DEAR Reader, it is our pleasure to present to you the Proceedings of the 20th Conference on Computer Science and Intelligence Systems (FedCSIS 2025), which took place on September 14-17, 2025, in Kraków, Poland.

FedCSIS 2025 was chaired by Jarosław Wąs. Moreover, Tomasz Hachaj was the Chair, while Marian Bubak, Marek Grzegorowski and Łukasz Rauch, were the Co-Chairs of the Organizing Committee.

This year, FedCSIS was organized by the Polish Information Processing Society (Mazovia Chapter), IEEE Poland Section Computer Society Chapter, Systems Research Institute of Polish Academy of Sciences, The Faculty of Mathematics and Information Science Warsaw University of Technology, The Faculty of Electrical and Computer Engineering of the Rzeszów University of Technology and The Faculty of Electrical Engineering, Automatics, Computer Science and Biomedical Engineering AGH in cooperation with The Faculty of Metals Engineering and Industrial Computer Science AGH, The Faculty of Materials Science and Ceramics AGH, and Centre for Computational Personalised Medicine SANO.

FedCSIS 2025 was technically co-sponsored by IEEE Poland Section, IEEE Poland Section Computer Society (Gdańsk) Chapter, IEEE Czechoslovakia Section Computer Society Chapter, IEEE Poland Section Systems, Man, and Cybernetics Society Chapter, IEEE Serbia and Montenegro Section Computational Intelligence Society Chapter, IEEE Serbia and Montenegro Section Young Professionals Affinity Group, Committee of Computer Science of the Polish Academy of Sciences and Mazovia Cluster ICT.

FedCSIS 2025 was organized in collaboration with the Strategic Partner QED Software, and sponsored by Intel+Lenovo, Jupiter as well as MDPI Electronics, MDPI Applied Sciences and MDPI AI journals. Moreover, FedCSIS 2025 has been conducted under Honorary Patronages of Professor Jerzy Lis, Rector of the AGH University of Kraków and of Aleksander Miszalski, Mayor of Krakow, as well as under patronages of the Ministry of Digital Affairs of the Republic of Poland, Polish Artificial Intelligence Society (PSSI), Forum Akademickie and Naukowe Towarzystwo Informatyki Ekonomicznej. Finally, media patronage was provided by Krakow.pl, TVP Info, TVP3 Kraków, and Kraków Convetion Bureau.

This year, the structure of the conference remained the same as last year. FedCSIS 2025 had a single Main Track with 5 Topical Areas, which was supported by 12 Thematic Sessions and a Competition. Such structure emphasizes the integrity of the conference and its closeness to the issues that are crucial for the world around us. Here, we recognize the fact that today (in 2025) it is difficult to envision research (and its applications) without an intelligence component. Reflecting this, all five Topical Areas, which constitute the Main Track, represent various aspects of Intelligence Systems. Moreover, the Thematic Sessions provide further insights into selected areas of Intelligence Systems, approached from different perspectives.

In this context, Proceedings that we present to you, consist of six parts. Part 1 contains Invited Contributions. Part 2 collects Main Track full papers (arranged alphabetically, according to the last name of the first author, with the Topical Area represented in the metadata). Part 3 contains Main Track short papers (again, arranged alphabetically, with the Topical Area represented in the metadata). Part 4 contains full papers, originating from the Thematic Sessions (again, arranged alphabetically, according to the last name of the first author, with the name of the Thematic Session stated in the metadata). Part 5 collects short papers from all Thematic Sessions. Finally, Part 6 is devoted to contributions originating from the Competition.

Keeping this in mind, let us now introduce Keynote Speakers, the remaining Invited Contributions, and the five Topical Areas of the FedCSIS 2025 Main Track.

I. Invited Contributions

FedCSIS 2025 invited four keynote speakers to deliver lectures providing a broader context for the conference participants.

- Damaševičius, Robertas, Kaunas University of Technology, Lithuania
  Keynote title: AI-Driven Innovations in Brain Cancer Research
- Dustdar, Schahram, TU Wien, Austria
  Keynote title: Active Inference for Distributed Intelligence in the Computing Continuum
- Jonker, Catholijn, TU Delft (main affiliation), Leiden University, Vrije Universiteit Amsterdam, Netherlands
  Keynote title: Hybrid Human-AI Intelligence to Strengthen the Reflective and Learning Capacity of Organisations
- Plank, Barbara, LMU Munich, Germany
  Keynote title: Human-centered LLMs for Inclusive Language Technology

Moreover, four past FedCSIS keynote speakers have been invited to prepare special contributions, which refer to the core focus of the conference series. These were:

- Atiquzzaman, Mohammed, University of Oklahoma, USA
  Contribution title: Q-ID: A Reinforcement Learning Framework for Adaptive Intrusion Detection
- Blum, Christian, Artificial Intelligence Research Institute, Spain
  Contribution title: Optimizing the Optimizer: An Example Showing the Power of LLM Code Generation
- Luković, Ivan, University of Belgrade, Serbia
  Contribution title: New Education Challenges in Profiling Digital Experts for a Digital Economy Era
- Skowron, Andrzej, Systems Research Institute Polish Academy of Sciences, Poland
  Contribution title: Interactive Granular Computing: Toward Computing Model for Complex Intelligent Systems

At the time, when you are reading this text, videos of the keynote presentations and of invited contributions, delivered

during the FedCSIS 2025 conference, are already available on the official conference website (www.fedcsis.org). We warmly encourage you to visit the website and watch these recordings to gain additional insights and perspectives shared by distinguished speakers.

Finally, as a part of official Conference Opening, a special presentation, entitled: *Paths to Zero Emission Computing—Reducing Energy Consumption, and carbon emissions in HPC and AI environments*, was delivered by Tikiri Wanduragala, Technology Leader Lenovo Infrastructure Solutions Group (ISG), Lenovo UK and Ireland. An extended abstract, outlining main pints of this presentation can be found in the Position papers of FedCSIS 2025 volume, published in the Annals of Computer Science and Information Systems book series.

II. Advanced Artificial Intelligence in Applications

This Topical Area covers a wide range of core aspects of intelligence systems, with a particular focus on AI. Nowadays, AI is usually perceived as closely related to the data, therefore, the scope of this Topical Area includes, among others, elements of machine learning, data science, and big data processing, with important emerging aspects such as interactive learning and human-centered AI, as well as interpretable learning, explainable AI, and trustworthiness. Furthermore, since the realm of AI is far richer, the ultimate goal of this Topical Area is to show relationships between all of the currently pursued AI subareas, emphasizing a cross-disciplinary nature of various research branches. From the perspective of the general scope of FedCSIS, this Topical Area embraces AI methods and examples of their applications in different practical fields.

This Topical Area was curated by:

- Artiemjew, Piotr, University of Warmia and Mazury, Poland
- Chelly Dagdia, Zaineb, University of Lille, France
- Corizzo, Roberto, American University, USA
- Zdravevski, Eftim, Ss. Cyril and Methodius University, Northern Macedonia

III. Computer Science & Systems

This Topical Area covers technical (or applicable) aspects of computer science and related disciplines. The Topical Area spans themes ranging from hardware issues close to the discipline of computer engineering via software issues tackled by the theory and applications of computer science, and to issues of interest to distributed, smart, data-oriented, multimedia and network systems.

The Topical Area is oriented on the research where the computer science meets the real world problems, real constraints, simulations and processing, model objectives, etc., in order to deliver Intelligence Systems. However the scope is not limited to applications, we all know that all of them were born from the innovative theory developed in the laboratory. We want to show the fusion of these two worlds. Therefore one of the goals for the Topical Area is to show how the idea is transformed into application, since the history of modern science shows the most successful research experiments had their continuation in the real world.

This Topical Area was curated by:

- Ferrando, Angelo, University of Modena and Reggio Emilia, Italy
- Pawłowski, Wiesław, University of Gdańsk and Systems Research Institute, Polish Academy of Sciences, Poland
- Wasielewska-Michniewska, Katarzyna, Systems Research Institute, Polish Academy of Sciences, Poland

IV. Network Systems & Applications

Modern network systems encompass a wide range of solutions and technologies, including wireless and wired networks, network systems, services, and applications. This results in numerous active research areas oriented towards various technical, scientific, and social aspects of network systems and applications. The rapid development of computer networks including wired and wireless networks observed today is evolving, dynamic, and multidimensional. On the one hand, network technologies are used in the majority of areas that make human life easier and more comfortable. On the other hand, the rapid need for network deployment brings new challenges in network management and network design, which are reflected in hardware, software, services, and security-related problems. Every day, a new solution in the field of technology and applications of computer networks is released. New network vulnerabilities, threats and attacks are also emerging. This Topical Area is devoted to emphasizing up-to-date topics in networking systems and technologies by covering problems and challenges related to intensive multidimensional network developments. Yet, it is inclusive and spans a wide spectrum of networking-related topics.

This Topical Area was curated by:

- Armando, Alessandro, University of Genova, Italy
- Furtak, Janusz, Military University of Technology, Poland
- Suri, Niranjan, Institute of Human and Machine Cognition, United States

V. Information Technology for Business & Society

This Topical Area emphasizes Intelligence Systems as a central theme while embracing a comprehensive perspective on the role of various technologies, Management Information Systems (MIS), and Decision Support Systems (DSS) in addressing contemporary challenges faced by businesses, organizations, and society. It seeks to provide a platform for exploring how advanced technologies–such as big data, data mining, machine learning, IoT, blockchain, cloud computing, and social networks–interact with and contribute to the continuous improvement of processes, decision-making, and innovation in diverse domains, including business, government, and social sectors.

The aim is to comprehensively understand how Intelligence Systems and related technologies can be effectively leveraged within MIS and DSS to drive innovation, support strategic

goals, and create value across various sectors and domains. This focus goes beyond the technical dimensions, integrating socio-technical and management perspectives to explore how these systems can be designed, implemented, and managed to meet real-world needs. This includes addressing challenges in organizational processes, decision-making frameworks, and strategies for achieving sustainable and continuous improvement.

This Topical Area was curated by:

- Cano, Alberto, Virginia Tech University, USA
- Dias, Gonçalo, University of Aveiro, Portugal
- Miller, Gloria, maxmetrics, Germany
- Naldi, Maurizio, LUMSA University, Italy
- Wątróbski, Jarosław, University of Szczecin, Poland
- Ziemba, Ewa Wanda, University of Economics in Katowice, Poland

VI. Software, System & Service Engineering

The Topical Area emphasizes the issues relevant to developing and maintaining software systems that behave reliably, efficiently and effectively. It investigates both established traditional approaches and modern emerging approaches to large software production and evolution.

For decades, it is still an open question in software industry, how to provide fast and effective software process and (intelligent) software services, and how to come to the software systems, embedded systems, autonomous systems, intelligence systems, or cyber-physical systems that will address the open issue of supporting information management process in many, particularly complex organization systems. Even more, it is a hot issue how to provide a synergy between systems in common and software services as mandatory component of each modern organization, particularly in terms of IoT, Big Data, Data Science, Artificial Intelligence, Machine Learning, and Industry 4.0 paradigms.

In recent years, we are the witnesses of great movements in the area of software, system and service engineering (S3E). Such movements are both of technological and methodological nature. By this, today we have a huge selection of various technologies, tools, and methods as a discipline that helps in a support of the whole information life cycle in organization systems. Despite that, one of the hot issues in practice is still how to effectively develop and maintain complex systems from various aspects, particularly when software components are crucial for addressing declared system goals, and their successful operation. It seems that nowadays we have great theoretical potentials for application of new and more effective approaches. However, it is more likely that real deployment of such approaches in industry practice is far behind their theoretical potentials.

This Topical Area was curated by:

- Luković, Ivan, University of Belgrade, Serbia
- Kolukısa Tarhan, Ayça, Hacettepe University, Turkey
- Popović, Aleksandar, University of Montenegro, Podgorica, Montenegro

VII. FedCSIS 2025 Competition—Predicting Chess Puzzle Difficulty, Second Edition

FedCSIS 2025 Challenge was entitled: Predicting Chess Puzzle Difficulty—Second Edition. It was the 11th data science challenge, organized within the scope of FedCSIS conference series. The goal was to build a model to predict the difficulty (measured as Lichess rating) of given chess puzzles. The 2025 competition was organized by:

- Ślęzak, Dominik, QED Software and University of Warsaw, Poland
- Ślęzak, Michał, Polish-Japanese Academy of Information Technology, Poland
- Świechowski, Maciej, Grail Team, Poland
- Zyśko, Jan, University of Warsaw, Poland

This year, 42 teams participated in the competition. They, collectively, submitted 1185 solutions. Team members represented 16 different countries from around the world, with largest number of representatives coming from Poland, Germany, United States and Singapore. After evaluation, the following contributions, found also in these proceedings, discuss the winning solutions:

- First place: Sebastian Björkqvist, Estimating the Difficulty of Chess Puzzles by Combining Fine-Tuned Maia-2 with Hand-Crafted and Engine Features
- Second place: Tyler Woodruff, Luke Imbing, Marco Cognetta, The bread emoji Team's Submission to the 2025 FedCSIS Predicting Chess Puzzle Difficulty Challenge
- Third place: Szymon Miłosz, Pretraining Transformers for Chess Puzzle Difficulty Prediction

VIII. Professor Zdzisław Pawlak Award

The above-described five Topical Areas of the FedCSIS Main Track reflect the five fundamental aspects of understanding, developing, and applying Intelligence Systems. This topical integrity is emphasized by the Professor Zdzisław Pawlak Award, presented in four categories: Best Paper, Young Researcher, Industry Cooperation, and International Cooperation. Here, note that although Professor Zdzisław Pawlak has been often recognized as "the father of Polish AI", his research achievements have gone far beyond AI itself, in particular toward AI applications and Intelligence Systems as we understand them. Accordingly, for this award contributions from the Main Track and from all Thematic Sessions are considered. This year, the following contributions have been awarded:

- In the category *Best Paper*: Preiß, Niklas and Westner, Markus, From Agents to Copilots: A Systematic Review of Digital Assistant Technology Adoption in Proprietary Productivity Software
- In the category *Young Researcher*: Lorenz, Alisa, A New Dimension of Acceptance? Introducing Perceived Public Value as Extension of UTAUT in the Smart City Context
- In the category *Industry Cooperation*: Sadel, Jakub, Tarasiewicz, Tomasz, Kowaleczko, Paweł, Ziaja, Ma-

ciej, Kostrzewa, Daniel, Benecki, Paweł and Kawulok, Michał, Keypoint-based metric for evaluating image super-resolution quality
- In the category *International Cooperation*: De Maeyer, Wannes, Van Overberghe, Steven, Cornelis, Chris and Restrepo Lopez, Mauricio, Estimating the entropy of covering-based rough set approximation operators

Young Researcher Award was sponsored by the MDPI Applied Sciences Journal, International Cooperation Award was sponsored by the MDPI AI Journal, Industry Cooperation Award was sponsored by the MDPI Electronics Journal, while the Best Paper Award was sponsored by the Mazovia Branch of Polish Information Processing Society.

Here, let us also note that Professor Zdzisław Pawlak Awards have been presented to authors of best papers since 2006.

IX. Statistics

Each contribution, found in this volume, was refereed by at least two referees and the acceptance rate of regular full papers was approximately 18.66% (47 accepted contributions, out of a total of 209 submissions representing 48 countries and 6 continents). Since we live in times when "data is the new oil", the long-term trend of acceptance of regular full papers is depicted in Figure 1. Note that this year the lowest, thus far, acceptance rate for regular full papers has been recorded.

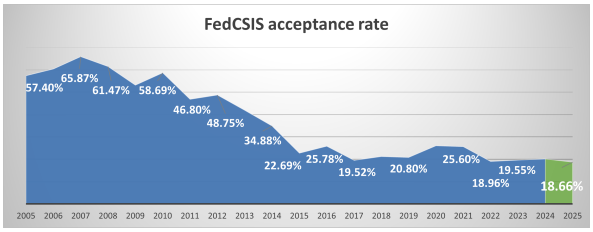

Figure 1. Acceptance rate for the regular full papers for the FedCSIS conference series since 2005 (when FedCSIS predecessor was organized for the first time).

X. Committees

The Senior Program Committee of FedCSIS 2025 consisted of:

- Arciuch, Artur, Military University of Technology, Poland
- Armando, Alessandro, University of Genova, Italy
- Artiemjew, Piotr, University of Warmia and Mazury in Olsztyn, Poland
- Bicevska, Zane, University of Latvia, Latvia
- Bumberger, Jan, Helmholtz-Centre for Environmental Research – UFZ, Germany
- Bylina, Beata, Maria Curie-Sklodowska University, Poland
- Bylina, Jarosław, Marie Curie-Sklodowska University, Poland
- Cano, Alberto, Virginia Commonwealth University, United States
- Charvat, Karel, Czech Center for Science and Society, Czech Republic
- Chelly Dagdia, Zaineb, University of Lille, France
- Chmielarz, Witold, University of Warsaw, Poland
- Cooper, Anthony-Paul, Durham University, United Kingdom
- Corizzo, Roberto, American University, United States
- Coronato, Antonio, Università Giustino Fortunato, Italy
- Cyganek, Bogusław, AGH University of Krakow, Poland
- Dan, Daniel, MODUL University, Austria
- Debar, Hervé, Télécom SudParis, Institut Mines-Télécom, France
- Dias, Gonçalo, University of Aveiro, Portugal
- Dörpinghaus, Jens, Federal Institute for Vocational Education and Training (BIBB), Germany
- Felkner, Anna, NASK—National Research Institute, Poland
- Fernandes De Muylder, Cristiana, Universidade FUMEC, Brazil
- Ferrando, Angelo, University of Modena and Reggio Emilia, Italy
- Fidanova, Stefka, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria
- Fornés Leal, Alejandro, Universitat Politècnica de València, Spain
- Franczyk, Bogdan, University of Leipzig, Germany
- Frank, Urlich, Universität Duisburg-Essen, Germany
- Furtak, Janusz, Military University of Technology, Poland
- Häckl, Dennis, University of Leipzig, Germany
- Helmrich, Robert, Federal Institute for Vocational Education and Training (BIBB), Germany
- Ioannidis, Sotirios, Technical University of Crete, Greece
- Iwanowski, Marcin, Warsaw University of Technology, Poland
- Janousek, Jan, Czech Technical University, Czech Republic
- Kadobayashi, Youki, Nara Institute of Science and Technology, Japan
- Kobyliński, Łukasz, Institute of Computer Science, Polish Academy of Sciences, Poland
- Kolukısa Tarhan, Ayça, Hacettepe University, Turkey
- Kubis, Marek, Adam Mickiewicz University, Poland
- Kwaśnicka, Halina, Wroclaw University of Technology, Poland
- Lacalle Úbeda, Ignacio, Universitat Politècnica de València, Spain
- Leyh, Christian, Technische Hochschule Mittelhessen (THM) – University of Applied Sciences, Germany
- Lirkov, Ivan, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria
- Luković, Ivan, University of Belgrade, Serbia
- Martinelli, Massimo, Institute of Information Science and Technologies, National Research Council of Italy, Italy
- Milašinović, Boris, University of Zagreb, Croatia
- Militzer-Horstmann, Carsta, WIG2 Institute for Health

Economics and Health Service Research, Germany
- Miller, Gloria, maxmetrics, Germany
- Moroni, Davide, Institute of Information Science and Technologies, National Research Council of Italy, Italy
- Mucherino, Antonio, IRISA, University of Rennes, France
- Naeem, Muddasar, Università Giustino Fortunato, Italy
- Nakayama, Minoru, Institute of Science Tokyo, Japan
- Naldi, Maurizio, LUMSA University, Italy
- Pałys, Tomasz, Military University of Technology, Poland
- Paszkiewicz, Andrzej, Rzeszow University of Technology, Poland
- Pawłowski, Wiesław, University of Gdańsk and Systems Research Institute Polish Academy of Sciences, Poland
- Popović, Aleksandar, University of Montenegro, Montenegro
- Procházka, Ales, University of Chemistry and Technology, Czech Republic
- Rangel Henriques, Pedro, University of Minho, Portugal
- Reinhold, Olaf, Social CRM Research Center, Germany
- Rishiwal, Vinay, Mahatma Jyotiba Phule Rohilkhand University, India
- Ristić, Sonja, University of Novi Sad, Serbia
- Rizvi, Syed Tahir Hussain, Wenn AsA, Sandnes, Norway
- Slivnik, Boštjan, University of Ljubljana, Slovenia
- Śluzek, Andrzej, Warsaw University of Life Sciences—SGGW, Poland
- Sołtysik-Piorunkiewicz, Anna, University of Economics in Katowice, Poland
- Speckesser, Stefan, University of Brighton, United Kingdom
- Stanescu, Liana, University of Craiova, Romania
- Stpiczyński, Przemysław, Maria Curie-Sklodowska University, Poland
- Suri, Niranjan, Institute of Human and Machine Cognition, United States
- Świątkowska, Joanna, Deputy Secretary General at European Cyber Security Organisation, Belgium
- Tiemann, Michael, Federal Institute for Vocational Education and Training (BIBB), Germany
- Tolvanen, Juha-Pekka, MetaCase, Finland
- Varanda Pereira, Maria Joao, Instituto Politecnico de Braganca, Portugal
- Wasielewska-Michniewska, Katarzyna, Systems Research Institute, Polish Academy of Sciences, Poland
- Wątróbski, Jarosław, West Pomeranian University of Technology, Poland
- Wróblewska, Anna, University of Technology, Poland
- Zaharie, Daniela, West University of Timisoara, Romania
- Zdravevski, Eftim, Ss. Cyril and Methodius University, North Macedonia
- Ziemba, Ewa, University of Economics in Katowice, Poland

The Program Committee of FedCSIS 2025 consisted of:

- Abromavičius, Vytautas, Vilnius Gediminas Technical University, Lithuania
- Adil, Muhammad, Institute of Marine Sciences CNR, Italy
- Ahmad, Muhammad Ovais, Karlstad University, Sweden
- Amodio, Pierluigi, Universita' di Bari, Italy
- Anastassi, Zacharias, ASPETE School of Pedagogical and Technological Education, Greece
- Arabas, Piotr, NASK—National Research Institute, Poland
- Asselborn, Thomas, University of Hamburg, Germany
- Awuni Kolog, Emmanuel, University of Ghana, Ghana
- Azad, Mohammad, Jouf University, Saudi Arabia
- Azevedo, Ana, CEOS.PP, ISCAP, P.PORTO, Portugal
- Bacco, Manlio, ISTI-CNR, Italy
- Badica, Costin, University of Craiova, Romania
- Badica, Amelia, University of Craiova, Romania
- Badr, Georges, Holy Spirit University of Kaslik, Lebanon
- Baldán Lozano, Francisco Javier, University of Málaga, Spain
- Banach, Richard, University of Manchester, United Kingdom
- Barišić, Ankica, ActiveEon, France
- Belciug, Smaranda, University of Craiova, Romania
- Ben-Assuli, Ofir, Ono Academic College, Israel
- Beuran, Razvan, Japan Advanced Institute of Science and Technology, Japan
- Białas, Andrzej, Research Network Łukasiewicz—Institute of Innovative Technologies EMAG, Poland
- Bicevskis, Janis, University of Latvia, Latvia
- Bieniek, Mariusz, University of Maria Curie Skłodowska, Poland
- Bjeladinović, Srđa, University of Belgrade, Serbia
- Boehm, Karsten, FH KufsteinTirol—University of Applies Science, Austria
- Borkowski, Boleslaw, Warsaw University of Life Sciences, Poland
- Bountakas, Panagiotis, Sphynx Technology Solutions AG, University of Piraeus, Switzerland
- Brdjanin, Drazen, University of Banja Luka, Bosnia and Herzegovina
- Brezovan, Marius, University of Craiova, Romania
- Bridova, Ivana, University of Zilina, Slovakia
- Brzoza-Zajęcka, Ada, AGH University of Krakow, Poland
- Cabri, Giacomo, Università di Modena e Reggio Emilia, Italy
- Calpe Maravilla, Javier, University of Valencia, Spain
- Carbone, Roberto, Security & Trust Unit, FBK, Italy
- Carchiolo, Vincenza, Universita di Catania, Italy
- Casalino, Gabriella, University of Bari Aldo Moro, Italy
- Chen, Haiming, Chinese Academy of Sciences, China
- Chiru, Costin, University Politehnica of Bucharest, Romania
- Christozov, Dimitar, American University in Bulgaria, Bulgaria
- Cicconetti, Claudio, IIT-CNR, Italy

- Ciucci, Davide, Università di Milano-Bicocca, Italy
- Colantonio, Sara, ISTI-CNR, Italy
- Corizzo, Roberto, American University, United States
- Cosulschi, Mirel, University of Craiova, Romania
- Coviello, Giuseppe, Politecnico Di Bari, Italy
- Cybulski, Piotr, Military University of Technology in Warsaw, Poland
- Czachorski, Tadeusz, IITiS PAN, Polish Academy of Sciences, Poland
- Czarnacka-Chrobot, Beata, Warsaw School of Economics, Poland
- Czarnul, Pawel, Gdansk University of Technology, Poland
- Damasevicius, Robertas, Vytautas Magnus University, Poland
- de Lara, Juan, Universidad Autonoma de Madrid, Spain
- Defigueiredo, Felipeaugustopereira, Ghent Univerity, Belgium
- Derezinska, Anna, Warsaw University of Technology, Poland
- Dery, Lihi, Ariel University, Israel
- Dimitrieski, Vladimir, Faculty Of Technical Sciences, Serbia
- Dionysiou, Antreas, University of Cyprus, Cyprus
- Dudycz, Helena, Wroclaw University of Economics, Poland
- Dutta, Arpita, National University of Singapore, Singapore
- Eisenbardt, Monika, Univeristy of Economics Katowice, Poland
- Eisenbardt, Tomasz, University of Warsaw, Poland
- Engelbrecht, Andries, University of Stellenbosch, South Africa
- Erata, Ferhat, Yale University, United States
- Faber, Łukasz, AGH University of Krakow, Poland
- Fajsi, Angela, University of Novi Sad, Serbia

ACKNOWLEDGMENTS

In conclusion, let us emphasize that delivery of FedCSIS 2025 required a dedicated effort of many people. We would like to express our warmest gratitude to all Topical Area Curators, Thematic Session organizers, members of the FedCSIS 2025 Senior Program Committee and members of the FedCSIS 2025 Program Committee (a total of more than 600 individuals), for their hard work in attracting and reviewing all submissions. We thank the authors of papers for their great contribution to the theory and practice of Computer Science and Intelligence Systems. We are grateful to Keynote and Invited Speakers for sharing their knowledge and experiences with the participants. Last, but not least, we acknowledge, one more time, Jarosław Wąs, Tomasz Hahaj, Łukasz Rauch, Anna Smyk, Anna Stolarczyk Piotrowska, Marian Bubak and Marek Grzegorowski, and their Team, Anastasiya Danilenka and Paweł Szmeja, as well as a fantastic group of student helpers. We are very grateful for your efforts!

We also hope to meet you again for the 21st Conference on Computer Science and Intelligence Systems (FedCSIS 2026) which will take place in Riga, Latvia, on August 23-26, 2026.

Co-Chairs of the FedCSIS Conference Series

Bolanowski, Marek, *Rzeszów University of Technology, Poland*

Ganzha, Maria, *Warsaw University of Technology, and Systems Research Institute Polish Academy of Sciences, Poland*

Maciaszek, Leszek, (Honorary Chair), *Macquarie University, Australia and Wrocław University of Economics, Poland*

Paprzycki, Marcin, *Systems Research Institute Polish Academy of Sciences, Poland*

Ślęzak, Dominik, *QED Software and University of Warsaw, Poland*

Proceedings of the 20th Conference on Computer Science and Intelligence Systems (FedCSIS)

September 14–17, 2025. Kraków, Poland

TABLE OF CONTENTS

MAIN TRACK

MAIN TRACK INVITED CONTRIBUTIONS

Active Inference in the Distributed Computing Continuum **1**
Schahram Dustdar

Multiscale MoE: A Mixture of Experts Framework with Attention-Driven Multi-Scale Learning for Brain Tumor Classification **3**
Ameer Hamza, Robertas Damaševičius

SHARE: An Interactive Learning System for Improving Legal Consultation Services and Training **13**
Stephanie Tan, Wendy Aartsen, Dicky van Hamersveld, Maarten van der Sanden, Catholijn Jonker

New Education Challenges in Profiling Digital Experts for a Digital Economy Era **25**
Ivan Luković, Marija Đukić, Dragan Stanojević

Q-ID: A Reinforcement Learning Framework for Adaptive Intrusion Detection **35**
Maisha Maliha, Mohammed Atiquzzaman

Human-centered LLMs for Inclusive Language Technology: The Need to Embrace Variation Holistically in NLP **43**
Barbara Plank

Optimizing the Optimizer: An Example Showing the Power of LLM Code Generation **47**
Camilo Chacón Sartori, Christian Blum

Interactive Granular Computing: Toward Computing Model for Complex Intelligent Systems **59**
Andrzej Skowron, Andrzej Jankowski, Soma Dutta

MAIN TRACK REGULAR PAPERS

Adoption and Evaluation of Mobile Gaming Applications for Pain Management in Paediatric Oncology: A Culturally Contextualised TAM-Based Framework and Mixed-Methods Pilot Study in Saudi Arabia **73**
Samah Almaghrabi, Natalia Beloff, Martin White

Digital Transformation in Saudi Public Universities: A Novel Framework for Adoption Drivers and Impact Analysis **87**
Saleh Z Alshehri, Natalia Beloff, Martin White

CADM: An LSTM-Based Model for Detecting Creative Accounting in Time-Series Data from Saudi-Listed Companies **99**
Maysoon Bineid, Natalia Beloff, Anastasia Khanina, Martin White

Comparison of Large Language Models Supporting the Polish Language in Terms of Faithfulness in Retrieval-Augmented Generation Applications **111**
Marcin Blachnik, Jakub Chmielewski

A Framework for Model-Driven AI-Assisted Generation of IT Project Management Plan and Scope Documents **121**
Jānis Rihards Blazevičs, Oksana Nikiforova, Oscar Pastor

A New Perspective of Associative Memories for Partial Patterns **133**
Soma Dutta, Jaewon Shin

Hybrid mutation MTD solution with dedicated SDN agents **145**
Mateusz Fronczyk, Mariusz Rawski

Towards a Framework for Systematic API Migrations **155**
Nikolas Jíša, Robert Pergl

Toward Conversational Decision Support Systems: Integrating LLMs in the Operations Research Methodology **165**
Mariusz Kaleta

Slurm plugin for HPC operation with time-dependent cluster-wide power capping **175**
Alexander Kammeyer, Florian Burger, Daniel Lübbert, Katinka Wolter

Assigning scientific texts to existing ontologies **185**
Lukáš Korel, Martin Holeňa

Estimating the entropy of covering-based rough set approximation operators **195**
Wannes De Maeyer, Steven Van Overberghe, Chris Cornelis, Mauricio Restrepo López

Simultaneous pursuit of accountability for regulatory compliance, financial benefits, and societal impacts in artificial intelligence (AI) projects **207**
Gloria Miller

Deep Differentiable Logic Gate Networks Based on Fuzzy Łukasiewicz T-norm **219**
Chan Duong Nguy, Piotr Wasilewski

Segmentation and Process Assignment of Semi-Structured Event Logs **231**
Piotr Przymus, Krzysztof Rykaczewski, Janusz Zieliński, Łukasz Mikulski

Addressing Skills Shortages through Low-Code/No-Code: Skill Profiles and Implementation Challenges **243**
Paul Rozbitski, Christian Leyh, Ching-Ho Ip

Keypoint-based metric for evaluating image super-resolution quality **255**
Jakub Sadel, Tomasz Tarasiewicz, Pawel Kowaleczko, Maciej Ziaja, Daniel Kostrzewa, Pawel Benecki, Michal Kawulok

A Comparative Study of LSTM Efficiency vs. Transformer Power for Localized Time Series Forecasting **265**
Twisampati Sarkar, Henry Chu

Real-time Container Tracking and Damage Detection at Seaports Using Deep Learning **277**
Sotiris Vasileiadis, Sheraz Aslam, Kyriacos Orphanides, Alessandro Cassera, Eduardo Garro Crevillen, Alvaro Martinez-Romero, Michalis Michaelides, Herodotos Herodotou

MAIN TRACK SHORT PAPERS

A Lightweight Optimization Approach to the Single-Person Pose Estimation Pipeline in RGB-D Cameras **287**
Vytautas Abromavičius, Rytis Maskeliūnas

Simple Idea Discovery in a Minimalist LLM Architecture Implementation **291**
Robert Chihaia, Maria Trocan, Florin Leon

Data Interoperability Using Smart Data Models and NGSI-LD for the Norwegian Agrifood Sector **297**
Rustem Dautov, Simeon Tverdal, André Skoog Bondevik, Svein Arild Frøshaug, Vera Szabo, Jan Robert Fiksdal

Automatic Parcel Damage Recognition Module for an Inspection Robot **303**
Wiktor Goszczyński, Szymon Wałęga, Janusz Chmiel, Bartłomiej Gawęda, Katarzyna Grobler-Dębska

Length-Preserving Hair Simulation via Bézier Curves and Artificial Neural Network **309**
Kali Gürkahraman, Ahmet Firat Yelkuvan, Rukiye Karakis

StarCraft strategy learning refinement using replay snapshotting **315**
Štefan Krištofík, Michaela Hanková

Applying Evolutionary Techniques to Enhance Graph Convolutional Networks for Node Classification: Case Studies **321**
Maciej Krzywda, Szymon Lukasik, Amir H Gandomi

AI classifier of defects in Artworks captured by active infrared thermography **327**
Peter Malík, Martin Orlej, Branislav Fajčák, Massimo Rippa

Attention-Based Multi-Task Learning and PPO Reinforcement Learning for Explainable Blood Glucose Prediction **333**
Sarmad Maqsood, Egle Belousovienė, Rytis Maskeliūnas

Forest-Inspired Reinforcement Learning Based On Nature Ecosystem Feedback Mechanisms **339**
Rytis Maskeliūnas, Robertas Damaševičius

Out-Of-Distribution Is Not Magic: The Clash Between Rejection Rate and Model Success **345**
Itay Meiri, Ran Dubin, Amit Dvir, Chen Hajaj

Digital Twin Micro-Services Architecture to Support a Scenario-based Integration of Smart Mobility Services and Simulations **351**
Damien Nicolas, Christophe Feltus, Ruben Antonio De Jesus Marques

Enhancing API documentation by inter-endpoint dependency graphs **357**
Panagiotis Papadeas, Dimitrios Gerokonstantis, Christos Hadjichristofi, Vassilios Vescoukis

Hybrid U-Net segmentation of vessels in fundus eye images **363**
Lesław Pawlaczyk

Enhancing Low-Cost Air Quality Sensors with AI for Smart Green Routing **369**
Laura Po, Martina Casari, Federica Rollo, Matteo Angelinelli, Giorgio Pedrazzi, Chiara De Pascali, Luca Nunzio Francioso, Roberta Turra

Metaheuristics for Rolling Stock Cyclic Job Scheduling Problems with Maintenance **375**
Radoslaw Rudek

Symbolic vs Black-Box Explanations: A Model-Driven Approach Using Grammatical Evolution **381**
Dominik Sepioło, Antoni Ligęza

Comparative Analysis of AI and Traditional Software GitHub Repositories Using Process Mining **387**
Oguzhan Tasci, Tugba Gurgen Erdogan

Challenges in Evaluating OSS Quality: Results from SLR on Quality Evaluation Tools **393**
Aslı Taşgetiren, Ayça Kolukısa Tarhan

Anomaly Detection for Unmanned Surface Vehicles Based on a Multi-Modal Bayesian Generative Model **399**
Micheale Tekulu, Ali Krayani, Pamela Zontone, Lucio Marcenaro, Francesco Caprile, Antonino Masaracchia, Carlo Regazzoni

Unified Data-Driven Prediction of Photovoltaics Output from Weather and Geographic Data Across Diverse Systems **405**
Joanna Wójcicka, Tomasz Hachaj

Evaluating Effectiveness of Nonlinear Dimensionality Reduction in Hedge Funds' Returns Forecasting **411**
Milica Zukanović, Aleksa Radosavčević, Ana Poledica, Pavle Milošević, Ivan Luković

Encouraging Sustainable Fashion Choices Through a Mobile Application **417**
Bianka Šimková

THEMATIC SESSIONS

Preface to Thematic Sessions **425**

THEMATIC SESSIONS REGULAR PAPERS

Multi-level Optimization-based Ensemble Machine Learning for Efficient Crop Yield Prediction in Saudi Arabia **429**
Raya Aldawoud, Zohra Sbaï

Leveraging Large Language Models for Automated Export Control Screening: Evaluating LLMs Framework **441**
Salem Alotaibi, Alexei Lisitsa, Antony McCabe, Joanna MacSween

AraXLM: Evaluating Arabic Diacritization Tools for Cross-Language Plagiarism Detection **451**
Mona Alshehri, Natalia Beloff, Martin White

Hybrid Approaches for Pneumonia Detection in X-rays: Combining CNNs and ML Classifiers **461**
Gabriele S. Araújo, Omar Andres C. Cortes, Olaf Reinhold, Fabio M. F. Lobato

Treating OCR Output as a Language (TOOL) – Improving OCR Output with Seq2Seq Translation **471**
Thomas Asselborn, Magnus Bender, Ralf Möller, Sylvia Melzer

Blackcurrant Plantations Monitoring Using Drones **479**
Jānis Bičevskis, Reinis Odītis, Ivo Odītis, Zane Bičevska

A Serious Game for Teaching Entrepreneurship and Strategic Management **489**
Boyan Bontchev, Sia Tsolova, Dessislava Vassileva

ELEVATE-AI: Evaluation of Learning Environments Via Assessment Tools Enhanced by AI **499**
Linda Burchiellaro, Francesco Faenza, Claudia Canali

Bridging Global Language Models and Local Spatial Data: The JackDaw Approach to Context-Aware Agriculture and Rural Planning **507**
Karel Charvat, Stein Runar Bergheim, Raul Palma, Adam Aron Rynkiewicz, Matúš Botek, Alexander Kovalenko, Pavel Kordík, Antonín Kubíček, Markéta Kollerová, Šárka Horáková

While-guard Synthesis by Abstract Static Analysis and CHC Solving **519**
Aleksandar S. Dimovski

Machine-Readable by Design: Language Specifications as the Key to Integrating LLMs into Industrial Tools **531**
Alexander Fischer, Louis Burk, Ramin Tavakoli Kolagari, Uwe Wienkop

Forecasting consent in organ donation: early assessment of machine-learning techniques **543**
Arianna Freda, Davide Maestosi, Maurizio Naldi, Gaia Nicosia, Andrea Pacifici

The Power of Preemptions in Scheduling on Shareable Resources **553**
Omer Lapidot, Tami Tamir

From Agents to Copilots: A Systematic Review of Digital Assistant Technology Adoption in Proprietary Productivity Software **565**
Niklas Preiß, Markus Westner

Vehicle Routing under Complex Access-to-Energy Constraints **577**
Alain Quilliot, Hélène Toussaint

An Application of Tensors in the Stochastic Reaction Diffusion Master Equation **587**
Md Mustafijur Rahman, Roger B. Sidje

Leveraging Business-IT Collaboration: Effective Design and Challenges of the IT Business Partner Role **595**
Constanze Riedinger, Christopher Rentrop, Melanie Huber, Stephan Zimmermann

Optimizing Deep Learning for Cotton Leaf Disease Detection Using Meta-Heuristic Feature Selection Algorithms **605**
Naeem Ullah, Francisco Martínez-Álvarez, Ivanoe De Falco, Giovanna Sannino

Implementation of random number generator service with IoT device **615**
Rafał Wojszczyk, Aneta Hapka, Kacper Akdağ-Ochnik

The price of customer presence in Attended Home Delivery with Customer Availability Profiles **625**
Roberto Zanotti, Daniele Manerba, Renata Mansini

THEMATIC SESSIONS SHORT PAPERS

Adiabatic Quantum Computing for the Subset Sum Problem: Preliminary Studies **635**
Cesar Freitas Bernardes, Pedro Castellucci, Douglas Gonçalves, Eduardo Duzzioni, Antonio Mucherino

Cognitive-Aware Peer Assessment: Design Implications from a Classroom Deployment **641**
Naama Bouskila, Lihi Dery

Machine learning for survival analysis: a comparative study on intensive care unit (ICU) patient data and simulations **647**
Lukáš Boček, Lubomír Štěpánek

Coverage of OpenStreetMap data at firm level. Assessing the suitability for social science representative firm samples and found data firm analyses **653**
Christian Gerhards

A Multithreaded Java-Based Video Encoder for Multicore Systems **659**
Beata Bylina, Maciej Okoń

reVISION: A Polish Benchmark for Evaluating Vision-Language Models on Multimodal National Exam Data **665**
Michał Ciesiółka, Filip Graliński

Applications and Challenges of Artificial Intelligence in Educational Course Design and Delivery **675**
Daniel Dan, Anna Wróblewska, Bartosz Grabek, Michał Taczała, Minoru Nakayama

Towards the automated classification of German job titles according to KldB **681**
Ralf Dorau, Kristine Hein

Active Inference in the Distributed Computing Continuum

Schahram Dustdar,
TU Wien, Austria

***Abstract*—Distributed applications now span sensors, edge nodes, fog clusters, and hyperscale clouds. Meeting service-level objectives across this "Distributed Computing Continuum" persistently fails when management is reactive, centralized, and blind to uncertainty. I argue for *predictive equilibrium* as the control objective and for a concrete diagnostic: the Kullback–Leibler divergence between a system's expected and observed causal behavior under perturbations, each modeled with a Bayesian network. This perspective draws from predictive regulation in neuroscience and the fluctuation–dissipation view of equilibrium in physics, and it sets the stage for *antifragility*—systems that get better because they were stressed, not despite it.**

I. Introduction

THE practical difficulty of continuum computing is not merely scale or heterogeneity but *nonstationarity*: workloads, topologies, energy states, and network conditions drift faster than operators can retune thresholds. Threshold rules act only after damage is visible; they presume that the future resembles the past and that a central brain has enough signal to decide well for everyone. In real deployments, devices often act with partial information, and local decisions interact in nontrivial ways, which makes steady Service Level Objective (SLO) compliance brittle. A different organizing principle is needed—one that regulates for stability while learning in the face of novelty.

