part of each data set.

Figure 1 shows the distribution of balanced accuracy measured at the diagnosed data set for the origin (base) model and how it changed after the given attack.

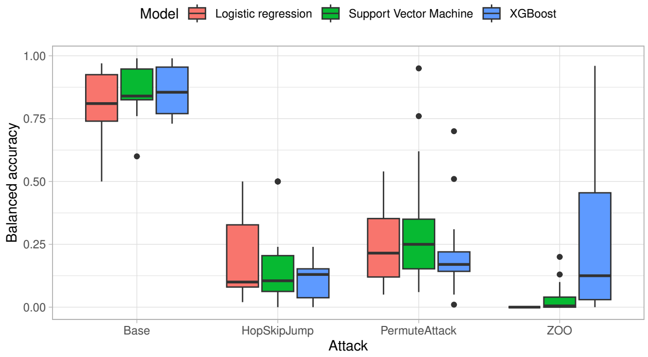

Fig. 1. Distribution of balanced accuracy in analyzed datasets across the type of model and attack

It can be seen that post-attack models in most cases result in worse performance than the base model. The median balanced accuracy for all base models is above 0.8 while in the case of the HopSkipJump attack, it is around 0.1. For Permute attack median value is slightly higher and equal to around 0.2. In the ZOO attack, these values are close to 0, but high dispersion of results for the XGBoost model can be observed.

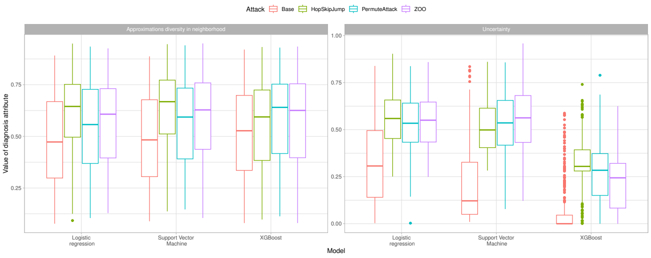

Fig. 2. Distribution of selected diagnostic attributes for the spambase data set

We calculated diagnostic attributes for each analyzed data set and attack, resulting in 264 tables with results (22 data sets × 3 model types × 4 attack variants (no attack + 3 others)). The distribution of two diagnostic attributes for the selected data set (spambase) is presented in figure 2. We used the Kolmogorov-Smirnov test to verify the null hypothesis that there is no difference between the distribution of the given diagnostic attribute before and after the attack. We also used the Wilcoxon test to examine the hypothesis that the median of differences between the paired attributes is zero. Both of these tests indicates whether there is a significant difference between diagnostic attribute before and after the attack. We summarize this data by calculating the fraction of cases in which the null hypothesis of a given statistical test was rejected at significance level $\alpha = 0.05$. Results are presented at three levels of aggregation — effectiveness of detecting attacks at the type of attack (table I), the type of model (table II), and diagnostic attribute (table III).

In the case of the HopSkipJump attack KS test rejected the null hypothesis in 88% cases while the Wilcox test in 95%.

[1] https://www.openml.org/

TABLE I
PERCENTAGE OF DETECTED DIFFERENCES BETWEEN DIAGNOSTIC ATTRIBUTES AT ATTACK LEVEL

Attack type	Kolmogorov-Smirnov	Wilcox
HopSkipJump	88.28	94.91
PermuteAttack	79.36	94.63
ZOO	81.25	94.83

The Permute attack and ZOO attack were slightly harder to detect — the effectiveness of the Kolmogorov-Smirnov test is 79% and 81% respectively. For the Wilcox test, values are close to 95%.

TABLE II
PERCENTAGE OF DETECTED DIFFERENCES BETWEEN DIAGNOSTIC ATTRIBUTES AT MODEL LEVEL

Model type	Kolmogorov-Smirnov	Wilcox
Logistic regression	84.47	92.59
Support Vector Machine	85.61	94.24
XGBoost	78.52	97.75

At the model type level, we detected 79% of attacks conducted on the XGBoost model, almost 84% on logistic regression, and 86% on SVM using the Kolmogorov-Smirnov test. With Wilcox test success rate is equal to 93% for Logistic regression, 94% for SVM, and 98% for the XGBoost model.

TABLE III
PERCENTAGE OF DETECTED DIFFERENCES BETWEEN DIAGNOSTIC ATTRIBUTES AT ATTRIBUTE LEVEL

Diagnostic attribute	Kolmogorov-Smirnov	Wilcox
Approximations diversity in neighborhood	87.76	98.96
Neighborhood size	72.45	96.35
Prediction consistency with targets in neighborhood	81.12	83.85
Target consistency with approximations in neighborhood	90.31	98.44
Target consistency with targets in neighborhood	87.24	95.83
Targets and approximations inconsistency in neighborhood	60.71	89.58
Targets diversity in neighborhood	88.27	96.35
Uncertainty	95.41	98.95

Another issue was the verification of diagnosis attributes effectiveness in attack detection. According to the Kolmogorov-Smirnov test, the highest detection rate was obtained for uncertainty (95%), target consistency with approximations in the neighborhood (90%), and targets diversity in the neighborhood (88%). In the case of the Wilcox test, we obtain similar high results for three attributes: uncertainty, approximations diversity in the neighborhood, and target consistency with approximations in the neighborhood.

V. CONCLUSIONS

In this paper, we have presented a novel approach to detecting adversarial attacks on machine learning classification models operating on tabular data. By analyzing differences in diagnostic parameters calculated on an approximated representation of the model under attack, we demonstrate that adversarial attacks can be detected in a statistically significant manner. Experiments performed on real-world datasets confirm the effectiveness of our method and its potential for further development as a detection technique for adversarial attacks.

A. Limitations

The method developed and presented in this paper has several limitations, which will be tackled in future works. Most notably:

- The robustness of the method to attack variability has not been subject to wider assessment — for the initial method validation a sample of three attacks was chosen, but it does not cover the range of currently known and published attacks on models designed for processing of tabular data.
- The method assumes that the model being monitored is replicable with a rough-sets-based method presented in previous work. In this paper, it was verified on three classification models, with the assumption that the underlying model replication method provides a layer of abstraction that is strong enough to consider our method model-agnostic. Verification of this hypothesis has not been a subject of this work.
- The computational efficiency optimization and scalability have not been, by design, within the scope o the work presented herein.
- The method has not been benchmarked against available AML detection techniques.

B. Future Work

Future work will be streamlined into three distinctive work streams.

First, we will broaden the range of scenarios on which the method is tested. The method will be verified on a larger representation of known attack methods and exploration of their attack parameter space. Special attention will be given to methods that attempt low-profile adversarial attacks, attempting to pass under the detection threshold of traditional monitoring tools. We also plan to compare our approach with other methods which aim to detect AML. Furthermore, we will verify the assumption of the method being model-agnostic, by checking how its effectiveness changes when used on a different original model being attacked.

The second workstream will be devoted to new features of the method:

- Concept drift detection - examining differences in diagnostic attributes behavior between changes in data resulting from malicious attacks and different types of concept drifts - both stochastic and deterministic in nature
- Exploration of possibility for new diagnostic attributes definition. Specifically - looking for diagnostic attributes that increase specificity and sensitivity of attack detection heuristics

In the third work stream, we intend to analyze the scalability of the method and prepare a thorough comparison of the presented attack detection method with available alternative adversarial attack detection methods.

We will also consider extending the set of diagnostic attributes with information obtained on the basis of approximation of diagnosed models with white-box models (e.g. rule-based models [29])

***Abstract*—The research aims to explore the effects of the war in Ukraine in 2022 on social media and brand management, as well as the ways in which companies and users engage with each other on social media platforms. The study examines the strategies used by companies to engage with users on social media during the war, the role of social media in shaping public perceptions and responses to the war, and the impact of social media engagement on companies' relationships with users and consumers. The study employs a survey research method to collect data from a sample of Polish individuals using structured questionnaires. The results of the study provide insight into the changes in social media and brand management in response to the war and the ways in which companies and users engaged with each other.**

I. Introduction

IN RECENT years, social media has become an increasingly important platform for brands to reach and engage with their customers. With the proliferation of social media networks and the widespread use of mobile devices, consumers are now able to access and interact with brands in real-time, anywhere, and anytime. This has led to a shift in the way that brands manage their online presence and reputation, as well as the way that they communicate and interact with their customers.

In 2022, the outbreak of the war in Ukraine caused a significant shift in social media and brand management. By the end of February 2022, companies abruptly altered the content they were posting on social media. [14]. Companies that had not previously shared their social or political views on social media were required to take a side in the conflict - either the side of Ukraine or the side of the Russian state, which initiated the war [19]. The lack of involvement of a brand in helping Ukraine was often criticized by social media users, who had previously been willing to buy products from the company. During the war in Ukraine, social media users all over the world identified with the people affected by the war in Ukraine and demanded that brands withdraw from the Russian market.

In times of war, more and more social media users began to believe that companies should openly address social and political issues and share their own views on the actions of the Russian state. The start of the war in Ukraine forced many companies to change the way they conducted their social media activities [1]. The war conflict required companies to adopt a new strategy and change the way they communicated with social media users, where consumer views of a particular brand are most often expressed. Numerous companies decided to limit their social media activity and give up their standard Internet activity. Many of them showed immediate help to Ukraine, and expressed their support for the eastern community with posts published on their social media. Companies began to organize aid campaigns and money collections, which they informed about on their social media. Those who had not previously published posts on social media were now forced to do so in order to express their support for Ukraine and to inform about the actions taken in this regard. The start of the war in Ukraine led to a change in the way brands communicated with their customers and the way they conducted their social media activities [23].

According to Wirtualnemedia.pl, in the first days of the war conflict in Ukraine, about 900,000 posts appeared on social media calling for help for the Eastern neighbors. The majority of these publications appeared on the social networking site Facebook - about 43%, and on Twitter - about 38% [26]. With the start of the war, social media was dominated by posts related to help for the Ukraine. After the Russian attack on Ukraine, a significant decrease in the number of ads published on Facebook was observed - on February 28, 2022, the number of ads on this social networking site decreased by 73% compared to the previous highest result in that month [25]. At the end of February 2022, ads on social media were mainly suspended, but posts that had been planned several months earlier and had to be published by brands on the internet could be still observed. These were posts from companies that had already been contracted in the past and had to be completed according to the company's regulations. These posts included the results of organized contests, planned events, or webinars [15].

There were also companies that completely suspended their social media business during the war crisis. These actions mainly resulted from the concern of brands about the reactions of consumers to the company's further actions on the internet during the war in Ukraine. Some companies remained active on their social media platforms but chose to disable comments under their posts. Such behavior did not win the sympathy of consumers. These actions were perceived by social media users as insincere, and silence was treated as an attempt to mask the brand's opinion on the war in Ukraine. The situation changed at the end of March 2022, when companies began to publish posts on social media again, but they were mainly related to the company's involvement in activities supporting Ukraine. The war in Ukraine had a significant impact on the way brands communicated with their customers and changed their social media activities.

The war in Ukraine in 2022 had significant impacts on social media and brand management, as well as on how companies and users engaged with each other on social media platforms [21]. In this research, we will explore how social media and brand management changed in response to the war, how companies' social media posts and strategies evolved during this time, and how users' attitudes towards these efforts were impacted. Additionally, we will examine the role that social media played in shaping public perceptions and responses to the war and how companies' social media engagement during this time affected their relationships with users and consumers. The study relies on data from social media platforms such as Facebook, Instagram, and Twitter [13].

We have formulated the following research questions: 1. How did social media and brand management change in response to the war in Ukraine in 2022? 2. How did companies' social media posts change during the war in Ukraine in 2022? 3. How did users' attitudes toward companies' social media engagement change during the war in Ukraine in 2022?

II. Method

For this study, we used literature review and survey research. Survey research is a method of collecting information from a sample of individuals using structured questionnaires or interviews. In order to verify consumers' opinions about the actions taken by companies on social media during the war crisis in Ukraine, we decided to conduct a study among the Polish community. This study took the form of a questionnaire survey in Polish language and aimed to identify consumers' feelings and observations about daily brand image management compared to the one during the war crisis, which affected Ukrainian community in 2022. The survey questionnaire was prepared using Google Forms software, and made available from March to April 2022. The survey was fully anonymous, and anyone interested could fill it out. In order to gather as many responses as possible, we made the questionnaire available on social media, especially on themed groups on the Facebook social networking site. The aim of the survey was to conduct a public opinion review on the perception of companies on social media and the activities of companies on social media during the war in Ukraine.

The study was conducted in accordance with the Declaration of Helsinki and approved by the Faculty Research Ethics Committee of the University of Economics in Katowice, Poland; Approval code: 135890, and date: April 3, 2022. The informed consent statement of each participant was collected at the beginning of the survey. The statement was following: "By taking part in this study, you are agreeing to allow us to collect data about managing the brand image in social media during the war crisis in Ukraine. This data will be used to help us better understand brand management during this crisis and will be kept strictly confidential. You may withdraw from the study at any time by contacting us."

In the conducted survey, 150 respondents participated. The questionnaire was filled out by both women and men. The majority of the surveyed were women, 114 of them, which is 76% of the people. The questionnaire was published on social media platforms, which influenced a large percentage of the surveyed being young - they were mostly school or university students. The number of respondents aged under 18 and over 56 was minimal. The largest number of people who participated in the survey were those aged 18 to 26 - there were 85.3% of them, 128 respondents. The next largest group of people participating in the survey were those in the age range of 27-35 (16 respondents). Three people aged 36-55, two people under 18 - 1.3%, and one person over 56.

III. Results

A. Brands' activities in social media during the Ukraine war crisis

The onset of the war crisis in Ukraine changed the way brands were managed on social media. In the early days of the war, companies were constantly seeking new ways to build their brand image on social media. They tried to help their eastern neighbors and kept the public informed about it on social media. Companies chose different ways to support Ukraine. Brands supported refugees, organized financial and material collections, fought against disinformation, and used social media profiles as a place to publish reliable information from around the world. Some companies also decided to withdraw Russian products from their own range, suspend production, or ultimately cease operations in Russia [20]. As the war in Ukraine began, companies from various industries began to engage in assistance for their eastern neighbors. Brands on social media platforms called for support for refugees and documented their efforts to help Ukraine. Similar strategies were adopted by well-known celebrities and influencers, who were often associated with a particular brand as a result of a campaign or promotion of goods. While helping their eastern neighbors, companies did not forget about keeping the good reputation of their brand [22]. An important step during the war crisis in Ukraine was the fight against disinformation. Many companies decided to run a certain type of news service on their social media platforms [5]. This activity was intended to eliminate fake news and reduce panic among people [16]. A new service called VPolshchi.pl was created by Virtual Poland in response to the onset of the war crisis in Ukraine [24]. The VPolshchi.pl service was intended to correct false information. VPolshchi.pl features current information on the military actions being carried out in Ukraine and the most important news related to the ongoing war. The news in this service are conveyed in Ukrainian and are intended to be helpful to the Ukrainian community. This news focuse on delivering accurate information about the current situation in Ukraine and informing about the organized aid efforts [22].

During the war in Ukraine, a significant number of refugees sought shelter in various countries, including Poland. Both individuals and businesses extended their support to these refugees through financial and material assistance. Companies organized campaigns to collect funds, food, clothing, medical supplies, hygiene products, and children's accessories for their eastern neighbors. Special hashtags and discount codes were created, where the use of such codes resulted in a specified amount of money being donated for the benefit of aiding Ukraine. These campaigns effectively encouraged consumers to participate in helping the refugees. One notable example is Rossmann pharmacy, which actively supported its eastern neighbor since the war's onset. They organized an aid campaign by offering a special -40% coupon for selected products to those who wished to support Ukrainian refugees. The company emphasized that this campaign was not merely a promotion but aimed to raise awareness among consumers. The discount was provided to individuals who would donate the purchased products to the refugees. This coupon was valid until March 8, 2022, and covered various hygiene products and children's accessories. The coupon was exclusively available to users of Rossmann's mobile application and could only be used once. [10].

The coffee roaster KawePale also joined the aid action for Ukraine. A post appeared on its Instagram announcing the campaign organized by the brand. The company created a universal discount code for use in the company's online store [11]. The use of this discount code will contribute 15% of the sales of the company's ordered coffees to the Polish Humanitarian Action. The Polish Humanitarian Action supports both people in Ukraine during the ongoing war and refugees coming to Poland [18]. In order to help Ukraine, companies organized their own collections or transferred funds to the existing ones. Information about the ongoing campaigns was announced on the social media portals of companies and among employees of the network who had the opportunity to get involved in the assistance and show solidarity with Ukraine. Such activities were undertaken by one of the Polish banks - ING Bank Slaski SA. On their Facebook profile, the bank posted information about a fundraising campaign for the Ukrainian community in connection with the ongoing war [7]. In addition, the bank declared that it would not only transfer the collected funds to help Ukraine but also double the amount collected.

InPost, one of the main logistics and transportation operators in Poland, also decided to help the Ukrainian community. The company decided to use its resources to help with the delivery of products collected as part of the aid campaigns organized throughout the country for Ukraine. The brand informed about its decision on the Facebook social media platform [8]. The logistics operator InPost not only organized product deliveries to the eastern border but also participated in numerous charitable collections supporting refugees from Ukraine. The company entered into cooperation with the Polish Red Cross. InPost helped the PCK in transportation of medical equipment, dressings, medicines, hygienic and medical supplies, as well as food products. Together with the Melissa brand, the company developed aid packages that were available for purchase through the InPost mobile application. Those willing to help the Ukrainian community purchased these packages, and the company delivered the goods to those in need in Ukraine. This transport was free of charge and was intended to support the Ukrainian community. In addition, in order to support refugees' lives outside their homeland, the InPost brand created a Ukrainian language version of the mobile application - InPost Mobile [9]. Communication service providers also supported people from Ukraine, initiating the creation of free starters for people from Ukraine. One of the mobile operators that supported Ukraine was the Plus Poland company [22]. The company announced on Twitter information about the organized action related to free starters for every person from Ukraine. This starter included a free package of 500 minutes and 10 GB for 30 days and required the person interested to show their residence card or passport at the sales point [17].

During the Ukraine war crisis, a group of companies emerged, that, after about two months of the war, still did not declare the withdrawal of their brand from the Russian market. This group included Leroy Merlin, Auchan, and Nestle. In April 2022, the opinions of internet users about these companies were critical. These brands were regularly boycotted on the internet, and previous customers of these businesses stopped purchasing products from their offerings [3]. The consequences of not leaving the Russian market, for example, affected the Leroy Merlin brand. Internet users were calling for a continuous boycott of this company on the internet, and social media users formulated a special hashtag #boycottleroymerlin, calling for the cessation of using the services offered by this company. Newer graphics appearing on the internet showed the disapproval of social media users. The Russian market was not abandoned by the Auchan hypermarket chain either. As a result of the companies' approach to the events taking place in Ukraine, a petition was issued by the National Boycott of Leroy Merlin, calling for the dismissal of the Polish management of the Leroy Merlin and Auchan chains [4]. Internet users described the attitude of these companies as cowardly and unworthy of imitation. Strikes were being organized under the stationary stores of the companies, calling for help for the Ukrainian community and the withdrawal of brands from the Russian market. Similarly to the company Leroy Merlin, the company Auchan tried to alleviate the tense situation it is facing. On March 11, 2022, the Polish branch of the company informed the social media site Facebook about the assistance organized for the Ukrainian community and declared that it has no influence on the decision of the parent company regarding the conduct of business in the Russian Federation [2]. In view of the expression of solidarity with

Ukraine, the company hoped for a gradual easing of the consumer boycott. The effect of the message shared online was the opposite, and about twelve thousand negative reactions and comments directed at the Leroy Merlin company were recorded under the published post [13].

B. Survey study group

The respondents were asked about their attention to businesses' online activity during the war crisis in Ukraine and its impact on brand posts on social media. The survey items are presented in tables I to V. Out of the total number of respondents, 63 indicated paying attention to companies' posts during the war, with 36 showing significant interest. On the other hand, 31 respondents stated not paying attention to these posts, and one person explicitly ignored business posts during the war. Additionally, 19 respondents were uncertain and chose the "Difficult to say" response (Table I).

The respondents observed both the actions taken by companies on social media during the war crisis in Ukraine and the changes in their posts. Out of the respondents, 63 rather and 36 definitely noticed a difference in the behavior of brands on social media during the war. Only 32 respondents did not perceive any changes in the companies' social media posts following Russia's aggression against Ukraine. Additionally, 19 respondents found it challenging to provide a clear answer to this question (Table I).

Furthermore, the war in Ukraine led to the emergence of numerous negative consumer opinions about specific brands on the internet. Among the surveyed respondents, 104 individuals confirmed seeing criticism directed at companies on social media in relation to the ongoing war in Ukraine. Conversely, 46 respondents did not notice any negative opinions about companies on the internet concerning the war's impact on the Ukrainian community (Table II).

During the war in Ukraine, respondents noticed negative comments about companies on social media, but they rarely shared their own opinions or comments under brand posts. Only 14 respondents confirmed commenting on content posted by companies on social media regarding the war in Ukraine. On the other hand, 136 respondents stated that they did not express their views on the internet about the actions of companies during the war crisis in Ukraine (Table II).The respondents were also asked to provide their opinions on companies' social media activity during the war in Ukraine. A significant number of respondents (98) believed that brands should not engage in standard activity, while 21 had different views, and 31 marked the response as "Difficult to say" (Table III).

The respondents unanimously agreed that businesses should deliver continuous updates on social media regarding their actions in response to the ongoing war in Ukraine, including providing material and financial aid to refugees. This view was shared by the majority, with 97 respondents expressing this opinion. Additionally, 108 respondents believed that businesses should show support for Ukraine on social media, while only 12 disagreed with this statement (Table III).

The surveyed individuals also believed that businesses should inform on social media about the withdrawal of Russian products from their own offerings - 123 responses of this type were given. According to the respondents, it is also important for companies to involve their brand's consumers in actively helping Ukraine and its refugees. Companies should also pay more attention to comments made under posts by brands on social media, especially during the ongoing crisis in Ukraine (111 responses). As claimed by the respondents, businesses should feel obligated to help the Ukrainian community and appeal for help among the followers gathered on social media networks (96 responses) (Table IV).

The survey respondents showed a keen interest in the support demonstrated by companies on social media for Ukraine. Out of the respondents, 104 individuals expressed their concern and engagement with this issue. The respondents were aligned in their demand for businesses to provide assistance to Ukraine, but not all respondents were discouraged from purchasing products from brands that did not take decisive actions regarding the war in Ukraine. The responses were divided regarding the question of purchasing products from brands that lacked solidarity with Ukraine. Fifty-eight respondents indicated that they would still purchase products from such brands, while 51 respondents held the opposite opinion. However, the responses were almost evenly distributed regarding consumer reluctance to purchase products from companies that did not criticize Russia's aggression against Ukraine. For this question, 53 respondents answered affirmatively, while 72 respondents had a negative response. Furthermore, a decisive majority of the respondents expressed their intention to continue following the social media profiles of brands that do not show support for Ukraine, with 100 respondents confirming this. However, 28 respondents found it challenging to provide a definitive answer, and 22 respondents were prepared to stop following such businesses on social media (Table V).

IV. Discussion

The study addressed issues related to the change in brand image management due to the war crisis in Ukraine and the new reality that modern businesses had to find themselves in. The study on the activity of businesses and brand image management in social media was based on a developed questionnaire survey that was made available on social media portals. One hundred fifty people participated in the study, expressing their own opinions on social media and their impact on the brand image, even in the face of the war crisis in Ukraine. The analysis focused on the behavior and views of modern consumers in relation to the actions taken by companies in social media.

During the war crisis in Ukraine, businesses sought to provide assistance to their eastern neighbors and ensured support for refugees both materially and financially. The responses confirmed that consumers pay close attention to the activities of companies in social media, and these actions significantly impact the brand perception of customers. The surveyed individuals base their opinions on the products

TABLE I
RESPONDENTS' ASSESSMENT OF POSTS BY BRANDS IN SOCIAL MEDIA DURING THE WAR IN UKRAINE

Statement	**Answer**				
	No	Rather not	Difficult to say	Rather yes	Yes
I pay attention to the actions taken by companies in social media during the war in Ukraine	0.6%	20.7%	12.7%	42%	24%
I notice a change in the posts published by brands on social networks as a result of the war in Ukraine	1,3%	18.7%	14%	40.6%	25.4%

TABLE II
OPINIONS OF NETWORK USERS ABOUT COMPANIES IN SOCIAL MEDIA DURING THE WAR CRISIS IN UKRAINE

Statement	Answer	Count
I notice negative opinions about companies appearing in social media during the time of war crisis in Ukraine	Yes	69.3%
	No	30.7%
I comment on content posted by companies' relationship on social media with the war in Ukraine	Yes	9.3%
	No	90.7%

TABLE III
RESPONDENTS' ASSESSMENT OF THE STATEMENTS ABOUT THE COMPANIES IN SOCIAL MEDIA AND THE WAR IN UKRAINE

Statement	Answer				
	No	Rather not	Difficult to say	Rather yes	Yes
During the war in Ukraine, companies should not conduct standard activity in social media	34.7%	30.7%	20.6%	10%	4%
Companies should inform via social media about the current actions of the brand taken in the era of the war crisis	4.6%	12.7%	18%	40%	24.7%
Businesses should show support for Ukraine on social media	2.7%	5.3%	20%	37.3%	34.7%

TABLE IV
RESPONDENTS' ASSESSMENT OF THE STATEMENTS REGARDING THE ACTIONS OF BRANDS DURING THE WAR IN UKRAINE

Statement	Answer				
	No	Rather not	Difficult to say	Rather yes	Yes
Companies should inform on social networks about the withdrawal of Russian products from its own offer	2.7%	4.7%	10.6%	34.7%	47.3%
Companies should pay attention to comments posted by followers on social networks during the war crisis in Ukraine	4%	6%	16%	35.3%	38.7%
Companies should involve followers in aid for Ukraine	5.3%	6.7%	24%	40.6%	23.4%

offered by brands, and the reputation of the companies - on the opinions of other users. In addition, due to Russia's aggression towards Ukraine, respondents have experienced a significant change in the themes of posts published in social media and have encountered more negative comments directed toward contemporary businesses. These negative comments are mainly directed toward companies that have not yet decided to withdraw their brand from the Russian market and have not withdrawn Russian products from their own offerings (as of the date of the survey). Respondents confirmed that, in their opinion, businesses should not conduct their usual activities in social media during the ongoing war crisis in Ukraine, and some of those surveyed replied that they would refrain from purchasing products from a company that is not supportive of Ukraine.

We have found the following answers to the research questions. The war in Ukraine in 2022 had a significant impact on social media and brand management, as companies were required to take a side in the conflict and express their views on social and political issues. This led to a change in the way that companies conducted their social media activities and communicated with their customers (Research question 1). During the war in Ukraine in 2022, companies' social media posts changed as they were required to take a side in the conflict and express their views on social and political issues. Many companies also limited their social media activity or changed the way they communicated with their customers in order to show their support for Ukraine (Research question 2). Users' attitudes towards companies' social media engagement changed during the war in Ukraine in 2022, as they began to expect companies to openly address social and political issues and share their views on the actions of the Russian state. Social media users also demanded that brands withdraw from the Russian market and show their support for Ukraine through their engagement with companies on social media (Research question 3).

There are several limitations to consider for the conducted research. First is the time period. The study focuses on events that occurred in 2022, which may not be representative of the current state of social media and brand management. The second is geographical scope. The study focuses on the impact of the war in Ukraine on social media and brand management, which may not be applicable to other countries or regions. The third is the causal relationship. The study suggests that the

TABLE V
RESPONDENTS' ASSESSMENT OF THE STATEMENTS ABOUT THE WAR IN UKRAINE AND THE ACTIVITIES OF BRANDS ONLINE

Statement	Answer				
	No	Rather not	Difficult to say	Rather yes	Yes
I pay attention to the support shown in social media by companies for Ukraine	8.7%	11.3%	10.7%	40.6%	28.7%
No firm action by the company in the relationship with the conflict in Ukraine discourages the purchase of products of a given brand	20%	28%	16.7%	20%	15.3%
I will resign from following the profile of a company in social media that does not show support for Ukraine	35.4%	31.3%	16.7%	9.3%	5.3%
I will resign from buying products of a specific brand that is not in solidarity with Ukraine	16.7%	22%	27.3%	22%	12%

start of the war in Ukraine caused changes in the way brands managed their social media presence, but it is not clear if this is the only factor that contributed to these changes. Other factors, such as changes in consumer behavior or the adoption of new social media platforms, may also have played their role. The forth is data sources. The study relies on data from social media platforms such as Facebook, Instagram, and Twitter, which may not be representative of the entire population or all social media activity.

***Abstract*—This paper presents an application of a mixture of Hidden Markov Models (HMMs) as a tool for verification of IoT fuel sensors. The IoT fuel sensors report the level of fuel in tanks of a petrol station, and are a key component for monitoring system reliability (billing), safety (fuel/oil leak detection) and security (theft prevention). We propose an algorithm for learning a mixture of HMMs based on a continual learning principle, i.e. it adapts the model while monitoring a sensor over time, signalling unexpected or anomalous sensor reports. We have tested the proposed approach on a real-life data of 15 fuel tanks being monitored with the FuelPrime system, where it has shown a very good performance (average area under ROC curve of 0.94) of detecting anomalies in the sensor data. Additionally we show that the proposed method can be used for trend monitoring and present qualitative analysis of the short and long term learning performance. The proposed method has promising performance score, the resulting model has a high degree of explainability, limited memory and computation requirements and can be easily generalized to other domains of sensor verification.**

I. Introduction

A Key element of a recent change in the industry – dubbed 'Industry 4.0' or 'The Fourth Industrial Revolution' – is the proliferation of 'smart', connected Internet of Things (IoT) sensors, which have an ever increasing role in process monitoring, and as such require verification to achieve reliable, safe and secure systems [1]. In case of fuel tank sensors, which measure the state of large tanks e.g. within a petrol station, lack of sensor verification leads to problems being not detected, which results in reliability issues (billing errors) but can also have serious consequences for safety (not detecting a leak and subsequent environmental contamination) and security (facilitate theft of the fuel).

A sensor verification, or validation, is an internal, external or combined process to detect sensor faults and prevent control failures [2]. In case of IoT sensors, this consists of tasks like preparing models for denoising and missing data imputation, anomaly outlier detection, accuracy and semantic analysis [1]. The nature of the analysis can be complex, e.g. for subsequence outliers (set of consecutive data points that jointly behave unusually) [3]. On the other hand, sequential accumulation of data provides opportunity of continual learning of the properties of sensor behaviour over time; the challenge is to maintain learning ability without forgetting previously learned patterns [4]. Sensor verification method thus should be effective at its tasks [3], but at the same time provide adequate, explainable diagnostic data for the operator or maintenance engineer [2], support data processing within the technical constraints of the IoT sensor suite [1] while correctly dealing with new incoming data [4]. Recently, there has been an emphasis on proposing a approaches both explainable and comprehensive, which are able to deal with real world data, e.g. mobile networks scenarios [5] or oil well monitoring [6].

A large number of approaches have been proposed for application-oriented modelling of time series [7] and quality control [8], [9], including statistical tests, decomposition methods, autoregressive models, neural networks, and probabilistic models. Among them, the Hidden Markov Models (HMMs) [10], [11], [12] have proven to be versatile and effective across many fields, including fault diagnosis [13], [14]. HMM models are attractive, as they have three attractive properties: effective among many application fields; popular, thus well-studied; explainable, as their decisions can be easily traced to parameters of the underlying model. Original single-model HMM formulation have been extended with mixture or ensemble HMM models [15], [16], [17], [18], to further improve their modelling capability. However, while in continual learning setting incrementally learned HMMs can be almost as good as batch learned models [19], corruption of previously learned patterns is one of the main issue [20].

This paper proposes a mathematical model based on a mixture of Hidden Markov Models (HMMs), to be used as a tool for verification of IoT fuel sensors, together with

This work was partially funded by National Center for Research and Development no POIR.01.01.01-00-0376/17-00 'A system for gathering and analysis of streaming data for fuel stations, for optimization of distribution costs and fuel sales as well as on-line monitoring for leakages-related issues' (FuelPrime).

experiments documenting its performance. Our proposition leads to essentially nonparametric, lightweight (in terms of required computational resources, especially memory), continually learning modelling approach that is able to provide a verification of a sensor data series through the detection of structural changes, outliers and anomalies. Additionally, we present a case study, or experience report, of running the proposed approach through real-life historic data of 15 fuel tanks, with verification of detected patterns; the proposed method achieves a high average area under ROC curve of 0.94. While our study is, for the sake of clarity of presentation, limited to the case of IoT fuel sensor verification, the method can be easily generalized to other domains of sensor verification.

Our approach falls within the task-agnostic category described in [21], as we assume unknown both task boundaries – in our case changes in fuel tank usage characteristics over time – and task labels – in our cases the classes of anomalies to be detected. We note that this is the most general, and hence most desired in a practical application setting. Our learning setting from the point of view of anomaly detection is unsupervised, as all data is used without explicit consideration of the labels [22]. According to the taxonomy given in [23], our approach falls into the *Task-Free Continual Learning* (TFCL), with disjoint data label spaces and no task identities provided.

II. Method

A. Hidden Markov Models

A Hidden Markov Model is a model of a system that at any time is in one of n distinct states. At discrete time intervals, state switching occurs in time independent, first order Markovian dynamics (i.e. depends only on the current state). HMM states are not directly observable, however each state has an associated set of parameters describing the emission probability of observable symbols. For the fuel tank monitoring, the observed sequence is the volume of the fuel or its delta, while states correspond to the current situation (idle, refill from a tanker, distribution of fuel to clients, etc.).

A HMM λ of n states is described by initial state probability vector $\Pi = \left[\pi_i\right]_{n\times 1}$, state transition probability $A = \left[a_{ij}\right]_{n\times n}$, emission probability – typically Gaussian, with mean and standard deviation μ_i, σ_i defined for each state. Three main algorithms – Forward, Vitterbi, Baum-Welch – provide tools for finding a probability of a sequence for a given model, state sequence for given data, and learning a model from data [10]. Other parameter identification schemes are possible [24]. In this work, all HMMs are ergodic, i.e. transition from a state to all other states is possible at the start of the training.

B. Mixture of HMMs

Mixed (hidden) Markov models were originally introduced for latent class models [15] in social sciences, and further adapted e.g. for accelerometer measurements [16] or data imputation [17]. Those models introduce hierarchical structure, with class membership dictating Markov model parameters. A different approach has been proposed in [18], where an ensemble of HMMs is generated over time through incremental Boolean combination in the receiver operating characteristic (ROC) space.

In contrast to the above-mentioned propositions, we use a different approach. Our physical sensor model does not require latent class modelling, and absence of labels prevents from using ROC-based verification within the model operation. Our objective with using mixtures is to capture rare historical data patterns, and thus prevent them from being subject to catastrophic forgetting [4]. Our proposition is to model a IoT sensor time sequence with a set of m HMM models $\mathcal{H} = \{\lambda_1, \ldots, \lambda_m\}$. We assume that the sensor data $\mathbf{x} \in \mathbb{R}^d$ is processed in windows or batches (e.g. a day's worth of data, d can vary between windows). We propose the following algorithm for mixed HMM sensor verification:

1) Initialize $\mathcal{H} = \emptyset$.
2) Read next window of sensor data $\mathbf{x}$. Use the Baum-Welch algorithm to identify parameters of a model for this data, $\lambda_{\mathbf{x}}$, for a predefined range of number of states (see Section II-C).
3) If $\mathcal{H}$ is empty, then $\mathcal{H} = \{\lambda_{\mathbf{x}}\}$ and goto 2. Otherwise use the Forward algorithm to compute probabilities $P(\mathbf{x}|\lambda)$ and $N(\lambda)$ function to compute numbers of free parameters of the models
$$p_{\mathbf{x}} = P(\mathbf{x}|\lambda_{\mathbf{x}}) \quad n_{\mathbf{x}} = N(\lambda_{\mathbf{x}}) \tag{1}$$
$$p_{\mathcal{H}} = \max_{\lambda\in\mathcal{H}} P(\mathbf{x}|\lambda) \quad n_{\mathcal{H}} = \sum_{\lambda\in\mathcal{H}} N(\lambda) \tag{2}$$
4) Compute the information criteria values (e.g. AIC or BIC) for two cases: (C1) extending the current set of models with $\lambda_{\mathbf{x}}$ – possibly with better likelihood, but at the cost of expanding the total number of parameters – and (C2) staying with previous contents of the $\mathcal{H}$:
$$b_{\mathcal{H}+\lambda_{\mathbf{x}}} = IC(p_{\mathbf{x}}, n_{\mathcal{H}} + n_{\mathbf{x}}) \quad b_{\mathcal{H}} = IC(p_{\mathcal{H}}, n_{\mathcal{H}}) \tag{3}$$
5) If $b_{\mathcal{H}+\lambda_{\mathbf{x}}} < b_{\mathcal{H}}$ add the new model for the next iteration $\mathcal{H}' = \mathcal{H} \cup \{\lambda_{\mathbf{x}}\}$; if not, leave models as they were $\mathcal{H}' = \mathcal{H}$.
6) Regardless of decision in 5, calculate the anomaly score as $a_{\mathbf{x}} = p_{\mathbf{x}} - p_{\mathcal{H}}$. If there are remaining sequences, goto 2, otherwise stop.

The motivation for the algorithm presented above is as follows. While a HMM model has a very good performance in modelling time series, building a model of a long (monthly, yearly) series would require frequent, expensive re-training on a very long data history. For our case, initial observation of the data exposed dominant cycle or seasonality, in a similar way it is seen in energy consumption, water usage or weather patterns. Hence it's natural to treat the signal as a collection of cycle periods, in our case days, keeping in memory only an ensemble of HMM models, as the memory cost of a HMM model is much smaller than daily data sequence (see Section IV-A). Changes in the ensemble of HMMs occur between daily batches of data.

The proposed algorithm balances model complexity (number of parameters) and the ability to describe the signal (data fit). The collection of models retained on algorithm's progress over individual cycles serves additionally as a signal descriptor and source of diagnostic information.

C. Implementation of sensor verification

The verification system was incorporated into the fuel station tank monitoring system, which consists of the three main parts: the station part (implements software and hardware related to data acquisition, connects directly to devices and sends data to the central server); the server part (receives data from many stations, automatically processes this data and tries to draw and present preliminary conclusions [25]); the analytical part (responsible for analysing the results of the server part and for making decisions with human supervision).

For the actual verification, we focus on daily windows, as this corresponds to the rhythm of normal monitoring/verification applied in the system. A daily sequence of data $\mathbf{x}$ is fed into the system, and it's anomaly score $a_{\mathbf{x}}$ computed; if high enough, a 'require inspection' alert is generated. We note that there are additional possible ways to get information from the model, which are discussed in Section IV.

For each daily model identification (step 2), we use exhaustive search over a set of states $n \in \{1, \ldots, 10\}$, with Bayesian Information Criterion (BIC) [26] for selection of the final model. As the HMM identification algorithm (the Baum-Welch procedure) can end in local optimum, $k = 10$ independent searches for given n are performed, and the best model is evaluated. The BIC is also used for mixture extension decision ($b_{\mathcal{H}+\lambda_{\mathbf{x}}}$ and $b_{\mathcal{H}}$ values).

III. Results

A. Description of the sensor

Fuel and water level is measured by the Automatic Tank Gauging device (ATG). An ATG uses probes located in each tank or compartment to measure fuel and water levels. Each probe consists of a long rod with floats or sensors. The probe rod also has thermistors to measure the fuel temperature. The ATG sends an electrical impulse to both probes independently (product level float and water level float). The probe sends back the pulse and the ATG measures the time elapsed from sending to receiving. On this basis, the height is calculated. Measurements from all underground tanks are sent to a central unit located in the station building through wired or wireless connection. From here they are sent to the server (see Section II-C). The common risks with this type of device are: (1) suspension of the probe when it gets stuck at a certain height of the rod and (2) inertia of temperature measurements – especially important during the delivery of fuel with a significantly different temperature. Of the available data, we use fuel (product) level readout, which contains rich data about the tank situation; the remaining two (temperature and water) are used to diagnose specific, known problem conditions.

B. Selection of test cases

To test the method, data from $n_t = 15$ fuel tanks that have been previously known to have malfunctions and issues were selected for analysis. Both short and long term history sequences were selected, mean sequence length was 183 days ($8 - 646$ days) while mean sample count was $\approx 591\,189$ ($30\,151 - 2\,531\,218$ samples). The sequences were annotated by experts (analytical team in charge of verification of the sensors), with a list of days with erroneous or anomalous readings. There are two types of outliers in the data: (1) related to real probe disturbances (e.g. when the float hangs on the rod and does not represent the height of the liquid accurately; or in the middle of a delivery and there are significant fuel fluctuations causing the float to sink temporarily) and (2) virtual errors (incorrect translation of the pulse length to the real height, occurs when raw current measurement values are mismeasured or misinterpreted).

C. Experimental procedure

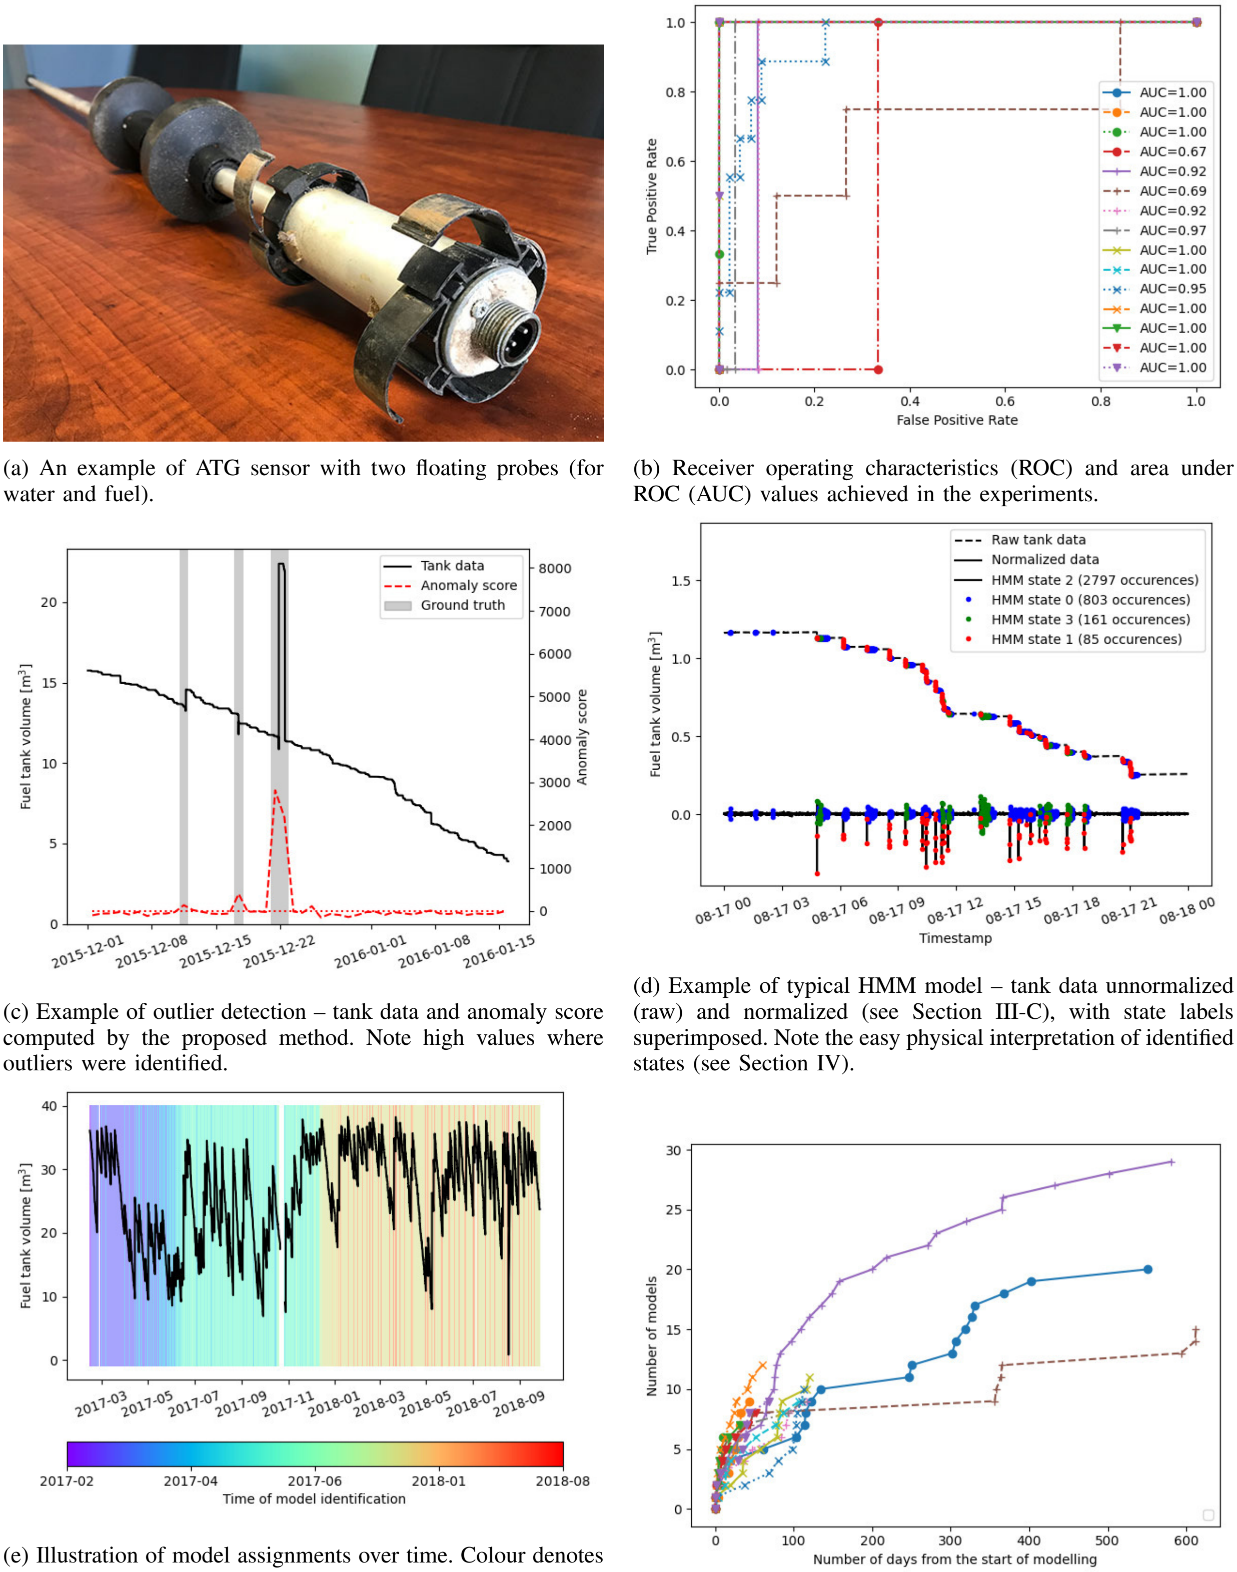
As each data sequence consists of fuel volume measurements at irregular intervals, the sequences were differentiated, normalized by time delta, and standardized[1] prior to inclusion in the experiments. Each normalized and standardized sequence has been cut into day's windows $\mathbf{x}$ and fed subsequently to the algorithm presented in Section II-B. For each sequence, the first half is treated as 'run-in' or training data, without using the labels (our case assumes they are unavailable during regular application). The resulting anomaly score $a_{\mathbf{x}}$ was recorded. The anomaly scores together with ground truth annotations were used to prepare ROC curves, with Area Under Curve (AUC) as the performance measure; for testing, positive labels were assigned to anomalies, while negative examples to normal levels.

Note that ground truth labels were generated especially for testing the proposed method, they are not required during the normal operation of the algorithm. We focus on evaluating the performance on the current set of data (current day), this is motivated by the performance measure of our underlying application setup, which is day to day monitoring of a fuel tank.

D. Algorithm performance

The average AUC score achieved by the method was 0.94 ± 0.11. In nine cases (no. 1-3, 9, 10, 12-15), the anomaly score was precise enough to correctly single out all anomalies, achieving maximum possible AUC value of 1.0. In two cases (no. 4 and 6) the results were strongly affected by difficulty of the problem, as the anomalies show with small changes in the signal, resulting in AUC values of 0.67 and 0.69. Remaining four cases (no. 5, 7, 8, 11) achieve $0.92 - 0.97$ (see Figure 1b). Almost all cases of mechanical failures (e.g. probe suspension) and faulty sensors were identified correctly. Anomalies (e.g. ripples or jumps within tank refill, especially in case 4)

[1] In actual application, the standardisation can be replaced by using mean and variance data from other tank with known history and similar characteristics, or estimated from physical tank properties, e.g. the total volume.



(a) An example of ATG sensor with two floating probes (for water and fuel).

(b) Receiver operating characteristics (ROC) and area under ROC (AUC) values achieved in the experiments.

(c) Example of outlier detection – tank data and anomaly score computed by the proposed method. Note high values where outliers were identified.

(d) Example of typical HMM model – tank data unnormalized (raw) and normalized (see Section III-C), with state labels superimposed. Note the easy physical interpretation of identified states (see Section IV).

(e) Illustration of model assignments over time. Colour denotes time of identification of a model assigned to given sample. Note two visible trend changes at 2017-04 and 2018-01; e.g. through the second half of the 2017 most assigned models were identified in the period right after 2017-04.

(f) Number of models as a function of days from modelling start, for given set of tanks. Consistent patterns are visible (see Section IV).

Fig. 1: Illustration of the proposed method and experiments' results.

were more difficult to spot, but the performance remained acceptable. In rare cases of tanks with a longer history, model adaptation (i.e. the process of conditional adding of a new HMM to an ensemble, see step 5 in Section II-B) had been seen interfering with a detection (outlier present within a new pattern was learned and not detected subsequently); however those cases could be isolated at the cost of increasing the sensitivity and potentially the number of false positives. A small portion of the errors were traced back to imprecise labelling of bad cases. Example detections are presented in Figure 1c. For our current results, a correlation study could not be carried out (correlation coefficients not statistically significant); an analysis of the results suggests that better AUC scores are achieved by bigger models, but not necessarily with longer training or test length, both when measured in number of days or number of samples.

IV. Discussion

A. Performance summary

Overall performance of the method was evaluated as very good, both in terms of quantitative score, and qualitative evaluation. Detailed inspection of the models revealed additional usage patterns, beyond the use of anomaly score. Adding a new model is usually connected with trend change of the series. If a high $p_{\mathcal{H}}$ value comes from a rare of old model (not matched lately, and previously matched to only a few cases), it may be additional signal of an anomaly. Finally some of the learned models could be tagged as interesting by the human observer and alert could be generated when they appear. The method has excellent aggregation properties; average number of parameters at the end of modelling was $n_p = 334$, which is less than 0.1% of the number of original samples.

B. Observed model behaviour

As expected, individual HMM within the ensemble represent daily behaviours of the tank being monitored. Example is presented in Figure 1d, note how the identified states (four in this example) correspond to known physical phenomena: stable level (s. 2), fuel unloading (s. 1), level oscillations after unloading (s. 3) and general or temperature induced oscillation (s. 0). Typically, the number of states is found in the range $3-7$, and most of the time they can be assigned some interpretation based on what happens inside the tank. We consider this correspondence a qualitative validation of our approach. Individual HMM inspection revealed that they contain features common mainly for the fuel type (e.g. diesel, gasoline, premium); this may make it possible to produce a tank-independent dictionary of HMMs that could be used as an initialization of the algorithm.

The step 5 of the algorithms prevents adding new models if previous adequately explain current data – until there's a trend change, when a set of new models must be added to keep the model accurate. In the example presented in Figure 1e two trend changes can be easily observed. Those trend changes are usually explainable by process or physical change (e.g. reassignment of fuel type for the tank, seasonal changes, general station usage type change resulting from roadworks). This trend change could be identified through analysis of model addition times, and provide additional monitoring information. Another view of this phenomenon can be seen in Figure 1f, where model count at given number of days from the start is presented. Often addition of models is seen in batches, on the beginning or when some trend change occurs.

C. Conclusions and future work

The proposed method has promising performance score, the resulting model has a high degree of explainability, limited memory and computation requirements and can be easily generalized to other domains of sensor verification.

As the objective of this work was a case study of the proposed algorithm, based on a mixture of HMMs, to the application of IoT sensor verification, further work will focus on extended analysis of the proposed approach, including: comparison with other approaches; detailed investigation of parameters, e.g. the effect of training sequence length; pruning the set of models $\mathcal{H}$ to remove rarely used, old models.

Acknowledgements

Authors wish to thank Bartosz Grabowski and Wojciech Masarczyk for insightful cooperation on research issues with neural networks sensor models, which led to the development of the method presented here. Authors also wish to thank anonymous reviewers for their insightful comments and remarks, which were basis for improvement of this paper and plans for future work.

***Abstract*—Demand for compute resources and thus energy demand for HPC is steadily increasing while the energy market transforms to renewable energy and is facing significant price increases. Optimizing energy efficiency of HPC clusters is therefore a major concern. Different possible optimization dimensions are discussed in this paper. This paper presents a digital twin design for analyzing and reducing energy consumption of a real-world HPC system. The digital twin is based on the HPC cluster at PTB. The digital twin receives information from multiple internal and external data sources to cover the different optimization opportunities. The digital twin also consists of a scheduling simulation framework that uses the data from the digital twin and real-world job traces to test the influence of the different parameters on the HPC cluster.**

I. Introduction

THE Physikalisch-Technische Bundesanstalt (PTB) operates a compute cluster at its Berlin site that is used by various departments within PTB. The cluster is the backbone of numerous research activities. The HPC cluster currently consists of 60 CPU nodes with CPUs from two generations and two special GPU nodes with 10 GPUs. This amounts to an energy consumption of approximately 30 kW. PTB plans to extend the installed compute power by another 50 kW in Berlin and, perspectively, to install a new cluster with over 200 kW installed power at its Brunswick site.

The PTB relies on HPC for many research activities in different departments including physics, mathematics and medicine. The new AI strategy of PTB will require more compute resources for AI applications and model training. Energy efficiency becomes a concern with this increased demand. While the energy efficiency of modern CPUs has improved over the years, the total energy consumption of HPC systems has increased at an even faster rate [1]. With this increasing energy usage, the total cost of ownership is impacted by increasing energy prices in a volatile market environment. Additionally, PTB, as a federal institution, is bound by the climate protection plan 2050 [2] and climate protection program 2030 [3] of the German federal government. New data centres, like the planned Brunswick site, need to meet the standards defined by the Blue Angel certificate for data centres [4].

Currently, the influence of different internal and external factors on the energy efficiency of the HPC cluster at PTB are not well understood. A digital twin can help in understanding those factors in detail and test changes to the system configuration without adverse effects to the production system and is commonly used for this purpose [5]. However, optimization goals and systems differ from every site and cluster. Thus, a specific, tailored solution is needed for this multi-factor optimization problem. Other HPC centres are also making efforts to improve their energy efficiency and are reporting on those efforts [6].

This paper introduces a design specification for digital twin of the HPC cluster at PTB. The digital twin shall help the operators of the cluster to improve the cluster operation with regards to several optimization goals. The digital twin collects data from various data sources for that purpose. In addition, the digital twin contains a simulation framework with a scheduling model. This simulation framework is used to test parameters and settings with regard to the combined optimization goals.

The next chapter presents the optimization dimensions that have to be taken into consideration. Chapter III presents the design specification of the digital twin and its different data sources. Finally, Chapter IV introduces the scheduling framework created to simulate the HPC cluster with data from the digital twin.

II. Background

Increasing the energy efficiency and energy usage of a compute cluster is a multi-dimensional optimization problem. Energy consumption, CO_2 emissions, energy cost, cooling and energy limitations have been identified to be of particular interest of PTB [7]. Optimizations for each of these goals are possible. Each of these dimensions needs a way to be monitored and a representation within the digital twin is required. The rest of this chapter describes these dimensions in detail:

A. Energy consumption

The most obvious optimization is the overall reduction of energy consumption by the HPC cluster. Different mechanisms

IEEE Catalog Number: CFP2385N-ART ©2023, PTI

Topical area: Information Technology for Business and Society

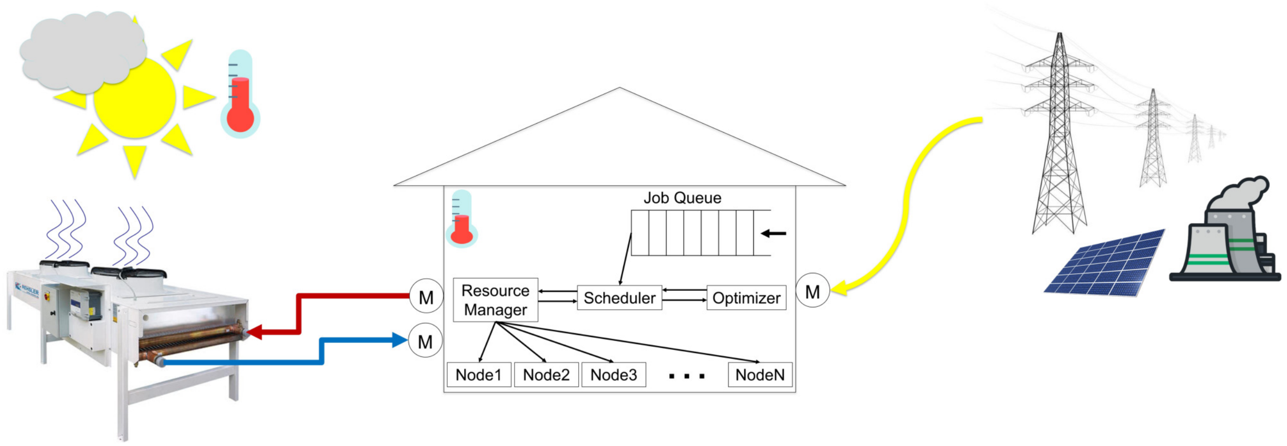

Figure 1. Schematic representation of the digital twin for PTBs HPC cluster

have been proposed like Dynamic Voltage and Frequency Scaling (DVFS) [8], turning off idle nodes [1], adapting jobs to the energy budget and running nodes at reduced frequencies [9]. The digital twin can be used to test different parameters and their effect on the cluster and monitor the long-term effect of configuration changes.

B. CO_2 emissions

The energy in the energy grid comes from different sources with different CO_2 emissions associated to them. Tracking the equivalent CO_2 emissions when using energy and moving jobs to times of low CO_2 emissions can help to reduce the CO_2 equivalent associated with the operation of the cluster. Since each energy source has different emissions, days with strong winds or low cloud coverage reduce emissions while sources like natural gas and coal used to cover base load in the energy grid increase emissions.

C. Energy cost

Energy prices for large consumers are dynamically determined at energy spot markets. These prices are volatile and shifting compute jobs to low-cost times can directly reduce energy costs. Optimizing for this goal can directly save energy costs. Using the data collected by the digital twin, it may be possible to identify a correlation between pricing and high energy availability, e.g. due to a lot of available renewable energy.

D. External influences

The weather has a direct influence on energy efficiency, hence most metrics, such as Power Usage Effectiveness [10], are averages over a year-long period to average certain weather and season related effects. PTB intends to move the cluster cooling to a free cooling system, which use temperature differences to cool the cluster. These machines are more efficient compared to classic compressor-based cooling machines but only work up to a certain outside temperature. Therefore, they might not provide sufficient cooling on extremely warm days. The cluster needs to adapt to such conditions, e.g. by limiting the amount of active nodes. Monitoring system temperatures and integrating weather forecast data into the digital twin, the HPC system can be configured to stay within defined operational parameters, e.g. by reducing system load.

Another problem might be limited energy availability. Other industries with high energy usage have developed so called demand response mechanisms to reduce energy consumption in cooperation with energy service providers when not enough energy is available. With increasing power demands of HPC clusters such strategies might be required for HPC as well and some strategies have been proposed [11]. Similar to the limitations imposed by insufficient cooling capacities, the cluster can be adjusted to using less energy when not enough energy can be supplied by the energy provider.

III. Digital Twin for HPC

A digital twin is used to reason about a real-world object with data available digitally. In order to do so, real world data needs to be collected and models about the object have to be created. The previous section introduced the relevant dimensions for the optimization problem. These dimensions need to be represented in the digital twin with data and models.

The HPC cluster receives compute jobs from the users in a job queue. The scheduler decides which jobs are run on which nodes at a certain time. A resource manager module manages the available system resources. The compute nodes execute the jobs submitted to the system. Each node has its own CPU, RAM and network connection. Some nodes also have GPUs. The general operation of the cluster is simulated via a scheduling simulation. This simulation is key to understand the cluster operation. Chapter IV introduces the scheduling simulation. The nodes operation can be estimated with energy estimates. No actual jobs need to run to simulate the scheduling simulation.

The simulation results and data is used by the optimizer component that influences the scheduler and the resource manager to change the operation parameters of the HPC

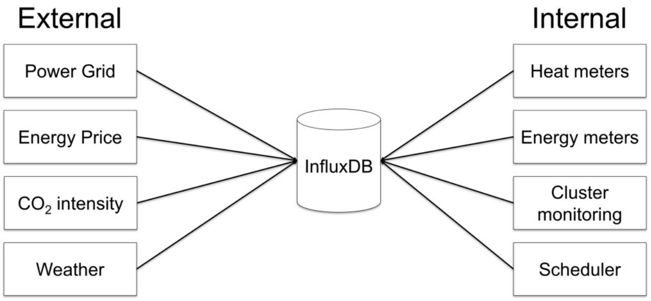

Figure 2. Software components of the digital twin with all data sources and models

cluster. This component is not yet functional but planned for future development with the results obtained by scheduling simulations from the simulation component.