A helpful lens comes from biology. Bodies do not maintain temperature or glucose by passively waiting for deviations; they *predict* and prepare. **Homeostasis** is reactive stabilization; **allostasis** generalizes it to **predictive regulation**, adjusting internal states in anticipation of expected demands. The **Free Energy Principle** reframes this as minimizing prediction error so organisms preserve their form and functions. Transported to engineered systems, the analogue is clear: components should anticipate loads, not just recover from violations, and success should be judged by how well predictions align with reality when the world is nudged.

The second lens is physical. In many systems, the relationship between internal fluctuations and responses to small perturbations is codified by the **Fluctuation–Dissipation Theorem**; departures from that relationship mark distance from equilibrium. Recent studies show how FDT violations reveal nonequilibrium brain dynamics. For computing, the physics is an analogy rather than a derivation, but it is a useful one: if a deployment's internal model predicts how a nudge will propagate and the observed response matches, we are near equilibrium; if prediction and observation disagree, we are not.

Putting these lenses together yields a working definition: **predictive equilibrium** is the condition in which a continuum system's internal model accurately represents its behavior under perturbations, such that deviations remain small enough to meet goals. This is not a static point but an active property sustained through ongoing modeling, anticipation, and reorganization. It entails dynamic balance (local parts keeping global SLOs on track), continuous reconfiguration (structure in service of goals), and predictive consistency (forecasts match outcomes under realistic nudges). Equilibrium so defined is the platform upon which antifragility can emerge.

To operationalize the idea, represent the deployment as a **Bayesian network** whose nodes are salient metrics and whose directed edges encode probabilistic dependencies within and across tiers. Choose a small, actionable vocabulary—latency percentiles by tier, queue depths, utilization, link RTT/loss, battery state, SLO flags—so the model remains interpretable and fast to update. Then specify a **perturbation** with clear semantics (bandwidth throttle, dependency delay, CPU cap, synthetic burst). Apply it twice: once to the model to produce an **expected** network (updating the affected conditionals) and once to the live system or a faithful twin to produce an **observed** network. The **KL divergence** between these distributions is the "distance-from-equilibrium" signal. Small divergence indicates predictive alignment; a spike signals a breakdown that warrants model revision, policy change, or both.

Why privilege KL divergence over raw SLOs? A latency breach only states that a guarantee failed. KL divergence localizes *why* predictions broke: edges may rewire (emergent dependency), weights may shift (weaker coupling), or noise may increase (stochasticity rose), all of which are visible in the comparative structure and parameters of the two networks. Moreover, the same divergence that warns of impending SLO drift

doubles as a *learning* signal for improving the internal model—a property traditional thresholds lack. Conceptually, this aligns with active-inference accounts where action is chosen to balance pragmatic value and information gain; minimizing KL between expected and observed behavior is precisely minimizing that mismatch.

An architecture built around predictive equilibrium emphasizes **local modeling, safe perturbation, and hierarchical synthesis**. Edge devices maintain compact, incremental BNs over their local neighborhoods and expose an "expectation API" that answers *What should happen here if bandwidth drops by 20% for 30 seconds?* Fog nodes orchestrate small, isolated perturbation campaigns (canaries, synthetic traffic), fit the observed BN, and compute divergence, while also enacting reorganizations—operator placement, replication factors, routing. A cloud-level meta-controller aggregates divergence summaries and, crucially, modulates the exploration–exploitation balance. Here the physics analogy pays off again: use an **FDT-inspired signal** as a *modulator* on the active-inference drive, transiently biasing decisions toward information gain when prediction degrades, then annealing back as equilibrium returns.

Consider a city-scale video analytics deployment. A fog controller periodically reduces uplink bandwidth by fifteen percent for a handful of cameras. The expected BN predicts mild queue growth and a compensatory frame-rate dip, preserving tail latency. Instead, observations reveal that a co-located GPU tenant injects bursty contention, creating a new dependency from that tenant's utilization to the canary's latency. KL divergence jumps. The controller updates the model (adding the edge), raises isolation for GPU tenants in that cell, and adjusts placement to avoid co-scheduling bandwidth-sensitive pipelines with bursty neighbors. In the next probe, divergence falls and the new policy holds. The system did not merely "heal"; it learned a structural lesson and retained it—an instance of antifragility in miniature.

Antifragility is not a slogan but a design criterion: systems should improve *because* stress exposes mismatches. In Taleb's sense, antifragile entities gain from volatility. In our setting, the gain is a better causal model and a sharper policy encoded in the BN and the controller; perturbations become training data that increase predictive fidelity and coordination skill. Equilibrium supplies the safety rails—keeping the system within acceptable performance bands while it harvests information from controlled nudges. There are limits. This is a **conceptual** framework; practical feasibility and cost remain to be demonstrated at scale. Perturbations must be safe and ethically scoped. BN learning must be sparse, incremental, and bounded in overhead. Multi-objective trade-offs (latency vs. energy vs. privacy), partial observability, and compliance constraints complicate modeling and may require task-specific variables and priors. Yet these are engineering questions, not theoretical roadblocks. A sensible validation path is to start in a digital twin, calibrate divergence thresholds to the system's natural variability, and then graduate to canary slices in production.

In sum, predictive equilibrium reframes continuum operations as a dialogue between model and world. Neuroscience supplies the instinct—prepare rather than react—and physics offers a ruler for distance from equilibrium. With Bayesian networks to represent expectations and KL divergence to measure their failure modes, we obtain both an early-warning gauge and a learning gradient. That combination is the essence of antifragility in engineered systems: *stay stable enough to learn, and learn enough to become more stable the next time*. In our previous work [1-5] some of the aspects above are detailed.

***Abstract*—The impact of brain tumors as a global health concern is due to their aggressive behavior, high mortality, and complexities in their diagnosis. While MRI remains the gold standard for identifying, monitoring, and detecting brain tumors, automated classification methods encounter many complications with respect to the diverse morphologies of tumors, similarities in their imaging features, and the potential variability in imaging conditions.CNNs can capture spatial hierarchies, but cannot generalize effectively and ViTs rely on the context to characterize the image modalities which means that, whilst they address some deficiencies of CNNs, they require extensive data and computational resources. To remedy some of the issues that each approach presents, we present multiscale MoE that leverages CNNs and attention-oriented modules. The proposed architecture uses multi-scale feature extraction, channel-spatial attention, and dynamic expert routing, which adequately collects tumor-specific features efficiently. We applied two different publicly available datasets, namely the Bangladesh Brain Cancer MRI and Figshare Brain Tumor dataset. For the Bangladesh dataset, the proposed model achieved overall accuracy of 96.92% and for FigShare dataset, the highest results achieved 96.42% accuracy. In contrast to state-of-the-art models, multiscale MoE achieved the highest testing accuracy 96.14%, and the lowest Brier score 0.0603. The proposed model has shown to have balanced classification results across the tumor classes and reduced the number of false predictions whilst maintaining efficient computational performance and thus has the potential to provide a valuable resource for clinical practice with respect to real-time applications.**

I. Introduction

BRAIN tumors, whether they are primary or metastatic, are a major global health challenge because of their high mortality rates and difficult clinical presentations [1]. Symptoms of brain tumors vary broadly sometimes dependent on location, size, or growth speed and can include debilitating headaches, seizures, neurological deficits, cognitive deficits, and problems with speech or vision [2]. Global health data suggests that this burden is increasing: in 2020, an estimated 308,000 new brain and CNS tumors were diagnosed around the world which led to approximately 251,000 deaths [3]. In the United States, the estimated number of new malignant brain tumors for 2023 to 2025 is expected to reach nearly 24,000 new cases per year with the projection of approximately 18,330 brain tumor related deaths in 2025. Despite advances in their treatment, the overall five-year survival rate is still below 35%, with even lower rates for more aggressive brain tumor types like glioblastoma at close to 7%. This clearly highlights the need for better methods for diagnosis and treatment [4].

Brain tumors are usually approached with a multi-modality approach involving surgical excision, chemotherapeutics, and radiotherapy, which is additionally accompanied with corticosteroids to control intracranial pressure, and anticonvulsant medications to control seizures [5]. Currently, MRI imaging is the gold standard in brain tumor imaging, used for identifying, localizing, and monitoring tumors because it is non-invasive and has greater spatial resolution than the other imaging modalities, and it gives the surgeon an idea of structural and functional information regarding tumor heterogeneity [6]. The advent of automated imaging approaches, driven by MRI precision, has prompted an interest in a collection of imaging variants to assist radiologists in classifying brain tumors based on multimodal MR imaging datasets and to provide images a radiologist would have a unique understanding of and the stages could potentially be determined as well [7].

AI and deep learning specifically, has arisen as a powerful remedy to this issue with unique advancements in assessing the vast amounts of medical images we produce each day [8]. CNNs are the current state-of-the-art for classifying brain tumors as they are able to learn spatial hierarchies and differences based on the spatial relationships between features in MRIs [9]. Recently, ViTs have emerged as a promising rival by modelling global dependencies and self-attention across patch data. Regardless, both approaches address limitations [10]. CNNs rely on intensive training with finite and homogeneous training sets and their performance is symptomatic of their training process, as their ability to classify imaged tumors are less generalizable across imaging conditions[11]. ViTs struggle as they require large amounts of training data and rigorous computational resources to offset their limitations. They also depend upon well-performing patch models over large regions of space and subject to varying spatial biases, which is more frequently defined differently in medical domains because of variability and size [12].

Another problem is the need to develop explainable AI models, which could provide the explanation and justification of its decision [13], [14].

In order to overcome these challenges and limitations, the Mixture of Experts (MoE) framework serves as a promising

path forward because it combines multiple sub-model, allowing each expert to focus on different features of the input such as shape of tumor, texture, and surrounding tissue context. In MoE architecture, each expert focuses on a different feature representation, while a gating mechanism selects the best expert for a given input and its properties. MoE can even manage inter-patient differences, irregular morphologies of tumors, and inconsistencies in medical imaging that often complicate single model approaches. By integrating the advantages of both CNNs and transformers in to a modular framework, the MoE framework can improve classification and generalizability and can improve interpretability of decision making processes. Thus, the Mixture of Experts approach not only addresses the various issues regarding current approaches to automated brain tumor classification but also opens up the possibility for more reliable, rigorously, sensitive and clinically useful AI-supported diagnostic tools. In this work, we proposed a multiscale MoE for the precise classification of brain tumors.

The contributions of this study are as follows:

- A novel Multiscale MoE architecture consist of five experts, multiscale feature extraction, channel-spatial attention, and dynamic expert routing mechanism has been proposed.
- Comprehensive evaluation has been conduction based on two benchmark MRI datasets based on calibration, and inference speed comapred to the SOTA methods.
- Expert utilization analysis revealing dataset-specific specialization patterns, improving interpretability of decision-making.

II. Related Works

In recent years, a number of researchers have proposed several methods for using MRI scans to detect brain cancers [15]. These methods include both conventional machine learning algorithms and deep learning models [16]. Here is a presentation of the pertinent research on brain tumor identification utilizing brain tumor datasets [17]. For example Muhammad et al.[18] presented a comprehensive examination of the various grades used to classify brain tumors. A detailed explanation was given of the procedures used to categorize brain tumors (BTCs), including preprocessing the tumor, determining deep learning features, and classification. They discussed the particular limitations and achievements of the existing deep learning techniques for Bitcoin. The importance of transfer learning for deep learning feature extraction was also covered.

Narmatha et al. [19] presented a methods for classification and segmentation using a fuzzy brain-storm optimization algorithm. With this approach, the target brain cluster's greatest priority is provided by the storm optimization. To find the best answer, the fuzzy procedure is iterated several times. An accuracy of 93.85% is given for the experimental procedure, which was conducted using the BRATS2018 dataset.

Sajad et al.[20] presented a CNN-based multimodal tumor categorization method. They first separated the tumor regions in the MRI data using CNN. They then performed an extensive data augmentation to train an efficient CNN model. Later, they improved the CNN model that was already trained using improved brain data. Tumors were classified using the final layer of the presented method, and it was shown that improved data yielded superior results on the selected datasets.

Mzoughi et al. [21] presented a method for making neuroradiology simple. This study's primary goal was to use volumetric 3D MRI to detect brain tumors. The authors classified the tumors using a Multiscale 3D CNN architecture to increase process efficiency. By using tiny kernels, the suggested approach can lessen the weight of both local and global information. Additionally, the data augmentation technique is used to improve model training. Ultimately, they used experimental findings to demonstrate the effects of data augmentation.

III. Proposed MultiScale MoE

Convolutional Neural Networks have been used for image classification tasks for more than a decade now, demonstrating great potential in various domains particularly in medical imaging. Despite their good performance, there were some issues in traditional CNNs which needed to be addressed such as their inability to extract global patterns, handle diverse features and focus on important regions. Although these issues were addressed individually through attention modules and multi-scale architectures in different studies but there is no comprehensive model that can tackle all the issues together. In this paper, we proposed a new model which can handle all these limitations single handedly by incorporating attention modules, multi scale feature extraction block and Multi scale Mixture of experts in a single architecture to ensure efficient and robust image classification for diverse feature maps.

A detailed diagram of proposed architecture is shown in Figure 1.

Stage 1 begins with initial feature extraction using a 7×7 convolution, batch normalization, ReLU activation, and max pooling, followed by the first MoE block consisting of five parallel expert networks and a dynamic router that assigns adaptive weights to each expert's output. The aggregated expert features are refined through a Channel Attention module, which applies both max-pooling and average-pooling operations to emphasize important channels, and a Spatial Attention module, which uses mean and max pooling across spatial dimensions to highlight critical spatial regions. An Auxiliary Classifier is connected at the end of this stage to provide intermediate supervision.

The proposed model starts with an initial feature extraction block which lays the foundation for deep feature extraction. This block accepts an input of size $(224 \times 224 \times 3)$ and passes it to a 7×7 convolutional layer with a stride of 2 to process low-level features such as textures and edges. It is followed by a batch normalization layer β to normalize the features for stabilized training and a ReLU activation function σ to introduce non-linearity in order to capture complex features. After that, a max pooling layer M_p with a kernel size of 3×3 and a stride of 2 is applied to reduce the spatial dimensions

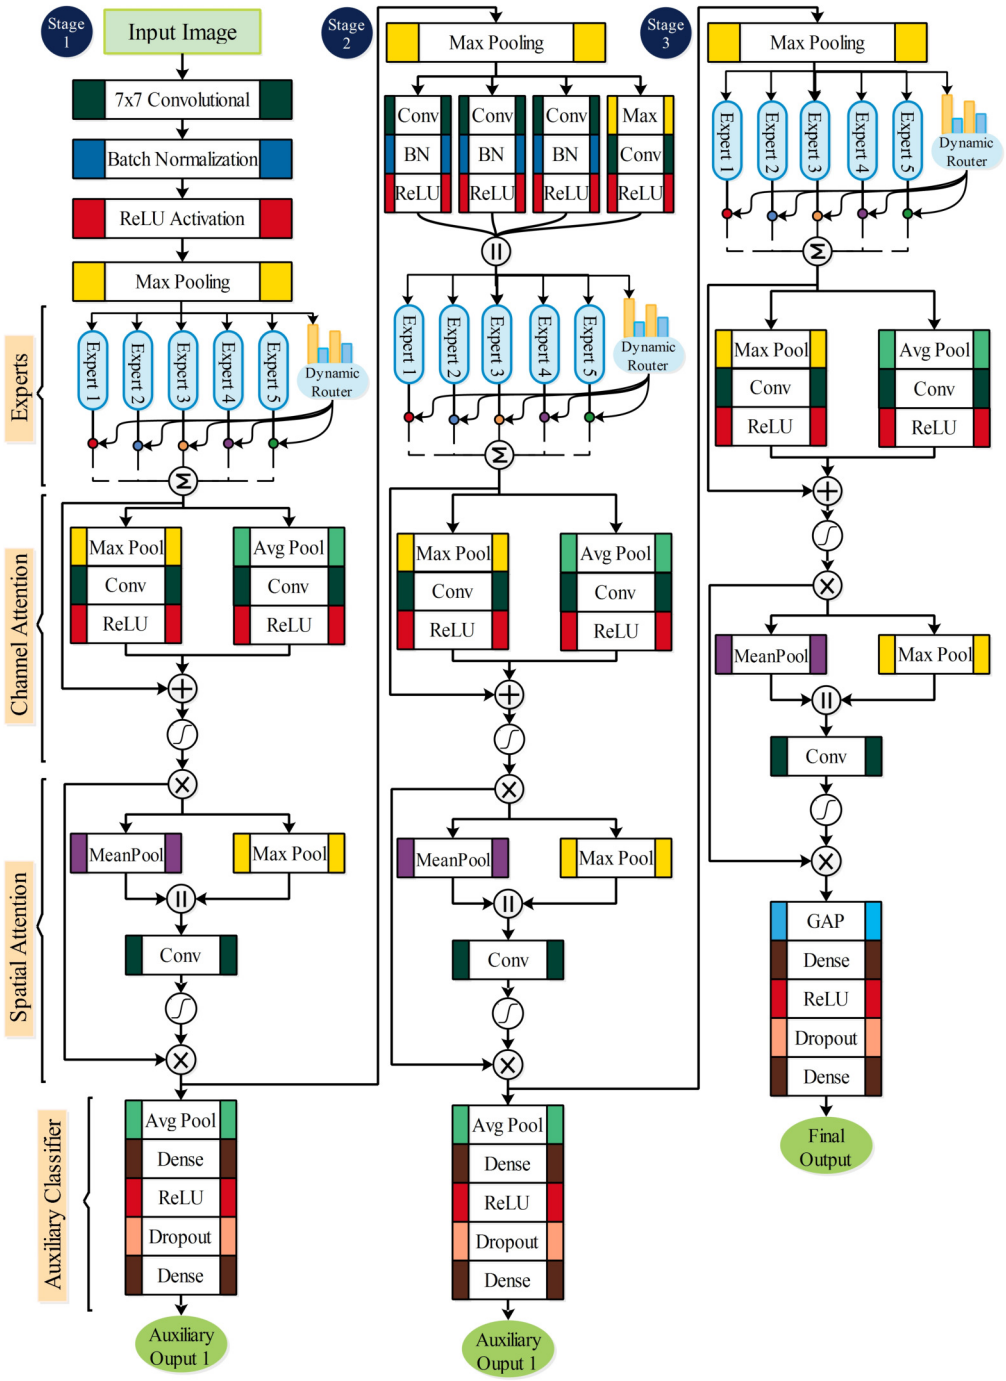

Fig. 1. Detailed architecture of the proposed Multiscale Mixture of Experts (MoE) framework for brain tumor classification. The model operates in three sequential stages, each comprising specialized processing modules.

from 224×224 to 56×56. However, after this block, the number of channels is increased from 3 to 64 for deep feature processing. Mathematically, this block can be represented as:

$$Z_1 = M_p\left(\sigma\left(\beta\left(W_1 * X\right) + b_1\right)\right) \tag{1}$$

Here, X represents the input tensor, $*$ represents the convolutional operation, W_1 represents the convolutional weights, and b_1 represents the bias term.

Stage 2 introduces a multiscale feature extraction block with parallel convolutional layers of varying kernel sizes and pooling operations to capture features at different spatial resolutions. The output is processed by a second MoE block with its dynamic router, followed again by channel and spatial

attention modules and a second auxiliary classifier.

Mixture of Experts: After initial feature extraction, the feature map is passed to the first block of the Mixture of Experts to extract complex features. This block is composed of 5 expert blocks and a dynamic router which assigns weights to each expert block. An expert block is a convolutional neural network that contains several convolutional, batch normalization, and activation layers to extract specialized features based on the input image.

In an expert block, the feature map is first passed through two 3×3 convolutional layers to extract features, where each convolutional layer is followed by a batch normalization layer to normalize the activations. A ReLU activation function is applied at the end to introduce non-linearity. All the expert blocks share the same architecture but have different weights that were initially assigned during training, making them specialized for different types of tumors. An expert block can be defined as:

$$E_i = \sigma\left(\beta\left(W^{''} * \beta\left(W^{'} * Z_1 + b^{'}\right) + b^{''}\right)\right) \tag{2}$$

Here, $W^{'}$ and $W^{''}$ represent the weights of both convolutional layers, and E_i represents the output of the i-th expert block.

On the other hand, a router is composed of an adaptive average pooling layer to summarize spatial information and two dense layers that produce a probability distribution over the 5 expert blocks. A ReLU activation is also applied between both dense layers. It can be defined as:

$$R_i = \psi\left(W_2 \cdot \sigma\left(W_1 \cdot A_p(Z_1)\right)\right) \tag{3}$$

Here, A_p represents adaptive average pooling, W_1 and W_2 represent the weights of the dense layers, and ψ represents the SoftMax activation function which converts the router weights into a probability distribution.

In the MoE block, the input is passed to each expert block and the dynamic router at the same time. The router analyzes the image and assigns weights to each expert block according to their specificity, ensuring that the most relevant experts receive the maximum weightage. The input is processed by each expert individually, and their outputs are multiplied with their respective weights and then added to generate the final feature representation. It can be defined as:

$$\hat{Y} = \sum_{i=1}^{5} R_i \cdot E_i(Z_1) \tag{4}$$

The block diagrams of the expert block and dynamic router are shown in Figure 2 and Figure 3, respectively.

Stage 3 incorporates deeper feature representations via a third MoE block, followed by attention modules and a Final Classifier consisting of global average pooling (GAP), fully connected layers, ReLU activation, dropout regularization, and a final dense layer for tumor type prediction. The architecture's modular design allows dynamic expert utilization, multi-scale feature capture, and attention-guided refinement, enabling robust and efficient classification across diverse MRI tumor appearances.

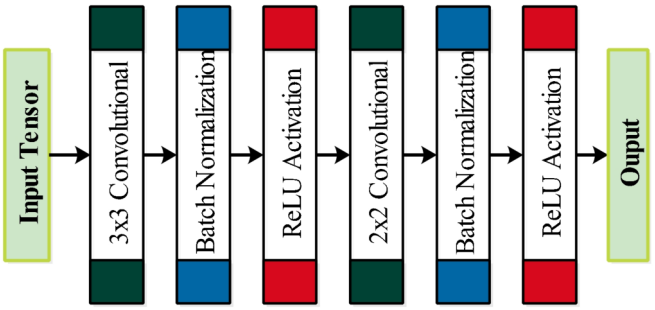

Fig. 2. Structure of an individual expert block used in the proposed Multiscale Mixture of Experts (MoE) framework. The block receives the input tensor and processes it through a sequence of layers: a 3×3 convolutional layer for local feature extraction, followed by batch normalization to stabilize training and ReLU activation to introduce non-linearity. A second convolutional layer with a 2×2 kernel is then applied for further feature refinement, again followed by batch normalization and ReLU activation. The output of this block provides specialized feature representations that contribute to the MoE's adaptive expert routing mechanism.

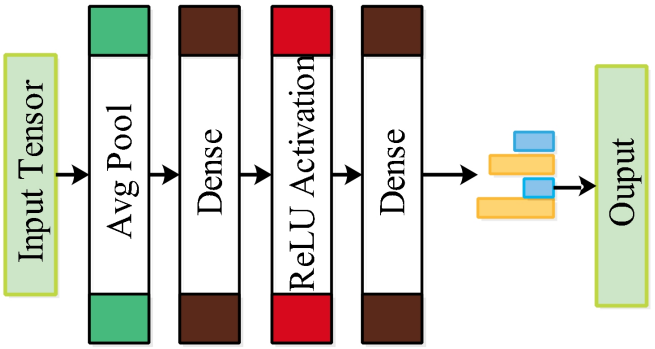

Fig. 3. Architecture of the dynamic router module in the proposed Multiscale Mixture of Experts (MoE) framework. The router receives the input tensor and applies an average pooling operation to capture global spatial information. The pooled features are passed through a fully connected (dense) layer, followed by a ReLU activation to introduce non-linearity, and then through a second dense layer to generate expert routing scores. These scores are normalized into a probability distribution, which determines the relative contribution of each expert in the MoE to the final feature aggregation.

Channel and Spatial Attention: The output of the Mixture of Experts block is passed to the channel attention module to calculate the channel-wise importance and emphasize the important features. For this purpose, the feature map is passed through two parallel blocks simultaneously. Each block is composed of a pooling layer, two convolutional layers, and a ReLU activation function. The only difference is that one block contains an average pooling layer while the other contains a max pooling layer to extract both local and global channel information. The outputs of both blocks are added, and a sigmoid activation function is applied to them to produce attention weights, which can be defined as:

$$A_c = \lambda\left[F_c\left(A_p\left(\hat{Y}\right)\right) + F_c\left(M_p\left(\hat{Y}\right)\right)\right] \tag{5}$$

Where

$$F_c = W_b * \sigma\left(W_a * Y + b_a\right) + b_b \tag{6}$$

Here, λ represents the sigmoid activation function, A_p and M_p represent average and max pooling, W_a and W_b represent the weight matrices of the convolutional layers, and b_a and b_b are their respective bias terms.

These attention weights are then multiplied with the original feature map to enhance the important features while suppressing the less important ones. Mathematically, it can be defined as:

$$Y_c = A_c \times \hat{Y} \tag{7}$$

These channel-wise refined features are then passed to the spatial attention module to emphasize spatially important locations. Here, the feature map is passed through average and max pooling layers simultaneously to capture both average and max features. The outputs of both layers are then concatenated and passed through a 7×7 convolutional layer and a sigmoid activation function to produce a spatial feature map, which is then used to weigh the spatial features according to their importance. Mathematically, it can be represented as:

$$A_s = \lambda\left(W_s * \left[A_p(Y_c) \parallel M_p(Y_c)\right] + b_s\right) \tag{8}$$

Here, $\parallel$ represents concatenation. This weighted feature map is then multiplied with the channel-wise recalibrated feature map to generate a channel and spatial-wise emphasized feature representation:

$$Y_s = A_s \times Y_c \tag{9}$$

Here, Y_c and Y_s represent the outputs of the channel and spatial attention modules, respectively.

Multi-scale Feature Learning: The recalibrated feature map is then passed to the multi-scale feature extraction block, which consists of four parallel layers, each with a different kernel size to extract information at various scales. Each branch is composed of a convolutional layer, batch normalization, and a ReLU activation function to extract and normalize features.

In Branch 1, the convolutional layer has a kernel size of 1×1 to capture pointwise features while reducing the dimensionality of the feature map. In Branch 2, the kernel size is increased to 3×3 to capture small and mid-sized tumors, while in Branch 3, a convolutional layer with kernel size 5×5 is used to extract contextual information.

The last branch, Branch 4, consists of a max pooling layer to summarize spatial information, followed by a 1×1 convolutional layer, batch normalization, and a ReLU activation to enhance spatial robustness in the model. The outputs of all the branches are concatenated before being passed to the next block. Mathematically, this operation can be represented as:

$$Y_M = \text{concat}[Y_1, Y_2, Y_3, Y_4] \tag{10}$$

Where the output of each branch is calculated as:

$$Y_i = \sigma\left(\beta\left(W_i * Y_s\right) + b_i\right), \quad \text{for } i \leq 3 \tag{11}$$

$$Y_i = Y_i(M_p), \quad \text{for } i = 4 \tag{12}$$

Here, W_i and b_i denote the weights and bias of the i-th convolutional layer, β is the batch normalization function, σ is the ReLU activation, M_p is max pooling, and Y_s is the input from the spatial attention module.

These multi-scale extracted features are then passed through another Mixture of Expert block with same architecture as before, however the depth of network is increased to 256 channels. This block ensures that features are extracted at various level of abstractions and model can learn to handle diverse range and types of tumors. Another channel and spatial attention module is incorporated after this Moe block to remove the noise from feature map and to pay attention on more tumor relevant features. It is then followed by another set of Moe block and attention modules incorporated in the very same architecture but with higher depth to extract progressively complex features. So, the input tensor after passing through three Moe blocks followed by attention modules, finally headed towards the main classifier for final classification.

Final and Auxiliary Classifier:

In the main classifier, the feature map is first passed through an adaptive average pooling layer to summarize the spatial information, and the output is passed to a dense layer that projects this information from a higher-dimensional feature space to a lower-dimensional feature space. A ReLU activation function is applied afterward to introduce non-linearity, followed by a dropout layer with a dropout rate of 0.5, which randomly deactivates 50% of the neurons to prevent the model from overfitting. Finally, another dense layer is used to convert the feature maps into class logits. Mathematically, this can be defined as:

$$C = W_2^{'} \cdot \partial\left(\sigma\left(W_1^{'} \cdot A_p(Y)\right)\right) \tag{13}$$

Here, ∂ represents the dropout layer, and $W_1^{'}$ and $W_2^{'}$ represent the weights of the dense layers.

Apart from the main classifier, two auxiliary classifiers are also introduced in the model—one after the first spatial attention module and another after the second spatial attention module. These auxiliary classifiers predict class labels from intermediate features, helping the model improve feature learning during the early stages of training.

Each auxiliary classifier consists of an adaptive average pooling layer followed by a dense layer, a ReLU activation, a dropout layer, and another dense layer—configured in the same way as the main classifier. The auxiliary losses are added to the model's overall loss only during training. During model evaluation (testing), only the loss from the main classifier is considered.

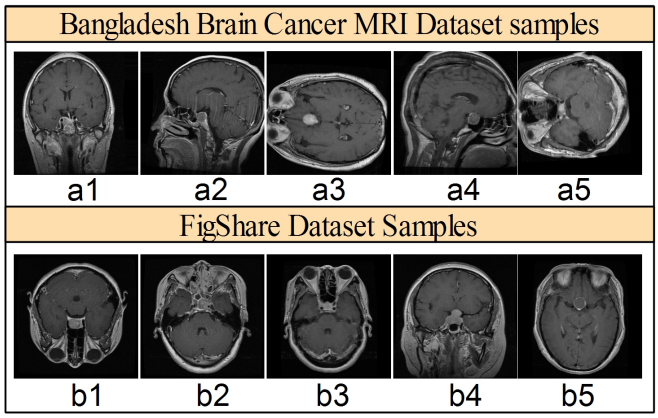

Fig. 4. a1-a5 presented the samples of Bangladesh brain cancer MRI and b1-a5 presented the sample images of Figshare dataset.

IV. Dataset Collection and Augmentation

The experimental design of this work uses two publicly available datasets of brain tumor image classification: https://data.mendeley.com/datasets/mk56jw9rns/1 and https://figshare.com/articles/dataset/brain_tumor_dataset/1512427. In both the Brain Cancer raw MRI data and the Figshare brain tumor dataset, which are displayed in Figure 4, there are three classes in the image classification data for brain tumors. The first dataset contains *Brain_Glioma*, *Brain_menin*, and *Brain Tumor*, while the second dataset includes *Meningioma*, *Glioma*, and *Pituitary Tumor*.

Consequently, Figshare dataset has limited number of images, which are insufficient to train deep learning models effectively. To solve this problem, the original images are splitted into 55% for training, 15% for validation, and 30% for testing. After that,we employed the data augmentation technique on training portion. In this method, three image translations are performed such as flip left, flip right, and rotation to increase the diversity of the dataset. The whole description of the datasets are described in Table I.

TABLE I
Brain tumor datasets with number of classes, images, and splits

No.of Class	Original Images	Train:Test: Validation
Bangladesh Brain Cancer - MRI dataset		
Brain_Glioma	2004	1102 / 602 / 300
Brain_Menin	2004	1102 / 602 / 300
Brain_tumor	2048	11026 / 615 / 307
Figshare brain Tumor dataset		
Glioma	1426	784 / 429 / 213
Meningioma	708	784 / 213 / 106
Pituitary tumor	930	784 / 280 / 139

V. Experimental Setup and Evaluation

A. Training and Parameters

For the training of proposed Mutliscale MoE model, 55% of data is used for training, 15% for validation during the learning phase, and the remaining 30% is allocated for testing. The training process is configured with a mini-batch size of 16, a learning rate of 0.00001, epochs is 50, number of experts is 5, auxiliary weights is 0.03, and the Adam optimizer. To prevent overfitting, early stopping is applied with a learning rate decay factor of 0.2, a patience value of 5 epochs, and a minimum learning rate threshold of 0.00001. All experiments are conducted using Python in a PyTorch environment, executed on a desktop system equipped with an NVIDIA RTX 3060 GPU 12 GB and 24 GB of system RAM.

B. Evaluation Metrics

To rigorously assess the performance of the proposed multiscale MoE model, we based on a comprehensive range of standard and complex evaluation metrics. The standard metrics are Precision, Recall, F1 score, and Support, which together provide a solid assessment of the models discriminative ability, sensitivity, and assessment of classification accuracy. In addition, we incorporated complex metrics such as Balanced Accuracy, F-beta score, Expected Calibration Error (ECE), Brier Score, and an Overall Testing. These metrics provide a fairly complete review of a models efficacy, including dealing with class imbalance, evaluating the tradeoff between precision versus recall when tailoring importance weights, and exploring the calibration of the predicted probabilities. Balanced Accuracy is important in providing equal performance for all classes, no matter how prevalent they are, while the F-beta score provides adjustable weighting so inferences can emphasize recall according to the requirements of any particular application. ECE and Brier Score are important measures of probabilistic reliability, measuring the covariance between predicted certainty and actual outcomes. Calibration-aware metrics are very important in clinical decision making, especially when it comes to high-stakes environments, when both predictive certainty and balanced performance for all classes are important to achieve accurate diagnosis, optimal treatment planning, and ultimately improve overall patient care. the complex metrices are mathematically defined as:

$$\text{BA} = \frac{1}{C}\sum_{i=1}^{C}\frac{\text{TP}_i}{\text{TP}_i + \text{FN}_i} \tag{14}$$

$$F_\beta = (1+\beta^2)\cdot\frac{\text{Precision}\cdot\text{Recall}}{(\beta^2\cdot\text{Precision})+\text{Recall}} \tag{15}$$

$$\text{BS} = \frac{1}{N}\sum_{i=1}^{N}(p_i - y_i)^2 \tag{16}$$

$$\text{ECE} = \sum_{m=1}^{M}\frac{|B_m|}{N}\,|\text{acc}(B_m) - \text{conf}(B_m)| \tag{17}$$

Where C is the number of classes, β calculates the weighting between precision and recall, and N is the number of samples.

VI. Results of Proposed Multiscale MoE

The classification performance of the proposed Multiscale MoE model on the Figshare dataset shows excellent discriminative performance for all three brain tumors, a shown in Table II. Class-wise results indicate that pituitary tumor is classified with the highest precision which is 0.99, demonstrating that while the model correctly classified almost every tumor type, it had an excellent ability to correctly avoid false positives for pituitary tumor while maintaining a high sensitivity to pituitary tumor classification. Glioma classification similarly showed robust performance across both precision and recall with a score of over 0.97 and culminating in an F1-score of 0.98., Meningioma classification while still showing strength precision is0.92, recall is 0.93, and F1-score is 0.93 showed a greater degree of incorrect classification then the other tumors. Examination of the confusion matrix in Figure 5 shows that of the 76 meningioma cases, 12 were found to be glioma and 3 were classified as pituitary tumors. Moreover, of the 59 gliomas, 8 were misclassified as meningiomas. These errors are likely a result of the similarity of radiological appearance for these tumor subtypes, particularly when tumors have overlapping anatomy, as well as more subtle similarities in texture and intensity data that could challenge the MoE model's ability to create distinct class separation boundaries from the MRI scans of these tumor types.

Meanwhile, compared to the Bangladesh dataset in Table II, the proposed model provides greater consistency and balance in performance for each tumor class overall, with each tumor class exhibiting precision, recall and F1-score values exceeding 0.95. Glioma detection remains highly superior precision is 0.98, recall is 0.98, and F1-score is 0.98, meningioma detection achieves balanced precision which is 0.96 and recall is 0.95, pituitary tumor showed exceptional recall is 0.99 with precision of 0.96. In Figure 6, the confusion matrix shows few false predicted classifications with meningioma 10 samples predicted as glioma and 22 samples predicted as pituitary tumor. In addition, a few pituitary tumor such as 9 cases were predicted as meningioma. Generally, the confusion matrix shows fewer cross-class prediction errors when compared to the Figshare results which could be attributed to differing greater inter-class separability. Nevertheless, as can be concluded from both results, the few predicted cases can be easily explained by the overlapping tumor morphology, similar distributions of partial volume effects related to the MRI acquisition.

The extensive performance evaluation of the proposed Multiscale MoE, on the Figshare and Bangladesh datasets, supports the models apparent classification performance, robustness and likely generalization from several sources of data (Figshare and Bangladesh). For the Balance Accuracy measure which is useful to evaluate overall performance across all classes independent of sample distribution was shown to achieve 0.958 for Figshare and 0.9691 in Bangladesh. Both values highlights that the model consistently provides high recognition accuracy independent, or with major class imbalances. Similarly, the F-beta scores that coincidentally achieved the same values (0.9591 for Figshare and 0.9691 for Bangladesh) supports the model's performance aspect of maintaining a fair balance between positive predictive value

TABLE II
Classification results of proposed multiscale MoE on both selected datasets

Class	Precision	Recall	F1-score	Support
Figshare Results				
Glioma	0.97	0.98	0.98	429
Meningioma	0.92	0.93	0.93	213
Pituitary Tumor	0.99	0.96	0.98	280
Bangladesh Results				
Glioma	0.98	0.98	0.98	602
Meningioma	0.96	0.95	0.96	602
Pituitary Tumor	0.96	0.99	0.97	615

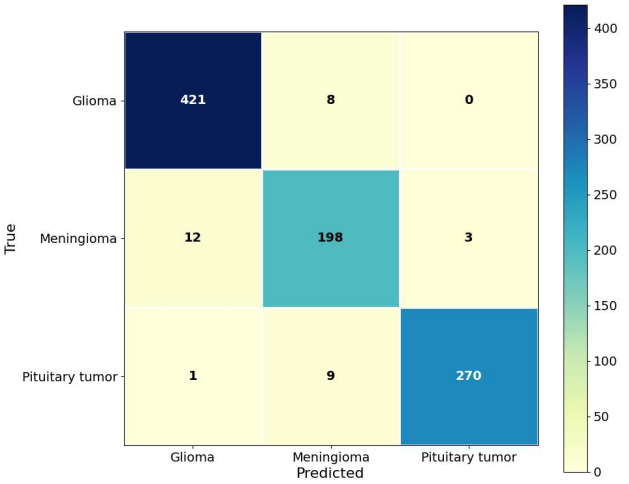

Fig. 5. Confusion matrix of proposed multiscale MoE on Bangladesh brain cancer dataset.

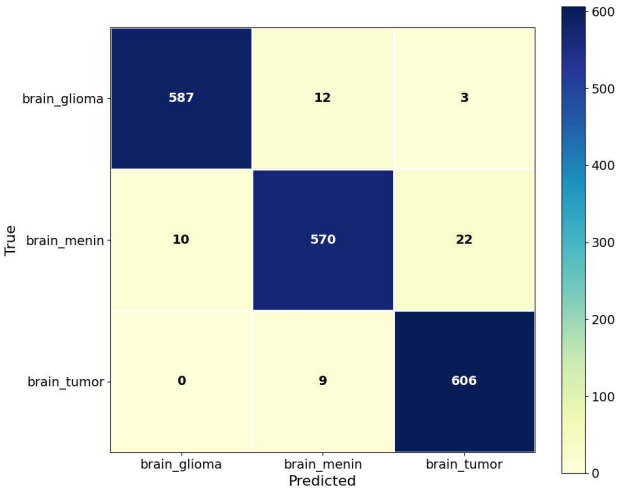

Fig. 6. Confusion matrix of proposed multiscale MoE on Figshare dataset.

(PPV) and sensitivity on both datasets. With the clinically important aim in not creating potential false negatives in brain tumours, we believe the model's F-beta performance being high shows that the model was successfully able to prioritize sensitivity for precision at some gotten trade-off.

Not surprisingly on reliability predictors, both the Expected Calibration Error (ECE) were quite low at 0.0229 for Figshare (and quite low at 0.0086 for Bangladesh) suggestively showing that close the predicted probability provided by model is to the actual observed outcome (the Bangladesh suggesting near perfect calibration). The Brier Score which is a metric of the mean squared difference between predicted probabilities (prediction) and actual outcomes (ground truth), were again shown to be lower in the Bangladesh dataset (0.0456) than Figshare dataset (0.0617), suggesting that model was making more confident and accurate probability assessments. The Overall Testing accuracy achieved over 96% for both datasets (96.42% for Figshare dataset and 96.92% for Bangladesh dataset) and demonstrated good fit and discriminative ability of the model supports its adaptable nature across datasets.

In sum, the performance results all imply that the proposed MoE model is able to provide excellent accuracy in classification, together with probability calibration which is very important in clinical environments where diagnostic accuracy remains paramount while confidence in predicted probabilities play a large role to reliable decision making and effective planning of the treatment decision.

TABLE III
COMPLEX METRICES PERFORMANCE OF PROPOSED MULTISCALE MOE ON SELECTED DATASETS

Metrics	Figshare Results	Bangladesh Results
Balanced Accuracy	0.958	0.9691
F-beta Score	0.9591	0.9691
ECE	0.0229	0.0086
Brier Score	0.0617	0.0456
Overall Testing	96.42	96.92

VII. ABLATION STUDIES

A. Model Computational Complexity

In the first experiment, an ablation study has been conducted aomng the proposed multiscale MoE model against state-of-the-art architectures such as Swin-T, SMViTv2-H and V-MoE based on parameters, GFLOPs and inference time, as shown in Table IV. The comparative results show that although SMViTv2-H [22] has the largest number of parameters 667M and GFLOPs 120.6, it has the highest inference time which is 24.50 seconds. Next, V-MoE [23] has the largest number of parameters which is 14.7B but a moderate GFLOPs value 12.35 and a reasonable inference time which is 11.71 sec, showcasing the efficiency of the expert-based architecture. Given the size of the model, while [24] had the least number of parameters which is 28M and GFLOPs 4.5, its inference time of 12.08 seconds may indicate a smaller representational capacity based on the reduced computational load. Our proposed multiscale MoE model returns a decent trade-off, remaining a lightweight model 25.27 million parameters with competitive computation complexity which is 11.95 GFLOPs. Furthermore, the proposed model exhibits the fastest inference time which is 10.85 sec of the entire study which we believe indicates that the proposed model is able to use multiscale feature processing and expert routing effectively, enabling the delivery of insights quickly and efficiently in a real-time enviroment.

TABLE IV
COMPARISON OF SOTA AND PROPOSED MODEL BASED ON PARAMETERS, GFLOPS, AND INFERENCE TIME.

Models	No. of Parameters	GFLOPS	Inference Time (s)
Swin T [24]	28	4.5	12.08
SMViTv2-H [22]	667M	120.6	24.50
V-MoE [23]	14.7B	12.35	11.71
Proposed	25.27	11.95	10.85

B. Comparison with state of the Art Models

The second ablation study described compares proposed multiscale MoE with leading state-of-the-art models, as shown in Table V. In performance measure F-beta, the proposed multiscale MoE model had the highest score for F-beta which is 0.951 indicating that proposed model provided the most focused balance between precision and recall score, and was best suited for classification tasks where the cost of both false positives and false negatives are critical. The ECE score of proposed model 0.0223 was slightly worse than the SMViTv2-H [22] model, which is 0.018, indicating that while our model was simultaneously reliable, SMViTv2-H [22] had a very slightly better measure of confidence with the prediction probability. Importantly, For the Brier Score the MoE had totally lowest value calculated for the Brier Score which is 0.0603 indicating that our proposed model had the highest accuracy of probability prediction. Finally, in testing accuracy score, our proposed MoE model had the highest score of 96.14% compared to all SOTA methods. While each individual performance measure demonstrates that the proposed MoE outperformed some of the competing methods, the collective measures prove that our proposed model not only had predictive performance better than state-of-the-art models, but also more reliable prediction probability and estimates.

TABLE V
ABLATION STUDY BASED ON F-BETA, ECE, BRIER SCORE, AND ACCURACY AMONG THE PROPOSED AND SOTA METHODS

Methods	F-beta	ECE	Brier Score	Accuracy (%)
Swin T [24]	0.925	0.030	0.075	94.80
SMViTv2-H [22]	0.945	0.018	0.062	95.90
V-MoE [23]	0.935	0.025	0.067	95.40
MViTv2-B [25]	0.940	0.020	0.065	95.60
Proposed MoE	0.951	0.0223	0.0603	96.14

C. Expert Utilization Across Selected Datasets

In this experiment, the utilization of each experts of proposed mutilscale MoE has been measured across the bangladesh brain cancer dataset, as shown in Figure 7. this

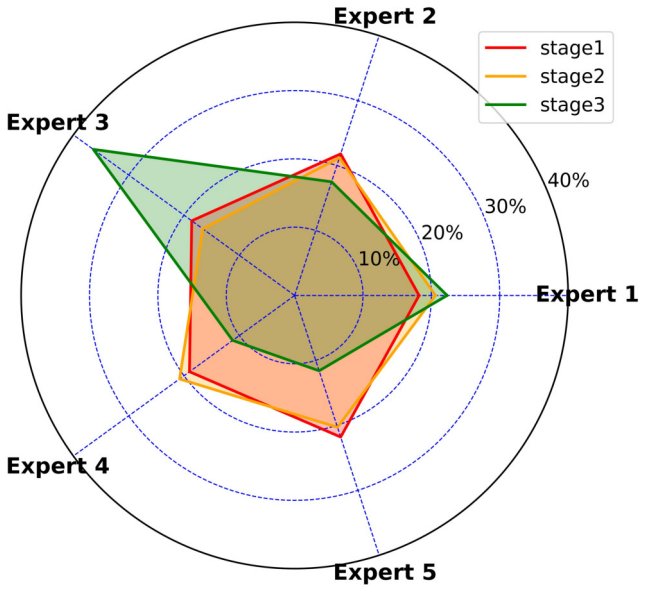

Fig. 7. Expert utilization patterns across the three stages of the proposed Multiscale Mixture of Experts (MoE) model on the Bangladesh Brain Cancer MRI dataset. The radar plot shows the percentage of routing weight assigned to each expert (Expert 1–Expert 5) by the dynamic router during different processing stages. In stages 1 and 2 (red and orange lines), the routing distribution is relatively balanced across experts, with moderate emphasis on Experts 1, 2, 4, and 5. In stage 3 (green line), Expert 3 dominates with nearly 40% routing weight, indicating its specialization in extracting high-level, fine-grained features critical for final classification, while other experts contribute in supporting roles.

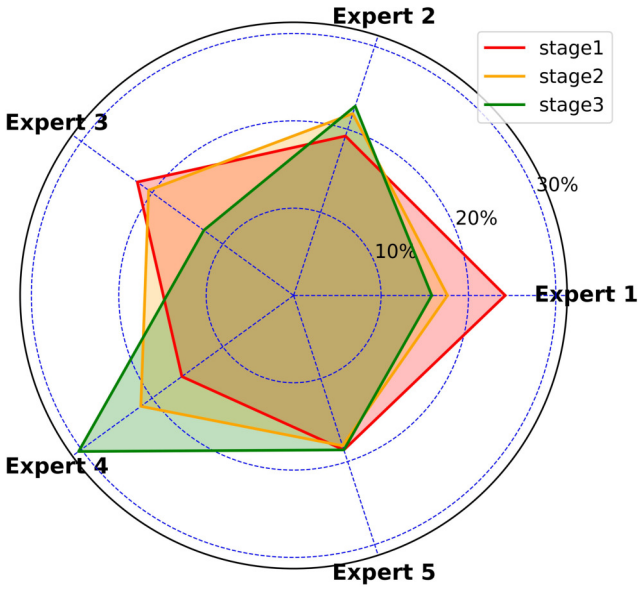

Fig. 8. Expert utilization patterns across the three stages of the proposed Multiscale Mixture of Experts (MoE) model on the Figshare Brain Tumor dataset. The radar plot displays the percentage of routing weight assigned to each expert (Expert 1–Expert 5) by the dynamic router during stage 1 (red), stage 2 (orange), and stage 3 (green). While stages 1 and 2 show a relatively balanced distribution across experts with moderate emphasis on Experts 2, 3, and 4, stage 3 exhibits a strong shift toward Expert 4, which receives the highest routing weight (over 30%), indicating its specialization in extracting discriminative features for the Figshare dataset's unique imaging characteristics.

plot clearly illustrates a distinct usage pattern of the proposed multiscale MoE experts in three stages. During the early stages, Experts 1, 2, 4, and 5 have relatively balanced and moderate routing weights, demonstrating the use of a distributed feature extraction approach in the beginning stages. A major shift occurred in stage 3 when the routing weight of Expert 3 increased substantially, to nearly 40%. This routing weight reflects that Expert 3 was the most prominent expert contributing to the eventual prediction decision. The increased weight of Expert 3 suggests that it was especially proficient at producing the fine-grained, high-level features required to classify thesubtle cases within the Bangladesh dataset. The other experts clearly contributed during this stage but their routing weights had decreased considerably, suggesting they were only being used in a supportive role of general feature representation rather than specific discrimination. The reliance on Expert 3 at the final stage represents the most low-level decision making and should provide a perspective about the versatility of the proposed model where the routing mechanism initiated relevant extremely relevant experts depending on the specific feature characteristics of the dataset.

In Figshare dataset, the routing behavior of experts shows an opposing pattern in specialization. The most apparent observation in this context was the increase in Expert 4 usage in stage three, overtaking Expert 3 whose share dropped significantly, as shown in Figure 8. Expert 4 became the expert with the highest routing weight during stage 3, with over 30%. This suggests that Expert 4 has learned feature extraction that is more appropriate given the unique imaging features of the Figshare dataset, which could include variations in tumor boundaries, texture distributions, and contrasts specific to different imaging modalities. All other experts 1, 2 and 5 showed relatively stable routing weights across the staging, indicating that the same experts participated consistently and contributed relatively equally in the decision making process when comparing with the Bangladesh dataset. Expert 3 lost its influence by later stages; it is clear from the data that what it had learned were less informative features for high level refinement processes in Figshare brain tumor model. Overall, the Figshare results exhibit more evenly shared expert utilization, where it appears the model was able to shift the use of experts on-the-fly as required; dynamically shifting emphasis under the final stage to Expert 4 when classifying images based on this dataset's unique properties.

VIII. Conclusion

Brain tumors are a significant global health challenge because of their inherent aggressiveness, poor patient prognosis, and difficulty in diagnosis. Notably, MRI scanning is acknowledged as the gold-standard diagnostic modality and ongoing treatment tool for brain tumors; however, automated classification techniques often struggle with the highly variable

morphologies of brain tumors, overlap in features, and different conditions on images. In this work, the study proposes multiscale MoE, a Mixture of Experts framework that unifies a CNN and attention-based modules in a single model that support multiscale approaches. The framework builds into the architecture a way to efficiently capture tumor-specific features using multiscale feature extraction, channel-spatial attention, and dynamic expert routing mechanism.

This study used two public datasets: the Bangladesh Brain Cancer MRI database and Figshare Brain Tumor dataset. the presented framework achieved precision, recall, and F1-scores greater than 0.95 for all classes of tumors including a balanced accuracy of 0.9691, a F-beta score of 0.9691, an ECE of 0.0086, a Brier score of 0.0456, and a general overall accuracy of 96.92%. With the Figshare dataset, precision scores approached 0.99, recalls approached 0.98, the balanced accuracy score was 0.958, the F-beta score approached 0.9591, the ECE was 0.0229, the Brier score was 0.0617, and a general overall accuracy of 96.42%. Compared to other state of the art models and approaches, multiscale MoE produced the highest testing accuracy 96.14% and the lowest Brier score 0.0603, and was ultimately the fastest model demonstrating inference times of 10.85 s without tuning.

Despite the promising results, there are limitations with the proposed multiscale model. it is reliant on MRI data because it was only trained and validated with data from two publicly accessible datasets and may not sufficiently reflect the vast variability routinely encountered in imaging protocols, tumor subtypes, and demographics when treating patients globally. This may have implications on the model's generalizability when implemented and applied in various medical environments.

Future work will focus on more data from more than one institute and add additional imaging modalities such as with PET and CT so that the model may learn from more various characteristics in tumours. Domain adaptation and transfer learning methods can be used to improve robustness across scanners and imaging acquisition protocols.

***Abstract*—Providing citizens with transparent, efficient, and consistent legal advice is a critical challenge to uphold governmental fairness in societies. However, this remains a tall order for already overburdened organizations. This paper proposes an interactive learning system that seeks to address these challenges through an organizational learning lens, in collaboration with the Legal Desk in the Netherlands. This system, called SHARE, serves the dual purpose of supporting legal consultations and enhancing the training of legal advisors. SHARE captures and stores strategic decision-making knowledge from experienced legal advisors and facilitates its transfer to less experienced advisors. We explain in this case study the system's approach, prototype design, and evaluation through exploratory user tests. Our findings suggest that this prototype has the potential to contribute towards improved knowledge management for conducting legal consultations within the Legal Desk. To conclude, we discuss the outlook and broader implications of this approach in knowledge-driven work environments.**

I. Introduction

Today's citizens expect government services to be more transparent, accessible, and responsive, and these expectations continue to rise. While there has been many efforts to improve service delivery, they often struggle to fully meet the public's growing demands. Despite advancements such as self-service online portals and more recent solutions like large language model-based chatbot government services [1], uptake remains limited. The success of digitization and automation often hinges on factors like capacity, location, country, cultural practices, and situational contexts. As a result, in-person and telephone channels still dominate most citizen interactions with their government [2]. This makes staff members, who can deliver professional, clear, consistent, and courteous services, crucial to citizen satisfaction. Such direct service places staff at the forefront of fostering a citizen-oriented approach, emphasizing the importance of their training and education. In this work, we present a case focused on enhancing legal knowledge exchange and training for legal advisors in the delivery of legal consultation services, in collaboration with the Legal Desk in the Netherlands.

Learning from experience is a cornerstone of legal education and training [3]. Drawing on past experiences helps inform future practice decisions, a form of learning that is essential in fields such as medicine, law, education, and business, where hands-on experience is critical for developing professional competencies. However, this form of competence requires on-the-job learning that takes years. At the Legal Desk, it takes new hires at least 1.5 years to become experienced advisors. This training time is essential but time-consuming for the Legal Desk that is overworked. Compared to 2022, 2023 saw a 24% increase in in-person counter visits (from 57,900 to 71,700) and 148% increase in consultation appointments (from 15,500 to 38,500) [4]. However, the number of legal advisors increased by 2 (from 256 to 258), and the number of more experienced legal advisors increased by 1 (from 31 to 32). The workload of the legal advisors has significantly increased with the rising demand and limited growth in personnel.

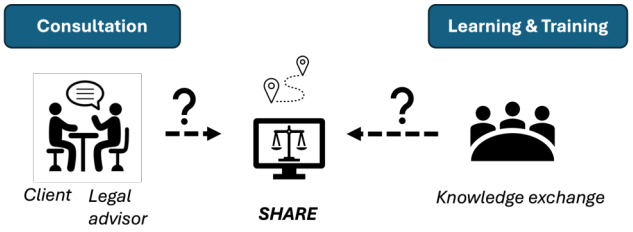

Fig. 1. SHARE aims to establish a knowledge connection between consultation and learning sessions within the existing workflow.

Our contribution is a novel interactive learning system called SHARE designed to improve legal consultation services and training of the legal advisors (see Figure 1). Our approach focuses on aligning structured and strategic knowledge elicitation, transfer, and management, while ensuring compatibility with existing organizational practices for ease of adoption.

We present this system as a solution to a highly complex and "wicked" problem [5], that is enhancing organizational learning to create more citizen-oriented legal services. Within the organization, there are many task and information interdependencies that are challenging to navigate and hence there is an intrinsic resistance for the solution. To this end,

we emphasize an open-ended, design-thinking approach from shaping the problem statement to co-creating solutions.

The SHARE system consists of physical tabletop components to support interaction and collaborative learning, next to a digital component (i.e., a web application) to capture and store structured legal information and the advisors' ways of working. This paper aims to explain a case study for the co-creation process, implementation, and the preliminary evaluation of this interactive learning system.

II. Related Work

A. Knowledge management system

Organizations rely on systematic approaches to retain knowledge. Despite of theoretical frameworks in organizational learning (e.g., single-loop, double-loop learning concepts [6], [7], organizational knowledge creation theory [8], and the five building blocks theory [9]), these approaches lack practical guidance and prescriptions and practitioners also match practical approaches to theory. A notable approach is Communities of Practice (CoP), which focuses on providing an informal learning environment where novices and experienced members of the community interact with each other [10], [11]. Through these interactions, CoP act as a forum for members to learn from each other and past experiences and to trigger joint systematic problem solving. CoP can also be formed by members outside of the organizational borders to help and enable learning within the organization (i.e., the scenario in this case study) [12].

Knowledge management is closely linked to organizational learning. It involves harvesting information and converting it into stored knowledge while ensuring that the knowledge is accurate and up-to-date. It may result in concrete and tangible outputs from the learning process, and facilitates in fortifying organizational memory. Organizational learning is a means to achieve continuous knowledge creation, retention, and utilization. Our physical and digital prototype solution which focuses on the knowledge elicitation, representation, retention, and the transfer process itself is situated at the intersection of complementary knowledge management and organization learning disciplines.

B. Legal learning and education

Legal education has traditionally relied on case-based methods, lectures, and moot court exercises to teach students legal reasoning and professional skills [13], [14]. A number of modern approaches focusing on experiential learning and gamification and interactive platforms have been proposed for legal education. Experiential learning leverages clinical programs (e.g., shadowing) and simulations, that aims to bridge the gap between theory and practice [15]. Gamification platforms also provide different scenarios for the legal learners to explore, providing a risk-free environment for practicing decision-making and experimentation [16].

Our proposed system shares some of the design goals as previous approaches (i.e., interactive and collaborative platform to access legal content [17]). However, our system is oriented towards legal advisors specifically via co-creation approaches so that we maximize likelihood of adoption of this new learning tool. We provide both low-tech (i.e., paper) and digitally innovative form-factors to create a more flexible learning framework.

C. Participatory design

Participatory approaches give substantive agency to stakeholders in product design and development. These approaches follow various traditions drawn from multiple disciplines, such as technology design, policy-making, and social sciences [18]. Belonging to the general approach in user-centered design, participatory design aims to incorporate a diverse range of perspectives, including for non-experts [19], [20]. It encourages continuous exploration and monitoring of the power dynamics between multiple stakeholders [21], [22]. Co-design is a type of participatory design that aims to foster user ownership by actively involving the stakeholders to contribute to the design solutions [23], [24]. The collaborations are more active and sustained, emphasizing on more equal partnerships and shared decision-making.

III. Approach

Our research methodology is principally based on practice-led research where the production, application, and evaluation of creative work leads the process of research [25]. Based on action research strategies that systematically generate and validate new information, procedures, and understandings thereof through practice [26], we emphasize on problem discovery and solving. In this section, we describe the objectives and the co-creation process leading to the design and implementation of the interactive learning system.

A. Conception and rationale

The main interdependent objectives of the SHARE interactive learning system are: (1) Ensuring consistency & quality in customized legal advice; (2) Improving knowledge retention & transfer within the Legal Desk; (3) Finding strategic and possible routes/solutions to cases; (4) Contributing to a citizen-oriented government.

Achieving consistency in customized legal advice (Objective 1) relies on effectively addressing the challenge of improving knowledge retention and transfer within the Legal Desk (Objective 2). Similarly, jointly exploring alternative strategic routes to appropriate advice in cases and problem-solving approaches (Objective 3) can only have a meaningful impact if Objectives 1 and 2 are also met. By addressing Objectives 1 through 3, the project makes a step towards fostering a citizen-oriented government (Objective 4). Citizens could be helped by an organization with streamlined learning and service delivery process. In this context, finding answers to our research questions (RQ) leads to meeting Objectives 1, 2 and 3. While ensuring and measuring consistency in custom legal advise depends on actively using the SHARE system, Objectives 2 and 3 form the foundation for developing the SHARE interactive learning system.

B. Co-creation process

The process started with observation sessions with three legal advisors at the counter and subsequently observing four consultation hours with clients. These exploratory observation sessions helped the core team to understand the workflow of the Legal Desk, the complexity of the cases, and expertise required to handle the cases.

Over a period of 12-months (May 2023-June 2024), the core team conducted a series of co-creations, design sessions, one-on-one appointments, and evaluation sessions with the Legal Desk advisors at the immigration law department. The first three sessions were scoping and brainstorming sessions. Over this period, we co-created various diagrams, mind maps, schematics, and sketches as a necessary endeavor to envision and materialize the SHARE prototype. Preliminary depictions were milestones of progress toward fulfilling the intended problem discovery and definition.

1) Shape Language: Along with post-its, pens, and papers for brainstorming, we also used the Shape Language [1] to support communication between the participants. Shape Language is designed as an intuitive communication instrument to address complex problems. It consists of 3D geometric shapes inspired by architecture (e.g., pyramids, spheres, cube, etc.). These geometric shapes are manipulated without instructions and free of predefined meaning to facilitate the abstraction of complex problems through a joint sense-making process. It has been shown that geometric shapes are related to emotions, metaphoric clues, and are associated with affective value that may assist in interaction and learning [27], [28] . The Shape Language was augmented with a 2D chip variant including triangles, circles, squares, bars/sticks, upon suggestions during the co-creations. They are incorporated in our proposed learning system to provide some tactile interactions that could support learning [29] (see Figure 2).

(a) (b)

Fig. 2. Shape Language in use during co-creation (a) and client test (b).

2) Transitioning into solution-building: The initial co-creation sessions were exploratory. Topics ranged from introducing the use of the Shape Language, identifying regularly occurring complex types of client situations (we here call these canonical situations) and design challenges. In line with the design thinking approach of continuous solution-finding [30], we had different goals per co-creation session, while maintaining an overarching approach to create a divergent thinking mindset, before eventually moving into solution design. The co-creation sessions were insightful to share knowledge and experiences, followed by the participants thinking *together* about feasible solutions to perceived obstacles and organically arriving at the desire to implement those solutions.

In December 2024, the team converged on the concept of using *canvases* as a type of laying field for case problem-solving. The idea is that these canvases physically represents the core topics, questions and answers essential for strategic information gathering on canonical situations and are designed to support conversations with clients. As canvases capture the diagnostic strategic knowledge of experienced legal advisors, jointly preparing the canvas content results in knowledge exchange with less experienced colleagues.

3) Elucidating strategic decision-making: We further define what the structure of strategic decision-making is in the context of using the canvases. The procedure starts with a so-called working thought and ends with an associated advice. The process resembles hypothetical reasoning. Based on an initial assessment of the situation and the desire or expectation to be able to provide specific advice to the client, the advisor forms a working thought (hypothesis). This working thought will be tested by asking targeted relevant questions searching for the key information. The key information they look for is two-fold: essential information that should always be satisfied for giving that advice, and also checking contradictions, i.e., information that invalidates the working thought and advice strategy. Depending on the answers and the evidence obtained, the associated advice is tailored to the client situation, or the working thought is reformulated and the process repeated until an advice is given. This procedure helps advisors to quickly capture the essential information about a case by choosing a route across the canvas(es). As the canvas contains the strategic knowledge of the more experienced advisors, it unlocks this knowledge for the less experienced advisors by following the same working thought and route for problem-solving.

4) Canvas co-design: Being able to formulate the above-mentioned working thoughts and questions to seek key information is essential for the success of the canvas approach. As a first approach we worked with a collection of questionnaires via Google forms to identify the key information and the most relevant questions asked by the advisors to obtain the essential answers from the client, drawing on their experience gathered from canonical case scenarios [2]. We asked the advisors to create a list of topics or the so-called knowledge card. For each knowledge card, we asked for the underlying reason why the knowledge card belongs to a canvas (with the assumption that there are some topics that are common between the canonical cases). We then asked the advisors to formulate several example questions for each knowledge card that the advisor

[1]See VormTaal: https://www.vormtaal.com/

[2]The elicited working thoughts and questions are not client-specific but based on canonical case scenarios. No personally identifiable information were included.

should ask or consider to obtain the key information. This process was intuitive, as the experienced advisor, after some initial questions, completed the Google form questionnaires for some of the earlier identified canonical situations, i.e., a specific *legal framework* (i.e., the combination of a legal topic $\{\text{family migration}, \text{integration}, \text{end of relation}\}$ with a geographical region pertaining to the legal case in question $\{\text{NL}, \text{EU}, \text{3rd countries}\}$).

In the following co-creation design session, the advisors placed the collected knowledge cards per canonical situation on a canvas. They exchanged knowledge and together arrived at the order of the questions and knowledge on the canvas or adjusted where necessary. Here, working thoughts resemble the concept of hypothesis based on the given facts from the situation and serves as the starting point of further investigation using the questions on the knowledge cards. The participants decided to create a so-called "situation canvas" to support the collection of information that is key to any case in legal field of immigration law. With this approach, the ideation of the prototype, i.e., the use of canvases to capture strategic decision-making to facilitate advice-giving during consultation, is finalized. While the physical versions of the canvases (i.e., paper versions) were straightforward and intuitive to implement given the defined workflow, we also agreed on a scalable *and* flexible implementation. This motivated a web application for building and interacting with the canvases to easily store and access canvas-derived information.

IV. The SHARE Prototype

The prototype consists of a *physical canvas* (in paper form) and a *digital canvas* (in web application form). The deliberate choice for having both is that each enhances different modes of communication. We chose to design both forms of the canvas, which showed to be of added value during the client test sessions (see Sec. VI-E) as advisors and clients have different preference. The differing properties of the physical and digital versions of the canvas system are related to explainability and accessibility of information and discussed in this section.

A. Situation canvas

The situation canvas provides the first impression of the key case details for physical paper and digital web version, respectively (see Fig. 3). In the situation sketch box, the Legal Desk advisors can use the 2D Shape Language chips (see Sec. III-B1) to visually represent the case situation. The situation information depicts the people involved and their relation to the client. For the physical version, these chips are available in different colors (red, yellow, green). In contrast, the web version supports "drag and drop" operation of the shapes, which we will extend in future work to include different colors and more flexible drawing options. After sketching the situation, the system provides a notes block to record additional key information on all the people involved in the client's case, their age, nationality, residence history, and dependency status. The web application version mirrors the paper version. Leveraging the situation sketch and the basic information gathered about the legal case, the advisors make an informed decision on the legal framework that is most relevant to the case (e.g., integration for 3rd country individuals).

B. Knowledge cards and conversation canvas

Each knowledge card includes a collection of questions related to a topic relevant to the chosen legal framework. Answer types ($\{\text{free text}, \text{single choice}, \text{multiple choices}\}$) are coupled to each question. Each knowledge card has two explanation fields for: *(i)* a generic explanation/information of how and why this knowledge card is important to *all* legal frameworks, and *(ii)* a canvas-specific explanation that contains information of why this knowledge card is important to the *particular* canvas. For example, suppose the users decide to create a knowledge card for "nationality". Explanation type *(i)* contains generic information such as a list of countries in EU, EEA, and Schengen area, which are facts regardless of the legal framework. Explanation type *(ii)* may contain information about Suriname, a former colony of the Netherlands. This information would be relevant to "Integration", compared to other legal frameworks, as the integration requirements could be different for individual of Surinamese nationality. Fig. 4 shows the paper and web version of the knowledge cards on a conversation canvas.

While the physical paper version and the digital web application are designed to present the same information, there are few key differences that emphasize the strengths of paper and digital versions respectively. First, the aforementioned explanation fields are available in the digital version as we store the information in a database. This is impractical to replicate for the paper canvas version because of the number of documents and the amount of both structured and unstructured information associated with each topic. Secondly, the paper canvas has a limited footprint (i.e., only a handful of questions would fit on paper). This is a deliberate design choice that encourages the advisors to choose the *most* relevant content on topical- and answer-level. The paper canvas limits the possibility of getting sidetracked by case-specific details, which would be of particular added value when dealing with complex scenarios while finding a strategic solution. The web application, however, is designed to be flexible and store unstructured information into structured templates. To strike a balance between generality and specificity, the web application enables the users to select which knowledge cards, questions, and answers should be shown on a specific canvas. The principle of putting information that is necessary and sufficient to cover the canonical scenarios when building canvases was explicitly communicated to the users.

C. Advice cards

Advice cards are unique features of the web application (see Fig. 5). Each advice card contains the advice name, supporting information to the advice, an explanation of the advice at Common European Framework Level - B1 Dutch language level (i.e., at a common every-day Dutch level rather than using legal jargon), and an action list pertaining to the advice.

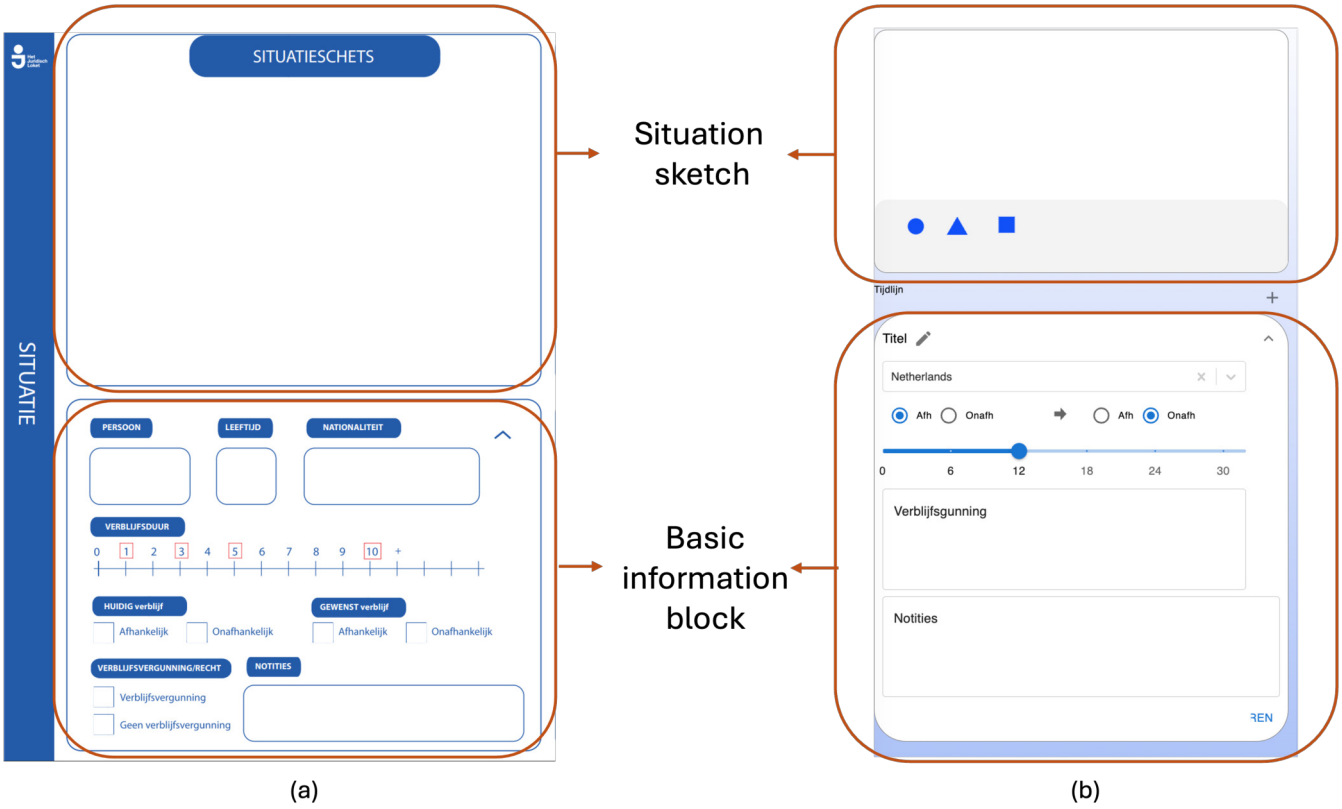

Fig. 3. Situation canvas in (a) paper and (b) web application (in Dutch, with labeled legends).

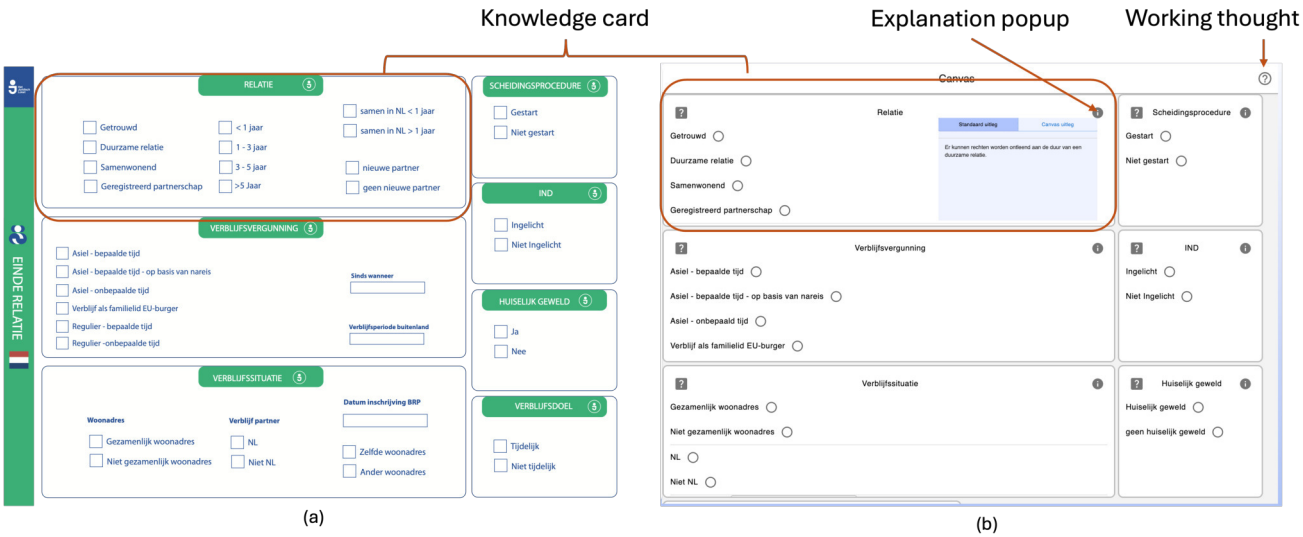

Fig. 4. Conversation canvas in (a) paper and (b) web application (in Dutch, with labeled legends).

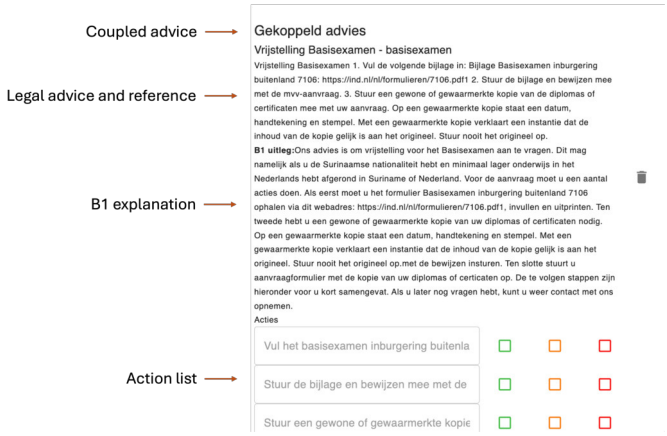

Fig. 5. Example of an advice with the actions list (in Dutch, with labeled legends).

Concretely, the action list should contain tasks to complete, for example, bringing proof of marriage certificate. Advice cards can be associated to the answer combinations on the canvas. When the desired advice cards are picked for the canvas during a conversation, the advisor can indicate the status of the actions in the action list, where "red" means the action cannot be completed, "orange" as action in progress, and "green" as action completed. This way, both the advisors and clients, and also the subsequent advisors taking over this case have a clear overview of the status of the case. The B1 Dutch explanation and the action list are automatically generated into a PDF document available for printing.

D. Automated advice suggestion

The conversation canvas is stored after creation and becomes non-editable during use (i.e., during consultation hours). The conversation canvas now contains strategic questions that need to be answered before giving advice to clients (the need depends on the strategic path of posing questions chosen by the advisor). Based on the single-choice and multiple-choice answers (excluding free text responses for this iteration), the web application automatically suggests predefined or previously given advices for which the answer choices match. This is achieved by storing the answer combinations along with the advice when the conversation canvas is saved. As the user selects the same answer combination in a new conversation canvas, the application back-end runs the match check. The matched advice is shown at the bottom of the conversation canvas. Advisors can review all matched advices and select applicable ones. After selection, the advices are modifiable for the specific instance without changing the original advices serving as more general templates.

V. Use Case

A. Give advice with the use of the canvas

In the current way of working at the Legal Desk, advisors take legal consultation hours (approximately 60-minute sessions for immigration law) with clients after intake at the desk. The consultation hours are oriented towards problem-solving for the client case. Case details are registered in Webtop in the form of text. Advice to the client can be emailed to clients.

The consultation process largely relies on strategic decision-making based on strong expert knowledge. The SHARE system aims to facilitate this process in improving the working experience of advisors and client engagement during consultation. Through the use of the situation and existing conversation canvases categorized by legal frameworks, the SHARE system enables a more streamlined process of asking questions and gathering evidence. We posit that using the system would benefit less experienced legal advisors in particular as they could rely on previous cases and their advice, and structured references of legal information. We also hypothesize that the SHARE system would be welcomed by clients as they can visualize their situation and work through the conversation canvas with the advisor during consultation. Results from the user test designed for this use case and our findings are presented in Sec. VI-A.

B. Create a canvas with a group

To complement "online" real-time support to advisors during client consultations, the SHARE system also facilitates learning "offline", especially during collaborative reflection sessions. We envision that advisors would discuss patterns from cases and create new conversation canvases, knowledge cards, and advice cards to suit their needs. Advisors could synthesize structured knowledge, supplemented by legal references, and store them in the web application.

Knowledge management and efficient knowledge transfer are critical for retaining institutional knowledge (to mitigate knowledge erosion), promote innovation (inspired by group discussions), and ensure continuity (to minimize the impact of employees turnover and retirement). Crossan et al. take these distinct stages together in the four pillars of a learning organization: intuition, interpretation, integration and institutionalization [31]. The SHARE system not only supports documenting explicit knowledge (e.g., links to documents, websites, etc.) but also captures tacit knowledge by enabling advisors to document each consultation in a structured way.