The collected data generally falls into two categories: internal data from the HPC cluster and data centre, and external data about the outside world. The core component of the digital twin is an InfluxDB database. InfluxDB is a time-series database, optimized for processing time-dependent data. A collector program for each data source continuously writes the data to the Influx database. A Grafana dashboard provides access to and visualizations of the data for the user. All data collectors, Grafana and InfluxDB are managed via Docker containers. The scheduling simulator also uses the data from the InfluxDB directly.

The cluster status, including job and node information, is collected with ClusterCockpit [12]. Energy usage is collected via energy meters installed on site. This includes energy used by the cluster and the cooling infrastructure. Heat meters are used to monitor the amount of heat removed from the cluster by the cooling system.

All external data sources have been chosen specific to PTBs location and requirements as well as the optimization goals described in Chapter II. The external data sources for the digital twin include energy grid information, weather forecast data, energy prices and the $\mathrm{CO_2}$ emission associated with the current energy mix in the energy grid. Information about the energy grid is obtained from Bundesnetzagentur [13]. This federal agency offers information about the German energy grid and the energy sources used at any given time. Energy prices are also retrieved from Bundesnetzagentur. $\mathrm{CO_2}$ estimations are retrieved from Electricity Maps [14]. Finally, weather information are retrieved from the German Meteorological Service (DWD) [15] via the Bright Sky API [16].

Figure 1 shows the architecture described in this Chapter in a schematic representation. The individual data collectors described in this Chapter can be found in figure 2. They are grouped into internal and external data sources with InfluxDB being the core component.

IV. Scheduling simulation framework

This section gives a brief overview of existing scheduling simulators and introduces a new scheduling simulator that uses the digital twin data of the PTB HPC cluster as input for its simulations and models the operation of the cluster.

Energy aware scheduling has been of interest in the community with various goals, metrics and proposed solutions [17]. Scheduling simulators have been used to test different scheduling algorithms or additional parameters without changing production systems or the need of running actual jobs. Slurm [18] is a scheduler used in production HPC systems. Simakov et. al. developed multiple Slurm simulator versions [19], [20] that follow the steady Slurm development. All versions allow to test different Slurm parameters without altering the corresponding production system. Slurm can be combined with other schedulers like NQSV and digital twins [5]. However, since every setup is different, a custom solution is necessary. Yang et al. [21] proposed a scheduling simulator that offers two pricing options for scheduling but does not support dynamic pricing based on constantly changing energy prices.

The data of the digital twin is used for the scheduling simulations. The simulator connects to the database in order to get both the internal and external data. Because the digital twin is a purpose-build solution, no suitable simulator exists. Therefore a new solution was developed.

For development, testing and validation purposes the simulator component presented in this paper can generate synthetic job traces. For longer, realistic job traces the simulator can read the standard workload format (swf) from the Parallel Workloads Archive [22] and can use job traces from this archive as input. Additionally, job traces from the PTB compute cluster can also be used as input.

Furthermore, the data from the digital twin database as well as the job traces are time dependent. The scheduling simulation can run at arbitrary time points. The simulator was designed in such a way that it can run a given job trace at a chosen start time and match the data from the digital twin database accordingly. This allows to test varying internal and external factors on the same job trace or the same internal and external factors on different job traces.

The results of the simulations can be used to tune the system parameters to meet the optimization goals from Chapter II. An automatic optimizer can be implemented as a component of the HPC cluster for automatic tuning and adjustment of parameters.

V. Conclusion

With increasing compute demand and thus energy demand of HPC clusters, energy consumption and availability becomes a concern for HPC cluster operators. Possible goals for optimizations like energy consumption, $\mathrm{CO_2}$ emissions, energy cost and external influences that affect energy and cooling have been discussed in this paper.

A design of a digital twin, a representation of a real-world HPC cluster at PTB, has been proposed. It has a time-series database at its core and is connected to data sources for the internal cluster aspects as well as external factors relevant for the optimization goals. The digital twin makes data about the cluster available to the administrators. This data helps to asses and monitor the efforts towards meeting desired efficiency goals over time.

As part of the digital twin, a scheduling simulator has been developed that simulates the operation of the cluster. It uses the data from the digital twin and allows to test different job traces. Because of the time dependence of the data, the simulator can map different job traces with multiple data points to test traces with different data. The digital twin can be used by the administrators to test various configuration parameters and algorithms for their effect on the optimization goals.

So far, the digital twin is only used for simulations. It has not yet been integrated with the scheduler of the real-world HPC system. However, this shall be done in the future.

With the scheduling simulation framework, as part of the digital twin, further empirical studies of the optimization goals are planned. These simulations are a first step towards more efficient cluster operation at PTB and are the basis for future improvements of the real-world HPC cluster, especially toward an automatic optimizer component as part of the scheduler.

***Abstract*— The aim of the study is to investigate and evaluate user preferences regarding two visual representations of uncertainty estimates for decision-making purposes. The research is concerned with the perception of fuzzy numbers, which are depicted either as triangles or as specifically constructed vectors. The study involves a series of pairwise comparisons in which participants must determine which representation reflects the change in the most possible value in a more salient way. The results are then analyzed and formally verified statistically. The study shows that there are specific circumstances where vector representations are more desirable than their triangle-based counterparts. The findings also suggest that there may be some differences in assessing these representations depending on gender. This examination expands our understanding of how subjects perceive different graphical methods for presenting change in a selected parameter uncertainty feature. From a practical standpoint, the findings offer suggestions for designing graphical user interfaces that present fuzzy data to users.**

***Index Terms*—Fuzzy number visualization, Fuzzy number vector representation, Visual processing, Project uncertainty, Usability.**

I. Introduction

UNCERTAINTY is a pervasive issue that must be addressed in numerous fields both those typically associated with precision such as physics or engineering, as well as areas where rather soft computing is prevalent, e.g., management, economics, and other social sciences. In particular, uncertainty needs to be handled while analyzing risk, building various models and making decisions [1]–[3], and not taking into account uncertainty can lead to often negative or even catastrophic results such as project failures [4], [5]. It is, thus, indispensable to control them and to analyse their behaviour on an ongoing basis.

The efficiency and effectiveness of managing uncertainty and solving related problems, for instance, in production, or project management can strongly depend how it is presented to persons analyzing the data. The importance of data visualization in the process of decision making has been stressed in many papers, for instance, showing its substantial positive influence on communication process [6]. There are also a number of various ways of graphically presenting uncertainty and they have been described and reviewed in numerous scientific publications (e.g., [7]–[10]).

In our previous papers [11], [12], we proposed the use of vectors to graphically visualize uncertainty defined by triangular fuzzy numbers. We have initially compared the usability and potential applications of triangle- and vectors-based representations of triangular fuzzy numbers. By performing experimental tasks, we found out that their capability to convey information may not be worse than that of triangles and is seen as even better by some of the users. This type of relatively simple fuzzy number requires to provide only three, point-type estimates and is commonly used in practice. For example, in project management, uncertainty of a time or cost estimate, encoded by a triangular fuzzy number, is fully defined by three parameters: the optimistic, the most possible, and the pessimistic value [13], [14]. This approach closely resembles the well-known PERT approach [15]–[17] that, albeit based on probability theory, also requires similar three parameters. In the PERT approach the beta distribution [18] is used with the corresponding *arithmetic* of random variables, while with triangular fuzzy numbers, the representation of the estimates and the mathematical operations are more straightforward and intuitional. Although in the literature one can find phrases "*fuzzy vector*", however it should be emphasized that these papers refer usually to fuzzy vectors that are different in nature from the current paper definition – compare, for example, the following works [19]–[23].

In the current study, we investigate the uncertainty visualizations as the traditional graphs of membership functions, and our own proposals of depicting them as vectors. Since the previous results have shown that the effectiveness and efficiency of both approaches are comparable, we decided to pursue this subject in more detail. Here, we focus particularly on the individuals' perception of the saliency of changes in the most possible value depicted both as triangles and vectors.

The focus on the most possible values results from the fact that in many cases the most possible values are taken as the basis for current decision making such as setting deadlines in

project planning. Therefore, the changes in the most possible values should be carefully controlled and their most suitable graphical representation is of great importance here. Moreover, monitoring variability in various aspects seems to significantly increase the chances for achieving project management success [24]. To extend our understanding how individuals perceive these changes portrayed in a different visual form, we designed and performed an experiment. The obtained outcomes are analysed and discussed in this paper. Since previous results [11] suggest that there can be some differences between men and women while assessing triangle- and vector-based representations, the gender effect was also included into our study.

The outline of the paper is as follows: In Section II, we present basic information about the triangular and vector representations of triangular fuzzy numbers. Section III includes the all the details about the experimental design and study subjects' characteristics which is followed by the results analysis section. The paper ends with a discussion and conclusions.

II. Membership functions versus vectors – two uncertainty visualization approaches

Let us suppose that a project cost or time item has been estimated by experts in the form of three values $\underline{r}, \hat{r}, \overline{r}$ – the optimistic, most possible and pessimistic values, respectively. The respective triangular fuzzy number will be denoted as $\tilde{R} = \left(\underline{r}, \hat{r}, \overline{r}\right)$. Its membership function $\mu_R(\mathrm{x})$ is defined on the set $\mathfrak{R}$ of real numbers and represents the possibility degrees of the respective real numbers. An example of $\tilde{R}$ (2,3,5) is shown in Fig.1. The alternative representation, put forward and examined in our previous study [11], [25], is based on vectors (Fig. 1). The vector $\vec{R}\left(\underline{r}, \hat{r}, \overline{r}\right) = \{m_R, s_R, \gamma_R\}$ will be defined by its starting point $(m_R, 0)$, where $m_R = \left(\overline{r} + \underline{r}\right)/2$, its length $s_R = \overline{r} - \underline{r}$, the angle in relation to the line $x = m_R$ computed as $\gamma_R = arc\,tan(\hat{r} - m_R)$; positive angles denote the inclination to the right and negative ones – to the left.

It is important to notice that the angle γ_R will be zero only if the most possible value $\hat{r}$ is equal to m_R, the arithmetic mean of the pessimistic and optimistic values $\overline{r}$ and $\underline{r}$. These two representations described above are investigated in an experiment described in following sections.

A. Study Subjects

In total, 88 individuals participated in the survey. However, five persons (four females and one male) were excluded from further analysis due to incomplete data.

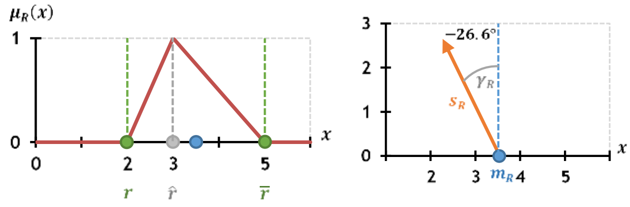

Fig. 1. Membership function based visualisation of parameter R determined by numbers 2, 3, 5 and its vector visualization.

III. Method

Thus, all the presented in this study results refer to 83 participants. They were primarily volunteer students aged between 18 and 46 years old from Wroclaw University of Science and Technology in Poland. The mean age was 23.42 years, with a standard deviation of 3.45. The group was highly homogenous in this regard, as the 25th age centile amounted to 23 and 75th – 24 years. Out of the participants, the majority were women, specifically 61 individuals, making up 73.5% of the total. All of them provided their informed consent to participate in the study.

A. Experimental Design and Task Description

The experimental design aimed to gain a deeper understanding of how individuals perceive changes in fuzzy number most possible value in both triangular and vector visualizations. Participants' task was to give subjective assessment of different variants of these representations in terms of their saliency of fuzzy number feature change. In particular, the effects described in the next subsection were examined.

Examined factors

The present study investigated two graphical representations of triangular fuzzy numbers: traditional triangle and vector-based visualizations. They were the first factor examined in the study, and their mathematical properties were concisely explained in Section II. The study specifically focused on how participants perceived changes in a single property related to fuzzy numbers: the information about the most possible value of the imprecise parameter in question. Graphically, this feature is associated with either the position of the maximum of the triangular fuzzy number membership function or the inclination angle of the vector. The study explored three distinct levels of change in the most possible value, which included (i) a change of two units from zero to two, (ii) a change of four units from zero to four, and (iii) a change of two units from two to four. The factors investigated and their corresponding levels are depicted in Fig. 2.

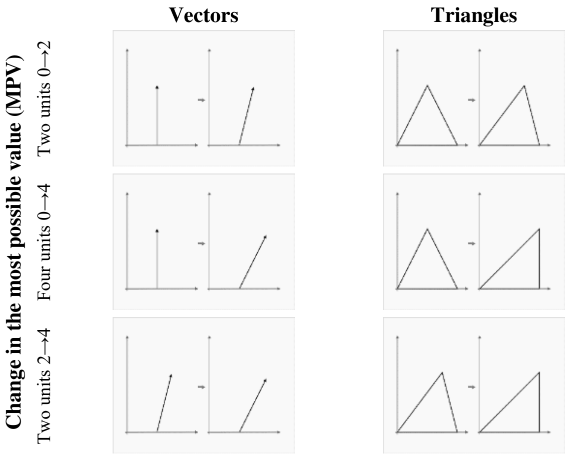

Fig. 2. Factors and their levels examined in the current study: visual representation (vectors, triangles), the most possible value change (MPV: Two units 0→2, Four units 0→4, Two units 2→4).

Dependent measures

We utilized two dependent measures to assess the subjective opinions of the respondents. To assess preferences, we obtained relative weights through pairwise comparisons of all experimental conditions. Pairwise comparisons have been demonstrated to enhance the accuracy of evaluations [26], [27] and have been successfully implemented in numerous studies for establishing hierarchies of preferences see, e.g., [28]–[32]). In this study, we utilized this approach within the Analytic Hierarchy Process (AHP) framework [33] to determine stimulus subjective perceptions and calculate consistency ratios for each participant.

To determine which figure showed a more noticeable increase in the most possible value of the fuzzy number, participants were asked to provide responses on a 5-point, two-directional linguistic scale recommended in the AHP approach.

By combining different levels of the two factors examined, we were able to identify six distinct experimental conditions. These conditions were generated by varying two types of graphical representations of triangular fuzzy numbers and three levels of indeterminacy changes (as shown in Fig. 2). To test all six experimental conditions, we applied a within-subject design where each subject participated in every condition.

B. Experimental Procedure

The data collection process for the study was conducted entirely over the internet. Participants were provided with general information about the research and a hyperlink to a slideshow containing a detailed audio explanation of the research. The final slide contained a hyperlink to the experimental application based on React.js, which opened in their default web browser upon clicking. After opening the software, the first page presented participants with the informed consent form, which they were required to read and accept before starting the examination. After providing their gender and age, the software displayed all necessary pairwise comparisons of the experimental conditions one by one, in a random order. During this process, the data were collected locally in the web browser's internal variables and were subsequently sent to a remote server after the completion of the entire procedure.

IV. Results

A. Descriptive statistics

The experimental data that was gathered was brought together and transferred to TIBCO Statistica version 13.3 software. The analysis included both consistency ratios and relative weights and was carried out taking advantage of typical descriptive statistics and analysis of variance. The outcomes of this examination are exhibited in the following sub-sections.

Consistency ratios

The consistency ratios of all the examined individuals were equaled, on average, 0.381 with a standard deviation amounting to 0.296. The median value of 0.263 was much lower than the mean, which suggest that the distribution was positively skewed. The consistency ratio ranged from a minimum value of 0.0421 to a maximum of 1.42.

Relative weights for studied stimuli

Table I displays the key descriptive statistics for the relative weights computed for all the stimuli that were investigated.

The greater the relative weight values, the stronger the perception of saliency of the change in the fuzzy number most possible value in a particular experimental condition. Pictures illustrating the change by four units exhibit the highest mean and median values, signifying the most salient perception of the changes. This observation was consistent for both triangle and vector representations.

In all cases, the median value was slightly smaller than the mean value, which indicates a somewhat positively skewed distribution. Furthermore, these experimental conditions had the highest variability, as evidenced by the larger standard deviations and mean standard errors.

B. Analysis of variance

The analysis of variance technique was employed to formally verify if the observed differences in average values were statistically significant. We have conducted this method to both consistency rations and relative weights. The results of these two analyses of variance are presented in the following subsections.

Consistency ratios

There were differences in the CR mean values for men and women with males being on average more consistent (0.356) than females (0.390). However due to the considerable standard deviations, the discrepancy occurred to not be meaningful, which was supported by performing one-way analysis of variance. Its results for gender differences in consistency ratios showed statistical insignificance at the level of $p = 0.65$ $[F(1, 81) = 0.21]$.

Relative weights for studied stimuli

To determine the statistical significance and extent of the differences in the mean relative weight values for the studied

TABLE I.
KEY DESCRIPTIVE STATISTICS OF RELATIVE WEIGHTS FOR ALL EXPERIMENTAL CONDITIONS

Graphic Represen-tation	Change Type	Mean	Median	Min	Max	Std Dev	Mean Std Error

effects, we performed a three-way analysis of variance, specifically analyzing the *Change Type* and *Graphical Representation* factors. We have also included the *Gender* effect, since our previous study [11] suggests that this may differentiate the results regarding the investigated stimuli. The results show that two of the three factors investigated were statistically significant. Specifically, the factors of *Change Type* and *Graphical Representation* had significant effects with: $F(2, 486) = 154.7$, $p < 0.0001$, and $F(1, 486) = 5.24$, $p = 0.0225$, respectively. The gender effect alone was statistically irrelevant, but its interactions with both *Graphical Representation* and *Change Type* were meaningful. The former one (*Graphical Representation* × *Gender*) at the level of $\alpha < 0.05$ [$F(2, 486) = 7.78$, $p = 0.0055$], whereas the latter *Change Type* × *Gender* at the level of $\alpha < 0.1$ [$F(2, 486) = 2.87$, $p = 0.0578$]. Additionally, the interaction between *Change Type* and *Graphical Representation* was statistically significant at the level of $\alpha < 0.05$ [$F(2, 486) = 7.13$, $p = 0.0009$].

Fig. 3 presents a visual representation of the mean relative weight values for the *Change Type* effect. The figure indicates that the study subjects perceived the most salient change in the most possible value for four-unit changes (CT_0→4). On the other hand, the difference between one-unit changes (CT_0→2 and CT_2→4) appears to be less clear-cut.

In order to explore the distinctions between the levels of the *Change Type* effect, a set of pairwise LSD post-hoc statistical tests were conducted. The results of these calculations indicate that the sole discrepancy that is not statistically meaningful pertains to two levels that entail changes of two units in the fuzzy number most possible value (CT_0→2 vs. CT_2→4 with $p = 0.368$). In other cases, differences were significant at $\alpha < 0.0001$.

Fig. 3 also displays the average relative weights for the two levels of the *Graphical Representation* effect. These findings corroborate the initial analysis graphically shown in the key descriptive statistics section. Specifically, the study subjects evidently recognized that changes in the fuzzy number most possible values visualized as triangles were more noticeable than those presented as vectors.

It seems that the most interesting results are associated with the interaction between *Change Type* and *Graphical Representation* [$F(2, 486) = 7.13$, $p = 0.0009$]. Fig. 4 graphically presents the differences in mean relative weights for this effect.

These data suggest that triangles were better suited for visualizing the change in the most possible value for CT_0→4 and CT_2→4 change types. However, the situation was reversed for the CT_0→2 level. In this case, vector representations were better rated than its triangular counterparts.

To further explore which of these differences were statistically significant a series of pairwise LSD post-hoc tests were carried out. The outcomes indicate that the suitability of triangle-based representation for the fuzzy number change in the most possible value is statistically significantly higher for CT_0→4 and CT_2→4 *Change Type* levels ($p < 0.001$ in both cases). Although, according to participants, the mean relative weights for vector representations were bigger for CT_0→2, the difference was statistically inconclusive ($p = 0.176$).

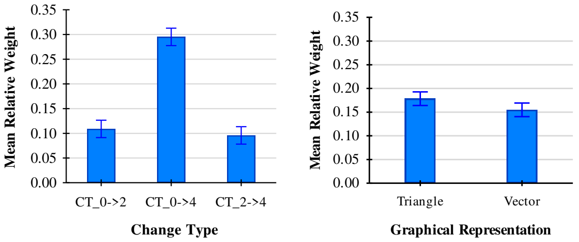

Fig. 3. Mean relative weights for *Change Type* [$F(2, 486) = 154.7$, $p < 0.0001$] and *Graphical Representation* [$F(1, 486) = 5.24$, $p = 0.0225$]. Bars denote 0.95 confidence intervals.

We also further examined the *Change Type* × *Gender* interaction effect [$F(2, 486) = 2.87$, $p = 0.058$], which is illustrated in Fig. 5. This graph suggest that women were more prone to perceive the changes in the most possible value as more salient than men if the changes were smaller, that is, amounted to two units. This phenomenon was inverted for the much bigger change involving four units.

Additional pairwise tests were employed to check which of the differences were statistically meaningful. The results of the LSD post-hoc tests, revealed that gender differences for smaller changes in most possible factors were irrelevant ($p > 0.15$). However, the difference between female and male study subjects for the bigger change was statistically significant at $p = 0.057$.

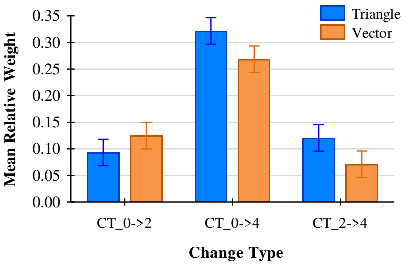

Fig. 4. Mean relative weights for *Change Type* × *Graphical Representation* interaction. Bars denote 0.95 confidence intervals [$F(2, 486) = 7.13$, $p = 0.0009$].

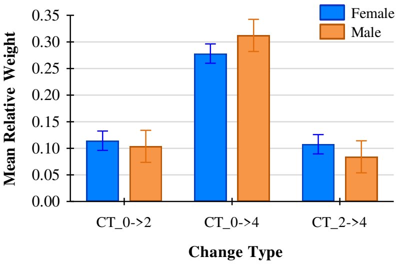

Fig. 5. Mean relative weights for *Change Type* × *Gender* interaction. Bars denote 0.95 confidence intervals [$F(2, 486) = 2.87$, $p = 0.058$].

The last significant effect from the performed analysis of variance, namely the *Graphical Representation* × *Gender* interaction, is visually demonstrated in Fig. 6. The graph shows that women considered triangular representations as better fitted to exhibit changes in most possible values than men did. On the other hand, males rated higher vector visualizations than women.

Again, we used pairwise LSD post-hoc analysis to verify the significance of the observed differences in mean relative weights. The findings, put together in Table VI, indicate that the observed gender discrepancies both for triangle and vector representations are statistically considerable ($p = 0.049$ and $p < 0.001$, respectively). Moreover, females significantly better perceived the change saliency if the fuzzy number change was presented as triangles than vectors ($p < 0.001$). For males, such an outcome was not detected ($p = 0.770$).

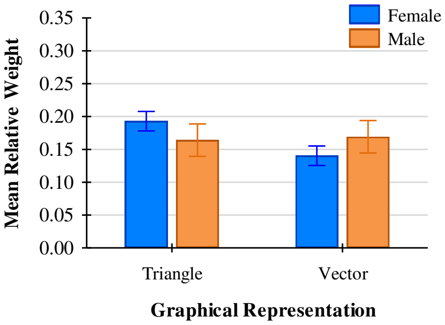

Fig. 6. Mean relative weights for *Graphical Representation* × *Gender* interaction. Bars denote 0.95 confidence intervals [$F(1, 486) = 7.78$, $p = 0.0055$].

V. Discussion of the Results and Conclusion

Our experimental study presented in this paper aimed to expand our understanding of how users perceive changes in triangular fuzzy numbers that are commonly used for expressing uncertainty. Specifically, we investigated two different visual representations of these fuzzy numbers, namely vector and classic, triangle-based ones along with various conditions concerned with their most possible values. The changes were depicted graphically through variations either in the vector angle or location of the maximum value of the membership function, and depended on the form of representation used. To gather study subjects' preferences towards the perceived saliencies regarding the change in the most possible value, we utilized pairwise comparisons within the AHP framework. Such an approach provided us with relative weights for all examined experimental conditions and allowed for comprehensive detailed formal statistical analysis. Gender differences in consistency ratios, computed according to this methodology, occurred to be statistically irrelevant. Furthermore, we identified statistically significant differences in the average relative scores for the two out of three factors studied, and three two-way interactions. The triangular-based fuzzy number representation, in general, were assessed as more appropriate than vectors for presenting changes in the most possible value. This factor considerably interacted with the *Change Type* effect. Triangles were better perceived in this experimental setup than vectors for large changes, and for changes more distant from the symmetrical case, that is vertical vectors and isosceles triangle. However, for smaller changes starting from that symmetrical situation, the reverse tendency was noticed suggesting that vectors could be better suited for detecting changes in such a case. Although this phenomenon was not statistically significant alone, the significance of the whole interaction certainly indicates that the application of vector representations should be studied in more detail in future research.

The general picture of the results obtained is further complicated by two additional gender interactions with *Graphical Representation* and *Change Type*. Females rated triangles considerably better than vectors, whereas for males the difference between these representations was unnoticeable. Moreover, triangles were relatively worse than vectors in terms of change saliency for men than women, but vectors were better perceived by male than female participants. As to the interaction with *Change Type* effect, men perceived big changes as more salient than women did. On the other hand, smaller changes of the most possible values were subjectively more noticeable for females than males. This suggest that females may be more sensitive in detecting smaller changes and less sensitive in identifying larger changes than males. This hypothesis, naturally, requires further empirical evidence. The discussed findings indisputably show that prospective research regarding graphical representations of uncertainty must involve gender-related analysis. This should be paid attention to already while designing and conducting the experiment, for instance, by ensuring similar number of man and women taking part in the study.

There are several possibilities of extending the presented study. Here, we confined only to the changes in one uncertainty feature of fuzzy numbers, that is, the most possible value. It is not clear, what would be the study subjects' perception of the saliency of changes if also the indeterminacy would be involved in the experimental setup. Thus, it should be subject to examination in future works as well. Since this study results showed that subjects' opinions depend considerably on the interaction between *Graphical Representation* and *Change Type* factors, another extension could include more levels of the *Change Type* effect to obtain a more comprehensive view of this outcome.

The results of this study contribute to the existing knowledge on how people perceive graphical representations of triangular fuzzy numbers. With the increasing use of artificial intelligence methods for handling inexact or ambiguous data, it has become crucial to develop suitable recommendations for user interfaces in computer programs that assist in solving problems with uncertainties.

The current investigation outcomes extend our understanding of individuals' opinions on the suitability of fuzzy number graphical visualizations in demonstrating uncertainty changes.

This can translate to provide appropriate recommendations for developing better graphical user interfaces with applications in such areas as production or project management. Given the presented results such interfaces should be carefully tailor-made individually for men and women.

***Abstract*—In this paper we propose two book recommendation methods based on emotions extracted from user reviews, using content-based filtering and collaborative filtering. The methods were experimentally evaluated on our own dataset that we collected from *Goodreads* – a popular website with large database of books and readers reviews. We created an experimental setup where the recommendation algorithms for carrying out the evaluation using two proposed evaluation metrics: coverage and average recommendations similarity.**

I. Introduction

PEERS feedback from interactions mediated by social media plays an increasingly important role in how we choose to approach different aspects of our lives. The lack of personal experience when taking decisions often leads to seeking the experience of peers by means of recommendations. Such recommendations can emerge in various forms including word of mouth, surveys, printed or online reviews, thus actively supporting our day-to-day life [13].

The aim of a recommender system is to provide meaningful recommendations to the users based on the products which might interest them, the recommendations trustworthiness being a mandatory characteristic. The design of a recommender system varies depending on the nature of products for which recommendations will be issued [9].

In this paper, we are focusing on a specific category of products, literature books. We propose and evaluate two recommender systems that incorporate emotion information based on two different recommendation techniques: content-based filtering and collaborative filtering.

Content-based filtering refers to recommending products which are similar to the product that is being watched [2]. Our proposed content-based filtering recommendation algorithm must observe the user interaction with a book and identify similar books based on certain book characteristics, such as book title or book author(s).

Collaborative filtering aims to mine the most similar users with the user of interest and to observe their preferences. Then, these preferences can be used to make predictions about what the user of interest might enjoy [3]. This allows the recommender system to also focus on products that the user of interest has not yet interacted with.

We appreciate that the outcome of our research is both fascinating and useful, because our methods use social generated data for identifying the similarities between the books, in addition to general publisher details about a given book (book title, author or genre).

The experimental dataset was collected from a popular book-oriented website, *Goodreads*, using our own customized web scraper.

The paper is structured as follows. In Section II, we present related works. Section III describes our proposed book recommendation algorithms, using content-based filtering and collaborative filtering. In Section IV, we provide an overview of the dataset and then we discuss the experimental results. The last section presents our conclusions.

II. Related Works

Chhavi Rana and Sanjay Kumar Jain [12] propose a system which makes content-based book recommendations based on the user navigation pattern. The system analyzes user's behaviour and then it predicts the category of books that would interest the user using content-based filtering. The authors observe the lack of accuracy of content-based recommendations, as after a certain amount of time, the users will be recommended the same similar items. Therefore they introduce a temporal dimension, which means that user navigation and most visited links are periodically analyzed and revised when using the content-based approach to make recommendations.

In [8], Jessie Caridad Martin Sujo and Elisabet Golobardes i Ribe present a system which recommends the book that best suits the reader based on the semantics of his or her writing style. They use posts from Twitter social network in order to determine the psychological profile of the user. The authors use a database consisting in characters text, associated personality type and corresponding book. Their proposed method computes the similarity between the Twitter post text and the cases database in order to recommend the most suitable book to the user.

An Enhanced Personalized Book Recommender System (EPBRS) is described in [15]. The proposed system uses the a similarity function based on Euclidean distance in order to identify users with similar interests. The recommendations are done using collaborative filtering by considering the books preferred by similar users. A dataset of reviews, users and associated ratings from Amazon bookstore was used for experiments. The book ratings are considered as features when making the predictions.

In [16], authors propose a system which is able to provide replies to queries regarding products details. The answer that is returned to the query is actually a review available for the product, which contains the relevant details. For experiments, they use two neural models, a simple model (NNQA) and a Transformer-based model (BERTQA). These models are evaluated regarding their ability to find the relevant reviews.

Anil Kumar and Sonal Chawla [6] make an analysis of the recommendation techniques which are most frequently used for book recommender systems. They also propose a new book recommender system based on Hybrid recommendation technique. The Hybrid recommender system works as follows: when the user searches for a book, the system computes the list of book recommendations using collaborative filtering on book ratings. Then the positive and negative user reviews for each book are identified such that the recommendation list will be sorted based on the number of positive reviews. The user is displayed the book recommendation list together with the details of the searched book.

Harsh Dubey and Suma Kamalesh Gandhimathi [4] propose a recommender system which uses Deep Learning GPT3 (Generative Pre-trained Transformer). The project refers to building an application which finds books that are similar to a certain book provided as input. On a web interface, the user must describe a book that he or she has enjoyed reading. OpenAI API module is used for generating the recommendations of books that are similar with the input book description, and the top 3 recommendations are displayed together with details about the books availability obtained using Google Books API.

III. System Design

Three main recommender system techniques can be identified: content-based filtering, collaborative filtering and a combination of both [2]. They differ in their data sources, as well as in how these data sources are interpreted, analyzed and processed for building the recommendations [9].

In this paper we propose two recommender system algorithms for literature book recommendation, corresponding to the two distinct techniques: content-based filtering and collaborative filtering. Both algorithms incorporate the emotion categorization of each book as an important feature for determining similarities between books.

The emotions are extracted from online book reviews and then used for creating an emotion-based categorization of books using the system we previously proposed in [7]. In total, there are 35 emotions considered: ’cheated’, ‘singled out’, ‘loved’, ‘attracted’, ‘sad’, ‘fearful’, ‘happy’, ‘angry’, ‘bored’, ‘esteemed’, ‘lustful’, ‘attached’, ‘independent’, ‘embarrassed’, ‘powerless’, ‘surprise’, ‘fearless’, ‘safe’, ‘adequate’, ‘belittled’, ‘hated’, ‘codependent’, ‘average’, ‘apathetic’, ‘obsessed’, ‘entitled’, ‘alone’, ‘focused’, ‘demoralized’, ‘derailed’, ‘anxious’, ‘ecstatic’, ‘free’, ‘lost’, ‘burdened’.

Field Name	**Field Description**
Book Id	The id which uniquely identifies the book
Book URL	The Goodreads URL of the book
Book Title	The title of the book
Book Series	The book series name
Book Author	The author(s) of the book
Book Overall Rating	The book rating, a number in interval [1, 5]
Book Ratings Number	The number of ratings available on Goodreads for the book
Book Reviews Number	The number of reviews available on Goodreads for the book
Book Full Description	The description of the book
Book Genres	Top 10 genres available for the book on Goodreads website
Book Pages	The number of pages of the book
Book Year	The year in which the book was published
Emotions	The book emotions computed using [7]

TABLE I
Book Entity Description

Field Name	**Field Description**
Review Id	The id which uniquely identifies the review
Review URL	The Goodreads URL of the review
Book Id	The id of the book for which the review is given
Author Id	The id of the user who wrote the review
Review Stars	The rating given by the review author, as integer in interval [1, 5]
Review Date	The date when the review was written
Review Tags	Review tags or keywords given by the review author
Review Content	The review (text) provided by the review author

TABLE II
Review Entity Description

The emotion extraction workflow takes as input the review, performs standard NLP text preprocessing techniques (tokenization, lower casing, removal of stop words) and determines the emotions present in the text by making word-matching with a list of adjectives and their corresponding emotion.

Our proposed recommendation algorithms were validated on the experimental dataset previously introduced in [7]. This data set was collected by us from Goodreads website using our own customized web scraper.

The dataset contains tabular data describing two entities, Book and Review, which are interrelated by a one-to-many relationship. For both entities, several parameters available on Goodreads website were extracted and captured as separate columns. They are described in Tables I and II.

A. Content-Based Filtering

Content-Based Filtering approach recommends items considering user preferences. The hypothesis of Content-Based Filtering is that users are usually more interested in those items that are similar to items they liked in the past [3].

We analyzed which fields of each book item can be used to better define its characteristics. We decided to use the Book Title, Book Series, Book Author, as well as the main emotions triggered by the book reading, which are computed during the extraction of sentiments from the book reviews.

The recommendation algorithm takes as input a review of a given user for a given book which is available in the database. The review consists of two components: a number in range $[1, 5]$ which represents a scaled value capturing how much the user liked the book (which will be referred as Review Stars) and the opinion of the user expressed in natural language text (which will be called Review Content).

The general idea of the algorithm is to use the input review in order to decide how much the user enjoyed the current book in order to recommend other relevant books to the user.

Algorithm 1 Content-Based Filtering Algorithm

```
1: if Review Stars $< 3$ then
2:     Extract the emotions from the Review Content
3:     if Review Content Emotions match Book Emotions $> threshold$ then
4:         Recommend a book which differs from the rated book
5:     else
6:         Recommend a book similar with the rated one
7:     end if
8: end if
9: if Review Stars $\geq 3$ and Review Stars $<5$ then
10:    Recommend a better book similar with the rated one
11: end if
12: if Review Stars $= 5$ then
13:    Recommend a book similar with the rated one
14: end if
```

The Review Stars is used to classify the level of satisfaction that the book provided to the user, as follows:

- The user did not like the book (Review Stars = 1 or 2).
- The user liked the book, but was not over-joyed (Review Stars = 3 or 4).
- The user loved the book (Review Stars = 5).

We detail each case of the algorithm used for Content-Based Filtering (Algorithm 1). The algorithm contains 3 main IF clauses that deal with each one of the possible three satisfaction levels extracted from the input review.

The first IF clause (line 1) refers to the case when the user did not like the book (Review Stars = 1 or 2). In this case, we need to know what caused this dissatisfaction. We will take into consideration the Review Content and extract the emotions. In order to decide what kind of books to recommend, we decided to compare the Review Content Emotions with the Book Emotions. In case they match with high value, we considers this indicates that the user did not like the overall idea of the book, the kind of emotions that the book made him or her feel. In this case, we will recommend a completely different book emotions-wise, because it is most likely that the user will prefer something different. If the Review Content Emotions and the Book Emotions do not match, we interpret this as indicating that the user did not perceive the book as expected; maybe he or she did not actually understand the meaning of the book. In this case, we will recommend a book that is similar with the current one, as we guess that the user is likely to enjoy a new book which provides emotions rather close with the ones present in current book.

The second IF clause (line 9) refers to the case when user liked the book, but was not over-joyed by it. The aim of the recommender system is to provide recommendations for products which are likely to offer the greatest experience. For this reason, we will recommend books which provide similar sentiments, but are higher in ratings than the current book.

The last IF clause (line 12) refers to the case when the user loved the book. In this case, we recommend to the user a book which is very similar to the current one, because he or she is likely to enjoy it as much.

When recommending new books, we include only books that the user has not seen, i.e. books to which the user has not yet given reviews.

By applying the content-based filtering algorithm (Algorithm 1) we obtain a list of books which are considered the user might enjoy, and the top 5 books are displayed to the user as recommendations.

B. Collaborative Filtering

Collaborative Filtering method aims to find similarities between users based on the user-item interaction [1]. The system divides the users into clusters by considering their past interactions and makes recommendations according to the preference of the cluster the user belongs [3].

Similarly to the Content Based Filtering method, the Collaborative Filtering algorithm takes as input a review of a user for a given book which is available in the database, with its two components, Review Stars and Review Content. Its pseudocode is presented as Algorithm 2.

Algorithm 2 Collaborative Filtering Algorithm

```
Compare the user of interest with all the users who provided reviews for the given book
if A similar user which matches $> threshold$ is found then
    The users are similar, recommend a book that the similar user liked
end if
```

So, we are interested in evaluating the similarity of the user of interest with other users from the database. In our model, the similarities between the user of interest and each of the users in database are computed based on the emotions that exist in their reviews given for the given book. Then we determine the 5 topmost users similar with the user of interest and we analyze their preferences. This means that we analyze their reviews to determine which other books these top 5 users rated.

We consider that a user liked a book if he or she provided 4 or 5 stars. Therefore, from all the books rated by the top 5 users, we will select only those which got 4 or 5 stars in the reviews. This will lead to a set of books which we consider the user of interest might enjoy.

In order to offer the greatest experience, we decided to filter the set of books according to the Book Overall Rating, assuming that higher rating means better book. Book Overall Rating is an attribute present for each book in our dataset and it represents the book rating as it is recorded on the *Goodreads*.

When a new review is given, the first step is to compute the emotions present in the review. The content of the review is pre-processed by removing unnecessary text from the review, tokenizing the review text into words and removing the stop words. Then we extract the emotions from the pre-processed text, using our own Emotions Extraction Algorithm introduced in [7]. Our emotion model is based on a list of maximum 35 emotions and their weights.

Following, we extract from the reviews dataset the set of reviews available for the rated book. This subset will be used with the purpose of finding similar users with the user who provided the review. Two users are considered similar if they provided review for the same book and the emotions which are available in their reviews match at least 50%.

The next step of the collaborative filtering algorithm is to identify the books that similar users liked in order to recommend them to the user of interest. In order to make recommendations, for each of the matching users we identify the rated books which received more than 3 stars (as we assume that the similar users liked these books) and were not yet rated by the user of interest, and we add them to the list of recommendations.

At this stage, we have obtained a list of recommendations which can be provided to the user of interest. Initially, we considered the default ordering of this list according to how were the books appended to the list. According to this ordering, the books preferred by the most similar users are located as topmost entries of this list. However, after a deeper analysis, we realized that this might not be the best possible ordering, because we would rely only on the most similar users in order to make recommendations, and this would restrict too much the space of possible recommendations. Therefore, we decided to define a better way to order the recommendations such that to not rely only on the preferences of the single topmost similar user. Consequently, we considered that a possibility is to order the recommendations list by the Book Overall Rating value, before providing the top recommendations to the user.

If the recommendation list does not contain the minimum number of 5 recommendations, the list is completed by adding the books with the highest rating available in the dataset.

IV. Experiments and Discussions

A. Dataset Preparation

The data set was pre-processed before the application of the recommendation algorithm. The aim of the pre-processing is to compute the books similarity matrix that contains the similarity value for each pair of books in the dataset.

We did not use all the fields of a book entity (see Table I) for our recommendation algorithms. Therefore we selected only those book features which are relevant and we combined them into a single text field. We consider to be relevant the following fields: Book Title, Book Series, Book Author and Emotions. The resulting string is stored into the books dataset as an additional column named “Combined Features”.

Then we converted each “Combined features” field of a book into a vector of token counts. We applied this processing for each book of the dataset, thus obtaining a matrix T of token counters with elements natural numbers. The total number of tokens is equal to the size of the vocabulary that is found by analyzing the “Combined Features” field of each book. So, if there are n books and the size of the vocabulary is m the resulting matrix of token counts will have size $n \times m$. The count matrix was created using *CountVectorizer* class of *Scikit-learn* library available in Python [10].

Fig. 1. Application Main Panel

Each row i of matrix T is a vector of counters describing book i. The similarity of two books i and j can be determined by applying a similarity measure to the vectors represented by rows i and j of T. In our implementation we have used the cosine similarity measure. If there are n books then the similarity matrix is a squared and symmetric matrix S of size n with real values in interval $[0, 1]$. We determined the books similarity matrix and we saved it into variable *cosine_similarity_matrix* [5].

For each input book $1 \leq i \leq n$, the books that are most similar with it can be determined by examining the row i of matrix S consisting of elements $S_{i,j}$ for all $1 \leq j \leq n$ of higher value.

B. Application Interface

In order to simplify the use of the proposed system, we developed a convenient application interface using *Tkinter* Python Library, which can be seen in Figure 1.

The button “Process input dataset” from Step 1 refers to processing the reviews and books dataset by extracting the emotions from reviews and categorizing the books emotions based using our approach previously introduced in [7].

Step 2 refers to applying one of the recommendation algorithms. For both recommendation algorithms, we have created two approaches: the first that takes into consideration only one review manually inserted by the user, and the second that takes as input a list of reviews provided in a *CSV* file. From the main console of the application, the user can choose which function to execute, by using the corresponding button on Step 2.

Using the first approach (a manually inserted review), another panel will appear on the screen (Figure 2). The user has to insert using the keyboard the following information: the user id, the book id, the number of stars and the review content. If the Recommender System would be used in a real setting, the information about the user id and book id would be automatically collected from the context (current

book selection and authentication information), but since our project is focused on the experimental evaluation of our algorithms (not on the actual graphical user interface of a Web-based deployed system), this information needs to be manually inserted by the user.

After filling in all the required fields, the user must press the button “Recommend” thus triggering the recommendation process. The Recommender System processes the input fields, applies the selected recommendation algorithm and displays the top 5 recommendations in the lower part of the panel.

The second implementation approach uses a list of reviews given in an input CSV file and applies the selected recommendation algorithm to each given review, rather than using a single review which was provided by the user as input.

Since using the second approach the results cannot be displayed in the same way as for the first approach, we had to find a meaningful way to display the output recommendations. We decided to store the results as a list inside an output text file. For readability, we also added to this file the information about the processed review, respectively Author Id, Book Id, Review Stars, Review Content and Emotions, together with the recommendations themselves.

C. Experimental Results

The dataset consists in 78 books and 6566 associated reviews, collected from *Goodreads* website. For majority of books (71 books) the reviews dataset contains 90 reviews, while for 7 books there are less than 90 reviews available.

These reviews were written by a total of 2658 users. 1755 users have written only 1 review, 795 users have written between 2 and 10 reviews, while 108 users have written more than 10 reviews (between 11 and 74 reviews).

The experimental setup is configured on Step 3 of the application workflow: Evaluate Recommender Systems (Figure 1). Firstly, the training and testing datasets have to be defined.

We have split the *Goodreads* dataset of 6566 reviews as 80% for training and 20% for testing. As different number of reviews are contained in the data set for each separate book, training - testing split was done for each book. Following this splitting procedure, the training dataset contains 5267 reviews and the testing dataset contains 1299 reviews.

The training reviews dataset was used for defining the book emotions feature, which means that the emotions were extracted from the review content and are attached to the book using our procedure previously introduced in [7].

The testing reviews dataset contains those reviews based on which the system will provide recommendations in order to perform the experimental evaluation of our proposed recommendation algorithms. Each entry in the testing dataset can be seen as a new review that is currently added by a user who expects to receive book recommendations.

Let us define the following parameters that are used for the rigorous definition of our proposed evaluation metrics:

- *Recommendation space* R refers to the total number of possible recommendations, i.e. the total number of books available in the books dataset (in our case 78).
- *User input space* U refers to the total number of user inputs u. A user input is a new review added for a certain book from the dataset.

$$u = (book, review), where\ book \in R$$

- *Test space* T refers to the subset of the input space $T \subset R$ used for experimental evaluation.
- A *recommendation* $f_i(u)$ refers to the output recommendation obtained when applying recommendation algorithm i. The output is a set of 5 books $r_i \in R$. $i = 1$ denotes the Content-based Filtering Algorithm, while $i = 2$ denotes the Collaborative Filtering Algorithm.

$$f_i \colon U \to R^5$$

$$f_i(u) = (r_1, r_2, r_3, r_4, r_5)$$

- *Total number of unique recommendations* $TNUR_i$ refers to the amount of unique books from the dataset which are returned as recommendations by algorithm i. In our case, $TNUR_1$ refers to the books returned as recommendations by Content-based Filtering algorithm and $TNUR_2$ refers to the books returned as recommendations by Collaborative Filtering algorithm.

$$TNUR_i = \bigcup_{u \in U} \{f_i(u)\}$$

- *Recommendations similarity* s refers to the similarity between recommendations $f_1(u)$ and $f_2(u)$ provided for the same user input u using the Content-based Filtering algorithm, respectively Collaborative Filtering algorithm.

$$s \colon R^5 \times R^5 \to [0, 1]$$

s is determined using Jaccard index.

$$s(f_1(u), f_2(u)) = \frac{|f_1(u) \cap f_2(u)|}{|f_1(u) \cup f_2(u)|}$$

Considering that each of the two algorithms provides a list of 5 recommendations, it follows:

$$s(f_1(u), f_2(u)) = \frac{|f_1(u) \cap f_2(u)|}{10 - |f_1(u) \cap f_2(u)|}$$

We propose two performance measures for evaluating our recommendation algorithms, as follows:

- *Coverage* C_i determines the proportion of books from R that the system was able to recommend using recommendation algorithm *i*.
$$C_i = \frac{|TNUR_i|}{|R|}$$
- *Average Recommendations Similarity* ARS is the average of the similarity between recommendations provided using Content-based Filtering and Collaborative Filtering algorithms.
$$ARS = \frac{1}{|T|} \sum_{u \in T} s(f_1(u), f_2(u))$$

For the Content-based Filtering algorithm, we have obtained a coverage of 96.153%, which means that that when suggesting book recommendations for the 1299 testing reviews, 75 books from the dataset were recommended.

The same coverage 96.153% is obtained for Collaborative Filtering algorithm (just simple coincidence).

Note that even if we obtained equal coverage values for both recommendation algorithms, the books which are not recommended by these algorithms are different. For the Content-Based Filtering algorithm the 3 not-recommended books from the dataset were: index 24 ("The Handmaid's Tale" by Margaret Atwood), 54 ("Charlie and the Chocolate Factory" by Roald Dahl) and 77 ("The Story of My Life" by Helen Keller), while for the Collaborative Filtering algorithm the books from the dataset which were not recommended are: index 63 ("The Good Earth by Pearl S. Buck | Summary & Study Guide"), 64 ("Sidekick to Mockingjay by Suzanne Collins" by Katherine R. Miller) and 70 ("The Road by Cormac McCarthy | Summary & Study Guide").

The *Average Recommendations Similarity* between the books recommendations received using the two algorithms is 5.71%. This rather low value was somehow expected. It shows that applying both recommendations algorithms on the same user input review generates rather different recommendations. In total, for our 1299 input reviews, 6495 recommendations were obtained using Content Based Filtering and 6495 were obtained using Collaborative Filtering, as both recommendations algorithms provide to the user the top 5 recommendations. Out of the 6495, only 602 were identical.

V. Conclusions

In this contribution, we presented two different algorithms for making valuable book recommendations considering also the emotions extracted from online book reviews submitted by book readers. The proposed recommendations algorithms are based on content-based filtering and collaborative filtering.

The emotions present in online book reviews are used to create an emotion-based categorization of books. Then the emotion categorization is considered as an additional book feature when computing the similarity between two different books, together with the book title and the book author(s).

We created an experimental setup using a books and reviews dataset that we collected from *Goodreads* website using our customized web scraper. We divided the reviews dataset into two groups: training and testing. The training consists in extracting the emotions present in the reviews and using them to categorize the books, while the testing refers to giving the reviews one by one as input to our system and receiving recommendations.

We proposed two performance metrics *Coverage* and *Average Recommendations Similarity*. Our experimental evaluation shows a good books dataset coverage on both recommendation algorithms, as almost all books from the dataset are given as recommendations for all the possible user inputs. On the other hand, the *Average Recommendations Similarity* metric provides low similarity values of recommendations generated using Content-based Filtering and Collaborative Filtering. This is expected, considering the different nature of the recommendation methods involved.

Abstract—**The exponential growth of data generated by the Moroccan commercial court system, coupled with the manual archiving of legal documents, has led to increasingly complex information access. As data classification becomes imperative, researchers are exploring automatic language processing techniques and refining text classification methods. In this study, we propose a BERT-CLSTM model for the classification of Moroccan commercial court verdicts. By adding a Convolutional Long Short-Term Memory Network to the task-specific layers of BERT, our model can get information on important fragments in the text. In addition, we input the representation along with the output of the BERT into the transformer encoder to take advantage of the self-attention mechanism and finally get the representation of the whole text through the transformer. The proposed model outperformed the compared baselines and achieved good results by getting an F-measure value of 93.61%.**

I. Introduction

TEXT classification is a machine-learning task that assigns a document to one or more predetermined categories based on its content. It is a key problem in natural language processing, with diverse applications such as sentiment analysis, email routing, offensive language detection, spam filtering, news classification, and language identification.

Text mining [1] is one of the most important approaches for analyzing massive volumes of textual data. Also, it is used to discover previously unknown relationships and propose solutions to aid decision-making. Many technologies are utilized in the text mining process to attain these aims. Text summarization, translation, categorization, and information extraction are a few examples. This paper's content is limited to text classification.

Despite the advances made in text categorization performance, there is still significant potential for improvement, particularly in the Arabic language. According to Internet World Stats, Arabic is the fourth most common language online, with over 225k users, representing 5.2% of all Internet users as of April 2019. Arabic NLP is still a challenging task due to the Arabic language's richness, complexity, and complicated morphology. Arabic features are assorted in abundance aspects compared to other languages. There are several forms of grammatical, variations of synonyms word, and numerous meanings of words which differ based on factors such as the order of the word.

Traditional text classification methods use sparse vocabulary features to represent documents and treat words as the smallest unit. Documents represented by such approaches typically have high dimensionality and sparse data, so the classification accuracy is low. Later, with the rise of distributed representation, the usage of high-dimensional dense vector representation documents such as the word2vec or Glove models gradually becomes mainstream. The word vectors trained using this type of method represent the contextual semantic information of the text. Recently, with the emergence of deep learning, more researchers use deep learning neural networks for text classification, such as convolutional neural networks (CNN) and recurrent neural networks (RNN). The method using deep learning for text classification involves feeding text into a deep network to generate a representation of the text and then feeding the text representation into the softmax function to calculate the probability of each category. CNN-based models [2], [3], [4] may generate text representations with local information, whereas RNN-based models [5], [6] generate text representations with long-term information.

Nowadays, the process of classifying verdicts of Moroccan commercial courts is done manually. Court staff read each verdict and classify it into a predefined category. This process has many drawbacks. First, the processing time is long. Second, court staff may make mistakes while filing the document, and third, the confidentiality of citizens' data is not respected. Based on the disadvantages of the current system, we propose a BERT-CLSTM model that can provide the same service in a short time. The proposed model combines the advantages of CNN and RNN.

The rest of the paper is structured as follows: Section II presents the related literature. In section III, we give details on the dataset created for this task of classification, the data preprocessing, and the model. Section IV presents the experimental setup, evaluation measures, and results, and we discuss them. Finally, conclusions are drawn in Section V.

II. Related Work

Over the past few years, several researchers have addressed the issue of automatic categorization of legal data and the exploitation of these huge amounts of court-generated data to assist in decision-making. The study presented in [7] aims to classify Arabic news articles based on their vocabulary features. They employed multi-label classifiers like Logistic Regression and XGBoost, with XGBoost achieving the highest accuracy at 84.7%, while Logistic Regression scored 81.3%. Additionally, ten neural networks were constructed, and CGRU proved to be the top-performing multi-label classifier with an accuracy of 94.85%.

Research [8] introduce AraLegal-BERT, a bidirectional encoder Transformer-based model that has been thoroughly tested and carefully optimized to amplify the impact of NLP-driven solution concerning legal documents. They fine-tuned AraLegal-BERT and evaluated it against three BERT variations for the Arabic language. The results show that the base version of AraLegal-BERT achieves better accuracy than the general and original BERT over the Legal text.

El-Alami et al [9] propose an Arabic text classification method based on Bag of Concepts and deep Autoencoder representations. It incorporates explicit semantics relying on Arabic WordNet and exploits Chi-Square measures to select the most informative features. To produce a high-level representation, they applied successive stacks of Restricted Boltzmann Machines (RBMs). Experiments showed that using the Autoencoder as a text representation model combined with Chi-Square and classifier outperformed state-of-the-art techniques.

Hazm et al [10] evaluated Arabic user comments on Twitter using a common form of Recurrent Neural Network (RNN), Long Short-Term Memory (LSTM). Experiments revealed that LSTM outperforms standard approaches in terms of accuracy while requiring less parameter computation, less working time, and more efficiency.

Alhawarat and Aseeri [11] implemented a CNN multi-kernel architecture with word embedding (n-gram) to classify Arabic documents of news. Regarding the current studies on Arabic text classification, their approach achieves very high precision using 15 of the publicly available datasets.

Galal et al [12] concentrated on classifying Arabic Text using a convolution neural network (CNN). They implemented GStem a new algorithm focused on extra Arabic letters and word embedding distances to group related Arabic words. Their studies have shown that it improves the accuracy of the CNN model when using it as a preprocessing stage.

Boukil et al [13] proposed a technique for categorizing Arabic datasets. They utilized an Arabic stemming algorithm to select and reduce features and employed Term Frequency Inverse Document Frequency (TFIDF) for feature weighting. Their study compared the CNN model and standard machine learning methods on a benchmark dataset. The authors found that the CNN model outperformed traditional methods, especially for large and complex datasets.

Al-khurayji and Sameh [14] proposed a novel method for Arabic text classification using Kernel Naive Bayes (KNB) classifier. Their approach involved preprocessing documents through tokenization, stop word removal and word stemming. They utilized Term Frequency-Inverse Text Frequency (TF-IDF) for feature extraction and represented terms as vectors. Experimental results on the collected dataset demonstrated the superiority of their methodology, showing excellent precision and efficiency compared to other baseline classifiers.

III. Research Methodology

In this section, we present the corpus created to train and evaluate our model, also the data preprocessing process, and finally, we explain the model architecture.

A. Dataset

The dataset created to train and evaluate our proposed classifier is a collection of Arabic verdicts issued from the Moroccan commercial courts. It consists of 2821 documents and 66900015 words. The average document size is 23715 words. Documents are categorized under four main classes: Unfair competition, Arbitration, Insurance, and Commercial lease.

The dataset was split into a training dataset (75% of each class) used to build the model and a testing dataset (25% of each class) used to evaluate the model's performance. The distribution of documents in each class is presented in Table I.

TABLE I
Distribution of documents in each class.

Class	Train	Test	Total
Unfair competition	523	175	698
Arbitration	509	163	672
Insurance	511	183	694
Commercial lease	557	200	757
Total	2100	721	2821

B. Data preprocessing

The first step in our preprocessing process was removing stop words, removing foreign characters, and punctuation by applying basic functions. Then, we execute the stemming algorithm, which transforms all words into their stems.

C. Model

The proposed BERT-CLSTM model exhibits two key characteristics. Firstly, it employs CLSTM to transform the task-specific layer of BERT, allowing our model to capture local and long-term text representations. Secondly, the output of BERT, along with the CLSTM representation, is fed into the transformer encoder. This facilitates the use of self-attention to focus the final text representation on essential segments. The architecture of the BERT-CLSTM model is illustrated in Figure 1.

1) CLSTM encoder: In order to make the representation of text focus on the information in the text. We use a convolution filter to extract features from T. Assume that the size of the convolution window is 1 × k, the output of the CLSTM encoder is:

$$P = CLSTM_k(T) \tag{1}$$

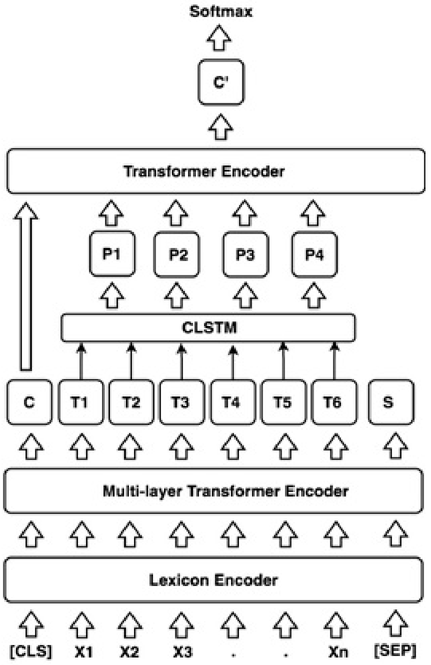

Fig. 1. Model architecture.

P is $\{P_1, P_2, P_3, ..., P_r\}$ and $r = mk + 1$. Through convolution operation, we can obtain the representation of sentences in windows with size K. For example, P_r is the representation of $T_{(r-1)}, T_r, T_{(r+1)}$.

2) Transformer encoder: Similar to multi-layer transformer encoder, to integrate information in P, we adopt transformer encoder to map the local representation P into the representation of whole text. The input of the transformer encoder is $\{C, P_1, P_2, P_3, ..., P_r\}$, and we use C' which corresponds to C as the representation of the whole text.

3) Output layer: The output of the model is represented as follows:

$$y = softmax(tanh(WC' + b)) \tag{2}$$

Where $\tanh$ presents the hyperbolic tangent function:

$$tanh(x) = \frac{sinh(x)}{cosh(x)} = \frac{e^{2x} - 1}{e^{2x} + 1} \tag{3}$$

IV. Results And Analysis

This section presents the experimental setup, including the parameters used for training and testing the model. We detail the evaluation measures, highlight the results, and provide a discussion of the findings.

A. Experimental setup

To evaluate our classifier, we used the created dataset (See section III.A). Table II shows the model hyper-parameters.

TABLE II
Major hyper-parameters of the model.

Step	Parameter	Value
BERT Embedding	Size of BERT	1024
BERT Embedding	BERT layer	Last 4
CLSTM Layer	Number of filters	128
CLSTM Layer	Filter sizes	3,4,5
CLSTM Layer	Pooling function	Max Pooling
CLSTM Layer	Dropout probability	0.5
CLSTM Layer	Number of epochs	30
Training	Optimizer	Adam
Training	Learning rate	1e-3
Training	Loss	Cross Entropy

B. Evaluation measures

We used a variety of metrics to evaluate the performance of the model. We began by calculating the **Precision** measure, which indicates the number of documents correctly predicted by the model out of all documents predicted. The precision measure may be calculated using the equation 4:

$$Precision = \frac{True\_Positives}{True\_Positives + False\_Positives} \tag{4}$$

Second, the **Recall** measure, which indicates the number of documents accurately predicted by the model out of the total of documents in the dataset. The recall measure can be computed using this equation 5:

$$Recall = \frac{True\_Positives}{True\_Positives + False\_Negatives} \tag{5}$$

Third, **F1-measure** which is a metric that can be calculated based on the precision and recall using the following equation 6:

$$F1\_measure = 2 * \frac{(Precision * Recall)}{(Precision + Recall)} \tag{6}$$

The last metric that we use is **Accuracy**. It is a metric used in classification problems used to tell the percentage of accurate predictions. We calculate it by dividing the number of correct predictions by the total number of predictions.

$$Accuracy = \frac{Number\_of\_correct\_predictions}{Total\_number\_of\_predictions} \tag{7}$$

C. Results

We applied the baseline models which are: Logistic Regression (LR), Extreme Gradient Boosting (XGBoost), Naive Bayes (NB), and Random Forest (RF). Then, for deep learning models, we use the CNN algorithm with the fastText embedding and of course, our proposed model which is BERT-CLSTM. Table 3 illustrates the details of the model's evaluation findings. Precision, Recall, F1-measure, and Accuracy are denoted by the letters 'P', 'R', 'F', and 'Acc'. respectively.

TABLE III
PERFORMANCE OF OUR MODEL AGAINST THE BASELINE MODELS.

Models	P (%)	R (%)	F (%)	Acc (%)
LR + count vectors	86.07	86.07	86.07	86.07
LR + word level (TF-IDF)	86.07	86.07	86.07	86.07
LR + N-gram vectors	86.07	86.07	86.07	86.07
LR + CharLevel vectors	84.81	84.81	84.81	84.81
XGBoost + count vectors	87.34	87.34	87.34	87.34
XGBoost + word level (TF-IDF)	85.44	85.44	85.44	85.44
NB + count vectors	85.44	85.44	85.44	85.44
NB + word level (TF-IDF)	84.81	84.81	84.81	84.81
NB + N-gram vectors	87.97	87.97	87.97	87.97
NB + CharLevel vectors	79.74	79.74	79.74	79.74
RF + count vectors	84.17	84.17	884.17	84.17
RF + word level (TF-IDF)	87.97	87.97	87.97	87.97
CNN + FastText	90.98	90.52	90.75	90.68
BERT + CLSTM (our model)	**93.81**	**93.42**	**93.61**	**93.55**

D. Analysis and discussion

Table III shows that our model outperformed the baseline models and the CNN model in terms of Precision, Recall, F1-Measure and Accuracy. In term of F1-Measure, our proposed model outperforms the CNN+FastText model by **2.86**, the RF+TF-IDF model and the NB+N-Gram by **5.64** as well as the XGBoost+count vectors model by **6.27** and the LR+N-Gram model by **7.54**.