We believe that such a system would promote Communities-of-Practice in introducing a way of working that anchors group learning. By collaboratively reflecting on representative and challenging cases using the SHARE system, advisors can actively engage with one another. This interaction encourages joint brainstorming of creative solutions, benefiting both experienced and less experienced advisors. While experienced advisors contribute their insights, less experienced advisors gain valuable knowledge to better prepare for consultation hours. Results from the user test designed for this use case and our findings are presented in Sec. VI-B.

VI. Evaluation

To evaluate the SHARE system prototype, we have conducted a series of usability tests focusing on the aforementioned two use cases. The usability tests aimed to assess the

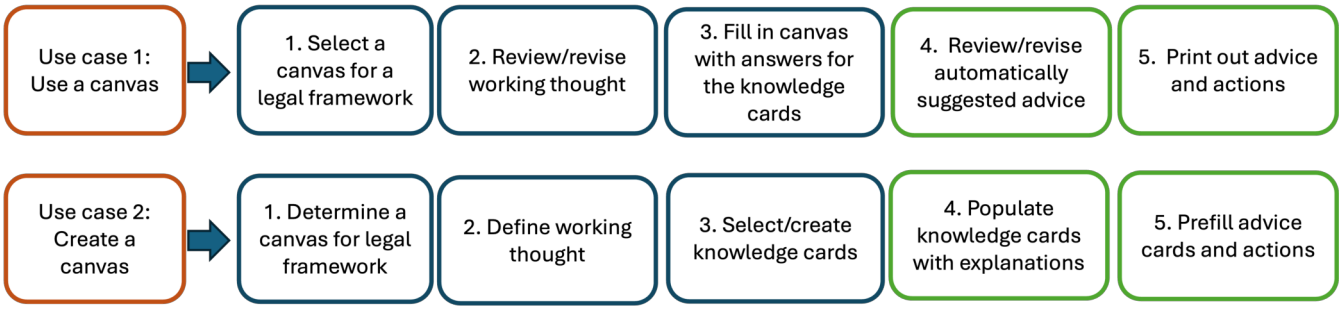

Fig. 6. Workflow of the two use cases of SHARE. Green-outlined boxes show the functionality that is only available in the web application, not on paper. Note that a canvas needs to be created before it can be used. SHARE provides a growing number of starter template canvases.

perceived usefulness and ease of use of the system. Post-task questionnaire evaluations were collected, with questions based on the questionnaire from [32]. The questionnaire is on the 7-point Likert scale, where 1 represents "extremely unlikely", 7 represents "extremely likely", and 4 represents "neutral" (see list of questions in Table I). Verbal feedback was recorded as notes by research members. Two additional observation sessions and a client test session were conducted, which provide triangulation to validate our findings and gain a more comprehensive understanding. While these pilot tests are preliminary due to a lean development process, they provide positive indicators for deployment of the system in the organization after the pilot and shed light on some limitations and future work.

A. *User test: giving advice*

This study focuses on using the SHARE system to advising clients. The experiment was conducted in two sessions at the Legal Desk headquarter office. The first session was attended by three more experienced legal advisors and the second session was attended by one experienced advisor, one strategic development manager, and four less experienced legal advisors. The categorization of experience level is made based on a combination of years of experience, self-assessment, and perception from the strategic development contact involved with the research team. The experimental setting is a low-fidelity role-play simulation. The participants were divided into groups of two with a member of the research team joining the experiment as a facilitator and primarily acted as the client seeking legal help.

In both sessions, the groups were presented with four example legal cases from the legal domain of integration and immigration law. These four cases are fictional but have been reviewed by an experienced advisor prior to the session to ensure that they are representative of actual cases. They were first asked to experience the paper print-out copy of the conversation canvas for the role-play consultation of one case. During this experiment the advisors filled out the situation sketch (i.e., basic information about the case and clients) and the interactive canvas (i.e., the canvas containing the strategic questions and their answer choices). Subsequently, they filled out a post-task questionnaire about this task [3].

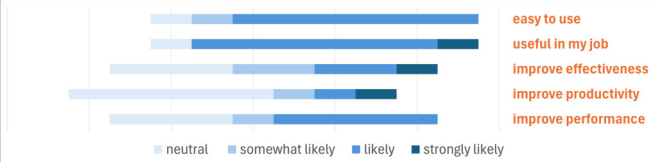

Fig. 7. Overview of ratings distribution of the web application for giving advice.

A tutorial walk-through of the web application was shown to the experiment participants before they started the experiment. The tutorial demonstrates basic operations in the application while working with an example case. It was played once at the beginning at the session. The participants then completed the tasks of working through four legal cases on their own work laptop. Advisors in the same group alternated the control of the application between cases. After completing the cases, the advisors were asked to fill the post-task questionnaire. The results are shown in Fig. 7 for the ratings distribution related to ease of use and long-term effect for job performance. The session concluded with a round-table discussion and feedback.

The results indicate a positive impression for perceived usefulness and ease of use. Despite the SHARE system being a proof-of-concept, the results show that there is potential to improve effective, productivity, and performance upon adoption and system iteration when giving advice to clients. In the context of this user test, results from the post-task questionnaire and after-scenario test from the paper and web version are comparable. Sample size of this comparison is small with three users that participated in evaluation of both versions. Therefore, our assessment remains qualitative. One user gave the feedback that "except of some points in the document (referring to the paper canvas), it is easy to fill in", and that "at first it take some getting used to [do the task]".

[3]This evaluation of the physical version was only conducted in the second session with the less experienced advisors, as the more experienced advisors were already familiar with the physical canvases from previous co-creation sessions.

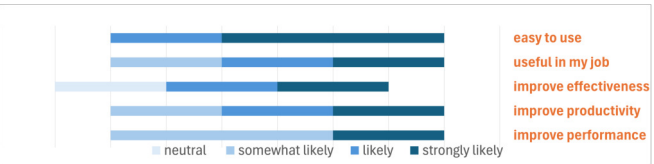

Fig. 8. Overview of ratings distribution of the web application for creating a new canvas.

B. User test: create a new canvas

This study aims to explore the usability of the SHARE system for creating a new *digital* interactive canvas, also as a means of learning and knowledge transfer between legal advisors. This study consists of one session attended by two more experienced and one less experienced legal advisors ($N = 3$). In this session, the advisors worked through a series of tasks in the web application, with increasing complexity [4]. A video tutorial of this creation process was shared with the advisors before the test session. Note that the tasks in the exercise were different from the ones shown in the tutorial video. The tasks mainly covered the following topics: (1) edit and create knowledge cards, (2) edit existing canvases, (3) create new canvases, and (4) edit and create advice cards.

We designed these tasks such that upon completion, the users should be able to make adjustments to existing components in the web application and create new content (e.g., a new canvas with complete knowledge cards and advice cards). The results of the post-task questionnaire are shown in Fig. 8 for a subset of the questionnaire questions related to ease of use and long-term effect for job performance. It shows a generally positive indication for perceived usefulness and ease of use in this *Create* mode of the web application.

C. Questionnaire results analysis

In Table I, we report the average of the ratings across subjects and all questions for perceived usefulness and perceived ease of use, for both user tests. After segmenting results from less experienced and experienced legal advisors, we found slightly higher averaged perceived usefulness scores (4.88 out of 7) from less experienced advisors than experienced advisors (4.25 out of 7). This result is in line with the intuition that experienced advisors may not need the SHARE system to facilitate them during advice consultation in the first place, therefore finding it less useful. Note that these opinions from the advisor were formed before learning about the usefulness according to their clients, see Sec. VI-E. We also note that the perceived short-term usefulness is lower than long-term usefulness for both use cases. To supplement these results and demonstrate the extent of inter-rater agreement, we calculate the Krippendorff's alpha values for over all the ratings on both user tests. We found that there is a fair agreement [33] in the advisors' evaluation for both use cases, 0.27 and 0.20, respectively. However, we also note the disparity in ratings among the advisors. With these results, we aim to demonstrate the collective perception of the SHARE system among advisors who agreed to our tests, and we emphasize that they are not implicative of generalization capability. These post-task questionnaires are self-reports and, though anonymized, taken in the presence of the research team, which leads to subjectivity and bias of the measure. While the results indicate a positive change with the use of the SHARE system, the lack of a control group and objective limits the ability to determine whether the perceived usefulness and ease of use can be attributed to the system itself.

Due to the small sample size, we supplemented the questionnaire with a round of post-task discussions where the advisors gave verbal feedback. We highlight the comments related to lack of usefulness on a short-term basis (translated from Dutch). These comments corroborate the average ratings that we see in the questionnaire.

> "I think that the SHARE web app is now designed with a structure that is flexible. The frame that has been set up is clear and easy to use. But it will take a lot of time in the short term to fill in all the legal information and to ensure that all components are complete. It is a product that will be very useful in the long term, it will still be quite a task to work everything out." - an advisor's feedback after the giving advice user test

> "I think this system has an incredible amount of potential. It will take a lot of work to process all the relevant legal information, but the app is user-friendly and offers the possibility to do so." - an advisor's feedback after the creating canvas user test

Even for the use case in giving advice (where the advisors use a fixed template canvas), one advisor points out that there is still much information to be filled in, potentially referring to the need to revise the advise card and action lists. Surprisingly, creating a canvas is perceived to be easier than using a canvas when giving advice, although creating a canvas is of higher complexity than using an existing canvas. It could be because some advisors already had been exposed to the web application during the "giving advice" user test which predates the "creating a canvas" user test (Sec. VI-B). These effects and observations need to be further confirmed with larger sample size in the future.

D. Observation sessions

In addition to our findings from the post-task questionnaires, observations were conducted in two separate accounts with a focus on observing aspects related to organizational learning (i.e., evidence of knowledge sharing within the organization) The first observation session aimed to inform the design of the physical canvas, which occurred before the "Giving Advice" test (see Sec. VI-A) and was attended by two experienced advisors and one less experienced advisor. The participants agreed that the overview and the visual aspects of

[4]Here we loosely determine the notion of complexity as the transition between different modules and the number of clicks to achieve the desired results.

TABLE I
PUEU RATINGS FOR "GIVING ADVICE" AND "CREATING A CANVAS" (MIN: 1, EXTREMELY UNLIKELY; MAX: 7, EXTREMELY LIKELY).

	Giving advice ($N = 9$)			**Creating a canvas** ($N = 3$)		
Perceived usefulness	Avg(Std)	Min	Max	Avg(Std)	Min	Max
Using the system in my job would enable me to accomplish tasks more quickly	4.6(1.4)	2	6	5.3(0.6)	5	6
Using the system would improve my job performance (short-term)	3.7(1.5)	2	6	4.7(1.5)	3	6
Using the system would improve my job performance (long-term)	5.2(1.0)	4	6	5.7(1.1)	5	7
Using the system in my job would increase my productivity(short-term)	3.3(1.1)	2	5	4.7(1.5)	3	6
Using the system in my job would increase my productivity (long-term)	4.9(1.2)	4	7	6.0(1.0)	5	7
Using the system would enhance my effectiveness on the job (short-term)	3.8(1.5)	2	6	4.3(1.5)	3	6
Using the system would enhance my effectiveness on the job (long-term)	5.2(1.1)	4	7	5.7(1.5)	4	7
Using the system would make it easier to do my job	5.2(0.8)	4	6	5.3(1.2)	4	6
I would find the system useful in my job	5.9(0.8)	4	7	6.0(1.0)	5	7
Perceived ease of use						
Learning to operate the system would be easy for me	5.8(1.0)	4	7	6.7(0.6)	6	7
I would find it easy to get the system to do what I want it to do	5.4(0.9)	4	7	6.7(0.6)	6	7
My interaction with the system would be clear and understandable	4.9(0.6)	4	6	6.3(0.6)	6	7
I would find the system to be flexible to interact with	4.8(0.8)	4	6	6.0(1.0)	5	7
It would be easy for me to become skillful at using the system	5.8(1.0)	4	7	6.7(0.6)	6	7
I would find the system easy to use	5.6(0.7)	4	6	6.7(0.6)	6	7

the physical canvas and the knowledge cards would be most helpful during collaborative reflection and client consultation hours. It also offers support to see the difference between exceptions or business-as-usual cases. The less experienced advisor especially appreciated the structure and the guidance of the canvas and the cards. The more experienced advisors specifically refer to the Shape Language and the value of using these in explaining complex issues. It was observable that the participants are slightly pushed out of their comfort zone, as the canvas is not intuitive and needs explanation. However, we interpret this as an opportunity as being out of comfort zone could encourage learning behavior and deliberations and interactions among each other [34].

The second observation session focused on observing advisors using the web application for knowledge transfer and sharing. In the session, the participants were supported in using the SHARE instrument while they discussed a case. It seems as if they adjust their way of thinking towards the way the elements work together. The way that the instrument is designed and its intentional generalizable layout provoked the participants to discuss nuances. This aspect energizes the meeting, whereas the explanation working through the exercises in creating a new digital canvas required effort from the participants. Strong form of expert knowledge gained from experiential learning consisting of both canonical and noncanonical work practices and their discussions was observable from the sessions.

E. Client test sessions

We observed the SHARE system being used in two client advice sessions with an experienced legal advisor. Both clients signed the informed consent to participate in the observation session and agreed to a short interview after the session. One case concerns social benefits with part-time work; another concerns right to stay in the Netherlands after end of relationship. To integrate the SHARE system in the consultation, the procedure is divided into 3 stages: (1) preparation of the interactive canvas and working thoughts for the case context acquired from the counter visit intake, (2) using the physical and digital canvases interchangeably during consultation, and (3) review the outcome of the consultation and integrate information into Webtop (which is the current system for registering case information). The research team did not give any other instructions on how to use the SHARE system.

Through observations of two client cases, we found that both the system and workflow have room for improvement, with some highlights from client feedback. The ad-hoc update of the canvases, given the case scenario, could be cumbersome yet necessary. Modifying the canvas template in the web application in preparation for a specific client takes approximately 5 minutes, as it involves reviewing the existing knowledge cards and choosing additional applicable others. The need to modify a template arose because of the currently limited number of templates. Over time, templates have to be made for all canonical cases to ensure broader case coverage. Modifying physical printed canvases requires manually manipulating the layout of knowledge cards on the PDF document. Another point of improvement is that the current advice print-outs lack proper formatting. The advisor resolved this by first creating the advice in SHARE, then copying it to Webtop where they could manipulate the layout, and then printing the advice from Webtop. This made this part less efficient in real-time consultations. For these reasons, the SHARE system still needs to be more integrated with the existing tools that the advisors have to use due to standard practices in the organization currently, both in terms of procedure and infrastructure.

However, both clients provided positive feedback on the utility of the canvas, particularly the paper version, and the shape chips (as part of the Shape Language kit, see Sec. III-B1). In one case, the chips played a significant role in guiding discussions around work and social benefits. After several attempts at verbal explanations, the advisor used the chips to demonstrate and clarify the different components of income, which the client understood. These tools were deemed

helpful in providing a clear and comprehensive overview during the consultations. One client indicated that she saw great potential in using the shape chips as they could symbolize certain concepts and facilitate understanding (translated from Dutch and paraphrased from original verbal feedback).

F. Limitations

1) Bias in results: Despite the general positive trend in how SHARE is perceived by the users at the Legal Desk, there are several sources of bias. In our practice-led approach, we are often deeply embedded in the research process both as a practitioner and an investigator. This dual role blurs boundaries between personal preferences and professional priorities and objective research goals. This likely has an impact on our evaluation of the prototype. While we mitigated these effects through the use of existing questionnaires to avoid leading questions, anonymous submission of the questionnaire, and leveraging the only non-Dutch and non-Dutch speaking researcher to conduct the user tests, these biases would still exist in our results. The use of the only post-task questionnaire is also less ideal due to the lack of objective measures of the consultation and learning process and the shortage of advisor participants (which is a niche group) who are already overloaded with work. More objective assessment of the prototype could be achieved through a scalable roll-out and experimentation based on procedural measures such as task completion time, and qualitative and quantitative metrics of legal advises. The management of the Legal Desk would have to agree with the time investment of their advisors at the cost of offering support to their clients. The evaluation of the system may need to become a continuous effort if and when they decide to roll out the system in the organization.

2) Mode of interaction: Because the SHARE prototype exists in two formats, a physical printout paper version and a web application version, one experienced advisor has reported difficulty in deciding which format to use, which suggests an ambiguity in the purpose of use of either of the two formats.

In the post-session interview, the advisor said that

> "Well, [I prefer] the web version but only if it is complete. The online version, I cannot work as fast as that, ok I'm going to create something else right now. During the meeting with a colleague, it is possible. But with a client, it is difficult and it takes time..."

This implies that the paper version has a clear advantage compared to the web application version during the two consultation hours with real clients. During our observations (without providing instructions to the advisor), it was clear that the advisor made an effort to use both paper and web version. She also reported that there was a lot of juggling, bringing too much cognitive load to keep up with using both formats while trying to hold a conversation with the client. Another possible reason is the insufficient familiarity and training, particularly for adjusting an existing canvas or creating an new canvas with the web application in the little time they have for preparing for a consultation hour.

This limitation could be addressed by further optimizing the dual-format usage, and by providing clear guidance on when to use which format. With further testing for both the paper version, digital version, and their combination with control groups in the experimental setup and clearly defined metrics for efficiency and effectiveness (e.g., time to complete the same task), we could make a more informed decision based on the (dis)advantages of both formats.

In the meantime, the advisor also indicated the potential of using the system for training new colleagues.

> "I think it will be useful to a new colleague...She will start advising for immigration law. It [the SHARE system] will be useful for learning and training and see how to do things. It'll be easier than me telling them this is how it works."

This statement corroborates the second observation session on assessing how SHARE contributes to enhancing organizational learning capacity, where group discussion and information exchange were observed. Even at this prototype stage, the advisor thinks that it will already be helpful in training with the existing form-factor and partial information (focusing on immigration law) in SHARE.

3) Filling in the appropriate legal content: In the current SHARE approach, an important challenge to address is to ensure sufficient coverage of legal frameworks and information. So far we have solicited information from the advisors and built the canvases manually with the advisors' contributions. The question is to which extent we can extend the SHARE web application to streamline and (partially) automatically generate the sets of relevant questions, after which the advisors only need to review, revise, and order the knowledge cards on the new canvas and supplement it with their expert knowledge. Given the flexibility of the SHARE web application, the advisors could review and revise the automatically generated information and supplement it with their expert knowledge. Using this approach, the process could be more time-efficient than starting from scratch using google forms and manually setting up the knowledge cards, references, and explanations.

Using a toy example case provided by a legal advisor regarding the right to invoke legal presumption for labor, we found that automatically generated responses from large language models to the expert-provided working thought led to a largely overlapping set of knowledge cards compared to the ones provided by the legal advisor. We note that while the automatically generated responses are a feasible starting point for automating the creation of canvases, some pivotal questions are only present in the legal advisor's approach. However, this provides us with an approach to scale the system beyond its prototype phase.

4) Technology integration, maintenance, and ownership: Paper and digital version of the SHARE learning system and their instructions are accessible and integrated into the Immigration Law department's Microsoft Teams channel. There is an agreement with the research team for light maintenance of the current version of the web application, and possibilities to answer any questions related to use.

However, the web application is currently not integrated into the technology stack at the Legal Desk. The integration is challenging due to the existing third-party software company already maintaining the technical infrastructure for the organization. The research team has limited resource to interface with the software company together with the Legal Desk and comply with existing regulations. For this reason, we have explicitly instructed the advisors not to put any personally identifiable information of the clients into the SHARE system. To allow for scalable deployment and to ensure that any potential information of the clients remains within the Legal Desk for privacy reasons, the web application needs to be integrated within the existing infrastructure (i.e. Microsoft Azure services) in the future.

VII. Discussion

A. Preserving the qualities of paper version of SHARE

As explained in the system's evaluation, both the physical paper and the interactive web versions of canvases have their advantages and disadvantages. The question naturally arises if we can combine the advantages of both versions. The idea was formulated to use tablets running the application on the table between advisor and client as an option that comes close. This approach maintains the benefits of physical interaction while incorporating the advantages of the interactive web version, providing the client with a clear overview and structure during the consultation. However, the advantage of touching the shapes for enhancing the feeling of co-creating and ownership for both the advisors and clients would not be captured by the use of the tablet. Further research is necessary to enable situated real-time and multimodal understanding of the advisor-client interaction.

B. Generalization to other departments and organizations

Currently SHARE focuses on the immigration law department at the Legal Desk but can be generalized and adapted to other topics and organizations by leveraging its core principles of flexibility and knowledge-sharing. On a content-level, it would be straightforward to augment the existing immigration law with other legal topics (e.g., labor relations) at the Legal Desk, as we could query the Knowledge Bank. On the approach-level, many disciplines show similar ways of working, that focus on experiences (i.e., the transition from inductive reasoning to deductive reasoning as novices become experts). Novices gain from inductive reasoning to build experience through trial-and-error. Experts rely on deductive reasoning for efficient problem-solving, which starts from general principles or rules (in our case, the working thoughts) to specific cases. The SHARE system explicates the problem-solving approach and we envision it to cut down spent and wasted effort in learning from trial-and-error. SHARE elucidates and trains users in acquiring a type of strategic and structured knowledge that is crowd-sourced by the experts and built collaboratively and organically within the organization. Taking these guiding principles of the SHARE system, organizations could adapt the content and approach to fit teams that wish to learn and train more efficiently.

C. Continuous engagement with the learning system: a mindset for organizational learning

Engaging continuously with learning systems requires consistent and regular interaction with both formal and informal channels of knowledge, including structured training programs, peer collaboration and feedback, and personal development initiatives. Organizations like the Legal Desk must integrate multiple components to support systematic learning, such as a technology platform for storing strategic expert knowledge (e.g., SHARE), a strong learning culture that encourages exploration and idea-sharing, and leadership that prioritizes continuous learning as a core value.

From a technical perspective, we envision the SHARE learning system evolving towards being more automated through the integration of richer datasets and more advanced underlying algorithms. This trajectory aligns with a broader goal of embedding SHARE within a hybrid human–AI learning organization for future work. Building on the framework introduced by Tan et al. [35], the human–AI learning loop is designed to support a dynamic spectrum of knowledge exchange modalities. These range from traditional human–human interactions to collaborative human–AI learning, and even fully autonomous multi-agent AI–AI knowledge transfer. Each mode and learning pathway contributes uniquely to the hybrid human-AI system's adaptability and capacity for continuous improvement, and foreshadows the potential of SHARE as a scalable learning platform.

From an organizational point of view, the full implementation of SHARE and the aforementioned human-AI learning framework involves aligning learning activities with strategic goals and existing work activities. Challenges such as time constraints, as seen in the Legal Desk's immigration law department, can hinder consistent engagement. This should be taken seriously since these time constraints may also lead to the lack of integration of organization learning into existing organizational systems [31] and eventually missing the opportunity to develop a sustainable learning ecosystem between the various groups of professionals [29].

Overburdened advisors often have to prioritize immediate tasks over dedicated learning, making it difficult to balance work responsibilities with continuous education. Flexible learning opportunities, such as micro-learning sessions or workflow-integrated learning, can help mitigate these challenges. To this end, we believe the SHARE system has taken a step in demonstrating how learning can be integrated into the way of working for an organization with limited resources. SHARE enables a minimum setup of the hybrid human-AI organizational learning framework where employees become part of a learning organization and actively contribute to joint knowledge transfer and development without requiring significant change to the way of working.

VIII. Conclusion

In this paper, we introduced a novel interactive learning system designed to enhance legal consultation services and training at the Legal Desk. Using a co-creation approach, we collaboratively defined the problem of the organization's high turnover rate among legal advisors and developed a solution motivated by this critical challenge. Our proposed system, SHARE, integrates physical tabletop components with a digital web application. SHARE supports the explication of strategic expert knowledge on conducting efficient and effective consultation hours to provide their clients consistently with appropriate and customized advice. SHARE stores and presents that strategic knowledge to all advisors (experienced and less experienced) in such a way that less experienced advisors benefit from this strategic knowledge. Each component serves distinct purposes and leverages its unique strengths, working in synergy to achieve the desired outcomes for improved learning and consultation experiences for clients. We evaluated the prototype using a combination of user tests, observations, and interviews. We found a positive perception towards the prototype (further confirmed by the deployment of the current prototype in the organization) both from the advisors and from the clients point of view. We discussed the limitations of the prototype and suggested potential future work. These include designing and measuring more objective measures and scaling up experimentation with more users. Overall, our findings highlight the potential of SHARE as an effective instrument for addressing organizational learning challenges by enhancing legal consultation experiences and training. Future iterations of the system can be further refined for impact and scalability, paving the way for broader adoption and sustained benefits within the Legal Desk. The system can also be extended and adapted for other organizations that experience similar knowledge erosion problems and users that do similar types of knowledge-intensive work as legal advisors.

Acknowledgment

This research was (partially) funded by an NL Ministry of Justice and Safety subsidy under the project title " SHARE — Vind Samen het Alternatief". We thank het Juridisch Loket for their contribution to this project.

***Abstract*—Nowadays, modern business includes acquisition and storing enormous data volumes, larger than ever before. Such data represent a significant value that an organization or a society can utilize to reach created goals and provide sustainable development. Unfortunately, a daily practice still intensively points out to the problem of a serious gap between the identified needs for knowledge, on one hand, and inability of the disciplines of Computer Science, Software Engineering, Informatics, and Data Science (CSSEIDS, for short), combined with the modern software technologies, to address such needs in an effective way, on the other hand. One of the important causes of such phenomenon is in a lack of strongly educated and interdisciplinary oriented experts showing an appropriate level of knowledge both in CSSEIDS, as well as in the disciplines of Business, Management and Economics, for a specific problem domain. In this paper, we address issues on how to come to more flexible and interdisciplinary oriented study models capable of producing various forms of digital managers and digital engineers, as a new profile of experts, ready to cope with digital economy and digital transformation in a modern society. Massive deployment of such experts is a way to significantly raise the level of organization maturity regarding capabilities for: information management, quality management, business processes, and big data analytics.**

***Index Terms*—Digital Transformation, Education of Digital Experts, Digital Engineer, Digital Manager.**

I. Introduction

NOWADAYS, modern business includes acquisition and storing enormous data volumes. Practically, we are faced with exponential growth in the amount of data collected. In [1], the authors discuss about big data as an emerging phenomenon. They state that "computing systems today are generating 15 petabytes of new information every day—eight times more than the combined information in all the libraries in the U.S.; about 80% of the data generated everyday is textual and unstructured data." As such, we can state that we are in the Age of Big Data. Current state of data and knowledge management in modern business, characterized by the big data age, is in that the data represents a significant value that an organization or a society can utilize to reach created goals and provide sustainable development. By [2], Big Data is the next frontier for innovation, competition, and productivity.

By our experience, in well-matured companies, the company management typically shows a clear recognition of needs for generating corporate knowledge from data. To address this need, they are ready to deploy quantitative, analytical methods, with the aim of effective data use in the decision process and various company management activities.

Despite that there is a clear recognition of significant worth ingrained in stored data, unfortunately it is still mostly unexploited. Data is operationally used in a short time frame, and then archived, without further utilization in the process of generating corporate knowledge. Tremendous amounts of data are available, while many institutions fail to make efficient use of the huge amount of data available, or look for patterns. One reason notified in [3] and [4] is that it is because the business appetite for doing so didn't exist, while the survey presented in [5] notifies the main obstacle to use advanced data analytics in the lack of understanding how to apply it.

Hereby we identify a great discrepancy between business needs on one hand side, and Information Technology (IT) capabilities on the other hand side. We notify significant needs for generation of corporate knowledge from data, while we notify inability of modern software products to effectively address these needs, despite that huge amounts of data already exist, and modern IT tools provide excellent technical capabilities. Such phenomenon can be perceived as a new form of Software Crisis introduced even in 1970's. However, it is never ending, present even for decades in various forms. Now, we can call such phenomenon a Big Data Crisis. From the managers' point of view, the phenomenon is perceived as an evident lack of return of investment (ROI) in big data projects in which engineers are unable to satisfy stakeholders' and managers' evident needs. However, from the engineers' point of view it is perceived as managers' and stakeholders' insufficient and unsatisfactory understanding of both IT capabilities, as well as business and decision processes.

However, Big Data Crisis is not just about perceiving factors 'on the surface' of the problem. It is to go deep into its causes and address them in a strategic way. We can identify the following main causes of Big Data Crisis, covering both managers' and engineers' side of the problem:

(A) Unsatisfactory level of organization maturity regarding the capacities for: information management; corporate knowledge management; business processes and institutionalization; and quality management;
(B) Unsatisfactory level of accumulated knowledge in a problem domain; and
(C) Unsatisfactory level of accumulated knowledge in the domain of computer science, software engineering, informatics, and data science (CSSEIDS), necessary for the development and formal specification of models for software products aimed at generation of company knowledge and decision support.

Addressing the Big Data Crisis causes is a strategic and long-life task. It implies addressing all its significant causes simultaneously.

In this paper, we intend to contribute to addressing (B) and (C) causes. It is an important endeavor related to the education process, and mostly formal academic education process. Our goal is to address issues on how to come to more flexible and interdisciplinary oriented study models capable of producing various forms of digital managers and digital engineers, as a new profile of experts, ready to cope with Digital Economy (DE) and Digital Transformation (DT) in a modern society. We believe that massive deployment of such experts is a way to address in some aspects the (A) cause, i.e. to significantly raise the level of organization maturity regarding capabilities for information management, corporate knowledge management, quality management, business processes, and big data analytics. Let us notify that full addressing of the (A) cause is out of the scope of this paper, and it is a matter of our future research work.

Apart from Introduction and Conclusion, the paper is organized through four sections. The analysis of present research works is given in Section II. In Section III we discuss current findings regarding present education models. Perspectives and requirements about the improved education process are discussed in Section IV, while in Section V we outline a more flexible and interdisciplinary oriented academic education model to cope with Big Data Crisis.

II. Related Work

In recent years, labor markets have experienced significant changes, primarily due to the rapid technological progress introducing new skill requirements for DE. This change resulted in a gap between the skills companies seek and the ones available in the job market. As a result, it is essential to align the education curricula with the industry requirements. Underscoring this point, in [6] it is argued that curricula must be regularly updated to prepare students effectively for the digital landscape. Similarly, in [7] the authors proposed a new framework to measure the alignment between higher education digital skills and industry requirements, deriving factors for graduate preparedness from a systematic analysis of the relevant literature.

To address the evolving needs of the labor market, the education sector is increasingly compelled to adopt a systematic approach to transformation enabled by digital innovations. The authors of [8] analyzed existing DT frameworks to identify the critical components that educational leaders must consider when developing strategies for effective digital change. This study reviewed contributions from 50 organizations involved in education policy, including research institutions and technology companies providing hardware, software, and digital consulting services, as well as 15 Ministries of Education. The findings highlighted four principal themes: Leadership (94%), People (67%), Technology (56%), and Experience (33%). In [9], the authors investigated whether education is perceived as an essential factor in the broader digital transformation narrative by analyzing scholarly works from diverse scientific fields. The findings suggest that both education and workforce competencies are crucial for advancing digitalization and that many barriers to technology implementation can be mitigated through targeted educational initiatives. Furthermore, in [10], the authors argue for the establishment of interdisciplinary research and education centers that focus on IT skills development through industry partnerships and experiential learning.

In [11], it is proposed a theoretical framework to guide development of study programs that align with job market requirements, addressing the shortage of DT leaders. The authors note that universities often struggle to adapt swiftly due to lengthy bureaucratic procedures and curriculum development cycles. The authors of [12] reported on an educational project from the University of Birmingham. In collaboration with industry partners, the aim of the project was to strengthen students' personal development in the digital domain and provide exposure to digital systems used across industries. Subsequent evaluations revealed that this initiative enhanced students' digital competencies, resulting in a 30% improvement in their knowledge of the digital skills covered.

The skills required for the digital economy era cannot be acquired through a single discipline; rather, they demand an interdisciplinary approach that combines academic learning with professional training. Supporting this view, the authors in [13] introduce an educational framework with two components: a Competence Model for identifying essential skills for DT and a Digital Transformation Maturity Model for evaluating both individual and organizational competencies. Similarly, in [14] the authors analyzed the profiles of modern, data-driven companies and identified two groups of skills required for Data Scientist roles: (1) professional and attitude skills and (2) critical thinking, communication, collaboration, organizational awareness, and ethics. Focusing on Brazil's emerging economy, in [15] the authors identified a misalignment between the skills required by IT companies and those taught in IT-related education programs. Companies' managers emphasized that non-cognitive or 'soft' skills distinguish exceptional IT

professionals. The study concluded that Computer Engineering programs tend to prioritize technical skills over social and emotional competencies, highlighting the need for a more holistic educational approach to produce well-rounded graduates.

In contrast, in [16] the authors examined students' perceptions, where students' population is one of the main groups entering the workforce, regarding studying in digital environments and their consequent preparedness for employment in DE. In a case study conducted in the city of Osijek in Croatia, the results indicated that 35.8% of students considered the traditional education model to be unsatisfactory. Additionally, 71.6% of respondents believed that acquiring knowledge in DE would likely or certainly benefit their future employment or self-employment. Similarly, in [17] it is investigated the impact of Digital Transformation Initiatives (DTIs) on the Future Job Prospects (FJPs) of senior engineering students, demonstrating a direct, empirically measurable relationship between comprehensive digital educational environments and enhanced perceptions of career readiness.

From almost all related works analyzed it follows that having deep digital skills will be more and more important factor of better employability in the future job market. A review of scholarly work on this topic highlights the need to revise higher education curricula to provide learning opportunities across diverse domains. Universities must foster stronger connections with industry, as these partnerships can co-create authentic learning opportunities and provide insights into evolving labor market demands. In response to this need, we propose fundamentals of a new education model that introduces the digital expert profiles of a Digital Manager and Digital Engineer. Such model emphasizes the importance of interdisciplinary knowledge, integrating technical competencies such as mathematics, statistics, and engineering with business, economics, social sciences, and soft skills, thereby producing graduates who are not only technically proficient, but also adaptable, collaborative, and prepared to lead in the DE era.

III. Initial Findings

One of the hot issues in creating Computing, Computer Science (CS), Informatics (I), or Software Engineering (SE) curricula in academic education is in what extent they are to be characterized as: (i) "self-contained", (ii) interdisciplinary oriented, or (iii) applied, and how to properly adjust a level of overlapping with other disciplines. It is not always easy to constitute high quality study programs that will properly meet the balance between those three characteristics, and to satisfy current and future needs of industry, at the same time.

As discussed in [18], in software industry of well-developed economies, we can notify a strong fitting between the skill and education requirements for specific job positions, and the level of education and experience of software engineers or IT experts being hired at those positions. Also, such software engineers typically show a higher level of specialization in some disciplines or problem domains. On the contrary, in underdeveloped or even developing economies, fitting between the required skills and education level for the job positions, on one hand side, and the level of education and experience of software engineers on the other hand side, is often not appropriate, and we can notice hiring overqualified or underqualified experts at some positions, to a wider extent. The level of specialization depth of software engineers to some disciplines or problem domains is not as strong, as in well-developed economies. However, it seems that a common characteristic of the Human Resource (HR) market in both cases is that interdisciplinary oriented professionals are always welcomed and better positioned, particularly as the requirements for such profiled experts are typically much over the HR market capacities.

In [15] the authors advocate about significant changes in the technology-related job market over recent years, mainly due to technological advances. It pushes industry toward new demands for skilled professionals, and it is a crucial factor to consider the future industry needs for HR experts. The authors notify: (i) a gap between industry needs and professional profiles available in the job market; and (ii) difficulties in finding employees who meet the required profile. All that results in financial loss and extra training expenses.

Absence of almost any academic education strategy leads to total leaving the academy to the operational market laws. Consequently, it comes to the two paradoxes [18]:

(P1) More interdisciplinary oriented experts, capable of covering a wide range of tasks, knowledge and skills are always significantly better positioned in the software industry HR market, while academic institutions offer study programs that are rather self-contained, i.e. oriented to a narrower knowledge scope; and

(P2) Students or young software engineers believe that they will be better positioned in software industry HR market just as they are good IT experts, i.e. programmers, while employers rather expect experts capable of recognizing and resolving their interdisciplinary oriented and complex requirements.

In [19], it is stated that the culture of interdisciplinary orientation of education is usually poorly developed, while interdisciplinary education is most likely in experiment phase. Even more, there is no consensus on how to evaluate the outcome of interdisciplinary education.

If we say here that academic institutions motivate, often 'in silence', education of 'more specialized experts', that means experts that are pure software or informatics engineers, mathematicians, business administration managers, or various domain experts.

Traditional taxonomy of education and research areas that is commonly applied in the academic accreditation process in some countries (e.g. in Serbia) is very rigid and comes to the disciplines of (a) science and mathematics; (b) engineering and technology; (c) social science and humanities; and (d) medicine. We identify study programs of the three categories, covering in some extent disciplines of CSSEIDS. Those are: (1) Specific study programs in Computer Science, Software

Engineering, or Informatics (CSSEI); (2) Study programs in (Applied) Mathematics (AM); and (3) Study programs in Economics, Business Administration and Management (EBAM). Many universities traditionally provide study programs in all three categories, for decades. A common belief among university education staff is that such traditional disciplines are quite enough to satisfy the needs of future HR market in the DE era.

By our long-term education experience, we identify the typical students' and even teachers' behavioral patterns of all three study program categories, as follows [18].

(1) Students from specific CSSEI study programs are predominantly technology oriented. Often, they express their animosity to the mathematical, and even more organizational, managerial or economics disciplines, with a belief that this knowledge is not necessary to them, and that someone else is to possess it. Study programs of this category often provide just a modest level of knowledge from mathematics and business administration. On the other hand, such students express their strong interest in learning a typical technology knowledge in IT.

(2) Students from AM study programs are predominantly formally oriented. They believe that technology knowledge is of a lower-level value. Also, they are not aware of the necessity of having a knowledge from business administration, management, or economics. Development of skills aimed at practical application of adopted knowledge in various application domains is often underestimated or even neglected. Students from this category believe that complexity of things is just of a logical nature – the things are more complex, just if they are logically complex, while other forms of complexity that evidently exist in engineering and science are rather neglected. Study programs of this category often provide a modest level of CSSEI knowledge, as well as business administration knowledge.

(3) Students from EBAM study programs show a strong awareness about the importance of having the CSSEI and AM knowledge in resolving the complex problems in organization systems. However, in a lack of formal knowledge from these disciplines, they believe that someone else is to resolve such problems, while their task is just to rent high quality CSSEI and AM experts to resolve the problems. Study programs from this category motivate learning a highly formalized knowledge from CSSEI and AM rarely.

Literally, we may say that the three identified behavioral patterns form "a universe of not joinable worlds" [18].

As such, a question arises: who will maintain the 'interfaces' between various disciplines? We need to systematically educate interdisciplinary oriented professionals capable of creating interconnections between various disciplines with a satisfactory deep level of knowledge of details. Our personal view is that academic education in CSSEIDS shows best chances to address this issue successfully, both in the areas of business and organization systems and scientific computations.

To perform some form of a test of our assumption, we consulted ChatGPT (June 2024). The findings are that "education in CSSEI can be closely related to digital manager skills in several ways. Strong technical foundation and problem-solving mindset are crucial for effective digital management. By aligning the technical expertise from CSSEI education with the strategic and operational skills required for digital management, professionals can effectively lead DT initiatives and drive organizational success in the digital age. By evolving the classical education approaches in CSSEI, we come to ability to (i) better prepare graduates for the multifaceted role of digital managers in modern companies; and (ii) equip them with business acumen, and leadership skills required to drive DT and innovation."

Despite that we identified the three behavioral patterns while developing data science curricula as discussed in [18], the patterns are general and should be strongly considered in creating new study programs in support of DE. DT as a movement to DE is driven by changes in: (a) business models; (b) culture; (c) behavior of individuals; and (d) how technology is driving and is driven by these changes [20]. It is much more driven by the first three factors, supported by IT, than has been driven by advancements in technologies themselves. As stated in [20], strategy, but not a technology drives DT. We can say that it should be strongly considered as an important assumption in creating any education program in support of DE and DT.

IV. New Education Perspectives

To provide a movement to DE by deployment of DT principles, an organization must create power for organization transformations that are predominantly disruptive by its nature. It means that the incremental model of improvements is considered too slow and inefficient in most cases. DT strongly implies a faster model of discontinuity with a full reconsideration of the company business model and acceleration of company management in better understanding of the transformation process. DT must provide scaling from digital experiments and pilots to digital best practices [21]. An enterprise ecosystem in DE is organized through five layers, i.e. digital platforms (given here from bottom to top): 1. IT Infrastructure Platform; 2. Delivery Platform; 3. Talent Platform; 4. Leadership Platform; and 5. Business Model Platform. The main characteristics of the digital platform layers are that they should be designed as multidisciplinary oriented, dynamically coupled with a possibility of easy adaptation, with evident capabilities for learning and reconfiguration, and easily extensible with porous borders. A strong requirement to apply DT principles successfully and transform organization into a DE enterprise ecosystem is to develop those new digital platforms. The development process of digital platforms is considered as a unique venture in each organization. There is no silver bullet, no way to buy it anywhere – it must be designed and implemented in the organization. Common requirements for such process are integration of business and IT needs and requirements; and establishing a clear collective vision of the

company management, with the main purpose to provide company growth, as the main business priority [21].

A strong prerequisite for initiating a DT endeavor is to provide enough DE experts with a new profile, capable of high-quality support of the DT process. By [22], workforce skills are the most difficult barrier for building organizational capabilities for DT. We are faced with an evident lack of well-educated digital experts ready to support DT process. This phenomenon is called Digital Talent Gap [22], [23].

Academic education is not an exception. It should be subjected to the DT process, to come to the strategic goals necessary to support movement to DE and effective production of digital experts, and by this contribute to overcoming the Digital Talent Gap problem. As such, academic education is also to be transformed in a way to reach the new digital 5-layered platform. In [24], the authors propose adjusted priorities of academic education and training of teachers with a goal to come to well-educated specialists capable of managing and using digital technologies.

By our viewpoint, academic education is always the first-class entity for profiling DE experts – Digital Managers and Digital Engineers. It should be combined with additional approaches to education, such as short courses, training of various forms, and company schools or universities. In [25], the author proposes several priorities of the academic education transformation. One of the priorities is integration of university and corporate education. While corporate universities provide ultra-modern, but not systematic enough and fundamental education, classical universities are criticized as being still far from modern society education and new teaching technologies. However, they offer very important fundamental knowledge necessary for an expert to last on the HR market and to be able for long-life self-learning and moving to emerging technologies easily. Another important priority identified in [25] is that universities should become drivers of DT of society and economy. Nowadays, a new mission of universities, their technology parks, and business incubators together with teachers is to contribute to the development of (youth) startups.

To address Big Data Crisis Causes (B) and (C) and provide a transformation of academic education to face with DE, we start from the hypothesis that formal academic education is to strongly motivate raising the level of: (i) interdisciplinarity and multidisciplinarity in profiling students' knowledge: (ii) abstraction and formalization skills: (iii) quantification, metrics, and analytical skills; (iv) specification, implementation, and integration skills; (v) business, management, communication, and soft skills; and (vi) problem domain skills. There are three general approaches to initiate modernization of a study program to face DE: a) starting with a CSSEI curriculum; b) starting with an EBAM curriculum; or c) hybrid or Integrated approach. The first approach motivates producing highly technically proficient digital engineers and, in some extent, digital managers, who can bridge the gap between technology and business. The second approach motivates producing digital managers with strong strategic and operational skills, who can understand and leverage technology. The third approach means creating a curriculum mostly from scratch. Integration in this approach means unifying existing CSSEI, EBAM, and possibly AM curricula. The outputs in all cases can be interdisciplinary programs, joint, double, or dual degree programs, or even just collaborative courses.

To initiate the process of study program transformation, it is important to identify and formulate the general requirements to the transformed curriculum. In this case, we predominantly address such requirements for a CSSEI program. A proposal of the general requirements includes the following:

(1) Interdisciplinary Curriculum;
(2) Project-Based Learning;
(3) Soft (Non-Cognitive, Metaskills) Skills Development;
(4) Industry Partnerships and Internships;
(5) Continuous Learning and Adaptation;
(6) Entrepreneurship and Innovation;
(7) Analytical Thinking and Data-Driven Decision Making;
(8) User Experience (UX) and Design Thinking;
(9) Cybersecurity and Compliance; and
(10) Mentorship and Networking.

Identification of those ten requirements was inspired by the authors' experience, as well as the related work research mostly presented in [15], [26], [27], [28], [29], [30], and [31].

(1) Interdisciplinary Curriculum is an important advantage, as traditional CSSEI programs focus heavily on engineering and technology-oriented subjects, while it is a requirement to integrate it with business, management, digital marketing, and leadership courses. Integration with mathematics (algebra, discrete mathematics, probability theory) and statistics is also a must. It is to strive for embedding more holistic educational experience and combine general engineering and CSSEI disciplines. By this, one can create a field where interdisciplinary and multidisciplinary education has room to grow.

(2) Project-Based Learning is an achievement where not only theoretical knowledge with isolated coding projects are practiced. It means real-world project-based learning, working in multidisciplinary teams, simulating the collaborative environment. It is even more effective if it is applied in coordination with the selected companies that are ready to provide their real word problems or case studies to be adapted to students' projects with the company experts ready to be involved in the mentorship program of project-based learning.

(3) Soft Skills, Non-Cognitive, or Metaskills Development is an achievement where focus is not on technical skills only. The program should incorporate soft skills training, such as communication, teamwork, leadership, emphasizing effective communication, conflict resolution, and team management. Required skills for DT era are entrepreneurial vision, creative ability, holistic vision, with a focus on collaboration, ethics and social responsibility, and codes and programming.

Majority of executives consider soft skills as increasingly important, while there are studies suggesting that both soft and hard skills are needed. In [32] and [33], the authors identify the following key leadership skills: communication skills, language knowledge, organizational skills, subject-specific

knowledge, digital literacy, and self-reflection. Executives are to be emphatic, open-minded, flexible, motivated, and stress tolerant. In [34] and [35] the authors identify behavioral leadership skills as core abilities of managers. They include motivational skills, team-building skills, and emotional intelligence. Also, in [35], the authors identify the Altro-centric leadership, as an other-centered leadership style, or adaptive leadership that is mandatory to support DT as a disruptive process. To provide such leadership style, increasingly important soft skills are empathy, humility, integrity and compassion, integrity, creativity, and human–ethical sense of judgement to AI's data-driven information and judgments. Managers' focus of such style is on coaching, motivating and empowering employees, while engineers' focus is on algorithmic management practice, particularly supported by Artificial Intelligence (AI) and Generative AI methods, and on handling quantifiable managerial tasks and quantitative performance evaluation.

(4) Industry Partnerships and Internships require strengthening partnerships with technology-oriented companies and startups. It includes internships, co-op programs, collaborative projects, experience and networking opportunities.

(5) Continuous Learning and Adaptation means that the curriculum is not just fixed with a static set of courses. It nurtures the culture of continuous learning and adaptability to teamwork. It insists to flexibility in offering elective courses on emerging technologies, providing access to online resources, and encouraging participation in workshops and conferences.

(6) Entrepreneurship and Innovation is a requirement for having courses on entrepreneurship, innovation management, and startup ecosystems. It should inspire students to think creatively and rationally, and take risks, allowing staying ahead of digital trends and implementing cutting-edge solutions.

(7) Analytical Thinking and Data-Driven Decision Making is an achievement in which not only coverage of data structures and algorithms with limited application to business contexts is enough. Instead, it requires having advanced courses in Data Analytics (DA), Machine Learning (ML), Business Intelligence (BI), decision theory, operational research, optimization methods, and stochastic processes. Emphasizing applications in strategic decision-making is expected.

(8) User Experience (UX) and Design Thinking requires integration of UX design, Human Computer Interaction (HCI), visualization methods, and design thinking courses. It provides emphasizing user-centric product development with full consideration of the Requirements Engineering (RE) discipline.

(9) Cybersecurity and Compliance requires fostering cybersecurity education and culture and including topics on regulatory compliance, risk management, and ethical considerations in digital management.

(10) Mentorship and Networking requires creation of various mentorship programs to connect students with industry professionals and alumni. It should provide guidance and career advice to the students.

In [22], critical skills gaps for DT are identified: Analytics, Big Data, Digital Strategy, Financial Modeling, Digital Marketing, Security, Privacy, Risk, Compliance, Smart Product Development, Software Development, and Web/mobile Development. We see those recognized skills for Digital Managers and Digital Engineers.

In [21], the author discusses new roles of Chief Information Officers (CIOs) in the DT process, by comparison to the past and well recognized CIOs' roles, as shown in TABLE I. It is evident that new roles of CIOs require much more proactivity, well understanding of both business and technology and applying strategic thinking effectively. As such, a new profile of a Digital Manager or even Digital Engineer should provide high-quality knowledge to cope with new roles of CIOs in DT, where CIOs take positions very close to strategic company management.

TABLE I.
CIO ROLES IN THE PAST AND IN DT FUTURE

Past CIO Roles	Future CIO Roles
Focus on IT outcomes	Focus on business outcomes
Sequencing of operations	Creating collaborative agenda
Support	Overcoming the unconquerable
Costs control	Developing the income plan
Process Reengineering	Data utilization
Outsourcing	Design of business
Focus on functions	Focus on (DT) platforms
Searching for parity	Searching for differentiation
In the scope of IT sector	Everywhere in the organization
Focus on IT risks	Focus on business risks

Finally, it worths to mention that a new notion of Digital Intelligence (DI) is proposed in [36] and [35]. By this, all employees, including managers, should develop DI as an ability to learn digital technologies, deal with digital technologies appropriately, read, decode and manipulate digital information, and acquire and apply new knowledge and skills connected to digital technologies to address insights and openness, and improve operational efficiency and outcomes.

V. A New Education Model

To cope with Big Data Crisis Causes (B) and (C) by applying DT in academic education, we propose introducing the profiles of Digital Manager and Digital Engineer. A body of knowledge of the study programs supporting the two profiles is to be based on four widely set-up scientific and engineering general disciplines (Fig. 1):

(1) Computer Science, Informatics, (Software) Engineering, and Data Science (CSIEDS);
(2) (Applied) Mathematics, Statistics, and Science (MSS);
(3) Business, Social Science, and Economics (BSSE); and
(4) Humanities and Soft Skills (HSS).

As such, a body of knowledge includes numerous disciplines. We give here a list of the disciplines grouped by the four general disciplines, not pretending to perceive it as a complete list of the knowledge being offered.

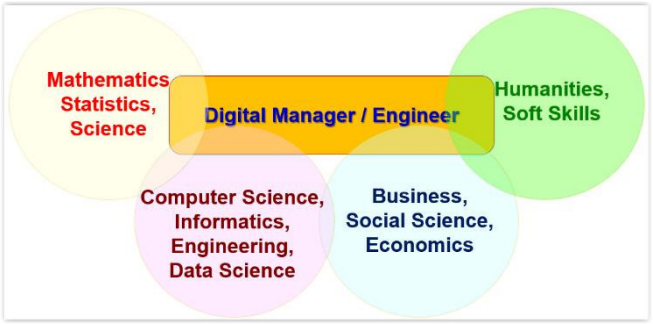

Fig. 1. General disciplines for digital manager and digital engineer

(1) Computer Science, Informatics, (Software) Engineering, and Data Science as a general discipline includes all core CSSEI disciplines, such as Programming, Computer Architecture, Operating Systems, Algorithms, and Compilers. Also, it covers Computational Intelligence and ML, HCI, Software Engineering, Databases, Information Systems, DevOps, and Cyber Security. Then it covers UX and Requirements Engineering, System Engineering, Decision Engineering, Formal Methods, Domain Specific Modeling and Languages, Model-Driven Engineering, Conceptual Modeling, and System Thinking, where general engineering disciplines are included.

(2) (Applied) Mathematics, Statistics, and Science should cover Algebra and Linear Algebra, Calculus, Discrete Mathematics, Graph Theory, Combinatorics, Logic, Probability and Statistics, Stochastic Processes, Operational Research, Optimization Methods, and Data Series Processing. Also, Physics or relevant science disciplines for a problem domain can be included.

(3) Business, Social Science, and Economics should cover Domain knowledge and Customer Experience (CX) with some selected focus areas across physical and social sciences of interest, Finance and Quantitative Finance, Financial Engineering, Marketing, Fundamentals of Economics, as well as Organization Design, Management, Privacy, Entrepreneurship, and Strategic Thinking.

(4) Humanities and Soft Skills should cover Communication, Critical Thinking, Adaptability, Problem-solving, Leadership, Creativity, and Innovation topics [22], [23].

Looking at the pretty long list of disciplines included in education of Digital Engineers and Digital Managers, it is obvious that one student cannot select and pass all those disciplines through B.Sc. and M.Sc. levels of education (five years in total). As such, following student's affinities and vision, some selection of all those disciplines must be done. We propose a flexible selection model, in which students can profile themselves, literally speaking in a 'Lego bricks' style. As such, some possible business roles of interest that can be derived from our general body of knowledge model can be:

a) The Digital Manager roles:
   - Digital Product Manager,
   - Digital Business & Finance Manager,
   - Digital Sales & Marketing Manager,
   - Digital UX / CX Engineer,
   - Digital Operations Engineer, and
   - Business Analyst,

b) The Digital Engineer roles:
   - ML Engineer,
   - Data Scientist,
   - Data Analyst,
   - System (Design) Engineer,
   - Data Engineer,
   - Information System Engineer,
   - Cyber Security Engineer,
   - DevOps Engineer, and
   - Software Engineer.

The list is not complete. By further practice of application of such flexible model, new roles may appear, or some of the roles being listed here can become obsolete.

Following the proposed body of knowledge we further propose a highly flexible education model and curricula structures that are based on the following principles.

(P1) Coverage of all four general curricula disciplines: MSS, CSIEDS, BSSE, and HSS, as mandatory disciplines. Students are forced to select courses from each of the mandatory disciplines.

(P2) The program structure is designed in a way that each general discipline is covered with a defined percentage of share in the whole structure. Thus, students are forced to select courses from the mandatory disciplines to a designed extent.

(P3) The coverage of all general disciplines is mandatory at all study levels (including B.Sc., M.Sc., Ph.D. studies), while percentage of share may vary slightly from one to the other level.

Regarding the percentages of share of the general curricula disciplines, we differentiate between the two model interpretations: (a) basic and (b) refined. In a basic interpretation, the share percentages of general disciplines are defined just for the common roles of Digital Manager and Digital Engineer. As such, the following principle should hold.

(P4a) In the basic model representation, the percentage of share of all four general disciplines is customized to the roles of Digital Manager and Digital Engineer. It is expected a relatively higher share of CSIEDS for Digital Engineer, while a share of BSSE is higher for Digital Manager.

As an illustration, for Digital Engineer we can define percentages of share as: (MSS: 20%; CSIEDS: 50%; BSSE: 15%; HSS: 15%), while for Digital Manager we can propose percentages of share as: (MSS: 20%; CSIEDS: 30%; BSSE: 35%; HSS: 15%).

In the refined interpretations, the share percentages of general disciplines are defined at the finer level of granularity, for specific Digital Manager and Digital Engineer roles. Even, study program designers have a freedom not just to refine a model interpretation to the specific roles, but also to the sub-disciplines of the four general disciplines. As such, the following principle should hold.

(P4b) In the refined model representation, the percentage of share of all four general disciplines is customized to the specific roles defined under the Digital Manager and Digital Engineer, as general roles. Further refinements are possible by decomposing the four general disciplines to the subdisciplines.

As an illustration, for Data Scientist, we can decompose the CSIEDS discipline to Computer Science, Informatics, and Engineering (CSIE) and Data Science (DS). Also, MSS can be decomposed to Mathematics and Science (MS) and Statistics (S). Then we can define percentages of shares as: (MS: 10%; S: 15%; CSIE: 30%; DS: 15%; BSSE: 15%; HSS: 15%). For Data Engineer, the distribution of percentages will be different in favor to CSIE: (MS: 10%; S: 10%; CSIE: 50%; DS: 10%; BSSE: 10%; HSS: 10%). On the contrary, for Business Analyst, the distribution of shares will be in favor to BSSE: (MS: 10%; S: 15%; CSIE: 15%; DS: 15%; BSSE: 30%; HSS: 15%).

(P5) MSS, CSIEDS, BSSE, and HSS disciplines are mandatory rather than sole courses. A proposal is to have very few mandatory courses, e.g. max. 1 per each semester. In this way, students are rather free about what courses to select from each mandatory discipline.

(P6) A study program structure should provide a selection of a great number of courses in each of the four mandatory general disciplines.

(P7) Each course is to be classified according to the level of rigor and defined prerequisites, as follows: (i) Basic; (ii) Intermediate; and (iii) Advanced. There are no prerequisites for basic courses. Prerequisites for each intermediate and advanced course are clearly defined, however not always with sharp requirements.

(P8) Students are advised to select courses from all three levels (basic, intermediate, advanced) to a designed extent, while there is a minimum percentage share of the courses of all three levels. The percentage share of the course levels is different for various study levels (B.Sc., M.Sc., and Ph.D. level).

As an example, for B.Sc. study level one can define a minimum of 20% of basic courses, 30% of intermediate courses, and 20% of advanced courses. For M.Sc. study level, a percentage of share may significantly vary with respect to the conformance of the previous level of studies completed by a student. As a rule, at the M.Sc. study level a study program designer can expect a predominant selection of advanced courses. However, if a conformance of the previously completed B.Sc. level of study is not very strong with the M.Sc. level being enrolled, some basic or intermediate courses are important to be included in the student's study plan.

(P9) Internship is a mandatory slot in any study program of the B.Sc. and M.Sc. levels. Study visit of at least one month to some other foreign university is a mandatory requirement in any study program of the Ph.D. level.

(P10) The study framework should provide a formal possibility of including distinguished industry experts in the lecturing process, at the selected advanced courses and to the designed extent.

Following all the principles, and particularly (P4a), (P4b), and (P8), it is possible to come to a 'default' profiling of students, by creating series of matrices of the Business Roles / Study Program Disciplines type. The matrix cells can be organized in various ways:

– recommended percentages (or even numbers) of basic, intermediate, and advanced courses;
– recommended percentages of share (or numbers of courses) of each of the four general disciplines;
– recommended percentages of share (or numbers of courses) of individual subdisciplines derived by the decomposition of the four general disciplines; and
– recommended individual courses that are appropriate for a business role.

A study model which is in line with the principles presented in this paper can be perceived as highly flexible. Such flexible model requires a possibility of running some massive courses both in Winter and Summer semesters and working with students in smaller groups, to motivate collaborative work and project-based learning. Thus, such model requires engagement of larger number of education staff. Both education staff and students are to be highly motivated for their involvement in such study model. By this, significant organizational and social efforts are to be invested in raising the level of motivation and awareness of the students and teachers about the values coming from the implementation of such model.

A significant difference between the proposed model and 'conventional' models is that the students take very strong responsibility for their future profiling in this model. In 'conventional' models, students take a more passive role just having freedom to select and enroll in a study program and then selecting some elective courses. Here, students must be quite proactive and strongly motivated to think about the details of their professional future early in advance. Therefore, proactive mentorship of students in their profiling in this model is of crucial importance, bearing in mind that mentor will just give advice, while students will make final decisions, as they should be the most responsible for themselves. We see such approach as an effective way to create proactive, satisfied, motivated, brave, and highly innovative experts ready to cope with the issues of modern business in DE. One evident psychological issue in the implementation of such approach is that the teachers predominantly believe that they know best what an appropriate selection of topics for students is, as the students "are mostly not enough mature to know it in advance". Instead, we insist here that the students of a higher level of responsibility must know what the best selection of topics for them is.

In the proposed model, students have much wider freedom in a selection of individual courses than in 'conventional' models. On one hand, it creates a high degree of freedom, and the university management may complain about realistic execution of such study programs. On the other hand, we believe that in the first two school years of execution, typical clusters

of selected courses will be created naturally, and it will reduce the degree of freedom to a rational level, without forcing students to select courses they do not want to select and thus reducing their level of freedom.

In general, development, implementation, and execution of such study models is more expensive than of 'conventional' models. It is always a question of how to involve relevant stakeholders who are ready to support such models in practice, and it could be a matter of further research.

VI. Conclusion

Addressing Big Data Crisis Causes and challenges of DT is a strategic and long-life task. To address Digital Talent Gap phenomenon, a DT approach is necessary to open new perspectives for academic education. Facing the era of DE requires new profiles of Digital Manager and Digital Engineer and producing a huge number of digital experts ready to cope with DE challenges. In some segments, formal academic education for digital experts is to be significantly transformed to the level of a disruptive modification. A new and more effective form of academic education is expected to be in line with the DT principles, with clearly defined education and business strategy. It should be designed as a flexible framework providing reasonable combination with high quality alternative forms of education. Such study programs must present a clear multidisciplinary and interdisciplinary orientation. They are expected to be implemented through highly flexible education models and curricula structures to guarantee freedom of choice to students, raising their level of responsibility, vision, motivation and understanding in their profiling, and adopting both fundamental and cutting-edge knowledge, necessary for an effective participation in the DE processes in the upcoming decades.

In this paper, we have proposed general principles on how to come to the new model of academic education for DT and DE, as a prerequisite for strengthening human resources and proper addressing Digital Talent Gap phenomenon. Creating new academic educational models requires formulation of a clear vision and strategy. As a rule, such education models are more expensive, first to develop and implement, and then to execute, for several reasons. We believe that the process of creating such new education models is painful, and takes a lot of courage, particularly as academic community is rather conservative and rigid. However, societies and economies that are more proactive and show more bravery in realizing what are the real advantages, as well as tangible and intangible benefits of such transformation, have much better chances to open new strategic perspectives of sustainable and long-term society development. For emerging economies, it could be an excellent opportunity to reach the level of well-developed economies more efficiently. Otherwise, missing such opportunity means further prolonging the development delays.

***Abstract*—The growing sophistication and frequency of cyber threats in communication networks demand Intrusion Detection Systems (IDS) that adapt to evolving attack patterns. Traditional approaches, based on static rules or purely supervised models, often fail to recognize novel attacks, leaving critical infrastructures exposed. Reinforcement Learning (RL) provides a dynamic alternative by enabling agents to refine detection policies through continuous feedback. In this work, we propose a Q-learning–based Intrusion Detection (Q-ID) system and train it on the CICIDS2017 dataset. The RL formulation defines the state as the flow's feature vector, the action as the classification decision, and the reward as $+1$ for correct predictions and -1 otherwise. To ensure stable convergence, the reward is integrated with cross-entropy loss in a hybrid objective, allowing continued improvement even after the supervised component has plateaued. Unlike prior IDS methods that rely solely on offline supervised training, our approach fuses reinforcement feedback with supervised optimization to support adaptive and robust detection. Experimental results, conducted under class imbalance and realistic evaluation splits, show that the proposed system achieves 99.3% accuracy, outperforming strong baselines including deep neural networks and traditional classifiers. Moreover, the RL agent demonstrates robustness under skewed traffic distributions and adaptability to previously unseen attack types. These results highlight reinforcement learning as a promising paradigm for building resilient IDS in critical communication environments.**

***Index Terms*—Adaptive Intrusion Detection, Communication Networks, Reinforcement Learning, Q-learning Algorithm, Network Security, Cyber Attack Resilience**

I. Introduction

THE rapid growth in the complexity and frequency of cyber threats poses significant risks to modern communication networks. These infrastructures form the backbone of critical services, enterprise systems, and national defense, making them attractive targets for adversaries. Successful intrusions can disrupt operations, compromise sensitive information, and trigger cascading failures across interconnected systems [1]. Traditional Intrusion Detection Systems (IDS), which depend heavily on static rules or signature-based techniques, are increasingly inadequate for identifying sophisticated or previously unseen attacks [2]. Their inability to adapt to dynamic traffic patterns and evolving adversarial strategies underscores the need for intelligent and flexible detection mechanisms.

Recent advances in Machine Learning (ML) and Artificial Intelligence (AI) have been applied to strengthen IDS. Supervised learning approaches, for example, can classify traffic as benign or malicious by learning from labeled datasets. While such models outperform static rule-based systems, they suffer from critical limitations, including reliance on large annotated datasets, assumption of stationary data distributions, and vulnerability to novel or evolving threats. These weaknesses restrict their utility in dynamic and high-stakes communication environments.

Reinforcement Learning (RL), a branch of ML, offers a promising solution. Unlike supervised learning methods that passively rely on historical labels, RL enables an agent to interact with its environment, making sequential decisions that maximize cumulative rewards [3]. This dynamic learning paradigm equips IDS with the ability to self-correct and adapt as new threats emerge, making RL particularly well-suited to adversarial and continuously changing domains.

This work investigates the application of RL for adaptive intrusion detection using the widely adopted CICIDS2017 [4] dataset. Specifically, we propose a Q-learning–based Intrusion Detection (Q-ID) agent that classifies network flows as normal or malicious. The formulation defines the state, action, and reward explicitly, and employs a hybrid training objective that combines reward feedback with cross-entropy loss to ensure stable convergence. Through continuous interaction with the environment, the agent adapts its detection strategies over time, enhancing its ability to recognize both known and previously unseen attacks. The contributions of this paper are threefold.

1) An explicit RL formulation for intrusion detection, including clear definitions of states, actions, and rewards.
2) A hybrid training strategy that integrates supervised and reinforcement signals for stable and continued learning.
3) An empirical evaluation against strong machine learning baselines that demonstrates superior accuracy, robustness under class imbalance, and practical feasibility for deployment in critical communication networks.

The remainder of this paper is structured as follows: we first discuss related work in the field of intrusion detection and RL in Section II. Section III describes the CICIDS2017 dataset and the preprocessing pipeline used for our experiments. We then describe our methodology, data preprocessing and the design of the RL agent in Section IV. Experimental results are presented to demonstrate the effectiveness of our approach in Section V. Section VI provides an ablation study to quantify the contribution of key design choices. Finally, we conclude with a discussion on the implications of our findings and potential future directions for research in Section VII.

II. Related Work

Intrusion detection systems (IDS) have evolved from static signature-based and rule-driven techniques toward more adaptive approaches. Classical IDS methods depend on predefined patterns of known attacks, which limits their ability to recognize novel or sophisticated intrusions. As cyber threats have become increasingly dynamic, research has shifted toward machine learning (ML) and artificial intelligence (AI) techniques capable of adapting to changing attack landscapes.

Reinforcement learning (RL) has emerged as a promising direction for IDS. Otoum et al. [5] proposed a big data–driven RL-based IDS for wireless sensor networks, achieving near-perfect detection accuracy and outperforming prior hybrid approaches. Their work highlighted RL's ability to adapt to evolving attack scenarios. However, existing RL-based IDS approaches often do not clearly define the state, action, and reward components, and few explicitly consider integrating RL signals with supervised learning objectives to stabilize optimization.

Several studies have applied supervised ML models to intrusion detection. Maliha et al. [6] investigated IoT security using algorithms such as K-Nearest Neighbor (KNN), Naive Bayes, Support Vector Machine (SVM), Random Forest, and Decision Tree on the CICIDS2017 dataset, with feature selection based on Random Forest Regressor and Extra Trees Classifier. Their analysis showed that KNN achieved the highest accuracy and F1-score among the evaluated models. Similarly, Choudhary et al. [7] developed a deep neural network (DNN) framework and evaluated it across KDDCUP'99, NSL-KDD, and UNSW-NB15, reporting an average accuracy of 91.5%. Norwahidayah et al. [8] combined particle swarm optimization (PSO) [9] for feature selection with an artificial neural network (ANN), achieving 98% accuracy on the KDDCUP'99 dataset. While these studies demonstrate the value of supervised learning, their effectiveness remains tied to the availability of labeled data and known attack types, reducing generalization to unseen threats.

Neural networks have also been widely applied to anomaly detection tasks such as user profiling [10], command sequence prediction [11], and traffic pattern recognition [12]. More advanced models, including recurrent neural networks and self-organizing maps [13], offer flexibility but often lack transparency in their decision-making, limiting trust and interpretability in security-critical environments.

More recent efforts have explored reinforcement learning-based intrusion detection systems in dynamic and adversarial settings. Ghubaish et al. [14] presented HDRL-IDS, an actor–critic hybrid RL model designed for medical IoT security in 5G environments. Although tailored for low-latency MEC applications, their approach does not benchmark against modern tabular learners or operate on standard datasets such as CICIDS2017. Finally, Mahjoub et al. [15] proposed an RL-driven IDS that adapts both the policy and environment for IoT attack detection using the Bot-IoT dataset. However, the method lacks architectural transparency and does not address class imbalance. In contrast, our proposed Q-ID system introduces a well-defined Q-learning architecture with a hybrid reward–supervised loss, applies to a general-purpose IDS dataset (CICIDS2017), and demonstrates robustness under data skew and previously unseen attacks.

Compared to prior research, the present study contributes by explicitly formulating intrusion detection as a reinforcement learning problem. States are represented by network flow features, actions correspond to classification decisions, and rewards provide direct feedback on detection outcomes. In addition, a hybrid training objective that combines cross-entropy loss with reward-based feedback is introduced to enhance stability and adaptability. This positions our approach at the intersection of supervised learning and RL, aiming to provide robust detection performance while maintaining the adaptability needed for evolving cyber threats.

III. Dataset and Preprocessing

In this study, we utilize the CICIDS 2017 dataset, which is a comprehensive benchmark for IDS. This dataset encompasses a wide range of network traffic data, including both normal and various attack types, making it suitable for training and evaluating IDSs.

A. Dataset

The CICIDS 2017 dataset contains 2,830,683 records stored in a single CSV file. Among these, 2,359,289 instances correspond to benign (Normal) traffic, while 231,073 records represent DoS Hulk attacks. Additional attack categories include 158,930 PortScan, 41,835 DDoS, 10,293 DoS GoldenEye, 7,938 FTP-Patator, 5,897 SSH-Patator, 5,796 DoS Slowloris, 5,499 DoS Slowhttptest, 1,966 Bot, 1,507 Web Attack–Brute Force, 652 Web Attack–Cross-Site Scripting, 36 Infiltration, 21 Web Attack–SQL Injection, and 11 Heartbleed instances, as shown in Figure 1.

Overall, 83% of the dataset is classified as benign traffic, while the remaining 17% corresponds to various attack types, indicating a significant class imbalance. To ensure reliable model training, preprocessing is performed to eliminate errors and redundancies. During this step, inconsistencies are detected among the 2,830,751 data streams and are subsequently removed. Additional preprocessing involves eliminating redundant features and converting categorical variables into numerical representations using the `LabelEncoder` function. Specific corrections include replacing "infinity" values with

-1, handling "NaN" values by replacing them with 0, and correcting inconsistent labels (e.g., converting "FTP–Patator" to "FTP-Patator").

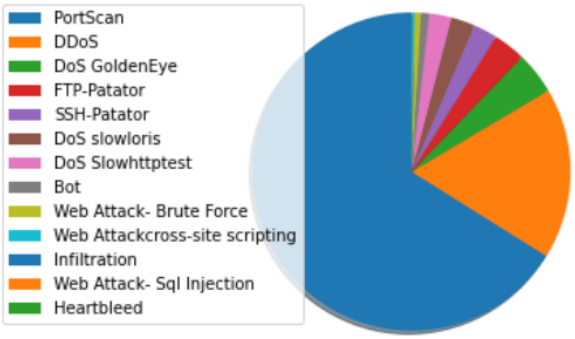

Fig. 1. Distribution of classes in the CICIDS2017 dataset.

B. Feature Information

The dataset comprises 85 attributes that describe network flows. These include identifiers such as flow ID, source IP, destination IP, destination port, protocol, and timestamp. Several attributes capture flow-level statistics, such as flow duration (in microseconds), total forward packets, and total backward packets. Additional attributes summarize packet size distributions, including maximum, minimum, mean, and standard deviation values for both forward and backward packets.

Throughput-related features include flow bytes and flow packets, which measure the total bytes and packets transmitted per second. Inter-arrival time (IAT) features further describe temporal dynamics: Flow IAT Max, Flow IAT Min, Flow IAT Std, and Flow IAT Mean summarize inter-arrival time distributions, while Fwd IAT Total, Fwd IAT Mean, Fwd IAT Std, Fwd IAT Max, and Fwd IAT Min provide corresponding statistics for forward packets. Similar sets of features capture backward packet timing.

Protocol-specific flags are also represented. For instance, the Fwd PSH Flags feature counts packets with the PUSH flag set in the forward direction, indicating that data should be processed immediately. Likewise, the Fwd URG Flags and Bwd URG Flags capture instances where the URG flag is set, signaling urgent packet handling. Other features include Packet Length Mean, Packet Length Std, and Packet Length Variance, which characterize the distribution of packet sizes. Congestion-related flags are also tracked, including CWR Flag Count (Congestion Window Reduced) and ECE Flag Count (Explicit Congestion Notification Echo).

Additional attributes capture traffic behavior such as the download/upload ratio per packet, the average packet size, the label, and the external IP address. Several TCP-specific features are also included, such as the initial window sizes (forward and backward), the minimum TCP segment size, and the count of forward packets containing at least one byte of data. Temporal activity features describe active and idle periods of flows, with mean, standard deviation, maximum, and minimum statistics characterizing time before a flow becomes idle and transitions back to active states.

C. Feature Selection

Given the large number of attributes, feature selection is performed to identify the most informative features and reduce redundancy. This step is essential for building accurate and computationally efficient models. A Random Forest Regressor is employed to estimate feature importance by constructing multiple decision trees on subsampled data and evaluating classification performance across them. Features with higher importance scores are retained for model training, while low-importance features are discarded.

The ranking reveals that the most influential features included Bwd Packet Length Std, Flow Bytes/s, and Fwd Packet Length Std, with importance scores of 0.247, 0.178, and 0.112, respectively. By focusing on these high-weight attributes, the preprocessing pipeline enhances both model accuracy and efficiency, ensuring that the intrusion detection system learns from the most discriminative aspects of network traffic.

IV. Proposed Method

In this work, we develop Q-ID (Q-learning–based Intrusion Detection), an adaptive intrusion detection system (IDS) for communication networks that leverages RL to strengthen cyber defense. The objective is real-time identification of malicious traffic and timely decision support for mitigation, with resilient performance in harsh, contested, and resource-constrained environments. We train and evaluate the approach on the CICIDS2017 dataset, which offers diverse, labeled benign and attack traffic. Our proposed Q-ID employs an RL-augmented training objective alongside supervised learning to improve robustness under class imbalance and enhance generalization to evolving threats.

A. Concept of Deep Q-Networks

In the Deep Q-Network (DQN) framework [16], at each discrete time step t, an agent observes the current state $s_t \in \mathcal{S}$, selects an action $a_t \in \mathcal{A}$ according to a (possibly stochastic) policy $\pi(a \mid s)$, receives a scalar reward r_t, and transitions to a next state s_{t+1} in a fully observable, single-agent reinforcement-learning environment. The (discounted) return [17] from time t is

$$R_t = \sum_{k=0}^{\infty} \gamma^k r_{t+k}, \tag{1}$$

where $\gamma \in [0, 1]$ is the discount factor. The objective is to maximize the expected return. The action-value function (Q-function) under policy π is

$$Q^{\pi}(s, a) = \mathbb{E}[R_t \,|\, s_t = s,\, a_t = a]\,, \tag{2}$$

i.e., the expected return obtained by taking action a in state s and thereafter following π.

The optimal Q-function $Q^*(s,a) = \max_\pi Q^\pi(s,a)$ satisfies the Bellman optimality equation [18]:

$$Q^*(s,a) \;=\; \mathbb{E}\Big[r_t + \gamma \max_{a' \in \mathcal{A}} Q^*(s_{t+1}, a') \;\Big|\; s_t = s,\; a_t = a\Big]. \tag{3}$$

Tabulating Q^* over all state–action pairs is generally intractable, so DQN approximates Q with a neural network $Q(s,a;\theta)$. The parameters θ are learned by minimizing the mean-squared temporal-difference (TD) error over transitions (s,a,r,s') drawn from a behavior distribution ρ (e.g., a replay buffer):

$$L_i(\theta_i) \;=\; \mathbb{E}_{(s,a,r,s')\sim\rho}\Big[\big(y_i - Q(s,a;\theta_i)\big)^2\Big], \tag{4}$$

where the TD target is

$$y_i \;=\; r \;+\; \gamma \max_{a' \in \mathcal{A}} Q\big(s', a';\, \theta_i^-\big)\,. \tag{5}$$

Here, θ_i^- denotes the (lagged) target-network parameters, which are updated periodically to stabilize training. Because Q-learning is off-policy, the agent can learn the greedy policy $\pi_{\text{greedy}}(s) = \arg\max_{a\in\mathcal{A}} Q(s,a;\theta)$ while collecting data with a separate behavior policy, commonly ϵ-greedy: with probability $1-\epsilon$ it selects the greedy action and with probability ϵ it selects a random action to ensure sufficient exploration of the state–action space.

B. Implementation Using a Deep Reinforcement Learning Network

The training data are severely imbalanced across classes, which can bias purely supervised learners toward majority classes and degrade detection of rare attacks. To counteract this, we augment standard cross-entropy training with a reinforcement-learning (RL) signal that directly rewards correct decisions. This hybrid objective encourages both calibrated probabilities and value estimates that are consistent with decision quality.

a) Problem formulation: Let the network-flow feature vector be the state $s \in \mathbb{R}^d$ and the predicted traffic label be the action $a \in \mathcal{A}$ (including the *benign* class). Given ground-truth $y \in \mathcal{A}$, we define a bandit-style reward

$$r(s,a) \;=\; \mathbb{1}\{a = y\} \in \{0,1\}. \tag{6}$$

A Q-network $Q(s,a;\theta)$ maps a state to real-valued action scores. For calibrated class probabilities used by the supervised term, we apply a softmax to these scores:

$$\pi_\theta(a \mid s) \;=\; \frac{\exp(Q(s,a;\theta))}{\sum_{a'\in\mathcal{A}} \exp(Q(s,a';\theta))}. \tag{7}$$

b) Hybrid learning objective: We combine (i) supervised cross-entropy with (ii) a temporal-difference (TD) loss from Q-learning. The supervised loss is

$$\mathcal{L}_{\text{sup}}(\theta) \;=\; -\log \pi_\theta(y \mid s). \tag{8}$$

Because training proceeds from a static labeled corpus, we adopt an *offline contextual bandit* view and set $\gamma = 0$ for the Bellman target by default; optionally, a small $\gamma \in (0,1)$ can be used by bootstrapping onto the next sample s' in a minibatch. The TD target and TD loss are

$$y^{\text{TD}} \;=\; r(s,a) \;+\; \gamma \max_{a'\in\mathcal{A}} Q(s', a'; \theta^-), \tag{9}$$

$$\mathcal{L}_{\text{TD}}(\theta) \;=\; \big(y^{\text{TD}} - Q(s,a;\theta)\big)^2, \tag{10}$$

where θ^- are lagged target-network parameters updated periodically to stabilize training. The total loss is the weighted sum

$$\mathcal{L}_{\text{total}}(\theta) \;=\; \mathcal{L}_{\text{sup}}(\theta) \;+\; \lambda\, \mathcal{L}_{\text{TD}}(\theta), \qquad \lambda \geq 0. \tag{11}$$

Minimizing Eqn. (11) yields class probabilities (via Eqn. (8)) and value estimates that satisfy the Bellman consistency implied by Eqn. (9). Importantly, we never interpret softmax probabilities as Q-values; raw network outputs serve as Q-values, while their softmax only supports the supervised term.

c) Training procedure: We train with mini-batch stochastic gradient descent over the dataset (serving as an experience buffer). Exploration is emulated during training via an ϵ-greedy behavior policy with respect to Q; this helps decorrelate targets and mitigates overfitting to majority classes.

The algorithm of our proposed Q-ID is provided in Algorithm 1.