Figure 2 shows accuracy scores for models. In term of Accuracy, our proposed model outperforms the CNN+FastText model by **2.87**, the RF+TFIDF model and the NB+N-Gram by **5.58** as well as the XGBoost+count vectors model by **6.21** and the LR+N-Gram model by **7.48**.

The proposed method has a better classification effect, and the reason is that the text representation matrix has strong feature representation ability and is more representative, which can provide more category information for text classification. This also highlights the advantage of using CLSTM, which gives the representations of text with local and long-term information, unlike the traditional methods that are based on the bag-of-words model.

V. CONCLUSION

Arabic is considered one of the most difficult languages to process, due to its high morphological ambiguity, writing style, and lack of capitalization. Therefore, every NLP task involving this language requires a lot of feature engineering and preprocessing. In this paper, we present our model that classifies the Moroccan commercial court verdicts into four categories. The model outperformed the compared baselines and achieved good results by getting an F-measure value of 93.61%.

***Abstract*—Citizens of the city of Sarajevo and of other industrial cities are faced with a record number of days of increased pollution. In the winter months, the city of Sarajevo faces a large number of days of pollution caused mainly by the use of fossil fuels in individual houses for heating purposes. The current situation can be changed by the massive use of energy from renewable sources such as solar energy. This paper aims to evaluate the potential of solar energy in the city of Sarajevo. The use of Geographic Information Systems (GIS) represents the most significant technological and conceptual approach to spatial data analysis. Using existing models for calculating incoming solar radiation integrated in the GRASS GIS and SAGA GIS software, we achieved the goal and calculated the results for solar energy potential in the city of Sarajevo and presented them for the specific settlements. The model was implemented on the basis of created Digital Elevation Model (DEM) from Google Earth – free datasets, using techniques to collect and convert data with different software. Comparative results of selected model research are evaluated using the collected solar irradiance values from the meteorological stations, other research results, and the solar energy potential estimated via the Photovoltaic GIS Information System (PVGIS).**

Keywords: QGIS, DEM, PVGIS, GRASS, SAGA, Solar energy potential

I. Introduction

THE COUNTRIES of the European Union are signatories to the Kyoto Protocol of 1997, which deals with the reduction of global warming of the planet by reducing the emission of greenhouse gases. GHG emissions decreased in the majority of sectors between 1990 and 2018, and particularly in energy supply, industry and the residential sector [1]. The European Union provides great support for electricity generation from renewable energy sources and gradually reduces the capacity consumption of fossil fuels. Solar energy is one form of renewable energy addressed by this research. The European Union significantly encourages the population to use this energy source to generate electricity.

Pollution in the city of Sarajevo is mainly caused by burning fossil fuels to heat individual housing units in settlements where individual housing prevails, and relatively more expensive prices for gas and electricity for heating. In most urban zones of collective housing (buildings) thermal energy is used for heating, consuming gas as a basic energy source, which is an environmentally friendly source of energy for combustion.

Insolation is considered the direct solar radiation that reaches the earth's surface. The duration of insolation correlates with the latitude of the measurement location, elevation, land relief, and cloud cover. The terrain (relief) is the main factor that changes the distribution of solar radiation regionally and locally. Variability in terrain altitude, the slope of the terrain, aspect terrain, as well as the effect of shading, give special strong local gradients. Accurate and spatially distributed solar irradiance data are desirable for various applications (environmental science, climatology, ecology, photovoltaic installations, land management, etc.).

The growing availability of geospatial data and the demand for better analytic insight have helped to move location analysis from departmental (GIS) experts to other users [2], i.e. organizations for decision-making or users who want to take decisions about photovoltaic installations.

This study is based on the calculation of the solar potential using GIS methods and using free resources such as datasets from Google Earth and free software Quantum GIS - QGIS calculation [3], Geographic Resources Analysis Support System – GRASS [4], System for Automated Geoscientific Analyses - SAGA [5]. The aim of this study is to use certain GIS methods to obtain the results of solar potential in the city of Sarajevo. Validation and comparison of the results with previous ones and those obtained from Photovoltaic GIS Information System PVGIS [6] could provide information about the accuracy of GIS methods for solar potential calculation.

The study work of the region Abruzzo in Italy provides a framework for analyzing the sustainability of renewable energy sources using GIS. They present a GIS-based methodology to support decision-making in energy supply from renewable energy sources. One of the primary data required for the study was Digital Elevation Model - DEM [7]. The r.sun [8] model is a complex and flexible solar radiation model, fully integrated within the open-source environment of GRASS GIS [9]. The implemented equations follow the latest European research in solar radiation modeling. Integration in GRASS GIS enables to use interpolation tools that are necessary for data preparation [8]. The assessment of photovoltaic potential in the urban area of Bardejov in Slovakia was performed by using r.sun and a 3D city model. It was emphasized that the city has the potential to generate about 45% of its current electricity consumption by installing PV systems, although the study area

This work was not supported by any organization

included only two-thirds of the entire city. This confirms that solar potential estimates performed by the r.sun model can be used to assess solar potential as well as in urban areas [10]. In the research and estimation of the solar potential of roof surfaces in Baton Rouge (USA) on the basis of LiDAR data, information about the buildings (slope and aspect of roofs) and information concerning the roof surfaces using GRASS GIS software results indicate the annual solar potential of approx.1598,7 (kWh/m^2) [11]. Gorički M. with the group uses DSM to calculate the solar potential in the small town of Sveti Križ Začretje in northwestern Croatia. The data for the study were provided by an unmanned aerial vehicle. To evaluate the solar potential, they used the SAGA GIS software annually with a solar potential of 1900 (kWh/m^2) on the southern parts of the house roofs [12].

Validation of the obtained results could be done on the basis of solar radiation measurements, which are measured daily by hydrometeorological stations. In Sarajevo there are stations that measure insolation but not solar irradiance.

In Europe, there are several hundred weather stations that directly or indirectly measure solar radiation [8].

In this paper, we will present the methodology for estimating solar potential using available GIS tools and compare the obtained results using the city of Sarajevo as an example. In the following, we will first introduce the selected area and the method of data collection, then model the data, choose the appropriate method for the budget, and use it with free GIS tools. At the end, we will discuss the obtained results.

A. Data analysis and preparation area

The city of Sarajevo was selected for the area of analysis due to the frequent pollution of the city and its population during the calendar year and the potential opportunity to make better decisions towards electricity generation from renewable energy sources, especially solar energy.

The area of the City of Sarajevo is located in the Mountain Valley macro-region in the Sarajevo-Zenica Valley, which is the southern end of the larger morpho structure. The lowest parts of the city area are located at an altitude of about 500 meters (zone of Rajlovac and Reljevo), while some of the settlement slopes in Stari Grad reach over 800 meters. The city center is located at an altitude between 540 and 550 meters. Mount Trebević (1627 meters) is a dominant mountain elevation near the city center. The Sarajevo Valley, where most of the city of Sarajevo is located, is in the east-west direction in a length of about 12 (km) and 1-1.5 (km) wide, with geographical coordinates 43.8563°N, 18.4131°E. The area of analysis is shown in Fig. 1.

Free software QGIS version was used to prepare and process data. Due to the widespread data availability and the possibility to repeat the results and the possibility to use free data for processing, the Google Earth application is used to download data from which DEM is created.

The area bounded by a red rectangle with dimensions (11.5 km long and 7.5 km wide) is an area for analysis. This is a very wide area for the creation of DEMs and an area of about 82 km^2. For this survey, we are collecting data for the following 6 settlements:

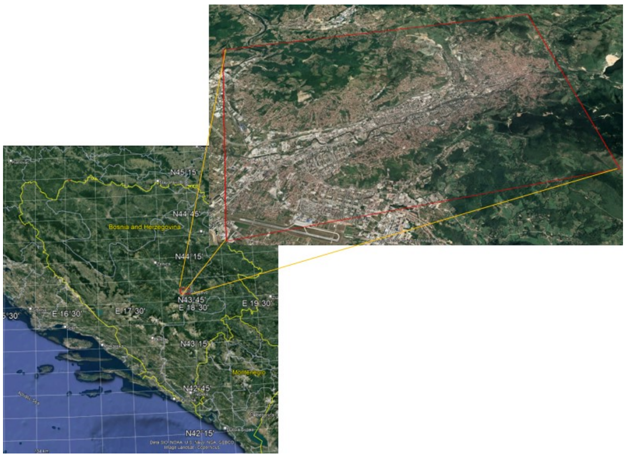

Fig. 1. A view of wider surroundings of the city of Sarajevo

1. Nedžarići, residential houses, lowland part of the city,
2. Grbavica, blocks of flats, lowland plant of the city,
3. Buća Potok, residential houses, hillside area, south –orientation,
4. Širokača-Krka, residential houses, hillside area, north orientation,
5. Šip, blocks of flats and meadows, mountainous area, south-west orientation,
6. Sedrenik-Grdonj, residential houses, south-west orientation.

B. Insolation and insolation data for Sarajevo

Insolation is the time for which the earth's surface receives direct solar radiation. The duration of solar radiation correlates with the latitude of the measurement location, altitude, land relief, and cloud cover. A heliograph is a measuring device consisting of a glass ball 9-12 (cm) in diameter recording the sun rays and focus them onto a strip of paper that burns under the influence of heat. Since older versions of heliographs did not indicate values below 120 (W/m^2), this threshold was retained by the World Meteorological Organization Convention and in more modern measuring instruments "unpublished" [13].

The term cloud cover refers to the degree to which the sky is covered with clouds, i.e. the size of the cloud cover relative to the entire sky. Smaller values mean brighter days, so the value of 1 means coverage of up to 10% of the sky with clouds, cloudiness 10 means that the sky is completely covered with clouds. According to [14] the annual insolation from the Bjelave hydro-meteorological station for a period of 20 years amounts 1919 hours i.e. 5(h) per day. The monthly sum of insolation (I) is calculated according to (1):

$$I = i_1 + i_2 + \cdots + i_n \tag{1}$$

$i_1, i_2, \ldots, i_n$ - the daily sum of sunshine duration for the first, second and i^{th} day of the month.

The annual insulation (I_g) is calculated according to (2):

$$I_g = I_1 + I_2 + \cdots + I_{11} + I_{12} \qquad (2)$$

$I_1, I_2, I_3, \ldots, I_{12}$ - represent the insolation for the first, second, third,..., and twelfth month, respectively [14].

C. Irradiation on a horizontal plane

The term irradiance is used to consider the solar power (instantaneous energy) falling on unit area per unit time (W/m^2). The term irradiation is used to consider the amount of solar energy falling on unit area over a stated time interval (W/m^2) [8]. According to [15] integrating the obtained value by time, the total energy of radiation the unit area in the observed interval is obtained. By integrating the intensity of solar radiation at different time intervals, we obtain hourly, daily, monthly, and annual irradiation (H):

$$H = \int_{t_1}^{t_2} G_{0n} cos\theta_z dt \qquad (3)$$

G_{0n} – extraterrestrial radiation intensity on a surface perpendicular to the radiation (W/m^2); G_0 – solar constant 1367 (W/m^2); n – ordinal number of days in a year.

$$H_0 = \int_{-\omega_s}^{\omega_s} G_0(1 + 0,34cos\frac{n}{356}360)$$

$$(sin\varphi sin\delta + cos\omega cos\delta cos\omega)d\omega \qquad (4)$$

$$H_0 = \frac{24}{\pi} G_0(1 + 0,364cos\frac{n}{356}360)$$

$$(\frac{\pi}{180}\omega_\mathbf{s} sin\varphi sin\delta + cos\varphi cos\delta sin\omega_\mathbf{s}) \qquad (5)$$

H_0 – the irradiation on a horizontal plane; (Wh/m^2); $\omega_\mathbf{s}$ – angle of sunrise (°); $-\omega_\mathbf{s}$ – angle of sunset (°); δ – solar declination (°); φ – latitude (43°52 for Sarajevo) (°).

The average annual extraterrestrial irradiation in the city of Sarajevo is obtained by calculating the average daily extraterrestrial irradiation for each day of the year. Table I shows the average monthly irradiation of a horizontal plate area 1 (m^2) at the latitude (43°52 for the city of Sarajevo). Calculated values of extraterrestrial irradiation do not take into account the influence of absorption, diffuse radiation and reflection of solar radiation, effects of clouds, pollution, height of the measuring plate, etc., which strongly influences the measurement results "unpublished" [13].

D. Data modeling

The digital elevation model (DEM) is considered one of the most important input data for the purpose of terrain's (relief) surface representation. DEM system [16]. There is no harmonized terminology about the name in the literature. Digital terrain model (DTM), this concept, which includes relief as well as other general geographic objects, refers to the part of the terrain that has certain distinctive features.

The specificity of this paper is reflected in the generation of DEM from free data sources. The quality and quantity of data as well as the method of collecting these data are the most important for obtaining quality DEM. The access was done through the free online application Google Earth and the data offered in it on the Internet. Fig. 2 shows the sequence diagram of steps that were performed to achieve the final DEM product. Creating a vector file in the Google Earth web platform, i.e. when such a trajectory is drawn over the desired area with sufficient desired density, a file with a .kml extension is formed. The trajectory is clearly marked with latitude, longitude, and altitude. A larger number of points in the trajectory represents a more detailed DEM. After creating the trajectory, data extraction was started using certain free-type applications. To convert a .kml file into a .gpx file, the GPS Visualizer was used, where a certain conversion method saved .gpx files. The next step was to create a .scv file where you can visually see the numerous values of each point from the trajectory with latitude, longitude and altitude and this process was done using TCX Converter - free software. By processing .csv file and inputting it into QGIS [3], we created a set of points from which we obtained DEM shown in Fig. 3 by post-processing and applied algorithm.

II. OVERVIEW OF GIS METHODS FOR ESTIMATING SOLAR POTENTIAL

To calculate the potential of solar radiation with GIS methods, certain raster data such as DEM or DTM terrain models are needed. Several methods have been developed and are used in different GIS tools. Each of these methods has its own specific parameters.

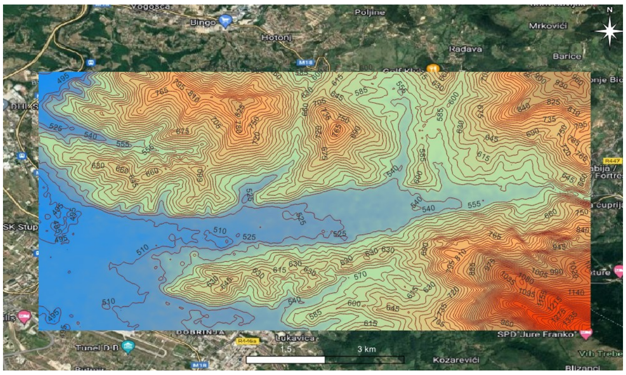

Fig. 3. Created DEM – City of Sarajevo

The free software GRASS GIS [4] and SAGA GIS [5] were used for calculations and analyses, and the data used were also obtained on a free basis or created by the authors.

The algorithm for the Satellite-Based Retrieval of Solar Surface Irradiance in Spectral Bands [17] has been implemented in PVGIS and is based on solar irradiance results. PVGIS [6] is often used as a basis for informative display of monthly and daily solar potential.

Hofierka and Šuri created an open-source solar radiation model called r.sun [8], GRASS GIS [4] is the best known open source software based on a methodology that uses equations published in the European Solar Radiation Atlas (ESRA) [18] and applies the r.sun model to calculate the solar potential. According to [5] SAGA is a specialized digital terrain analysis tool on a comprehensive and widely used GIS platform for scientific analysis and modeling. It is designed for easy and efficient implementation of spatial algorithms and thus serves as a framework for the development and implementation of geoscientific methods and models. Today, SAGA is a modular programmable GIS software that provides raster analyses of DEM and DSM substrates to estimate solar potential, with the ability to input specific data such as solar constant, atmospheric pressure, atmospheric height, humidity, etc. Solar radiation models integrated into GIS systems provide rapid, cost-effective, and accurate estimates of radiation over large areas, considering surface slope, aspect, and shading effects. Significant progress has been made in the development of solar radiation models over the past two decades [8].

III. SOLAR ENERGY POTENTIAL CALCULATION

A. Solar radiation and photovoltaic data

PVGIS [6] is an information system that allows the user to get data on solar radiation and photovoltaic system energy production, at any place in most parts of the world. It is completely free to use, with no restrictions on what the results can be used for, and with no registration necessary. PVGIS can be used to make several different calculations. As an example of solar potential in the city of Sarajevo, we used the PVGIS SARAH2 database, which uses predefined samples of satellite image resolution ($5km$ x $5km$) for the period from 2005 to 2020 [6]. PVGIS provides monthly solar potential values, from which we calculated the mean annual potential. Table II. shows the solar radiation for each settlement and refers to the radiation at an abduction angle with a calculated optimal plate angle. Table III. represents the solar radiation on a horizontal panel, i.e.the panel at an angle of 0^o.

B. Geographic Resources Analysis Support System

The installed GRASS GIS [4] software with version 7.6.1 was used to analyze the terrain of the observed area and then calculate the solar radiation. In the first case, a database was created with the basic element of DEM resolution ($30m$ x $30m$), shown in Fig. 3. The DEM was used to create slope and aspect, shown in Fig. 4. These two graphical representations are very important for us to calculate the solar potential in the selected area with the setting of certain parameters (Linke coefficient of atmospheric turbidity and albedo). GRASS does not count the annual solar radiation for the whole year but for each day separately. Fig. 5 illustrates solar irradiance for 01 July and the locations from which it was collected for records and analysis. Given the width of the workspace shown in Fig. 5 on the left and the resolution of ($30m$ x $30m$) and the diameter of a point from Fig. 5 from which the data was collected, which is about 200 (m), it is understandable that when collecting the solar potential from one of these points and repeated procedures, there is a possibility that we will not hit the previous pixel, but neighboring ones. Thus, there is a possibility that the value of the potential will also be different, but not drastically. The solar radiation map for the middle day of December is shown in Fig. 5 on the right.

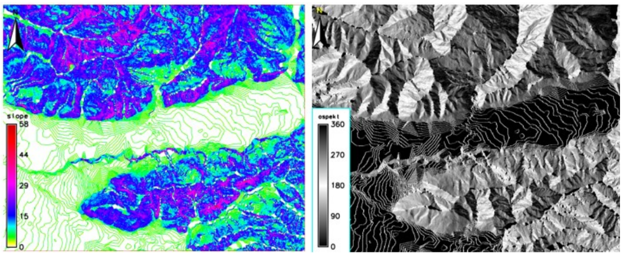

Fig. 4. Graphical presentation of slope on the left side and aspect on the right side

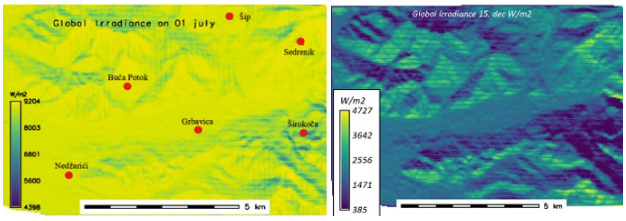

Fig. 5. Locations for collecting data for Solar irradiation for the 01. July on the left, and Solar irradiation data for 15. December on the right

The mean value of solar potential for each month for a given location is determined from the daily values, which are shown in Table IV.

TABLE IV
AVERAGE SOLAR IRRADIATION ON THE MONTHLY BASIS IN DIFFERENT SETTLEMENTS (kWh/m^2) [4]

Sett:	Nedzar	Grbav	Buca Pot	Sirok	Sip	Sedren
Jan	67	67	110	14	74	97
Apr	188	185	213	69	194	208
July	242	241	246	186	244	247
Nov	72	69	109	15	80	102
SUM:	1798	1776	2113	944	1879	2045

Very interesting are the areas of the city located on the slopes of mountain Trebević, where the solar potential ranges from about 0.4 (kWh/m^2) in winter to 7 (kWh/m^2) in summer. The results obtained with this method range from about 950 (kWh/m^2) in areas of the city facing north and northwest, located on the sides and foothills of the mountain Trebević, to 1800 (kWh/m^2) in areas located in the lowland part of the city, to 2100 (kWh/m^2) on the slopes of the city facing south, southeast and southwest.

C. System for Automated Geoscientific Analyses

SAGA GIS [5] was used to calculate the solar potential in a wide area of the city of Sarajevo. Unlike GRASS, it can calculate solar potential for the whole year. The algorithm for calculating the solar potential also uses as a basis the created DEM of areas, based on which the Sky view factor is calculated, and accordingly the algorithm calculates the solar radiation with the adjustment of certain parameters. For this calculation, we used a created example of DEM resolution $(30m$ x $30m)$. To display the average value of solar potential on monthly basis in Fig. 6, we set the algorithm sampling for each day of the month and each half hour during the day, which is a rather detailed calculation.

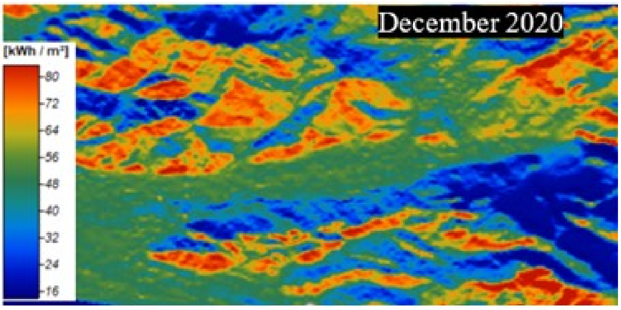

Fig. 6. Solar radiation map for December

The SAGA GIS results for 2020 range from 1449 to 2099 (kWh/m^2). A more detailed overview of the selected sites/locations is shown in Table V.

TABLE V
SOLAR POTENTIAL RESULTS IN SPECIFIC SETTLEMENTS (kWh/m^2)

Sett:	Nedzar	Grbavic	Buca Pot	Sirok	Sip	Sedre
Jan.	59	54	66	33	67	93
April	191	187	199	173	198	216
Aug.	211	208	218	182	218	230
Dec.	49	55	44	15	58	82
SUM:	1777	1729	1875	1449	1861	2099

It is expected that the result of solar potential in the settlement of Sedrenik is greater than the potential in the lowland parts of the city due to the higher location and orientation of the settlement to the south and southwest. The lowest solar potential is illustrated in the area of Širokača, which is located on the northern side of the Trebević Mountains, adding extra shade in the morning hours Fig. 6.

The dark shades on the map show fairly shaded areas and slopes facing north and northwest, where we get the lowest values of solar radiation.

IV. DISCUSSION AND COMPARISON OF RESULTS

The estimated results of solar potential in Sarajevo Canton "unpublished" [13] amount ca. 2700 (kWh/m^2). The annual irradiation on a horizontal plane of 1 (m^2), based on insolation, was estimated in range of 1100 to 1550 (kWh/m^2) according to the study "unpublished" [19]. The annual solar potential PVGIS, GRASS and SAGA for the Sarajevo area is shown in Table VI. Using PVGIS does not require extensive foreknowledge and expertise to obtain results, which makes PVGIS very easy to use. To use GRASS and SAGA GIS, it is necessary to have good knowledge in managing GIS applications and a good knowledge of the factors that affect the amount of solar radiation. There is a noticeable difference in solar potential results, especially in methods (GRASS and SAGA) in which we used DEM ($30m$ x $30m$) compared to PVGIS results which uses satellite image resolution ($5km$ x $5km$) from its database, shown in Table VI.

TABLE VI
AVERAGE ANNUAL SOLAR POTENTIAL (kWh/m^2)

Settlement	PVGIS	GRASS	SAGA
Nedžarići	1349	1798	1777
Grbavica	1355	1776	1729
BućaPotok	1360	2113	1875
Širokača	1274	944	1449
Šip	1348	1879	1861
Sedrenik	1347	2045	2099

The differences are especially noticeable in parts of the city that are in the shadow of mountain Trebević in winter months. Colleagues from Croatia, who used SAGA in research [12] concluded that the solar potential results appear to be quite large and that the actual energy of solar energy that can be obtained annually from solar radiation is much lower. Although Sveti Križ Začretje (Croatia) is 200 (km) farther north than Sarajevo, SAGA provided them results for solar potential of about 1900 (kWh/m^2).

V. Conclusion

The aim of this study was to obtain solar potential results in the city of Sarajevo using certain GIS methods. We found that GIS methods provide the user with detailed insight into solar potential with the availability of certain datasets and the level of GIS management expertise required to perform such an analysis. Based on the size of the satellite image resolution sample that makes up the PVGIS database, it can be concluded that PVGIS is more commonly used for large-area solar potential calculations, such as states. Since GRASS and SAGA do not have predefined datasets, they can use detailed DEM for input data. Due to the level of detail of the DEM created ($30m$ x $30m$), we have a more pronounced relief of the area we analyzed, so the shading effects are more visible, especially in winter months, which was reflected in the calculation of solar potential at these locations. Thus, we conclude that GRASS and SAGA are better suited for calculations of smaller areas. Based on the results, we get the impression that in micro-sites, the detail of DEM significantly increased the difference of solar potential in certain areas compared to the results of PVGIS. Looking at the solar potential results through the details of DEM samples, we can conclude that GRASS and SAGA provide more accurate results, which has been confirmed by some previous works. The results of GRASS and SAGA differ very little with maximum deviations up to 0.96%, except for the results for settlements at the foothill of mountain Trebević. Unfortunately, the validation of the results cannot be established due to the lack of measuring stations that record solar radiation (the nearest registered stations are located in Budapest and the Austrian Alps). A possible improvement in terms of more accurate solar potential results could be achieved by creating a digital surface model LIDAR record or satellite image resolution (1m x 1m).

***Abstract*—The manufacturing industry relies on continuous optimization to meet quality and safety standards, which is part of the Industry 4.0 concept. Predicting when a specific part of a product will fail to meet these standards is of utmost importance and requires vast amounts of data, which often are collected from variety of sensors, often reffered to as Industrial Internet of Things (IIoT). Using a published dataset from Bosch, that describes the process at every step of production, we aim to train a machine learning model that can accurately predict faults in the manufacturing process. The dataset provides two years of production data across four production lines and 52 stations. Considering that the data generated from each production part includes more than four thousand features, we investigate various feature selection and data preprocessing methods. The obtained results exhibit Area Under the Receiver Operating Characteristic Curve (AUC ROC) of up to 0.997, which is remarkable and promising even for real-life production use.**

***Index Terms*—Industrial Internet of Things, Industry 4.0, Machine malfunction prediction, Machine failure prediction**

I. Introduction

THE ONGOING progression of the fourth industrial revolution, accompanied by a fundamental shift towards digitization, referred to as Industry 4.0, is advancing at an exponential rate [1].

In Industry 4.0 systems, the goal is to utilize different temperature sensors, pressure sensors, audio sensors, camera devices, etc., as Industrial Internet of Things (IIoT) devices for machine monitoring and operation control in industrial environments [2]. However, performing machine fault diagnosis and failure prediction is challenging, especially considering the explainability and interoperability requirements.

Introducing predictive maintenance to production environments can provide many benefits, albeit with a few challenges. Some benefits include heightened productivity, decreased system faults, minimized unplanned downtimes, optimized utilization of financial and human resources, and improved planning of maintenance interventions as stated in [3] [4]. In addition, employing machine learning is an effective means of accomplishing prognostics and predicting failures [5]. Predicting when a part of a product will fail is paramount in identifying and preventing defects, thereby improving product quality and safety [6]. By leveraging data generated from each production part, manufacturers can determine whether a part has a weakness and take appropriate action.

Bosch, a leading manufacturer, recognizes this need and has started recording data at every step of the production process. In 2016, they published an anonymized dataset on Kaggle that provides valuable insights into two years of production data across four production lines and 52 stations [1]. Each workstation in the production process performs a variable number of tests and measurements on each part, generating 4,264 features. This experiment aims to train a machine learning model that can accurately predict faults in the manufacturing process using this dataset.

Given the vast number of features in the dataset, data preprocessing and feature selection is a critical step in the model development process [7], [8]. The enormous data growth requires using big data architectures for efficient, robust, and timely processing of it [9]. In turn, it requires the use of efficient algorithms for optimizing hardware resources and minimizing computational cost [10].

In this paper, we perform analyses and feature extraction techniques for numerical, date, and categorical data types to ensure only the most relevant data are used to train the model. With this approach, we aim to create a highly accurate machine-learning model that can aid the manufacturing industry in predicting faults in the manufacturing process using a training dataset where 6,879 parts out of 1,183,747 were labeled as failed, which is a 0.58 error rate. This relatively low error rate presents a significant challenge in creating an accurate predictive model. Figure 1 shows the number of failed parts per line on the left and the number of failed parts per station, indicating that station S32 has a significantly higher number of failures than the rest.

We aim to solve a classification problem to predict whether a product part will fail to meet quality and safety standards during manufacturing. To achieve this, we trained separate machine learning models such as Random Forest, Decision Tree, GradientBoostingClassifier, AdaBoostClassifier, and XGBoost. After evaluating the performance of each model, we found that the XGBoost model had the highest accuracy in predicting faults. Therefore, it was chosen as the final model for the task.

This paper is organized as follows. Section II extensively reviews the machine-learning approaches used for machine

[1] https://www.kaggle.com/c/bosch-production-line-performance

malfunction prediction. In Section III, we introduce our proposed method and provide a detailed explanation of the approach that we are using. Section IV describes the dataset used in our study and presents the results obtained from our experimental analysis. Finally, in Section V, we summarize our findings and conclusions from our research, discussing the potential impact of our work on the manufacturing industry.

II. Related Work

The foundation of this study lies in the preprocessing and feature extraction of numerical and time series data, as well as in classification for malfunction prediction. In the following, we delve into related research on these topics.

A paper focuses on methods for fault prediction [11] and using raw sensor data elaborates on the differences between the Support Vector Machine (SVM) and the Multilayer Perceptron (MLP) for fault prediction. This paper presented an initial development of a supervised machine learning algorithm for diagnosing faults in rotating machinery in the oil and gas industry. They aim to create a simple, easily implementable model that enables quick, informed decision-making. Some preprocessing steps explained in the study are filling in the missing values using linear interpolation, feature engineering performed to introduce the correlation between a data sample and preceding samples in chronological order, and data related to downtime and start-up periods filtered out. As a result, the SVM algorithm demonstrated higher precision than MLP but lower recall for the positive class.

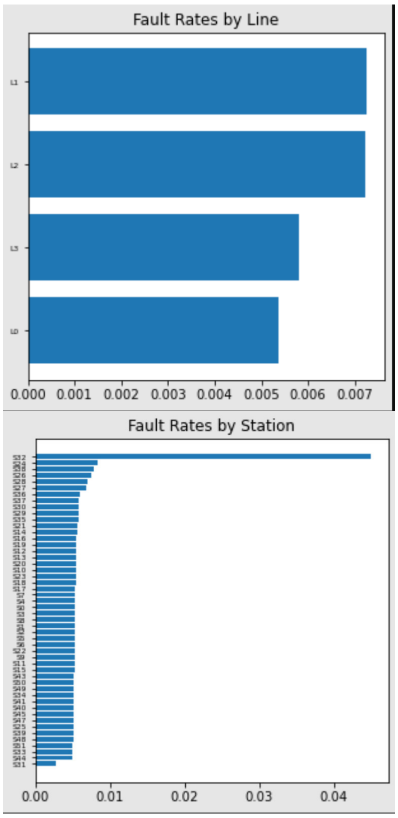

Fig. 1. (above) Number of failed parts by a production line in the training dataset (below) Number of failed parts per production station in the training dataset

[12] discusses the problem of hardware failures in circuits due to aging or variations in circumstances. While self-healing and fault tolerance techniques can recover circuitry from a fault, fault prediction can be used as a pre-stage to these techniques. The proposed method for early fault prediction of circuits uses Fast Fourier Transform, Principal Component Analysis, and Convolutional Neural Network to learn and classify faults. The approach was validated by testing it on two different circuits (comparator and amplifier) using 45 nm technology, providing a fault prediction accuracy of 98.93% and 98.91%, respectively.

Not only hardware failures but, in an article from [13], software failures were also analyzed. The quality of software depends on its bug-free operation, and identifying bugs in the early stages of development can reduce the cost of testing and maintenance. Software defect prediction models can identify bugs before release using historical data from software projects for training. The study used software change metrics for defect prediction, and the performances of machine learning and hybrid algorithms were compared. This study uses different machine learning techniques to create defect prediction models, including Random Forest, Multilayer Perceptron, Fuzzy-AdaBost, and Logitboost. With Logitboost, was reached the best accuracy.

Focusing on the feature extraction part, [14] proposes new damage classifiers for locating and quantifying damage based on a supervised learning problem. A new feature extraction approach using time series analysis is introduced to extract damage-sensitive features from auto-regressive models. The coefficients and residuals of the AR model obtained from this approach are used as the main features in the proposed supervised learning classifiers, which are categorized as coefficient-based and residual-based classifiers. These classifiers are validated using experimental data for a laboratory frame and a four-story steel structure. They are shown to be able to locate and quantify damage, with the residual-based classifiers yielding better results than the coefficient-based classifiers. Furthermore, comparative analyses show that these methods are superior to some classical techniques.

The following related work uses the same dataset in our paper and solves a classification problem for faulted parts. The authors of [15] used the Bosch dataset uploaded on Kaggle. First, they trained a model that predicts which parts are most likely to fail. Then, to manage many categorical features, they employed the FTRL(Follow The Regularized Leader) algorithm to train a model using solely categorical features. Afterward, they stacked the probability predictions with numerical and date features as a new column. This technique serves as a means of reducing features, in which all the categorical features are condensed into one feature column. The top 200 features were used to train an XGBoost model on the entire training dataset, which consists of approximately 1 million samples. The training data were randomly divided into three subsets, each containing 33% of the data. Three separate XGBoost models with the same hyperparameters were trained on 67% of the data and evaluated on the remaining 33% of the data.

Authors in [16] propose a systematic feature engineering and selection methodology considering data from a variety of sensors. From the originally recorded time series and some newly generated time series, a variety of time and frequency domain features are extracted and then selected. Such approaches can be also used in the machine malfunction problems where there is abundancy of time-series data originating from IoT devices and sensors.

The main focus in many related papers is typically on data preprocessing, and this was also our primary focus. Our work dealt with numerical features and extracted additional features from the date values, emphasizing capturing the time dependence between different parts. For example, in [15], the feature extraction was made directly on the features combined, while we deal with numerical and date features separately with different techniques for each. However, we also devoted significant attention to analyzing the raw data, as the time series data provided by Bosch were anonymized and normalized, which made it necessary to create estimations of the duration in the time series data. We were able to leverage this information to develop additional features based on the date values.

Additionally, we paid careful attention to null values during feature extraction, given the large number of numerical values we were dealing with (970 in total). Finally, we addressed the challenge of imbalanced data by performing downsampling and oversampling. We use a gradient-boosted decision tree as our primary model for malfunction prediction. This robust algorithm can handle complex data structures and identify the most valuable features for predicting the desired outcome.

III. Methods

The primary objective of this paper is to develop a fault prediction model using the Bosch dataset. The dataset was released by Bosch in 2016 as a challenge to improve its future defect reduction efforts. Furthermore, we aim to solve a classification problem using the dataset. We trained different models separately, Random Forest, Decision Tree, GradientBoostingClassifier, AdaBoostClassifier, and XGBoost. After evaluation, we found that the XGBoost model produced the highest accuracy.

The numerical data in the dataset contains many zero values, with 929,125,166 fields or 80.91% of the total being empty. However, this is not surprising, as each part goes through a specific set of stations and measurements, and empty cells indicate that a part did not undergo a particular measurement at a certain station or line. As such, these zero values are not considered missing data, and filling them using standard methods like mean imputation or forward/backward filling is inappropriate.

The dataset comprises 970 numerical columns, including the Id and Response columns. There are no columns with all null values, so such columns cannot be dropped. However, 227 columns have 99% null values, and their relevance must be determined to decide whether to keep or discard them. Upon closer inspection, we found that 11 of these columns have non-zero values for parts that were not classified as failed, and these can be immediately removed. We calculated Pearson correlation coefficients between the 11 columns and the Response variable to ensure these columns are irrelevant. That indicated correlation values close to zero, meaning they are not significantly correlated with the outlier parameter and can be safely removed.

Our next step is to use the XGBoost model to identify the most and least significant numerical features to reduce the set of features. First, we ran the model on the remaining 227 columns from the previous step and found that 107 features had a significance of 0.005 or less, so we removed them. This process left us with 852 numerical features.

Next, we applied the XGBoost model to the remaining 852 columns and removed those with more than 90% null values and a significance of 0, resulting in the removal of 218 columns. It brought the total number of numerical features down to 634, reducing the percentage of empty fields to 47.58% from the initial 80.91%.

Of the remaining 534 columns, 100 had a significance greater than 0 and more than 90% non-zero values, so we used them directly in the model. For the remaining 434 columns, we found that, on average, 49 columns had over 50% non-zero values. Therefore, for each of these 49 columns, we merged 10 zero columns and used them in the combining process, where the first non-zero value is taken. As a result of these steps, we ended up with 149 numerical features and 13.58% null fields.

Moving next to the date features, we have extracted some features from the existing date features, and then we have added additional date features with a focus on time dependence between parts.

To include time dependence, we added the following time domain features:

1) Number of parts in one takt (6 minutes). To calculate the number of parts that pass through the measuring stations in one takt, we look for the consecutive parts with the same starting takt where the first column is the takt and the second column is the number of parts that pass in the same takt.
2) Number of failures in the next 1, 10, 24 hours
3) Number of failures in the last 1, 10, 24 hours

The date features represent the date and time the measurements were taken. These features can be important because they capture temporal patterns and trends that may be relevant for predicting the target variable.

Since the test and training data are consecutive parts with indices from 1 to 2,367,494, the specified features are appropriate for the training and unlabeled data.

Of the 4,258 categorical features, 1,913 are duplicates and will be removed. Among the remaining ones, 1,549 have a single value, and 428 have multiple values. Any empty feature will also be discarded. Categorical feature values are represented as classes denoted by T followed by a number, which labels different processes. For instance, column L1_S24_F1269 contains four classes: 'T1372', 'T618624', 'T83888', and 'T8389632'. After removing duplicates and empty features, we use one-hot encoding to represent each category with an integer. One-hot encoding transforms a single variable with d distinct values into d binary variables, where each observation indicates a particular binary variable's presence (1) or absence (0). This results in a vector of size 988 for each row, but since most values are zero, we end up with a sparse matrix. To avoid overfitting, we will compare the performance of the model with and without categorical features.

Moreover, we will reduce the dimensionality of the resulting matrix using a dimensionality reduction algorithm. Sparse PCA is an unsupervised learning method used in statistical analysis to identify sparse features that can reconstruct the data. We will replace the 988 features with 5 features obtained from Sparse PCA.

After processing the features, we have 1,183,747 rows and 173 features from the training set, of which 19 are date, 149 are numeric, and 5 are categorical.

Classification models aim to assign data to different classes, but in an unbalanced dataset, one class may have a much larger number of samples than the other classes. It creates a majority class and a minority class, which can be problematic during model training because the model may not learn enough about the minority class. In our case, the defect class is the minority class, with only 6,879 parts, or 0.58% of the training data being defects.

One effective approach is to reduce the sample size of the majority class and increase the weight of the minority class. It can be achieved by either downsampling the majority class or oversampling the minority class. Downsampling may lead to a loss of information, while oversampling can result in overfitting. [17] elaborate on the sampling approaches, and they suggest that downsampling approaches give a better overall performance on all datasets. Thus, we tested the model with both techniques, and the best results were achieved by oversampling the minority class and downsampling the majority class.

IV. Experiments

In this section, we describe the datasets and the experimental results obtained in our study.

A. Data description

Bosch, a leading manufacturing company, has made a dataset available on Kaggle as part of a research project to assess the quality and safety of its manufacturing recipes. The dataset tracks parts as they move through the production lines, each with a unique identifier that serves as a row in the dataset. The dataset is a time series, with each row representing a specific section and the date attribute providing the time when each measurement was taken.

The dataset contains three types of characteristics: numeric, categorical, and date characteristics. Each feature is named according to a specific convention, including the line, station, and feature number. For example, the feature L1_S25_F2202 was measured at line 1, station 25, and has a sequence number of 2202. Therefore, this feature is measured in column L1_S25_D2203, since each feature Lx_Sy_Fn is calculated at time Lx_Sy_D(n+1).

By processing the column names, we concluded that there are four lines and 52 segment stations. Each line performs a specific production process, and one line can have multiple stations where different operations are performed, such as machining, turning, and welding. Line L0 has stations S0 to S23, line L1 has stations S24, S25, line L2 has stations S26, S27, S28, and line L3 has stations S29 to S51. Each workstation performs various tests and measurements on a given part, resulting in 4,264 features. We have 969 numeric features, 1,156 date features, and the rest are categorical.

The date features are normalized and given as takt time, which is a value for how long it takes for a process to fulfill the demand. To determine the period the data represent, we analyzed the unique values in the date features. There are 105,413 unique values, ranging from 0 to 1,718.48, with a rate of 0.01. Figure 2 shows a graph of the values and their frequencies, indicating space in the middle, meaning no measurements were made during that period.

We conducted an autocorrelation analysis using a lag function to understand the time dependence between the parts further. The results are presented in Figure 3, where the most significant values are at 1,675, with 7 local maxima corresponding to 7 days of the week. Therefore, 16.75 in the normalized data correspond to one week, and the data have a granularity of 6 minutes. It means that 0.01 corresponds to 6 minutes, and 1 corresponds to 600 minutes or 10 hours, indicating that the data correspond to two years.

For each part, we determined the maximum and minimum date, their difference, and the station with the maximum and minimum time. We also calculated the path size for each part by counting the number of non-zero values. Additionally, we found the week for the maximum and minimum dates by calculating a module of 16.75 on such values. Given the week, we labeled each day of the week, where 1 is Monday, 2 is Tuesday, 3 is Wednesday, 4 is Thursday, 5 is Friday, 6 is Saturday, and 7 is Sunday. Therefore, there are a total of 10 date features. In addition, as described previously, we added 9 features based on time dependence. Overall, in addition to focusing on the preprocessing of the data, we also analyzed the raw data to extract useful features for our model.

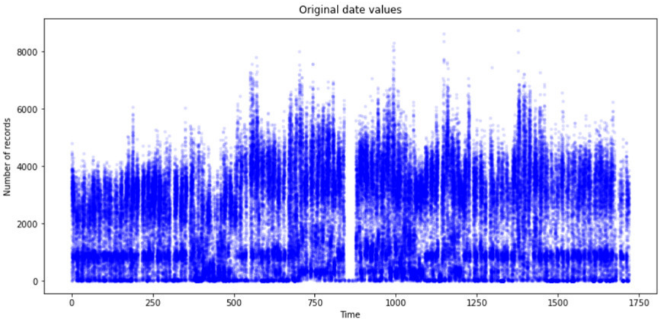

Fig. 2. Date values with frequencies

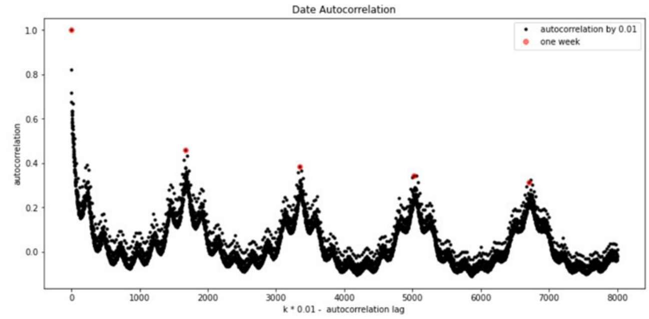

Fig. 3. Autocorrelation of date features. Autocorrelation for the number of observations recorded daily as a function of the time lag between them.

B. Experimental setup

After extracting features from the dataset, we train multiple classifiers on a balanced dataset. The classifiers include Random Forest, Decision Tree, Gradient Boosting, Ada Boosting, and XGBoost. Next, we will compare the accuracy results between 20% of testing data and the entire training dataset. Then, using the unlabeled dataset, we will predict the number of faults.

To obtain the best results, we have trained models using different combinations of features. We found that including all features (date, numerical, and categorical) resulted in the worst accuracy. Therefore, we removed the categorical features, leading to the models' highest accuracy. We also compared the results using standardized features and raw features. Standardized features yielded better results, and we used Z-Score Standardization. Z-Score Standardization is a widely used method to standardize data in machine learning. It transforms each value of a given feature in the dataset to a representative number of standard deviations away from that feature's mean. The resulting standardized value measures how far the raw value is from the mean in standard deviation units.

C. Accuracy results

Because we are dealing with an unbalanced dataset, for correct accuracy results, we have to consider true positives, true negatives, false positives, and false negatives. AUC-ROC (Area Under the Receiver Operating Characteristic Curve) plots the true positive rate (sensitivity) against the false positive rate (1-specificity) at various threshold settings and calculates the area under the curve. The AUC-ROC score ranges from 0 to 1, with higher values indicating better performance. MCC (Matthews Correlation Coefficient): MCC is a correlation coefficient used in binary classification that considers true positives, true negatives, false positives, and false negatives. MCC ranges from -1 to +1, with +1 indicating a perfect classification, 0 indicating a random classification, and -1 indicating a completely wrong classification. F1-Score (F-Measure): F1-score is the harmonic mean of precision and recall. It provides a single score that balances precision and recall and is often used to measure a model's performance in binary classification. F1-score ranges from 0 to 1, with higher values indicating better performance.

After several tests of the parameter values, the following obtained the best result using the XGBoost classifier: learning_rate=0.2, n_estimators=100, max_depth=16, min_child_weight=3, colsample_bytree=0.9, gamma=1, subsample=0.9, booster='gbtree', objective='binary:logistic'.

Table I reports results regarding AUC ROC, MCC, Precision, Recall, and F-Score on the training dataset. Table II provides accuracy scores on 20% testing data.

TABLE I
SUMMARY OF ACCURACY SCORES ON TRAINING DATASET

Model	**AUC ROC**	**MCC**	**Precision**	**Recall**	**F-Score**
Random Forest	0.705	0.148	0.53	0.71	0.51
Decision Tree	0.717	0.149	0.53	0.72	0.51
Gradient Boosting	0.691	0.22	0.56	0.69	0.59
Ada Boosting	0.629	0.187	0.57	0.63	0.59
XGBoost	**0.906**	**0.808**	**0.9**	**0.91**	**0.9**

TABLE II
ACCURACY SCORES ON 20% TEST DATA

Model	AUC ROC	MCC
Random Forest	0.801	0.613
Decision Tree	0.986	0.972
Gradient Boosting	0.917	0.837
AdaBoost	0.903	0.809
XGBoost	**0.997**	**0.994**

The evaluation metrics also provide additional insights into the performance of the models. For example, the XGBoost model achieved the highest accuracy of all the models, indicating that it correctly classified most test sets. In addition, the XGBoost model also has the highest F1 score, meaning a good balance between precision and recall. On the other hand, the other models, such as Gradieng and Ada Boosting, struggled to classify the fault class, reflected in their lower F1 scores. The MCC scores were also generally low for all models except XGBoost, indicating that the models had trouble with the imbalanced nature of the dataset. However, the AUC-ROC scores for Random Forest and Decision Tree were relatively high, suggesting they could distinguish between the positive and negative classes reasonably well. The results indicated that the XGBoost model is the most effective for this classification task.

Using the best accuracy model, XGBoost, to classify the additional unlabeled dataset, we identified 60,028 out of 1,183,748 samples as faulty. It means that the fault rate in the unlabeled dataset is approximately 5.07%. This information can help identify potential issues in the manufacturing process and improve the quality control procedures. However, the accuracy of the classification results on the unlabeled dataset may vary depending on the data's quality and representativeness and the model's performance on unseen data.

V. Conclusion

This paper presented a novel approach to predict malfunctions in manufacturing processes using the Bosch manufacturing dataset. The dataset is large and complex, containing many features with varying data types.

In this study, we addressed the challenge of handling a large number of features in the Bosch manufacturing dataset. The feature extraction process was a crucial step in the predictive modeling pipeline. We performed an iterative feature selection process to identify the most relevant features for predicting malfunctions in the manufacturing process. Additionally, time-dependent features were added to the dataset, improving the predictions' accuracy. The feature selection process was carried out carefully to ensure the selected features were relevant for the prediction task while avoiding overfitting the training data. The selected features were then used to train and evaluate various machine learning models. Handling the unbalanced dataset was another key factor in achieving high accuracy scores, and this was accomplished by performing both downsampling on the majority class and oversampling on the minority class. The study results showed that XGBoost outperformed the other models in terms of accuracy scores, including AUC ROC, MCC, and F1-score.

The proposed approach of supervised malfunction prediction using machine learning models and feature engineering can have significant implications in the manufacturing industry. Manufacturers can proactively prevent downtime, optimize maintenance schedules, and minimize production losses by accurately predicting malfunctions. As a result, it can improve manufacturing operations' efficiency and productivity, leading to cost savings and increased profitability. Moreover, the approach can also help identify patterns and insights in the data that can be used for process optimization and improvement.

In future work, we aim to extend our study to include categorical features. While we made significant progress in feature extraction and handling unbalanced data, the categorical features remain an important part of the dataset that needs further investigation. Therefore, we plan to explore various techniques for feature extraction on categorical data and evaluate their impact on the model's overall accuracy.

***Abstract*—Healthcare professionals are often overworked, which may impair their efficacy. Text search engines may facilitate their work. However, before making health decisions, it is important for a medical professional to consult verified sources rather than unknown web pages. In this work, we present our approach for creating a text search engine based on verified resources in the Polish language, dedicated to medical workers. This consists of collecting and comprehensively analyzing texts annotated by medical professionals and evaluating various neural reranking models. During the annotation process, we differentiate between an abstract information need and a search query. Our study shows that even within a group of trained medical specialists there is extensive disagreement on the relevance of a document to the information need. We prove that available multilingual rerankers trained in the zero-shot setup are effective for the Polish language in searches initiated by both natural language expressions and keyword search queries.**

I. Introduction

WHEN seeking content in a domain-specific text, a medical professional is faced with the dilemma of whether to consult a work published by a verified source or to query the Internet. Often, verified documents are published only in print, and so browsing them is time-consuming. On the other hand, a lot of Internet content is created by non-professionals and is not error-free, thus finding accurate data is difficult. This is especially true in the case of non-English online resources. However, querying Google or Wikipedia is tempting when one has to act under time constraints, for example, during a medical appointment. Considering the workload of healthcare workers [1], this statement holds even more significance. To address this issue, medical publishers attempt to provide online access to their domain-specific resources.

This paper describes the results of a project aimed at creating an intuitive search engine encompassing 852 books on medicine published in the Polish language. The tool is designed to find a book passage (usually a paragraph) relevant to a question posed in natural language and to present it to the user.

We present our novel approach to data annotation, which distinguishes between information needs and term queries. Our annotation data analysis shows extensive disagreement between trained specialists regarding document relevance. We evaluate several rerankers for the domain-specific task in the Polish language, for which currently only zero-shot rerankers are available. Our experiments prove the superiority of such reranking models to a strong BM25-based baseline. It is found that rerankers trained on vast multilingual data in a zero-shot setup perform better than a language-specific model fine-tuned to minor domain reranking data.

The rest of the paper is organized as follows. Section II concerns related work in biomedical and medical natural language processing, especially information retrieval. In Section III, we explain our task as a reranking problem, differentiating it from a full retrieval setup, and provide an overview of our search engine configuration. In Section IV we describe a typical use case for our system, which determines our annotation process presented in Section V. In Section VI we report statistics and the conclusion of the collected dataset and present our dataset preparation steps. Then, in Section VII the reranking task setup is described, which leads to Section VIII, where reranking models are presented, and Section IX, where their results are reported. In sections X and XI the possible future work and conclusions of this paper are presented.

II. Related work

Recent findings in Natural Language Processing, particularly Large Language Models (LLMs), have significantly increased the level of language understanding not only in general-oriented tasks, but also in biomedical and medical tasks [2], [3], [4], [5], [6]. In [7] the authors present a benchmark for a question-answering task in the medical domain, and show that the answers provided by LLMs are in agreement with expert knowledge in 93% of cases. Another medical benchmark is introduced in [8], where the authors conclude that pretraining language models from scratch results in gains over fine-tuned general-domain language models. However, a comprehensive survey on biomedical question-answering [9] shows the immaturity of such systems in a real-life scenario. All the above-mentioned models and benchmarks presented are in English, and no such corpora and models exist for the Polish language, which differentiates this work from the others.

To make a binding decision on a medical case, a human expert (for example, a doctor) prefers to rely on verified medical knowledge sources, rather than one (even precise) answer generated by a language model. This is mainly due to the phenomenon of artificial hallucination [10], [11], [12]. Relevant information may be found in a digital resource by a ranking function (e.g. BM25), optionally modified by a reranker. One existing benchmark for the reranking task [13] is available for the English language. [14] reports on the machine translation of the MS MARCO dataset [15] into multiple languages. The authors claim that their reranking models perform well even in non-English languages when fine-tuned in a zero-shot manner. Healthcare decision-making based on a search engine are examined in [16], [17], and some medical search models and datasets are proposed in [18], [19], [20].

III. Search engine setup

According to [13], models based on reranking are superior to full retrieval models. Moreover, it is easier to perform automatic evaluation on reranking models than full retrieval models, because such evaluation avoids cases when the model retrieves a document unseen by any human annotator. For these reasons, we decided to formulate our task in a reranking setup.

In order to meet commercial expectations, we needed to craft as strong baseline as possible. We started with the SOLR engine, equipped with the Polish Morfologik [21] lemmatizer. We handcrafted the scoring function, awarding full n-gram matches higher scores than word matches. Moreover, we used carefully adjusted weights to ensure case sensitivity, as this is crucial for the recognition of medical abbreviations (AED, DIC, etc.).

IV. Medical search case scenario

To mirror user needs we fabricated case scenarios, namely real-world situations that may cause an Information Need (IN) on the part of the system user. A case scenario consists of an event description, initial conditions, and the Information Need, represented in two forms: a natural language expression and a term query. We define an IN as an abstract term: the knowledge that a user wants to acquire from the system.

An example scenario is shown here:

- Event description: *A 30-year-old female patient presents to a PCP (Primary Care Provider) in a small town. She has severe sore throat and a high temperature.*
- Initial conditions:
  - The doctor measured the patient’s temperature (38.5 °C).
  - The doctor confirmed characteristic symptoms of tonsillitis: distended and reddened mucous membrane of the tonsils and palate.
  - The patient reported that she is breastfeeding.
- Natural language description of the IN: *I want to learn how to treat tonsillitis in a breastfeeding woman.*
- Term query: *tonsillitis in a breastfeeding woman - treatment*

TABLE I
Statistics for annotators

	mean	stdev
Information Needs annotated	39	43
total queries used	264	230
total passages annotated	12,068	10,662
time for an Information Need	67 min	55 min
time for a query	6 min	2 min
time for an annotation	8 sec	3 sec
relevant/all annotations ratio	0.29	0.17

V. Annotation process

We hired 21 medical workers (doctors, paramedics, and medical students) for consultation on system requirements and for the annotation process. Initially, they were asked to propose some INs that they may encounter in their work. Additionally, to collect other potential INs, we used the website https://konsylium24.pl/, which is a Polish web forum for medical staff. The website verifies whether users are listed in Polish doctors’ registers.

Once the set of INs had been established, we started the annotation process. After logging in, an annotator chooses an IN which he/she feels familiar with. The selection window is presented in Figure 1.

The annotator inputs a number of **queries** for each IN to a SOLR-based search engine, so that for one IN there are always multiple queries. The user may input any words that may help them find a relevant document (synonyms, hyperonyms, etc.).

Example queries for the above-mentioned IN may be: *how to treat tonsillitis in a breastfeeding woman?; tonsilitis breastfeeding treatment; breastfeeding medicines tonsilits; breastfeed woman amigdalitis;* etc.

The annotators were advised not to exceed 20 queries for an IN, and to stop when further enquiry was unlikely to return new relevant passages. The annotation platform returned a maximum of 5 pages, with 10 passages per page, for a query, as in Figure 2. The annotators were asked to read all returned passages and to tag them as relevant/irrelevant to the IN only, regardless of the input search query. If the same passage was returned again within an IN in response to a different query, the annotator would tag it once more. In total, the annotators spent over 478 hours actively tagging the passages. Statistics on their work are given in Table I.

The aim of the procedure was to acquire a more accurate dataset for training and evaluation than a simple query–passage relevancy dataset, which would be limited by the top documents returned by SOLR for one query. The dataset should help the reranker learn semantic structures such as synonyms and hyperonyms.

Query within given information need
Information need
One passage
Decision: Yes/No
Pagination. Annotators are instructed to annotate all 5 pages.

Fig. 2. Passages annotation view for a given Information Need.

VI. Dataset preparation

We rejected INs with fewer than 100 annotations. The dataset consists of 231 INs, each of them represented by a natural language description and one best-fitted term query. In total, we obtained 230,808 triplets of the form (IN, passage, relevancy annotation). Of these, 50,608 decisions were positive and 180,200 were negative, which means that about 22% of annotations were marked as relevant. A passage could be annotated more than once with different tags within the same IN, for example, if two or more annotators worked with the same IN. An analysis of mismatched annotations is presented in Table III. The results show weak agreement on IN–passage relevance between annotators. The mixed opinion percentages range from 15.6% (for two annotations) to above 50% (seven annotations and more). Carelessness on the part of the annotators is probably not the main reason for the disagreement, as we monitored their activity in the annotation platform.

VII. Task setup

We carried out experiments with Information Needs being represented firstly by a term query and then by a natural language expression.

For each IN, we queried the backbone SOLR-based search engine. The returned documents (no more than 500 for each IN) formed an input sample for the reranking model. The proposed model was expected to return the same set of documents sorted in order of decreasing relevance.

TABLE II
Information Need statistics. Annotations concern relevance for (IN, passage) pairs. There may be multiple annotations for one pair.

items per IN	minimum	maximum	mean	median
queries	1	109	21	15
returned passages	50	2279	439	325
annotations	100	4491	999	714
decision: relevant	1	1868	219	119
decision: irrelevant	23	4396	780	562

The golden truth relevance of a document is binary. The document is regarded as relevant to an IN if it was tagged as positive by at least 50% of annotators. NDCG@10 and NDCG@50 are used as evaluation metrics. NDCG metric is well defined in [22].

VIII. Models

For a baseline, we used the SOLR-based model described in section III.

HerBERT [23] (huggingface: allegro/herbert-base-cased) is a Polish-language model which achieves good results in Polish language understanding tasks [24]. We fine-tuned it on our training dataset. Unfortunately, there are no mass Polish corpora for reranking to use along with our data.

There exist some multilingual neural cross-encoder rerankers running on Polish texts. They use an mT5 [25] or mMiniLM [14] backbone, also trained on Polish texts. These models are further fine-tuned for document reranking on multilingual MS MARCO datasets using one or more

TABLE III

Statistics on annotations for (Information Need, passage) pairs. One pair may be annotated by multiple annotators, **k** represents how many annotators annotated given (Information Need, passage) pair. Column **annotiations** equals to **k*pairs with k annotations**. Column **all annotations relevant** is simply a number of annotations in which all the annotators agree that a given pair is relevant. Column ≥ **0.5 annotations relevant** stands for a number of pairs in which at least half of the annotators agree that a pair is relevant.

k	pairs with k annotations	annotations	annotations %	all annotations relevant	all annotations irrelevant	annotations mixed	all annotations relevant %	all annotations irrelevant %	annotations mixed %	≥ 0.5 annotations relevant	≥0.5 annotations relevant %

languages other than English (but not including Polish). The authors of [14] proved that these models learn to rerank documents in this zero-shot setup. We used mT5-based rerankers (huggingface: unicamp-dl/mt5-base-mmarco-v2, unicamp-dl/mt5-3B-mmarco-en-pt, unicamp-dl/mt5-13b-mmarco-100k) and mMiniLM-based rerankers (huggingface: cross-encoder/mmarco-mMiniLMv2-L12-H384-v1), which vary in terms of number of parameters and inference time. We used these rerankers in two setups: without fine-tuning (no-ft) and with additional fine-tuning to our training data (ft). We did not fine-tune the mT5-based rerankers because of the long inference time, which meant that they would not be useful as production models. We also tested several multilingual bi-encoders, among which mpnet (huggingface: paraphrase-multilingual-net-base-v2) [26] performed best. All fine-tuned models were trained separately on term queries and natural language queries.

IX. Results

The results are given in Table IV. Almost all cross-encoder rerankers achieve better results than the SOLR baseline. Only HerBERT performs worse, probably due to its being trained with only 100 samples of INs, in contrast to other transformer models that were trained previously on the multilingual MS MARCO dataset containing millions of samples. Cross-encoder rerankers based on mMiniLM are the fastest as regards inference time and achieve results that are much better than the baselines, but not as good as those of the larger models, especially the reranker based on mT5 13B. Further fine-tuning of the reranker based on mMiniLM on our 100 samples dataset improves its quality on natural language queries, but not on term queries. All of the cross-encoder models produce better results when trained on term queries than when trained on natural language queries. This also holds for HerBERT, although that model did not see multilingual MS MARCO or another reranking dataset with short queries. For the bi-encoder mpnet the opposite is true, possibly because of the similarity of the natural language sentences in the corpus on which it was trained.