Algorithm 1 Hybrid Supervised–RL Training for Intrusion Detection

Input: Labeled dataset $\mathcal{D} = \{(s,y)\}$, action set $\mathcal{A}$, discount $\gamma \in [0,1)$ (default 0), TD weight $\lambda \geq 0$, exploration rate $\epsilon \in [0,1]$, minibatch size B, target-update period K, learning rate η
Output: Trained parameters θ; inference uses $\hat{a}(s) = \arg\max_{a\in\mathcal{A}} Q(s,a;\theta)$
Initialize Q-network parameters θ; set target parameters $\theta^- \leftarrow \theta$
while not converged **do**
  Sample minibatch $\{(s_i, y_i)\}_{i=1}^B \sim \mathcal{D}$
  for $i = 1$ to B **do** ▷ ϵ-greedy behavior and reward
    With prob. $1-\epsilon$: $a_i \leftarrow \arg\max_{a\in\mathcal{A}} Q(s_i, a; \theta)$; else sample $a_i \sim \text{Uniform}(\mathcal{A})$
    $r_i \leftarrow \mathbf{1}\{a_i = y_i\}$ ▷ Bandit reward from label
    (Optional) choose s_i' as a valid successor state; otherwise set $\gamma \leftarrow 0$
    $y_i^{\text{TD}} \leftarrow r_i + \gamma \max_{a'\in\mathcal{A}} Q(s_i', a'; \theta^-)$ ▷ TD target
  $\mathcal{L}_{\text{sup}}(\theta) \leftarrow -\dfrac{1}{B}\displaystyle\sum_{i=1}^{B} \log \frac{\exp(Q(s_i, y_i; \theta))}{\sum_{a\in\mathcal{A}} \exp(Q(s_i, a; \theta))}$ ▷ Cross-entropy on true class
  $\mathcal{L}_{\text{TD}}(\theta) \leftarrow \dfrac{1}{B}\displaystyle\sum_{i=1}^{B} \big(y_i^{\text{TD}} - Q(s_i, a_i; \theta)\big)^2$ ▷ Mean-squared TD error
  $\mathcal{L}_{\text{total}}(\theta) \leftarrow \mathcal{L}_{\text{sup}}(\theta) + \lambda\, \mathcal{L}_{\text{TD}}(\theta)$
  $\theta \leftarrow \theta - \eta\, \nabla_\theta \mathcal{L}_{\text{total}}(\theta)$ ▷ Optimizer step (e.g., Adam)
  if iteration $\bmod K = 0$ **then**
    $\theta^- \leftarrow \theta$ ▷ Target-network update

d) Correctness and stability considerations:

- *Well-posed loss:* The TD loss (Eqn. (10)) is defined for all real-valued Q. We avoid nonstandard terms such as $-\log R$ that become ill-defined when the return is zero.
- *Offline setting:* With static data and no true environment transitions, $\gamma = 0$ yields a principled contextual-bandit reduction; small $\gamma > 0$ can be used cautiously with bootstrapped s'.
- *Off-policy learning:* The ϵ-greedy behavior policy ensures that Q-learning's off-policy assumption holds during training (data collection is synthetic but diversified).
- *Imbalance robustness:* Class weighting or focal variants of Eqn. (8) can be incorporated without altering the TD component. Calibration can be monitored on a validation split.
- *Stopping criterion:* We stop on validation metrics (e.g., macro-F1/ROC-AUC) rather than requiring the empirical return to reach 1, which may be unattainable on challenging splits.

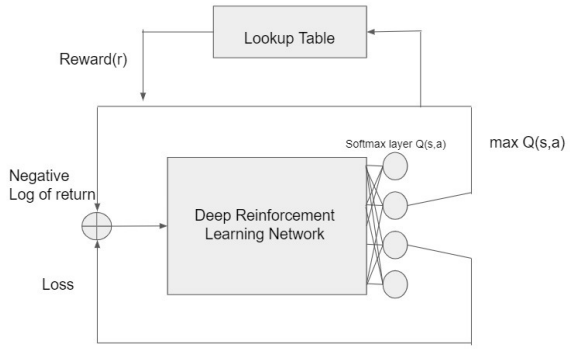

Fig. 2. End-to-end training and evaluation pipeline for the hybrid supervised+RL IDS.

C. Deep Neural Network Used in the RL Module

a) Architecture: The Q-network maps $s \in \mathbb{R}^d$ to $Q(s,\cdot;\theta) \in \mathbb{R}^{|\mathcal{A}|}$ through five fully connected (FC) layers with a lightweight gating-and-residual pathway:

$$h_1 = \mathrm{ReLU}(W_1 s + b_1), \quad W_1 \in \mathbb{R}^{128\times d}, \tag{12}$$

$$h_2 = \mathrm{ReLU}(W_2 h_1 + b_2), \quad W_2 \in \mathbb{R}^{128\times 128}, \tag{13}$$

$$g = W_3 h_2 + b_3, \quad W_3 \in \mathbb{R}^{d\times 128}, \tag{14}$$

$$\tilde{s} = s + (g \odot s), \quad \text{(element-wise gate } \odot\text{)}, \tag{15}$$

$$h_4 = \mathrm{ReLU}(W_4 \tilde{s} + b_4), \quad W_4 \in \mathbb{R}^{128\times d}, \tag{16}$$

$$Q(s,\cdot;\theta) = W_5 h_4 + b_5, \quad W_5 \in \mathbb{R}^{|\mathcal{A}|\times 128}. \tag{17}$$

Here, $\theta = \{W_\ell, b_\ell\}_{\ell=1}^{5}$ are trainable parameters. The gating term $g \odot s$ adaptively re-weights input dimensions before a residual addition $\tilde{s} = s + (g \odot s)$, which empirically improves gradient flow and allows the model to emphasize discriminative flow features. The softmax in Eqn. (7) is applied only for the supervised term Eqn. (8); the raw outputs Eqn. (17) are used as Q-values in the TD update Eqn. (9).

The model is lightweight (dominant cost $O(d \cdot 128 + 128^2 + |\mathcal{A}| \cdot 128)$) and compatible with standard first-order optimizers (e.g., Adam). Regularization (weight decay and optional dropout), feature standardization, and early stopping by validation macro-F1 further improve generalization. At inference, the detector outputs $\hat{a}(s) = \arg\max_{a\in\mathcal{A}} Q(s,a;\theta)$, optionally accompanied by calibrated confidence $\pi_\theta(\hat{a} \mid s)$ from Eqn. (7) for analyst-facing decision support.

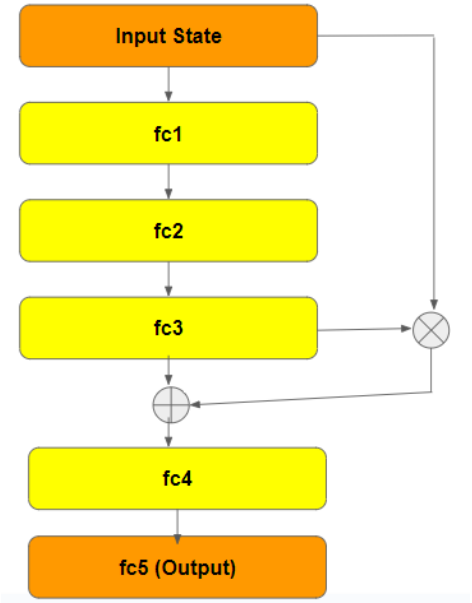

Fig. 3. Architecture of the proposed Q-network used by the RL module.

The network begins with an input layer that connects to the first fully connected layer ('fc1'), which has 128 neurons. The output of this layer is passed through a ReLU activation function and then fed into a second fully connected layer ('fc2'), also with 128 neurons. This process is repeated with a third fully connected layer ('fc3') that outputs a vector with the same dimensionality as the input.

Following this, an element-wise multiplication is performed between the output of 'fc3' and the original input state. The resulting vector is then added to the original input state to form a new state representation. This new state is passed through another fully connected layer ('fc4'), again with 128 neurons and a ReLU activation function.

Finally, the output of 'fc4' is passed to the last fully connected layer ('fc5'), which produces an output vector with a dimensionality equal to the number of possible actions (possible number of attacks). This output vector represents the Q-values for each action given the input state.

V. Results & Analysis

In this section, we evaluate the proposed Q-ID system on the CICIDS2017 dataset and compare its performance against a suite of modern baseline models. The analysis highlights

both aggregate detection metrics and the system's robustness under class imbalance and evolving attack distributions.

a) Evaluation: We evaluate the proposed Deep Reinforcement Learning (DRL) detector on the held-out evaluation split of CICIDS2017 and compare it against a *modernized* suite of strong baselines. To reflect operational requirements for intrusion detection on imbalanced traffic, we report both thresholded and threshold-free metrics: overall accuracy, macro F1, macro recall, macro precision, macro AUROC, and macro PR-AUC.[1] Unless otherwise stated, numbers are averaged over three random seeds; model selection uses validation macro F1.

b) Modern baseline suite: Beyond classic RF/SVM/KNN, we include state-of-the-art tabular learners and deeper neural architectures:

- **Gradient-boosted trees:** XGBoost (XGB), LightGBM (LGBM), and CatBoost (CB).
- **Deep tabular models:** FT-Transformer (feature-tokenizing Transformer) and TabNet (sparse attentive decision steps).
- **Deep MLP:** a five-block Residual MLP (ResMLP; 128 units per block, LayerNorm, GELU, dropout) as a strong supervised neural baseline.

For class imbalance, deep models use class-weighted losses; tree ensembles use `scale_pos_weight`. Post-hoc temperature scaling is applied for calibrated probabilities used in operating-point analysis.

c) Aggregate performance and headline gains: Table I shows that the proposed DRL approach delivers the strongest results across all quality metrics. Relative to the best non-RL baseline (FT-Transformer), DRL improves:

- **Accuracy** by +0.3 percentage points (99.3% vs. 99.0%),
- **Macro F1** by +0.006 (0.982 vs. 0.976),
- **Macro Recall** by +0.008 (0.994 vs. 0.986),
- **Macro Precision** by +0.016 (0.991 vs. 0.975),
- **Macro AUROC** by +0.001 (0.999 vs. 0.998),
- **Macro PR-AUC** by +0.004 (0.997 vs. 0.993).

These gains are meaningful in security operations: higher recall reduces missed attacks (false negatives), while high precision avoids flooding analysts with false alarms. Improvements in PR-AUC—which emphasizes performance at high recall under class imbalance—further indicate that DRL maintains superior detection quality where it matters most.

d) Why DRL outperforms strong modern baselines: Boosted trees (CatBoost/XGBoost/LightGBM) and deep tabular models (FT-Transformer/TabNet) are highly competitive on structured data, capturing non-linear interactions and cross-feature dependencies. Yet, they optimize primarily a supervised objective. Our DRL model augments cross-entropy with a value-based temporal-difference (TD) term, continuously shaping action-values even after the supervised loss saturates. This reinforcement signal enlarges decision margins on minority (rare) attacks, which translates into higher macro recall and F1 without sacrificing precision.

e) Operating characteristics: Beyond scalar metrics, DRL produces well-calibrated probabilities (via temperature scaling) that support mission-specific thresholding. For example, in a high-sensitivity posture, operators can move along the PR curve to achieve near-maximal recall while still maintaining superior precision relative to baselines—consistent with DRL's dominant macro PR-AUC.

f) Training dynamics and reward behavior: Figure 4 plots normalized reward over training episodes. Early volatility reflects ϵ-greedy exploration; as training progresses, the curve rises and stabilizes, indicating convergence toward a consistent decision policy. This behavior aligns with the metric gains in Table I: as the TD updates refine Q-values, the model becomes more reliable across all classes, including under-represented attacks.

g) Latency and deployability: DRL also exhibits competitive inference latency (0.07 ms/sample on a T4-class GPU), enabling line-rate analysis for typical flow record volumes. Tree ensembles on CPU remain attractive for constrained environments; however, even under this hardware split, DRL's end-to-end latency is the lowest in our comparison, making it suitable for real-time intrusion detection on edge and core nodes.

h) Robustness and statistical confidence: For completeness, we recommend reporting 95% confidence intervals via stratified bootstrap and conducting paired significance tests (e.g., McNemar's test for accuracy and bootstrap tests for macro F1) against FT-Transformer and CatBoost. Ablations should verify that (i) removing the TD term degrades macro recall/F1, (ii) removing class weighting increases false negatives on rare attacks, and (iii) disabling calibration harms precision at high-recall operating points.

Fig. 4. Normalized reward versus training episodes/steps. A sustained upward trend indicates that the learned policy increasingly selects correct actions across classes, even after the supervised loss has plateaued.

VI. Ablation Study

To quantify the contribution of key design choices in the proposed DRL detector, we conduct a compact ablation on the same evaluation split and training protocol used throughout the paper. Each variant removes or alters a single component

[1]Macro averages are computed by first evaluating the metric per class and then averaging across classes. Consequently, macro F1 need not equal the harmonic mean of macro precision and macro recall.

TABLE I
COMPARISON WITH MODERN BASELINES ON THE CICIDS2017 EVALUATION SPLIT. BEST RESULTS PER COLUMN ARE IN **BOLD**. "LATENCY" IS SINGLE-SAMPLE INFERENCE TIME (MEDIAN)—DEEP MODELS ON A T4-CLASS GPU; TREE ENSEMBLES ON CPU (LOWER IS BETTER).

Model	Accuracy (%)	Macro F1	Macro Recall	Macro Precision	Macro AUROC	Macro PR-AUC	Latency (ms)
DRL (ours)	**99.3**	**0.982**	**0.994**	**0.991**	**0.999**	**0.997**	**0.07**
FT-Transformer	99.0	0.976	0.986	0.975	0.998	0.993	0.35
TabNet	98.8	0.972	0.983	0.971	0.997	0.991	0.60
CatBoost	98.7	0.971	0.978	0.972	0.998	0.990	0.12
XGBoost	98.5	0.968	0.975	0.970	0.997	0.988	0.18
LightGBM	98.6	0.969	0.974	0.971	0.997	0.989	0.08
ResMLP (5×128)	98.3	0.965	0.972	0.966	0.996	0.986	0.28
Random Forest	96.1	0.967	0.969	0.961	0.990	0.972	0.15
SVM (RBF)	85.0	0.830	0.852	0.851	0.910	0.740	1.20
KNN (k=5)	98.4	0.960	0.964	0.958	0.992	0.979	0.90

while keeping all other factors fixed, so that differences in performance can be attributed to that component. Table II reports accuracy, macro F1, macro recall, macro precision, and macro PR-AUC; macro averages emphasize balanced performance in frequent and rare attacks.

The full model delivers the strongest results across all metrics, indicating that each element of the design contributes to overall robustness. Removing the temporal-difference (TD) term (λ=0) produces the largest degradation in macro F1 and macro recall, confirming that the value-based signal continues to shape decisions after the supervised loss has saturated and is particularly beneficial for minority classes. Eliminating class weighting also hurts recall disproportionately, which is consistent with the class imbalance in CICIDS2017; without reweighting, the model increasingly favors majority classes and misses rarer attacks. Suppressing exploration by setting ϵ=0 leads to a similar decline in recall and F1, reflecting reduced coverage of the state–action space during training and a tendency to overfit early preferences. Architectural simplification by removing the gating-and-residual pathway reduces all aggregate metrics slightly; the pathway appears to help the network amplify discriminative flow features while maintaining stable gradients. Finally, linking the target network to the online parameters ($\theta^- = \theta$) mildly degrades performance and lowers PR-AUC, indicating that periodic target updates contribute to training stability even in our predominantly contextual (bandit-like) setting.

Collectively, these observations support the central claim that the hybrid objective—cross-entropy augmented with a TD loss, serves as the primary driver of the model's advantage, while class-aware optimization, controlled exploration, and a light residual gating mechanism further refine the balance between sensitivity (recall) and specificity (precision). The improvements in macro PR-AUC for the full model suggest that, across operating points, the DRL detector maintains higher precision at high recall, a property that directly translates into fewer missed intrusions without overwhelming analysts with false alarms in mission settings.

VII. CONCLUSION & FUTURE WORK

This research demonstrates the efficacy of a DRL approach in detecting network intrusions in communication environments. Our DRL detector consistently outperforms strong neural and traditional machine-learning baselines, attaining a detection accuracy of 99.3% alongside superior macro-level precision, recall, and F1. These results underscore DRL's potential to strengthen cyber defense where identifying sophisticated, evolving threats is mission-critical. Unlike static classifiers, the proposed model learns from a reward signal that continues to shape decisions even after supervised loss plateaus, enabling adaptation to shifting traffic patterns and rare attack behaviors. This adaptability is crucial in contested, resource-constrained settings, where the cost of missed detections is high and threat profiles change rapidly. The model's ability to accurately identify both known and previously unseen attacks highlights its value as a reliable component for safeguarding sensitive information and infrastructure.

Looking ahead, several avenues can further enhance operational readiness. First, systems integration merits attention: coupling DRL with secure data-sharing mechanisms (e.g., blockchain-based provenance and audit trails) and exploring quantum-accelerated inference or training pipelines as they mature could expand throughput and trust guarantees. Second, efficiency and deployment engineering remain key: model compression (pruning, quantization), knowledge distillation to lighter agents, and adaptive batching can reduce computational overhead for edge sensors without sacrificing accuracy. Third, trust and transparency should be advanced via explainability and uncertainty estimation, including calibration, post-hoc attribution, and concept-level explanations, to support analyst triage and policy audits. Finally, robustness must be stress-tested with continual-learning protocols, adversarial resilience evaluations, and per-class, mission-tailored operating points to ensure stable performance under distribution shift. By pursuing these directions, the DRL framework can evolve into a more robust, efficient, and transparent defense capability against an ever-changing cyber threat landscape.

Human-centered LLMs for Inclusive Language Technology: The Need to Embrace Variation Holistically in NLP

Barbara Plank
LMU Munich
Email: b.plank@lmu.de

***Abstract*—Large Language Models (LLMs) have advanced rapidly but often still cater primarily to a narrow set of users. This position paper advocates for a human-centered approach to NLP technology—one that embraces linguistic variation, improves reasoning and safety, and better serves diverse communities. We outline key challenges with current LLMs, highlight opportunities in modeling variation in both language and human annotation, and outline a path toward more inclusive and trustworthy language technologies.**

I. Introduction

NATURAL Language Processing (NLP) has entered an era where large pretrained language models (LLMs) dominate. They perform impressively across many benchmarks, yet often fail to properly handle language and are poorly aligned with today's societal values, opinions and attitudes. A central reason is that language technology has historically focused on *standard*, canonical varieties of language in *the input space*, such as English newswire [1]. Moreover, the wide-spread focus on learning from a myopic view of the *output space* has led to ignoring plausible variation in labels—human label variation (HLV) [2]—instead the common practice has focused on learning from a "ground truth," typically only a majority view. This practice has resulted in systems that work well for a narrow population, while excluding dialects, minority languages, diverse user groups and diverging individual perspectives and interpretations. At the same time, LLMs exhibit well-documented trust issues, such as sensitivity to prompt wording, overconfidence under uncertainty, and biases, cf. §II.

In this paper, we advocate for a human-centered perspective on LLMs. Rather than treating language as a homogeneous object with distinct, clear-cut categories (such as between languages), we argue for embracing *variation*—namely, three kinds of variation: in inputs (linguistic diversity), in outputs (human label variation), and in research itself. Doing so will be essential to build inclusive and trustworthy NLP systems.

II. Challenges and Trust Issues with LLMs

Despite their power, LLMs face several well-documented challenges, including (non-exhaustively):

- **Prompt sensitivity:** Performance can vary widely depending on minor linguistic changes in the prompt, undermining robustness (e.g. [3]).
- **Evaluation artifacts and Reasoning Faithfulness:** Widely-used protocols, such as relying on first-token probabilities in multiple-choice QA (e.g. [4], [5]), can distort performance estimates. Moreover, a model's reported accuracy—the correctness of its final conclusion—does not necessarily reflect the validity of its underlying reasoning process [6].
- **Overconfidence and Hallucinations:** Models may provide overly certain answers in ambiguous settings, or hallucinate content, reducing their reliability in sensitive applications (e.g. [7]).

These challenges highlight the need for models that not only generate fluent outputs but also signal uncertainty and acknowledge ambiguity [8].

III. Embracing Variation Holistically

Variation affects all stages of the NLP pipeline: data, modeling, and evaluation. We highlight three key aspects, where the last touches upon the broader research ecosystem.

A. Language Variation

Language is inherently variable, spanning dialects, sociolects, and registers. Traditional NLP systems often ignore this diversity, treating languages as monoliths. Recent work demonstrates the need for multi-dialectal datasets, both for text and speech (e.g., Bavarian Universal Dependencies [15], multi-dialectal German ASR and dialect-to-standard translation [16]). To tackle such issues, robust modeling strategies that can handle non-standard forms are needed. Techniques such as noise injection or subtoken-level modeling provide partial solutions [9], but a broader shift toward valuing non-standard data is required [1].

At the same time, we need systems that not only understand language varieties but also capture the fine-grained nuances of linguistic expressions. For instance, while safety guardrails are important, current LLMs can be overly sensitive, leading to false refusals where harmless requests are blocked. This issue has been systematically studied with resources such as XSTest [13]. To address this, we argue that models must be made safer for the *right reasons*. One promising line of work is steering methods that enable targeted mitigation: for example, Wang et al. propose a surgical and flexible single-vector ablation

approach that reduces false refusals while preserving model performance and inference efficiency [14].

B. Human Label Variation and Pluralistic Alignment

Equally important is variation in human judgments. Annotation is not always reducible to a single "ground truth." Disagreement among annotators often reflects genuine ambiguity or multiple valid perspectives rather than mere noise [2], [10]. Embracing this human label variation (HLV)—through collecting distributions, explanations, or multi-perspective annotations—enables models that better align with human diversity.

HLV also resonates with current discussions of *pluralistic alignment*, which argues that AI systems should not optimize for a single normative view of correctness, but instead represent and respect the spectrum of human perspectives. Sorensen et al. [17] outline a roadmap to pluralistic alignment, emphasizing that different values and interpretations can legitimately coexist. Similarly, Rieser's ACL 2025 keynote [18] highlights the importance of building AI that acknowledges multiple standpoints rather than enforcing one "canonical" answer. By treating variation in human labels as signal rather than noise, we can move toward alignment strategies that capture the richness of human perspectives and support more inclusive language technology.

C. Research diversity and interdisciplinarity

Finally, we need to address variation not only in model inputs and outputs, but also in our research design and the broader research ecosystem. Embracing variation in research means fostering interdisciplinary collaboration while centering human needs and agency. This requires continuously asking whether the AI technologies we develop are those that people truly need and want [19], [20]. Only by integrating diverse perspectives throughout the development process and engaging with insights from multiple disciplines can we build research that captures the richness and diversity of human language—and, by extension, human communication.

IV. Toward Trustworthy Human-Centered NLP

Building inclusive language technology requires a shift in perspective toward **human-centered NLP**. Human-centered NLP emphasizes that systems must serve diverse communities, respect linguistic variation, and ultimately support human needs and agency—to design NLP systems with humans in mind from the ground up. The reason this shift is necessary is simple yet profound: **variation is inherent to language**. Human language is characterized by productivity, ambiguity, and a rich spectrum of linguistic variation across speakers, dialects, registers, and contexts. This variation, while natural and inevitable, exposes the limitations of NLP systems typically trained on narrow and standardized datasets.

Variation inevitably gives rise to **uncertainty**. Ambiguity in meaning, multiple valid interpretations, or disagreements in human judgments all contribute to uncertainty in language processing. Yet, today's models are not good at handling uncertainty: they often fail to recognize when they do not know, and instead provide overly confident answers even in ambiguous or adversarial cases, and may hallucinate. Such behavior undermines user trust and risks excluding communities whose language varieties fall outside the models' dominant (post-)training distributions.

Understanding and explicitly modeling uncertainty, however, is not only key to technical robustness but also central to human-centered NLP. A human-centered perspective requires systems that acknowledge and communicate their limitations transparently. If models can identify when they may be wrong, or signal when several plausible interpretations exist, users are better equipped to interpret outputs, retain agency, and make informed decisions.

This brings us back to the central question: *what is trust?* As early as 1979, David G. Hays offered a concise and influential definition:

> *Trust arises from knowledge of origin as well as from knowledge of functional capacity.* [21]

Decades later, this observation remains highly relevant. Today, the topic of trustworthiness in NLP and AI is an ongoing discussion deserving special attention [22], [23]. To establish trust in a human-centered way, it is time to rethink how we design tasks and their evaluation protocols. Why now? It is increasingly difficult to predict a priori when models trained on web-scale data will work well. In a hypothetical world with complete knowledge of both origin and functional capacity, each task instance could be routed to the most suitable model (or agent, nowadays), enabling not only the full use of LLM capabilities but also trust in their predictions. The absence of such knowledge today is directly tied to our lack of confidence in deploying models in real-world scenarios.

This challenge is compounded by a dramatic shift in the field: with the advent of large generative language models, the traditional compartmentalized notion of tasks is breaking down. General-purpose, task-agnostic approaches demand that we move toward a more holistic view of language, placing trustworthiness—and thus human-centered NLP—at the core [12]. This requires rethinking what constitutes a task and developing multi-faceted evaluation protocols that go beyond narrow benchmarks, toward assessing both the origins and the functional capacities of our models. For example, it is an opportunity to rethink the classical NLP tasks we designed, go beyond classification labels (e.g., Natural Language Inference labels) but more towards the nuanced human understanding of languages (e.g., explanations, or more broadly, to uncover more about the reasons and processes beyond an outcome).

V. Conclusion

LLMs offer tremendous potential, but their inclusiveness and trustworthiness remain limited. By embracing variation in language and annotation, and by grounding our models in human-centered principles, we can move toward a *Trust LLM Ecosystem*: NLP systems based on modular, agentic AI that are uncertainy-aware, robust and inclusive and can thereby

better serve diverse communities [11] and support trustworthy interaction with language technology.

ACKNOWLEDGMENT

This position paper is an extended version of an earlier keynote talk I gave at the Annual Meeting of the Association for Computational Linguistics (ACL) 2024 in Bangkok, Thailand. I thank the ACL 2024 organizers, particularly Andre Martins, Vivek Srikumar and Lun-Wei Ku for inviting me. I thank all FedCSIS 2025 organizers, particularly Marcin Paprzyck, for inviting me to Krakow and the opportunity to write this position paper, and present a keynote at FedCSIS. Thanks to all MaiNLP and CIS members for the feedback on earlier versions of the talk. Finally, I would like to acknowledge the European Research Council for funding DIALECT 101043235 that has in large parts enabled research to support my vision of the *variety space* [1] – toward technology that in future is able to capture the full spectrum of variation in natural language, with all its rich, beautiful yet challenging spectrum of diversity.

***Abstract*—The integration of Large Language Models (LLMs) into optimization has created a powerful synergy, opening exciting research opportunities. This paper investigates how LLMs can enhance existing optimization algorithms. Using their pre-trained knowledge, we demonstrate their ability to propose innovative heuristic variations based on a semantic understanding of the algorithm's components. To evaluate this, we applied a non-trivial optimization algorithm, Construct, Merge, Solve & Adapt (CMSA)—a hybrid metaheuristic for combinatorial optimization problems that incorporates a heuristic in the solution construction phase. Our results show that an alternative heuristic proposed by GPT-4o outperforms the expert-designed heuristic of CMSA, with the performance gap widening on larger and denser graphs.**

I. Introduction

THERE is a wide variety of optimization algorithms of all kinds and flavors. A simple search using the term 'optimization algorithm' in databases like Scopus or platforms like GitHub yields thousands of results, with that number growing every year. Additionally, optimization researchers often maintain private collections of their algorithms. All these algorithms—open-source or proprietary, and implemented in diverse programming languages—can potentially be improved. By refining their original code with modern techniques and technologies, we can achieve more efficient designs and implementations that go beyond what their creators originally envisioned.

In recent years, the development and growth of Large Language Models (LLMs)—popularized by models such as OpenAI's GPT-4 [24], Anthropic's Claude [31], Google's Gemini [32], Meta's Llama 3 [33], and recently DeepSeek [11]—has opened the door to a wealth of new possibilities. Among the most transformative advancements is code generation. Tools like GitHub Copilot[1], which integrates seamlessly with code editors like Visual Studio Code[2], Windsurf[3], and Cursor[4], an editor with built-in LLM capabilities, have become essential tools for many software developers, revolutionizing their daily workflows. For example, a Python developer could request an LLM to generate a template for invoking external APIs, and the LLM would automatically produce the required code. LLMs have become invaluable for streamlining coding tasks, especially those that are routine and highly repetitive [14]. Therefore, it is natural to wonder: if LLMs excel at simple programming tasks, could they also aid in improving sophisticated optimization algorithms?

One of the recent examples of leveraging LLMs in optimization algorithms is the development of frameworks for generating new black-box metaheuristics [30]. Finding an effective metaheuristic, for example, for a combinatorial optimization problem can be a significant challenge. However, using LLMs to build upon an existing metaheuristic as context and employing them as tools to discover new heuristics or more efficient implementations (e.g., reducing RAM usage or computation time) in a given programming language remains a largely unexplored area. Implementing metaheuristics, unlike other algorithms, requires a focus on computational efficiency, mathematical expressions in scientific computing, and efficient data structure selection. Thus, designing new algorithms in this field demands expert implementation skills.

In this paper, we demonstrate how LLMs like GPT-4o can be leveraged to enhance a sophisticated optimization algorithm, specifically the Construct, Merge, Solve & Adapt (CMSA) hybrid metaheuristic [1, 3, 2]. Starting with an expert-developed C++ implementation of CMSA for the Maximum Independent Set (MIS) problem (of approximately 400 code lines), we employed an in-context prompting strategy combined with interactive dialogue (see Figure 1). Our results show that the LLM successfully comprehended the complex logic and parameter interactions within the CMSA implementation for MIS, demonstrating algorithmic insight to discover novel heuristics while suggesting improvements to the C++ codebase. This successful example opens up new possibilities for enhancing existing complex optimization algorithms by using LLMs as assistants.

The paper unfolds as follows. In Section II, we introduce code generation using LLMs, making it accessible for readers without prior experience in this field. We also explain the MIS problem and provide a brief overview of the CMSA algorithm. Next, in Section III,We present our methodology for enhancing

CMSA for the MIS problem using LLMs, detailing the process and providing steps for result reproducibility. Section IV presents our experimental results and their interpretation. The limitations of our approach and future research directions are discussed in Section V. The paper concludes by summarizing our key findings and emphasizing the potential impact of LLMs on existing metaheuristics.

II. Background

A. Code Generation with LLMs

Code generation is one of the primary research areas in LLMs [14, 16, 6]. The concept is straightforward: given a prompt, such as *"I need an algorithm to sort a list of numbers in Python"*, the LLM is expected to return a corresponding algorithm (e.g., `Quicksort`) implemented in Python. This capability arises because LLMs are trained on massive amounts of data, which include code from diverse programming languages available on the internet. These codes are sourced not only from GitHub repositories but also from StackOverflow, technical documentation, scientific articles, and publicly available books.

A more explicit prompt can lead to more sophisticated responses. For example, the prompt *"I need an efficient sorting algorithm for a list of numbers in Python, which can be processed in parallel, utilizing modern optimization techniques"* in GPT-4o generates a `ParallelMergeSort`. While efficient, it can be further refined by interacting with the model. For instance, asking *"Find new ways to improve it"* results in an enhanced version using techniques like optimized `Quicksort` for small arrays, better memory management with `NumPy`, and heap merge for combining sorted arrays. This approach leverages `MergeSort`'s ease of parallelization. However, the model might have suggested a different algorithm if the focus was on memory optimization without parallelism. This emphasizes the importance of prompt design and iterative refinement of responses [39].

LLM response quality depends on the data used for training, and with the refinement of datasets and the increase in size, their performance in code generation has improved [38]. Moreover, no LLM is flawless when it comes to generating error-free code. Continuing with the `ParallelMergeSort` example, a model might return code with bugs, so interaction with the model (e.g., copying and pasting error messages from the Python interpreter) is necessary to refine the responses. One could even ask the model to generate its own test suite to verify its algorithm. Different LLMs for these tasks are generally evaluated through benchmarks. One of the most widely used is HumanEval [7], which features programming challenges that assess language comprehension, algorithmic competencies, and basic mathematics—some of which are comparable to straightforward software developer interview questions.

Furthermore, *code generation using LLMs* is a broad area, as code may originate or be destined for very different domains, including the following: data science code for analyzing data and building predictive models [35]; systems code for managing hardware and low-level operations [17, 10]; frontend code development for web applications and UI [37]; and optimization code for solving complex computational problems. Each domain presents its own unique challenges and requirements, with our focus being on the latter, specifically in the field of metaheuristics.

Concerning the automatic generation of metaheuristics with LLMs, given the famous "No Free Lunch Theorem" [36], researchers understand that no single metaheuristic algorithm can outperform all others across all optimization problems. This fundamental principle naturally leads to an interesting possibility: LLMs could serve as powerful automatic generators of black-box metaheuristics, significantly reducing the time needed to find the 'best' implementation of a metaheuristic for a specific problem. In this context, LLMs could be tasked with discovering novel variations and operators that

create new metaheuristics—potentially even surpassing state-of-the-art algorithms for particular problems [30].

The first notable demonstration of heuristic discovery using LLMs was conducted by FunSearch [27], which showcased the potential of leveraging LLMs to generate novel heuristics for the Bin Packing (BP) Problem through a heuristic evolution process. However, a recent study [29] points out that the heuristics developed by FunSearch face challenges in generalizing across diverse BP problem instances. While FunSearch relies on an incomplete or suboptimal base program as a starting point, our approach starts with a complete and carefully designed implementation of an optimization algorithm. Other related works can be summarized as follows. Stein and Bäck [30]'s LlaMEA is a framework that integrates evolutionary algorithms with LLMs to iteratively generate and refine novel black-box metaheuristics during runtime. Similarly, Hemberg et al. [13] proposed LLM GP, combining genetic programming with LLMs to evolve operators through LLM assistance. Meanwhile, Pluhacek et al. [26] demonstrated via prompt engineering that LLMs can generate innovative metaheuristics by identifying and decomposing six high-performing swarm algorithms for continuous optimization.

While these studies already give a glimpse of possible use cases for LLMs in optimization, they primarily focus on creating new algorithms rather than improving existing ones—that is, building upon pre-existing complex code. This distinction is significant given the vast landscape of published optimization algorithms—a simple GitHub search for 'optimization algorithm' returns over 20,000 results, representing a wealth of algorithm implementations that could benefit from improvement. This is why we believe an opportunity exists to create a subfield focused on generating code from existing optimization algorithms. Building on this, our work explores using LLMs to enhance implemented algorithms, enabling the models to uncover new heuristics overlooked by experts in the original implementations. In this sense, our approach treats LLMs as assistants to researchers, not replacements. By doing so, we leverage LLMs to work with existing code (as context) and improve it using the current knowledge these black-box model models have gained during their pre-training phase.

B. Maximum Independent Set (MIS) Problem

To validate our hypothesis that LLMs can enhance existing optimization algorithms, we will employ an algorithm (detailed in the following subsection) to solve the Maximum Independent Set (MIS) problem, a well-studied and NP-hard combinatorial optimization problem with applications in network design, scheduling, and bioinformatics. Formally, the MIS problem is defined as follows: Given an undirected graph $G = (V, E)$, the objective is to find a largest subset $S \subseteq V$ such that no two vertices in S are adjacent in G, i.e., there is no edge $(u, v) \in E$ for all pairs $u \neq v \in S$. Figure 2 shows three examples of optimal MIS solutions (non-white nodes) in different graphs.

C. CMSA

Construct, Merge, Solve & Adapt (CMSA) is a hybrid metaheuristic, also known as a matheuristic, that combines elements of classical metaheuristics with exact solvers (such as Integer Linear Programming (ILP) solvers) for combinatorial optimization [3]. Each CMSA iteration is a sequence of four fundamental phases:

1) **Construct:** Generates solutions probabilistically through a probabilistic greedy mechanism (remember this phase; it will be key in the next section).
2) **Merge:** Combines solution components from the generated solutions to form a reduced subproblem.
3) **Solve:** Applies an exact solver (in the case of the MIS: an ILP solver) to optimally solve the reduced subproblem.
4) **Adapt:** Updates parameters and data structures based on the quality of the solution returned by the solver.

This hybrid architecture combines the efficiency of metaheuristics for search space exploration with the precision of exact methods in reduced spaces. The CMSA algorithm is controlled by some key parameters. First, and most importantly, each solution component has an associated *age* value, which is initialized to zero when a component is added to the subproblem. Moreover, a solution component in the subproblem is subject to an increase of its age value, in case it does not form part of the subproblem's solution generated by the exact solver. In this context, the parameter age_{max} plays a crucial role, defining the maximum age of solution components before they are removed from the incumbent subproblem, thereby preventing stagnation and encouraging diversity. Other parameters include n_a, which sets the number of solution constructions per iteration, t_{max}, the total CPU time, t_{limit}, the time limit for the ILP solver per iteration, and $0 \leq d_{rate} \leq 1$, which controls the determinism rate for solution construction. Note that higher values of d_{rate} lead to more deterministic solution constructions, while lower values increase randomness. Well-chosen values for these parameters ensure a balanced exploration of the search space, effective exploitation of promising areas via exact subproblem solving, and efficient use of computational resources.

We selected CMSA for the purpose of this paper due to its relative complexity in implementation as compared to simple metaheuristics. For instance, implementing CMSA for the MIS problem in C++ presents significant technical challenges. The four phases must be precisely defined, properly integrated, and implemented efficiently to leverage the framework's full potential. This complexity would only increase when dealing with more sophisticated optimization problems. In essence, a CMSA implementation demands expertise not only in metaheuristics and exact methods but also proficiency in C++ (or whatever programming language is chosen for implementation).

For our study, we utilize the original C++ implementation to solve the MIS problem, which was provided by CMSA's inventor and can be downloaded from our repository (https://github.com/camilochs/optimizing-the-optimizer). This choice

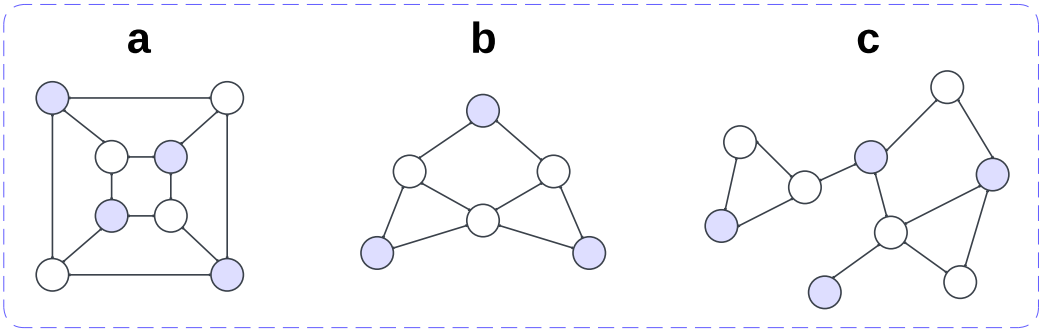

Fig. 2: Examples of maximum independent sets.

serves two crucial purposes: first, it ensures we are working with a well-implemented version of the algorithm, and second, it presents an interesting opportunity to test LLMs' capability to enhance expert-written code. This scenario allows us to evaluate whether LLMs can identify potential improvements even in code developed by domain experts. Our findings are presented in the following section.

III. LLM-Improved CMSA for MIS

In this section, we present a methodology for leveraging LLMs to improve existing optimization algorithms. By "improve existing optimization algorithms," we specifically mean expert-crafted implementations that have already been optimized for performance, rather than simplistic or baseline versions. In contrast, prior approaches often start from scratch—generating code from an initial prompt and refining it iteratively—or rely on overly simplified implementations that fail to reflect the complexity of real-world optimization problems. Our approach centers on dialog-based interaction with an LLM via a chatbot interface, uncovering novel improvements in the code that even an expert can benefit from. We detail this in the following subsections.

A. Discovering New Heuristics

LLMs are pattern-recognition machines [23, 28], and code is a rich source of structured textual patterns. This allows LLMs to identify underutilized elements—such as variables or functions—that could play a strategic role within a heuristic. Such insights may be missed by human experts, especially in complex codebases. These discoveries require a deep syntactic and semantic understanding of both the code and the optimization problem, enabling them to suggest meaningful modifications to heuristic strategies, going beyond superficial code changes. In this way, LLMs can serve as advanced assistants for optimization algorithm designers, offering novel heuristic improvements informed by reasoning over their vast pretraining knowledge.

To demonstrate our methodology, we employ an LLM to improve one of the heuristics in the CMSA code used to solve the MIS problem. Specifically, the function `generation_solution()` implements the solution construction phase of the CMSA framework [1]:

```
while (int(positions.size()) > 0) {
    double dec = standard_distribution(generator);
    int position = 0;

    if (dec <= determinism_rate) {
        position = *(positions.begin());
    } else {
        int max = candidate_list_size;
        if (max > int(positions.size())) {
            max = int(positions.size());
        }

        double rnum = standard_distribution(generator);
        int pos = produce_random_integer(max, rnum);

        set<int>::iterator sit2 = positions.begin();
        for (int i = 0; i < pos; ++i) {
            ++sit2;
        }
        position = *sit2;
    }

    greedy_sol.score += 1;
    greedy_sol.vertices.insert(increasing_degree_order[
     position]);

    if (age[increasing_degree_order[position]] == -1) {
        age[increasing_degree_order[position]] = 0;
    }

    positions.erase(position);

    for (auto sit = neigh[increasing_degree_order[position
     ]].begin();
         sit != neigh[increasing_degree_order[position]].
     end(); ++sit) {
        positions.erase(position_of[*sit]);
    }
}
```

Listing 1: Probabilistic greedy algorithm for MIS in CMSA.

It implements a greedy randomized construction heuristic that selects exactly one vertex $v_i \in \tilde{V}$ at each step (where $\tilde{V}$ is the set of nodes that can feasibly be chosen), until the MIS solution is complete:

$$v_i = \begin{cases} v_{\text{min}} & \text{if } r \leq \alpha \\ v_{\text{random}} \in \text{CL}(k) & \text{otherwise} \end{cases}$$

where

- v_{min} is the vertex with minimum degree (among the ones from $\tilde{V}$)

- r is a random number between $[0, 1]$
- α is the determinism rate
- CL(k) is a candidate list of size k
- v_{random} is a randomly selected vertex from the candidate list

The heuristic combines deterministic greedy selection (based on vertex degree) with randomization to create diverse solutions. It selects vertices either by taking the best available vertex (greedy choice) with probability α, or by randomly selecting from a restricted candidate list with probability $(1 - \alpha)$.

1) New heuristic from the LLM: The original greedy heuristic, while efficient in terms of runtime, fails to incorporate the `age` variable—a key element of the CMSA framework. It only uses the `age` variable to restart the solutions, meaning it is not utilized in the candidate selection mechanism. In Figure 3, we present two example dialogues of interactions with the LLM according to our approach. Let us begin with the first one. In case (a), the LLM proposes an enhanced heuristic that takes into account both node degrees and the current age values. The vertex selection mechanism suggested by the LLM can be technically described as follows:

$$v_i = \begin{cases} \text{argmin}\{P_w(v_j) \mid v_j \in \tilde{V}\} & \text{if } r \leq \alpha \\ \text{roulette-wheel selection w.r.t. } P_w(.) \text{ values} & \text{otherwise} \end{cases}$$

where $P_w(v_j)$ is a weighted probability:

$$P_w(v_j) = \frac{w(v_j)}{\sum_{v_l \in V} w(v_l)}, \quad w(v) = \frac{1}{2 + age(v)} + \frac{1}{1 + \text{degree}(v)} \quad (1)$$

The weight function $w(v)$ favors vertices with low age and degree values to promote diversity in the selection process. Thus, the LLM was able to change the original heuristic by incorporating the `age` values to diversify the node selection process, while balancing it with degree information through a composite weight function. It makes a lot of sense to decrease the probability of solution components with high age values being incorporated in newly constructed solutions.

Although the LLM successfully identifies an overlooked use of the `age` variable within the CMSA construction heuristic, any dialog-based system ultimately requires human feedback [5]. As such, the LLM occasionally makes mistakes. For example, as shown in Figure 3 (a), the line `double weight = 1.0 / (1 + age[v])` may result in a division by zero, since `age` values in CMSA are set to `-1` for solution components that do not belong to the subproblem. The human-provided fix consisted in replacing `1 + age[v]` with `2 + age[v]`. Notably, this kind of use of the `age` variable—despite its initial flaw and the correction provided through human feedback—had never been considered by any researchers working on CMSA algorithms.

> This new CMSA variant is henceforth called `LLM-CMSA-V1`. It was obtained by replacing the `generate_solution()` of the original CMSA implementation with the new function provided by the LLM.

2) Improving `LLM-CMSA-V1` with the LLM: Since our methodology relies on dialog-based interactions with the LLM via a chatbot interface, it is also possible to request improvements to previously generated code—still available in the current session context. For example, one might ask: *"Are there ways to enhance the dynamic selection heuristic to allow for a more diverse and advanced search?"* The LLM responds with several suggestions, one of which involves incorporating the concept of entropy. The C++ code provided by the LLM is characterized by a corresponding change, which involves replacing the definition of $P_w(.)$ (see Equation 1) with the following entropy-adjusted probabilities:

$$P_H(v_j) = \frac{P_w(v_j) + H}{\sum_{v_l \in V} P_w(v_l) + H}$$

where

$$H = -\sum_{v_l \in V} P_w(v_l) \log(P_w(v_l))$$

The entropy adjustment increases selection diversity by adding the system's uncertainty to each probability.

> This CMSA variant is henceforth called `LLM-CMSA-V2`. We directly replaced the `generate_solution()` function of the original CMSA with the LLM-generated code.

B. Code Optimization Strategies

After discovering the two new CMSA variants with the help of the LLM, it is also possible to request a different kind of improvement—not in terms of proposing new algorithmic heuristics, but rather in enhancing the underlying C++ code. These enhancements may involve the use of more efficient data structures, changes in data types, or other low-level optimizations that preserve the algorithmic logic. For instance, one might ask: *"Could the LLM create an improvement at the C++ code level?"* In other words, is there a more efficient way to implement the new CMSA variants without altering their core behavior?

It is reasonable to assume that, since the LLM has been pre-trained on vast amounts of source code, it could suggest highly optimized C++ implementations—even for contexts such as optimization algorithm design (e.g., metaheuristics), where low-level improvements to data structures or code organization are not typically the focus of human designers. This leads us to the next prompt, which we apply to both previously generated heuristics, `LLM-CMSA-V1` and `LLM-CMSA-V2`:[5]

[5]This prompt uses the "C++ code" checkbox, as shown in Figure 3 (b).

Fig. 3: Two LLM interaction patterns: (a) a direct request to improve a heuristic using CMSA's `age` parameter, and (b) an iterative dialogue to enhance both heuristic quality and C++ performance through error correction. Both use in-context learning as a prompting strategy [12, 20].

Human prompt

Given the following heuristic implemented in C++ (`generate_solution()`), without altering its core logic or functionality, please analyze the code to identify potential **improvements in the use of data structures, cache optimization, and other low-level optimizations. Focus on enhancing performance by suggesting more efficient data structures, reducing memory overhead, improving data locality, and leveraging modern C++ features where applicable.** Please provide an updated version of the code with comments explaining each optimization.

However, dialog-based interactions with the LLM are not free from hallucinations—that is, the model may generate code with bugs or memory management issues in C++ (as shown in Figure 3 (b)). One effective way to address these problems is through human feedback, engaging in a trial-and-error refinement process with the model—a common practice in code generation workflows (see [5]). Eventually, the LLM produces code that compiles successfully. Upon reviewing the final output, it becomes evident that the generated code is more complex, less readable, and incorporates unconventional or less familiar programming techniques. For example, it replaces the `set` and `vector` data structures with more advanced, low-level alternatives:[6]

```
#include <bitset>
...
// Constants for optimization
constexpr size_t BLOCK_SIZE = 64;
...
// Bitset for boolean operations
std::bitset<32768> available;
// Adjust size based on max n_of_vertices
available.set();
// Aligned vector to optimize cache usage
alignas(BLOCK_SIZE) std::vector<int> active_vertices;
active_vertices.reserve(n_of_vertices);
```

Listing 2: Fragment code optimization suggested by LLM.

Meanwhile, the original code is shown in the following listing.

```
set<int> positions;
vector<int> position_of(n_of_vertices, 0);
for (int i = 0; i < n_of_vertices; ++i) {
    positions.insert(i);
    position_of[increasing_degree_order[i]] = i;
}
```

Listing 3: Fragment of original code from CMSA.

The logic remains the same, except for changes in variable names: `positions` is replaced with `available`, and `position_of` is substituted with `active_vertices`.[7]

Although the changes do not affect the heuristic's logic but rather the underlying C++ structures, they do not always lead to measurable improvements in efficiency, specifically in reducing the runtime, which in practice would allow us to explore better candidates when building a valid CMSA solution. Nevertheless, the generated code compiles and runs correctly.

> The two new CMSA variants with these performance improvements will be named: `LLM-CMSA-V1-PERF` and `LLM-CMSA-V2-PERF`.

This iterative process with the LLM, asking it to identify underutilized variables or functions in the existing code, demonstrates its potential as a sophisticated assistant for optimization experts. For instance, in this case, the LLM proposes a new CMSA construction heuristic utilizing the `age` parameter. Unlike simple code generation, the LLM enhances not only the algorithm itself but also the existing code (e.g., C++ implementations), suggesting improvements without altering its logic. This opens the door to using LLMs not just for developing optimization algorithms but also for updating and refining sophisticated legacy code, leveraging the extensive knowledge embedded in LLMs.

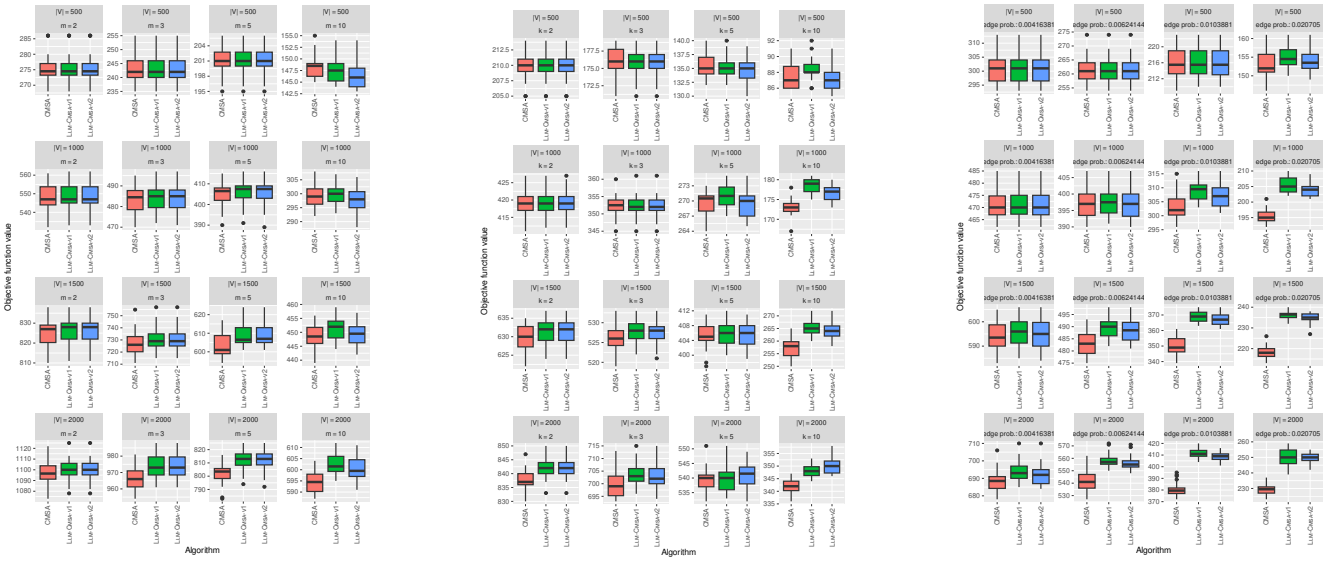
C. Reproducibility

Although it is not possible to replicate the exact results of an LLM, due to their autoregressive nature that predicts the most probable token based on a probability distribution (with the next token being determined stochastically) [18], it is possible to reproduce similar responses by using the same prompts, the same LLM, and its parameters. For this reason, our repository (https://github.com/camilochs/optimizing-the-optimizer) includes a *chatbot* that implements the same prompts used in our research (as shown in Figure 3). In fact, each element in Figure 3 (textbox and checkbox) loads pre-built prompts, known as in-context prompts [12, 20], to eliminate the need for manual input. Thus, our chatbot features two types of in-context prompts: (1) external ones, related to the C++ CMSA code for the MIS, and (2) internal ones, focused on improving the heuristic, the C++ code, and specifying which function in the code requires enhancement. Next, we will assess the quality of the heuristics proposed by the LLM.

IV. Empirical Evaluation

This section is divided into two parts: the preliminary phase (setup, benchmark, and CMSA parameter tuning) and the experimental results.

A. Preliminary



First, we used Chatbot Arena [9] to test various LLMs without incurring costs. [8] For our experiments, we finally selected GPT-4o (version: 2024-11-20)[9] as it is one of the top-performing models to date. Experiments concerning algorithm

[6]The comments in the code were generated by the LLM.

[7]Explicitly instructing the prompt to retain the variable names might have avoided this issue.

[8]https://lmarena.ai/

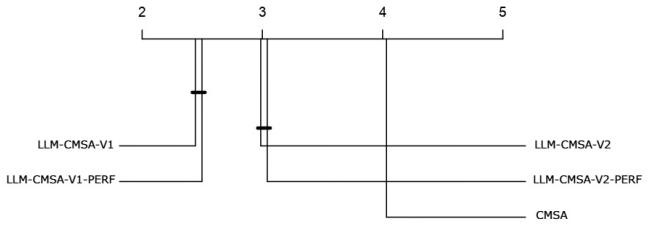
[9]The parameters used for the LLM were the default values: `temperature = 0.7` (controls randomness in responses), `top-p = 1` (nucleus sampling threshold for token probability), and `max-output-tokens = 2048` (maximum number of tokens in the output).

(a) Barabási–Albert (b) Watts–Strogatz (c) Erdős–Rényi

Fig. 4: Comparative analysis of solution quality: Original CMSA vs. LLM-CMSA variants (V1 and V2).

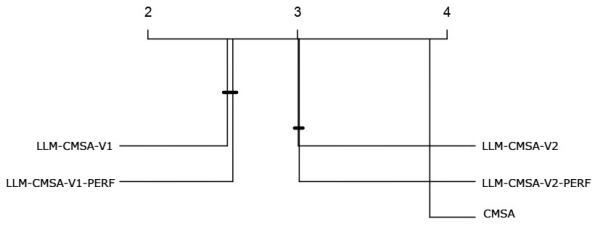
variants `CMSA`, `LLM-CMSA-V1`, and `LLM-CMSA-V2` were conducted on a cluster equipped with Intel® Xeon® CPU 5670 processors (12 cores at 2.933 GHz) and 32 GB of RAM.

Our benchmark set consists of three types of graphs: Barabási-Albert, Watts-Strogatz, and Erdős-Rényi graphs, with four different sizes and four density levels (see Figure 4). For each combination of size and density level, the benchmark set contains 1 tuning instance and 30 testing instances. This makes a total of 48 tuning instances and 1440 testing instances. We used a limited tuning set to find robust, general parameters, deliberately avoiding the overfitting that would result from tuning on a set identical to our evaluation instances. The parameters of all three CMSA variants (original, V1, V2) were tuned using `irace`, a tool for tuning algorithm parameters based on problem instances [22]. Due to the lack of space (and not being the important point of this paper), we do not report the final values here. We used 150, 300, 450, and 600 CPU seconds as computation time limits for graphs of the four different sizes.



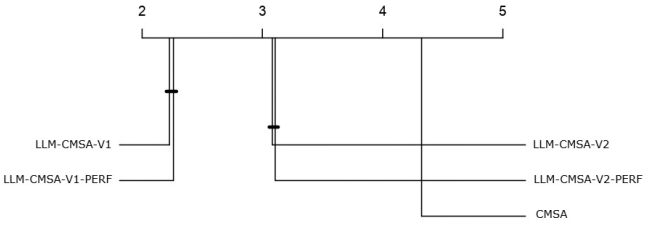
B. Numerical Results

In addition to the three tuned algorithms, we also tested two variants obtained by using the efficiency-improved C++ codes described in Section III-B. These two variants are henceforth called `LLM-CMSA-V1-PERF` and `LLM-CMSA-V2-PERF`. Each of the five algorithms was applied exactly once to each testing instance. The results of the main three variants are reported employing box plots in Figure 4. The considered graph size and density level are indicated at the top of each box plot. The main key observation is that both LLM-generated CMSA variants outperform the standard CMSA variant with growing graph size and density. This clearly shows that the suggestion of the LLM to make use of the age values for solution component selection during solution construction was a very good one.



To be able to make statistical claims, we produced so-called critical difference (CD) plots (see Figure 5), in which the algorithms' whiskers show their average ranking concerning a set of problem instances. Moreover, algorithm whiskers are connected by a bold horizontal bar in case they perform statistically equivalent.[10] Figure 5 shows three CD plots, one for each graph type. In these plots we also included the efficiency-optimized LLM-generated CMSA variants. The following observations can be made. Even though both `LLM-CMSA-V1` and `LLM-CMSA-V2` outperform `CMSA` with statistical significance for all three graph types, in all three cases the first variant outperforms the second variant. This means that the idea of using the entropy of the selection probabilities was not fruitful. Moreover, the efficiently-optimized algorithm variants are statistically equivalent to their non-optimized counterparts. This means that, even though they might save RAM, which is a non-tested hypothesis, they do not benefit by producing better results. Furthermore, preliminary checks indicated no significant runtime improvements from these C++ optimizations in our test environment, suggesting the original expert implementation was already highly efficient or that the specific low-level changes were not impactful in this context.

Finally, Figure 6 shows two representative examples of the convergence behavior based on 10 runs of the main three CMSA variants. In both examples, the LLM-generated CMSA



[10]The critical difference (CD) plot, which uses the Friedman test for overall differences and the Nemenyi post-hoc test for pairwise comparisons, is a recognized standard for the statistical comparison of multiple randomized algorithms for combinatorial optimization.

variants quickly produce solutions of a quality that standard CMSA does not even obtain at the end of its runs.

V. Discussion

Our study highlights the potential for LLMs to engage in algorithmic reasoning, successfully identifying conceptual enhancements for CMSA, such as the `LLM-CMSA-V1` heuristic which outperformed the expert baseline. Interestingly, the LLM's subsequent suggestion incorporating entropy (`LLM-CMSA-V2`), while plausible, was less effective. Perhaps its added complexity was not beneficial, or even detrimental, within the specific CMSA/MIS context, making the simpler LLM-proposed V1 superior. This observation reinforces the need for rigorous empirical validation of any proposed heuristic. However, our study also has the following limitations: due to space constraints, we tested only one LLM (GPT-4o) for CMSA improvements, and future work could benefit from comparing additional LLMs, especially open-weight ones. Additionally, we did not explore using GPT-4o to enhance other complex algorithms for additional optimization problems. These limitations could be addressed in an extended article. Despite these limitations, our comprehensive analysis of CMSA with new heuristics for solving MIS instances presents promising opportunities for new lines of research emerging from our work:

1) **Specialized benchmarks.** While our study focuses on CMSA for the MIS problem, the field lacks benchmarks tailored to optimization. Just as general-purpose code generation relies on standard benchmarks, we need domain-specific ones to evaluate LLMs' ability to discover improved heuristics.
2) **LLM-based agent integration.** Figure 3 illustrates manual interaction, but tasks like execution and debugging could be handled by autonomous agents. A platform where such agents collaborate on improving existing optimization algorithms may yield major advances [15, 21].
3) **Adapt code to the target domain.** Optimization algorithms often require adaptation—not only by switching programming languages to improve performance and maintainability, but also by transitioning from single-threaded execution to parallelism (e.g., using CUDA). LLMs can support this process [25, 19, 8], though domain-specific fine-tuning may be necessary.

An underlying issue in using LLMs for code generation is how we deal with errors. Although they may produce similar outcomes, errors made by a human programmer (or optimization researcher) and those produced by an LLM differ fundamentally in origin. Understanding these conceptual differences is essential for developing sound methodologies for integrating human- and machine-generated code [4].

On the other hand, a fundamental question arises: should the LLM be credited for discovering a superior heuristic compared to the best implementation by a human expert? While prompt design clearly influences the outcome, it raises important questions about authorship, ownership, and the role

of AI in scientific discovery (see [34]).

VI. Conclusions

In our research, we demonstrate that LLMs can be effectively applied to enhance existing optimization algorithms. We used the non-trivial Construct, Merge, Solve, and Adapt (CMSA) algorithm implemented in C++ to solve the classical Maximum Independent Set problem. By leveraging in-context prompts with GPT-4o, the model successfully understood the operational context of the CMSA implementation and proposed conceptually new heuristics for the probabilistic construction phase. After a thorough comparative analysis, the heuristics proposed by the LLM outperformed those manually designed by an expert in CMSA. This highlights the potential of LLMs not merely as tools but as artificial collaborators capable of identifying unused code segments through semantic analysis and contributing meaningfully to the complex task of algorithm design.

***Abstract*—We present an approach based on the Interactive Granular Computing (IGrC) model as the basis for developing foundations of Complex Intelligent Systems, *i.e.*, Intelligent Systems dealing with complex phenomena (IS's). The generalization of GrC to IGrC was proposed to support the design of IS's treated in IGrC as examples of complex granules (c-granules) with control. To make such systems successful, it is necessary to enable such systems to have continuous interaction with the physical world. The control of c-granules aims to properly implement the physical semantics of specified transformations of c-granules in the physical world. This implementation is based on the discovery of relevant configurations of physical objects, which provides the basis for perceiving relevant data about these objects and their interactions through the control of c-granules. Additionally, to create high-quality models that serve as the basis for the behavior of IS's, these configurations must be adaptively adjusted by control to allow for the perception of relevant data used to induce those models. Unlike information granules from GrC, the correct implementation of c-granule transformations cannot be restricted to the abstract space. An important property of the IS's discussed here is that they cannot be separated from interactions with the physical world. Hence, they cannot be confined to an abstract space. In particular, the relevance of IGrC in searching for rough computational building blocks for cognition is discussed. These computational building blocks are modeled by complex granules (c-granules) and their networks. It is also proposed to use IGrC as the basis for developing IS's grounded on cognitive computing.**

***Index Terms*—(interactive) granular computing (IGrC); informational-physical complex granule (c-granule); network of c-granules; control of c-granule; reasoning module; rule module; implementational module; decomposition module; rough set; modeling of rough membership function in IGrC.**

I. Introduction

IN THIS paper, we summarize the current status of the IGrC model research based on published papers (see, *e.g.*, [1]–[6] and the developments presented in papers available at https://dblp.org/pid/s/AndrzejSkowron.html) as well as unpublished results, paying special attention to the IS's based on IGrC, the structure of c-granules with control and the role of rough sets in IGrC. We also provide an overview of the potential applications of IGrC-based IS's in various fields. Further details regarding IGrC and such applications will be provided in our future publications.

In the rough set approach, reasoning or decision making strategies are developed based on approximation spaces [7]–[10] which depend on perception about a finite set of objects or situations. For example, based on approximation spaces it is possible to estimate the degree of membership of these objects into given concepts (or classification). This is estimated using the degree of inclusion of some neighborhoods of the considered object (granule) into the considered concepts.The neighborhoods (granules), consist of indiscernible or similar objects to the perceived one. Problems related to how such membership functions are modeled are outside of the existing theory of rough sets. However, for IS's dealing with complex phenomena such an approach is not satisfactory because IS's should be able to construct membership functions based on the current perception of the physical world. As envisaged by many researchers (see, *e.g.*, opinion by Frederick Brooks cited later [11]) if models of the vague concepts related to complex phenomena are constructed using traditional mathematical modeling, then they would lack in quality. Rough membership functions are examples of such models. We propose to support modeling of such concepts basing on Interactive Computing Model (IGrC). In a sense, we are following the discussion on necessity to modify the Turing test by putting into sync not only issues of language and reasoning but also perception and action [12].

In IGrC we follow the suggestion of Professor Leslie Valiant, the Turing award winner. According to his opinion the most important problem of AI is the characterization of the computational building blocks for cognition (see http://people.seas.harvard.edu/~valiant/researchinterests.htm). IGrC is attempting to model these computational building blocks for cognition using dynamic complex granules (c-granules) generated along interactive granular computations. One should note, that many of such computational building blocks are not pure mathematical objects; for instance, they can be specified in natural language by complex vague concepts with physical semantics containing both abstract and physical objects when aspects of perception and action are considered in realization of semantics.

In IGrC, we deal with complex granules (c-granules) com-

posed out of abstract objects and/or physical objects. Such objects are necessary to enable IS's to deal with perception and action issues. IGrC aims to introduce tools for generating and controlling computations over (networks of) complex granules (c-granules)[1] so that the given requirements can be satisfied. These requirements may concern of the final states of computations (specified by some relevant properties of networks of c-granules) or the whole trajectories of computations (specified, *e.g.*, by some invariants over computations on the (relevant parts) of networks of c-granules). These networks are like networks of physical pointers enabling IS's to continuously interact with the real physical world for better perceiving situations in it. They express realization of the physical semantics expressed by specifications of transformations of networks of c-granules. Information about perceived situations in the physical world is stored in i-layers of network of c-granules and is used by control of c-granule for selection of the relevant transformation of the current network of c-granules. The proposal of the IGrC model combines together many different ideas spread nowadays over different domains such as multi-agent systems, robotics, cognitive science, complex adaptive systems, to name only a few of them (see, *e.g.*, [13]–[22]). In the paper, we restrict discussion about control of c-granules as a compound c-granule to an informal description of its behavior. The discussion on a more formal control specification and its physical semantics will be covered in one of our forthcoming paper.

The IGrC model is created as the basis for the design and analysis of c-granules, in particular IS's. The proposed IGrC model differs from the classical Turing model by corroborating the idea of synchronizing the four components: language, reasoning, perception, and action. In the IGrC model, granular computations form the basis for reasoning that supports problem solving by c-granules.

Problem solving (or decision support) using c-granules (in particular, IS's) requires a proper understanding of real-world situations consisting of configurations of interacting physical objects. Therefore, the control of c-granules must include skills for perceiving situations in the physical world enabling the formation of associations between physical and abstract objects. These skills are supported by reasoning over granular computations performed by the control of c-granules. Consequently, these computations cannot be confined to the abstract space alone. Moreover, they depend on physical laws [23].

The paper is structured as follows. In Sect. II we present motivations and rudiments of the IGrC model. Rough complex granules as computational building blocks for cognition are discussed in Sect. III. In Sec. IV the role of rough sets in problem solving by IS's is outlined. The roadmap for developing a rough cognitive computer based on IGrC is outlined in Sec. V. Finally, we present conclusions.

[1]Networks of c-granules can be treated as higher order c-granules.

II. Rudiments of the IGrC model

A. Motivation

There is a huge literature about Granular Computing (GrC) (see, e.g., [1], [24]–[37] and references from these works) encompassing many different issues of GrC concerning. *e.g.*, philosophy, methodology, frameworks, tools, methods, models. However, it is also emphasised in [29]:

> *The current studies of decision-making with GrC lack a theoretical foundation and normative research paradigm.*

The IGrC model is a substantial extension of the GrC model. Granules from GrC can be treated as special cases of c-granules from IGrC[2]. In Table I GrC and IGrC are compared based on several important features.

The IGrC model (see, *e.g.*, [1]–[6] and https://dblp.org/pid/s/AndrzejSkowron.html) is the computing model on which we propose to develop such theoretical foundations for the design and analysis of IS's. Here, one should take opinions of many researchers which emphasizes that in case complex phenomenon classical mathematical modeling is not satisfactory. For example, according to Frederick Brooks [11]:

> *Mathematics and the physical sciences made great strides for three centuries by constructing simplified models of complex phenomena, deriving, properties from the models, and verifying those properties experimentally. This worked because the complexities ignored in the models were not the essential properties of the phenomena. It does not work when the complexities are the essence.*

Hence, one can not expect that humans are able to derive models of the vague concepts related to complex phenomena using traditional mathematical modeling resulting in construction of the high quality models of these concepts. The current discussion on Turing test [12] is also worthwhile mentioning here:

> *The Turing test, as originally conceived, focused on language and reasoning; problems of perception and action were conspicuously absent. The proposed tests will provide an opportunity to bring four important areas of AI research (language, reasoning, perception, and action) back into sync after each has regrettably diverged into a fairly independent area of research.*

According to the above opinions and many other evidences in different areas (see *e.g.*, [6]) construction of models for complex vague concepts related to complex phenomena in the physical world should be based on an unconventional computing model able to deal with abstract and physical objects for providing modeling interactions of IS's with the

[2]Any information granule inf from GrC can be identified as a c-granule g_{inf} consisting of an i-layer with inf and two transformation specifications: $store$ and $read$ (labeled by the addresses pointing out to the physical memory). These specifications may be used by control of the c-granule to either store inf in the p-layer of g_{inf} or read inf from it into the i-layer, without information loss.

TABLE I
COMPARISON OF GRC AND IGRC

	GrC	IGrC
GENERAL FEATURES OF COMPUTING MODEL		
based on the abstract Turing computation model	YES	NO
computations are pure mathematical objects	YES	NO
issues of language, reasoning, perception and action are brought into sync	NO	YES
advanced reasoning tools based on the computing model that facilitate the control of computations involving both abstract and physical objects are being developed and utilized in the computing model	NO	YES
MAIN FEATURES OF GRANULES		
abstract semantics of (information) granules	YES	YES
physical semantics of (complex) granules	NO	YES
features (attributes) of granules defined using the abstract space only	YES	NO
features (attributes) of granules dependent on interaction with physical objects	NO	YES
granules are equipped with control	NO	YES
the dynamics of granules are defined apriori in the abstract space only	YES	NO
the dynamics of granules depends on their control and interactions with physical objects	NO	YES
associations between abstract and physical objects related to granules are being constructed and used in the computing model	NO	YES
skills for encoding information into physical objects provided in the computing model	NO	YES
skills for decoding information from physical objects provided in the computing model	NO	YES
changes of granules are being made based on the abstract space only	YES	NO
changes of granules are restricted to their abstract parts only	YES	NO
changes of the information represented in granules are being made based on the abstract space only	YES	NO
changes of the information represented in granules are also being made based on interaction with physical objects	NO	YES
STATES, TRANSITION, COMPUTATIONS IN COMPUTING MODEL		
states: granules interacting with physical objects	NO	YES
transition relation (association) defined based on information in the abstract space only	YES	NO
transition relation (association) dependent on interactions with physical objects	NO	YES
computations consist of abstract states only	YES	NO
computations depend on physical laws	NO	YES
adaptation of steering of granular computations provided by control of granules dependent on interaction with physical objects	NO	YES

physical world in the process of perceiving of situations. We propose to base processes of construction of models for such concepts on IGrC.

Novelty of this paper is in (i) further clarifying the role of physical semantics for specifications of transformations of networks of c-granules and issues concerning its generation in the physical world by control of c-granules, (ii) adding discussion on searching for rough computational building blocks (c-granules) over computations of IGrC based on information (decision) systems as well as (iii) emphasizing usefulness of IGrC for developing foundations of cognitive computing by IS's. Our claim is that the foundations of IS's should be based on the unconventional IGrC model.

B. Basic postulates

We assume that IS's are equipped with c-granules which are able to perceive fragments of the physical world (hunks of matter [38]). In this process two layers of c-granules are important, namely the informational layer (i-layer) and the physical layer (p-layer). In the i-layer, spatiotemporal windows (addresses) (see Fig. 1) are specified in a given language; say w, addresses in a sense parts of the physical world included in the regions $\|w\| \subseteq \mathbb{R}^3$ of the physical space defined by w, were $\mathbb{R}$ is the set of reals. Complex granules perceive these parts of the physical world using their control, in particular an implementational module (IM) of control is responsible for defining so called physical semantics of specifications labeling spatio-temporal windows. Roughly speaking, on the basis of a given specification labeling a given spatio-temporal window, the IM constructs a configuration of physical objects and initiates interaction of the c-granule control with and in this configuration. The control of c-granule perceives the properties of this configuration and stores them (as the results of the implementation) in the i-layer. One should note that these results may be different from the expected ones which are given in the specification. In the process of perceiving relevant information about the situation, the control of c-granule may activate or generate a family of c-granules linking the i-layer

Links to a spatio-temporal hunk (portion of physical objects) in different moments (or periods) of time t_1 ,..., t_7 specified by the c-granule control using specifications of spatio-temporal windows pointing to different fragments (portions of matter) of the 3- dimensional physical world.

Fig. 1. Example of spatio-temporal window.

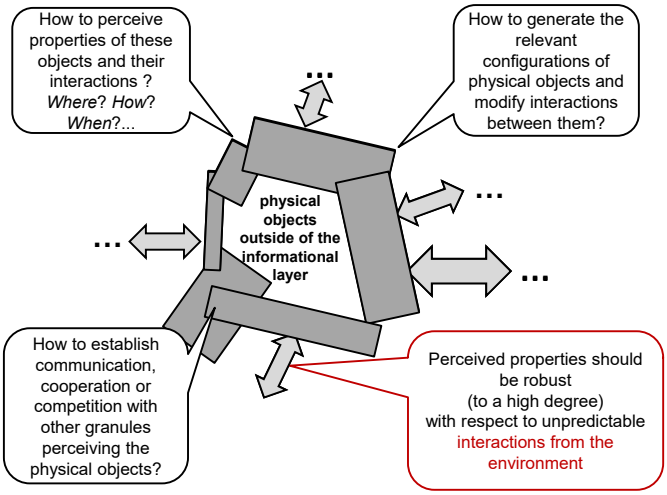

Fig. 2. Queries about a network of physical objects [6].

with the p-layer, creating a network of c-granules, *i.e.*, a higher order c-granule. The c-granules of the network should create a robust configuration with respect to interactions with the environment. The c-granules of such a configuration should be like *niches* considered by John Holland [15]. Better understanding of niches from formal (mathematical) point of view is still a challenge. There are several important issues to be resolved by control of c-granules in construction of networks of c-granules for perceiving situations. Among them a few are as follows (see Fig. 2):

- How to perceive properties of the objects and their interactions in a concerned configuration? (Where, how, when to do this).
- How to generate the relevant configurations of physical objects and modify interactions between them?
- How can cooperation or competition be organized in societies of c-granules to support problem solving?
- How to ensure that the perceived properties are robust (to a high degree) with respect to unpredictable interactions from the environment?

Interaction is a critical issue in the understanding of IS's dealing with complex phenomena. For example, in [39] the following opinion is presented:

> *Interaction is a critical issue in the understanding of complex systems of any sorts: as such, it has emerged in several well-established scientific areas other than computer science, like biology, physics, social and organizational sciences.*

Hence, one of the central issue concerns about interactions which should be treated properly by the computing model as on the basis of this IS's need to be designed and analyzed.

In IGrC model, we assume that interactions take place between configurations of physical objects and they can be partially perceived by c-granules. Three types of interactions of objects are distinguished:

1: interactions between distinguished abstract objects from the i-layer; elaborated in GrC, *e.g.*, for granulation or aggregation of granules (see, *e.g.*, [26], [40]);
2: interactions between some distinguished physical objects from the p-layer; studied in physics and represented in domain knowledge data bases and/or physical laws by the relevant (information) granules in GrC;
3: interactions between some abstract objects from the i-layer and some physical objects from the p-layer; for perceiving situations in the physical world a special interfaces between abstract and p-layers is realized by networks of so called informational-physical complex granules (c-granules, for short).

Example 1: Association in abstract i-layer of c-granule g. Let us assume that $f : X \to Y$, where X, Y are sets and f is a function from X into Y computed by an algorithm A. Computation of values of f are realized by interaction in i-layer of an abstract granule g_{arg} representing arguments of f and the granule g_A representing A. g_A is computing values of f on argguments sent by g_{arg}.

Example 2: Association between abstract i-layer and p-layer of c-granule g

$$f : X \overset{g}{\hookrightarrow} Y,$$

denoting a specification of the association for IM of the control of c-granule g with necessary details for its realization in the physical world and information about the expected results from Y.

Association f is realized using the physical semantics induced by the control of c-granule g responsible for implementation and perception:

- *Implementation step* : For given granules representing $x \in X$ and a specification of f, IM of the control of g extends (by some relevant new c-granules) the current c-granule g

to a new c-granule. This new granule provides 'physical pointers' from the object in which x has been directly encoded to a physical object in o_x, associated to x (by f). The object o_x is pointed out in the p-layer of this new c-granule by a spatio-temporal window w.

- *Perception step*: Some properties of parts of o_x, and other objects from the new c-granule as well as properties of interactions between them (and with the environment) are perceived by IM of the control of g and used for computing the value of f on x. This is done, in particular by decoding information from some parts of directly accessible physical objects of the new constructed granule into i-layer of g or inferring information on the basis of the:
  i. already perceived information and/or
  ii. available knowledge bases or physical laws.

Note that encoding and decoding mentioned above are the basic associations between abstract objects and physical objects 'directly accessible' by the control of g. Associations of abstract objects with more compound physical objects are realized as it is described above using physical objects which are not necessarily 'directly accessible'. Information about associations of abstract and 'not directly accessible' physical objects is inferred by the control of c-granule on the basis of already perceived information stored in the information layer as well as domain knowledge and/or physical laws about the perceived physical objects and their interactions. Hence, computations realized by the control of c-granules depend on domain knowledge and/or physical objects [23]. Moreover, one can see that information about the realized associations between abstract and physical objects is, in general, only partial and relative to the perception skills offered by the control of c-granule.

C. Comments on structure of complex granules (c-granules)

Any c-granule is a dynamic object consisting of, at any moment of local time of c-granule, the following components (see Fig. 3):

- information granules (i-granules) stored in its i-layer: some distinguished (families, collections of) objects from (parts of) the i-layer (considered in GrC); in general any i-granule consists a family of specifications of spatio-temporal windows labeled by perceived or stored information; this information may contain different components, *e.g.*, related to specification of the transformation of the current network of c-granules being under the control of the original c-granule (see Fig 4) or information perceived so far through a particular window;
- physical granules (p-granules) located in its p-layer: some distinguished (families, collections of) objects from (parts of) the p-layer;
- associations between i-granules and p-granules; these associations are specified by formal specifications of transformations and realized as the physical semantics by IM of the control of c-granule through implementation in the physical world; the physical semantics in the form of a network of c-granules under the control of the original c-granule (in a more general case the c-granules from the network may have their own control too) makes it possible to perceive partially the current situation in the physical world; these associations (it should be noted that these associations are not purely mathematical (abstract) objects) satisfy the following conditions:
  1) if p-granule g_p (collection of physical objects) is associated to i-granule g_i then g_i specifies a part of the physical space where g_p is located;
  2) g_i contains information so far perceived about g_p by the control of the original c-granule;
  3) g_i also contains a specification of the goal for realization of which g_p was created in the physical space.

Objects from g_p may be directly accessible by the control of the original c-granule, *i.e.*, information from g_i may be directly encoded into objects from g_p or some features of objects from g_p may be decoded into g_i. Sometimes an object from g_p may not be directly accessible by the control of the original c-granule. Then three distinguished three parts, namely soft_suit, link_suit, and hard_suit of the original c-granule take part in perceiving information (see Fig 3).

In Fig 3 a general structure of c-granule is presented. In soft_suit there are physical objects that are directly accessible, *i.e*, objects whose properties can be decoded into the i-layer by measurements or objects into which some relevant information from the i-layer can be encoded. The physical objects from the link_suit are used for transmission of interactions from soft_suit to hard_suit and hard_suit contains physical objects to be perceived according to the specifications of spatio-temporal windows represented in the i-layer. The scope of c-granule is a specification of spatio-temporal window in which other spatio-temporal windows are included. For a given specification of spatio-temporal window w, by $\|w\|$ we denote a region of the physical space corresponding to w. In a more general case w may represent a nested list of spatio-temporal specifications, *i.e.*, its components may represent new lists of specifications of spatio-temporal windows (Fig 3).