In our opinion, the ft mMARCO MiniLM appears to be the best model for production applications. Its inference time is satisfactory and increases the NDCG@10 from 34.30 to 43.76 in term queries, and from 28.18 to 40.52 in natural language queries. The NDCG@50 gains are not less resounding-respectively from 32.72 to 34.80 and from 25.16 to 32.53. However, in terms of business terms, we value NDCG@10 over NDCG@50, since we expect a user to be more likely to browse only the top ten search results than 50.

X. Future work

The next step is to perform an automatic translation of the MS MARCO dataset into the Polish language and to fine-tune a Polish or multilingual model. It would be beneficial to test models that have also been pre-trained on Polish medical text corpora. Another suggestion is to replace the SOLR search system with a fast bi-encoder network or late interaction transformer [27] in order to enrich the reranker input with passages using synonyms in the medical domain, which are difficult to create manually. After releasing the product for commercial use, we will collect real users' logs for the model training dataset, and run A/B tests.

TABLE IV

MODELS' RESULTS ON THE TEST DATASET. FINE-TUNED MODELS ARE TRAINED SEPARATELY ON TERM QUERIES AND NATURAL LANGUAGE QUERIES. THE INFERENCE TIME IS AVERAGED FOR ONE NATURAL LANGUAGE IN QUERY WITH UP TO 500 DOCUMENTS FOR BATCH SIZE 30 AND THE NVIDIA A100 80GB MODEL CARD. FOR BI-ENCODERS, DOCUMENT ENCODING IS NOT INCLUDED IN THE INFERENCE TIME, AS IT MAY BE DONE OFFLINE. THE ABBREVIATION FT INDICATES FINE-TUNING ON OUR TRAINING DATASET, AND NO-FT INDICATES NO FINE-TUNING.

	term query		natural language query			
method	NDCG@10	NDCG50	NDCG@10	NDCG50	inference time [s]	params
random baseline	6.19	7.12	4.58	5.99	-	-

no-ft mT5 13B	45.45	39.97	44.87	36.25	93.47	12921M

XI. CONCLUSIONS

In this paper, we have described the process of collecting datasets for a search engine for healthcare professionals. We placed emphasis on cooperation with specialized end users. We built models for queries formulated either in natural language or by means of keywords. We distinguished between an information need and a query that serves to satisfy such a need. We fine-tuned and evaluated several rerankers, which turned out to perform better than the baselines. In our experiments, searching with term queries yielded slightly better results than the use of natural language queries. Moreover, we observed a considerable lack of consent in annotations between qualified medical workers.

Our work is based on Polish medical texts, for which no mass reranker corpora or reranker models are available, except for those fine-tuned in a zero-shot manner. We have shown that the described setup is sufficient for creating a production-ready reranker for Polish medical texts and that zero-shot trained multilingual reranker models perform better than rerankers trained on a language-specific model fine-tuned on only a small number of INs.

***Abstract*—As part of our ongoing project to prove Artin's solution of Hilbert's 17th problem in Mizar we are formalizing a great deal of basic field and Galois theory. In this paper we report on our formalization so far: we present basic mathematical structures and our Mizar definitions enriched with some main results. We also discuss some of our design decisions as well as subtleties – in particular connected with Mizar types.**

I. Introduction

INTERACTIVE theorem proving aims at developing systems to be used to formalize, that is both formulate and prove, mathematical theorems and theories in an accurate and comfortable way. The ultimate dream is a system containing all mathematical knowledge in which also mathematicians develop and prove new theorems. To come at least a little closer to this goal much effort has been spent building large repositories of computer-verified theorems such as the Coq library [7], the Isabelle2017 library [16], and the Mizar Mathematical Library [18]. A number of important mathematical theorems has been proven to illustrate the capability of interactive theorem proving, the most prominent examples being the proof of Kepler's conjecture in HOL Light [14], the Feit-Thompson theorem in Coq, and the Jordan curve theorem in Mizar.

Mizar [2], [12] is one of the pioneering systems for formalizing mathematics, after 50 years Mizar's proof checker still is actively developed and its library maintained and extended. One of the latest achievements in Mizar is the proof of the MRDP theorem solving Hilbert's 10th problem in the negative [20]. Another challenging problem is Hilbert's 17th problem: Given a multivariate polynomial that takes only non-negative values over the reals, can it be represented as a sum of squares of rational functions? Artin's positive solution [1] is a highlight in abstract algebra, introduced what today is known as formally real fields and initiated the development of real algebra.

Soon after starting the formalization of formally real fields it became clear that much more field theory is necessary than expected: not only field extensions and algebraically closed fields, but also basic Galois theory. Therefore we decided to formalize what usually appears in a one-semester graduate course on higher algebra [21], [9]. The main results of our formalization so far are

1) existence and uniqueness of splitting fields
2) existence and uniqueness of algebraic closures
3) simple extensions: characterization by intermediate fields, finite field extensions of characteristic 0 are simple
4) normal extensions: characterization by minimal polynomials, splitting fields, and fixing monomorphisms, counter example $\mathbb{Q}(\sqrt[3]{2})$
5) separable extensions: finite field extensions of characteristic 0 are separable, counter example $X^p - a$ for characteristic p, finite fields are perfect
6) formally and maximal formally real fields: formally real fields are exactly the ordered fields, sums of squares are exactly the total positive elements, real closed fields are maximal formally real

The complete formalization with entire proofs can be found in the Mizar Mathematical Library in the article series `FIELD_xx` and `REALALG_xx`.

To prove that maximal formally real fields are real closed we will formalize the fundamental theorem of Galois theory stating that for a (finite) Galois extension E of F the intermediate fields of E and F are in a one-to-one correspondence with the subgroups of E's Galois group. Note that a finite field extension E over F is Galois if and only if E is both separable and normal over F, so that for F with characteristic 0 a finite Galois extension E is also simple.

Related Work Formalizations of both field and Galois theory have been performed in different proof assistants: In Coq Galois theory has been developed to prove the Abel-Ruffini theorem [4] and also real closed fields can be found in [6]. Lean provides the theory up to the fundamental theorem of Galois theory [5]. General field theory also has been formalized in Isabelle - in particular the existence of algebraic closures of fields has been proved [8].

II. The Mizar System

Mizar is the name for both the proof checker and the formal language in which definitions and proofs are written. Mizar has often been described in the literature, for example in [19], [13], [10], [12] and [3]. We therefore here give only a very rough description of Mizar.

Mizar's logical basis is classical first-order logic, extended with so-called schemes. Schemes introduce free second-order variables enabling the definition of induction schemes among others. In addition, Mizar objects are typed, the types forming a hierarchy with the fundamental type `set`. The user can introduce new (sub)types describing mathematical objects such as groups, fields, vector spaces, or polynomials over rings or fields. The development of the Mizar Mathematical Library relies on Tarski-Grothendieck set theory – a variant of Zermelo-Fraenkel set theory using Tarski's axiom about arbitrarily large, strongly inaccessible cardinals which can be used to prove the axiom of choice. Mizar proofs are written in natural deduction style. The rules of the calculus are connected with corresponding (English) natural language phrases so that the Mizar language is close to the one used in mathematical textbooks, see [11] for an introduction to the Mizar language.

To define (algebraic) domains Mizar provides so-called structure modes fixing the domain's sets of elements and operations. So, for example[1]

```
definition
struct (addLoopStr,multLoopStr_0) doubleLoopStr
 (# carrier -> set,
    addF, multF -> BinOp of the carrier,
    OneF, ZeroF -> Element of the carrier #);
end;
```

defines the necessary backbone of rings and fields. Note that `doubleLoopStr` inherits from both `addLoopStr` and `multLoopStr_0`, that is it joins the operations of additive and multiplicative groups. Properties such as commutativity or the existence of inverse elements are described by attribute definitions for appropriate structures such as

```
definition
let L be addLoopStr;
attr L is right_zeroed means
  for a being Element of L holds a + 0.L = a;
end;
```

Here for elements `a` and `b` of (the `carrier`) of `R` `a+b` is a shortcut for `(the addF of R).(a,b)`. The type `Field` then is defined as a `doubleLoopStr` with the appropriate collection of attributes:

```
definition
mode Field is
  Abelian add-associative right_zeroed
  right_complementable associative commutative
  well-unital almost_left_invertible
  distributive non empty doubleLoopStr;
end;
```

As a consequence a Mizar object of type `Field` obtains all properties described by the defining attributes. We note here, that Mizar types have to be non-empty, so that each mode definition requires an existence proof.

Concrete algebraic domains are built by instantiation of structures. The field of rational numbers $\mathbb{Q}$, for example, is given by the set `RAT` of rational numbers and binary operations `addrat` and `multrat` defining addition and multiplication for elements of `RAT`. These are then glued together by the following

```
definition
func F_Rat -> Field equals
  doubleLoopStr(#RAT,addrat,multrat,1,0#);
end;
```

Note, that using the set `RAT` in defining the field `F_Rat` gives a particular representation of the rational numbers $\mathbb{Q}$ to be used when arguing about the rational numbers using the field `F_Rat`. Of course there are other fields, that is fields with a different set of elements, isomorphic to $\mathbb{Q}$. In fact any field of characteristic 0 contains a subfield isomorphic to $\mathbb{Q}$, so that every field of characteristic 0 can be considered as a field extension of $\mathbb{Q}$.

III. Field Extensions and Field Adjunctions

If F is a subfield of E then E is called a (field) extension of F. Note that this definition in particular means that the elements of F are a subset of the elements of E. Subfields (and subrings) already have been defined in Mizar, so we get

```
definition
let R,S be Ring;
attr S is R-extending means
  R is Subring of S;
end;

definition
let F be Field;
mode FieldExtension of F is F-extending Field;
end;
```

Note that in the definition instead of postulating that F is a subfield of E we demand that a ring R is a subring of another ring S. In this way our definition gets more flexible. For example, this allows to show that $\mathbb{Q}$ extends $\mathbb{Z}$. For fields, however, our definition is equivalent to the one from the literature given above, as stated by the following

```
theorem
for F,E being Field
holds E is FieldExtension of F iff
      F is Subfield of E;
```

There is an alternative equivalent definition stating that F embeds into E. In human mathematics it's obvious to switch between these two – ignoring usually the embedding. We decided to use the first option as it makes it easier to consider polynomials of F as polynomials of E (and also makes it more straightforward to define F-fixing morphisms needed later): In Mizar a polynomial of E must have coefficients of type E. Thus the second option would require to take care of the embedding φ: not p, but $\varphi(p)$ then is a polynomial of E.

However, even though an element $a \in F$ can naturally be considered as an element of E, this has to be made explicit in a typed system like Mizar: for a being an element of F and b an element of E the term $a+b$ is not defined as a and b must have the same type. This type can be element of E or element of F, if b turns out to be in F. In Mizar type casts are realized with the help of the `reconsider`-statement for changing types of objects, or one defines a functor for changing types, usually denoted by `@`. In both cases the result is independent of the field, that is for $a, b \in F$ we get

[1] Throughout the paper Mizar code is written in verbatim style

```
a + b = @(a,E) + @(b,E);

reconsider a1 = a, b1 = b as Element of E;
a + b = a1 + b1;
```

Both versions now allow to shift from one field to another. Note that this also works in towers of fields.

For $T \subseteq E$ the adjunction of F with T is the smallest extension of F containing T. Thus both $F(T)$ is an extension of F and E is an extension of $F(T)$. To "attach" both types to $F(T)$ we defined the type of `FAdj(F,T)` as subfield of E:

```
definition
let F be Field, E be FieldExtension of F;
let T be Subset of E;
func FAdj(F,T) -> Subfield of E means ...;
end;
```

Then the type of the field `E` can be easily changed into `FieldExtension of FAdj(F,T)`, if necessary. Because Mizar's typing mechanism allows to enrich types with further attributes the type of `FAdj(F,T)` can be "extended" with `F-extending`, hence then is `FieldExtension of F`. Note that this typing is necessary to prove $F(T_1 \cup T2) = F(T_1)(T_2)$ for $T_1, T_2 \subseteq E$, because then E must have type `FieldExtension of F(T`$_1$`)` on the right-hand side – in contrast to `FieldExtension of F` on the left-hand-side.

IV. Splitting Fields

A splitting field of a polynomial $p \in F[X]$ is an extension E in which p splits into linear factors and is generated by p's roots, e.g. $E = F(\alpha_1, \ldots \alpha_n)$ where the α_i are the roots of p – or equivalently a smallest field extension of F in which p splits:

```
definition
let F be Field;
let p be non constant Polynomial of F;
mode SplittingField of p
                        -> FieldExtension of F means
  p splits_in it &
  for E being FieldExtension of F
  st p splits_in E & E is Subfield of it
  holds E == it;
end;
```

Note again that in Mizar a mode definition requires an existence (but no uniqueness) proof, because the introduced type – here `Splittingfield of p` – is not allowed to be empty. Our proof follows [21] and does not use algebraic closures: Iterating Kronecker's construction [23] ensures that there exists an extension of F in which p splits, so one easily shows that there is a smallest one – of course this then is the extension of F generated by p's roots. Consequently, that a splitting field of p is generated by the roots of p now follows as a theorem.

```
theorem
for F being Field
for p being non constant Polynomial of F
for E being SplittingField of p
holds E == FAdj(F,Roots(E,p));
```

To prove uniqueness of splitting fields we introduced the notion of being isomorphic over a field F, e.g. there is an isomorphism that fixes the elements of F. Note that such an isomorphism also fixes polynomials $p \in F[X]$. We then lifted isomorphisms from $F_1 \longrightarrow F_2$ to $F_1(\{a\}) \longrightarrow F_2(\{b\})$ where a and b are algebraic elements of F_1 and F_2 respectively. Because splitting fields are generated by roots of a polynomial, hence by algebraic elements, then follows

```
theorem
for F being Field
for p being non constant Polynomial of F
for E1,E2 being SplittingField of p
holds E1,E2 are_isomorphic_over F;
```

so a splitting field of a non-constant polynomial is unique up to isomorphism.

V. Algebraic Closures

An algebraic closure A of F is an extension of F which is both algebraic closed and algebraic over F, that is every non-constant polynomial of A has a root and every element $a \in A$ is the root of a non-zero polynomial of F.

Our proof follows Artin's classical one as presented by Lang in [17]: Kronecker's construction is applied to each polynomial $p \in F[X]\backslash F$ simultaneously to get an extension E of F in which every non-constant polynomial $p \in F[X]$ has a root in E. For that we need the polynomial ring $F[X_1, X_2, ...]$ with infinitely many variables, one for each polynomial $p \in F[X]\backslash F$. The sought-after field extension E then is (isomorphic to) $F[X_1, X_2, ...]/I$, where I is a maximal ideal generated by all non-constant polynomials $p \in F[X]$. Note that to show that I exists Zorn's lemma is necessary.

Iterating this construction gives an infinite sequence of fields, whose union defines an extension A of F, in which every non-constant polynomial $p \in A[X]$ has a root. The field of algebraic elements of A then is an algebraic closure of F. With this existence proof we can define

```
definition
let F be Field;
mode AlgebraicClosure of F
                      -> FieldExtension of F means
  it is F-algebraic &
  it is algebraic-closed;
end;
```

To prove uniqueness of algebraic closures again the technique of lifting morphisms is applied: a monomorphism $F \longrightarrow A$, where A is an algebraic closure of F can be extended to a monomorphism $E \longrightarrow A$, where E is any algebraic extension of F. In case that E is algebraically closed this monomorphism is an isomorphism.

```
theorem
for F being Field
for A1,A2 being AlgebraicClosure of F
holds A1,A2 are_isomorphic_over F;
```

Note that the existence of the lifted monomorphism again relies on Zorn's lemma.

VI. Simple Extensions

An extension E of a field F is simple, if E is generated over F by a single element $a \in E$, e.g. $E = F(\{a\})$. The element a then is a primitive element.

```
definition
let F be Field, E be FieldExtension of F;
attr E is F-simple means
  ex a being Element of E st E == FAdj(F,{a});
end;
```

For infinite fields F we proved that a finite extension E of F is simple if and only if the number of intermediate fields between E und F is finite. In Mizar the intermediate fields of given fields E and F can be defined as a functor giving the appropriate set: because the elements of such a field must be a subset of the elements of E, one can pick up the subsets of the elements of E which constitute a field using Mizar's `replacement`-scheme.

```
theorem
for F being infinite Field
for E being F-finite FieldExtension of F
holds E is F-simple iff
        IntermediateFields(E,F) is finite;
```

The theorem holds for finite fields also. The proof, however, follows easily from group theory, in particular every finite extension of a finite field is simple.

For fields with characteristic zero we also proved that a linear combination of a and b generates $F(a, b)$ – in fact in doing so we already showed that in fields with characteristic 0 irreducible polynomials are separable.

```
theorem
for F being 0-characteristic Field
for E being FieldExtension of F
for a,b being F-algebraic Element of E
ex x being Element of F
st FAdj(F,{a,b}) = FAdj(F,{a+@(x,E)*b});
```

Note that to take the element x from F we again have to shift x into E using the functor `@`.

VII. Normal Extensions

An extension E of F is normal, if every polynomial over F that has a root in E – or equivalently every minimal polynomial – already splits in E. There is a number of equivalent characterizations of (finite) normal extensions (usually shown in a ring proof), for example, that normal extensions are given by splitting fields of polynomial $p \in F[X]$:

```
theorem
for F being Field,
    E being F-finite FieldExtension of F
holds E is F-normal iff
   ex p being non constant Polynomial of F
   st E is SplittingField of p;
```

Note that one direction of this theorem can be be automated by enriching the type `SplittingField of p` with the attribute `F-normal`. This is done using Mizar's cluster mechanism:

```
registration
let F be Field;
let p be non constant Polynomial of F;
cluster -> F-normal for SplittingField of p;
end;
```

Then the type `SplittingField of p` is extended to `F-normal FieldExtension of F` instead of only `FieldExtension of F`, so all theorems about normal extensions can be automatically applied.

Another important characterization deals with fixing morphisms. It states that for (finite) normal extensions E an F-fixing monomorphism $h : E \longrightarrow K$ into a larger field K actually maps to E only, and therefore is an isomorphism. Note here, that an extension E of F is finite if and only if there exist (algebraic) elements $a_1, \ldots a_n \in E$ such that $E = F(\{a_1, \ldots a_n\})$.

```
theorem
for F being Field
for E being F-finite FieldExtension of F
holds E is F-normal iff
   for K being FieldExtension of E
   for h being F-fixing Monomorphism of E,K
   holds h is Automorphism of E;
```

The proof turned out to be technical because one needs to show $h(E) = h(F(\{a_1, \ldots, a_n\})) \subseteq F(\{h(a_1), \ldots, h(a_n)\})$. In human mathematics this is almost obvious just because every element $a \in F(\{a_1, \ldots, a_n\})$ is given by $p(a_1, \ldots, a_n)$ for some polynomial $p \in F[X_1, \ldots X_n]$. The formal proof in Mizar is by induction on the degree of multivariate polynomials and hence needs to reduce the degree of a multivariate polynomial in order to apply the induction hypothesis.

VIII. Separable Extensions

A polynomial $p \in F[X]$ is separable, if p has no multiple roots in the (any) splitting field of p. This is equivalent to p being coprime with its formal derivative. An algebraic extension E of F is separable, if for all $a \in E$ the minimal polynomial μ_a is separable.

```
definition
let F be Field
let p be non constant
     Element of the carrier of Polynom-Ring F;
attr p is separable means
  for a being
       Element of the SplittingField of p
  st a is_a_root_of p,(the SplittingField of p)
  holds multiplicity(p,a) = 1;
end;
```

Note the use of the `the`-operator in the following definition which nicely puts into mind the fact that a splitting field is unique up to isomorphism. This, unfortunately, is not expressed by the definition as `the` just takes an arbitrary element of the non-empty type `SplittingField of p`. All the obvious properties about polynomials over isomorphic fields nevertheless have to be proved. In particular the fact that separability indeed is independent of the splitting field is established not before the following

```
theorem
for F being Field,
    p being non constant Polynomial of F
holds p is separable iff
   ex E being FieldExtension of F
   st p splits_in E &
      for a being Element of E
                 holds multiplicity(p,a) <= 1;
```

In fields with characteristic 0 every irreducible polynomial p is separable (such fields are called perfect), because p must be square-free to be relatively prime with its formal derivation. In fields with prime characteristic p, however, the polynomial $X^p - a$ is reducible only if a has a p-th root and then equals $(X - a)^p$. In the other case $X^p - a$ is irreducible and because $\sqrt[p]{a}$ is a p-fold root of $X^p - a = (X - a)^p$ in its splitting field we get

```
theorem
for p being Prime
for F being p-characteristic Field
for a being Element of F
st not a in F|^p
holds X^(p,a) is irreducible inseparable;
```

where `F|^p` denotes the subfield F^p of all p-th roots in F. Indeed, $F^p = F$ if and only all irreducible polynomials of F are separable, which we applied to finally prove that every finite field is perfect. On the other hand the field $F_p(X)$ of rational functions over a field F_p with characteristic $p \neq 0$ is not perfect.

IX. Formally Real Fields

Finally we return to our original motivation of formalizing formally real fields and Artin's solution of Hilbert's 17th problem. A field F is formally real, if -1 is no sum of squares. In this – and only this – case F can be ordered. Here, orders are usually defined as positive cones, the set of positive elements [22]. Note that formally real fields have characteristic 0. A first main result from [1] we proved states, that the elements of F that can be described as sums of squares are exactly the total positive ones:

```
theorem
for F being formally_real Field
for a being Element of F
holds a in Sums_of_squares_of F iff
      for P being Ordering of F holds a in P;
```

So, to solve Hilbert's 17th problem it's crucial to identify the total positive elements of the real numbers. In general fields allow for different orderings. Maximal formally real fields F – in the sense that there is no proper extension of F which again is formally real – however, have only one ordering, the set of squares `SQ F`:

```
definition
let F be Field;
attr F is maximal_formally_real means
  F is formally_real &
  for E being F-algebraic FieldExtension of F
  st E is formally_real holds E == F;
end;
```

```
theorem
for F being maximal_formally_real Field holds
SQ F is Ordering of F &
for P being Ordering of F holds P = SQ F;
```

We also proved that in maximal formally real fields every polynomial of odd degree has a root and that the field of real numbers is maximal formally real. Maximal formally real fields F then are characterized as real closed fields: a field F is real closed if the splitting field of the polynomial $X^2 + 1 \in F[X]$ – e.g. the field $F(i)$ – is an algebraic closure of F.

```
definition
let F be Field;
attr F is real_closed means
  not -1.F in SQ F &
  the SplittingField of X^2+(1.F)
                       is algebraic-closed;
end;
```

Note that this definition does not make use of orderings. So far we proved that real closed fields are maximal formally real. Maximality easily follows from the fact that -1 is a square in $F(i)$, hence the main part here is to show that real closed fields F are formally real, e.g. that the squares of F form an ordering. This requires to show that for $a, b \in F$ we have that $a^2 + b^2$ again is a square. This is shown by considering the polynomial $p = (X^2 - a)^2 + b^2$ in $F[X]$. p has no roots in F, but is reducible, because $F(i)$ is algebraic closed. So we get $p = p_1 \cdot p_2$ for irreducible quadratic polynomials p_1, p_2. Note that p splits in $F(i)$ by assumption, so the roots of p are $\pm\sqrt{a \pm b \cdot i}$ giving

```
theorem
for F being real_closed Field
for a,b being non zero Element of F
for p being Polynomial of F
  st p = Subst(X^2+b^2,X^2-a)
for i being a_Root of X^2+(1.F)
for ai,bi,w1,w2 being Element of
                the SplittingField of X^2+(1.F)
  st ai = a & bi = b &
     w1^2 = ai + i * bi & w2^2 = ai - i * bi
holds Roots(the SplittingField of X^2+(1.F),p)
    = { w1, -w1, w2, -w2 };
```

Of course also p_1 splits in $F(i)$, so $p_1 = (X - \alpha) \cdot (X - \beta) \in F(i)[X]$ must take two of these roots. But then $\alpha \cdot \beta =: v \in F$ and also $\alpha \cdot \beta = \sqrt{a^2 + b^2}$, so $a^2 + b^2 = (\alpha \cdot \beta)^2 = v^2$.

The other direction – that maximal formally real fields are real closed – will be proved by showing that for fields F, in which both the set of squares is an ordering and every polynomial of odd degree has a root, the extension $F(i)$ is algebraic closed. This is done by starting with a splitting field E of an arbitrary non-constant polynomial p. Then E is a Galois extension of F, because it's finite, normal and separable. Applying the fundamental theorem of Galois theory (and Sylow's theorems about finite groups) one can show that in fact $E = F(i)$, so p splits in $F(i)$ [22]. To formalize this we first need to further develop Galois theory in Mizar.

X. Conclusion and Further Work

We have presented the beginnings of formalizing field and Galois theory in Mizar. Three main lessons of our Mizar formalization so far we consider worth mentioning: Mathematical types such as rings, fields, vector spaces, topological spaces, and so forth are usually considered helpful in proof assistants as they automate applying theorems. However when it comes to field extensions where objects such as elements, subsets, and polynomials are shifted between different fields, it's often necessary to explicitly cast types in order to apply definitions or theorems. So, for example, that for a polynomial $p \in F[X]$ the degree of p is the same when considering p as a polynomial in an extension E of F is not obvious for Mizar: the type `Polynomial of F` has to be changed into `Polynomial of E`, which is expressed by the following

```
theorem
for F being Field, E being FieldExtension of F
for p being Polynomial of F,
    q being Polynomial of E
st p = q holds deg p = deg q;
```

Secondly, dealing with polynomials tends to cause much more work than expected: many properties considered obvious by human mathematics require a formalization resulting in a number of technical lemmas. For example, for $p_1, p_2 \in F[X]$ and $a \in F$ because of $(p1+p2)(a) = p_1(a)+p_2(a)$ obviously follows

$$\sum_{i=1}^{n} p_i(a) \;=\; (\sum_{i=1}^{n} p_i)(a)$$

by a straightforward induction. To prove this in Mizar the n polynomials have to be put together in a finite sequence `f`, so that $p = \sum_{i=1}^{n} p_i =$ `Sum f`. The second finite sequence `g` contains $p_i(a)$ for $i = 1, \ldots n$, hence `Sum g` $= \sum_{i=1}^{n} p_i(a)$ in the following

```
theorem
for F being Field
for f being FinSequence of Polynom-Ring F
for p being Polynomial of F st p = Sum f
for a being Element of F,
    g being FinSequence of F
st len g = len f &
   for i being Element of dom f,
   q being Polynomial of F
     st q = f.i holds g.i = eval(q,a)
holds eval(p,a) = Sum g;
```

Thirdly, the omnipresent "uniqueness up to isomorphism" also increases the formalization's length: each property carrying over to isomorphic fields has to be explicitly stated and proved. Of course, for example, because two splitting fields E_1 and E_2 of a polynomial $p \in F[X]$ are isomorphic the multiplicity of a root of p in E_1 and E_2 is the same. This, however, has to be stated and proved as a theorem. Another example concerns ordered fields: it's obvious that a field isomorphic to an ordered field is also ordered, but again this has to be explicitly proved.

The next step of our formalization will be the combination of normal and separable extensions to establish Galois extensions and their corresponding Galois groups. Group theory in Mizar is well developed, in particular Sylow's theorems can be found in the Mizar Mathematical Library. Galois theory will enable to further extend the formalization of real algebra. In particular the fundamental theorem of Galois theory will allow to conclude the proof that maximal formally real fields are real closed as a main step towards Artin's solution of Hilbert's 17th problem.

***Abstract*—E-commerce is a very popular method that lets consumers to purchase goods and services. The ability to purchase items online has increased the need for effective recommendation systems. Such recommendations usually relete to products in which the customer may be interested. However, there are wider opportunities to tailor e-commerce to individual customer needs and behaviour. In this paper, the architecture of the e-commerce platform (named AIM^2), which allows providing a dedicated interface to selected user groups, is discussed. A key component of the platform is the module responsible for dividing customers into groups, using selected clustering methods. Each of the implemented methods can be parameterised to adapt the customer segmentation to a given e-commerce business owner's requirements. This article describes the results of an analysis of the impact of selected methods and parameters on clustering results. Moreover, it identifies key metrics that should be considered when selecting clustering conditions during the implementation of the platform. Finally, the main results of the pilot implementation of AIM^2 are presented to assess the effectiveness of the multi-variant user interface.**

I. Introduction

ONE major drawback of existing e-commerce systems is that they display little ability to take into account differences in the users' knowledge, style, and preferences. Meanwhile, users of the systems are different, and the interfaces served to them could be different. The concept of AUI (Adaptive User Interfaces) is increasingly frequent in implementation in the modern IT systems, but this trend is less visible in e-commerce. AIM^2 platform, described in the paper, is an example of the practical implementation of the AUI concept in e-commerce systems. Its aim is to serve dedicated e-commerce user interfaces based on user groups defined by clustering using AI methods, monitoring the results and optimizing the solution.

Personalized web-based system user interfaces can be defined as systems that can automatically adjust their presentation, content, and structure based on the user's characteristics, needs, or preferences [12]. Such solutions can improve the usability and effectiveness of the interface by its adaptation to the user's behaviour. It may also reduce the user's cognitive load, which in turn reduces the user's tiredness and the number of committed errors. Better UX may increase the user's satisfaction and motivation. Design and implementation of AUI may be a complex task, requiring usage of interdisciplinary solutions [15]. Such system may be based on multi-agent infrastructure [3] but nowadays, great opportunities are offered by AI methods as well.

Among the various existing approaches to creating self-adaptive user interfaces is the use of AI-based clustering to divide customers into groups and serve these groups with a dedicated interface. AI clusterization methods leverage advanced algorithms to discover hidden patterns, structures, or relationships within datasets. Information about users' activities, events, purchases and other factors that should potentially affect the interface can be used to group e-commerce users. If designated user groups are served with an interface tailored to their behaviour, an increase in the e-commerce performance can be expected, which should ultimately have a positive impact on profitability in business terms.

In Section 2 previous works on using clusterizaton methods in e-commerce are described. Section 3 briefly shows the architecture of AIM^2 platform and research methodology. Experiments related to clusterization methods and their parameters are detailed and discussed in Section 4. Section 5 concludes the work.

II. Related Work

Clusterization methods are an effective way to group similar items together and provide personalized recommendations. However, the choice of method depends on the specific requirements and limitations of the e-commerce interface. Commonly used clusterization methods are:

- Hierarchical methods, which create a hierarchical structure of clusters by iteratively merging or splitting clusters, e.g. agglomerative clustering and divisive clustering;
- Partitioning methods, which divide the dataset into a predetermined number of clusters, e.g. K-means, K-medoids, and Fuzzy C-means clustering;
- Density-based methods, which focus on identifying regions of high-density data points and separating them from sparse regions, e.g. DBSCAN (Density-Based Spatial Clustering of Applications with Noise);

Project "Self-adaptation of the online store interface for the customer requirements and behaviour" co-funded by the National Centre for Research and Development under the Sub-Action 1.1.1 of the Operational Programme Intelligent Development 2014-2020.

- Spectral, which utilizes the concept of spectral graph theory, which relates the eigenvectors and eigenvalues of a similarity matrix to the underlying structure of the data;
- Model-based methods, which assume that the data points are generated from a statistical model or distribution, e.g. Gaussian Mixture Models (GMM) and Expectation-Maximization (EM) algorithm.

Almost all of the methods mentioned were verified for their application for e-commerce solutions.

Hierarchical clustering in e-commerce applications is discussed in [18]. It is worth noting that the standard algorithm for hierarchical agglomerative clustering (HAC) can be slow even for medium data sets [1]. Research related to the record linkage system for e-commerce products was also conducted using this approach [9]. HAC algorithm used for customer segmentation was described in [10] and the findings could also be used to segment e-commerce customers.

K-means algorithm can be used for segmenting e-commerce customers to obtain groups of customers with different characteristics [5]. In the clustering customer purchase data can be taken into account [17]. According to researchers K-means clustering is quite efficient algorithm. However, its computational difficulty is influenced by the size of the dataset, the number of clusters, and the initialization of the cluster centroids. K-medoids (uses the medoid instead of the mean) was used for e-commerce customer segmentation [21]. Classification method of e-commerce user behavior based on Fuzzy C-Means Clustering was proposed to improve the clustering analysis effect of e-commerce user behavior in [20].

DBSCAN [8] was used to process uneven density data based on information from e-commerces [19]. DBSCAN algorithm seems to be more advantageous when compared to other algorithms because doesn't need one to specify the number of clusters within the knowledge a priori [13].

Some researchers have also compared the effectiveness of different clustering algorithms used in e-commerce solutions. A comparison of the performance of the K-means and DBSCAN (Density-based spatial clustering of applications with noise) algorithms in e-commerce applications indicated slightly better results obtained by the second method [2]. In another study, an accuracy comparison indicated an advantage for DBSCAN over K-means [7]. DBSCAN seems to correspond more to human intuitions of clustering, rather than distance from a central clustering point (e.g. K-means) [13].

In some e-commerce applications spectral clustering can be an effective clustering method [6]. There is also the possibility of using spectral clustering in conjunction with K-means clustering [22].

There are relatively few publications on the application of the GMM method [23] to e-commerce-related analysis. Some possibilities for applying this method in product recommendation are indicated [11]. According to [16] the K-means method has lower computational requirements, and could potentially yield clustering results similar to those of the GMM method.

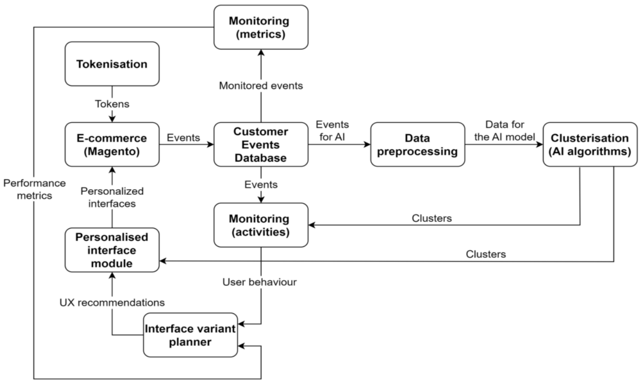

Fig. 1. AIM^2 Business Architecture

III. AIM^2 ARCHITECTURE

The AIM^2 business architecture contains the core modules of the system and key integration interfaces (Fig. 1). It includes:

- Tokenization - responsible for ensuring the anonymity of the data collected by the platform;
- E-commerce - Adobe Magento-based e-shop with implementation of PWA (Progressive Web App) technology;
- Customer Events Database - e-commerce customer behaviour data storage;
- Preprocessing - the module to prepare data to analyse and to decrease the time required to generate clusters;
- Clusterisation - analyses the information collected about the behaviour of e-commerce customers and to divide them into groups characterised by similar shop use;
- Monitoring - identifies user patterns that can be used to design variants of dedicated interfaces and verifies the performance of the interface variants;
- Interface management - supports variants definitions shown to selected users;
- Self-adaptation algorithm - automatically implement micro changes to the interface and accept or reject them depending on the impact on e-commerce performance metrics.

The interface adaptation process starts with initial clustering of e-commerce customers, using learning data from a possible long period. One of the clusterization effects is a set of customer groups that are heterogeneous based on certain characteristics. The AIM^2 platform has four clustering methods implemented: agglomerative clustering, the K-means method, DBSCAN and spectral clustering. Some of them can be applied with different parameter values, e.g.:

- model (type=string, default='kmeans') algorithm used - k-means ('kmeans'), agglomerative clustering ('agg'), DBSCAN ('dbscan') and spectral ('spectral')
- pca (type=float, default=0.999) - the amount of data variance retained is greater than the percentage specified in the parameter

- init (type=string, default='k-means++') - method for initialising cluster centres for the k-means algorithm:
  - 'k-means++' samples the dataset and counts k-means on it [4],
  - 'random' randomises the centres.
- max_iter (type=integer, default=300) - maximum number of iterations in the k-means algorithm

The choice of clustering module parameter settings affects the allocation of customers into clusters and, consequently, the interface variants that will be provided to them. For this reason, it is important to properly tune this module and match the requirements of a particular e-commerce. The research conducted was aimed at verifying the outflow of different values of clustering parameters on its effects. The quality of clustering can be considered in two aspects - the objective one, resulting from classical methods of cluster evaluation (as: Silhouette score, entropy, Calinski-Harabasz score and Davies-Bouldin score) and contextual, resulting from the requirements for clusters intended to be the basis for providing different variants of the e-commerce customer interface. During the research, experiments were carried out on a dataset covering a period of 4 months (548.922 e-commerce user sessions) to verify the impact of the choice of clustering method and the parameters (pca, init, max_iter) on the distribution of customers in the clusters. From a business point of view, clusters should be of similar size, since it makes most sense to prepare a dedicated interface variant. There should not be too many clusters (groups of customers), because the creation of an interface variant is a non-zero cost, so from a business point of view, it is preferable to use methods that generate clusters with a size of no less than X% of the population (X can be treated as a parameter and vary depending on the specific e-commerce, for the purposes of the study X=5 was assumed).

IV. Research results

The research was carried out in two stages. In the first part, clustering was performed with all four methods available on the AIM^2 platform (Tab. I).

The following were analysed: clustering time, number of clusters, size of the largest and smallest cluster. From the point of view of the adopted business requirements, the clustering time (without pre-processing) should be as short as possible, the number of clusters not exceeding 10 and the size of the smallest cluster not less than 5% of the total number of customers (91.819 e-commerce users were clustered in the experiment).

K-means and DBSCAN clustering were found to be significantly more time-efficient than the other methods. Nevertheless, the duration of the longest clustering (using the spectral method) would also be acceptable, as it would be feasible in the time allowed for cyclic updating of the cluster composition in AIM^2.

The number of clusters obtained, in particular as many as 282 clusters generated using the DBSCAN method, is noteworthy. This is well beyond the upper limit of the number of clusters taken as a business requirement. The lack of predictability of the number of clusters and the inability to reduce the number of clusters make the DBSCAN method practically useless from the point of view of the self-adaptation mechanism of the e-commerce interface implemented in AIM^2. The other three methods had the number of clusters set to 10. This number, from a business point of view, seems to be the maximum number of interface variants that should be served to e-commerce customers.

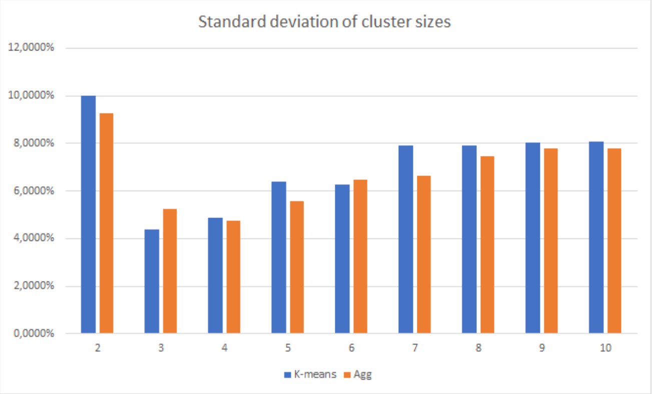

Fig. 2. AIM^2 Standard deviation of cluster sizes

The next characteristic analysed was the size of the largest and smallest cluster. In order to prepare a reasonable dedicated interface variant, the number of customers to whom it will be delivered should be sufficiently large. In this aspect, the DBSCAN method was again found to be useless, as the smallest clusters contained only one client. It turned out that the problem with the number of clusters also occurred with the spectral method. In this case, the largest cluster covered more than 93% of all customers, which calls into question the sense of preparing interface variants for the remaining clusters.

In summary, the results obtained from the experiment allowed to select two of the most promising approaches - agglomerative clustering and K-means method. A detailed analysis was carried out for them, taking into account the different clustering parameters. Further research looked at the impact of clustering parameters on the results obtained. The primary parameter influencing the results was the clustering method, with the additional ones being the fixed number of clusters, pca, init and max_iter.

Firstly, it was checked how the cluster size changes, depending on a fixed number of groups (from 2 to 10), with constant values for the other parameters (pca=0.999, init=k++, max_iter=300).

For the data set analysed, it turned out that the smallest standard deviation of cluster counts was calculated in both methods for 3–4 clusters (Fig. 2). Additionally, it was noted that the agglomerative clustering method yielded a lower standard deviation of cluster sizes in most cases. This means that clusters with less variation can be expected. From the point of

TABLE I
CLUSTERING EFFECTS OF THE METHODS AVAILABLE IN AIM^2

Clustering method	**Clustering time [mins]**	**Number of clusters**	**Largest cluster**	**Smallest cluster**
K-means	4	10* (fixed)	29,7389%	3.4895%
Agglomerative	122	10* (fixed)	29,7302%	2.9438%
DBSCAN	15	282	29.7302%	1 customer
Spectral	188	10* (fixed)	93.6353%	0.1993%

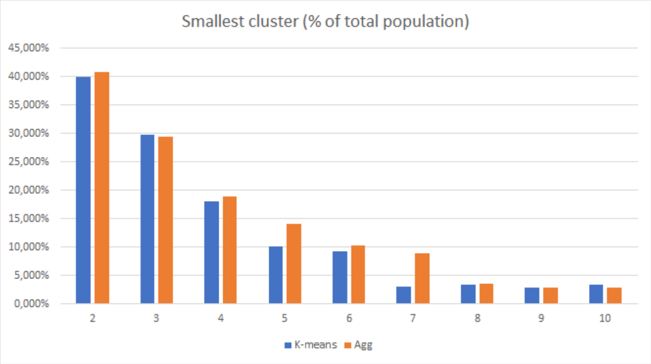

Fig. 3. Smallest clusters

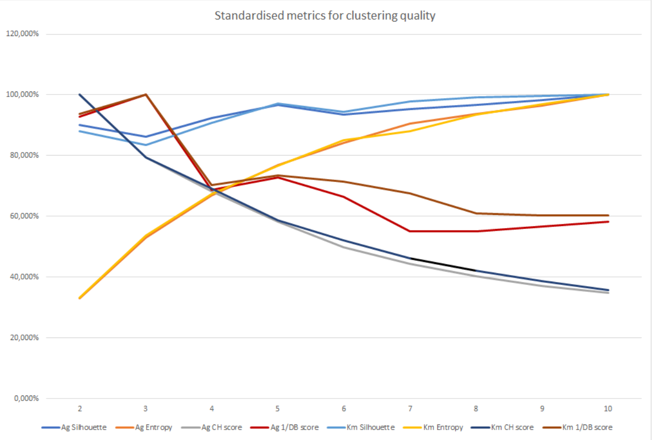

Fig. 4. Standardised metrics for clustering quality

view of variants of the e-commerce interface, agglomerative clustering therefore appears to be slightly better in this aspect. Similar conclusions can be drawn from an analysis of the size of the smallest clusters (Fig. 3). Assuming a cost-efficiency threshold for the development of an interface variant of 5% of the customer population size, it appears that results for more than 6 clusters with the K-means method and for more than 7 clusters with agglomerative clustering should be rejected. The difference does not seem large, but can be significant when choosing the optimal clustering parameters for the delivery of a dedicated e-commerce interface.

When selecting clustering parameters due to business requirements, typical clustering quality indicators cannot be overlooked. Cluster quality analysis for agglomerative clustering and the K-means method, with different numbers of clusters, was carried out for the indices: Silhouette score, entropy, Calinski-Harabasz (CH) score and Davies-Bouldin (DB) score. Given that the first three indicators should be as high as possible and DB as low as possible, it was assumed for simplicity that the analysis would include DB' metric:

$$DB' = \frac{1}{DB} \tag{1}$$

Under this assumption, the goal of clustering optimization is to maximize the value of all quality indicators. For the purpose of the analysis, the values of the indicators were standardized, assuming that the highest value is 100% (Fig. 4).

The results show that there is a very high correlation between the values of quality indicators for both clustering methods. In addition, it can be seen that the values of two indicators increase as the number of clusters increases, and the values of two indicators decrease. The intersection point for the three indicators is a value of 4 clusters. This value can be considered the minimum number of clusters worth generating for a multi-variant e-commerce interface.

The study showed that the other clustering parameters available in AIM^2 affect the clustering results to a lesser extent.

Increasing the value of max_iter (even 10 times) had no effect on the resulting clusters, so the default value (300) is sufficient.

On the other hand, the option of using the pca parameter to reduce cluster generation time with agglomerative clustering may be interesting. After setting pca=0.95, agglomerative clustering took 13 minutes, almost 10 times faster than calculations with pca=0.99. At the same time, the composition of the clusters has practically not changed, so the reduction in the quality of the input data for clustering should be acceptable.

Slightly more influential is the decision to initialize cluster centers. In the case of random selection of cluster centers, the clusters differ from the selection of the 'k-means++' option. However, the changes applied only to individual clusters, and the standard deviation of cluster sizes was larger each time for the random selection of cluster centers.

Considering the results obtained, for the data set used in the experiment, it could be recommended to use agglomerative clustering with 4 clusters [Fig. 5, 6], due to the smallest variance in cluster size. The number of clusters could be increased (up to a maximum of 7 clusters) if business considerations required it. If cluster calculation time needs to be reduced, the pca parameter could be further changed to 0.95.

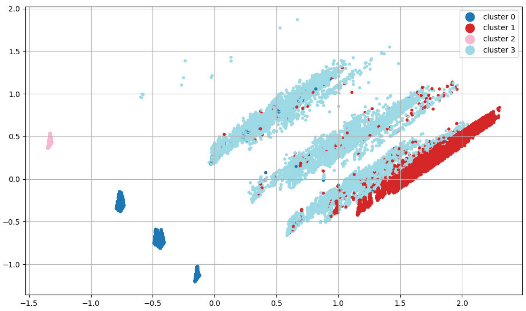

Fig. 5. Scatter plot along the two most significant dimensions produced by the PCA decomposition of the initial dataset

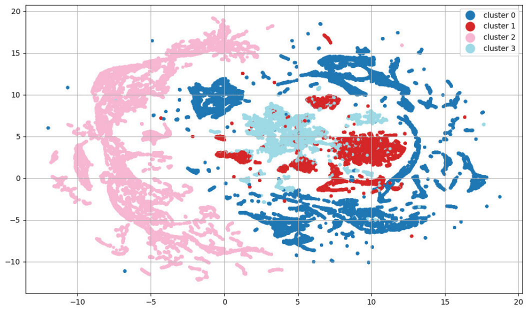

Fig. 6. Scatter plot along the dimensions of low-dimensional representation produced by the UMAP algorithm[14]

V. Conclusion

In this paper, different clusterization methods for multi-variant e-commerce interfaces were reviewed and their performance was compared. Summarizing the results of the study, it can be concluded that after taking into account business requirements and clustering quality metrics, agglomerative clustering for 4-7 clusters or K-means method for 4-6 clusters can be selected for clustering e-commerce customers. In addition, when choosing agglomerative clustering, it is possible to reduce the value of the pca parameter, in order to speed up calculations. The research has identified the most promising clustering methods that can be used to provide specific groups of e-commerce customers with dedicated user interface variants. The results obtained will be used to further develop and validate the AIM^2 platform in future implementations.

***Abstract*—In various classification problems beside high accuracy data analysts expect often understanding and certain insight into the process of classification. To help them understand why a trained model selects a particular decision, how confident it is in the assigned decision, and to enable interactive improvement of trained models we present QMAK. The tool visualizes not only classification models but also the processes classifying individual objects. Five classical machine learning models and their classification process are visualized with QMAK: neural network, decision tree, k-nearest neighbors, classifier based on principal component analysis (PCA) and rough set based classifier. QMAK provides also exemplary functions enabling users to modify trained models interactively.**

***Index Terms*—explainable machine learning, classification visualization, interactive classifier.**

I. Introduction

As THE field of machine learning matured, beside a predicted value data analysts started to expect some insight into how a trained model made a decision. They expect explanation why decision was selected and how much the model is sure of its decision. Understanding why classification models classify incorrectly some cases can help both authors and analysts improve their models. Yet further step it is to provide the ability of modifying a trained model in an interactive process.

There are many visualization tools dedicated to machine learning but most of them use various charts, sometimes quite advanced, to visualize data, training metrics and classification results, for example Neptune [1]. Many others can visualize classification models based on the graph structure like Graphviz [2] and TensorBoard [3], or on the tree structure like dtreeviz [4], or both, for example Weka [5]. However, only the models having one of these two structures can be visualized with those tools. The tools visualizing classification models reflecting their specific structure are often most advanced and most detailed in how they present a model, but they are usually dedicated to a single model type, for example Netron [6] and NN-SVG [7] that visualize neural networks.

QMAK is a visualization and interactive platform gathering different classification models. It provides a framework not only for visualization and interaction with models but also for visualization of the classification process. It allows users to compare both the structure of different models and how they differ in the classification processes provided with the same object to be classified. QMAK implements visualization of popular machine learning models and gives examples of how users may interact with models to improve their classification accuracy. The platform can be used also as a didactic tool during machine learning courses.

II. System Overview

QMAK is a graphical tool providing the following features: visualization of data, classifiers and single object classification, interactive classifier modification by a user, classification of test data with presentation of misclassified objects, and experiments comparing classification accuracy of different classifiers using different types of tests. It is an open source software issued under the GNU General Public License. The tool and its demo are available at http://rseslib.mimuw.edu.pl/qmak.

QMAK uses Rseslib library [8], [9] as the source of classification models. The version 3.3.0 provides visualization of five classifiers: neural network, decision tree, k-nearest neighbors, classifier based on principal component analysis (PCA) and rough set based rule classifier. Users can implement new classifiers and their visualization and add them easily to QMAK.

Neural network in QMAK is trained with the classical backpropagation algorithm and sigmoid activation functions [10]. Visualization of a neural network presents the neurons and the connections between them (see Figure 1). The neurons from the last layer correspond to decisions. The color of a connection represents its weight as it is defined in the legend. A user can select a neuron to display the exact weights of its input connections and its bias. They can also modify a trained network by adding new neurons in hidden layers and retraining the network. Visualization of classification presents also the strength of the output signal from each neuron with intensity of its color, and the exact value of the output signal after clicking on a selected node.

The decision tree in QMAK is implementation of the well-known C4.5 algorithm [11]. It is visualized by presenting the structure of the tree (see Figure 2). After selection of a node the decision distribution of the training objects entering that

node is displayed, and the branching condition for an internal node or the assigned decision for a leaf node. A user can cut off the subtree of any internal node and convert it to a leaf. Visualization of classification presents a decision tree with the path from the root to a leaf node highlighted in green corresponding to a classified object.

K-nearest neighbours classifier [12] provides distance measures working for data with both numerical and categorical attributes and optimized with attribute weighting. It optimizes automatically also the number k of nearest neighbours and applies weights in voting by nearest neighbours. Visualization of k-NN classifier projects all training objects onto the two-dimensional area of the window, marking the objects of each decision class with a different color. The process of searching for placement of the objects that most faithfully reflects the true distances between them in the induced metric, is displayed live, and can be stopped at any time. A user can select one object and hover the cursor over another one to display the attribute values of both objects and the true distance between them. Visualization of classification by k-NN classifier projects only the classified object and its k nearest neighbors onto the window area, also searching for placement most faithfully reflecting the true distances between them. As in the model visualization, the neighbors from different decision classes have different colors, and a user can display their attribute values and the true distances between them.

The visualized search for the best placement of objects in the two-dimensional area of the QMAK window for k-NN classifier uses an algorithm that combines simulation of spring-line attraction and repulsion with simulated annealing. Each object is assigned random initial coordinates, sampled uniformly from the unit square. The coordinates are then refined in an iterative process. In each iteration two distances are computed for each pair of objects: the true distance in the induced metric and the Euclidean distance between the current coordinates. The difference between these two distances is later applied as the multiplication factor to the vector between the current coordinates of the objects to obtain the force vector. The correction vector for each object is computed as the sum of all force vectors for that object. At the end of each iteration, the correction vectors are multiplied by a scaling factor, reduced to a maximum length, and applied to the current coordinates. The scaling factor decreases exponentially with each epoch to ensure long-term pseudostability of otherwise chaotic N-body problem, while reduction to maximum length reduces instabilities in early iterations.

PCA classifier finds a separate model of principal components for each decision class using Oja-RLS rule [13]. Its visualization projects all training objects onto the plane spanned by a selected pair of principal components of the model for a selected decision class. The objects of each decision class are marked with a different color. The objects closer to the plane are represented by larger dots, the ones more distant from the plane are represented by smaller dots. A user can switch between different decision classes and different pairs of principal components. Visualization of classification by PCA classifier marks additionally the position of the classified object on the presented plane.

Rough set classifier uses the algorithms computing discernibility matrix, reducts and rules generated from reducts [14], [15], [8]. Its visualization presents the decision rules with their length, support and accuracy. A user can filter and sort the rules by attribute occurrence, attribute values, rule length, support or accuracy. Visualization of classification shows only the rules matching the classified object enabling the same filtering and sorting criteria as visualization of the classifier.

Beside visualization of classification QMAK integrates also other features. Users can run experiments comparing the accuracy of different classification models, or the accuracy of the same classification model for different parameter settings,

Figure 2. Decision tree (upper left), k-nearest neighbors classifier (upper right), PCA classifier (lower left) and rough set classifier (lower right) visualized in QMAK

for example, using cross-validation or multiple random split and test. In those experiment all five visualized classification models are available for testing as well as other non-visualized classifiers: Support Vector Machine, AQ15, Naive Bayes, RIONIDA, and others.

The tool provides also three kinds of data graphs presenting different types of correlations between categorical and numerical attributes.

III. System Usage

QMAK can help users understand why a particular decision was selected. For example, the classification path for an object in a decision tree shows the attributes and the conditions on these attributes determining the decision. K-nearest neighbors model shows the training objects identified as the most similar to the classified object and used to vote for the predicted decision. Rough set classifier shows the decision rules matching the classified object.

Using QMAK users can also find out how confident a classifier is in the assigned decision. In neural network it is indicated by the difference between the strength of the output signal from the winning neuron and the strength of the signals from other neurons. In k-nearest neighbors model one can compare the number and the placement of the nearest neighbors with the winning decision with the number and the placement of the neighbors with other decisions.

Users can also find out which element of an already trained classifier needs to be improved. QMAK highlights misclassified objects in red, and for each misclassified object a user can command the classifier to visualize its classification. In some cases, the user can later modify the classifier interactively. QMAK demonstrates a few examples of such interaction.

Similar weights of the connections between two layers in a neural network like between the two hidden layers in Figure 1, may indicate the first of those two hidden layers was given too few neurons and the second of the two layers was unable to learn the desired functions on its neurons. A user can either train a new network with a different structure or add new neurons to hidden layers of the existing network and retrain it.

In a decison tree if a branch misclassifies many test objects that branch can be the result of overfitting to a training set. In QMAK a user can prune such a branch by turning the inner node from which the branch comes out into a leaf node.

In k-nearest neighbors model one can check whether changing the number of neighbors selected to vote or changing the voting method fixes classification of misclassified objects. The number of neighbors and the voting method can be changed without retraining an already trained classifier. Moreover, if many test objects are misclassified by a k-NN classifier because of a small subset of training objects, a user may consider removal of such objects from the training set.

IV. System Extensibility

The platform is designed to make addition of both new classification models and their visualization as simple as possible. It is intended to allow users implement visualization of their classifiers in such way that they do not need to have any knowledge of how a tool presenting visualization, in particular QMAK, is implemented. To achive that, a simple interface with two methods is defined.

The first method implements visualization of the structure of a classification model:

```
void
draw(JPanel canvas)
```

The second method implements visaualization of the process classifying a single test object:

```
void
drawClassify(JPanel canvas, DoubleData obj)
```

In both methods the author of a classifier uses the provided `canvas` object to draw whatever is best to visualize the classifier.

Many visualization tools provide graph-based framework for implementing visualization. But many classification models, for example: k-nearest neighbors, rule-based classifiers, support vector machine, do not fit such framework. In QMAK the author gets a general object-frame in which they can draw any graphical representation of a classifier or classification process. Decision trees and neural networks have graph-based visualization, k-NN and PCA classifiers each presents a certain type of projection of selected objects represented as points onto two-dimensional area, and rough set classifier present text description of the components of the model. Moreover, visualization can be animated like in case of k-nearest neighbors classifier.

After implementation of the two interface methods in the source code of a classifier a user can easily add it to QMAK using menu or by adding an entry in the configuration file. It does not require any change in QMAK itself.

V. Summary

The paper presents QMAK, an open platform for visualization of classification models and classification process.

Two main features that distinguish QMAK from other machine learning visualizers are that it integrates visualization of five different classification models in one tool and that all five models visualize also the very process of classifying a single object. This unique value of QMAK can help data analysts interpret their data and the models built from data in a way that has hitherto been unavailable. The platform can also be an important alternative as a didactic tool for teaching of machine learning.

Thematic Tracks

PARTS 4 and 5 of FedCSIS 2023 Proceedings contain contributions originating from Thematic Tracks. Let us present each one of them.

I. Advances in Programming Languages

Programming languages are programmers' most basic tools. With appropriate programming languages one can drastically reduce the cost of building new applications, as well as maintaining existing ones. In the last decades, there have been many advances in programming languages technology, in traditional programming paradigms such as functional, logic, and object-oriented programming, as well as the development of new paradigms, such as aspect-oriented programming. The main driving force was, and will be, to better express programmers' ideas. Therefore, research in programming languages is an endless activity and the core of computer science. New language features, new programming paradigms, and better compile-time and run-time mechanisms can be foreseen in the future. Here, the potential future role of AI models in programming should also be taken into account. In this context, the aim of this Thematic Track was to provide a forum for exchange of ideas and experience in topics concerned with programming languages and systems.

II. Artificial Intelligence in Agriculture

AI is increasingly used in agriculture, to address multiple issues, from plant disease detection to weeding automation, soil status monitoring, crop prediction, irrigation management, and decreased use of resources, for improving product quality and process productivity. AI can, in fact, provide highly positive effects on precision agriculture by optimizing, automating and forecasting multiple aspects of farming and revolutionizing the sector, providing helpful information and driving decisions using multiple sources of data and different sensors. Moreover, in the climate change era, AI can improve sustainability by optimizing the use of resources, such as in the case of water and soil management. This Thematic Track welcomed contributions concerning all aspects of interdisciplinary research and applications related to AI in agriculture.

+ Martinelli, Massimo, National Research Council of Italy, Italy
+ Moroni, Davide, National Research Council of Italy, Italy
+ Procházka, Ales, University of Chemistry and Technology & Czech Technical University CIIRC, Czech Republic

III. Artificial Intelligence in Digital Humanities, Computational Social Sciences and Economics Research

This Thematic Track was dedicated to the computational study of social sciences, economics and humanities, including all subjects like, for example, education, labor market, history, religious studies, theology, cultural heritage, and informative predictions for decision-making and behavioral-science perspectives. Besides new discoveries, it was dedicated to the reflections about their growth within the field of computer science and it emphasized the interdisciplinary exchange and dissemination with a clear focus on computational and AI-based methods. Since there is a clear methodological overlap between the considered domains of social sciences, economics and humanities, and often similar algorithms and AI approaches are considered for them, this track should be seen as a place for discussing a “joint toolbox” as a support for scholars from these fields with human and context-aware agents. It included also research related to trustworthy data infrastructure housing both quantitative and qualitative data.

IV. Challenges for Natural Language Processing

This Thematic Track consisted of contributions related to all aspects of NLP. Of particular interest were works addressing NLP tools, multimodal problems, cross-lingual learning and processing of natural languages. Moreover, this track was also hosting the NLP-related competitions, results of which are presented in Part 6 of these proceedings. This Thematic Track was co-organized by the Multi-task, Multilingual, Multi-modal Language Generation COST Action (CA18231).

Thematic Track organizers:

+ Kobyliński, Łukasz, Institute of Computer Science, Polish Academy of Sciences, Poland
+ Kubis, Marek, Faculty of Mathematics and Computer Science, Adam Mickiewicz University, Poland

V. Complex Networks: Theory and Application

In the nature and the world around us, one can observe many network structures that interconnect various elements such as cells, people, urban centers, network devices, companies, manufacturing machines, etc. Moreover, it is easy to notice that most of them evolve over time. The analysis of such systems from the complex networks point of view allows for better understanding of the processes within them, which can be used to optimize their structure, improve their management methods, detect failures, improve their operating efficiency and plan their development and evolution. The main goal of this Thematic Track was to exchange knowledge and experience between specialists from different areas who, in their research and design work, use theories and solutions characteristic for complex systems.

This Thematic Track was organized within framework of the project financed by the Minister of Education and Science of the Republic of Poland within the “Regional Initiative of Excellence” program for years 2019–2023. Project number 027/RID/2018/19, amount granted 11 999 900 PLN.

Thematic Track organizers:

+ Bolanowski, Marek, Rzeszów University of Technology, Poland
+ Kondratenko, Yuriy, Petro Mohyla Black Sea National University, Ukraine
+ Paszkiewicz, Andrzej, Rzeszów University of Technology, Poland

VI. Computational Optimization

Many real world problems, arising in engineering, economics, medicine and other domains, can be formulated as optimization tasks. These problems are frequently characterized by non-convex, non-differentiable, discontinuous, noisy or dynamic objective functions and constraints, which ask for adequate computational methods. The aim of this Thematic Track was to stimulate the communication between researchers working on different fields of optimization and practitioners who need reliable and efficient computational optimization methods. Contributions related to both theoretical and practical aspects of optimization methods were represented.

Thematic Track organizers:

+ Fidanova, Stefka, Bulgarian Academy of Sciences, Bulgaria
+ Mucherino, Antonio, IRISA, University of Rennes, France
+ Zaharie, Daniela, West University of Timisoara, Romania

VII. Computer Aspects of Numerical Algorithms

Numerical algorithms are widely used by scientists engaged in various areas. There is a special need of highly efficient and easy-to-use scalable tools for solving large scale problems. This Thematic Track was devoted to numerical algorithms, with the particular attention focused on the latest scientific trends in this area and on problems related to implementation of libraries of efficient numerical algorithms. The main goal of this track was to facilitate meeting of researchers and exchange of their experiences.

+ Stpiczyński, Przemysław, Maria Curie-Skłodowska University, Poland

VIII. Cyber-Physical Systems Software Engineering

This Thematic Track has its roots in the IEEE Software Engineering Workshop (SEW), which is the oldest Software Engineering event in the world, dating back to 1969. It was originally run as the NASA Software Engineering Workshop and focused on software engineering issues relevant to NASA and the space industry. After the 25th edition, it became the NASA/IEEE Software Engineering Workshop and expanded its remit to address many more areas of software engineering, with emphasis on practical issues, industrial experience and case studies in addition to traditional technical papers. Since its 31st edition, it has been sponsored by IEEE and has continued to broaden its areas of interest. Now it is an integral part of the FedCSIS conference series, as one of important Thematic Tracks.

One extremely hot new area are Cyber-Physical Systems (CPS), which encompass the investigation of approaches related to the development and use of modern software systems interfacing with real world and controlling their surroundings. CPS are physical and engineering systems closely integrated with their typically networked environment. Modern airplanes, automobiles, or medical devices are practically networks of computers. Sensors, robots, and intelligent devices are abundant. Human life depends on them. CPS systems transform how people interact with the physical world just like the Internet transformed how people interact with one another. Accordingly, this Thematic Track brought together researchers with interest in software engineering, both with CPS and broader focus. Moreover, it provided a forum for reporting on past experiences, for describing new and emerging results and approaches, and for exchanging ideas on best practice and future directions.

Thematic Track organizers:

+ Bowen, Jonathan, Museophile Ltd., United Kingdom
+ Hinchey, Mike, Irish Software Engineering Research Centre, Ireland
+ Szmuc, Tomasz, AGH University of Science and Technology, Poland
+ Zalewski, Janusz, Florida Gulf Coast University, United States

IX. Cyber Security, Privacy, and Trust

Nowadays, information security is a backbone for protecting both user data and electronic transactions. Protecting communications and data infrastructures of an increasingly inter-connected world have become vital. Security has also emerged as an important scientific discipline whose many multifaceted complexities require synergy of computer science, engineering, and information systems communities. Information security has some well-founded technical research directions which encompass access level (user authentication and authorization), protocol security, software security, and data cryptography. Moreover, some other emerging topics related to organizational security aspects have appeared beyond the long-standing research directions. In this context, this Thematic Track focused on the diversity of the cyber information security developments and deployments in order to highlight the most recent challenges and report the most recent researches. It was designed as an umbrella for all cyber security technical aspects, user privacy techniques, and trust. In addition, it went beyond the technicalities and covered some emerging topics like social and organizational security research directions.

Thematic Track organizers:

+ Białas, Andrzej, Institute of Innovative Technologies EMAG, Poland
+ Masud, Mohammad, United Arab Emirates University, United Arab Emirates

X. Data Science in Health, Ecology and Commerce

This Thematic Track was a forum for exchange of ideas concerning all forms of data analysis, data economics, information systems and data based research, focusing on the interaction of those three fields. Here, data-driven solutions can be generated by understanding complex real-world (health-related) problems, critical thinking and analytics to derive knowledge from (Big) data. The past years have shown a forthcoming interest on innovative data technology and analytics solutions that link and utilize large amounts of data across individual digital ecosystems. Here, scenarios, in the field of health, smart cities or agriculture, merge data from various IoT devices, social media or applications and demonstrate the great potential for gaining new insights, supporting decisions, or providing smarter services. Together with inexpensive sensors and computing power they provide foundation of a world that bases its decisions on data. However, this is only the beginning of the journey, and the pertinent methods and technologies, and the potential application fields, as well as the impact on society and economy, have to be explored. This endeavor needs the knowledge of researchers from different fields applying diverse perspectives and using different methodological directions to find a way to grasp and fully understand the power and opportunities of data science. Bringing together researchers and practitioners of pertinent fields was one of focal points of this Thematic Track.

+ Reinhold, Olaf, University of Leipzig / Social CRM Research Center, Germany

XI. Distributed Edge AI – Risks and Challenges

The advent of end and edge nodes, with increased computational and storage capabilities, makes it possible to perform a large range of computations, with special focus on AI-based tasks on privacy-sensitive data, locally at the edge. This makes it possible to rely on a backend cloud only for communicating results of non-private data, for example by aggregation, or performing computations requiring the combination and further processing of results from different edge devices, or historical data sources, as it is done in the federated learning approaches. In addition, this increase in computation capabilities enables also neighboring edge devices to perform tasks collaboratively, leveraging each other's computational resources, before offloading data and computations to the cloud backend.

This Thematic Track focused on AI and ML techniques related to edge computing systems, and security and privacy approaches in view of data sharing, in order to enable smart and sustainable planning and operation of resource constrained IoT ecosystems, and edge computing applications. It was organized within the scope of the European ITEA3 MIRAI R&D project.

Thematic Track organizers:

+ Hristoskova, Anna, Sirris, Belgium
+ Klein, Sarah, Sirris, Belgium

XII. Information Systems Management

This Thematic Track facilitated a forum for exchange of ideas, for practitioners and theorists working in the broad area of information systems management in organizations. It focused on three complimentary directions: management of information systems in an organization, uses of information systems to empower managers, and information systems for sustainable development. Here, the interest encompassed all aspects of planning, organizing, resourcing, coordinating, controlling and leading the management function to ensure a smooth operation of information systems in organizations. Moreover, the contributions discussing the uses of intelligence systems and information technology to automate or otherwise facilitate the management function were included. Researches on the influence of intelligence systems on sustainability were welcomed as well.

Thematic Track organizers:

+ Bicevska, Zane, University of Latvia, Latvia
+ Chmielarz, Witold, University of Warsaw, Poland
+ Duan, Yanqing, University of Bedfordshire, United Kingdom

+ Leyh, Christian, University of Applied Sciences, Germany

XIII. Internet of Things – Enablers, Challenges and Applications

The Internet of Things (IoT) is a technology which is rapidly emerging around the world. IoT applications include: smart city initiatives, wearable devices aimed to real-time health monitoring, smart homes and buildings, smart vehicles, environment monitoring, intelligent border protection, logistics support. IoT is a paradigm that assumes a pervasive presence in the environment of many smart things, including sensors, actuators, embedded systems and other similar devices. Widespread connectivity, getting cheaper smart devices and a great demand for data, testify to that the IoT will continue to grow by leaps and bounds. The business models of various industries are being redesigned on basis of the IoT paradigm. This Thematic Track focused on the IoT challenges in networking and information management, security and privacy, logistics, situation awareness, and medical care. It was organized within the scope of the European ASSIST-IoT and aerOS projects.

Thematic Track organizers:

+ Chudzikiewicz, Jan, Military University of Technology, Poland

+ Zieliński, Zbigniew, Military University of Technology, Poland

XIV. Knowledge Acquisition and Management

Knowledge management is a large multidisciplinary field having its roots in management and AI. Activity of an extended organization should be supported by an organized and optimized flow of knowledge to effectively help all participants in their work. The aim of this Thematic Track was to discuss approaches, techniques and tools in the knowledge acquisition and other knowledge management areas with a focus on contribution of AI for improvement of human-machine intelligence and face the challenges of this century. It shared information and experiences, as well as delved into current trends of methodological, technological and implementation aspects of knowledge management processes.

Thematic Track organizers:

+ Berka, Petr, Prague University of Economics and Business, Czech Republic

+ Hauke, Krzysztof, Wrocław University of Economics, Poland

+ Owoc, Mieczyslaw, Wrocław University of Economics, Poland

+ Pondel, Maciej, Wrocław University of Economics, Poland

XV. Meta Environment for Citizens, Business and Entertainment

This Thematic Track was focused on the development of Web 3.0, in particular in relation to the use of virtual reality (VR) and augmented reality (AR), on top of emerging technologies such as blockchain and widely understood IoT. The genesis of those ideas and components came from the video game industry, but also, its strong presence in business, medicine, banking, government, etc. All that, placed on top of IoT and other solicited concepts, as well as blockchain technologies, allowed discussion of new ideas related to the amalgamation of the technology aspects. The goals of the track were to expand understanding of current composition of different technologies cross business areas, including those that indicate the initial or minor presence in business and its opportunity to strengthen its presence, discover new areas of development of discussed subjects, as well as redesign well known applications with the new approach and concepts. Moreover, researches and observations related to the use of technology in business, medicine or science in a way that increases efficiency as well as ensuring a qualitative leap were welcome.

Thematic Track organizers:

+ Szumski, Oskar, University of Warsaw, Poland

+ Tan, Qing, Athabasca University, Canada

XVI. Multimedia Applications and Processing

Multimedia, computer vision, graphics, and machine learning have become ubiquitous in modern information systems, creating new challenges for detection, recognition, indexing, access, search, retrieval, automated understanding, and processing, resulting in many applications based on image and signal processing, machine learning and various multimedia technologies. Recent advances in pervasive computers, networks, telecommunications, and information technology, along with the proliferation of multimedia mobile devices, have stimulated the rapid development of intelligent applications. These key technologies, using virtual reality, augmented reality, and computational intelligence, are creating a multimedia revolution that significantly impacts a broad spectrum of consumer, business, healthcare, educational and governmental domains. Advancements in AI resulted in the rapid growth of both methods and applications of machine learning approaches in computer vision, image processing, and analysis. Further advances in parallel computing, in the first decade of the 21st century, combined with development of deep neural networks, became a real game-changer in machine vision. This Thematic Track covered a range of AI-based theories, methods, algorithms, technologies, and systems for diversified and heterogeneous digital multimedia, imaging, computer graphics and machine learning areas. Moreover, it provided an opportunity for researchers and professionals to discuss present and future challenges and potential collaboration for future progress in these fields.

Thematic Track organizers:

+ Iwanowski, Marcin, Warsaw University of Technology, Poland

+ Kwaśnicka, Halina, Wrocław University of Science and Technology, Poland

- Śluzek, Andrzej, Khalifa University, United Arab Emirates
- Stanescu, Liana, University of Craiova, Romania

XVII. Practical Aspects of and Solutions for Software Engineering

This Thematic Track was a follow-up to the KKIO series of software engineering conferences, organized, since 1999, under the auspices of the Polish Information Processing Society. The track was focused on emerging challenges and solutions for software engineering industry. A particular interest was related to validation and demonstration of practical applications of the proposed approaches. The track gathered contributions concerned with practical aspects of software engineering, relevant to the IT industry (including challenges and needs), research ideas and solutions aimed at addressing such aspects, and became a place to establish the cooperation between scientific and industrial partners.

Thematic Track organizers:

- Jarzębowicz, Aleksander, Gdańsk University of Technology, Poland
- Przybyłek, Adam, Gdańsk University of Technology, Poland
- Staroń, Mirosław, University of Gothenburg, Sweden

XVIII. Recent Advances in Information Technology

The aim of this Thematic Track was to provide a platform for exchange of ideas between early-stage researchers, in computer science and intelligence systems, Ph.D. students in particular. Furthermore, it provided all participants an opportunity to get feedback on their studies from experienced members of the AI and IT research communities. In fact, this track – as in previous years – played the role of so-called Doctoral Symposium, a well-established tradition of the FedCSIS conference series. Here, special care was taken to provide support and mentoring for young researchers and to facilitate frutiful discussion and exchange of ideas.

Thematic Track organizers:

- Dedinec, Aleksandra, Faculty of Computer Science and Engineering, Ss. Cyril and Methodius University, North Macedonia
- Gil, David, Computer Technology Department, University of Alicante, Spain
- Kowalski, Piotr, Systems Research Institute, Polish Academy of Sciences and AGH University of Science and Technology, Poland
- Łukasik, Szymon, Systems Research Institute, Polish Academy of Sciences and AGH University of Science and Technology, Poland

XIX. Rough Sets: Theory and Applications

This Thematic Track discussed research related to the state-of-the-art and future perspectives of rough sets, considered from both a theoretical standpoint and real-world applications. Rough set theory is a versatile mathematical framework that has proven successful in AI, knowledge representation, approximate reasoning, data mining, machine learning, and pattern recognition, among other areas. The track was devoted to all the mentioned areas, with an additional emphasis on problems of modeling AI processes using rough set-based techniques. The track provided an opportunity for interdisciplinary exchange and collaboration among scientists from diverse backgrounds, including mathematics, computer science, statistics, physics, engineering, and social sciences. Moreover, it allowed staying up-to-date with the state-of-the-art in rough set theory and its applications, and to discuss future research directions and opportunities. Last but not least, the track was synchronized with Rough Set School which provided a more fundamental background for the theory and applications of rough sets.

Thematic Track organizers:

- Artiemjew, Piotr, University of Warmia and Mazury in Olsztyn, Poland
- Chelly Dagdia, Zaineb, UVSQ, Paris-Saclay, France
- Mani, A., Indian Statistical Institute, India

XX. Scalable Computing

The world of large-scale computing continuously evolves. The most recent addition to the mix comes from numerous data streams that materialize from exploding number of cheap sensors installed "everywhere", on the one hand, and ability to capture and study events with systematically increasing granularity, on the other. To address the needs for scaling computational and storage infrastructures, concepts like: edge, fog and dew computing emerged. Novel issues, involved in "pushing computing away from the center", did not replace open questions that existed in the context of grid and cloud computing. Rather, they added new dimensions of complexity and resulted in the need of addressing scalability across more and more complex ecosystems consisting of individual sensors and micro-computers (e.g. Raspberry PI based systems) as well as supercomputers available within the Cloud (e.g. Cray computers and/or machines for large ML model training, facilitated – for instance – within the MS Azure Cloud). Addressing research questions that arise in individual "parts" as well as across the ecosystem viewed from a holistic perspective, with scalability as the main focus, was the goal of this Thematic Track.

Psychological Safety, Leadership and Non-Technical Debt in Large-Scale Agile Software Development

Muhammad Ovais Ahmad
Dept. of Computer Science
Karlstad University
Karlstad, Sweden
Email: ovais.ahmad@kau.se

***Abstract*—Psychological safety has been hypothesised as an important antecedent of the success of agile software development (ASD) teams. However, there is a lack of investigation on psychological safety in large-scale agile (LSA) software development teams. This study explored the antecedents and effects of psychological safety on LSA teams. We conducted semi-structured interviews with software professionals working on LSA project in a Scandinavian technology company. The results suggest that building a psychologically safe environment is a multi-dimensional factor that requires proactive leadership approach, open communication and constructive feedback. The focus should be on designing teams for learning, remuneration safety, and a well-prepared onboarding process for new team members. A psychologically safe environment contributes to effective teamwork, work satisfaction, and promotion of learning. Absence of such an environment leads to brain drain, highlighting the consequences of neglecting this essential aspect of organisational culture. Future research directions are proposed in this paper.**

***Index Terms*—Psychological safety, leadership, non-technical debt, agile, large-scale, software development.**

I. Introduction

AGILE methods help software companies improve the quality of their products while maximising customer value. It also helps to have an efficient response to defects, improved communication, and effectiveness of coordination [2]–[5]. Nonetheless, it presents various management challenges, some of which originate from inadequacies in the ongoing and closely-knit communication necessary for the effectiveness of Agile methods. According to Boehm and Turner [35], agile brings various challenges such as development process conflicts, business process conflicts, ratings), and people conflicts. The foundation of the Agile approach rests on collaborative relationships and the interconnectedness among team members. It is of utmost importance that any questions teammates may have about the possible ramifications of expressing their opinions – whether it pertains to identifying gaps in others' work or struggles within their own tasks – do not hinder the overall performance. To enhance productivity in software development, it is important to understand the factors that influence individual and team performance. Additionally, it is important the team members feel safe and to "*offer ideas, admit mistakes, ask for help, or provide feedback in hierarchies*" [34].

Psychological safety is an important factor for teams working in agile environments and performing knowledge-intensive software tasks [1]–[3]. Psychological safety is "*a shared belief held by members of a team that the team is safe for interpersonal risk-taking*" [6].

ASD methods have been designed for small-scale projects, but their potential positive outcomes have made them attractive to LSA software development projects. Kalenda *et al.* [5] and Dikert *et al.* [4] reported LSA success factors (i.e., management support, executive sponsorship and teamwork support) and challenges (i.e., difficulty in implementing agile methods, coordination challenges in a multi-team environment, mid-level managers' unclear role in ASD, too much pressure and workload, and lack of knowledge, coaching and training [4, 5]. Another concept that significantly affects software development is "non-technical debt" (NTD). NTD covers non-technical or social aspects of software development [2]. Several factors contribute to social, process and people's debts in software engineering (i.e., lack of knowledge; lack of communication, collaboration and coordination; inadequate management decision; low developer morale; lack of psychological safety, etc.) [2], [4], [5].

To be successful in an agile environment and be able to handle the aforementioned challenges, teams must engage in more open communication and close collaborative relationships among their members. To do so, psychological safety is an important condition of the agile team environment. Psychological safety has been extensively studied in social science [3], [7–9] and has played an important role in organisational research, as reported in the Google Aristotle project [3], [10]. Psychological safety has positive effects on team performance, job satisfaction and team reflexivity . In the context of ASD, limited research has been conducted on psychological safety [33], specifically in LSA projects. To fill this knowledge gap, we need a holistic understanding of what it takes to work effectively in LSA teams. Thus, in the present study, we seek to answer this research question:

RQ: What are the antecedents and effects of psychological safety on LSA teams?

To answer the RQ, we report the qualitative findings from a survey of eight software professionals working on an LSA project in a Scandinavian technology company.

In Section II, we explain the LSA and psychological safety concepts. The research method that we used is presented in Section III, followed by the results in Section IV. The study's limitations and threats to validity are reported in Section V. We end this paper with the discussion and conclusion in Section VI.

II. Background

ASD is a set of iterative and incremental methods captured in the Agile Manifesto. The latter focuses on team interaction, working software, customers' requirements and promptness to change [12]. Such methods are used in both small-scale and large-scale ASD projects [4], [5]. There is a growing body of research on scaling ASD. Dikert [4] listed a range of LSA definitions and concluded that *large-scale denote software development organizations with 50 or more people or at least six teams*. There is a wide range of frameworks such as LeSS, SAFe, DAD, Spotify, Nexus and Scrum-at-Scale.

LSA teams face various challenges (i.e., managing complexities and interdependencies, diverse teams, roles and personalities, sub-optimal processes, conflicting agendas between teams, and complex and ambiguous goals) [4], [5], [13], which lead to NTD (i.e., social, process and people's debt) [8], [14]. The causes of social debt are gender biases; lack of communication and collaboration; power distance; organisational silos and lack of kindness [2]. Process debt mostly occurs when organisations ignore process competence development, process divergence and uncontrolled external dependencies [2]. People's debt is caused mostly by priggish members, demotivation of non-senior members, inadequate management decision and lack of psychosocial safety [2]. Most of these issues are either people-oriented or environment-related concerns. Enhancing psychological safety has a moderating effect on communication deficiencies and collaboration issues, whereas the intensity of task-related collaboration exhibits both promoting and mitigating effects [2].

There is a positive correlation between managers' openness and transformational leadership, on one hand, and psychological safety, on the other hand [15]. Leader's inclusiveness important. It encompasses verbal and behavioural actions of leaders aimed at signalling an invitation for open comments and feedback that are respected and valued, plays a pivotal role in cultivating an environment characterized by psychological safety [36]. Nonetheless, the process of feedback should always be approached with a mindful consideration of the potential conflicts it might elicit. It is important to recognize that not all forms of conflict are disadvantageous. Task-related conflicts, emerging from differing viewpoints concerning a specific task, might not yield as many adverse effects as relationship conflicts, which stem from interpersonal frictions, like harbouring negative sentiments towards an individual [37]. Further, psychological safety is important for successful collaboration, open communication, knowledge and information sharing, and learning from failures and performance [6], [16–19]. Inter-team coordination has no positive relation to team performance, but psychological safety has a significantly high positive correlation to team performance [7]. Social agile practices (e.g., daily scrums, retrospectives or pair programming) positively influence psychological safety, transparency, communication and ultimately, productivity [20].

To create a psychologically safe environment, it is vital to establish collective responsibility for team performance [21], [22]. Safdar *et al.* [11] quantitatively investigated knowledge sourcing in new product development teams through a psychological safety lens. Their study's results show that psychological safety plays a significant role in a software engineer's knowledge source selection. A software engineer who feels a high level of psychological safety is inclined to consult team members, whereas a software engineer with a low level of psychological safety tends to choose external sources [11]. In the ASD context, to institutionalise psychological safety, individuals, teams and the leadership should combine their efforts to implement strategies for no-blame, open and collective decision-making in the team and proactively supporting a psychologically safe environment [33].

Thorgren and Caiman [38] investigated the role of psychological safety in implementing agile methods across cultures. Their results show that psychological safety is essential for the successful implementation of agile methods in cross-cultural teams. Further, their investigation indicated that by cultivating psychological safety within a team, the possible conflicts and tensions that may arise from the intersection of agile practices, values, and the work environment culture can be reduced [38].

Hennel and Rosenkranz [20] conducted three case studies in two large insurance companies and one software development company. The goal was to investigate the effects of psychological safety and agile practices on team performance. Their results suggest that social agile practices (e.g., daily stand-ups, retrospectives, and Sprint planning) influence psychological safety, transparency, communication, and ultimately productivity [20].

III. Research settings

The grounded theory (GT) approach involves a set of steps for data collection, analysis, formulation of theory parameters and reporting [23]. The GT helps researchers to identify common patterns across interview transcripts by constantly comparing data at different levels of abstraction [24]. This approach does not rely on a preconceived hypothesis rather aims to uncover the interviewees concerns in the process. In this study, the focus was on the experience in LSA development project, working environment challenges and strategies in real-world settings.

We conducted semi-structured interviews with seven agile practitioners from a Scandinavian technology company. The selected case company is a partner in the NODLA project and uses various agile methods in their large-scale projects and product development. NODLA project aiming to investigate large-scale ASD and non-technical debt, funds by the Knowledge Foundation in Sweden.

TABLE I. INTERVIEWEES BACKGROUND

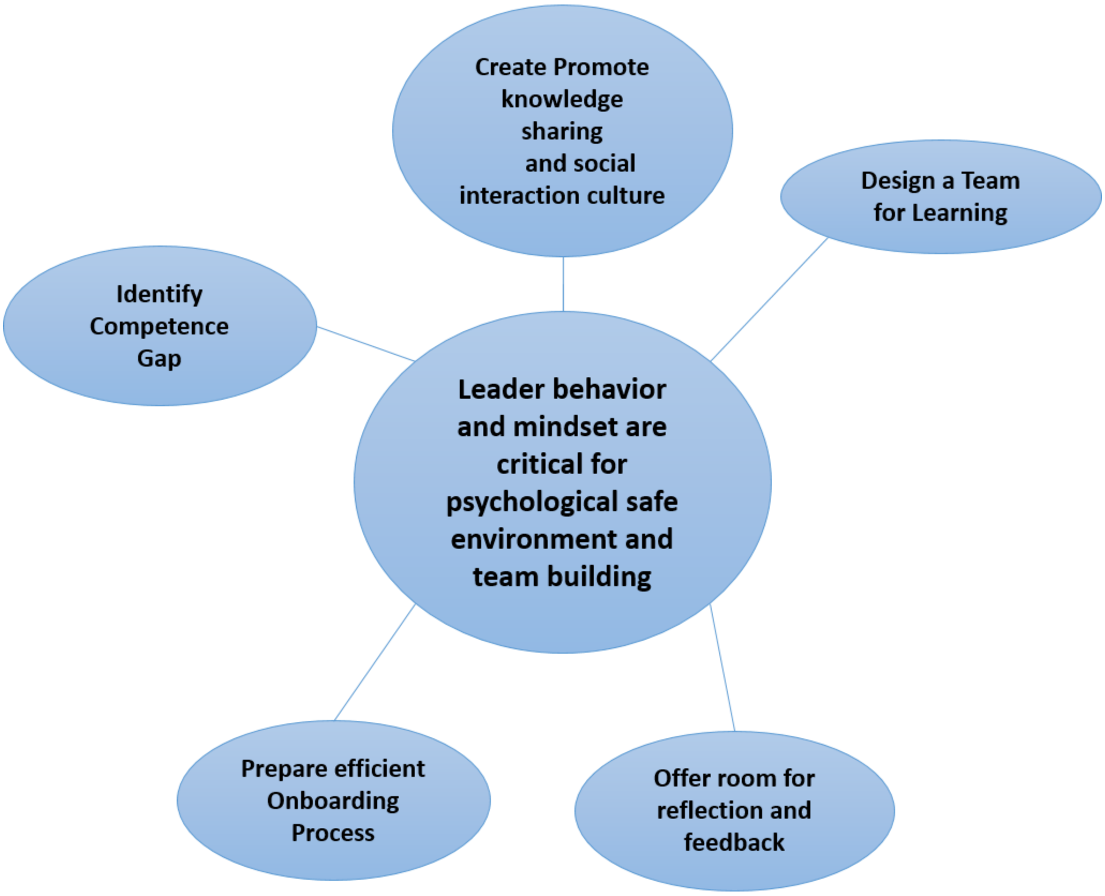
ID	Interviewee's title	Development Experience
EL1	Developer – Integration specialist	1 year
EL2	Project Manager	2 years
EL3	Scrum Master	7 years
EL4	Developer – with multiple roles	20 years
EL5	Manager	10 years
EL6	Scrum master	5 years
EL7	Business analyst – with multiple roles	3 years

The interviews were recorded via the Zoom application, each lasting 1–2 hours. These interviewees performed different roles and some have multiple responsibilities. Table 1 shows that interviewees were from diverse roles, including software developers, project managers, Scrum masters, and business analyst.

Out of seven participants, four participants have more than five years of experience, whereas remaining three interviewees have 1 - 3 years of working experience. All of the study participants had practical agile methods experiences. The interview questions were based on four broad areas: professional background; agile way of working in their team; communication, collaboration and knowledge-sharing practices; and teamwork environment. Each transcript was meticulously analysed by means of line-by-line reading to identify key points. Each identified point was recorded as an open code, which went through an iterative process of comparison throughout the analysis. Such techniques help researchers to check and compare a new code against the previously identified ones [23].

IV. RESULTS

The results of this study are presented in four sub-sections. First, the significance of leaders' behaviour as a key antecedent of fostering psychological safety is emphasised. Second, the importance of leaders' formation of teams with a focus on learning is highlighted. Third, the need to cultivate trusting and respectful interpersonal relation-ships, both inside and outside ASD teams, is noted. Lastly, the findings reveal that a lack of psychological safety within a company contributes to brain drain, highlighting the con-sequences of neglecting this essential aspect of organisational culture. The



Create Promote knowledge sharing and social interaction culture
Design a Team for Learning
Identify Competence Gap
Leader behavior and mindset are critical for psychological safe environment and team building
Prepare efficient Onboarding Process
Offer room for reflection and feedback

Fig 1. Leadership role to enable psychological safety environment for LSA Software Development

Fig. 1 shows leadership role to enable psychological safety environment, whereas Fig. 2 shows its effects in LSA software development projects context.

A. Leader behaviour

The leaders' role is critical for preparing a good work environment where all team members feel comfortable in expressing their thoughts and ideas without fear of criticism or retribution. An interviewee said that paying attention to both customer and employee satisfaction should be the focus:

"*Our top focus is to be a great place to work and to have happy employees* and *at the same time, be a customer-centric organisation. That's where the agility mindset comes into play because if we have happy customers, then we normally deliver good value to our other stakeholders*" (EL5).

Establishing a psychologically safe environment is important as it gives individuals the confidence to speak up if they are unhappy about something.

"*I haven't felt at least that people are afraid to speak their minds because people do speak their minds if they are unhappy with something*" (EL2).

In such a safe environment, team members can engage in enjoyable activities outside of work, which can foster stronger relationships and promote team cohesion. An interviewee expressed the scenario as follows:

"*We do a lot of things together, like* [when we're] *off works and stuff. So, it's fun*" (EL1).

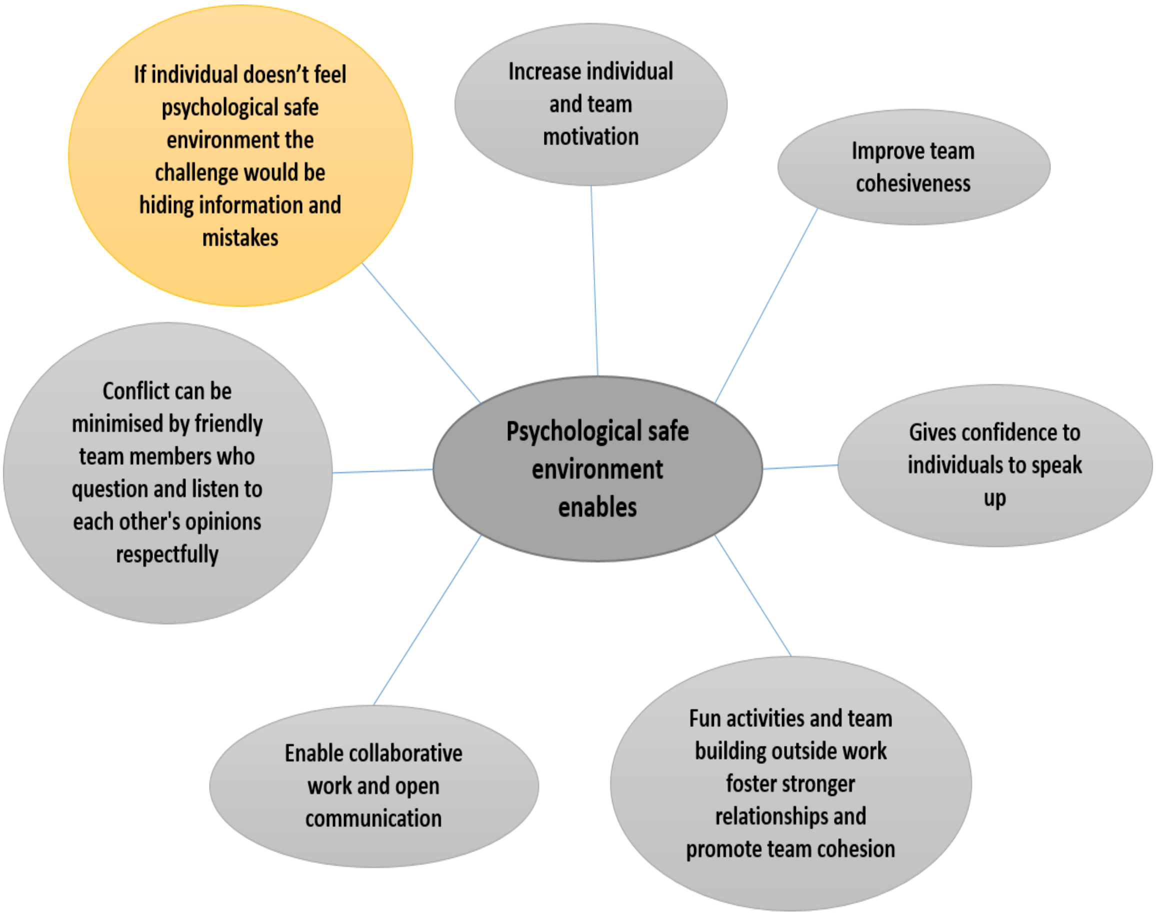
However, establishing such a safe environment comes with its challenges. An interviewee highlighted the hidden fear of openly admitting their team's mistakes or underperformance of activities:

"*It's very helpful to reflect and always keep in mind what we can do better and change next time. It is a problem to tell the truth if* [there is] *something that you think did not go as well as you wanted to. Maybe I can be a little bit scared to tell the whole truth. I think that could be a problem*" (EL1).

B. Trusting and respectful interpersonal relationships

When the work environment is respectful and trustworthy, the results are always positive despite strict time constraints or deadlines. This is very important in software development as it is a knowledge-intensive activity with many discussions around customers' demands. A psychologically safe environment enables difficult conversations without the need to tiptoe around the truth. In the case company, the team members were supportive and helpful towards one another, and they often worked collaboratively:

"*If I have a problem, I'm never alone. If I do not act alone, I need to ask someone. If I do that, they will always help me. We do a lot of funny things together. I do not think*



If individual doesn't feel psychological safe environment the challenge would be hiding information and mistakes
Increase individual and team motivation
Improve team cohesiveness
Conflict can be minimised by friendly team members who question and listen to each other's opinions respectfully
Psychological safe environment enables
Gives confidence to individuals to speak up
Enable collaborative work and open communication
Fun activities and team building outside work foster stronger relationships and promote team cohesion

Fig 2. Psychological safety environment and its effects for LSA software development

that we have had any conflicts. It is a really good team, and we are really supporting and lifting up each other. So, I think that everyone can see that our team is very friendly" (EL4).

It can also be a sign of team cohesiveness when everyone works towards the same goal. It is noteworthy that being friendly does not mean that professional activities are overlooked. Listening to each team member's opinions is essential to avoid conflicts, as an interviewee explained:

"*...friendly team is something that we do not have to be too much friends with. We question each other and listen to each other's opinions. I think that one of the reasons why we do not have this conflict. We are very friendly and we don't want to fire our voices if that can lead to a conflict*" (EL4).

Furthermore, it is important that meetings and discussions at the workplace should not be only work-related. It should also offer an opportunity for team members to connect and engage with one another on a social level.

"*Suppose there are problems, how people tell if they're satisfied and if they're ill or something. So it's just like a social meeting as well, not just work*" (EL3).

C. Brain drain

Brain drain occurs when employees feel that the work conditions are too demanding or feel a lack of intrinsic motivation or stimulation from their work and a lack of remuneration safety. Attraction and retention of skilled employees require competitive remuneration packages, a safe environment and a collaborative corporate culture. It is reasonable to assume that when employees feel safe psychologically and remuneratively, they are more likely to stay with the company. When a good employee leaves, it has an immediate effect on the team members and their work. An interviewee highlighted such skills gap:

"*He was a really good programmer, and we miss him a bit*" (EL6).

"*To be brutally honest, I know that some people left last year because they thought that they weren't getting paid enough*" (EL2).

However, employees' resignation from the company is not just due to the salary; it is a multidimensional factor, for example, caused by the nature of work, the place of work and some personal reasons. A senior team member expressed his observation:

"*One of the reasons that I've heard is that it's about the salary. That is important, and* [the income] *can differ if we live here* [a Scandinavian country's capital] *permanently as well. [The reasons for quitting] can depend on a lot of things. Some of my closest colleagues and I discuss. Sometimes, it feels like* [employees] *leave* [after just a short time]. *They understand things differently than what has actually happened to them*" (EL4).

When developers have no internal drive or interest in their work, it can be challenging to retain these less satisfied employees. Intrinsic motivation comes from activities that an individual finds enjoyable or stimulating, even without external rewards. Multiple interviewees highlighted such lack of exciting work, for example:

"*A risk or a factor that people want to live. It is not fun to have too much* [work] *to do and not fun* [activities] *to do; actually* [it is] *always tricky*" (EL1).

"*The most common reason is that they get another job offer on something they really want to work with. It has nothing to do with our company. It's more like they're going to work with something they appreciate more*" (EL7).

According to another interviewee, individuals leave their jobs because they feel that the work conditions are unsatisfactory and their work is too demanding.

"*They think that the conditions are not good enough. [They] are addicted to having projects; maybe like some months, they have much to do. And then for half a year, it's hard to get projects that they're used to, so they don't have much to do, and they feel under-stimulated and like, 'I want a new job so I can have more tasks to do'*" (EL1).

D. Designing a team for learning

Organisations need to develop the idea of designing teams for learning, which involves multiple factors such as an efficient onboarding process, creating a culture of continuous learning and knowledge sharing, reflection and feedback and so on. The starting point for designing a team for learning is to identify the competence development gap and then a good onboarding process for new employees. A point of caution in the onboarding process is whom to involve and when to be involved. When the process includes only senior members of the company, it becomes stressful for them. An interviewee expressed this situation as follows:

"*We have found that in the management team with the overall responsibility for competence development, that kind of role is sort of missing at the moment. We were working with scale agile. We had to fill in who would be responsible for each role, and we saw that overall competence development was lacking. We have an operation manager who is leading operations but maybe not clearly responsible for competence development*" (EL5).

"*Onboarding is a big issue that we have to work with and maybe not just talk about it. We have to take care of the people who are here and remain with a nice spirit. I think that it is important because if we get bigger and bigger, it puts a lot of pressure on senior consultants, and we have to be careful of them*" (EL3).

Software development is a knowledge-intensive activity, where knowledge sharing is an important element. An interviewee expressed positive experiences about their safe environment for sharing knowledge:

"*We have quite recently started knowledge-sharing sessions. One person in our team is responsible for administering these meetings and setting up the agenda. So, we are starting to work with it as it is in our spring planning to have knowledge sharing and talk about how we can do things better. It's an initiative from me or my colleagues who are the value-stream managers*" (EL3).

Along with the work practices, another aim was to establish good enterprise social media platforms (e.g., Slack, Microsoft Teams, etc.) for internal communication and social interaction within the company.

V. Limitations and threats to validity

We collected the data from interviews with software professionals from a Scandinavian software company. All the codes and concepts were directly obtained from the interviews. Our findings are sufficiently grounded in the substantive data [23] but cannot be generalised on a large scale due to the limited number of participants. Therefore, caution should be taken when applying these results to other software companies. The inherent limitation of the GT is that it is only based on a particular investigative context [25].

James and Busher [26] highlighted the risk regarding the authenticity of the participants in digital interviews. We were confident that all the participants were interviewed with the permission of the company representative and with a signed NDA. In this way, such risks are mitigated in this study. The GT approach used in this study involved subjective interpretation of the data. The findings and the emerging concepts presented in this study are based on the researchers' interpretation of the data, which may differ from other researchers' interpretations. Despite these limitations, this study's findings offer valuable insights into psychological safety, leadership and NTD in LSA development. The concepts are sufficiently supported with quotations from the participants' interviews, and the findings are discussed in detail and characterised by some existing concepts.

VI. Discussion and conclusion

In this study, we explored the antecedents and effects of psychological safety on LSA teams. The results suggest that building a psychologically safe environment is a multi-dimensional factor that requires a proactive leadership approach, a competent team design that focuses on learning, open communication and feedback, remuneration safety, and a well-prepared onboarding process for new team members. These factors contribute to effective teamwork, work satisfaction and learning, as well as promote a safe and collaborative learning environment.

Our results show that a psychologically safe environment can be enabled through enjoyable activities outside of work that also foster stronger relationships and promote team cohesion that is less prone to conflicts. In a software development project, team cohesion magnifies the impact of psychological safety on knowledge sharing [27]. Psychological safety directly contributes to effective [28]. The lack of psychological safety contributes to social and people's debts [8], [14], whereas a high level of psychological safety has significant positive correlations to LSA team performance [7] and the success of process innovations [17], mitigating effects of the lack of both communication and collaboration [8].

To create a more psychologically safe environment, leaders and the management should show appreciation for employees [19] and provide opportunities for their involvement in projects so that they can learn from their mistakes and failures. Detert and Burris [39] revealed a positive correlation between the managers' openness and transformational leadership with psychosocial safety. The management needs to identify competence gaps and design teams for learning. It is also evident that providing room for reflection and open feedback is important; otherwise, individuals or teams will hide their real troublesome situations. High-quality interpersonal relationships among the team members enhance their psychological security, leading to positive and effective learning [16, 32] and sharing behaviours [29]. Trust and organisational support are enablers of psychological safety at work [16]. Our results show that trusting and respectful interpersonal relationships in LSA teams help avoid conflicts and prepare a breeding ground for a safe and collaborative learning environment. Dreesen et al [14] and Ahmad et al [2] reported that lack of psychological safety in software development contributes to social debt.

A key manifestation of high-quality relationships is relational coordination, along with shared goals, shared knowledge and mutual respect [30], [31]. Relational coordination is "*a mutually reinforcing process of interaction between communication and relationships carried out for the purpose of task integration*" [30](p. 301). This is more important in software development as this knowledge-intensive activity requires creativity in solving a particular problem and completing a task. This recommendation would enable double-loop learning instead of a single loop in teams.

Agile teams strive for continuous improvement through recurrent feedback and introspection [40]. Psychological safety cultivates an environment wherein team constituents are enabled to provide and accept valuable feedback and facilitate learning [34]. While multiple studies in the realm of social sciences demonstrate that PS cultivates learning-oriented actions like soliciting feedback, experimentation, and deliberation of mistakes [6], [9], its pivotal role in LSA has not been recognised. The nature of ASD entails intricate knowledge that is collectively shared among multifaceted teams and evolves swiftly.

Edmondson highlighted psychosocial safety importance and its impact on learning within team and performance [6]. It is also important to design teams for learning and have a well-prepared onboarding process for new employees. It is vital to know whom to involve and when to involve senior members of a team or a project because it builds pressure on senior consultants and creates the need to take care of existing teams while remaining focused on company growth. It is interesting to note that despite the psychologically safe environment, the company noticed a brain drain due to the lack of both remuneration safety and intrinsic motivation and an office location far from the employees' families and friends. These findings highlight the importance of providing remuneration safety and addressing the factors that may lead to employee turnover. More research is needed to explore these issues in greater depth and develop strategies for solving them.

Future research should prioritise investigating the relations among organisational culture, employee diversity and psychological safety, as well as their impacts on team building, job satisfaction and performance. This includes addressing the reasons why knowledgeable team members leave the company. Another important area of study involves identifying competence gaps and designing teams that prioritise learning, including effective methods for assessing individual and team competencies, strategies for fostering continuous learning, proactive leadership and the significance of providing opportunities for reflection and open feedback. Additionally, exploring the influence of social activities on team cohesion and conflict prevention can provide insights into fostering strong relationships. It is also essential to investigate factors beyond psychological safety, such as remote work, intrinsic motivation and office location proximity to family and friends, in order to mitigate their impacts, prevent brain drain and enhance employee satisfaction and loyalty while creating inclusive and supportive environments for LSA teams and projects.

In conclusion, this study offers the above-mentioned recommendations. Overall, a psychologically safe environment can foster increased confidence, collaboration, communication, motivation and job satisfaction of individuals and teams. Finally, exploring both task and social cohesion regarding learning and performance in LSA teams and projects would be of interest. We posit that future research has the potential to delve into the impacts and advantages of psychological safety on the intricacies of agile teams and their effectiveness to develop and deliver software products. In light of this, we intend to expand upon the present study by examining the influence of psychological safety on software quality, individual and team learning.

***Abstract*—In recent times, software developers widely use instant messaging and collaboration platforms, as these platforms aid them in exploring new technologies, raising different development-related issues, and seeking solutions from their peers virtually. Gitter is one such platform that has a heavy userbase. It generates a tremendous volume of data, analysis of which is helpful to gain insights about trends in open-source software development and the developers' inclination toward various technologies. Analyzing these trends helps these platforms better cater to the needs of the developers, in turn increasing the usage of these platforms and promoting collaborations between more developers. The classification techniques can be deployed for this purpose. The selection of an apt word embedding for a given dataset of text messages plays a vital role in determining the performance of classification techniques. In the present work, the comparative analysis of nine-word embeddings in combination with seventeen classification techniques with onevsone and onevsrest has been performed on the GitterCom dataset for categorizing text messages into one of the pre-determined classes based on their purpose. Further, two feature selection methods have been applied. The SMOTE technique has been used for handling data imbalance. It resulted in a total of 1836 classification pipelines for analysis. The objective is to analyze their performances to recommend efficient pipelines for the classification task at hand. The experimental results show that word2vect, GLOVE with 300 vector size, and GLOVE with 100 vector size are three top-performing word embeddings having performance values taken across different classification techniques. The models trained using ANOVA features performed similarly to those models trained using all features. Finally, using the SMOTE technique helps models to get a better prediction ability.**

***Index Terms*—Functional Requirements, Non-Functional Requirements, Deep Learning, Data Imbalance Methods, Feature Selection, Classification Techniques, Word Embedding.**

I. Introduction

THE development of modern complex software systems requires a lot of meticulous planning and large teams of software developers and designers. The members of these teams are often geographically distributed across various locations and rely on online communication and collaboration modes. Many open-source projects and software development teams have shifted towards platforms such as Gitter and Slack due to the features and the support they offer for collaboration between software developers worldwide.Gitter has revolutionized team communications and project coordination, especially for distributed software development teams, by providing a user-friendly way of managing and organizing conversations. Gitter also provides public access to user-generated data, and the historic data is accessible indefinitely through chat room logs. Classifying the purpose of the messages in the developer communications on such platforms assists in better organization of messages into categories, making them easy to be retrieved by the users as per their requirements and deriving various insights into the general trends in open-source software development. This classification also helps understand the major reasons why people use these platforms for. Then, the platforms can be updated to fulfill the requirements of the users, which attracts more people to use these platforms, promoting better collaborations, meaning both the organizations running the platforms and the developers benefit from this. Manual classification of this data is not feasible due to the sheer volume of the data available. So there is a need to deploy Machine Learning (ML) techniques to automate the process and minimize the errors in classification.

The objective of the present work is to perform a comparative analysis of the classification pipelines developed using nine different word embeddings, two feature selection techniques, and thirty-four classifiers. We believe this analysis will help establish a strong foundation for future researchers to select the techniques and pipelines resulting in the best predictive ability of the developed models to identify the purpose of messages in developer communications. For this purpose, GitterCom dataset, which contains around 10,000 messages from various channels on Gitter has been adopted.

Each message in it has three labels viz. Purpose, Category, and Sub-Category, which the dataset creators curated manually. The process of creation of classification pipelines started by applying nine different word-embedding techniques to vectorize the data into a numeric form for further analysis. These word-embedding techniques generate an abundance of features, not all of which are influential in the classification task. Hence, two feature selection techniques, namely One-Way ANOVA and PCA are employed to synthesize or extract the most relevant and influential features to optimize the performance of the models. Then to test the predictive ability of the word-embedding and feature-selection techniques, we have used seventeen different variants of classification techniques with one-vs-one and one-vs-rest approaches. The classification techniques are used by considering various ML and Neural Network (NN) classification algorithms and ensemble learning methods in association with them. The predictive ability of these classifiers was validated using the 5-fold cross-validation method. The SMOTE data sampling technique is also applied to combat data imbalance, leading to incorrect and unreliable results. Finally, the performance of the developed models has been compared using evaluation metrics such as Accuracy, Sensitivity, Specificity, and Geometric Mean, which are extracted using the Box-plot Visualization technique and the Friedman Test.

II. Related Work

The proposed research is based on classifying and analyzing the purpose or rationale behind developer communications on modern instant messaging and communication tools. The developers use it for project coordination or technological discussions. This research also performs a comparative analysis of various NLP models that best analyze the communications on such platforms. In this work, we have used the 'GitterCom' dataset introduced by Parra et al. [1], a manually created dataset of 10,000 messages from developer discussions on the Gitter Platform.

The related work is divided into two sub-sections. The first sub-section focuses on the earlier works that have studied developer communications on instant messaging platforms such as Slack or Gitter. The second sub-section is dedicated to the analysis of messages on other platforms such as Q&A platforms (Eg: Stack Overflow), Social Media Platforms (Eg: Twitter), etc. In both sections, we perform a critical comparison of the previous endeavors with our research approach.

A. Instant Messaging and Communication Tools for Software Developers

Earlier research works performed an empirical study of the properties of the communications on Gitter and Slack. While some of these works focused on topics discussed and problem resolution, others introduced certain classes to classify the purpose or rationale of the messages in such communications. The survey confirmed that various classification techniques were used to identify the topic of discussion or the purpose and rationale of the messages. Ehsan et al.[2] performed an empirical study of developer discussions in Gitter to understand the nature of developer discussions, the type of questions developers ask, and the proposed solutions. The authors proposed an approach for the automatic identification of discussion threads in developer chatrooms using hierarchical clustering algorithms and other heuristics. They identified four patterns of responses based on the response length and complexity. The authors also created a taxonomy of resolution types and discussed topics in the chatrooms. The topics discussed were classified into five types - Installation and configuration, Debugging and troubleshooting, Feature requests and enhancements, Code review and feedback, and General discussion.

Sahar et al. work focused on the analysis of how developers discuss issue reports in Gitter chat rooms related to open-source systems [3]. The authors proposed an approach involving clustering algorithms to identify issue report discussions automatically. These discussions were classified into four types based on the number of messages, participants, and duration of the discussion. In our work, we employ various word embedding techniques to assess which technique captures these key patterns and strategies the best, aiding the classification performance. The above two works broadly focus on identifying the topics of discussion and defining a classification nomenclature based on it. Our work focuses on a possible next step of their research, which is to build and compare Machine Learning pipelines that can automatically classify present and incoming messages based on the considered classification nomenclature.

A study with a research methodology similar to ours was done by Parra et al. [4]; their objective was built upon their previously published paper (Parra et al.[1]) in which they introduced the GitterCom dataset for the first time. The three categories defined to classify each message in the developer discussions based on its purpose in this paper (team-wide, personal benefits, community support) were derived from the work of Lin et al. for the Slack platform [5]. The authors also analyzed the performances of nine supervised machine learning and deep learning algorithms, such as SVM, Decision Trees, AdaBoost, LSTM, etc., along with certain data sampling techniques to classify the purpose of a given message as one of the pre-defined categories. A key difference between our work and theirs is the analysis of the benefits of various word embedding techniques in better capturing the contexts and patterns of the messages which aid the classification. We also explore the possible effects of feature selection techniques since they help reduce the complexity of the models while retaining the key features of the data.

The analysis of the topics and discussion and purpose of messages was also undertaken for Stack Overflow. Lin et al. performed an empirical study to understand the purposes for which developers use Slack [5]. Upon surveying 53 software developers, the authors found that the developers self-reported using Slack for various purposes. They broadly classified these purposes into personal benefits, community support, and team-wide purposes. Another such empirical study was undertaken by Stray et al. [6]. The authors explored the use of Slack for communication and project coordination in virtual agile development teams as they studied the communications of a group of 30 software developers at a large software development organization. They found that the messages could be broadly classified into one of the following purposes: general information/coordination, general discussions, problem-focused communication, technical communication, and socializing.

Alkadhi et al. performed an exploratory study to investigate the presence of rationales in chat messages during software development [7]. They collected and analyzed chat messages from three open-source software development teams on GitHub comprising students working on capstone projects. Based on this analysis, the authors defined a set of categories for the types of rationale found in the messages - Design, Functionality, Implementation, and Maintenance. Their findings also indicate the usefulness of classification algorithms such as SVM and Naïve Bayes and the data sampling techniques for automatically identifying and classifying messages based on the rational information they contain. Our work, however, focused on recommending the best techniques and pipelines for building such models to extract the best performance out of them rather than just checking for feasibility. In subsequent work, Alkadhi et al. presented a new approach called REACT (Rationale Extraction from Chat Transcripts) [8]. They considered five rationale elements for their work - issues, alternatives, pro-arguments, con-arguments, and decisions. The REACT approach enabled the developers to explicitly record the rationale in messages on the Slack platform through manual annotation.

B. Other Communication Tools for Software Developers

Various other platforms facilitate software development communication. The concept of such tools is based on Question & Answer forums like Stack Overflow and social media platforms like Twitter. Software developers spread out across various geographic locations relied majorly on such platforms for communication and coordination before the advent of the modern instant messaging tools dedicated to facilitating such discussions. Q&A platforms such as Stack Overflow encourage efficient problem-solving, community support, and knowledge sharing among its users across the globe. Social Media sites like Twitter also help in this regard by providing real-time updates, networking opportunities, and crowd-sourced solutions through hashtags and mentions to reach out to relevant experts for assistance.

The current tags provided for questions on Stack Overflow are based on the technologies used or being referred to in the question. Classifying these questions based on the purpose or context will serve the users better since it makes the process of finding relevant posts quicker. Beyer et al. performed such work where they obtained a taxonomy of seven question categories: API change, API usage, Conceptual, Discrepancy, Learning, Errors, and Review, and they manually curated a dataset consisting of 500 posts classified into these categories [9]. The authors then developed classification models using the Random Forest and SVM algorithms along with data sampling techniques and performed a comparative analysis with 82 different configurations regarding the preprocessing and representation of the input text data to analyze which configuration captured the context and intricacies of the data better. In place of such configurations, we explored word embeddings for this reason since they offer better generalizability to out-of-vocabulary words as they provide continuous representations of words by considering semantic equivalence, something which pre-processing techniques might struggle with.

Venigalla et al. undertook a similar study using the Latent Dirichlet Allocation Algorithm to model six questions topics based on their purpose [10]. The authors also came up with names for those topics based on the taxonomy used in the literature. They also used various Machine Learning algorithms, such as Linear SVC, Logistic Regression, Multinomial Naive Bayes, Random Forest, etc., to develop classification models for the questions on Stack Overflow.

Guzman et al. performed an analysis of the tweets on Twitter related to software applications[11]. The intention was to obtain tweets that could be useful for developers by using classification algorithms. The purpose of these tweets includes improvement suggestions, user needs, bug reports, feature requests, etc. The authors introduced ALERTme, an approach to automatically classify, group, and rank such tweets. This approach relied on classification algorithms such as Multinomial Naive Bayes and word-embedding techniques such as TF-IDF for classification.

We preferred Gitter over such platforms because Gitter's data has been largely untapped for such analysis, and Gitter provides more intricate and essential details of software development pipelines and requirements as developers use it regularly to discuss such details.

III. STUDY DESIGN

This section presents the details regarding various design setting used for this research.

A. Experimental Dataset

We plan to use the GitterCom dataset for this experiment, the first manually labeled dataset of Gitter instant message histories in open-source systems. It contains 10,000 messages collected from 10 open-source software development Gitter communities (1,000 messages per community). Each message in this dataset was manually labeled to capture the purpose of the communication expressed by the message. Each record in the dataset consists of the following information: (i) The channel of communication (ii) the Message ID (iii) The date and time when the message was posted (iv) The author of the message (v) The message in plain text (vi) Purpose of the message (vii) The subclass of the purpose it belongs to - category (viii) The subclass of the category it belongs to i.e., the sub-category.

In this experiment, we intend to predict the Purpose label for any given message. There are three possible classes (labels) of purpose:

- **Personal Benefits** - Includes messages posted to satisfy the developer's personal needs.
- **Team-wide activities** - Includes messages related to the discussion among the members of a team working on software development activities related to the system they are developing.
- **Community Support** - Includes messages posted for general discussions among developers from communities or special-interest groups who intend to explore new tools and frameworks or brainstorm ideas.

B. Word Embeddings

The textual data of the dataset is to be represented in numeric vector form for further analysis. To achieve this, nine different word embedding techniques, including Continuous Bag of Words (CBOW), Skip-Gram (SKG), Global Vectors for Word Representation (GloVe) (with 50 dimensions, 100 dimensions, and 300 dimensions), Word2vec, fastText (FST), Generative Pre-trained Transformer (GPT), and Generative Pre-trained Transformer-2 (GPT-2), will be applied on the dataset. These techniques help represent the textual data as a vector in an n-dimensional space. All the stopwords, spaces, and other bad symbols will be removed from the textual data before applying the word embedding techniques. The generated vectorial representations will then be used to develop models to determine a message's purpose. [12].

C. Feature Selection Techniques

Since vectorial representations are used as inputs to develop the classification models, and each of the vectorial representations contains a lot of columns (features), some of which may not be as influential as the others, optimization of the data and selection of the influential features becomes crucial to improve the performance of the models. To extract the important features, we plan to use two different Feature Selection Techniques - One-Way Analysis of Variance (One-Way ANOVA) and Principal Component Analysis (PCA) to discard irrelevant features and obtain the set of relevant and influential features.

D. Training of Models from Imbalanced Data Set

Upon analysis of the dataset, if we observe the problem of class imbalance in our dataset, i.e., the number of data samples in each class is different, we resort to the data sampling techniques to enhance the performance of the developed models. We propose to use the Minority Oversampling Technique (SMOTE) on the dataset to balance the data in such a scenario.

E. Classification Techniques

We propose to develop thirty-four different classifiers to perform a comparative analysis of the developed models. For that, classification algorithms such as Multinomial Naive Bayes (MNB), Bernoulli's Naive Bayes (BNB), Gaussian Naive Bayes (GNB), Decision Tree Classifier, Logistic Regression, K-Nearest Neighbours Classifier, Random Forest Classifier, Extra Trees Classifier, Multi-Layer Perceptron with Limited-memory BFGS, Stochastic Gradient Descent, and Adam Optimizers will be utilized along with ensemble modeling techniques such as Bagging with KNN, Multinomial Naive Bayes, Logistic Regression and Decision Tree Classifiers, Ada Boost Classifier and Gradient Boosting Classifier. Each classification technique mentioned above will be implemented using one-vs-Rest and One-vs-One Multi-class classification strategies, thus giving a total of thirty-four classifiers. These classification strategies are defined below:

- **One-vs-One classification**: The model trains on pair-wise comparisons between each possible combination of classes. The final prediction is made by aggregating the votes from all binary classifiers.
- **One-vs-Rest classification**: The model trains a binary classifier for each class to distinguish between that class and the rest of the classes combined. The item is assigned to the class having the maximum probability of having that item.

IV. Research Methodology

In this work, we started with pre-processing the dataset by removing unnecessary punctuation, spaces, and stop-words. We also had to manually delete some records that consisted of messages with empty or unrecognizable symbols. After obtaining the pre-processed dataset, We applied nine different word embedding techniques to extract numeric feature vectors from the messages on the Gitter platform. We considered these features as inputs to develop models for predicting the purpose label of a given message. After applying the word-embedding techniques, we employed the One-Way ANOVA, and PCA to obtain the best combination of relevant features. The One-Way ANOVA test helps find features with equal variance between groups, which means these features don't impact the response much and hence can be discarded. PCA considerably reduces the number of features while trying to retain a significant portion of the variance in the original dataset.

To make the computation of the models simpler and feasible, we sampled 3000 rows randomly from the dataset. Then, we observed the presence of a class imbalance in the sampled rows as the no. of messages with the 'Team-wide' purpose label was much higher than other labels. To combat this issue, we employed the Synthetic Minority Over-sampling (SMOTE) technique, which creates synthetic data samples based on the original data. The models obtained using the above techniques were trained using 34 different classifiers developed using various classification algorithms and ensemble methods and implemented using both One vs. One and One vs. Rest Classification strategies. The predictive ability of these classifiers was validated using the 5-fold cross-validation method. The performance of the developed models was compared using evaluation metrics such as Accuracy, Sensitivity, Specificity, and Geometric Mean, which were extracted using the Box-plot Visualization technique and the Friedman Test.

The detailed overview of the proposed framework is shown in Figure 1. The initial glance of the figure suggests that the

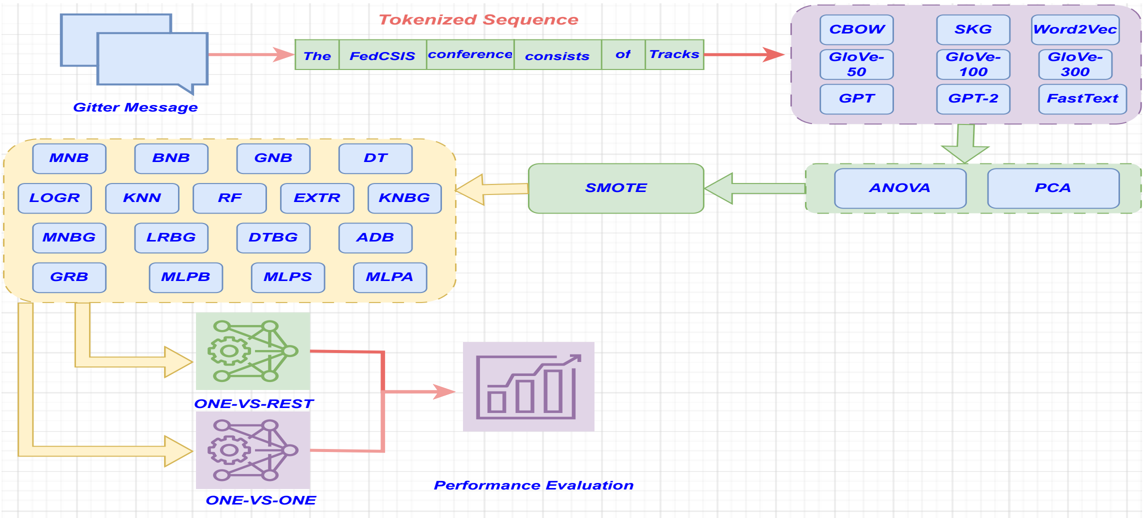

Fig. 1: Framework of proposed work

proposed framework is a multi-step process involving feature extraction from text data using word embedding techniques, removal of irrelevant features, handling class imbalance using SMOTE and development of prediction model using seventeen classification algorithms implemented using two multi-class classification strategies. First, the messages in the GitterCom dataset is pre-processed by removing unnecessary characters and stopwords. Then as shown in Figure 1, these messages are tokenized and nine different word embedding techniques are applied to find the numeric vector representations of these messages. Then the feature selection techniques of One-Way ANOVA and PCA are employed to discard the non-influential features of the numeric data. The next step involves applying the SMOTE technique to handle the presence of class imbalance in the dataset.Then, the prediction models are developed using seventeen classification algorithms, implemented using two multi-class classification strategies – One vs One and One vs Rest. The performance of the models developed using these two strategies is then evaluated using various evaluation metrics.

V. Empirical Results and Analysis

In this work, we applied nine different word embedding techniques, two feature selection techniques, one class balancing technique, and thirty-four different classifiers to analyze and classify the purpose of the messages posted on the Gitter platform. Thus, a total of 1836 [1 dataset * 9 word-embedding techniques * (2 sets generated using feature selection techniques + 1 set of original data) * (1 set generated using a class balancing technique + 1 original dataset) * 34 classifiers] distinct predictive models were built. The predictive ability of the developed models was evaluated using the Accuracy, Sensitivity, Specificity, and Geometric Mean (G-Mean) metrics. These models were validated using the 5-fold cross-validation method.

Accuracy is the most commonly used metric for evaluating the performance of a classifier. It is a measure of the proportion of the correctly classified instances out of the total number of available instances. While it is a useful metric, it can give misleading results in the presence of a class imbalance in the data. Hence, we also incorporate the Sensitivity and Specificity metrics to deal with this issue. While sensitivity is the measure of the proportion of the actual positive cases correctly identified by the classifier, Specificity is the measure of the proportion of the actual negative cases correctly identified by the classifier. Although these two metrics give better predictions than Accuracy in the presence of imbalanced data, there are some instances where these metrics fail, such as when the classifier always predicts the majority class; the models would get high sensitivity but low Specificity. To deal with such cases, we also consider the Geometric Mean metric, which is the geometric mean of both Sensitivity and Specificity.

Tables I and II report the accuracies obtained for the various models developed by applying different classifiers to original data and sampled data on different sets of features. By analyzing the information in the table, the following inferences can be derived that the model with the highest accuracy is obtained by applying the Random Forest Classifier using the One vs Rest classification strategy on the data obtained from the Word2Vec word embedding technique and employing the SMOTE technique to address the class imbalance problem. Similarly, Table I reports the Geometric Mean (G-Mean) values obtained for the various models developed by applying different classifiers to original data and sampled data on different sets of features. By analyzing the information in the table, the following inferences can be derived that the model with the highest accuracy is obtained by applying the Random Forest Classifier using the One vs Rest classification strategy on the data obtained from the Word2Vec word embedding technique and employing the SMOTE technique to address the class

imbalance problem. This model gives the highest classification accuracy, sensitivity, and specificity, as mentioned in Table II.

A. COMPARATIVE ANALYSIS

In this section, we examine and compare the efficacy of the models created through a diverse set of word-embedding

TABLE II: Sensitivity and Specificity

techniques, classification algorithms, feature selection, and data sampling techniques. To evaluate the models devised for classifying the purpose of the messages in Gitter communications, we have employed evaluation metrics for statistical analysis, box plots for visual representation, and the Friedman test to identify the significant differences among the models.

The Friedman test is a non-parametric test used to determine if there is a significant difference in the average ranks of multiple related samples. In our research, this test was used to test the validity of the following hypothesis:

- **Null Hypothesis** - *The predictive abilities of the models developed using the combination of various word-embedding techniques, classifiers, feature selection, and data sampling techniques are similar.*
- **Alternate Hypothesis** - *The models' predictive abilities developed using various word-embedding techniques, classifiers, feature selection, and data sampling techniques significantly differ.*

B. Word-Embedding Techniques

The text messages present in the dataset were converted to a numeric vector representation to develop classification models. The nine-word embedding techniques employed for this purpose are Continuous Bag of Words (CBOW), Skip-Gram (SKG), Global Vectors for Word Representation (GloVe) with 50 dimensions (GLOVE50), 100 dimensions (GLOVE100), and 300 dimensions (GLOVE300), Word2Vec (W2V), fastText (FST), Generative Pre-trained Transformer (GPT), and Generative Pre-trained Transformer-2 (GPT2).

Comparison of Word-embedding techniques using Box Plots: Figure 2 provides a graphic representation of the values of the evaluation metrics - Accuracy, Sensitivity, Specificity, and G-Mean of different word embedding techniques applied in the form of Box-plots. While we can observe that the average G-Mean is highest for models based on the GPT-2 word-embedding technique with a value of 0.54, followed by GPT with 0.49, the highest maximum G-Mean is for the models developing using Word2Vec word embeddings with a value of 0.9978, followed by GloVe 300d with a value of 0.9972. The Q3 G-Mean is highest for models with GPT-2, followed by GloVe 300d. Comparing the accuracies of the models provides more stable results as models built using Word2Vec and GloVe 300d emerge as the best-performing models in terms of maximum, Q3, and median accuracy values, while models using GPT and GPT-2 lag behind in this analysis. Since the box plots for the G-Mean values don't paint a clear picture, we rely on the Friedman Rank Test to draw inferences.

Comparison of Word-embedding techniques using the Friedman Test:
The study also employs the Friedman test to evaluate the performance of the models developed using various word embedding techniques. This test aims to test the validity of the null hypothesis, which states that "the different word embedding techniques do not significantly impact the performance of the classification models developed." The test was carried out at a significance level of 0.05 and with nine degrees of freedom. Table III displays the Friedman mean ranks of the G-Mean metric obtained for the various word-embedding algorithms. A lower mean rank indicates a better-performing technique. GloVe 300d has the lowest mean rank of 3.77, followed by Word2Vec, which has a mean rank of 4.05. CBoW has the highest mean rank of 6.2, followed by GPT, which has a mean rank of 6.01. From these observations, it can be inferred that models developed using GloVe and Word2Vec have the highest predictive ability, while the models that use CBoW or GPT suffer the most. Another inference that can be drawn is that models developed with word embeddings with generic pre-trained vectors perform superior for the Gitter-Com dataset compared to those developed with other word-embedding techniques, even those that are domain-specific to software systems.

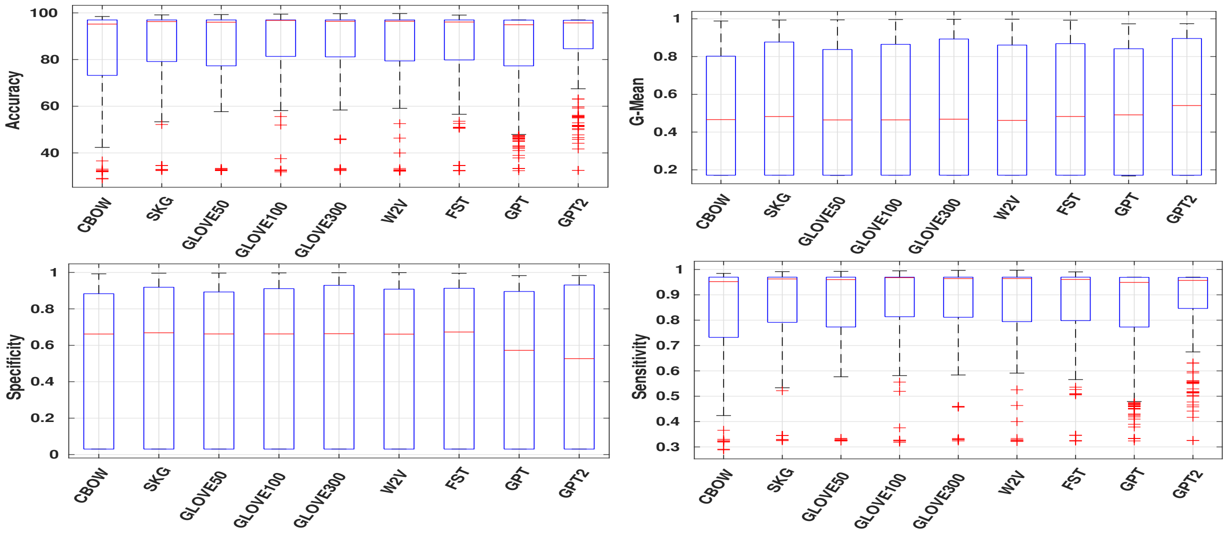

Fig. 2: Performance of Nine Word Embedding

TABLE III: Friedman: Nine Word Embedding

	Accuracy	G-Mean	Specificity	Sensitivity
CBOW	6.11	6.2	6.06	6.11
SKG	4.72	4.25	4.25	4.72
GLOVE50	5.22	5.6	5.63	5.22
GLOVE100	4.57	4.96	4.98	4.57
GLOVE300	3.89	3.77	3.83	3.89
W2V	3.74	4.05	4.12	3.74
FST	5.31	4.71	4.65	5.31
GPT	6.04	6.01	6.01	6.04
GPT2	5.39	5.45	5.47	5.39

C. Feature Selection Techniques

In this work, we have employed two different feature selection techniques - the One-way analysis of variance test and Principal Component Analysis. These techniques were applied to reduce the complexity of the models by retaining or generating the relevant features and discarding the rest. This gave us three different sets of features to compare, the original feature set and the feature seats generated using the feature selection techniques.

Comparison of the Different Sets of Features using Box Plots:

Figure 3 provides a graphic representation of the values of the evaluation metrics - Accuracy, Sensitivity, Specificity, and G-Mean of the models trained using selected sets of features and all features in the form of Box-plots. From the figure, we can draw the inference that the models developed by considering all the features have a marginally better predictive ability for the GitterCom dataset. The average G-Mean of the models developed using the original data is 0.483, with a maximum G-Mean of 0.998 and a Q3 G-Mean of 0.879. The mean G-Mean of the models that use the ANOVA test (0.471) and PCA (0.461) is also quite close to the mean G-Mean of the original data, with ANOVA performing better than PCA for the GitterCom dataset. This is also backed up by the box-plots of accuracies of the models where the models built with all the features slightly out-performs the ANOVA test-based models, which in turn perform much better than models built by considering PCA.

Comparison of the Different Sets of Features using the Friedman Test:

This study also considers the Friedman test to compare the performance of the models using the set of all features or the sets of features generated by the feature selection techniques. This test aims to test the validity of the null hypothesis, which states that "there is no significant difference in the performance of models trained on the data with different sets of features." Table IV displays the Friedman mean ranks of the G-Mean metric obtained for models trained on the original and selected set of features. The models trained using the original feature set have the lowest mean rank of 1.76. The models trained using the feature set generated from the One-way ANOVA test have a slightly higher mean rank of 1.87, and the models trained using PCA have the highest mean rank of 2.37. This analysis indicates that introducing feature selection techniques depreciates the model's performance and that the model works best with all the original features. However, the One-Way ANOVA test models only perform slightly worse than the models with all the features since the mean G-Mean and the mean Friedman ranks are quite close. Hence, if certain word-embedding techniques generate a large number of features for the GitterCom dataset, the One-Way ANOVA test can be considered for feature selection.

TABLE IV: Friedman: Feature Selection Techniques

	Accuracy	G-Mean	Specificity	Sensitivity
AFV	1.86	1.76	1.75	1.86
ANOVA	1.94	1.87	1.88	1.94
PCA	2.2	2.37	2.37	2.2

D. Class Balancing Technique

The Synthetic Minority Oversampling Technique (SMOTE) was used to rectify the class imbalance problem of the dataset, as this technique synthesized data points for the minority classes of the “personal benefits” and “community support” classes.

Comparison of original data and SMOTE synthesized data using Box Plots:

Figure 4 provides a graphic representation of the values of the evaluation metrics - Accuracy, Sensitivity, Specificity, and G-Mean in the form of Box-plots for the models developed using original data and the balanced data obtained from the SMOTE technique. From the figure, we can draw the inference that the models developed by applying the SMOTE technique have a much better predictive ability for the GitterCom dataset compared to the models relying on the original data. The average G-Mean of the models developed using SMOTE is 0.857, with a maximum G-Mean of 0.998 and a Q3 G-Mean of 0.956, which indicates that 25% of the models created using SMOTE have a G-Mean greater than 0.956. Since the

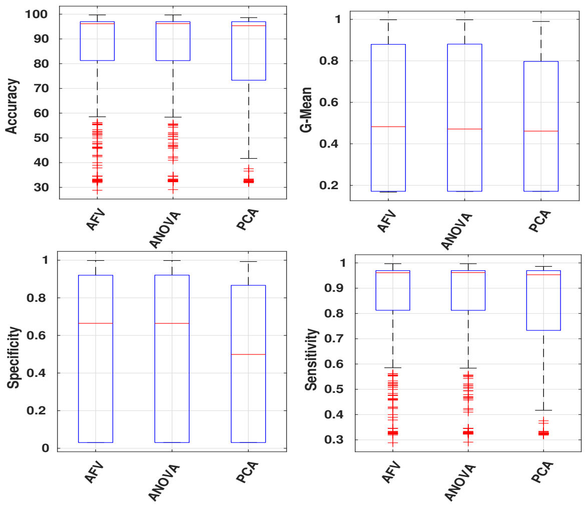

Fig. 3: Performance of Feature Selection Techniques

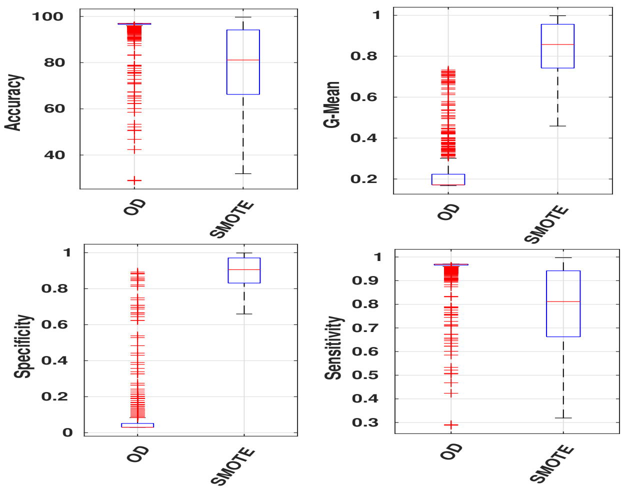

Fig. 4: Performance Class Balancing Technique

original data is highly class-imbalanced, accuracy is not a reliable metric for this analysis since it projects the models with original data to perform better than models with the SMOTE synthesized data.

Comparison of original data and SMOTE synthesized data using the Friedman Test:
This study also employs the Friedman test to compare the performance of the models developed using the original imbalanced dataset and the SMOTE-synthesized dataset. This test aims to test the validity of the null hypothesis, which states that "there is no significant difference in the performance of models trained with dataset having balanced or imbalanced classes, and the algorithm used to balance classes has no significant impact on their performance." Table V displays the Friedman mean ranks of the G-Mean metric obtained for models trained on the original and the SMOTE-balanced dataset. While the latter models have a mean rank of 1, the former models have a mean rank of 2. This is in accordance with the inference obtained from the box plots, thus declaring the use of the SMOTE data sampling technique to improve the performance of the models trained on the GitterCom dataset. The mean ranks of Accuracy provide a different picture where the models trained using the original data have a mean rank of 1.2 which is lower than the mean rank of the models trained using the SMOTE balanced dataset (1.8). This shows the unreliability of the accuracy metric in the presence of class-imbalanced data, thus establishing the G-Mean as the dependable metric in such circumstances.

TABLE V: Friedman: Class Balancing Technique

	Accuracy	G-Mean	Specificity	Sensitivity
OD	1.2	2	1.99	1.2
SMOTE	1.8	1	1.01	1.8

E. Classification Techniques

In this work, we have used seventeen different classification algorithms such as Multinomial Naive Bayes (MNB), Bernoulli's Naive Bayes (BNB), Gaussian Naive Bayes (GNB), Decision Tree (DTC), Logistic Regression (LRC), K-Nearest Neighbours (KNN), KNN with Bagging (KNBG), Multinomial Naive Bayes with Bagging (MNBG), Logistic Regression with Bagging (LRBG), Decision Trees with Bagging (DTBG), Random Forest (RF), Extra Trees (EXTC), Ada Boost (DBG), Gradient Boosting (GRB), Multi-Layer Perceptron with Limited-Memory BFGS (MLPB), SGD (MLPS) and ADAM (MLPA).

Comparison of Classification Techniques using Box Plots:
Figure 5 provides a graphic representation of the values of the evaluation metrics - Accuracy, Sensitivity, Specificity, and G-Mean of different classification algorithms applied in the form of Box-plots. From the figure, we can observe that while tree-based classifiers generally perform better than the rest, the Naive Bayes-based classifiers lag behind in their performance. Random Forest and Extra Trees Classifiers have the highest maximum and Q3 G-Mean values, while Bernoulli and Multinomial Naive Bayes classifiers have the least values. The median G-Mean values paint a slightly different picture as Gaussian Naive Bayes has the highest value, followed by the Decision Tree classifier. The accuracy box plots suggest that Random Forest and Extra Trees classifiers are best performing, followed by Decision Trees with Bagging, while Gaussian Naive Bayes lags behind. Since we can't zero in on the best-performing classifier using the Box Plots, we rely on the Friedman Rank test.

Comparison of Classification techniques using the Friedman Test:
The study also employs the Friedman test to evaluate the performance of the models developed using various classification algorithms. This test aims to test the validity of the null hypothesis, which states that "the choice of the classification algorithms does not significantly impact the performance of the classification models developed." The test was carried out at a significance level of 0.05 and with seventeen degrees of freedom. Table VI displays the Friedman mean ranks of the G-Mean metric obtained for the various classification algorithms. A lower mean rank indicates a better-performing algorithm. We can observe that the Decision Tree classifier has the lowest mean rank of 4.53 among all classifiers, followed by the Extra Trees Classifier at 4.81 and the Random Forest Classifier at 5.46. Bernoulli's Naive Bayes Classifier has the highest rank of 14.13, followed by the Multinomial Naive Bayes classifier with Bagging, with a mean rank of 12.09. Thus, we can infer that the Decision Tree Classifier is the best-performing classification algorithm for the GitterCom dataset, followed by Extra Trees and Random Forest Classifiers, while Bernoulli's Naive Bayes classifier performs the worst for the dataset.

F. One-vs-One and One-vs-rest multi-class classification:

The above-mentioned classification algorithms were implemented using one-vs-one and one-vs-rest multi-class classifi-

TABLE VI: Friedman: Class Balancing Technique

	Accuracy	G-Mean	Specificity	Sensitivity
MNB	10.95	11.3	11.3	10.95
BNB	13.73	14.13	14.13	13.73
GNB	14.52	6.69	6.69	14.52
DTC	10.36	4.53	4.53	10.36
LRC	7.18	10.16	10.16	7.18
KNN	8.6	9.79	9.79	8.6
KNBG	6.23	9.25	9.25	6.23
MNBG	10.45	12.09	12.09	10.45
LRBG	7.87	10.89	10.89	7.87
DTBG	5.85	8.04	8.04	5.85
RF	5.75	5.46	5.46	5.75
EXTC	5.54	4.81	4.81	5.54
ADB	10.34	9.54	9.53	10.34
GRB	11.26	7.45	7.45	11.26
MLPB	10.19	8.95	8.95	10.19
MLPS	6.61	9.63	9.63	6.61
MLPA	7.57	10.31	10.31	7.57

cation strategies, thus generating thirty-four different classifiers for this analysis.

Comparison of the two classification strategies using Box Plots:

Figure 6 provides a graphic representation of the values of the evaluation metrics - Accuracy, Sensitivity, Specificity, and G-Mean of the two classification strategies applied in the form of Box-plots. From these figures, we can observe that the One-vs-Rest slightly out-performs the one-vs-one strategy as the models developed using the former have a maximum G-Mean of 0.9977 and a Q3 value of 0.86 as compared to its counterpart's values of 0.9974 and 0.85. The accuracy box plot also gives similar results as one-vs-rest has slightly higher maximum and median accuracies as compared to models using one-vs-one classification.

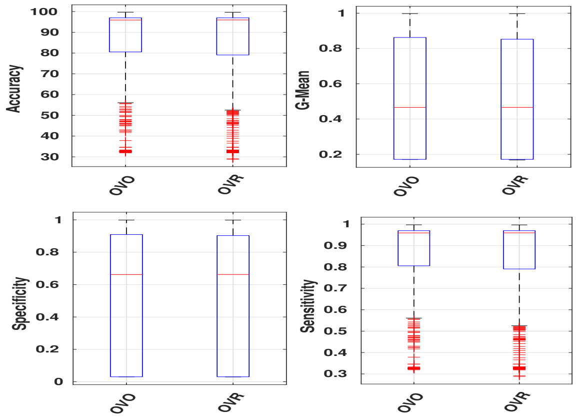

Fig. 6: Performance One-vs-One and One-vs-rest multi-class classification

Comparison of Classification strategies using the Friedman Test:

The study also employs the Friedman test to evaluate the performance of the models developed using the two classification strategies. This test aims to test the validity of the null

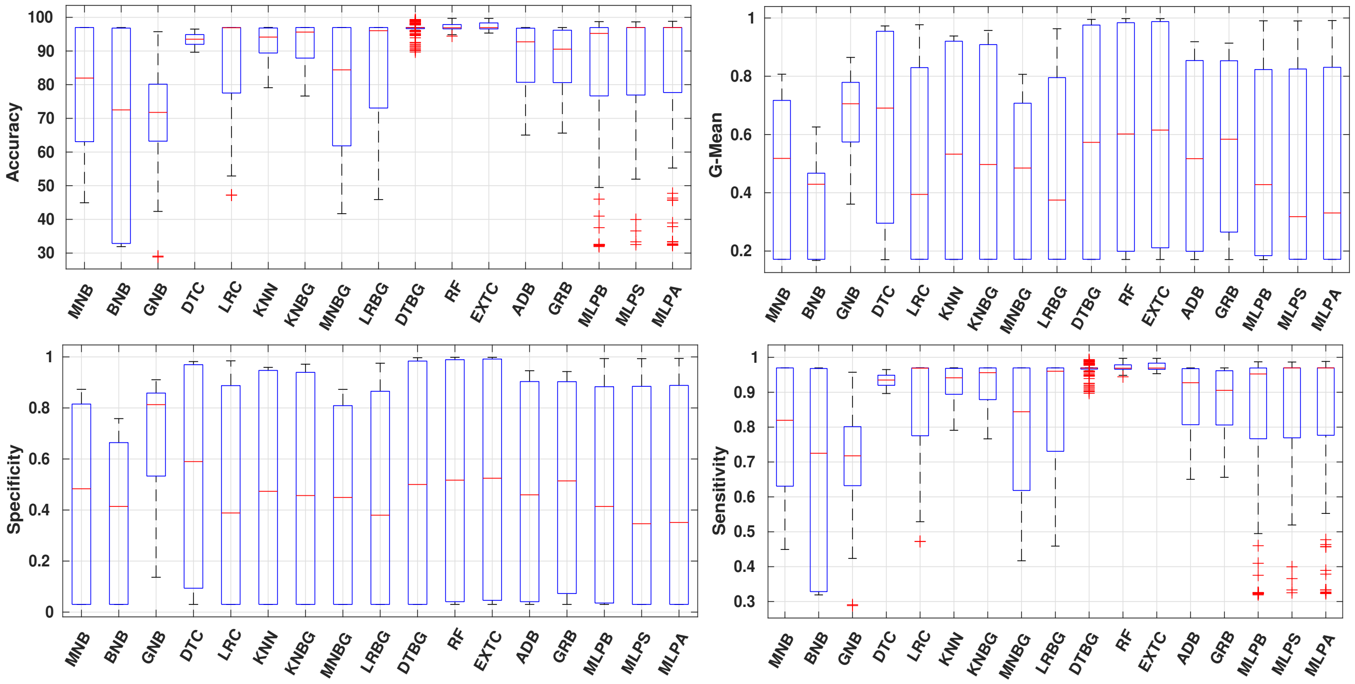

Fig. 5: Performance Classification Techniques

hypothesis, which states that "the choice of the classification strategy does not significantly impact the performance of the classification models developed." The test was carried out at a significance level of 0.05 and with two degrees of freedom. Table VII displays the Friedman mean ranks of the G-Mean metric obtained for the various classification algorithms. We can observe that the models using one-vs-one classification have a slightly lower Friedman mean Rank of 1.47 as compared to the one-vs-rest models' rank of 1.53. This trend is also followed by the mean ranks of accuracies of the two strategies. Thus, the Friedman Rank test concludes that the one-vs-one classification is slightly better than the one-vs-rest classification.

TABLE VII: Friedman: One-vs-One and One-vs-rest

	Accuracy	G-Mean	Specificity	Sensitivity
OVO	1.49	1.47	1.48	1.49
OVR	1.51	1.53	1.52	1.51

VI. CONCLUSION

Analyzing and classifying the purpose of the messages on software messaging and collaboration platforms such as Gitter provides various benefits, such as analyzing the present open-source development trends and understanding why developers prefer such platforms. Automated message classification can save time and labor and reduce misclassification errors. This paper aims to improve the classification accuracy of the purpose of the messages in the GitterCom dataset by finding the right combination of ML and NLP techniques for the best performance. Various word-embedding techniques, feature selection techniques, classification algorithms, and a data sampling technique were employed in this work. The comparative analysis helps analyze each technique's merits and demerits for analysis of the GitterCom dataset. The key conclusion obtained in this work are:

- Models trained using GloVe 300d and Word2Vec perform superior to models trained with other word-embedding techniques, even the ones that are domain-specific to software systems.
- The application of feature selection techniques slightly degrades the performance of the classifier models. However, the ANOVA test is still a viable alternative in case the computational complexity of the models needs to be improved.
- The class-balancing technique (SMOTE) improved the performance of the models by addressing the class imbalance problem.
- The tree-based classification algorithms outperformed others as the Decision Trees classifier emerged as the best, followed by Random Forest and Extra Trees classifiers.
- The one-vs-one multi-class classification strategy performed better than the one-vs-rest classification for the GitterCom dataset message purpose classification.

While our research focuses on the purpose of the messages, future research could look into insights that can be drawn from messages of each type of purpose. The team-wide purpose messages can be used to analyze collaboration patterns and geographical trends influencing the development projects. Similarly, the personal benefit messages can be used to analyze the commonly faced issues and the extent of help being provided to these users on the platform. Topics of discussion can be analyzed to identify the latest trends and popular technologies in software development. These insights help update the platforms to suit the needs of the developers better, attracting more users and promoting collaboration. Developing such models also helps users understand these trends, which they can incorporate into their own development practices, making them more efficient. Future research to draw insights from the data of such developer communication platforms can be made easier by adapting the techniques and pipelines shown to be more effective and hence recommended by the paper.

***Abstract*—Over the past few years, notable advancements have been made through the adoption of self-attention mechanisms and perceptual optimization, which have proven to be successful techniques in enhancing the overall quality of image reconstruction. Self-attention mechanisms in Vision Transformers have been widely used in neural networks to capture long-range dependencies in image data, while perceptual optimization has been shown to enhance the perceptual quality of reconstructed images. In this paper, we present a novel approach to image reconstruction by bridging the capabilities of Vision Transformer and Perceptual Compressive Sensing Networks. Specifically, we use a self-attention mechanism to capture the global context of the image and guide the sampling process, while optimizing the perceptual quality of the sampled image using a pre-trained perceptual loss function. Our experiments demonstrate that our proposed approach outperforms existing state-of-the-art methods in terms of reconstruction quality and achieves visually pleasing results. Overall, our work contributes to the development of efficient and effective techniques for image sampling and reconstruction, which have potential applications in a wide range of domains, including medical imaging and video processing.**

I. Introduction

COMPRESSIVE Sensing (CS) is an important technique in the field of signal processing and computer vision. CS is a technique for acquiring and processing signals at a lower rate than required by the Nyquist-Shannon sampling theorem. CS is used for image reconstruction, by reconstructing a high-quality image from a set of low-quality or incomplete observations. It has emerged as an alternative to traditional image compression techniques. The potential of CS and image reconstruction in computer vision lies in their ability to enable high-quality imaging and data acquisition with minimal resources. Indeed, CS can be used to reduce the amount of data required to capture an image, making it possible to store or transmit images more efficiently. It can also be used to reduce the amount of data required for image processing, enabling real-time processing of large datasets. Most CS approaches are CNN-based models, which represent a limitation by the receptive field of the convolution kernels and their non-ability to handle long-term dependencies.

Deep learning models have shown impressive success in various computer vision tasks, but they are not always efficient at processing large and complex images. One possible solution to this problem is to incorporate visual attention mechanisms into deep learning models, inspired by the way humans selectively process relevant information and filter out distractions. Attention mechanisms allow deep learning models to focus on important regions of an image and suppress irrelevant information, leading to improved accuracy and efficiency.

In addition to visual attention, which is a selective process that allows us to focus on important information in the environment while ignoring distractions, we can also find visual perception, which refers to the process of interpreting and making sense of visual information from the environment. This process involves multiple stages of processing, where the basic features of a stimulus (e.g., color, shape, motion) are detected and encoded then integrated into meaningful objects and scenes. Overall, visual attention and visual perception are both important processes in visual recognition. Visual attention allows us to selectively focus on important information in the environment, while visual perception allows us to interpret and make sense of visual information. These processes are intricately linked and work together to support our visual experiences.

In this paper, we propose a novel CS approach for image sampling and reconstruction. Our proposed model combines self-attention and perceptual information to selectively attend to different regions of an image at multiple levels of abstraction. We evaluate the effectiveness of our proposed model using experiments on benchmark datasets and demonstrate that it outperforms existing models in terms of reconstruction quality.

Hence, the main contributions of this paper are :

- We propose a framework based on a hybrid architecture that combines the self-attention mechanism provided by vision transformers for image long-range dependencies and global context modeling with the advantages of convolutional neural networks for optimal local feature extraction.
- We propose to add a transformer-based coding path, so the model coding is done in two paths, a CNN-based CSNet sampling path, and a transformer path. These two paths are linked by a fusion layer to merge the features and produce the vector that presents the input image.
- We use a perceptual optimization in the training process, to semantically guide the model to learn long-range

and local high-frequency details of visual and contextual features.

- Finally, we run extensive experiments to evaluate our approach in term of reconstruction quality and compare it to state-of-the-art methods on different image compression benchmarks.

The remainder of this paper is organized as follows. In section II, we present and discuss previous works on image-based CS reconstruction. In section III, we explain the proposed approach. In section IV, experimental results and comparisons with State-Of-The-Art (SOTA) methods are carried out. Finally, in section V, we summarize our findings and present some opportunities for future works.

II. Related Work

In this section, we present a CS image reconstruction literature review. We first discuss the existing deep learning-based CS methods. Then we review the recent development of vision transformers for image reconstruction.

A. Deep learning-based CS approaches

Compressing Sensing theory was first proposed in 2004 by David Donoho [1]. Deep learning-based CS approaches have been proposed to solve the CS reconstruction problem through the extraction (learning) of significant features from the input signal itself. Several reconstruction algorithms based on CNNs have been proposed to overcome the complexity of traditional methods. At the outset, Kulkarni et al. [2] developed a non-iterative reconstruction model using CNN (ReconNet). Based on iterative thresholding algorithms, Zhang et al. [3] proposed the convolutional ISTA-Net model for image recovery. Afterward, Shi et al. proposed a Scalable Convolutional Neural Network (SCSNet), and right after proposed a sampling reconstruction framework called CSNet [4], which replaces the sampling model with a convolutional layer. However, these methods have limitations due to their random sampling. To address this problem, Siwang Zhou et al. in [5] have proposed a Block-Based Image Compressive Sensing (BCS-Net), which uses block correlation for sampling. Nevertheless, the model training overlooked the semantic information of the image to draw the prior knowledge. Hence, in order to improve the reconstruction quality by considering the prior knowledge, Wenxue Cui et al. [6] have proposed a non-local CSNet (NL-CSNet) based on non-local self-similarity priors.

However, all the previous methods did not consider perceptual information, which is important for visual and semantic content reconstruction of the images. Recently, in [7], Bairi et al. proposed a perceptual-optimized CS framework that uses perceptual information for image reconstruction. The model is based on an auto-encoder, which is trained using perceptual optimization. Despite its power in the reconstruction of semantic information, this model still lacks high-frequency feature extraction.

B. Transformer-based image reconstruction

The first transformer was proposed by Vaswani et al. [8] for Natural Language Processing (NLP) tasks. In the latter, the long-range dependencies were given by multi-headed self-attention and feed-forward Multi Layer Perceptron (MLP) block. Among the best-known models dealing with this type of task are BERT [9] and GPT [10]. Based on the transformer force in NLP, transformers were recently integrated into the context of image processing. For classification tasks, the innovative work of Vision Transformer (ViT) [11] divides an image into 16 by 16 patches, to use the previous multi-headed self-attention and feed-forward MLP to build a classifier. In addition to the original ViT, transformer models, with different versions and architectures were proposed for several computer vision tasks namely for classification [12], [13], [14], [15], [16], [17], [8], for object detection [18], [19]and for image segmentation tasks [20], [21], [22].

Few works have investigated transformers for image reconstruction. Indeed, this task produces images as a final output, which is more difficult than high-level vision tasks such as classification, segmentation, and object detection, whose outputs are labels or areas. For transformer-based image reconstruction, Hanting et al. [23] proposed a pre-trained model called IPT that can be used for computer image reconstruction tasks. This approach suffers from the large number of parameters and image features are still extracted from CNN. A concurrent work [24] proposed a U-shaped transformer for image reconstruction, which is built upon the UNet architecture and based on the Swin's transformer block. However, these models, based solely on pure transformers, overlook local feature identification and low-frequency information. To preserve the advantages of both CNN-based networks for the local description and the transformer for long-range dependencies handling, Liang et al. [25] proposed a SwinIR model for the restoration of compressed or noisy images based on both Swin transformer blocks and CNNs which were designed for image classification in [15], this model showed better results than those obtained by IPT. Similarly, a transformer-based image reconstruction (TIC) method is developed in [26]. The latter uses a canonical architecture of the VAE variational autoencoder in the form of convolutional layers and Swin transform blocks to capture long and short-term dependencies of the input image. Test results on the Kodark dataset show the good performance of this approach. Dongjie et al. [27] extend the technique of self-attention in compressed sensing to overcome the limitations of convolution layers in modeling global features, by a CSformer model that combines the advantages of CNNs and transformers. The model contains a sampling module as a convolution layer and a reconstruction module in the form of two branches that integrate local and global-range dependencies. Nevertheless, these architectures need the integration of perceptual information, which helps the reconstruction of semantic details of the image.

III. Proposed approach

In this section, we present the proposed PCST-Net framework by using self-attention through vision transformer for better feature extraction and visual perception to make sense of these features. Fig.1 illustrates the proposed approach architecture. Indeed, it is based on CS sampling/reconstruction autoencoder which adopts an attention mechanism to capture long-range contextual information. The learning process is guided by the image's visual content information. The proposed approach involves two neural networks, an encoder, and a decoder. The encoder network compresses the input images by projecting them into a lower-dimensional space, while the decoder network restores the original image representation from the compressed representation. The network is trained in an end-to-end manner to minimize image reconstruction error, allowing it to find the optimal parameters that enable sampling and reconstruction for any input image.

A. Sampling network

The Sampling network (Encoder) is a combination of CNN and transformer models to take advantage of the spatial locality and self-attention mechanisms. The CNN model is inspired by PSCS-Net[7] and is laid out as three Convolution/MaxPooling blocks. In the original CS framework, encoded data are the result of sampling the input image. The latter are called encoded data as they correspond to the rows of the sampled image. In the context of deep learning, the encoded data is arranged rather like an ordinary 3D tensor like any CNN feature map. Theoretically, they still correspond to CS sampled vectors, just stacked in a 3D tensor. When we apply the sampling operator S_{CNN} on the input image x, we obtain y_1, which corresponds to the encoded data obtained by the CNN sampling Network.

$$S_{CNN}(x) = W_s^1 * x \tag{1}$$

In Eq.1, the network operates on 2D image patches with the convolution operator $(*)$ with the sampling Matrix W_s^1. Such an operation projects an input image $x \in R^{d_x}$ onto one of the encoded vectors $y_1 \in R^{d_y}$. The sampling matrix W_s^1 is a composition of convolutions and nonlinear activation functions f that allows for better features extraction. The obtained result y_1 can be written as:

$$y_1 = S_{CNN}(x) = f(W_3 * f(W_2 * f(W_1 * x + b_1) + b_2) + b_3) \tag{2}$$

Transformer-based encoder aims to capture long-range visual dependencies through the self-attention mechanism. It is composed of a projection layer and a transformer block which is the architecture of the ViT backbone [11]. An image projection is a lower-dimensional representation of the image. In other words, it is a dense vector representation of the image. First, the image is divided into P × P non-overlapping patches, then this feature projection layer projects the input patches having a size of (P x P x C) into a dimension of (1 x Pd) such that Pd is the projection dimension. The self-attention mechanism is an integral component of a transformer, which explicitly models the interactions between all entities in a sequence. For an input sequence of Np elements, self-attention captures the interaction between all Np entities and encodes each entity in terms of global contextual information. For this fair, three weight learning matrices are defined, *Queries* ($W^Q \in \mathbb{R}^{Pd*q}$), *Keys* ($W^K \in \mathbb{R}^{Pd*k}$), and *Values* ($W^V \in \mathbb{R}^{Pd*v}$). The input sequence X is projected onto these weight matrices to obtain:

$$\begin{aligned} Q &= XW^Q \\ K &= XW^k \\ V &= XW^V \end{aligned} \tag{3}$$

Self-attention is formulated by:

$$A = softmax(\frac{QK^T}{\sqrt{q}})V \tag{4}$$

Fig.2 shows the transformer block architecture which consists of two LN normalization layers, a multi-headed self-attention layer MSA and a MLP made up of two fully connected layers, the τ norm is inserted before MSA and MLP.

The multi-headed self-attention MSA comprises several blocks of self-attention, each block has its own set of learnable weight matrices *Query*, *key*, and *Value*. Multi-headed self-attention runs h times in parallel, such that h is the number of heads, then concatenated into a single matrix. This block takes a series of sequences I patches of size (Np x Pd) as input and globally calculates the self-attention between them. The whole process of this block can be formulated as follows:

$$\begin{aligned} F_t &= MSA(\tau(I)) + I \\ y_2 = S_{ViT}(x) &= MLP(\tau(F_t)) + F_t \end{aligned} \tag{5}$$

The transformer path is composed of four transformer blocks. Feature fusion aims to extract the most discriminating information and eliminate redundant information. The fusion function combines the global features of the transformer and the local features of the CNN by a fusion strategy, such as addition or average. The fusion of y_1 and y_2 is given by Eq.6.

$$y = Fusion(y_1, y_2) \tag{6}$$

Since the stems of the transformer and the CNN have different dimensions, we need to modify the characteristics of the transformer to match those of the CNN.

B. Reconstruction Network

The upsampling network (Decoder) is designed in [7] as a three-block de-convolutional network to learn the inverse convolution filters to reconstruct images. The decoder returns y to the input space by obtaining the feature representation in the image recovery process. The decoder represents a nonlinear mapping that is learned from measurements y to its original image x by training. The decoder is symmetric with the CNN sampling network and consists of three layers: the input layer and two hidden layers. The decoder function (Eq. 7) is used to

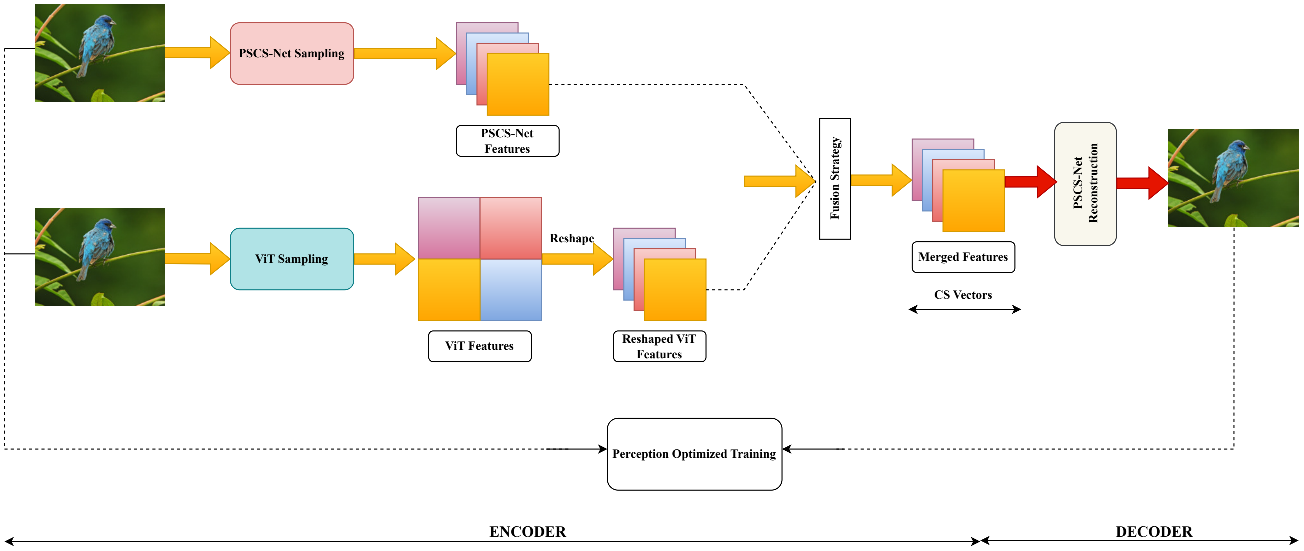

Fig. 1: Overview of the proposed image reconstruction-based framework: the model is trained using the combination of visual perception and self-attention.

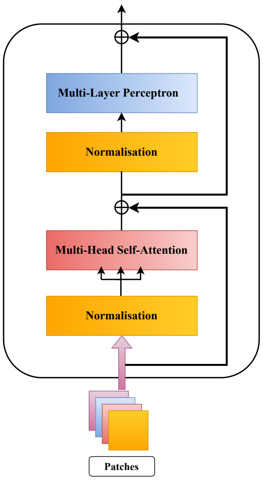

Fig. 2: Architecture of a transformer block

recover the reconstruction images $\widetilde{x}$ from measurement vector y.

$$\widetilde{x} = R(y) = f(W_6 * f(W_5 * f(W_4 * y + b_4) + b_5) + b_6) \quad (7)$$

C. Training of PCST-Net

To semantically guide our model to learn visual and contextual features, we use perceptual loss optimization in the training process as shown in [7]. The used perceptual loss measures the distance between images in high-level feature space using a pre-trained compressing sensing network [4] (CSNet). This model is originally trained on ImageNet dataset. The PCST-Net network is trained in an end-to-end fashion through the minimization of the global loss term expressed as:

$$\mathscr{L}_{total}(x, \widetilde{x}) = \alpha_1 L_p(x, \widetilde{x}) + \alpha_2 L_2(x, \widetilde{x}) + \alpha_3 L_s(W, b) \quad (8)$$

With : L_p in Eq.9 is the perceptual loss, L_s in Eq.10 is the sparsity loss, and L_2 in Eq.11 is the L_2 Norm between the original and reconstruted image. The three terms are weighted by α_1, α_2, and α_3, respectively.

$$L_p(x, \widetilde{x}) = MSE(\phi(x) - \phi(\widetilde{x})) \quad (9)$$

Where ϕ is the sampling operator of CSNet to compute the difference between the feature vector of the input image x and the predicted image $\widetilde{x}$.

$$\mathrm{L}_s(W_s^1, b) = 1/2\beta_1 \sum ||W_s^1||^2 + \beta_2 \sum_{j=1} KL(\rho||\rho_j) \quad (10)$$

The first term of L_s in Eq.10 limits the weight parameters W with L_2 norm as to penalize large weight. The second term is the sparsity regularizer. β_1 is the penalty term and KL is the Kullback-Leibler divergence for penalizing active code units. β_2 is the intensity of the sparsity, ρ is the sparse factor, and ρ_j represents the mean value of activation of the j^{th} neuron in each batch of the training set.

$$L_2(x, \widetilde{x}) = \sqrt{\sum_{i=0}^{M-1} \sum_{j=0}^{N-1} (x(i,j) - \widetilde{x}(i,j))^2} \quad (11)$$

The L_2 Norm is used to profit from the qualities of pixel-wise loss functions.

The goal of training PCST-Net model is to minimize $\mathscr{L}_{total}$ as shown in Algorithm 1. First, parameters W_s^1, W^Q, W^K, and W^V are randomly initialized to serve the purpose of symmetry breaking. Then, encoded data y and the reconstruction images $\widetilde{x}$ are obtained through the encoder and decoder subnetworks, respectively.

Algorithm 1 PCST-Net training

```
Input:
Input original image $x$
Output:
Sampling Network weights $W_s^1$, $W^Q$, $W^K$, and $W^V$
Encoded data $y$
Reconstruction Network weights $W_r$
Instructions:

IV. Experiments and Results

In this section, we first introduce the dataset used for PCST-Net model training and the evaluation metrics. Second, we present the model settings for better training (Section IV-B). Next, in section IV-C, we conduct an experimental study on image compression benchmarks for model objective evaluation and compare the proposed approach with state-of-the-art methods. Finally, in Section IV-D, we evaluate the quality of PCST-Net image reconstruction with a subjective evaluation.

A. Datasets and evaluation metrics

PCST-Net is trained using a large-scale dataset which is COCO 2017 dataset [1]. 118k and 40k images have been used for training and validation respectively.

We evaluate our PCST-Net on different widely used benchmark datasets, such as Set5 [28], Set14 [29], and BSD100 [30].

To evaluate the model, two metrics are computed: Peak Signal to Noise Ratio (PSNR) and Structural Similarity (SSIM). PSNR measures image reconstruction quality, while SSIM, a perceptual metric, quantifies image degradation.

B. PCST-Net model settings and training

1) Model hyper-parameters selection: After an axial empirical study, the hyper-parameters of the model are set to 256 x 256 x 3, 8 x 8 x 3, and 8 x 8 x 3 for Image size, Patch size, and Block size, respectively. The perceptual loss function is optimized using the Adam optimizer with a batch size equal to 32 and a learning rate of 0.002 for 100 epochs.

2) Fusion strategy selection: Our method adopts an addition strategy to merge the features of different paths. To illustrate the effectiveness of this method, we construct a variant in which the features of the CNN and the transformer are averaged rather than summed.

Fig.3 shows the PSNR results of the two models on Set5, Set14, and BSD100. The feature addition fusion operation shows superior PSNR performance with different compression ratios. The feature averaging operation achieves a close performance when the compression ratios are lower than 10%, but above this compression ratio, the addition shows its efficiency against the average.

3) Path selection: **PCST-Net** is a **Dual Path** model that aims to combine the efficiency of convolution in extracting local features with the capability of the transformer in modeling global representations. To compare the advantages of the two branches-based approach, we created a **Single Path** model called **SPCST-Net**, which uses only the transformer path for compression. The results of the tests on three datasets (Set5, Set14, and BSD100) are presented in Fig.4.

Obtained results on Set5, Set14, and BSD100 datasets confirm that PCST-Net helps in recovering more details and semantic information of the images compared to PSCS-Net (based only on CNN) or SPCST-Net (based only on transformers).

C. Objective Evaluation

The results of the comparative study of PSNR and SSIM, between the different state-of-the-art reconstruction methods namely ISTA-Net+[3], CSNet+[4], NL-CSNet*[6], DPA-Net[31], CSFormer[27], PSCS-Net[7], and our PCST-Net, applied on the Set11, Set5, and BSD100 reconstruction datasets are shown in Table I-III, while varying the compression ratio between 0.1 and 0.5.

Our experimental results show that our approach achieves higher performance for image reconstruction compared to state-of-the-art algorithms.

TABLE I: Comparaison of PSNR(dB) and SSIM on Set5

Algorithm/Ratio	0.1	0.2	0.3	0.4	0.5
ISTA-Net+[3]	28.61 0.8315	33.12 0.9058	35.45 0.9408	36.94 0.9612	38.42 0.9804
CSNet+[4]	32.59 0.9062	36.05 0.9481	38.25 0.9644	40.11 0.9740	41.79 0.9803

D. *Subjective Evaluation*

In this section, we describe the subjective evaluation to visualize the quality of reconstructed images. This qualitative assessment is done with the naked eye by noting the differences between images at a ratio of 0.25. We also provide PSNR and SSIM values for each image to highlight quantitative differences.

The visualization obtained by PCST-Net in Fig.5 shows again that the use of both perception and self-attention gives the best result compared to other reconstruction methods. Obtained results suggest that the combination of self-attention and perceptual optimization can provide a powerful tool for improving the quality of image reconstruction. The use of self-attention mechanisms to capture long-range dependencies in the image data can lead to better sampling performance, while the incorporation of perceptual optimization can enhance the perceptual quality of the reconstructed images.

V. Conclusion

In this paper, we proposed a novel approach for image sampling and reconstruction that combines Vision Transformer and perceptual optimization techniques. Our approach leverages the power of self-attention to capture the global context of the image and guide the sampling process while optimizing the perceptual quality of the sampled image using a perceptual loss function. We have demonstrated the effectiveness of our proposed approach through experiments on several benchmark datasets, and we have shown that it outperforms existing state-of-the-art methods in terms of reconstruction quality

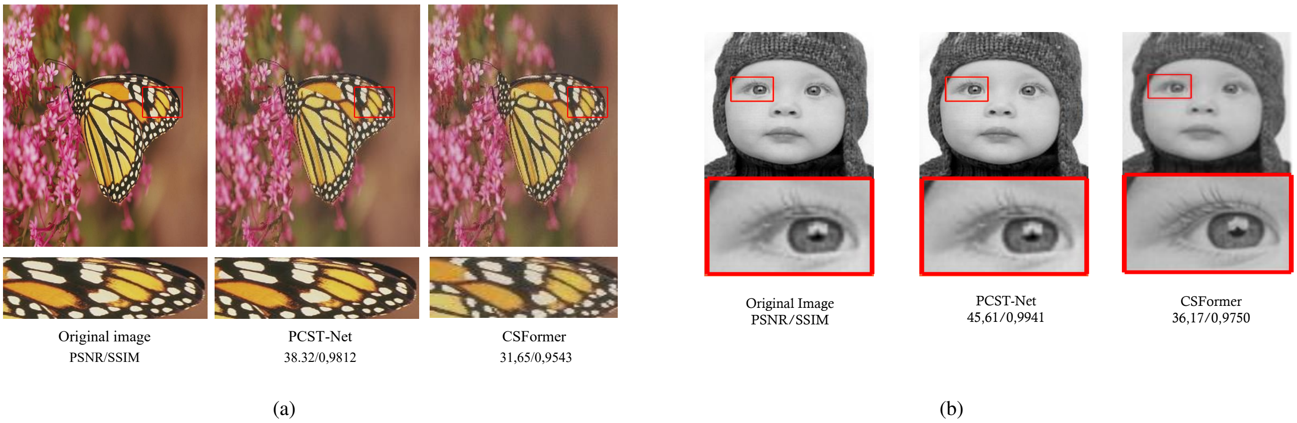

Fig. 5: Comparison of the visual quality of image reconstruction using a ratio of 0.2(a) and 0.4(b).

and visual fidelity. Our approach has potential applications in a wide range of domains, including medical imaging, video processing, and computer graphics. In conclusion, our work contributes to the development of efficient and effective techniques for image sampling and reconstruction, which are critical components in the field of multimedia processing. We believe that our proposed approach can serve as a foundation for future research in this area, and we hope that it will inspire further innovations in the field of computer vision.

***Abstract*—Image captioning is the task of generating semantically and grammatically correct caption for a given image. Captioning model usually has an encoder-decoder structure where encoded image is decoded as list of words being a consecutive elements of the descriptive sentence. In this work, we investigate how encoding of the input image and way of coding words affects the result of the training of the encoder-decoder captioning model. We performed experiments with image encoding using 10 all-purpose popular backbones and 2 types of word embeddings. We compared those models using most popular image captioning evaluation metrics. Our research shows that the model's performance highly depends on the optimal combination of the neural image feature extractor and language processing model. The outcome of our research are applicable in all the research works that lead to the developing the optimal encoder-decoder image captioning model.**

***Index Terms*—image captioning, neural image feature extractors, embedding models, LSTM**

I. Introduction

IMAGE captioning is a task of generating a verbal description of an image. It combines Natural Language Processing (NLP) and Computer Vision. Image captioning solutions are used in many application areas. They are adapted for content-based image retrieval or automated labeling of online images. Also, in the human-machine interaction field, they are used to assist visually impaired people in understanding the surrounding world or to search fast for photos on the internet.

We focus in this paper on the baseline captioning model [24] consisting of encoder and decoder. Encoder extracts a pair of image and text features in parallel. Text features encoder is responsible for the dense representation of each word in embedding space providing semantic context for each token. Image encoder uses convolutional neural network (CNN) backbone which extracts high-level image features. Decoder combines image and text features and generates the resulting image caption. It is based on the long-short term memory (LSTM) module [18], that generates the descriptive sentence word-by-word.

In this work, we improve the effectiveness of the baseline image captioning model by changing the encoding of the input data. We assume that different image features extractors, even pretrained on the same training set, provide with various high-level knowledge of the image content and similarly, different language processing models extract different semantics of captions.

During experiments, we investigated how different encoding of an image and text influence the captioning accuracy. We tested several backbone models based on pretrained CNN networks and embedding schemes as image and language inputs, respectively. It allowed us to investigate which pairs work best, hence finding the optimal combination of neural image feature extractor and language processing model.

As a result, we achieved 20 models trained on CNN networks: Xception, InceptionV3, Resnet152V2, Resnet50, VGG16, VGG19, DenseNet121, DenseNet201, MobileNet, MobileNetV2 along with Glove and FastText embeddings. For training and testing we used MSCOCO 2014 dataset and as the evaluation metrics: BLEU, METEOR, CIDEr, SPICE, ROGUE-L, WMD. Finally, thanks to the mentioned metrics, we assessed which pairs of image features and embeddings produce better results on the baseline image captioning model.

This paper is organized as follows. Section II describes how image captioning methods evolved from template-based techniques to deep neural architectures. Next, in section III, we describe how our base image captioning model is built and what neural image features extractors and language embedding models we use. The experimental procedure applied in our research is presented in Section IV. Section V have experimental analysis and finally, the final conclusions are found in Section VI.

II. Previous works

Image captioning methods combining text and visual data belong to the multi-modal machine-learning approaches [22], [40], [59]. Captioning models can be divided into traditional and deep-learning-based. Originally, traditional image captioning methods were based on hard-coded rules and human-made features. In [27], [29], [36], authors applied fixed templates with blank slots filled with various objects, descriptive tokens and situations extracted from images by the object detection systems. On the other hand, in [12], authors used already existing, predefined sentences. They created space of meaning from images features and compared images with sentences to find the most appropriate sentences for a photo. Despite semantic and grammatical correctness, captions from traditional methods differ often from the way a human described the image content.

Deep learning image captioning methods tries to overcome those limitations. In pioneering work [25] authors suggested that neural networks can interpret deep semantics of images and word embeddings. They proved that combined image features extracted by the convolutional neural networks (CNN) and word embeddings could hold semantic meaning. In [11], authors suggested passing image features and text features sequentially and individually to the language model. Inspired by the success in machine translation, [51] proposed using an encoder-decoder framework in image captioning, which has recently become dominant in the image captioning field.

Paper [24] by Karpathy et al. introduced architecture similar to human perception. Method generates novel descriptions over image regions, with R-CNN (Regional Convolutional Neural Networks) [13] for image feature extraction and recurrent neural network (RNN) to iteratively generate consecutive words of caption. Model using the multimodal embeddings space tries to find the parts of the sentence that best fits the image regions. Differently from other proposed methods ([9], [25], [51]), where a global image vector was used, Karpathy focused on image regions, and a separate caption described each region. Finally, a spatial map generates the target word for image regions. These image captioning approaches, focusing on generating captions for each region of an image, are called dense image captioning [23], [49], [54].

Encoder-decoder architecture [2], [15], [51], [55] considers the task of image captioning as the sequence-to-sequence problem. Encoder encodes the image to the fixed length vector using the image features extractor. Most widely used are CNN networks as VGG [14], [32], [45], ResNet [32], [34], [56] or Inception [10], [53]. Decoder, which in image captioning is represented by a language model, generates natural language descriptions to the output. Most popular approaches used RNN. However, due to the vanishing gradient problem that occurs in long sequence tasks, LSTM which is a variation of RNN achieved better results [18]. Most popular encoder-decoder approaches are the CNN-RNN [33], [41], [51] and GRU [8].

During the rapid development of image captioning methods, researchers also investigated other aspects of captions than just comparability to human judgment. Researchers focused on captions with a specific style. In [2], authors improved the descriptiveness of generated captions by combining CNN and LSTM. In [52], authors focused on captions for visually impaired people. Developed model tends to create captions that describe the surrounding environment.

III. Preliminaries

A. Image captioning model

Image captioning encoder-decoder model investigated in this study is depicted in Fig. 1. Encoder consists of two parts working, in the learning phase, simultaneously. One is for handling image features and another is for handling words in sequences. Firstly, image features are extracted using one of the image features extractors described in the next section. They are processed by a dense (fully connected layer) layer with ReLU (rectified linear unit) activation functions [37]. Its usage was motivated by promising results in very deep vision neural networks [17]. Compared with non-linear functions like sigmoid, ReLU is faster and harder to overfit. Dense layer is responsible for reducing the dimension of the image feature space (i.e. the length of the feature vector) to 256 to match the size of the word sequence prediction output.

In parallel, the text input (caption) is transformed into the sequence of indices of consecutive sentence words. Although the length of a caption varies, the length of vector of indices is constant and equal to 51, which is the maximum sentence lenght (i.e. number of words in the longest caption sentence). Such a vector is fed to the embedding layer. It encodes the semantic meaning of words represented by vectors in embedding space. We used pretrained Glove and FastText embeddings as two alternative ways of encoding the consecutive words of a descriptive sentence. Thanks to the embeddings layer, we reduced the text features size from the vocabulary size to the vectors of embeddings. Embedding vectors are passed through a long-short term memory (LSTM) model of size 256. After the LSTM layer, the outputs of language model and the image part of the image captioning model are added and finally forwarded to the decoder consisting of two dense layers.

Long-short term memory (LSTM) was designed for long-sequence problems and can predict next word in the sequence based on its predecessors. Each LSTM unit consists of three gates, that control and monitor the information flow in LSTM cells. Forgetting gate decides, which information from previous iteration will be stored in the cell state or is irrelevant and can be forgotten. In the input gate, the cell attempts to learn new information. It quantifies relevance of new input value of the cell and decides to process it or not. Output gate transfers the updated information from the current iteration to the next iteration. State of the cell also contains the information along with a timestamp.

Decoder processes an image feature vector and a sequence vector to predict captions. Following two dense layers processes, added language and image model to reduce the number of features to the vector of size equal to vocabulary size. Finally, the softmax layer generates the probability distribution of the next word in the sequence and selects the word with maximum probability. Previous words are converted to embeddings during training to develop the next word. Image feature vector is fed to the decoder. Goal of the training is to minimize loss function based on the error between target and predicted words.

Trained model predicts captions word-by-word, where the prediction of the next word is based on the previously generated one and image features. At each iteration, greedy search algorithm looks for the word in the dictionary with the highest probability of following words in the sequence. Process continues till the end of the caption is detected or the max length of the caption is achieved. Greedy search takes only tokens with the highest possibility of occurring in the final sequence based on previously generated tokens.

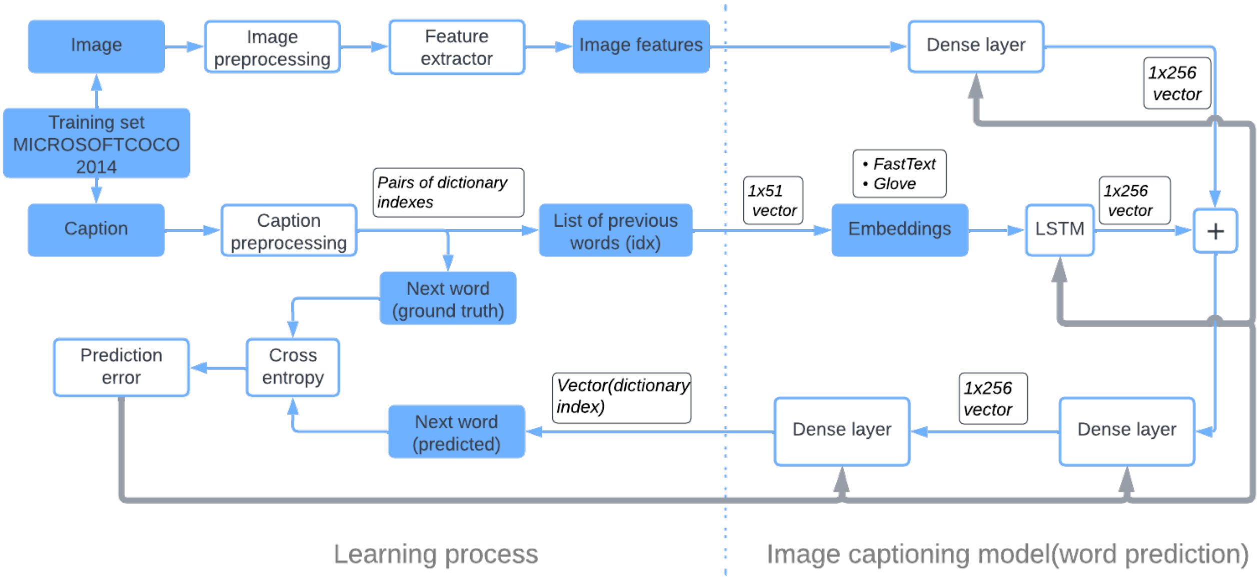

Fig. 1: Diagram of image captioning model training process.

B. Neural image feature extractors

Image features are essential in image captioning. In our experiments we used backbone CNN networks pretrained on a large number of images, the backbone networks. It makes possible to focus on the captioning model and restrict training to the remainder of the model.

The VGG [44] is a group of convolutional neural networks (CNNs) widely used for image classification tasks. Most popular variants are VGG16 and VGG19. VGG16 consists of 13 convolutional and 3 dense layers and was trained to recognize 1000 object classes referring to objects depicted on input 224x224x3 color images. By cutting out the dense layers, the backbone network that produces the image feature vector of length 4096 has been obtained. VGG19 has 3 more CNN layers than VGG16. Thanks to this, allows to learn richer representations of the data and achieves higher prediction results. On the other hand, VGG19 is more exposed to the vanishing gradient problem, than VGG16 and requires more computational power.

The Resnet [16] network was created to support many layers while preventing the phenomenon of vanishing gradient in deep neural networks. Most popular variants are Resnet18, Resnet50, and Resnet100, where the number represents a number of layers. Network architecture is built among two stages. In the beginning, the stack of skip connections is built. Those layers are omitted and the activation function from the previous layer is used. In the next stage, the network is learned again, layers are expanded and other parts of the network (residual blocks) learn deeper features of the image. Residual blocks are the heart of residual convolutional networks. They add skip connections to the network, which preserve essential elements of the picture till the end of the training, simultaneously allowing smooth gradient flow.

The Inception [47] model was created to deal with overfitting in very deep neural networks by going wider in layers rather than deeper. It is build among inception blocks that process input and repetitively passes the result to another inception block. Each block consists of four parallel layers 1x1, 3x3, 5x5, and max-pooling. 1x1 is to reduce dimension by channel-wise pooling. Thanks to that network can increase in depth without overfitting. Convolution is computed between each pixel and filter in the channel dimension to change the number of channels rather than the image size. 3x3 and 5x5 filters learn spatial features of the image in different scales and act similarly to human perception. Final max-pooling reduces the dimensions of the feature map. Most popular versions of the Inception network are Inception, InceptionV2 and InceptionV3.

The InceptionV3 [48] incorporated the best techniques to optimize and reduce the computational power needed for images features extraction in the network. It is a deeper network than InceptionV2 and Inception, but its effectiveness was not compromised. Also, use auxiliary classifiers that improve the convergence of very deep neural networks and combat the vanishing gradient problem. Factorized convolutions were used to reduce the number of parameters needed in the network and smaller asymmetric convolutions allowed to fasten computations.

The Xception [6] is a variation of an Inception [47] model that decouples cross-channel correlations and spatial correlations. Architecture is based on depthwise separable convolution layers and shortcuts between convolution blocks, as in Resnet. It consists of 36 convolutional layers divided into 14 modules. Each module is surrounded by residual connections, except the first and last module. It has a simple and modular architecture and achieved better results than VGG16, Resnet and InceptionV3 in classical classification challenges.

The backbone networks based on the three above ones, in contrast to the VGG16, produce the image feature vector of length 2048.

DenseNet [21] Network was created to overcome vanishing gradient problem in very long deep neural networks, by simplifying data flow between layers. Architecture is similar to Resnet, but thanks to the simple change in connection between layers, DenseNet allow to reuse parameters within network and produce models with high accuracy. Structure of DenseNet is based on stack of connectivity, transition and bottleneck layers, grouped in dense blocks. Every layer is connected, with every another layer in dense way. Dense block is main part of DenseNet and reduces the size of feature maps by lowering their dimensions. In each dense block dimensions of feature maps are constant, but number of filters change. Between each dense block, transition layer is placed to concatenate all previous inputs, hence reduce number of channels and number of parameters needed in the network. Also, between every layer bottleneck layer is placed to reduce number of inputs especially in far away layers. DenseNet also introduced growth rate parameter to regulate quantity of information added in each layer. Most popular implementations are DenseNet121, DenseNet201, where number denotes quantity of layers in the network.

MobileNet [20] is a small and efficient CNN Network especially designed for mobile computer vision tasks. It is built of layers of depthwise separable convolutions, composed of depth-wise and point-wise layers. MobileNet also introduced width multiplier and resolution multiplier hyperparameters. Width multiplier allows to decrease computational power needed during training, resolution multiplier decreases the resolution of the input image during training. Most popular versions of MobileNet are MobileNetV1 and MobileNetV2. In comparison with MobileNet, MobileNetV2 introduced inverted residual blocks and linear bottlenecks. Also, Relu activation function was replaced by Relu6 (ReLu with saturation at value 6). Thanks to that accuracy of the model significantly improved.

C. Word embedding models

Word embeddings are vector representations of tokens that are fed to a deep learning model. The most common embedding systems used for natural language processing and image captioning are Glove, Word2Vec and FastText.

One of the first word embedding techniques was one-hot encoding, where each token is encoded to the binary vector representation. Method is based on the dictionary created for all unique tokens in the corpus. A fixed-length binary vector with the size of a dictionary represents each word. Index of the word in the vector represents presence. If a word is present in with vector, just one value is one and others are 0. It is a straightforward technique that captures a wide variety of words but misses the semantic relation of words. Furthermore, fixed-length vectors are sparse, which is not computationally efficient.

Computationally efficient, Word2Vec [35] method simultaneously captures semantic relations between words. It is based on two techniques: CBOW (Continuous Bag of Words) allows the prediction of words from the context word list vector and the Continuous Skip-Gram model, a simple one-layer neural network that predicts context based on a given word.

FastText [4] comes from the Word2Vec model but analyzes words as n-grams. An algorithm is similar to the CBOW from Word2Vec but focuses on a hierarchical structure, representing a word in a dense form. Each n-gram is a vector and the whole phrase is a sum of those vectors. To achieve a word embeddings vector, training is similar to the CBOW.

Glove [39] word embeddings are based on unsupervised learning to capture words that occur together frequently. Thanks to the global and local statistics, it creates semantic relations in the whole corpus. Furthermore, it uses global matrix factorization to represent the word of lack of words in the document. It is also called the "count-based model" because Glove tries to learn how the words co-occur with other words in the corpus, allowing it to reflect the meaning of the words conditionally of the other words.

D. Text evaluation metrics

Image captioning is a task that belongs to both computer vision and natural language processing (NLP) domains. It must capture objects, the relations between them and the whole scene context to produce readable sentences in natural language. Due to the complexity of the image captioning results, the evaluation of the image captioning is still a complicated and comprehensive problem.

Evaluation metrics in image captioning measure the correlation of generated captions with human judgment. They estimate grammatical correctness, the complexity of the description and how generated caption generalizes the corresponding image. Evaluation metrics apply their own technique for computation and have distinct advantages. Standard evaluation metrics for image captioning are BLEU-1 to BLEU-4, METEOR, ROUGE-L, SPICE, and WMD [43]. They calculate word overlap between candidate and reference sentences and range it between 1-100. Higher values indicated better results.

BLEU (Bilingual Evaluation Understudy) [38] metric measures the correlation between predicted and human-made captions. It compares n-grams in predicted and reference sentences, where more common n-grams result in higher metric values. It is worth mentioning that metric exclusively count n-grams, locations of the n-grams in sentences are not considered. Metric also allows addition weights for specific n-grams to prioritize longer, common sequences of words. Usually, the 1 to 4-grams used when computing the metric – the respective variants are called BLEU-1 up to BLEU-4.

METEOR (Metric for Evaluation of Translation with Explicit Ordering) [3] measures the correlation between the predicted caption and human judgment. Compared with BLEU, parts of the sentence are analyzed, not the whole corpus. METEOR algorithm have two stages. At first, tokens from reference captions and candidates are compared. In the second stage final result is calculated. METEOR also analyzes and allows synonyms.

CIDEr (Consensus-based Image Description Evaluation) [50] metric calculates correspondence between candidate and reference captions. It is based on the TF-IDF metric, calculated for each n-gram. It is widely used for SCST [41] training, where the strategy is to optimize the model for a specific metric. It results in higher results during the testing phase compared with [41]. Furthermore, CIDEr optimization during training impacts on high scores in BLEU, METEOR and SPICE metrics.

ROGUE-L (Recall-Oriented Understudy for Gisting Evaluation) [30] is a set of metrics: Recall, F1 and precision. Algorithm finds the longest common sequence of tokens between predicted and reference captions. Sequences must be in the same order but not next to each other.

WMD (Word Mover's Distance) [26] is based on a machine learning model to count similarity between texts. Metric is distinguished from others because it measures common sense between texts. It does not investigate the occurrence of tokens. Instead, it measures the semantic length between sentences by counting the probability of the occurrence of synonyms.

All the above metrics are used in various NLP tasks. However, according to some investigations [7], they do not correlate with a human judgment, what makes them not adequate to measure the similarity of image captions [1]. Among the known metrics the one that correlates with the human judgment is SPICE (Semantic Propositional Image Caption Evaluation) [1]. This metric measures similarity between sentences, represented by a directed graph. SPICE algorithm at the beginning creates two directed graphs. First one is for all reference captions and the second is for the candidate sentence. Graphs elements can belong to three groups. First group is objects and activity performers, the second group consists of descriptive tokens (adjectives adverbs) and the last group represents relations between objects and links other groups of tokens on the graph. Based on this representation, sentences are compared.

IV. Experimental setup

A. Datasets

There are several datasets used for image captioning. They differ in the number of images and their size, also captions can vary in format and length. Most commonly used are Flickr8k [19], Flickr30k [58] and MSCOCO 2014 [5], [31]. All these sets consist of a number of images with associated captions, usually 5 per image.

Dataset Flickr30k includes 30k images and each photo has five captions. Training set consists of 29k images and 1k is for testing. Flickr8k is a subset of Flickr30k and contains 8k images, with five annotations for each picture. Each caption fully describes a scene and is entirely based on human judgment. In the test split, there are 7k images and the rest of the data is used for testing.

During our experiments, we used for the evaluation and training the MSCOCO dataset. It consists of more than 120k images from various everyday scenes. Five captions describe each photo in natural language. In the image captioning area, the most popular MSCOCO data partitioning for testing, validation and training purposes is Karpathy split [24], where there are 113k images in training, 5k in validation and 5k in test disjoint subsets.

B. Image preprocessing

Motivated by [24], and considering the variety of available pretrained object detection CNN models and language processing models, we conducted experiments to check how input data to the model can affect the learning process. The whole experimental process involves encoding images and text features simultaneously and generating a final sequence of tokens (caption) word by word during decoding.

Images from the dataset are resized and normalized before entering the image captioning model to be compatible with one of the CNN networks. For VGG16, VGG19, Resnet152V2, Resnet50, DenseNet121, DenseNet201, MobileNet, MobileNetV2 input shape is 224x224x3 and 299x299x3 for InceptionV3, Xception. As a result, we obtained features vectors with the following sizes, corresponding to the preprocessed input image: 4096-element vector for VGG16, VGG19; 2048 for InceptionV3, Xception and Resnet152V2; size 1024 for denseNet121; size 1920 for DenseNet201; 1000 elements for MobileNet; size 1280 for MobileNetV2. We used CNN models pretrained on the ImageNet [42] dataset, where the network's fully connected layers is removed since we do not need

[1] The authors of [7] propose their own metric, but due to much its much lesser (more that 10x) popularity comparing with SPICE, we decided to use that latter in the current study.

the probability distribution on 1000 image categories from ImageNet.

C. Text preprocessing

A separated preprocessing was performed for captions. At the beginning, all words were converted to lowercase, tokenized. We removed punctuations, hanging single-letter words and discarded rare words that occurred less than five times. As a result, we achieved the following vocabularies, also called dictionaries: Flickr8k, Flickr30k, and MSCOCO 2014, that will be used to create embedding matrixes from embedding vectors. Before being handled by LSTM Network, word sequences must be represented in word embeddings vectors. In our model, Glove and FastText have been used as embedding.

Preprocessed captions, consumed by the captioning model, are appended with *start* and *stop* tokens to mark the beginning and end of the sentence, respectively. In the next step, a vocabulary of all words occurring in the captions in the training set is prepared (along with *start* and *stop* tokens). As a result, a dictionary of all words in our corpus is produced to identify tokens by index explicitly. Each generated word is processed by embedding prior to its providing into the LSTM model input.

We adopted pretrained versions of FastText and Glove to extract the text features. We preprocessed sentences from the train and test dataset (described in the previous section) and finally achieved a vocabulary of size 7293. Each word is then embedded to a 200-element vector for Glove and 300-element vector for FastText word embedding space.

D. Training and testing

During training, the model processes combined 256-element vector of word embeddings and image feature vectors based on the CNN model for a given image. At each time step model predicts a word for the processed image and compares it with the ground truth word from the training set, which corresponds to the processed image. Predicted word and ground truth word (from the training set) are compared using the cross-entropy measure (see Fig. 1).

During the testing, image captioning model is fed by a preprocessed photo. In the beginning, at the 0-time step, there is no previously predicted word. Therefore, to denote the start of prediction, a start of sentence token *start* is used. Words are served as the embeddings, corresponding to the dictionary. Next, the image captioning model predicts words recursively until the sentence's end (marked by *stop* token) or the maximum length of the sentence has been reached and adds it to the word list. At each step, the chance of the occurrence of one word next to another is calculated using embeddings specific to the tested text features. Finally, a full caption for the tested image is generated and compared with ground-truth phrases for the tested image, using specific metrics.

E. Evaluation

We investigated the performance of each image encoder, with each text encoder mentioned previously, with BLEU-1 – BLEU-4, METEOR, ROGUE-L, WMD, CIDEr, and SPICE metrics. The complete process is repeated for other CNN architectures and embedding methods to achieve a comprehensive perspective of the performance of different CNN architectures along with different embedding methods. Backbone-embedding pairs tested during experiments are presented in Table. I. The complete process of evaluation is presented in Fig. 2.

For further analysis, we also examined word and bigrams occurences from a training set and predicted captions to determine why some captions are incorrectly generated and what are the collocations of a training set with the parts of the sentence that do not describe the real image content.

V. Results

Table I shows the results of image captioning metrics calculated for different image and text features extractors. We analyzed all models accordingly to the BLEU-1 – BLEU-4, METEOR, ROUGE-L, WMD, CIDEr, and SPICE metrics. Following the literature, to evaluate the performance we used most recent CIDEr and SPICE metrics, keeping the remainder for comparative purposes. For the same purposes we added four reference methods in last four rows of the table.

From the obtained results, we can see that model performance depends mostly on the CNN backbone used. Best results considering the CIDEr metric has been achieved for Xception backbone feature extractor, second place belong to DenseNet201. The spread between the highest (Xception with Glove, 78.13) and the lowest (VGG with Glove, 67.35) metrics value equals 10.78 points difference, which makes the model strongly dependent from the image backbone feature extractor. The evaluated quality of caption extractors is correlated with the accuracy of backbones. Practically for each metric, the order of models sorted by the metric value is similar to the order of backbones when sorted by accuracy both in top-1 and top-5 variants[2]. One cannot observe any remarkable superiority of one embedding model over another. For some metrics the Glove model performs better, while for the remainder – the FastText. In most cases, FastText embeddings achieve higher results than Glove for the same image features extractor. Which suggests that FastText adapts easier for different CNN models, than Glove. Long feature vectors does not imply higher performance. The longest feature vectors that are generated by VGG backbones does not imply higher values of measures. The winning models are using 2048 (Xception) and 1920 (DenseNet201) vectors. Average time of sequence generation is not correlated with the model complexity (no. of model params). Differences in execution time between models spreads from 874 to 1417 ms. The fastest is DenseNet201, which is also second best model.

Example correct captions obtained by the Xception + Glove pair are given in Table II, the respective images are shown

[2] Where top-n means that – in case of complete initial model of the backbone (i.e. model that contains both, the convolutional and fully-connected layers) the proper answer i.e. predicted class is among n-classes of highest output probability.

TABLE I: Evaluation results for MSCOCO 2014 test dataset (5000 images). Metrics' values are averaged over the whole test dataset. Higher results implies better image captioning performance.

(c) (d)

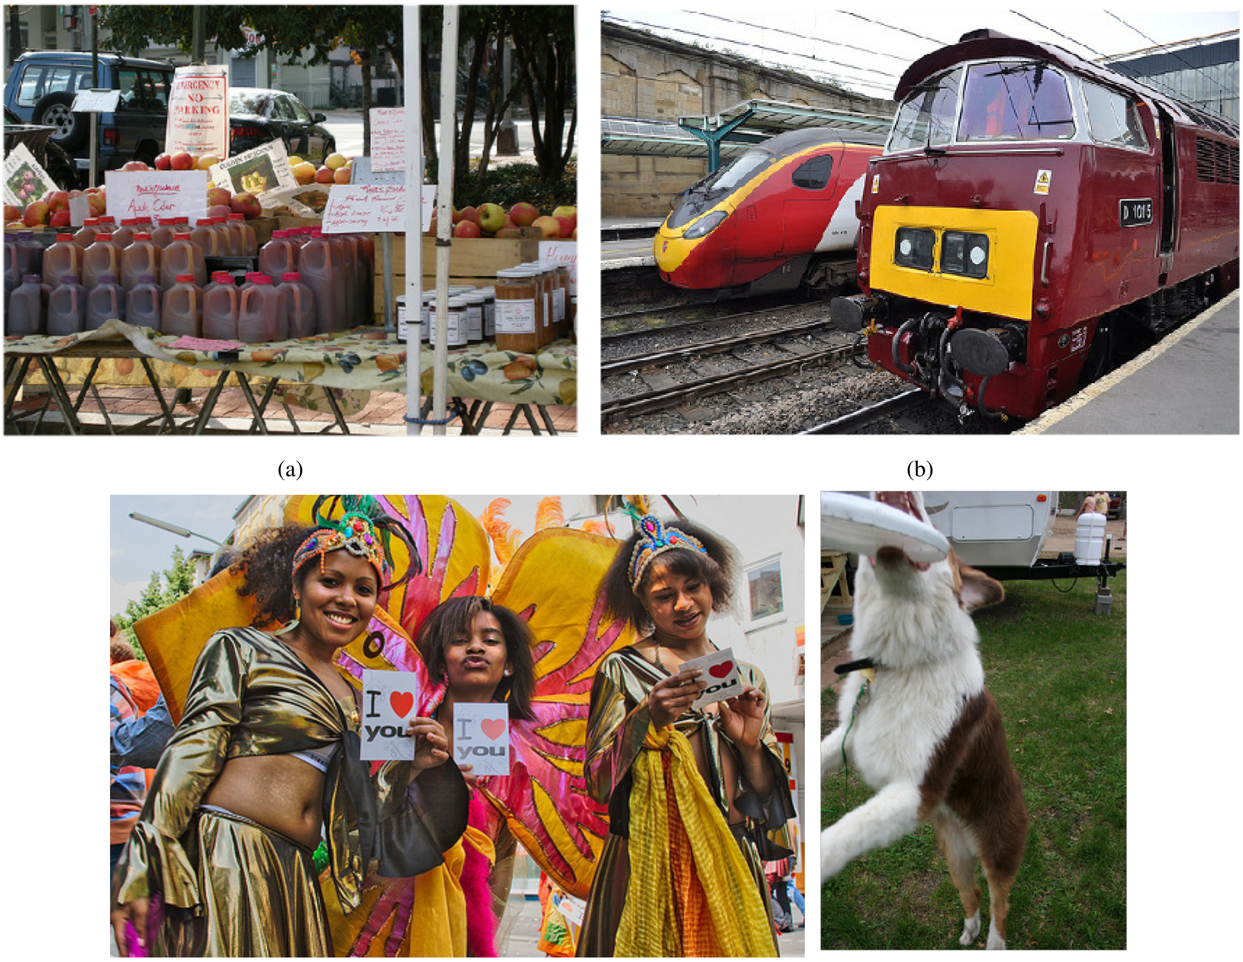
Fig. 3: Images with properly predicted captions (see Table II for details)

in Fig. 3. The table contains ground-truth 5 captions from the dataset metadata, captions obtained from the model and values of metrics. The generated captions sound good, are grammatically correct and consistent with the image content.

In contrast to the above, Table III presents inadequately predicted captions for four images obtained using different methods.

During this experiment, we checked that the resulting captions' wrong parts occur more often in the training set data. For Fig. 4d wrong part of the caption is the *with people standing*. Bigram *with people* occurs 1328 times, *people standing* 2740 times in training set. Those bigrams occur relatively often compared to other parts of the sentence. Also, for Fig. 4b bigrams that form *laying on a couch* occur very often in MSCOCO 2014 training dataset. Especially in the example Fig. 4c, bigrams "front of", "woman holding" are very common in the training dataset.

To explore deeply the possible reasons for incorrect captions, we investigated vocabulary of single words and bigrams used for training. The total size of vocabulary (the number of unique words) equals 26335 for 113350 images described using 5 alternative sentences each, which gives us 566747 captions. The similar numbers for the training set are the following: number of images 5000, of sentences 25000, of unique words: 7197 among which 503 words were used only in the captions in the test set (the remainder i.e. 6694 words are also present in the training set vocabulary). Considering the fact that each of investigated models is being learned on the training set, only words that are present in this vocabulary are used to predict ANY output sentence (correct or not). In case the captions in the test set, the number of words that was not present in the training set equals 503. This implies that, object, actions, situation, scene elements etc. that was described using these words, would never be produced properly (when testing,



(a) (b) (c) (d)

Fig. 4: Images with improperly predicted captions (see Table III for details)

the words in the test set vocabulary are obviously not used).

For further analysis, we tried to find why parts of the sentence are inadequate and how it is affected by training data. Regarding that, we examined how bigrams from predicted captions compare to those in the training set. We extracted bigrams from the MSCOCO 2014 training set with the number of their occurrences. Then we also extracted bigrams from predicted captions. As a result, we achieved a summary of bigrams in the training dataset and in a set of predicted captions, along with a number of their occurrences. The result for four example images are shown in Fig. III. Not surprisingly, the model, to construct captions, is using more frequent bigrams from the training set.

VI. Conclusions

In this paper, we analyzed how image features and word encoding affect the results of the encoder-decoder image captioning model. Our experiments proved that encoding input data plays in this area the primary role. During our research, we recognized that image captioning involves merging features from different modalities. Because of that, encoding of both image and features must cooperate, so finding the optimal pair for specific model architecture is crucial and we can significantly improve the results of the model predictions with that principle. The influence of the image feature extractor by the CNN backbone is crucial in this type of captioning model, it affects more the performance than the word embedding scheme. The Xception with Glove and DenseNet201 with FastText, according to our experiment are the best combinations of models' components.

The outcome of our research are applicable in all the research works that lead to the developing the optimal encoder-decoder image captioning model.

***Abstract*—Data-driven models used for predictive classification and regression tasks are commonly computed using floating point arithmetic preserving accuracy by automatic scaling even in high non-linear functions. With respect to distributed sensor networks like the IoT, sensor data is acquired on low-resource embedded systems and delivered to data servers characterized by big data volumes. In specific use cases and domains, local predictive modelling on low-power devices is desired or required. But heterogeneity of host platforms and dynamic programming disables machine code deployment. This work addresses Tiny ML on very low-resource devices (microcontrollers, less than 32 kB RAM and ROM) by using a stack-based Tiny Virtual Machine providing core ML operations to implement Decision Trees (DT), Artificial Neural Networks (ANN), and Convolutional Neural Networks (CNN). VM program code is always provided in textual format and compiled just-in-time to Bytecode to ensure portability, servicability, and mobility. Two damage diagnostics use-cases demonstrate the suitability of the VM approach, and even time consuming computational tasks do not compromise the overall responsiveness of the platform by using a real-time approach. This work addresses the underlying integer arithmetic operations required to implement efficient and fast computable ML models on microncontrollers.**

***Index Terms*—Tiny ML, Virtualization, Embedded Systems.**

I. Introduction

To ADDRESS ubiquitous computing, edge computing, and distributed sensor networks, driven by a significant increase in device density and sensor deployment toward smart and self-contained sensors, advanced and dependable data processing architectures are required. Tiny machine learning is a new and challenging field [1]. In order to calculate ML models, high precision floating point arithmetic is frequently used. Only integer arithmetic (8–32 bits) is offered by low-resource tiny embedded systems, therefore direct training using integer arithmetic [2] or model transformation and freezing [3] are required, ideally on the target device itself [4]. These issues are also addressed in our study. Ultra low-power devices place additional restrictions on the computation of deep learning (DL) models [5] and hardware designs are becoming more popular [6]. An example for such a tiny low-resource embedded system is shown in Fig. 1.

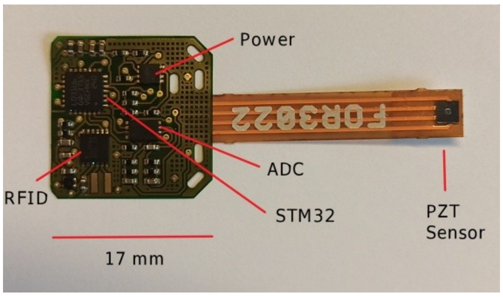

Fig. 1. An example of a highly integrated and miniaturized sensor node with a STM32 ARM Cortex microcontroller supplied entirely by an RFID energy harvester (source with courtesy: IMSAS, B. Lüssem, University of Bremen).

In this study, a real-time capable and extendable application-specific stack virtual machine (REXA-VM) with several distinctive and unique features is introduced and analyzed, specifically addressing ML computations. In contrast to common integer-based ML models using 8 bit scaled arithmetic [2], this VM supports 16 and 32 bit operations. The novelty of this work is the capability of a VM to process common ML models delivered in text format. The program text embeds model parameters as well the forward computation function for a specific already trained model. Virtualization of services and data processing in embedded devices play an important role in heterogeneous network environments [7].

Another problem involves non-continuous energy supply, such as that delivered to the sensor node from external sources utilizing RFID/NFC. This type of non-continuous energy supply introduces severe power restrictions limiting the set of usable microcontrollers (mainly without FPU) and necessitates real-time data processing to the appropriate degree. Running computationally expensive operations without jeopardizing IO event handling (i.e., the device's responsiveness) requires the VM's real-time capability, which is not covered in this work. It is anticipated that a REXA VM node receives remote communications over wireless tech-

This work was supported by DFG Grant 418311604

nology. Direct transmission of program text code to the VM for processing and compilation is possible.

II Arithmetic

Linear and moreover non-linear functions are commonly computed using at least 32 Bit Floating Point (FP) arithmetic. FP bases on an exponential representation (and approximation) of real numbers. Most ML models are linear or non-linear functions. Deep neuronal networks with non-linear activation functions can approximate highly non-linear models. The dynamic scaling of FP values and operations enables the computation of functions with high gradients and large value interval spans. Although, there is 16 Bit FP arithmetic, this reduced precision arithmetic commonly have no advantages over fixed point arithmetics (XP) except providing a higher dynamic range. The required dynamic range depends on the value range of the input and output variables as well as on latent (hidden) variables of intermediate functions, e.g., hidden nodes of an ANN. XP is often used in hardware implementations of ANNs [8] and rely on integer arithmetic that is the only available arithmetic on low-resource computers, e.g., the STM32 ARM Cortex M microcontroller series. XP arithmetic has the disadvantages of underflow and the requirement of software post-correction (multiplication) when used on microcontrollers, lowering the arithmetic's performance.

In contrast to common numerical approaches, in this work, XP values are replaced by in-advance dynamically scaled arithmetic (SA) using <value,scale> tuples. Scaling is only applied after an aggregating operation was performed, e.g., the computation of a vector product in an ANN layer, as illustrated in Fig. 2. This is relaxed by the fact that N Bit integer arithmetic (e.g., 32) is assumed at the core, but only M=N/2 Bit integer values (e.g., 16 Bits) are used to represent operands and result values. SA is used in this work to approximate complex (nested) functions. The scaling values are computed from data for a particular function, e.g., an ANN classifier. The relative approximation error increases with decreasing (real) values. A scaling factor can be shared by multiple values (e.g., vector elements), reducing memory requirements.

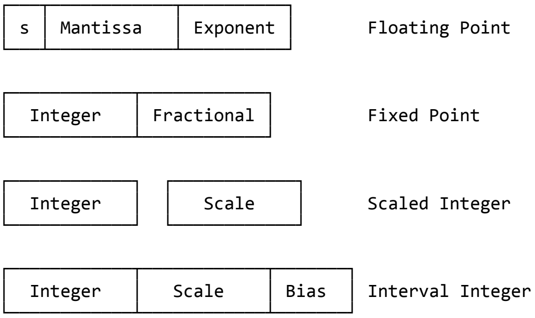

Fig. 2. Comparison of different arithmetic classes

A function F is transformed to a an integer approximation by:

1. Decomposing arithmetic expressions (and functions) in scalable arithmetic functions;
2. Annotating original expressions and functions with value intervals based on a representing test data set (input and output values of the composed function);
3. Calculating the scaling factors based on the interval annotations and pre-defined function value range annotations, e.g., a pre-defined sigmoid function.
4. Calculating the approximation error for the test data (eventually modifying the functional structure or changing scaling factors to reduce the overall function error).

The transformation process is not addressed in this work. Values of function variables (input, output, latent) in a specific data context and application can lie in a small interval, e.g., [0.11,0.12]. Pure scaling, e.g., with M=16 Bits), would use k=250000, but the entire integer range would be only [27500,30000], effectively reducing the resolution to 12 Bits with significantly increased approximation error. To increase the usable range for integer approximations of real numbers, a bias offset can be introduced, approximating a real number by a <bias,scale,value> tuple. But this kind of arithmetic would require post-corrections and dedicated arithmetics, and scaling factors and bias must be specified for each particular value (in contrast, to pure scaling), increasing memory storage.

A data-driven predictive model function is composed of vector operations and transfer functions. The approximation error in such a composed and chained functional system is accumulative. Using linear transfer functions the error is linear accumulative and show no exploding gradients. But using non-linear functions, e.g., based on logarithmic functions, the approximation error is non-linear with exploding gradients and underflows, at consist of approximation based on SA and approximation of non-linear functions itself, as discussed in Sec. IV.F.

III Virtual Machine

Details of the REXA VM architecture, features, capabilities and the compiler can be found in the technical paper [9]. In the following section the ML-relevant features are summarized only. The REXA-VM may be implemented in compact embedded systems with a microcontroller and as little as 8 KB of data RAM and 16 kB of code ROM. In large-scale and heterogeneous networks, virtualization and Machine Learning (ML) are essential for unified sensor and data processing [10]. A scriptable Tiny ML interface and signal analysis numbers utilizing 16-bit scaled arithmetic are two important features. This VM supports 16 and 32 bit operations natively, preventing frequent arithmetic overflow and underflow problems. In contrast to common integer-based ML models using 8 bit scaled arithmetic [2], this VM supports 16 and 32 bit operations.

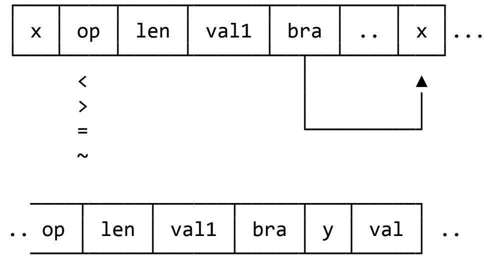
The REXA VM was designed especially for the deployment on low-resource microcontrollers with less than 64 kB RAM and low clock frequencies below 50 MHz. It utilizes a freely programmable ISA, but the ISA of the VM used in this work is closely related to the FORTH programming language [11]. The VM is a pure stack processor, i.e., most operations processing data via multiple stack memories with a zero-operand instruction format. The VM instruction loop processes Bytecode programs stored in a code segment (CS).

Each VM program consists of data and instructions stored in a code fragment in the CS. The main user program memory is the code segment of the VM (CS), which is organized in byte cells and has a static fixed size. An important feature of the CS is the direct embedding of program data besides code instructions. The Bytecode is compiled just-in-time by an integrated compiler. The VM and the compiler operate both incrementally, i.e., the processing time of each of them can be limited and scheduled, a primary feature required in single IO task programs with a main loop processing IO events and performing computations. Since the ISA of stack processors consists mostly of zero-operand instructions, it supports fine-grained compilation at the token level. The source text can be directly stored in the code segment (in-place) referenced by a code frame (or any other data buffer, alternatively). Most instruction words can be directly mapped to a consecutively numbered operation code.

IV ML Modells

A Decision Trees

Decision trees, as lightweight predictor models well suited for tiny embedded systems, can be efficiently stored in Linear Search Tables (LST), as introduced earlier for compiler parsing.



Def. 1. Format of a Linear Search Tree (LST) implementing a decision tree

Decision trees consist of nodes associated with input variables x_j or output variables y_k (and specific outcomes of a prediction). Directed edges connecting nodes are functional evaluations of a node variable.

There are three basic operations: Binary relation (</>), equality (=), and nearest value approximation (≈). The data format is shown in Def. 1. Each slide starts with the input variable to be evaluated (or target for output), the operation applied to choices, a field specifying the number of choices, and value-branch pairs. Decision tress can always approximated by integer arithmetic without error accumulation or exploding gradient (and underflow) issues. Therefore, the decision tree is here the gold standard for classifications problems and compared with ANN implementations.

B Artificial Neural Network (ANN)

An ANN consists of two parts:

1. The data, i.e., for parameter, input, and output variables;
2. The structure and functions processing the data.

For the sake of simplicity, fully connected networks are assumed, but any irregular network structure is a sub-set of a fully connected structure and can be used with the following operational architectures, too. In contrast to common ANN software frameworks, REXA VM provides only core vector operations, as discussed later on. The parameter data is embedded in a code frame by using the initialized *array* constructor. Both parameter and input/output data can be stored in the program code frame, shown in the next section.

ANN computations are decomposed in vector operations provided by the VM platform, discussed below. It can be shown that the complexity and memory requirement of this (textual data) approach is low even for complex network structures. Compiled code embedding data require typically less than 1 kBytes of RAM.

The principle structure of an ANN model and its forward computation using the vector operations discussed at next is shown below. There are initialized parameter arrays (weights, biases, and scaling factors) and latent variable arrays (neuron output).

```
array input N
array wghtsL1 { 1 2 3 .. }
array biasL1  { 1 2 .. }
array scaleL1 { 1 2 .. }
array outL1 N
..
: fwd
  .. vecmul
  .. vecadd
  .. vecmap
  ..
;
```

C Convolutional Neural Networks (CNN)

The structure of a CNN consists of different layers. A minimal basic layer architecture set consists of:

1. A convolutional layer applying a kernel filter mask to an input image (linear multiply-summation operation) producing a filtered output image;
2. A pooling layer extracting relevant features from images by applying special filters (e.g., a maximum value selection);
3. An ANN layer (commonly fully connected).

CNN computations are decomposed in vector operations provided by the VM platform, discussed below. The complexity and memory requirements is much higher than compared with ANN implementations. Especially the ANN layer is connected to all elements of the arrays of the pooling layer. Memory requirement is typically more than 4 kBytes, depending on the network structure, input dimension, and layer sizes. More details and evaluations can be found in the use-case sections.

The principle structure of a CNN model and its forward computation using the vector operations discussed at next is shown below (here the first convolution and the second pooling layer are merged to save storage space). There are initialized parameter arrays (kernel weights, biases, and scaling factors) and latent variable arrays (intermediate images, neuron outputs).

```
array input N
array kernL1p1 { 1 2 3 .. }
array kernL1p2 { 1 2 3 .. }

```

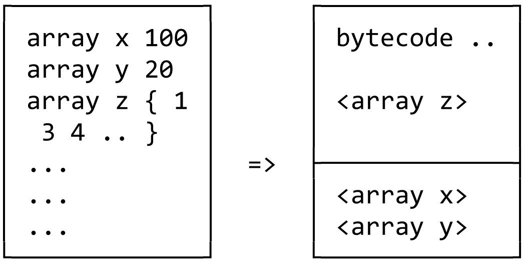
D ML Core Operations

ANN and CNN computations required efficient and generic vector operations crucial to implement ML on microcontrollers. The REXA VM provides a core set of vector operations that can be used for the computation of ANN and CNN models. Training using classical error back-propagation is currently not supported due to requirement of storing a suitable training and test data set.

All the basic operations you need to implement ANNs and perform forward activation computations are:

1. Element-wise vector operations (e.g., *vecmul*: *op1vec op2vec dstvec scalevec*);
2. Dot-product operation performing a sum of product data fusion (*vecprod*: *veca vecb scale* → number);
3. A folding operation for node layer computations (*vecfold*: *invec wgtvec outvec scalevec*);
4. A convolution operation for CNN computations (*vecconv*: *invec wgtvec outvec scale inwidth kwidth stride pad*). This function also serves as a pooling operation;
5. A mapping operation applying a function elementwise (*vecmap*: *srcvec dstvec func scalvec*);
6. A reduction operation applying a function to all elements returning an aggregate (*vecred*: *vec vecoff veclen op*); Supported functions are *min*, *max*, *sum*, and *average*;
7. A vector reshape operation shrinking or expanding a vector (*vecshape*: *srcvec dstvec scale*);
8. A generic scaling operations (*vecscale*: *srcvec dstvec scalevec*).

Vector operations commonly operate on arrays embedded in code frames, as shown in Def. 2. Scaling is typically applied after an aggregation operation (results of operation), e.g., after computing a sum of products (using 2N arithmetics), to avoid overflow. Some operations use one scaling factor for all elements, discussed in the following section.



```
array x 100
array y 20
array z { 1
 3 4 .. }
...
...
...
```

=>

```
bytecode ..

<array z>

<array x>
<array y>
```

```
<array>: [LEN:2][DATA:LEN*WORDSIZE]
```

Def. 2. Initialized arrays embedded in-place in code frames and non-initialized arrays stored at the end of the compiled code frame

E Vector Operations

The core set of vector operations provided by the REXA VM supporting integer arithmetic ANN computations is summarized in Tab. 1.

Vector Operation

`array <ident> <#cells>`
Allocates a data array at the end of the code segment

`array <ident> { v1 v2 .. }`
Allocates an initialized data array inside the code segment.

`vecload`
`( srcvec srcoff dstvec -- )`
Loads a data array into another array buffer. The source can be any external data provided by the IOS or internal embedded data.

Vector Operation

`vecscale`
`( srcvec dstvec scalevec -- )`
Scales the source data array with scaling factors from the scale array and stores the result in the destination array. Negative scaling values reduce, positive values expand the source data values.

`vecadd,vecmul`
`( op1vec op2vec dstvec scalevec -- )`
Adds two vectors element-wise with an optional result scaling (value 0 disables scaling). Both input and the destination vectors must have the same size. Constant down-scaling of all elements is provided by a negative scaling value (instead of vector reference).

`vecfold`
`( invec wgtvec outvec scalevec -- )`
Performs a folding operation *ivec* × *wgtvec* with a given filter. The weights vector *wgtvec* must have the size ||*invec*||*||*outvec*||.

`vecconv`
`( invec wgtvec outvec scale inwidth wgtwidth stride pad -- )`
Performs a two-dimensional kernel-based convolution operation *ivec* ⊗ *wgtvec*. The width of the input and kernel matrix (still a linear array) must be provided, the width of the output and the heights are computed automatically from the vector lengths. If *wgtwidth* is negative, a pooling operation is performed. The *wgtvec* argument provides then the height of the filter and the operation to be performed.

`vecmap`
`( srcvec dstvec func scalevec -- )`
Maps all elements from the source array onto the destination array using an external (IOS) or internal (user-defined word) function, e.g., the sigmoid function.

`vecred`
`( vec vecoff veclen op -- index value / valueL valueM )`
Reduces a vector to a scalar value. Supported operations are *min* (1) and *max* (2) returning position and value, *mean* (4) and *average* (8) returning a double word value.

TAB. 1. BASIC VECTOR ANN FUNCTIONS OPERATING ON EMBEDDED OR EXTERNAL ARRAY DATA (E.G., THE SAMPLE BUFFER)

Vector operations always operate on single data words (16 bit), but internally 32 bit arithmetic is used to avoid over- and underflows. To scale to signed 16 bit integer, some of the operations use a scale factor or scale factor vector (negative scale values reduce, positive expand the values by the scale factor) to avoid overflows or underflows in following computations, similar to scaled tensors in [4,12]. Vector operations can access arrays stored in code frames or provided externally by the host application (e.g., a signal buffer).

The *vecconv* operation can be used for convolutional and pooling layers (pooling is used if *wgtwidth* is negative and the *wgtvec* value contains the weight matrix height combined with the pooling function selector). The application of an activation function must be done separately using the *vecmap* operation, e.g., by applying a *sigmoid* function to all elements of a vector.

The computation of these operations are defined by the following formulas:

$$\begin{aligned}
&\mathrm{vecmul}\left(\vec{a},\vec{b}\right)=\left(a_1\cdot b_1,a_2\cdot b_2,..,a_n\cdot b_n\right)^T\\
&\mathrm{dotprod}\left(\vec{a},\vec{b}\right)=\sum_{i=1}^{n}a_i\cdot b_i\\
&\mathrm{fold}\left(\vec{a},\hat{c}\right)=\left(\sum_{i=1}^{n}a_i\cdot c_{i,1},\sum_{i=1}^{n}a_i\cdot c_{i,2},..,\sum_{i=1}^{n}a_i\cdot c_{i,n}\right)^T\\
&\mathrm{conv}\left(\vec{a},\vec{c}\right)=\sum_{i=1,+s}^{a_h}\ \sum_{j=1,+s}^{a_w}\ \sum_{k=1}^{c_h}\sum_{l=1}^{c_w}a_{i+k,j+l}\cdot c_{k,l}\\
&\mathrm{map}\left(\vec{a},f\right)=\left(f\left(a_1\right),f\left(a_2\right),..,f\left(a_n\right)\right)^T\\
&n=\left|\vec{a}\right|=\left|\vec{b}\right|,\left|c\right|=n\cdot m
\end{aligned}\tag{1}$$

F Activation Functions

There are different transfer (activation) that are used in ANN and CNN modells, mosr prominent examples are:

- Linear function (*linear*) without x- and y-limits
- Logistic or sigmoid function (*sigmoid*) with y-limit=[-1,1]
- Tangents hyperbsolic function (*tanh*) with y-limit=[-1,1]
- Rectifying linear unit (*relu*) with one-side open y-limit=[0,∞)

The *linear* and *relu* functions can be directly implemented with integer arithmetic without loss of accuracy (except due to integer discretizing). The highly non-linear *sigmoid* and *tanh* functions require an appropriate approximation by using a hybrid approach of the usage of a (compacted) look-up table (LUT) and interpolation. The *tanh* function can be neglected since it can be replaced in most cases by the *sigmoid* function without loss of generalization (of course, prior to training).

Trigonometric functions and functions composed of trigonometric functions are implemented with segmented linear and non-linear look-up tables. For example, the error of the discrete sigmoid function is always less than 1%, while only requiring 30 bytes of LUT space and less than 10 unit operations, as shown in Alg. 1. These software functions can be immediately implemented in hardware, too. The LUTs are computed with Alg. 2.

```
static ub1 sglut13[] = { <24 values> };
static ub1 sglut310[] = { <6 elements> };
// y scale 1:1000 [0,1], x scale 1:1000
sb2 fpsigmoid(sb2 x) {
  sb2 y;
  ub1 mirror=x<0?1:0;
  if (mirror) x=-x;
  if (x>=10000) return mirror?0:1000;
  if (x<=1000) {
    y = 500+(((x*231)/1000));
    return mirror?1000-y:y;
  } else if (x<3000) {
    ub2 i10 = ((fplog10((x/5)|0)/2))-65;
    y = ((sb2)sglut13[i10])+731;
    return mirror?1000-y:y;
  } else {
    ub2 i10 = ((fplog10((x/10)|0)/10))-14;
    y = ((sb2)sglut310[i10])+952;
    return mirror?1000-y:y;
  }
  return 0;
}
static ub1 log10lut[] = { <100 values> }
// x-scale is 1:10 and log10-scale is 1:100
sb2 fplog10(sb2 x) {
  sb2 shift=0;
  while (x>=100) { shift++; x/=10; };
  return shift*100+(sb2)log10lut[x-10];
}
```

Alg. 1. Range-segmented and LUT-based implementation of the sigmoid function with less than 1% approximation error (using approximated LUT-based log10 function)

The LUT tables can be computed as follows:

$$\text{log10lut} = \left\{ int\left(\log_{10}\left(\frac{i}{10} \right) 100 \right) : i \in \mathbb{I}, 0 \le i \le 99 \right\} \qquad (2)$$

The *fpsigmoid* function LUTs are computed iteratively using the *fplog10* function, described by the following pseudo code algorithm Alg. 2:

```
sglut13 := []
for x=1 to 2.95 step 0.05 do
  i10 := int(fplog10(int(x*1000/5))/2)-65
  if sglut13[i10] = undefined then
    sglut13[i10] := int(sigmoid(x)*1000)-731
  endif
done
sglut310 := []
for x=3 to 9.9 step 0.1 do
  i10 := int(fplog10(int(x*1000/10))/10)-14
  if sglut310[i10] = undefined then
    sglut310[i10] := int(sigmoid(x)*1000)-952
  endif
done
```

Alg. 2. Computation of the LUTs for the scaled integer sigmoid function

The accuracy (relative error) of the sigmoid approximation is plotted in Fig. 3 with an input and output scaling factor of 10000 (i.e., 1:10000). For $x > -3$ the error is below 5% and decreases to 1% in average. Only for $x < -3$ the relative error increases significantly due to the integer resolution.

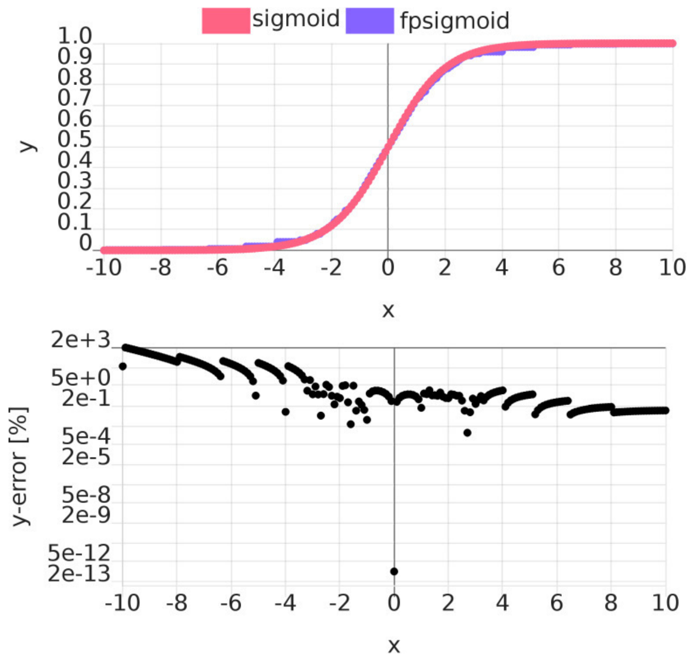


Fig. 3. Relative discretization error of scaled integer LUT-interpolated approximation of the *sigmoid* function

V Evaluation

Computation time results for ANN and CNN models are shown in Fig. 4 and 5. The code size required to store static and dynamic model parameters are shown in Fig. 6 and 6. Two different host platforms were tested: A generic i5 x86 clocked @2900 MHz (during test) and a STM32F103C8 microcontroller clocked @72 MHz with 20 kB RAM. All tests are processed by the operational same REXA VM. The computation time was normalized to the CPU clock frequency to enable comparison between different platforms. The REXA VM provided a code segment with 6k words capacity and a data stack with 256 words. The VM was compiled with GNU CC (gcc version 7), and the ARM-STM32 version was compiled with the Arduino software toolkit. With the configuration described above, 3 kB RAM remains for the VM program stack, which is sufficient. The REXA VM allocates memory only statically on the heap, there is no dynamic memory allocation during run-time.

The computational times were plotted against the number of neurons (ANN) and cells (CNN). The number of cells of a CNN is the sum of the static parameters and dynamic variables.

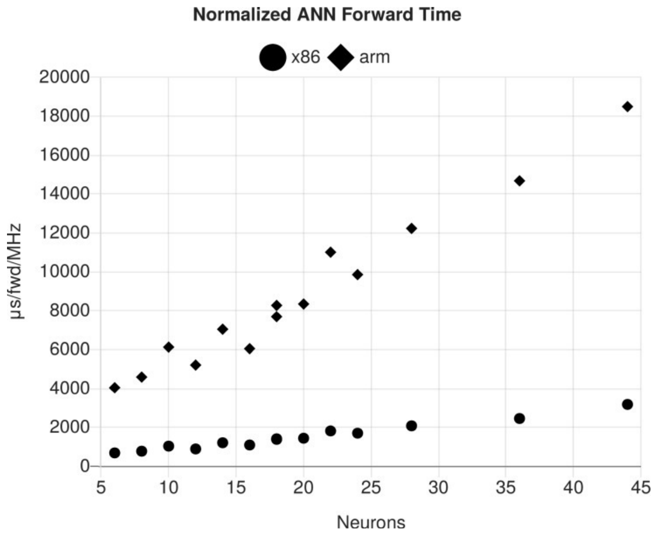

Fig. 4. Normalized computation times for ANNs of different size (with two, three, and four layers) and two different host platforms (Generic i5 x86 @2900 MHz and STM32F103C8 @72MHz) as a function of neurons. The computation time is approximately linear with the number of neurons (independent of network layer structure)

.

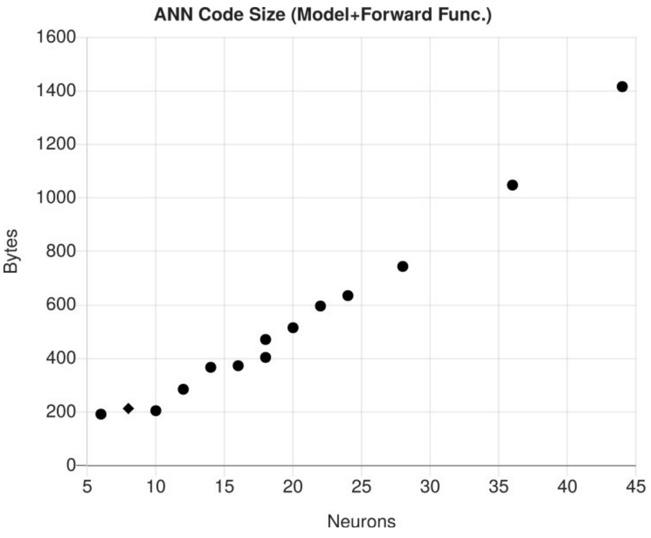

Fig. 6. Code size of ANN as a function of the number of neurons.

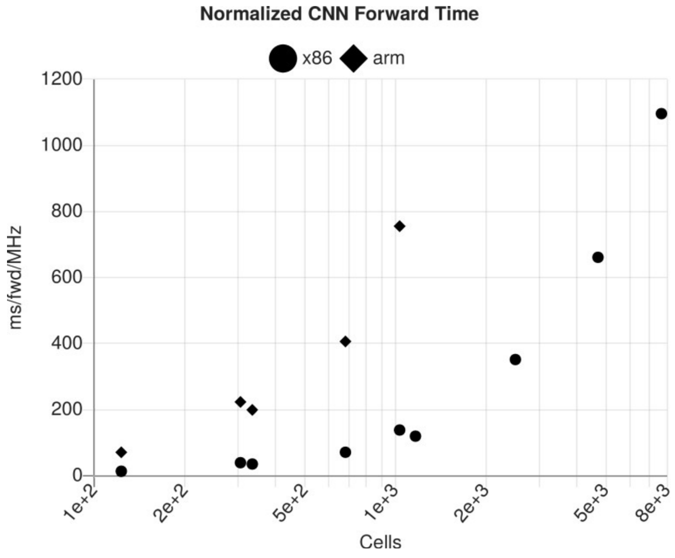

Fig. 5. Normalized computation times for CNNs of different size (with one and two convolution-pooling layer pairs) and two different host platforms (Generic i5 x86 @2900 MHz and STM32F103C8 @72MHz) as a function of cells (product of parameters and variables). The computation time grows about O(*n-log(n)*) with the number of cells *n*.

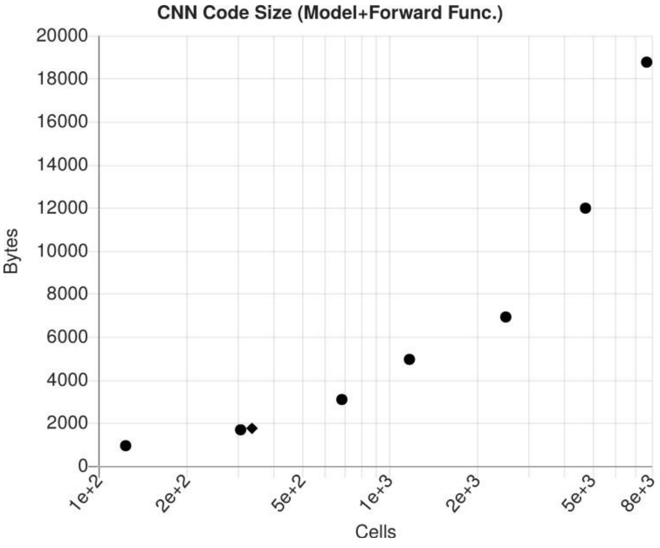

Fig. 7. Code size of CNN as a function of the number of cells.

The performance test shows the suitability of a low-resource microcontroller to store and compute small and medium sized ANN and even smaller CNN models. The forward (inference) computation time is always below one Second, typically about 10-100 ms with 16 MHz clock frequency. The required code space (including model data and code) is below 10 kBytes, typically about 1-2 kBytes. The ARM Cortex M processor under performs by a factor of 5 compared with a x86 processor, which is well known.

VI USE CASES

A Damage detection with an ANN

In this use-case, aggregated feature variables derived from time-dependent Ultrasonic signals (Guided Ultrasonic

Waves, GUW) from multi-path measurements were used to predict a damage in a composite materials and to estimate its location. Details can be found in [13]. The processing architecture is shown in Fig. 8.

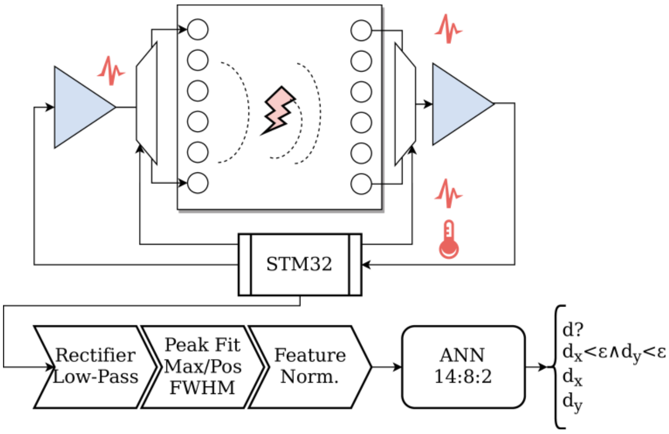

Fig. 8. Multi-path GUW measurement and data processing for damage detection (classification and location regression)

The feature variables were computed from the signal hull, mainly by analyzing the first main maximum (position and width). The hull signal was computed using (1) the analytical signal via the Hilbert transform (using FFT) and (2) by applying a rectifier and low-pass filter. Only the second method can be implemented on the STM32 microcontroller. Assuming six measuring paths and the two most significant feature variables normalized peak position and peak height, additionally using a measure temperature and the base frequency of the pitch signal, the feature vector consists of 14 variables in total. This scaled feature vector is the input for a simple ANN (three layers, one hidden, typical layer structure [14,8,2], sigmoid activation functions). The output of the ANN provided an estimation of the x- and y-coordinates of the damage location (or close to 0 if there is no damage detected). This is a hybrid classification and regression model. If only classification is required, one output neuron is sufficient.

The ANN with a [14,8,1] layer structure providing a binary damage classification was trained and transformed to the proposed integer numerics requiring about 1k Bytes code size, shown in Ex. 1.

Ex. 1. REXA VM program for an ANN classifier for damage prediction from 14 aggregate feature variables and two output variables (parameter values are only for illustration)

The ANN requires only 620 Bytes in the CS memory of the REXA VM. The computation time (prediction) is about 1 ms/MHz (Intel x86 i5, i.e. 0.5μs @2900 MHz) and about 5 ms/MHz (STM32 ARM Cortex).

B Damage detection with a CNN

Similar to the previous use-case, single-path Ultrasonic time-dependent measuring signals are used to predict a damage in a composite material. In contrast to the previous example, no strong aggregate feature variables could be identified. Instead, a discrete wavelet transform using high- and low-pass filters are used to decompose the sensor signal into wavelet coefficients (first 5 levels were chosen). The output of the filters (detail and approximation) are decimated by a factor of two, retaining only the even samples, since each filter output contains half of the frequency content, but an equal amount of samples as the input signal. With increasing level the number of data elements decreases by a factor 2. To provide the output of multiple levels in matrix form, the higher levels are expanded. Here, we shrink the lower levels to the number of elements of the highest level (5). The original signal window contained about 2000 samples, finally providing only 50 data points for the fifth DWT decomposition layer. All DWT vectors are combined into a 50 × 5 elements matrix, treated as a two-dimensional spectogram image. The processing architecture is shown in Fig. 9.

A simple CNN was used to classify signals and predict damages. The CNN consists of one convolution layer with three filters (3 × 3 pixel), striding and padding set to two, output applied to a *relu* function, followed by one max-pooling layer (striding=2, padding=0). Finally, a softmax/fully connected two-neuron layer performs the classification (sigmoid activation function). The REXA VM program is shown in Ex. 2.

Ex. 2. REXA VM program for a CNN classifier for damage prediction from 50 × 5 feature variables (DWT spectogram) and two output variables (parameter values are only for illustration)

The CNN requires only 1500 Bytes in the CS memory of the REXA VM, fitting into a STM32F103C8 (20 kBytes RAM). The computation time (prediction) is about 30 ms/MHz (Intel x86 i5, i.e. 10μs @2900 MHz) and about 150 ms/MHz (STM32 ARM Cortex).

Due to the high integration level and the minimization of components the measuring data is characterized by noise (analog and digital sources), drift, and a superposition by environmental signals (main AC line, e.g.). Despite the data quality limitations, a damage prediction accuracy about 95% can be achieved by the CNN. Considering the low complexity of the CNN, the results showing the suitability of even simple data-driven classifier models processed directly by a material-integrated sensor node with a low-resource microcontroller.

VII Conclusion

The stack-based REXA VM was introduced targeting CPUs with integer arithmetic only and providing virtualization and a unique set of vector operations used to compute Artificial and Convolutional Neural Networks under high resource constrains. It could be shown that even with less than 20 kBytes of RAM memory (simple) CNNs can be computed. The VM has a built just-in-time text-to-Bytecode compiler. A ML model is provided on programming level with a mix of data and computational statements. The VM uses a shared code segment for program text and compiled Bytecode with embedded data without necessity to have a dynamic memory management (heap). The computational times for medium sized ANNs and small CNNs are about 1-300 ms/MHz, reasonable for sef-powered sensor networks. The source code of the REXA VM can be downloaded from github [14].

***Abstract*—With the growing demand for computing power, new multicore architectures have emerged to provide better performance. Reducing their energy consumption is one of the main challenges in achieving high performance computing. Current research trends develop new software and hardware techniques to achieve the best performance and energy compromise. In this work, we investigate the effect of processor frequency scaling using Dynamic Voltage Frequency Scaling on performance and energy consumption for the WZ factorization. This factorization is implemented both without optimization techniques and with strip mining. This technique involves transforming the program loop to improve program performance. Based on time and energy tests, we have shown that for the WZ factorization algorithm, regardless of the presence of manual optimization, it pays to reduce the frequency to save energy without losing performance. The conclusion can be extended to analogous algorithms — also having a high ratio of memory access to computational operations.**

***Index Terms*—processor frequency scaling, performance, energy, WZ factorization**

I. Introduction

MULTICORE architectures are now common in all computing environments, from portable handheld devices to HPC computing platforms and supercomputers. The advent of multicore architectures has increased application performance by allowing them to run at a higher level of parallelism. This opened a new era for High Performance Computing (HPC). Of course, the increase in efficiency is closely related to the increase in energy consumption. Computing energy is currently a serious problem with dire environmental and economic consequences, and its mitigation is extremely important.

Top500 [1] is a website that has been updating the top 500 supercomputers list for performance in the LINPACK [2] benchmark since 1993. GREEN500 [3] is a complementary list to part of the TOP500 list, which since 2007 has ranked the top 500 supercomputers in terms of energy efficiency. The discrepancy between the energy-saving supercomputers and the fastest supercomputers may be seen from their respective positions in both lists. The relationship between performance and energy consumption is unclear and depends on many factors.

Energy efficiency can be achieved on the following two levels: hardware [3] and software [4], [5], [6], [7], [8], [9], [10]. The first approach is based on innovation in computer hardware, represented by microarchitecture and advances in the design of integrated circuits. Based on the software, the second approach can be divided into two categories: optimization of energy consumption at the operating system level and optimization of energy consumption at the application level. The approach to optimizing power consumption at the operating system level focuses on minimizing the power consumption of the entire node through the use of techniques such as clock and power gating [11], dynamic voltage, and frequency scaling (DVFS) [12], [13]. In contrast, application-level optimization methods use application-level parameters and models to maximize the energy efficiency of the application.

Some papers have analyzed the energy impact of numerical linear algebra algorithms that do not change the code but only control software parameters (e.g. block size) accordingly. ATLAS (Automatically Tuned Linear Algebra Software) [14] is an example of the automatic tuning of a library to the architecture of the machine for reducing execution time. The focus of the paper [15] is to propose a method for tuning the ATLAS library, whereby it is possible to replace the execution time tuning process by tuning the energy consumption. In that work, the performance and the number of MFlops/J as well as the execution time and energy consumption were investigated for single and double precision for different array sizes.

In the article [16], different techniques related to algorithm transformation were used to reduce static and dynamic energy consumption on multicore machines with shared memory. In particular, one of the most popular matrix factorizations, namely the LU factorization, was considered. In the LU factorization code, the most energetically expensive instructions were extracted, and then, by performing a code transformation, an attempt was made to reduce their number. That work investigated the effect of the number of threads on dynamic and total energy consumption, performance, and also the number of

MFlops/W for different matrix sizes at a fixed number of threads.

The authors of [17], [18], present algorithms for solving systems of equations, trying to improve their performance, in particular in parallel. Improvement in performance was obtained by appropriate transformation of the underlying algorithm using looping tiling and appropriate data structures. There are currently not too many studies in the literature on the analysis of both efficiency and energy consumption in the context of loop transformations.

In our work, we study a numerical algorithm (the WZ factorization) in which loops are transformed. This algorithm concerns numerical linear algebra, particularly solving systems of equations on multi-core architectures using OpenMP in constant performance and energy consumption.

In this paper, we will focus on the combination of two approaches at the software level, namely the DVFS technique (at the operating system level) and the optimization of the program algorithm (at the application level) on one of the latest multicore architectures. The main idea is to capture the actual performance and energy consumption of a multi-threaded computing application when it is executed on a multicore computing platform by changing the clock frequency.

The LU factorization is a well-known factorization used to solve the linear systems. From the very nature, this factorization is sequential. Throughout recent years, parallel implementations of LU decomposition have been implemented on various modern computers. In particular, the researchers have taken into account the improvement of its parallel performance. The WZ factorization is designed straight into parallel computers of SIMD type according to Flynn classification and it seems to be a potentially attractive alternative to Gaussian elimination or Cholesky factorization for parallel computations, especially for SIMD computers. The advantage of the WZ factorization is that it simultaneously evaluates two columns or two rows instead of one column or one row as it happens with the LU factorization. The WZ factorization has a fewer number of iterations of the loop but more computations in each iteration in comparison with the LU factorization. For the WZ factorization, we can achieve higher parallelism. The algorithms with higher parallelism are desirable for multicore architectures.

In work [19], we presented the detailed implementation of multi-threaded WZ factorization with OpenMP [20] on multicore architecture using various nested loop transformation strategies to program optimization. In this work, we investigate the effect of CPU frequency scaling on performance and energy consumption for the WZ factorization in two selected versions, namely basic and strip-mining (optimized). We selected these versions for testing based on the results of the work [21]. Strip-mining is a loop transformation technique to improve memory performance. Additionally, we are examining the influence of the parameter value of the strip-mining — block size — for the WZ factorization in the strip-mining version on energy efficiency.

The rest of the paper is organized as follows. Section 2 introduces the DVFS technique. Section 3 describes the WZ factorization algorithm using OpenMP programming models in two versions. Section 4 presents the numerical experimental evaluation of the impact of processor frequency scaling on performance and energy consumption for WZ factorization on multicore architecture. Lastly, Section 5 concludes the paper.

II. DVFS — PROCESSOR FREQUENCY SCALING

Nowadays, computers incorporate various energy management techniques that support the reduction of energy consumption. Examples are Dynamic Voltage Frequency Scaling (DVFS) or, for example, the use of special instructions and specialized coprocessors. DVFS [12], [13] is a technique that reduces the clock frequency and voltage level of various computing node components (CPU, DRAM, etc.) at the cost of some performance degradation. Today, DVFS is widely supported by energy-saving and efficient processors supplied by different vendors under different names (eg SpeedStep for Intel [22] and PowerNow processors or Cool'n'Quiet for AMD processors [23]). DVFS can reduce the power consumption of a CMOS chip such as modern processors by reducing the frequency at which it operates as shown in the formula:

$$P = CfV^2 + P_{static}$$

where C is the capacitance of the transistor gates, f is the operating frequency, V is the supply voltage, and P_{static} is a static power which is mainly due to various leakage currents. The voltage required for stable operation is determined by the clock frequency of the circuit and may be reduced if the frequency is also reduced. This can result in a significant reduction in energy consumption due to the compound V^2 shown above.

However, dynamic power CfV^2 alone is not the total power of the system. Due to the static power consumption and the asymptotic execution time, it has been shown that the power consumption of the software shows a convex energy behavior, i.e. there is an optimal processor frequency at which energy consumption is minimized [24].

III. WZ FACTORIZATION

We present shortly the WZ factorization [25], [26]. We transform a square and nonsingular matrix $\mathbf{A}$ into a product of two matrices, namely $\mathbf{WZ}$. The matrix $\mathbf{W}$ is a matrix of the form of a butterfly with units on its main diagonal, the matrix $\mathbf{Z}$ is a matrix of the form of an hourglass. Both the matrices are complements of each other in the sense of the structure of non-trivial elements (one has non-trivial elements in places where the other has zeros/units — and vice versa). The forms of these matrices can be seen in Figure 1.

We chose this numerical algorithm here because it's quite complicated and difficult to optimize by the compiler. Figure 2 presents a parallel basic algorithm for the WZ factorization for an even size of the matrix (we only consider even sizes — without loss of generality).

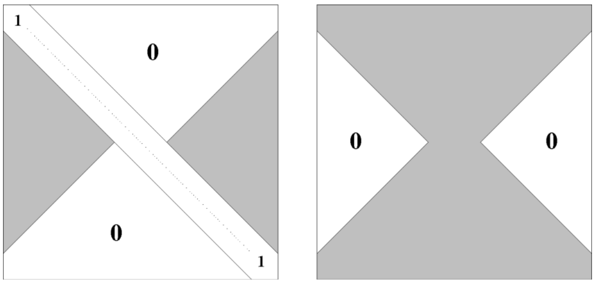

Fig. 1: The output of the WZ factorization — forms of the matrices **W** (left) and **Z** (right).

```
for(k = 0; k < n/2-1; k++) {
    // the following four lines are omitted
    // in the next versions of the algorithms
    // (thay are always the same)
    p = n-k-1;
    akk = a[k][k];    akp = a[k][p];
    apk = a[p][k];    app = a[p][p];
    detinv = 1 / (apk*akp - akk*app);
#pragma omp parallel for
    for(i = k+1; i < p; i++) {
        w[i][k] = (apk*a[i][p] - app*a[i][k])
                  * detinv;
        w[i][p] = (akp*a[i][k] - akk*a[i][p])
                  * detinv;
#pragma simd
        for(j = k+1; j < p; j++)
            a[i][j] = a[i][j]
                      - w[i][k]*a[k][j]
                      - w[i][p]*a[p][j];
    }
}
```

Fig. 2: The parallel basic algorithm for the WZ factorization — pseudocode.

Considering performance and energy consumption, it is important to have optimized algorithms and their implementation. A general technique for improving performance is to take full advantage of feature multicore architectures. A good example is the use in the code of loop optimization as the most common critical places are just the loops. One of the known loop optimization techniques is strip-mining. A loop in the process of strip-mining is divided into two loops, where the inner one has BLOCK_SIZE iterations and the outer one has n/BLOCK_SIZE iterations (n is the number of iterations in the original loop). The strip-mining alone can have some positive impact on the performance (by easing the automatic vectorization process).

In Figure 3, we present a parallel strip-mining algorithm for the WZ factorization with the parameter of this algorithm, namely n/BLOCK_SIZE. We use the compiler clause __assume which tells the compiler that a given condition is fulfilled — here, we declare that ii and jj are multiples of the BLOCK_SIZE.

The number of floating-point operations for the WZ factorization is:

$$\frac{2}{3}n^3 + O(n^2)$$

and number of memory access is:

$$\frac{7}{6}n^3 = O(n^2)$$

what gives the ratio of memory access to computations — $\frac{7}{4}$. This means that we need almost two memory accesses for one floating point operation to perform our algorithm.

```
for(k = 0; k < n/2-1; k++) {
    . . .
#pragma omp parallel for
    for(i = k+1; i < p; i++) {
        w[i][k] = (apk*a[i][p] - app*a[i][k])
                  * detinv;
        w[i][p] = (akp*a[i][k] - akk*a[i][p])
                  * detinv;
        start = RDTTNM(k+1, BLOCK_SIZE);
        for(jj = start; jj < p;
                        jj += BLOCK_SIZE) {
            __assume(jj % BLOCK_SIZE == 0);
#pragma simd
            for(j = jj; j < jj+BLOCK_SIZE;
                        ++j)
                a[i][j] = a[i][j]
                          - w[i][k]*a[k][j]
                          - w[i][p]*a[p][j];
        }
    }
}
```

Fig. 3: Parallel strip-mining in the basic algorithm — pseudocode.

IV. Numerical Experiments

A. *Methodology*

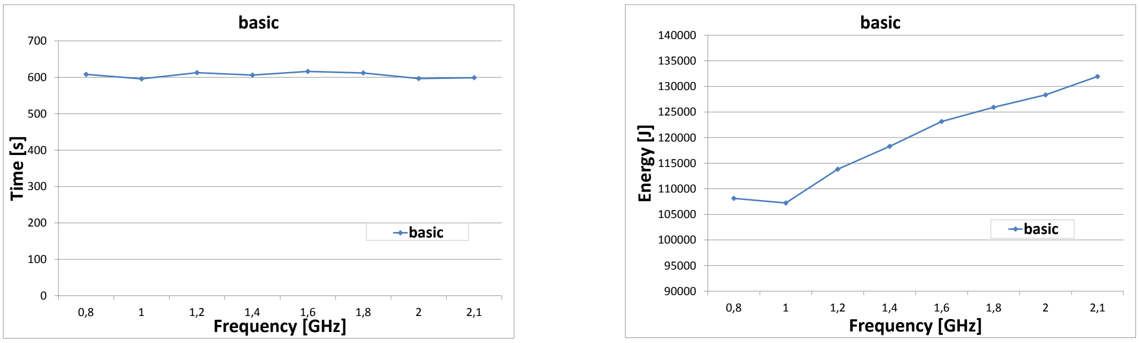
We test two types of versions of the WZ factorization algorithm: the basic algorithm and block algorithms with strip-mining. Our test dataset is a random square matrix with dimensions of $n \times n$ double-precision values, $n = 32768$. So our test dataset is 1073741824 cells, which is 8GB of data. All versions of the algorithm match the row-wise layout and are implemented in C++ with vectorization and parallelism. The following block sizes were checked during the tests: 64, 128, 256, 512.

Our experimental setup includes the following computing platform equipped with a multicore processor with the following parameters:

- processor: Intel(R) Xeon(R) Gold 5218R
- CPU @ 2.10GHz HT (2x20 cores)
- Cache: L1: 32KB, L2:1024KB, L3: 28MB

The following software was installed during tests:

- operating system: CentOS 7.5;
- kernel: Linux 3.10.0;



(a) Runtime

(b) Energy consumption

Fig. 4: Runtime and energy consumption of `basic` for data size 32768

TABLE I: Energy efficiency for `basic` (32768)

Frequency [GHz]	Time [s]	Total energy [J]	Performance [Gflops]	Energy efficiency [Gflops/J]
0.8	607.88	108132.066	38.59	0.217
1.0	**595.58**	**107218.43**	**39.38**	**0.219**
1.2	612.59	113827.77	38.29	0.206

1.8	611.79	125920.48	38.34	0.186
2.0	596.57	128343.30	39.32	0.183
2.1	598.88	131927.20	39.17	0.178

- icc compiler v. 2021.5.0 with the following compiler options:
  `-qoenmp -O3 -ipo -no-prec-div`
  `-fp-model fast=2`

We used the RAPL (Running Average Power Limit) interface [27] to measure the power and energy consumption of CPU-level components. We access RAPL energy meters via Machine-Specific Registers (MSR). Counters are 32-bit registers that indicate the amount of energy used since the processor was started, they are updated approximately once every 1 ms or 1000 Hz. Since its introduction, RAPL has been widely used in energy measurement and modeling. The results presented in the work [27] suggest that RAPL can be a very useful tool for measuring and monitoring energy consumption on multicore computers without the need to implement complicated power meters. The experience of the authors of the work [28] and our experience [21], [29] with RAPL confirms the results from the literature. RAPL is able to measure the energy consumption of a complex scientific application with acceptable accuracy and detail.

We carry out 5 iterations of each version of the algorithm for each tested frequency and then average the results to obtain a statistically correct result. As shown in [21], running HT for the tested versions of the WZ factorization algorithm has no benefit in speeding up the calculations so we run all versions without HT on 40 threads.

We made changes to the clock frequencies using CPU frequency scaling. The `intel_pstate` driver is used by default to control the performance of Intel processors on GNU/Linux systems. With this driver, we did not get a satisfactory effect of forcing the clock frequency, so we used the `acpi_cpufreq` driver, which by default follows the `conservative` governor. Governor `conservative` increases or decreases the clock frequency depending on the core load, selecting one of several available frequencies from the minimum to the maximum supported by the editor. For the Intel Xeon Gold 5218R processors we use, the permissible frequencies range from 0.8 GHz to 2.1 GHz. Using the `cpupower` program, we change the minimum and maximum values of the CPU frequency limit to a given level. The frequency setting was done for all cores of both installed processors with the commands:

```
cpupower frequency-set -d 1800000
cpupower frequency-set -u 1800000
```

for setting the minimum and maximum frequency limit values to 1.8 GHz.

We conducted our tests for frequencies ranging from 0.8 GHz to 2.1 GHz, making changes every 0.2 GHz, 0.8 GHz is the lowest frequency to which we could lower the clock.

B. The performance and energy consumption for `basic` WZ factorization algorithm

First, we measure the runtime of the `basic` version of the WZ factorization algorithm. The test results are presented in Figure 4.

In Figure 4 on the left diagram we can see that the algorithm runtime is similar regardless of the clock frequency. The difference between the shortest operating time (frequency 1.0

GHz) and the longest (frequency 1.6 GHz) is 3% (20 seconds). In Figure 4 on the right diagram we can see that the energy consumption increases with increasing clock frequency. For a higher frequency, we have a greater instantaneous power consumption, hence, with a similar runtime, we have a greater energy consumption. We have the lowest energy consumption for the frequency of 1.0 GHz. Lots of energy were consumed at the highest frequency. Lowering the clock frequency to 1.0 GHz saves about 19% of the energy consumed here.

In Table I, we have a summary of the runtime, total energy, performance, and energy efficiency for the `basic` algorithm. We can see that both the best performance and the energy efficiency of the algorithm will be achieved at the frequency of 1.0 GHz. Thus, there are benefits to lowering the clock frequency.

C. The performance and energy consumption for `basic-sm` versions of WZ factorization algorithm

Next, we test block versions of the WZ factorization algorithm with strip-mining (abbreviated as `sm`). We consider four block sizes: 64, 128, 256, 512 so we have the following versions: `basic-sm-64`, `basic-sm-128`, `basic-sm-256`, `basic-sm-512`. Our goal is to answer the question of whether the `sm` optimization will affect the performance and energy consumption and whether the additional clock frequency scaling for the `sm` version will also have a positive effect on the reduction of energy consumption without loss of performance.

The test results are presented in Figure 5. Here we see a similar situation as in the case of the `basic` version, the operating time of the tested versions of the algorithm slightly fluctuates for different frequencies (left diagram in Figure 5), while the energy consumption increases with increasing frequency (right diagram in Figure 5). We can also observe that the lowest energy consumption for each of the tested blocks was for the lowest tested frequency: 0.8 GHz. In addition, we can notice that, regardless of the frequency, block 64 was the weakest, both in terms of operating time and energy consumed. The best, however, are blocks 256 and 512.

In Table II and Table III, we have a summary of the runtime, total energy, performance and energy efficiency for the `basic-sm-256` and `basic-sm-512` versions of algorithm respectively.

In this case, other than for the `basic` version of the algorithm, the best performance and the best energy efficiency are not achieved for the same frequency. It is the same for both blocks, the best performance was obtained for the 1.4 GHz frequency and the best efficiency for 0.8 GHz. Here, too, we can infer that lowering the frequency (in the case of our algorithm to 0.8 GHz) results in less energy consumption. We save 21% of energy consumption without losing time for block 256 and save 19% of energy consumption lose about 2% (11 seconds) of time for block 512 compared to 2.1 GHz. If we look at high frequencies (2.0 and 2.1 GHz), we get slightly better results in terms of efficiency and energy efficiency for block 512 compared to block 256. However, if we want to reduce energy consumption without losing time, a bit better results are observed for block 256. The Figure 6 shows a juxtaposition of tests for the `basic` and `baisc-sm -256` versions. Lowering the clock to 0.8 GHz we can see that strip-mining will pay off regardless of the clock frequency. Meanwhile, if we use the clock frequency reduction mechanism, we can get 21% for `basic-sm-256` without wasting time, and for `basic` equal to 19% without wasting time, but for `basic-sm-256` it pays to lower the clock frequency to 0.8 GHz, and for `basic` it is enough to 1.0 GHz.

V. Conclusion

In this paper, we focused on the combination of two approaches, namely the DVFS technique and the optimization of the strip-mining loop. Our goal was to answer the question of whether traditional methods of strip-mining loop optimization in combination with the DVFS technique will reduce energy consumption without major losses on performance. Measurements were made on a 2nd Generation Intel Xeon Scalable Processors using the Intel RAPL interface.

There are a lot of memory references in our algorithm, so frequency scaling does not significantly affect performance, as our tests showed. The reduction of the frequency to the level of 0.8–1.0 GHz did not cause a decrease in performance in the case of the `basic` version, Table I. We improved memory access using strip-mining transformation, which resulted in a performance increase of about 9%. Although in the case of the `basic-sm` versions lowering frequency we lose a bit of performance (less than 2%, Table II), we can still lower the frequency while maintaining better performance than for the basic version.

Our tests also showed two facts. First, the first version of the `basic` will use more energy than the `basic-sm`, which means that the strip-mining transformation will pay off. Second, with this algorithm, the frequency scaling affects the energy consumption. By reducing the frequency to 0.8 GHz, we can reduce the power consumption for `basic-sm-256` by 21%, Table II.

The conclusion from our tests is that the highest frequency is not always the best in terms of time and energy consumption. For the WZ factorization algorithm, it pays to reduce the frequency to save energy without losing performance. The frequency that works best during experiments is the smallest that can be tested here, i.e. 0.8 GHz.

In the future, we plan to extend our tests by a wide one a range of architectures, including graphics cards. Moreover, we will evaluate the performance and energy consumption impact of various execution systems for OpenMP loop configurations and transformations for WZ and the three decomposition main kernels in dense linear algebra algorithms (Cholesky, LU and QR).

***Abstract*—The flow and accumulation of water are essential aspects when it comes to generating realistic terrains. In this article, we have set out to create a method for generating the distribution and levels of water in a virtual world. Our method fully simulates the water entering and exiting the system through rainfall, perspiration, and flowing out of the domain. Also, it simulates the phenomena of flow and accumulation in an iterative process. According to our observations, only allowing the user to influence the terrain and then simulating the placement of water bodies provides a natural result while preserving a high level of control.**

I. Introduction

THE rapid growth of the game and movie industries has generated a rise in demand for virtual worlds generation methods, especially when generating realistic natural environments. Modeling the environment by hand is, of course, still possible but only realistic when it comes to small parts of the vast virtual worlds that have become common. The workforce needed to create a whole extensive world by hand would be too substantial to consider these days. That is why the need for an automatic generation has drastically risen over the last decade to shorten this possibly tedious process.

The field in recent years has been moving in various directions depending on the use case being considered. Some algorithms focus purely on generating realistic natural environments from a humble set of parameters. While these methods usually provide very little control over the result, they are strongly based on geological knowledge (like tectonic plates) and climate data [1] and produce compelling results. These algorithms provide the foundation for most automatic world generation research. However, since the desired methods are supposed to replace modeling by hand, the methods at the forefront of interest usually provide much control over the result while still retaining a satisfying level of realism. The user may want to place mountain tops in certain specific places or keep a section of the environment flat. Unfortunately, the problem that arises seems to be that walking that thin line between control and realism is not so obvious and means that some natural processes might become neglected in the generation process.

We have observed that one of the environmental aspects that has a high chance of being treated like that is the placement and flow of water bodies in the result. While the methods usually aim for realistic placement of rivers and lakes, it is achieved mainly by some heuristic metrics rather than simulation loops. In most cases, the water bodies are just placed according to the positions specified by the user, and the environment is supposed to adjust independently to those requirements.

Since the flow and accumulation of water are essential aspects when it comes to keeping the veil of realism intact, we have set out to create a method for generating the distribution and levels of water in a virtual world. We have decided on a method that fully simulates the process of water entering and exiting the system (through rainfall, perspiration, and flowing out of the domain) and also simulates the phenomena of flow and accumulation in an iterative process. The method in itself does not offer much control over the result. However, the user can still use a terrain generation method which allows for controlling the shape of the terrain and place valleys and depressions in places where they want rivers and lakes to appear, and by applying our algorithm after that, the likelihood of meeting those water bodies placement expectations is very high. We have observed that only giving the user the ability to influence the terrain and then simulating the placement of water bodies naturally usually provides a very natural result while still preserving a high level of control based on our human intuition of where water is most likely to flow in a system of a given shape.

II. Related work

Terrain generation methods are usually grouped into two distinct categories based on their output. The first and more popular category is generating a heightfield representing the resulting terrain. In contrast, the second group of algorithms focuses on producing a three-dimensional output using various volumetric structures.

We first examine the former category, which, while having some apparent drawbacks – not being able to model things like caves and overhangs – usually provides the performance edge, which is invaluable for most iterative world creation pipelines [2]. One approach to the problem of 2D generation is constructing the terrain from primitive structures and defining their connections using a tree structure [3]. The primitives can be modeled by hand or generated from real-life data, for instance, using point cloud data from photogrammetry [4]. The method can yield compelling results, but the quality depends on the artist's skill in fitting those primitives together. While still cutting much modeling time, this approach cannot guarantee realistic results and will only provide partially automatic generation.

A significant subset of methods focuses on getting a more realistic result by employing geological knowledge. One of the aspects which can be used is the presence of tectonic plates since the process of forming mountains is influenced mainly by their movement and the placement of their borders. The position and shape of the plates can be generated from features that the user wants to appear in the final result, like the position of mountain tops and rivers [5]. The tectonic plate information can then be used to simulate the geological terrain folding process. Another example of using geological knowledge would be generating the resulting terrain using examples from the real world. Various distributions of geological parameters can be gathered for specific regions of the Earth, like the Himalayas or Norwegian fjords. Given some user input like positions and heights of mountain tops, the generation process can then try to recreate those distributions in the virtual environment [6]. This can produce convincing and realistic results, but since the output is majorly based on real-life data, it is limited to only resembling naturally occurring environments.

Rough sketches of the desired results can also guide the generation of terrains. The user could draw a 2D representation of the required scene using color-coded shapes or control points representing various topographical features like mountain ridges, plateaus, rivers, etc. [7], [8]. Unfortunately, this approach, like some of the methods mentioned above, suffers from very varied levels of realism in the resulting terrain based on the input data.

A good compromise between control and realism seems to be allowing the user to create maps of geological parameters that should be applied to the domain instead of specific topographical features that must appear in the resulting terrain. One such geological parameter is the tectonic uplift defining the growth rate of a particular point in the two-dimensional domain. The generation method can then simulate the growth of mountain ranges using the geological data provided while considering other factors like fluvial erosion [9].

Now we focus on the volumetric algorithms to briefly overview the rest of the generation methods spectrum. After adding dimension, a primitive-based modeling solution is still an excellent way to produce a convincing environment. It seems to be one of the most prominent methods for volumetric generation. One possible approach is basing the primitive structures on B-splines [10], which most artists are used to working with. The result becomes more flexible since it can model things like overhangs, allowing for smoother control but straying further from geological realism. The terrain could also be generated using a generalization of the previously mentioned primitive tree-based method [11]. Unfortunately, since the primitives must now be positioned across three dimensions, the work required to create desired scenes significantly increases.

There also exists a middle ground between the two representations – each point on a flat plane could hold a series of layers that are present above it together with their heights, representing a narrow column of the resulting terrain. This approach could either be used in conjunction with the standard two-dimensional methods or be extended with the ability to create a layer containing only air, allowing us to model things like caves and overhangs [12].

What most of the described methods have in common is that they treat the placement of water bodies in the result more like an afterthought rather than a significant step of the algorithm. Rivers and lakes are usually generated using heuristic methods to fit the generated environment, or their placement is dictated purely by the input data, which allows for setting their positions by the user almost entirely.

To design our algorithm, we needed to choose a terrain generation algorithm that would serve as a base for our water flow simulation. We have decided on using the method by Cordonnier at al. [9], which – apart from using the previously mentioned uplift maps – also considers the flow of water to be a significant factor in the process of erosion that is being simulated. This allowed us to use some of the water flow data structures already present in the solution as a jumping-off point for our method.

III. Method

A. Starting off point

The base method [9] operates over domain $\Omega \subset \mathbb{R}^2$ and aims to compute the function $h\colon \Omega \to \mathbb{R}$ representing the height of the terrain at each domain point. During the initialization step the method generates a terrain graph G defined over a discretization of the domain achieved by computing the Voronoi cells of points distributed over the domain using the Poisson distribution. In order to perform the fluvial erosion step the algorithm also computes a directed stream graph G_S, based on the same nodes as graph G, representing the water flow in the system, which serves as the foundation of our method.

Each node v in the graph G_S is represented by the cell's surface area a_v and a generating point p_v. The edges in the graph G_S represent the flow of water. Each node is connected to its lowest (in terms of height during this iteration) neighboring region, apart from points on the very edge of the domain where we assume the water flows out of the system. This creates disjointed components in the graph G_S (each in a form of a directed tree with the lowest - in terms of height - node forming the root), which in the original method are called lakes. Connection between these trees are stored in a separate lake graph G_L with edges defining the lowest connection between them - the minimum height at which one lake would start overflowing to the other.

The base method performs an additional step to merge the trees in G_S (representing lakes) into a complete graph. This is done by connecting them according to the connections in G_L. The algorithm allows itself to do that based on the assumption that all lakes are fully filled at all times – an assumption that we reject in the design of our method. That is why our solution is based on a disconnected stream graph; any mentions of it from now on will refer to this version.

At the base level of the solution, we have also incorporated different types of rock layers into the terrain representation [13]. Each point in the domain bears the characteristics of all layers below it with appropriate weights. This modification improves the overall realism of the result but does not influence the structure of the proposed water accumulation algorithm.

B. Algorithm modification

Algorithm 1 presents a general description of our modified fluvial erosion algorithm. A water accumulation step, performed during each iteration, and a lakes computation step have been added. Since a stream graph built for the current elevation of nodes is required for the correct computation of lakes, it is necessary to recreate this graph after the last change in elevation caused by erosion.

Algorithm 1 Base fluvial erosion algorithm [9] extended by adding water accumulation and lakes computation (underlined sections)

```
Require: $u$ {uplift map}, $i_{max}$ {maximum number of iterations} and $P$ {terrain sample points}
compute terrain graph $G$
for $i = 1$ to $i_{max}$ do
    compute stream graph $G_S$
    update accumulated water level in $G$
    update $G_S$ with edges resulting from lake overflow
    compute the new elevation values $h(v)$ after uplift and erosion for $v \in V(G)$
end for
compute stream graph $G_S$
update accumulated water level in $G$
compute the lakes list $L$
determine the elevation values $h(p)$ for $p \in P$ by interpolating values $h(v)$ for $v \in V(G)$
return $h$ {elevation map} and $L$ {lakes list}
```

1) Water accumulation: Each vertex v of the terrain graph G stores information about the volume V_v of water collected on the part of the terrain represented by this vertex. The initial value of V_v is 0.

In this model, it was assumed that two factors had the most significant impact on the change in the accumulated water level: the increase in water resulting from precipitation and the evaporation phenomenon. Let us consider the first one. Due to the immense time scale of the simulation (millions of years), we assume that the amount of water that will accumulate at the bottom of the lake represented by its root v during a given iteration will be proportional to the time δt of the iteration and the basin area A_v, i.e.,

$$V_v^{rain}(t + \delta t) = \delta t \cdot rA_v(t + \delta t),$$

where r is a constant describing the amount of precipitation per unit area.

The evaporation phenomenon leads to a partial loss of water in each iteration. We assume that the amount of water that has evaporated will be proportional to the iteration time and the area of the considered lake. Studies on the characteristics of natural lakes [14] have shown that the relationship between the volume V of a lake and its water surface S is approximately $V \sim S^{6/5}$. Thus, the volume of water lost can be written as:

$$V_v^{evap}(t + \delta t) = \delta t \cdot eS_v = \delta t \cdot eV_v^{5/6}(t),$$

where e is a constant controlling the evaporation rate. Using this approximation allows us to estimate the water loss due to evaporation without repeatedly determining the actual areas of the lakes.

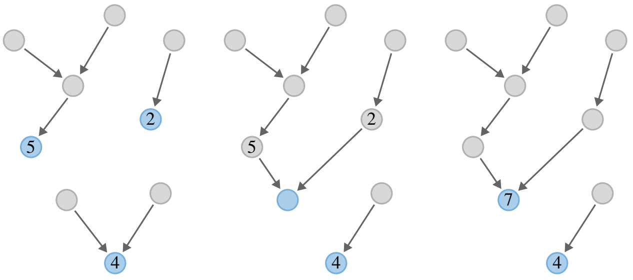
The formula for changing the volume of water during an iteration of δt is then:

$$\Delta V_v(t + \delta t) = \delta t \left(rA_v(t + \delta t) - eV_v^{5/6}(t) \right).$$

It is also worth noting that because each iteration of the stream graph G_S contains different connections, it is necessary to traverse all the vertices belonging to a given subtree and move the water accumulated in them so far to the current root. This step is performed before calculating the change in water volume so that water accumulated at other vertices can also participate in evaporation. The water-shifting process is illustrated in Figure 1.

In the stream graph G_S created during each iteration of the algorithm, roots of trees contained in G_S do not have receivers – water does not flow from them to another node. If the tree's root is at the edge of the terrain, we can assume that rainfall water flows out of the domain. Otherwise, the water should stagnate in the area of the tree (starting from the root), creating a lake.

2) Computing and merging lakes: The key element of the described modification is the algorithm for determining the water level in each lake. The non-trivial nature of this task results from the fact that more water can be accumulated in the lake than the surrounding area can hold. Therefore, a solution is needed that will allow for modeling the flow of water between lakes, as well as combining several lakes into



(a) i-th iteration (b) $(i + 1)$-th iteration (c) result

Fig. 1. The process of water shifting to its current roots in a stream graph. The numbers in the vertices indicate the volume of water accumulated in them. Different edge structure between iterations is caused by the erosion process which changes the height of the nodes resulting in the need to update the stream graph.

Algorithm 2 Determining the water level in lakes

```
Require: $G_S$ {stream graph}
$G_L \leftarrow$ lakes graph determined by $G_S$
$L \leftarrow V(G_L)$ {merged lakes set}
for all lakes $k$ in $V(G_L)$ do
    $v \leftarrow$ root of $k$
    $V_k^{rem} \leftarrow V_v$ {the water remaining to fill up is all the water collected in the root}
    $V_k^{acc} \leftarrow 0$ {water accumulated in a given lake}
    $l_k \leftarrow$ neighbor of $k$, to which the lowest passage from $k$ leads
    $V_k^{miss} \leftarrow$ the amount of water needed to reach the crossing height $(k, l_k)$
end for
while the flow is non-zero or no lakes have merged do
    $s \leftarrow$ network source, $t \leftarrow$ network sink
    $N \leftarrow$ empty lake network; $V(N) = \{L, s, t\}$
    for all lakes $k$ in $L$ do
        if $V_k^{rem} > 0$ then
            append to $N$ arc $(s, k)$ with capacity $V_k^{rem}$
        end if
        if $V_k^{miss} > 0$ then
            append to $N$ arc $(k, t)$ with capacity $V_k^{miss}$
        else
            append to $N$ arc $(k, l_k)$ with capacity $\infty$
        end if
    end for
    $SCC \leftarrow$ set of strongly connected components in $N$
    for all strongly connected components $H$ in $SCC$ such that $|H| > 1$ do
        collapse the vertices belonging to $H$ into one pool $m$
        determine $l_m$ and $V_m^{miss}$
        remove the component lakes and add a new merged lake $m$ to $L$
    end for
    $F \leftarrow$ maximal flow in $N$
    for all arcs coming from the source $(s, k)$ in $F$ do
        subtract the flow value at $(s, k)$ from $V_k^{rem}$
    end for
    for all arcs entering the sink $(k, t)$ in $F$ do
        add the flow value at $(k, t)$ to $V_k^{acc}$
        subtract the flow value at $(k, t)$ from $V_k^{miss}$
    end for
end while
for all lakes $k$ in $V(G_L)$ do
    $h^{acc} \leftarrow$ water level based on $V_k^{acc}$
end for
return $G_L$ {graph of lakes supplemented with information about the water level $h^{acc}$}
```

one. The pseudocode of the developed algorithm is described in Algorithm 2.

a) Computation of water volume and surface height: During the algorithm, it is necessary to determine the volume of water required to reach a certain surface height. We can approximate the volume of the lake by the sum of prisms whose bases are the Voronoi cells of individual vertices of the terrain graph located underwater, and the height is the difference between the height of the surface h^{acc} and the height of the vertex h_v. The volume approximation method is illustrated in Figure 2 and described in Algorithm 3.

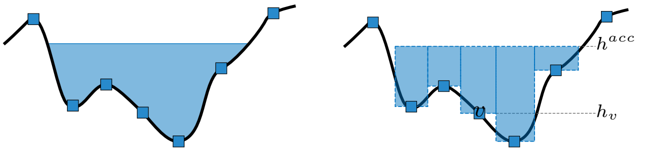
Algorithm 3 Determining the volume of water needed to reach the given height of the surface

```
Require: $G_S$ {stream graph}, $k$ {lake}, $V_k^{acc}$ {volume of water accumulated in a given lake} and $h^{target}$ {target surface height}
$V^{total} \leftarrow 0$
$Q \leftarrow$ empty queue
for all lakes $l$ forming part of the combined lake $k$ do
    if root of $l$ is below $h^{target}$ then
        append root of $l$ to $Q$
    end if
end for
while $Q$ is not empty do
    remove vertex $v$ from $Q$
    $V^{total} = V^{total} + a_v \cdot (h^{target} - h_v)$
    for all nodes $w$ in the set of children of $v$ do
        if $h_w < h^{target}$ then
            append $w$ to $Q$
        end if
    end for
end while
$V_k^{miss} \leftarrow V^{total} - V_k^{acc}$
return $V_k^{miss}$ {the amount of water needed to reach a given height}
```

It is worth noting that the lake for which calculations are made can be either a single tree in the stream graph or a combination of several trees into one merged lake.

At the end of the lake computation algorithm, a reverse operation is required, i.e., calculating the height of the water surface based on the volume of collected water. The method chosen for this purpose consists of gradually flooding the tops of the lake to increase the height until the lowest unflooded top is above the existing water surface. A detailed description of this step is provided in Algorithm 4.

b) Finding strongly connected components: Strongly connected components are essential in constructing a network describing the water flow between lakes. They represent



(a) The actual volume of water in the lake

(b) Approximating the volume of water by the sum of the prisms

Fig. 2. Cross-section of an example lake filled with water to the level of h^{acc}

Algorithm 4 Determining the height of the lake surface for a given volume of water

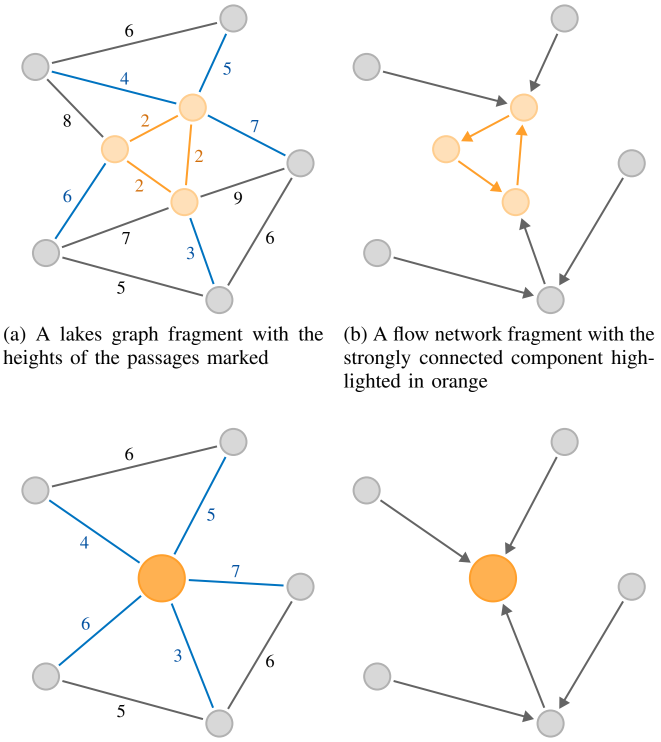
```
Ensure: $G_S$ {stream graph}, $k$ {lake} and $V_k^{acc}$ {volume of water accumulated in a given lake}
  $Q \leftarrow$ empty priority queue {priority – lowest height}
  $V_k^{below} \leftarrow 0$ {volume of land under the lake}
  $A_k^{acc} \leftarrow 0$ {surface area}
  $h_k^{acc} \leftarrow \infty$
  for all lakes $l$ forming part of the combined lake $k$ do
    append root of $l$ to $Q$
  end for
  while $Q$ is not empty and the lowest vertex of $Q$ is below $h_k^{acc}$ do
    remove the lowest vertex $v$ from $Q$
    $A_k^{acc} \leftarrow A_k^{acc} + a_v$
    $V_k^{below} \leftarrow V_k^{below} + a_v \cdot h_v$
    $h_k^{acc} \leftarrow \frac{V_k^{acc} + V_k^{below}}{A_k^{acc}}$
    for all nodes $w$ in the set of children of $v$ do
      if $h_w < h_k^{acc}$ then
        append $w$ to $Q$
      end if
    end for
  end while
  return $h_k^{acc}$ {surface height}
```

groups of two or more lakes connected by passages at the same height and filled with water at least up to that height. Adding water to the system of lakes thus connected would result in a combined rise in the level of all the constituent lakes. To model this behavior, lakes belonging to the strongly connected component are represented by one vertex when determining the flow. This means that the water flow network and the lake graph G_L must be modified at each iteration, as shown in Figure 3.

Tarjan's algorithm [15] was used to find strongly connected components in the directed lake graph G_L. It allows us to determine all such components in time $O(V+E)$. Since each vertex except sources and sinks has precisely one outgoing arc in the considered network, the complexity, in this case, will be $O(M)$, where M is the number of lakes.

c) Computing the maximum flow: Flow in a network of lakes allows the determination of the amount of water flowing out of each lake and into each lake. The arcs from the source to the lakes with the capacity of the collected water model the water that directly flows into the basin of a given lake due to precipitation. The arcs from the lakes to the estuary with a capacity representing the volume to the lowest passage represent the water accumulating in the basin. The arches between the lakes allow water to flow through passages.

Push-relabel is the chosen algorithm for determining the maximum flow in the network. An appropriate implementation of this algorithm [16] allows obtaining a complexity of $O(V^2\sqrt{E})$, which in the case of the considered network is $O(M^2\sqrt{M})$.



(a) A lakes graph fragment with the heights of the passages marked

(b) A flow network fragment with the strongly connected component highlighted in orange

(c) A lakes graph fragment after the collapse of the strongly connected component. Only those edges incident with the component, which have the smallest height, are left

(d) A flow network fragment after the collapse of the strongly connected component

Fig. 3. Modification of the lakes graph and the water flow network as a result of replacing the strongly connected component with one merged lake

d) Optimizations: The first optional optimization of the lake computation algorithm is the step of joining pairs of lakes for which the lowest passage is at the same level as both of their roots. This situation occurs primarily in the first iterations of the erosion algorithm when many vertices are at the same level. This optimization will connect many lakes that consist of only one vertex, significantly reducing the lake network's size.

The second optimization used consists of the lakes' initial filling with the water collected in them. This step is done after executing the 8 line in Algorithm 2. For lake k, V_k^{acc} becomes $\min(V_k^{rem}, V_k^{miss})$, and V_k^{rem} and V_k^{miss} will be reduced by same amount. This means that if more water has accumulated in the lake than is necessary to fill it, then already in the first iteration of the lake computation algorithm, water from it can flow to the remaining reservoirs.

3) Computational complexity: The water accumulation step involves traversing the stream graph to move water from the non-root vertices to the roots and determining a new value for each lake's water volume. Hence the complexity of this step is $O(N+M) = O(N)$, where N is the node count in stream graph G_S. Since each iteration of the basic fluvial erosion algorithm requires $O(L \cdot N + M \log M)$ operations, where L

is the terrain layer count, adding a water accumulation step does not affect the complexity of the iterations.

In order to determine the complexity of the lake determination algorithm, all steps described in the Algorithm 2 should be considered. Determining the lakes graph in line 1 has a complexity of $O(N)$ due to the need to traverse all edges of the terrain graph and its planarity. The loop in line 3 executes M times, calling Algorithm 3 for each lake. However, since within Algorithm 3, each vertex of the terrain graph will be queued at most once, the total execution time for all iterations of this loop will be $O(N)$. The situation for the loop in line 38 is analogous, so this fragment also has a complexity of $O(N)$.

Let us now consider the execution time of one iteration of the lake determination algorithm. The complexity of the loops in 13, 30 and 33 is $O(M)$. Finding strongly connected components using Tarjan's algorithm also requires $O(M)$ operations. Collapsing them into one vertex is also $O(M)$ complex. This step involves traversing all the vertices of the found components and updating the arcs in the network incident with those vertices. We assume that we can find a specific arc and then modify or delete it in constant time, which is possible, for example, by using hash tables as collections of arcs. The most demanding operation, with a complexity of $O(M^2\sqrt{M})$, is finding the maximum flow in the network.

The last key issue is the number of iterations performed by the lake determination algorithm. The chosen stopping condition means that in each iteration except the last one, there must be either a combination of at least one strongly connected component with a cardinality greater than 1 into one lake or a non-zero flow.

Each iteration in which a newly merged lake is created reduces the number of network vertices representing the lakes by a minimum of one. This means that at most $M-1$ of such iterations is possible.

The lake merging operation is the algorithm's only element that modifies the network structure between successive iterations. This means that if the lakes do not connect, the network in the next iteration will be the same network with the volumes of the arcs minus the value of the last maximum flow, resulting in zero flow. There can therefore be at most M iterations in which the lakes do not merge. Hence the total number of iterations is limited by $O(M)$.

The total computational complexity of the lake determination step is $O(N + M^3\sqrt{M})$. It is worth noting, however, that the number of vertices in the network decreases with each strongly connected component collapse, so in practice, later iterations of the water level determination algorithm run faster.

4) Computation of lakes and the basic erosion algorithm: In our modified fluvial erosion algorithm, water overflow between lakes is a separate step independent of lake overflow during the iteration. This approach proved necessary to preserve the realistic and varied resulting terrain.

The first attempts to extend the erosion algorithm consisted of replacing the original overflow of lakes with a model that would consider water stagnating in depressions. However, this approach did not produce the expected results. Since the terrain was almost flat in the first iterations, the water stagnated at numerous points and led to the formation of craters. It was, therefore, necessary to separate the overflowing and the computation of lakes. The first of these stages allows us to shape the relief, while the second only determines which places in the existing area should be flooded with water.

5) Elevation computation for vertices on the boundary of the domain: The original version of the fluvial erosion algorithm described in [9] assumes that vertices of the terrain graph located on the edge of the domain never change the height. As a result, the edge of the resulting terrain is always at 0. As the rest of the land is uplifted, this leads to the formation of a steep slope along the entire length of the border.

This problem can be eliminated by determining the vertices' elevations on the domain's border in the same way as for the other vertices. However, since some of these vertices do not have receivers, it is necessary to modify the original formula [9, eq. (2)].

The proposed modification consists in replacing the value $h_w(t + \delta t)$ with 0 and replacing the distance $\|\mathbf{p}_v - \mathbf{p}_w\|$ with a large constant, for example, the domain size. This is equivalent to introducing artificial vertices of constant elevation 0 into the terrain graph, which are ignored when determining rivers and lakes. So the formula for vertices without a receiver is:

$$h_v(t + \delta t) = \frac{h_v(t) + \delta t u_v}{1 + \dfrac{k\sqrt{A_v}}{D}\delta t},$$

where D is the domain size.

Thanks to this modification, the resulting terrain has a natural-looking edge. It gives the impression of a fragment cut out from a larger area, allowing it to be used in various applications without additional processing. In addition, the terrain more accurately reflects the features marked on the uplift speed map, giving the user more control over the outcome.

IV. Results analysis

The new proposed version of the whole terrain generation algorithm has been implemented in C++ as an *Unreal Engine 5* plugin. The plugin allows the user to generate terrain based on required input parameters and save it in one of the available formats. All reported results were obtained on a PC with an AMD Ryzen 7 1700 3.0 GHz and 16 GB RAM, supplied with an NVIDIA GeForce GTX 1080.

The algorithm's parameters allow the user to control the amount of water accumulating in lakes as well as decide the threshold for considering a stream of water to be a river. Figure 4 shows an example of the result of our method with generated lakes and rivers on display.

Figure 5 demonstrates the influence of the water accumulation parameters on resulting lakes. An increase in precipitation creates an increase in water flow in the system, which raises the water levels of the lakes, possibly even causing overflow

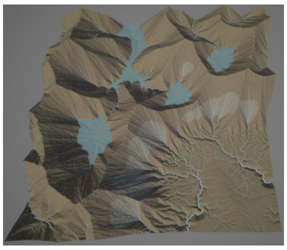


Fig. 4. Terrain with generated lakes and rivers

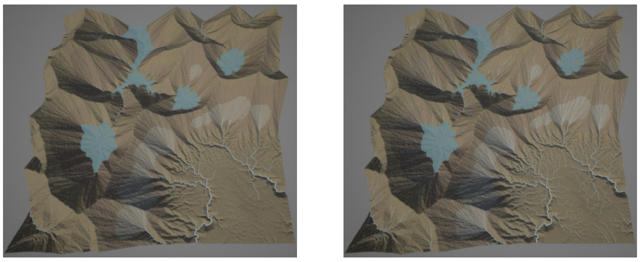
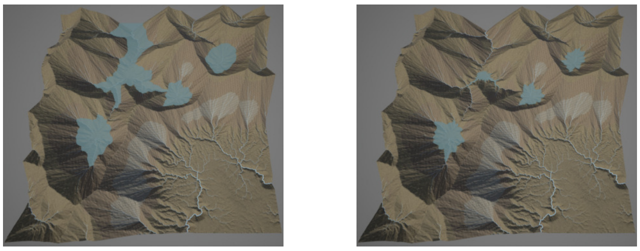


(a) Terrain with a high river threshold (b) Terrain with a low river threshold

Fig. 6. The impact of the river threshold parameter on the resulting terrain



(a) Terrain with increased precipitation (b) Terrain with increased evaporation rate

Fig. 5. The impact of water accumulation parameters on the resulting terrain

and joining some of them together. On the other hand, increasing the evaporation rate causes the water levels to fall, resulting in some of the lakes completely drying out.

Figure 6 shows the river network for different inclusion threshold levels. Setting a high value for the threshold results in highlighting only the most pronounced rivers in the basin, while keeping the value low allows us to keep even the small streams in the scene.

The computation time of the algorithm has been tested for multiple input terrain parameter presets:

- *Basic* – a constant terrain uplift on the whole domain
- *Perlin* – uplift of the domain defined by 2D Perlin noise
- *MountainSimple*, *MountainSteep* – uplift map typical for mountain regions; the second preset allows for steeper slopes
- *MountainLayers* – uplift map typical for mountain regions but with each layer subdivided into 5 additional sublayers

The key aspect of the algorithm is the time required for generating the terrain (Figure 7). The performed tests show that generating the terrain in low resolution (a 5 km × 5 km region with mesh vertices about 2.5 m from each other) takes from a dozen to several dozen seconds (Figure 7a). Such a resolution is enough to give the user a general idea of the topographical aspects of the resulting terrain. It allows for a quick iterative process of refining the result. The highest resolution (a 5 km × 5 km region with mesh vertices about 0.5 m from each other) in most cases computes in less than 30 minutes (Figure 7c) and allows the user to glimpse the precise shape of the result.

In one specific case, the time is substantially lengthened. When the uplift map is constant, the terrain remains mostly flat, resulting in a significant amount of puddles instead of a handful of big lakes resulting in the apparent rise of processing time (Fig. 7c) caused by the parts of the method that are dependant on the number of lakes. The other parameter set that was an outlier in terms of processing time, but this time by not that big of a margin, was the Mountain Layers preset. This is caused by the extended calculation time of the erosion step since multiple layers need to be considered.

It is worth noting that since the node and edge counts in the terrain graph are not dependent on the water accumulation input data but only on the size of the terrain and the sampling rate, the execution time of the lake generation process is invariant to different input parameter sets.

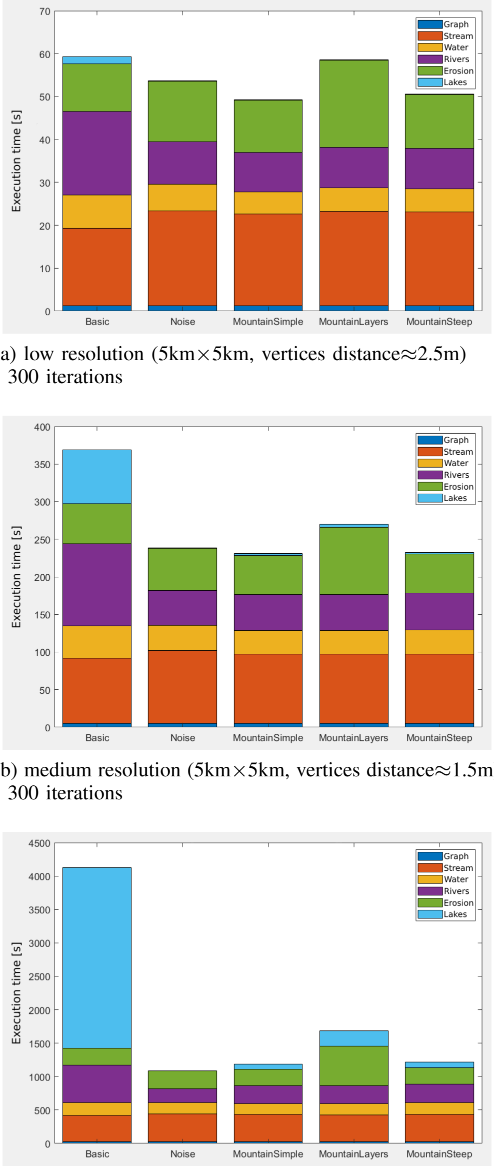
The extension of the terrain generation algorithm by adding the water accumulation and lake generation step impacts the total processing time marginally. The only exception is the *Basic* preset. However, since it is an artificial example created only for the purposes of testing the processing time and the method aimed at generating realistic environments, this result can be disregarded. For the highest resolution examples presented in the paper, the additional lake calculations only take up from 15% to 23% of the total computation time.

V. Conclusion

The modification presented in this paper to the base fluvial erosion algorithm [9] can allow the user to obtain diversified terrains in a few seconds to several dozen minutes. While the base method was only capable of generating terrains consisting of topographical features such as mountains, hills, plains the extension developed by us makes it possible to also add bodies of water to that list – rivers and lakes. This creates a much more natural looking environment since not only do we end up with more diverse features in the result but all of these features are also simulated simultaneously, interacting with each other during the generation process and in turn leading to a more lifelike result.

Rivers and lakes are created fully automatically. Rivers flow from higher to lower terrain points and naturally join together. Lakes form in natural depressions where water accumulates. The user can suggest the desired locations of water reservoirs by using the uplift velocity map.

During further research, the presented new version of the algorithm, could also allow us to diversify the terrain's shape by changing the erosion result for submerged vertices. Such



(a) low resolution (5km×5km, vertices distance≈2.5m) - 300 iterations

(b) medium resolution (5km×5km, vertices distance≈1.5m) - 300 iterations

(c) high resolution (5km×5km, vertices distance≈0.5m) - 300 iterations

Fig. 7. Execution time results for different resolutions

a change could depend on a total change in height for all nodes belonging to a given lake or the phenomenon of sedimentation. It is worth noting that in the described version of the modified algorithm, it is not necessary to compute lakes after each iteration. However, any method improvement that would affect the erosion result for underwater vertices will also require information about the water level during the algorithm's evaluation.

Further improvements of the method may also relate to the user's level of control over the final terrain – for instance the ability to determine the location of water reservoirs. Currently, the user can suggest where rivers and lakes should appear using the uplift map, but their occurrence is not guaranteed. An alternative is to add the option of forcing some connections in the flow graph, freezing the height of selected vertices, or imposing additional conditions on them, which would facilitate the insertion of selected topographic features. This however, could lead to some loss of realism over more control given to the user.

***Abstract*—In precision agriculture, non-invasive remote sensing using UAVs can be employed to observe crops in visible and non-visible spectra. This paper investigates the effectiveness of state-of-the-art knowledge distillation techniques for mapping weeds with drones, an essential component of precision agriculture that employs remote sensing to monitor crops and weeds. The study introduces a lightweight Vision Transformer-based model that achieves optimal weed mapping capabilities while maintaining minimal computation time. The research shows that the student model effectively learns from the teacher model using the WeedMap dataset, achieving accurate results suitable for mobile platforms such as drones, with only 0.5 GMacs compared to 42.5 GMacs of the teacher model. The trained models obtained an F1 score of 0.863 and 0.631 on two data subsets, with a performance improvement of 2 and 7 points, respectively, over the undistilled model. The study results suggest that developing efficient computer vision algorithms on drones can significantly improve agricultural management practices, leading to greater profitability and environmental sustainability.**

I. Introduction

PRECISION agriculture has become increasingly important due to the growth of the world's population—which is expected to reach nine billion people by 2050—and the resulting need to increase food production [1]. However, the resources that sustain agriculture are becoming increasingly scarce, degraded, and vulnerable to climate change. This has led to the need for more sustainable and efficient agricultural practices that make optimal use of available resources.

Unmanned aerial vehicles (UAVs), also known as drones, have emerged as valuable tools for precision agriculture due to their versatility and affordability [2]. They can capture high-resolution images and data from agricultural fields, which can be used to monitor crop growth, identify diseases and pests, and optimize irrigation. By providing farmers with accurate and timely information, drones can help reduce costs, increase yields, and minimize the use of inputs such as water, fertilizer, and pesticides. Traditional ground-based methods, such as manual exploration or satellite remote sensing, cannot match the level of detail that drones can provide. Drones can fly over crops and capture images and data in real-time, enabling farmers to make informed decisions quickly. Another benefit of drones is their ability to quickly and efficiently cover large areas. Drones can fly over fields and acquire data in hours, which would otherwise take days or weeks with traditional methods. This can help farmers save time and resources and make more timely decisions. Newer techniques now allow their application in swarm configurations, significantly improving their efficiency and the range of tasks they can perform [3].

One area of particular interest in precision agriculture that could benefit significantly from using drones is weed mapping. Weed mapping is critical in precision agriculture because it allows farmers to apply herbicides accurately and reduce overuse, which can cause environmental and health problems. Convolutional Neural Network (CNN)-based models have been recently proposed to perform semantic segmentation and identify weeds in images captured by drones or other aerial vehicles [4], [5], [6]. However, these models are typically computationally expensive, making them difficult to implement on drones with limited processing power and limited battery. These limitations and the need for real-time responses call for lightweight solutions.

In cases like this, knowledge distillation (KD) can help. KD is a technique that allows a smaller model to learn from a larger, more complex model, often referred to as a *teacher* [7]. The goal is to transfer the knowledge learned from the teacher to a smaller, lighter *student*, which can be used on resource-limited devices such as drones.

In this study, we explore the application of different knowledge distillation techniques to evaluate their effectiveness in the context of drone-based weed mapping. The focus is on using the WeedMap dataset [8] and proposing specific, extra-lightweight architectural designs that aim to achieve superior weed mapping capabilities while maintaining minimal computational time. This technology can improve weed management practices, leading to more sustainable and efficient agriculture.

The rest of this paper is structured as follows. Section II reviews related work. Sections III and IV describe materials and methods. Section V reports and discusses the experimental results. Section VI concludes the paper and outlines future developments in our research.

II. Related Work

Many precision agriculture tasks have been addressed thanks to the recent development of computer vision techniques and remote sensing data collection methodologies. Recent tasks include disease and pest identification, abiotic stress assessment, growth monitoring, crop yield prediction, and weed mapping.

A. Weed Mapping

Weed mapping is a semantic segmentation task in which each pixel of an image is assigned a class. Deep learning algorithms have significantly outperformed more traditional techniques in this task. Dos Santos et al. [4] were among the first to demonstrate the superiority of CNNs, particularly AlexNet, over traditional machine learning approaches such as SVM and Random Forest. Lottes et al. [9] used a CNN with two decoders, one for detecting stem position and the other for plant segmentation. They used the BoniRob dataset and one collected with a UAV for evaluation. They obtained an mAP of 79.2% for stem detection and 75.3% for segmentation. SegNet with ResNet50 as an encoder was used in [6], achieving an F1 score of 64.6%.

Depending on the bands acquired, multispectral images can contain information on the growth and health status of a plant and its species. Consequently, they can improve the accuracy of deep learning models compared to models trained only with RGB. Furthermore, multispectral image sensors can be easily integrated into UAVs. The popular U-Net was used on a dataset available on the Internet to separate weeds from crops and soil, achieving an F1 score of 89% and a mIoU of 98% [10]. WeedNet, a semantic segmentation network based on SegNet, was developed and trained on the WeedMap dataset and achieved an F1 score of 80% [5]. WeedMap contains two sets of images of sugar beet fields collected in Germany (Rheinbach) and Switzerland (Eschikon). Both were collected using UAVs equipped with multispectral cameras. The former used a 5-channel RedEdge-M camera, while the latter used a 4-channel Sequoia camera. The authors also trained SegNet using various combinations of the acquired channels, resulting in an AUC of 84.3% [8]. On the WeedMap dataset, the DeepLabV3 architecture for semantic segmentation was compared with SegNet and U-Net, achieving an F1 score of 81% on the Rheinbach subset [11]. Mozzam et al. [12] used patch-based training with a modified VGG model on the same dataset, also using the Eschikon subset. The patches were chosen by hand, and those that contained both classes were removed. On the Rheinbach subset, the accuracy reached 92%, and on Eschikon 90%. WeedMap has been used here for benchmarking purposes, as it has become the preferred dataset in several works due to its volume and quality.

B. Knowledge Distillation

Knowledge distillation is a popular method for "compressing" neural models [7]. However, previous studies have shown a significant size gap between student and teacher networks, which limits the effectiveness of KD. Mirzadeh et al. [13] showed that the gap between student and teacher could not be arbitrary and proposed a solution for this problem, called *teacher assistant knowledge distillation*. This method requires training one or more teaching assistant networks and is computationally expensive. In addition, errors of the teaching assistant can accumulate and transfer to the student. To mitigate these problems, Jafari et al. [14] introduced *annealing KD*, which achieves state-of-the-art performance in natural language understanding and computer vision tasks. In annealing KD, the teacher's goals are annealed to convey the information provided by the teacher to the student gradually. The predictions are annealed using a temperature parameter that gradually decreases during training. After this first phase, the student is trained with the ground truth. Although it can handle the capability gap problem, annealing KD is still vulnerable to noisy data and teachers' results. In addition, the training requires deciding when to switch from the first to the second phase, which can be challenging. Inspired by continuation optimization, Jafari et al. [15] tried to solve the above problems by introducing *continuation KD*. This method starts with an easy-to-train objective function that becomes increasingly complex as the training progresses, allowing the student model to learn and gradually improve its performance.

Several works have already used KD to obtain lightweight models suitable for UAVs. For example, Li et al. [16] have applied this technique for video saliency estimation, while Liu et al. [17], Yu [18], Ding et al. [19], and Luo et al. [20] used it for object detection, object recognition, action recognition, and UAV delivery, respectively. However, to our knowledge, no work has investigated knowledge distillation to produce efficient and accurate models tailored for UAVs in the context of weed mapping.

III. Materials

This section will discuss the dataset and the preprocessing and augmentation techniques implemented.

A. Dataset

Discrimination between weeds and crop plants is a significant challenge in agricultural imaging. To address this problem, the present study relied on the WeedMap dataset proposed by Sa et al. [8], which consists of orthomosaic maps of sugar beet fields (variety Beta vulgaris "Samuela") with three classes: background, crop, and weeds. Despite the limited number of classes, the dataset demonstrates a level of complexity comparable to larger semantic segmentation datasets, such as Cityscapes [21]. This complexity stems from the subtle differences between crop and weed classes and the limited number of examples. In particular, cultivated plants occupy 15-20 pixels, while individual weeds occupy only 5-10 pixels. Therefore, using pre-trained models or additional techniques, such as data augmentation, is necessary to improve the performance of the segmentation model.

More specifically, the dataset used in this study includes eight orthomosaic maps divided into two subsets based on the location of the fields: Rheinbach in Germany and Eschikon in Switzerland. The orthomosaic maps were further divided into tiles, resulting in 971 tiles for the Rheinbach subset and 700 tiles for the Eschikon subset. Data were acquired using two unmanned aerial vehicles: a DJI Inspire2 equipped with a RedEdge-M camera for the Rheinbach subset and a DJI Mavic Pro with a Sequoia camera for the Eschikon subset. The RedEdge-M camera acquired five channels of raw image data, including red, green, blue, near-infrared (NIR), and red edge (RE). On the other hand, the Sequoia camera acquired the same channels except for the blue channel.

B. Data Preprocessing

Although the dataset has already been thoroughly processed by the authors [8], further preprocessing is necessary. First, since the orthomosaic maps are not rectangles, they have some black areas at the edges, which generate many completely black tiles. As a first preprocessing step, these tiles were removed, reducing the dataset to 557 tiles for the Rheinbach subset and 561 for the Sequoia subset. In addition, the height of each tile of 360 is quite problematic because it must be divisible by $2^i, i > 3$ as some convolutional filters would require. For this reason, four crops of size 256×256 were extracted from each image. This also reduces the computational load.

C. Data Augmentation

The authors of the dataset implemented a *random horizontal flip* during their experiments, a commonly used augmentation technique because it does not distort the image. However, a *vertical flip* can also be used without problems for images acquired from a nadir direction. Similarly, random rotations can be applied to images with a degree range of 0 to 360. To resolve the class imbalance, *selective random rotation* was used, applying the increment only to examples containing at least one pixel of the minority class (i.e., weeds). This approach helped to increase the number of images containing weeds, improving the model's ability to learn the minority class. This technique was applied only to the Eschikon subset, which had a weed representation of only 0.166% and later increased to 0.499%. The Rheinbach subset, on the other hand, already had a weed representation of 0.706%.

IV. Methods

Two different architectures, both Transformers, were used. The first, used as a teacher, is HRNet+OCR+PSA [22], [23]. The second is a modified version of Lawin [24], which is a Vision Transformer (ViT) [25] suitable for semantic segmentation. In particular, we lightened the architecture by obtaining an extra-light model, which we named "Lawin-L0". Both architectures have achieved state-of-the-art results on the Cityscapes, ADE20K, and COCO-Stuff reference datasets. However, they cannot be directly applied as-is. Weed mapping, like other precision agriculture tasks, benefits from some bands of the non-visible spectrum, particularly the NIR and RE bands. This hinders the application of deep learning models, which are typically suited to be fed RGB images. A concatenation layer with a modified first convolution layer is needed to handle other channels besides RGB.