C-granules may have own control (c-granules with control) or can be without control (with empty control). Compound granules such as networks of c-granules or societies of c-granules are constructed from basic (atomic) c-granules. Details of construction of societies will be discussed elsewhere.

It should be noted that

- through interaction of i-granules from g_i with p-granules directly accessible by the control of the considered c-granule from g_p, information represented in i-granules may be encoded into p-granules;
- through interaction of i-granules from g_i with p-granules from g_p directly accessible by the control of the considered c-granule, the encoded information in these p-granules may be transmitted to some target p-granules from g_p;

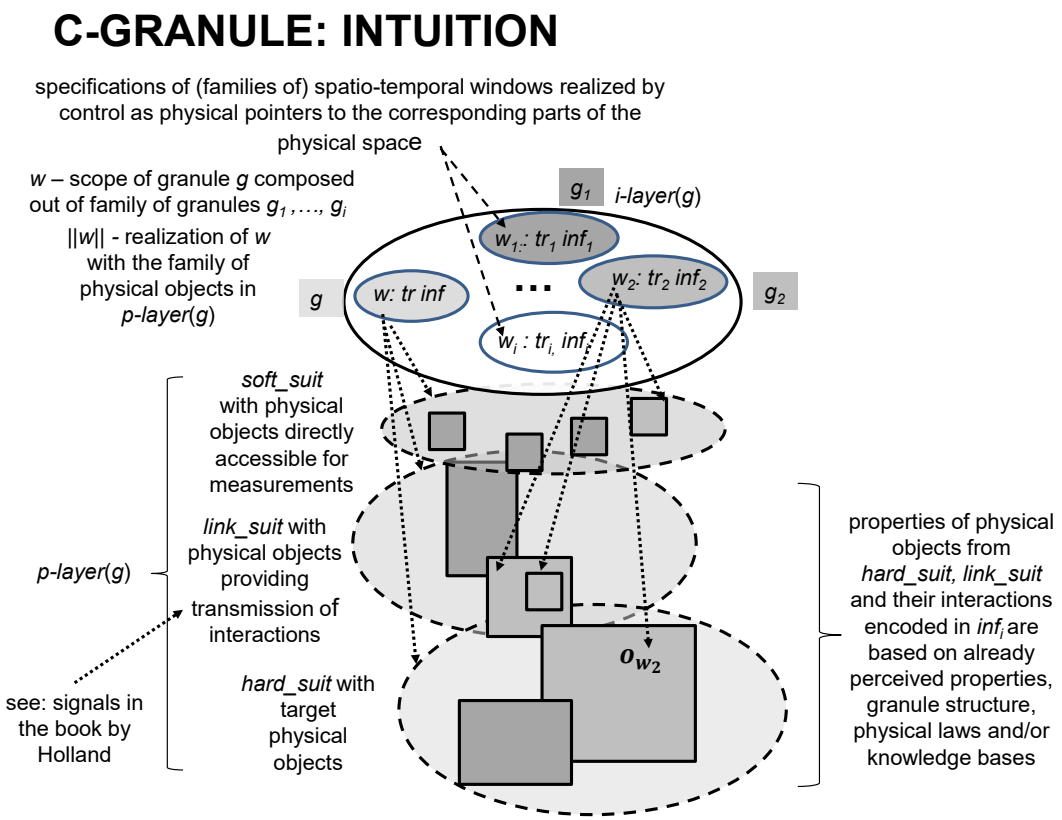

Fig. 3. C-granule intuition.

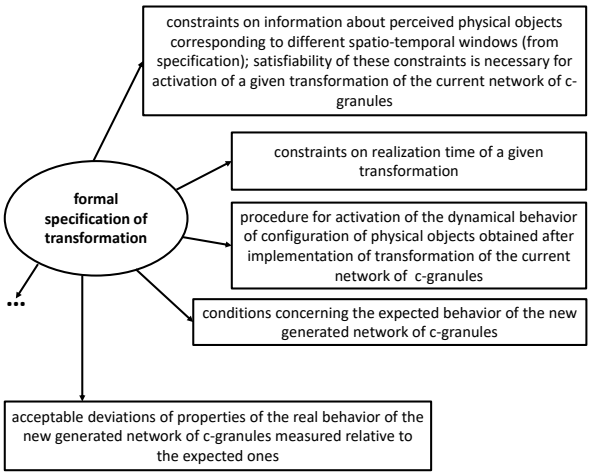

Fig. 4. Information stored in i-layer about transformation of network of c-granules.

- through interaction of i-granules from g_i with p-granules from g_p it may be decoded information from p-granules and stored in i-granules;
- information in the information layer of c-granule may be updated not only through interaction with the directly accessible objects; especially information about objects from g_p may be updated on the basis of reasoning using already collected information and also domain knowledge bases and/or physical laws.

D. Dynamics of complex granules (c-granules)

Dynamics of c-granules is defined by control of c-granule. Formally, the control may be understood as a distinguished c-

granule with the i-layer, which describes the control behavior determined by the p-layer. An intuition of control is presented in Fig. 5.

Control organizes (and initiates) communications (transmissions, interactions) between the i-layer and p-layer using network (configuration) of relevant c-granules (generated by its IM). The considered network collects in the i-layers the properties of perceived physical objects and their interactions.

The control of C-granules includes different modules that act as sub-granules of the control granule. These sub-granules interact with each other and with the environment to carry out target tasks (needs). Among them the basic ones are the following:

- cycle module (CM);
- rule module (RM);
- implementational module (IM);
- decomposition module (DM);
- reasoning module (ResM).

More advanced control may contain many other modules such as a learning module (LM), adaptation module (AM), or domain knowledge module (DKM).

The CM is responsible for the realization of the basic cycle of control of the original c-granule.

The RM consists a set of rules of the form

$$\alpha \Rightarrow_{tr} \beta,$$

where

- α is a condition of the rule verified on information about the status of perception of the current situation,
- tr is a specification of transformation of the current network of c-granules; this specification describes which c-granules in the network should be eliminated, suspended, modified, not changed etc[3] and
- β is the property of the expected result of realization.

Thus, the set of rules should be designed by the designer or learned from data.

The IM is a module responsible for generation of the physical semantics for a given specification of transformation (see Fig. 6). IM first tests the possibility of direct realization of a given specification in the physical world. If this is not possible, DM requires decomposition (see Fig. 7) of this specification, otherwise IM creates the relevant configuration of physical objects and initiates interactions in it aiming to realize the specification in the physical world.

More formal description of the DM is provided in [41]. It should be noted that the development of the DM module requires discovery of several decomposition languages. This discovery process can be supported by chatbots [42] helping to learn the strategy of divide-and-conquer of complex vague concepts (expressed in natural language) in human problem-solving. The key role in this process is played by information granulation [43], [44].

[3]More details on specification of transformations will be presented in our next paper.

The ResM is an important module supporting reasoning of the control of c-granules. For example, it allows control to decide if the current status of perception of the situation is satisfactory for selection of a rule from a given set of rules or to decide if the deviation of the expected results expressed in the rule from the real results obtained after implementation of a given transformation is acceptable. When such deviations are not acceptable, ResM may support adaptation of the current set of rules.

In Figures 8 - 9 is presented an illustrative example related to the ResM structure in one of our recent projects.

Control of c-granule aims to provide the most relevant decision systems for approximation of concepts. Information (decision) systems are represented in i-layer of c-granule; they are not isolated and not a priori given but they are modified by control of c-granule and (indirectly by) through interactions with the environment. Objects in information (decision) systems are (fragments of) multiple and/or multivariate time series represented in i-layer of c-granule obtained as a result of perceiving the situation in the physical world along computations of c-granule over networks of c-granules. Attributes represent properties of such objects. There is a necessity of providing possibility to change the currently used attributes during computation for proper identification of perceived situation (making it possible to select the relevant transformations for realization). Decisions are elements of complex game, *i.e.*, pairs consisting of complex vague concepts labeled by specification of transformation (*e.g.*, decision (plan)) related to this concept. Complex games are discovered from such decision tables. Development of strategies for discovery of rough membership functions for different complex vague concepts are necessary.

Hence here is a necessity to develop different reasoning (judgment) methods supporting, *e.g.*,

- discovery of complex games and their adaptation (reasoning about changes - rough calculus);
- identification of the relevant properties of situations in the physical world;
- control of computations over networks of c-granules toward generating computations satisfying a given specification; this may be related to the whole computation or to its final state;
- estimation of rough membership degrees of the perceived in the physical world situations to the considered concepts;
- resolving conflicts between rules specifying transformations to be performed;
- discovery of new sources of the relevant for the considered problem data (data governance [45]);
- discovery of compound sensors and/or actuators, robots.

Let us also emphasize the important role of reasoning methods in supporting discovery of relevant rough computational building blocks for cognition (rc-granules in IGrC) or aggregation of decisions (*e.g.*, in synthesis of complex sensors, materials or robots). One should note that there are several 'white spots' in formal reasoning methods waiting to

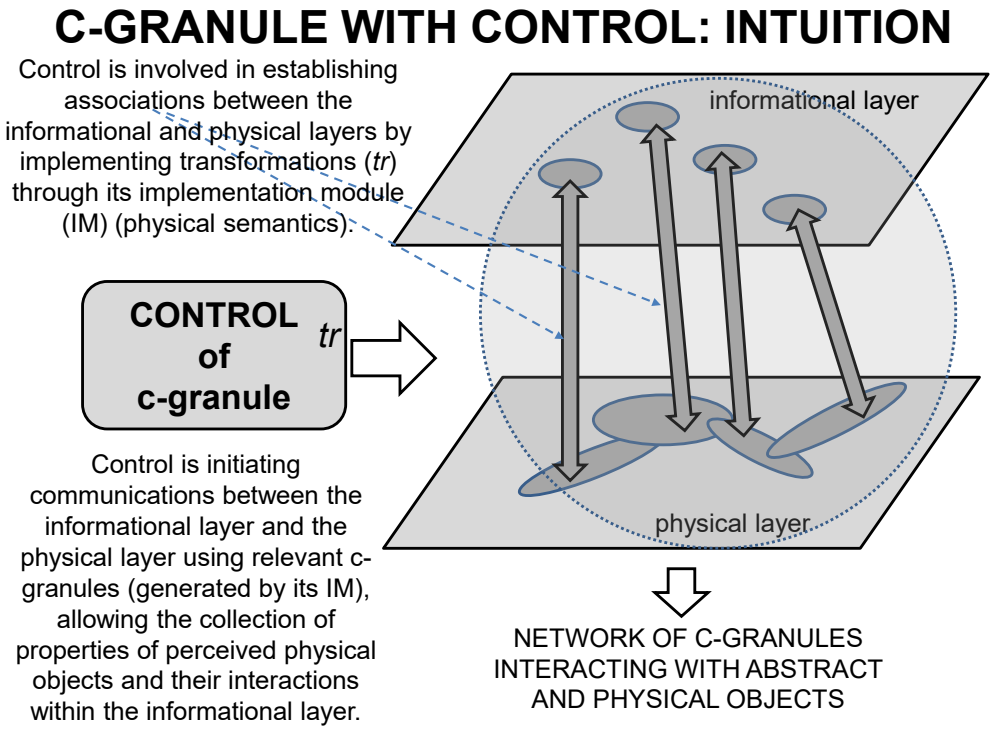

Fig. 5. C-granule with control: intuition.

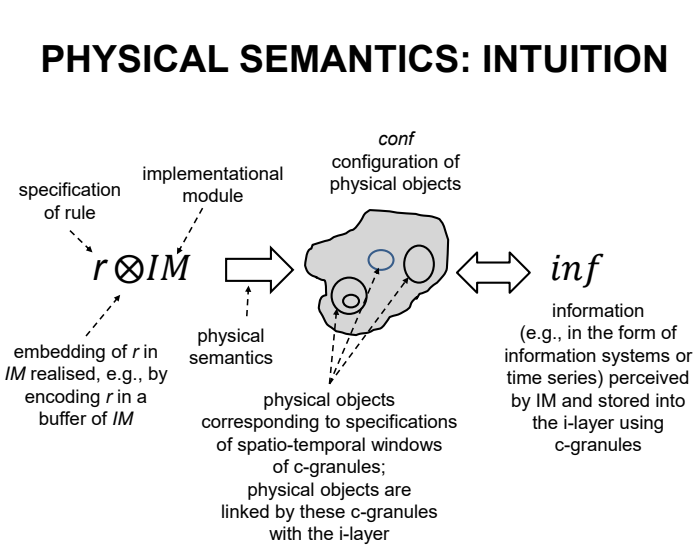

Fig. 6. Physical semantics: intuition.

be filled by the relevant methods. One example of such 'white spot' concerns experience based reasoning (see *e.g.*, [46], [47]). Hence, is is necessary to develop reasoning methods for supporting dialogues of IS's with experts to help them in performing of experience based reasoning [48], [49].

Control of c-granule in interaction with the physical world generates computations over networks of c-granules. The aim of the control is to assure whether the generated computations satisfy given requirements or target goals. They may concern the final states of such computations or the whole trajectories of computations (*e.g.*, in case of required invariants to be preserved in computations). One should note that these

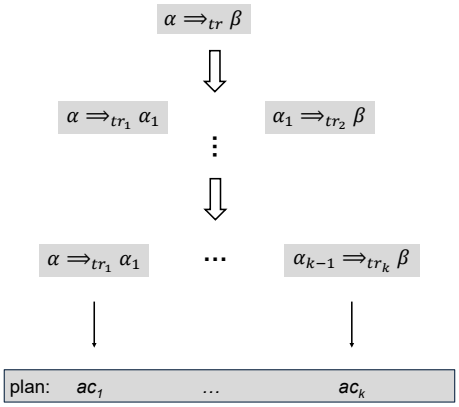

Fig. 7. Decomposition.

computations are not pure mathematical objects, they are unconventional because they are constructed over abstract and physical objects. In particular, they may depend on domain knowledge or physical laws [23].

III. Discovery of rough complex granules (RC-granules) as computational building blocks for cognition and the language of game of Wittgenstein

As it was observed in Sect. I, nowadays rough membership functions are defined as pure mathematical objects. However, according to the cited opinion by Frederick Brooks [11] models of these functions, being often models of vague concepts related to complex phenomena, can't be constructed (induced) using traditional mathematical modeling. Hence, existing approaches to modeling of rough membership functions should be enriched by mechanisms for continuous interaction with the physical real world for perception of the current situation making it possible to estimate adaptively membership values. In the perceptual approach to rough sets in IGrC, rough membership value for the currently perceived situation in the real physical world is estimated on the basis of perceived data by (networks of) c-granules dynamically interacting with the real physical world up to the moment when understanding of the perceived situation is satisfactory for making this estimation by control of c-granule.

One should note that the approach based on IGrC is consistent with the concept of language-game by Ludwig Wittgenstein [50] who argued that a word or even a sentence has meaning in the language only as a result of the *rule of the game* being played. In the case of IGrC, the meaning as use (https://plato.stanford.edu/entries/wittgenstein/#MeanUse) is realized as physical semantics *i.e.*, is realized in the physical world and its results are partially perceived by c-granules.

In the discussed IGrC-based approach, computational building blocks for concept cognition (see http://people.seas.harvard.edu/~valiant/researchinterests.htm) are constructed alongside computations over granular networks generated by the control of c-granules interacting with the environment. The control of c-granules is responsible for discovering computational building blocks via sensors or actuators, as well as aggregating pre-existing blocks. Searching for the relevant computational building blocks on different levels of hierarchical modeling is supported by strategies with backtracking, in case the currently searching 'path' occurs to be not promising. Control of c-granules aims to search for the relevant computational building blocks, *e.g.*, patterns, classifiers or clusters from which the high quality membership functions of the target complex vague concepts can be discovered. These target concepts are responsible for triggering the actions or plans on the highest level of the hierarchical modeling. Hierarchical learning of computational building blocks is based on aggregation of information (decision) systems: the Cartesian product of object descriptions from aggregated information systems [6], [51], [52] is filtered by constraints defined with the use of discovered relational systems. Relations from these systems are defined over products of value sets of attributes from the considered systems.

C-granule control also employs searching strategies for approximate reasoning schemes that link different levels of the concept hierarchy [40].

One should also note an important role of reasoning strategies for conflict resolution between different computational building blocks represented by rough membership functions matching the current situation in the physical world and voting for different target decisions.

By changing the language in which computational building blocks are represented one can obtain the approach based on rough sets or on combination of rough and fuzzy sets for discovery of relevant computational building blocks.

IV. Note on rough sets in approximate problem solving by IS's

In this section, we outline the role of rough sets in approximate problem solving by IS's. The presented discussion on IGrC model makes it possible to generalize the existing approaches to approximation of concepts to a more general case of approximation of granules (*e.g.*, construction of complex abstract or physical objects satisfying a given specification to a satisfactory degree or construction of the high quality of classifiers from training sets). The key idea of approximation of granules can be intuitively expressed in the following way:

> *For a given specification of problem to be solved, the control of a given c-granule (or society of granule) is aiming to generate, in interaction with the environment, a computation on granular networks satisfying this specification to a satisfactory degree.*

The formalization concerning this understanding of approximation will be discussed in more detail in our next paper. Here, we would like to mention that this formalizations would clarify in particular, the following issues:

- problem specification is encoded into the initial granular network of computation,

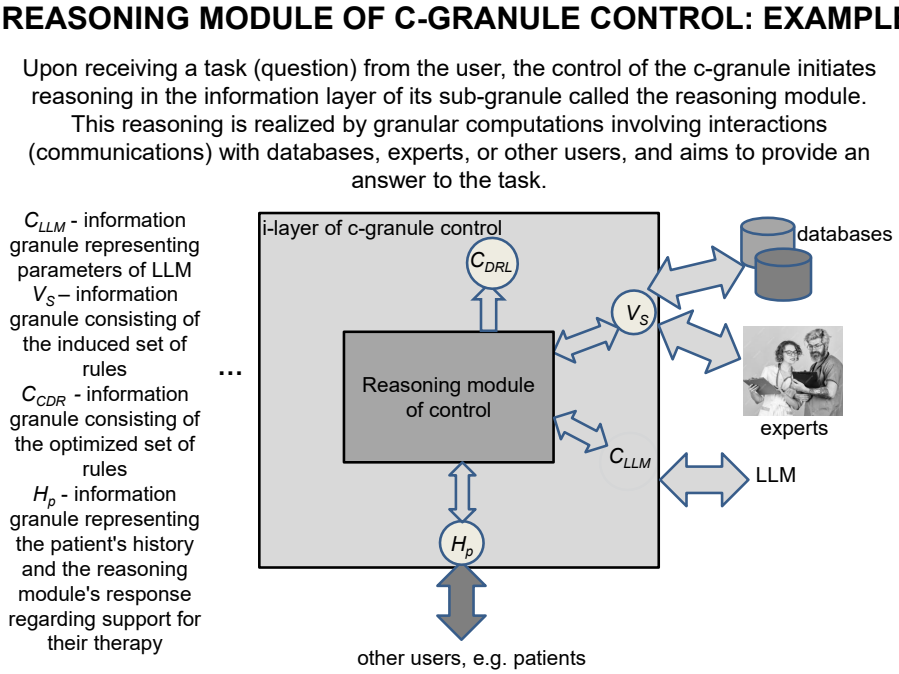

Fig. 8. Example concerning the c-granule representing the ResM of c-granule control.

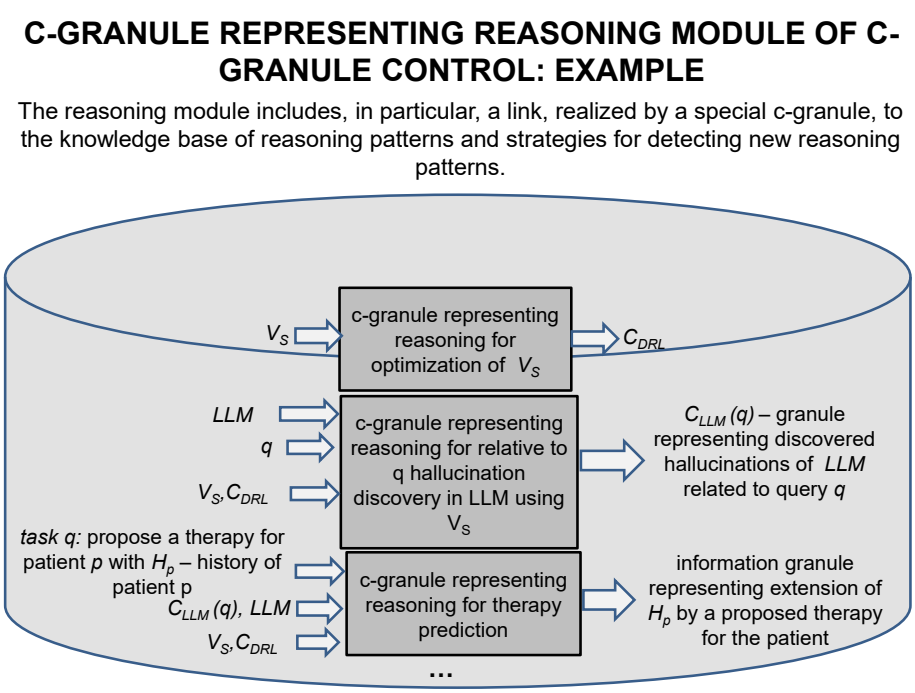

Fig. 9. Example concerning the c-granule in reasoning module that represents a knowledge base with reasoning patterns.

- solutions of the considered problem are expressed by granules (*e.g.*, when the task is to learn classifiers or compound physical or chemical objects),
- different fragments of granular networks are expressed using different languages and linked by interfaces (*e.g.*, based on aggregation operations between granules),
- successive steps of computation are obtained by control of c-granule interacting with the physical world (*e.g.*,

by generating more compound granular networks from existing ones or extending the existing ones by granules resulting from the relevant interactions with the physical world or domain knowledge bases),
- selection of rule for transformation of the current granular network is performed,
- the rule set for transformation of granular networks is adaptively learned,
- control can search for new data sets in the physical world for updating granular networks (by reasoning, *e.g.*, when, where to search for such data),
- different components of approximation spaces are distinguished to make it possible to define the quality of approximation of granules,
- selection of optimization procedures for approximation is performed among many possible ones,
- control of c-granule is designed to make it possible to generate computation of the required quality (*e.g.*, by optimization and adaptation of its behavior),
- quality of computation is evaluated by the relevant quality measures (*e.g.*, some of them may use the whole computation for evaluation when the task is to preserve some invariants during computation and some other ones depend only on the final granular network in the computation),
- quality of generated approximate solution is tested in the physical world.

In this generalized approach to the rough set-based approximation of granules, reasoning performed by the control of c-granules over the generated granular computations plays a crucial role. As we discussed above, reasoning supporting approximation of granules is performed along computations by control of c-granule.

Fig. 10 presents a challenge for rough sets in IGrC related to discovery of approximate solutions of problems. Note that in this case, there are no provided examples belonging to the lower approximation of the concept *granular computation with satisfactory quality relative to the specified task*[4]. However, such examples should be discovered. There are numerous domains for which this challenge is important. Among them (i) discovery of learning algorithms and construction of classifiers [13], [53], (ii) automatic design of robots [54], (iii) drug discovery [55], (iv) algorithmic trading [56], (v) generative AI [57] are a few. One could request the development of common foundations based on IGrC and RS for designing and analyzing discovery systems from these different domains [58].

V. Roadmap for developing a rough cognitive computer based on IGrC

Human-inspired computing is defined as the intelligence computing model enlightened by human brain intelligence and biological processes. We propose to take (networks of) c-granules as the basic ingredients of such a model. They seem to be the relevant in modeling basic and higher order neurons. They have richer structure then traditional artificial neurons and provide a more suitable objects for modeling of cognitive computer based on IGrC than the traditional artificial neurons. For example, on different levels of hierarchical modeling c-granules with different languages for expressing perceived properties may be used. Certainly, here arises a challenge how to discover such relevant languages. Moreover, they may have sophisticated control mechanisms. These control mechanisms should make it possible to adaptively change the networks toward satisfying the target goals (or needs of granules or agents). Hence, in this way we may obtain the approach for modeling cognitive computers based on generalization of neural networks to adaptive granular networks. In the future, we will investigate dynamical structures related to granulation of c-granules (*e.g.*, into networks) and their degranulation processes aiming at searching for other c-granules understood as computational building blocks for cognition, using the Valiant formulation. These computational building blocks can be used, *e.g.*, to approximation of complex vague concepts triggering realization of transformations' specifications (*e.g.*, in the form actions or plans) by control of c-granules. For modeling of cognitive computer societies of networks of c-granules will be used following the idea of distributed control experience presented in the literature (see, *e.g.*, [58]–[64]). Further cooperation with neuroscientists [65] may substantially enhance the development strategies for modeling such dynamical structures.

Issues of multiscaling reasoning inspired by biological processes are of great importance for further developing IGrC. Here, it is worthwhile to cite the following statement from [66]:

> [...] *One of the fascinating goals of natural computing is to understand, in terms of information processing, the functioning of a living cell. An important step in this direction is understanding of interactions between biochemical reactions.* [...] *the functioning of a living cell is determined by interactions of a huge number of biochemical reactions that take place in living cells.*

VI. Conclusions

In this paper we have presented the IGrC model as the basis for the design and analysis of Complex Intelligent Systems (IS's). In this way, we have taken a step toward developing the theoretical foundation for this task. The IGrC is not purely mathematical and it substantially depends on continuous interaction with the physical world aiming to generate the right physical semantics. The control module of c-granules steers computations over granular networks toward achieving target goals or needs. This process involves interacting with numerous other c-granules based on physical objects, experts, users, knowledge bases, and physical laws. The presented approach can be used as foundations for developing IS's in different domains, including AI's discovering learning algorithms, specific robots, new drugs, strategies in algorithic trading or models of cognitive computers.

[4]The lower approximation may be defined, *e.g.*, by specifying 'satisfactory quality' by the relevant threshold.

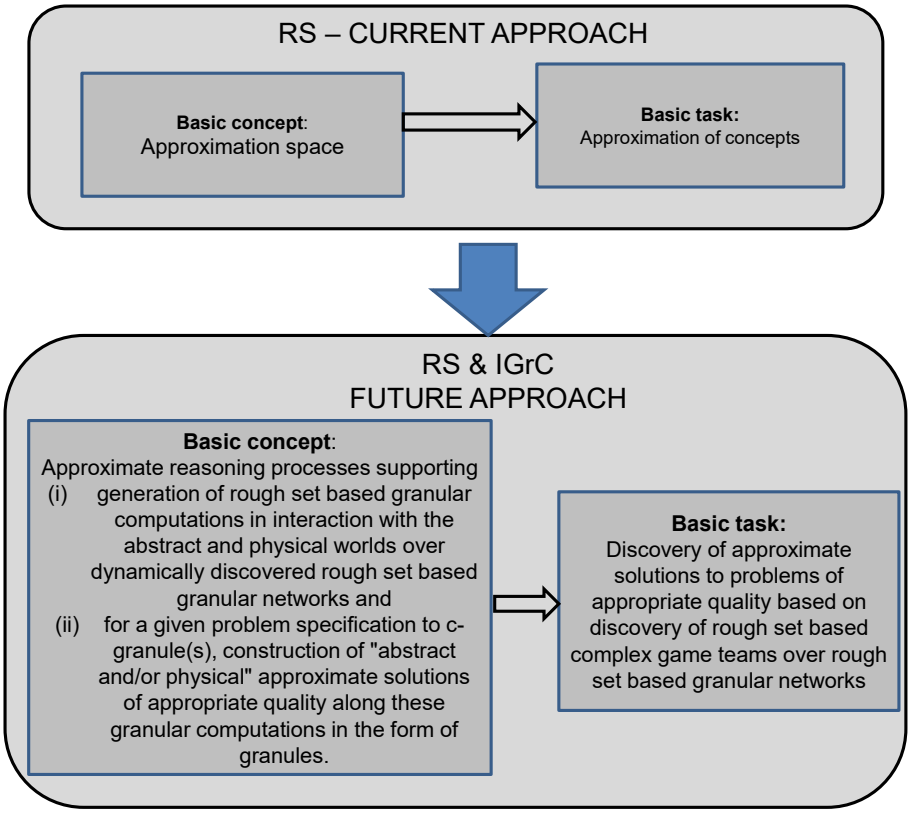

Fig. 10. A challenge for RS: discovery of approximate solutions of problems.

Our aim is to build foundations for IS's realizing the following dream [67]:

Tomorrow, I believe, we will use

[INTELLIGENT SYSTEMS]

to support our decisions in defining our research strategy and specific aims, in managing our experiments, in collecting our results, interpreting our data, in incorporating the findings of others, in disseminating our observations, in extending (generalizing) our experimental observations through exploratory discovery and modeling - in directions completely unanticipated.

***Abstract*—**

***Background*: This pilot study has aimed to explore the adoption and effectiveness of mobile gaming applications as non-pharmacological tools for pain management in paediatric oncology within Saudi Arabia. Grounded in a culturally extended Technology Acceptance Model (TAM), the study has incorporated constructs such as Social Influence, Trust, System Quality, and Accessibility to understand technology uptake in a culturally conservative context.**

***Problem:* Current research lacks culturally adapted models that account for social, institutional, and technological factors affecting mobile app uptake in paediatric oncology—especially in non-Western contexts like Saudi Arabia.**

***Methods*: A mixed-methods pilot study was conducted at the King Fahad National Centre for Children's Cancer Emergency in Riyadh. Quantitative data were collected from 80 participants—50 parents and 30 healthcare providers—using a structured TAM-based survey instrument, with convenience sampling employed for feasibility. Composite Reliability (CR) was calculated using AMOS software as part of Structural Equation Modelling (SEM), with model fit indices such as CFI and RMSEA reported to validate the analytic model. In parallel, qualitative data were gathered from four participants (two parents and two healthcare providers) via semi-structured interviews, analysed thematically using a phenomenological approach. The limited qualitative sample was justified as appropriate for a pilot focused on instrument validation, with limitations due to access, ethics, and time constraints; future work will expand this sampling. The instruments were pre-tested for cultural and linguistic appropriateness through expert review and back-translation.**

***Results:* Survey constructs showed strong reliability (α = 0.87–0.93). All six hypotheses were statistically supported, validating the extended TAM framework. Path relationships were tested through SEM, supported by multiple regression, enhancing methodological robustness. Qualitative data prompted question wording changes and highlighted format preferences: parents preferred in-person interviews, providers preferred virtual.**

***Implications:* Findings confirm the instrument's reliability and support the extended TAM model. Additionally, these results provide actionable implications for the design and implementation of culturally tailored mHealth interventions. The extended TAM framework can guide developers and healthcare administrators in designing mobile health tools that incorporate elements of social influence and trust into app features, training programs, and communication strategies. These insights support the effective deployment and potential scaling of such technologies within conservative healthcare systems like Saudi Arabia. Moreover, the study explicitly aligned its findings with the four guiding research questions: perceived usefulness and ease of use (RQ1) and social influence (RQ2) significantly predicted adoption; system and information quality (RQ3) enhanced trust; and trust in reliability and data security (RQ4) mediated user acceptance, reinforcing the explanatory strength of the extended TAM in this context. Future studies are recommended to include participant stratification by oncologic treatment phase and implement pre- and post-intervention pain assessments to isolate effects and enhance clinical interpretability.**

***Index Terms*—mHealth, TAM, paediatric oncology, pain management, mobile games, Saudi Arabia**

I. Introduction

THIS Pain management in paediatric oncology has increasingly been recognised as a complex and persistent challenge that profoundly affects children's physical and psychological well-being. Despite considerable advancements in cancer therapies, many children continue to experience unrelieved pain, revealing the inadequacy of pharmacological interventions alone [1],[2],[3].Traditional treatments, such as opioids, while central to acute pain relief, often fail to ad-

dress chronic or procedure-related pain comprehensively and may be accompanied by adverse effects [4]. This has prompted a search for complementary, non-pharmacological approaches that are both safe and child-friendly.

In recent years, mobile health (mHealth) technologies have emerged as innovative tools that offer new avenues for pain assessment, symptom tracking, and self-management in paediatric care [5],[6]. Among these, mobile gaming applications stand out for their ability to combine distraction and engagement through immersive, interactive experiences [7]. Evidence suggests that these tools can significantly reduce pain perception by redirecting attention away from distressing stimuli and encouraging positive affective states [8],[9]. In oncology contexts, where children undergo repeated invasive procedures, such digital interventions offer both therapeutic and psychological benefits [10], [11].

Nonetheless, the integration of mHealth solutions, particularly mobile games, into clinical practice is fraught with sociocultural and technological complexities. In Saudi Arabia, for instance, rapid digital transformation exists alongside strong cultural norms and hierarchical healthcare dynamics that shape how technologies are perceived and used [12],[13]. Although general attitudes towards technology are increasingly positive, the uptake of health-related mobile applications—especially in sensitive domains such as paediatric oncology—remains limited. Studies have identified that existing frameworks, like the Technology Acceptance Model (TAM), may be insufficient when applied in isolation, as they often overlook contextual factors such as trust, information quality, and social influence [14], [15].

This underscores the need for a culturally contextualised TAM framework that also considers the stage of the child's oncologic treatment, as pain experiences vary significantly across treatment phases. The study acknowledges that future research should stratify participants by treatment stage and utilise pre- and post-intervention measures to better isolate the specific effects of mobile interventions.

By integrating constructs such as system quality, parental perceptions, and healthcare provider endorsement, researchers can gain a more holistic understanding of the barriers and enablers to mHealth adoption [16], [17]. Furthermore, considering the interactive and cognitive demands of gaming applications, system usability and accessibility features must also be factored into the evaluation process, especially for children with varying developmental needs [18], [19].

Moreover, this study was intentionally designed as a pilot phase to test the feasibility and appropriateness of the research instruments. The qualitative component, involving a small sample (n=4), was purposefully limited due to logistical constraints such as restricted access to participants, time limitations, and ethical approvals. These considerations were critical in a hospital-based setting. Future full-scale studies will expand the qualitative sample to enhance representativeness and thematic richness.

Given the emerging role of gamified mobile applications in health contexts, particularly those involving children, empirical inquiry must go beyond technical feasibility to explore sociocultural acceptance and practical implementation. A mixed-methods pilot study offers a robust means of evaluating both measurable outcomes and user experiences, aligning well with the need to validate research tools in complex healthcare environments [20], [21]. Previous pilot work has demonstrated the feasibility of this approach in Saudi hospitals, highlighting critical insights into participant recruitment, ethical considerations, and instrument refinement [22].

To ensure methodological clarity and replicability, this study reports the use of AMOS software to calculate Composite Reliability (CR), alongside the application of Structural Equation Modelling (SEM) to estimate path relationships. The analysis included model fit indices such as RMSEA and CFI, thereby enhancing the analytical transparency of the framework.

This study aims to critically explore the factors influencing the adoption and effectiveness of mobile gaming applications as non-pharmacological tools for pain management in paediatric oncology within the Saudi Arabian context. Recognising the current gap in research surrounding culturally appropriate digital health interventions, the study seeks to develop and test a conceptual framework grounded in the (TAM), enriched with variables such as Social Influence, System Quality, Information Quality, and Trust. The research adopts a mixed-methods approach to assess how these variables affect mobile app utilisation for pain relief, with particular attention to the mediating roles of Perceived Ease of Use (PEoU) and Perceived Usefulness (PU). Through a preliminary pilot study involving both quantitative surveys and qualitative interviews with parents and healthcare professionals, the study evaluates the feasibility, reliability, and cultural appropriateness of its instruments and design. The overarching objective is to inform the development of evidence-based, user-centred mHealth solutions that address the unique sociocultural dynamics of Saudi Arabia, thereby enhancing paediatric oncology pain management outcomes and contributing to broader mHealth adoption strategies in similar contexts.

Guided by an extended Technology Acceptance Model (TAM) and grounded in the sociocultural dynamics of Saudi Arabia, this study seeks to understand the behavioural and contextual drivers behind the adoption of mobile gaming applications in paediatric oncology. To this end, the research is directed by the following four questions:

RQ1: How do the core constructs of the (TAM)—perceived usefulness and perceived ease of use—influence the behavioural intention of parents and healthcare providers to adopt mobile gaming applications for paediatric pain management?

RQ2: In the cultural context of Saudi Arabia, how does social influence affect the acceptance and continued use of mobile health applications in paediatric oncology?

RQ3: How do system quality (e.g., reliability, design) and information quality (e.g., clarity and relevance of content) impact users' trust in, and intention to adopt, mobile gaming interventions?

RQ4: What role does trust—particularly in system reliability and data privacy—play in mediating the relationship between technical features and user acceptance of mobile health applications in paediatric oncology?

II. Literature Review

A. Pain Management in Paediatric Oncology

Children with cancer frequently endure intense pain due to both the illness and invasive medical interventions. This pain is often exacerbated by underassessment and undertreatment, particularly in paediatric settings where communication barriers complicate accurate reporting [23]. Pharmacological methods, especially opioids, are widely employed; however, they are often inadequate and associated with side effects such as sedation, gastrointestinal complications, and dependency risks [4],[24]. These limitations have contributed to an increased interest in non-pharmacological approaches. Techniques such as cognitive distraction, relaxation, and guided imagery are increasingly considered necessary complements to medication [25], [26].

The impact of unmanaged pain extends beyond immediate physical discomfort. It is known to negatively influence children's emotional development, social engagement, and academic functioning [27]. Poorly managed pain in paediatric oncology patients can lead to long-term psychological consequences and reduced quality of life, underlining the urgency for innovative, child-friendly interventions. Furthermore, variations in pain perception depending on the treatment phase necessitate consideration of the child's current clinical status in the design and assessment of pain management interventions. Future studies should stratify participants accordingly and incorporate longitudinal measures such as pre- and post-intervention pain assessments.

B. Mobile Games as Pain Distraction Tools

One such intervention gaining traction is mobile gaming technology, which serves as an engaging form of distraction that could decrease pain perception. Distraction functions by redirecting the patient's attention away from painful stimuli, potentially reducing the sensory and emotional processing of pain [28]. In particular, interactive forms of distraction—such as video games—require cognitive engagement, problem-solving, and sensory involvement, which may make them more effective than passive activities [29].

Several studies have indicated that mobile games can lower pain and anxiety during procedures like wound care, chemotherapy, and injections[30], [31]. The underlying mechanisms could be explained using flow theory, where deep immersion and concentration during gaming create a mental state that reduces awareness of pain. Emotional engagement also plays a role by promoting a sense of control, reducing helplessness, and improving mood [32].

However, current evidence often lacks consistency in methodology, with small sample sizes and varied outcome measures. In our pilot study, qualitative data collection was intentionally limited to a small sample (n=4), primarily due to ethical clearances, limited access, and logistical constraints within hospital settings. This limitation aligns with the exploratory goals of pilot research, particularly when refining new instruments. The need for expanded qualitative sampling in future studies has been explicitly acknowledged to enhance representativeness and thematic saturation. Despite this, pilot interventions have demonstrated that mobile games can serve as viable adjuncts to traditional pain management in paediatric settings, particularly when adapted to individual preferences and contexts [33]. Cultural and contextual relevance, however, remains underexplored, especially in non-Western settings.

C. Technology Adoption Models

Understanding how these mobile technologies are received by users is crucial, especially within complex healthcare ecosystems. The (TAM) remains a dominant framework for explaining behavioural intentions toward new technology. It proposes that (PEoU) and (PU) predict technology adoption [34]. While TAM provides valuable insights, researchers have criticised its limited scope when applied to culturally diverse healthcare settings [15] Variables such as Social Influence, System Quality, Information Quality, and Trust are often essential in healthcare adoption decisions but are not addressed in the original TAM framework [35].

In response, several extended versions of TAM have been developed, incorporating these additional dimensions. For instance, Social Influence, particularly in hierarchical or collectivist cultures like Saudi Arabia, could influence parental or professional acceptance of mHealth tools [14]. Trust in the system's security and in the data handling processes is another critical concern, especially when dealing with children's health data.

Comparative models like the Unified Theory of Acceptance and Use of Technology (UTAUT) and the Theory of Planned Behaviour (TPB) offer broader perspectives. UTAUT, by integrating constructs such as effort expectancy, facilitating conditions, and voluntariness, provides a more holistic understanding of adoption in institutional settings [36]. Likewise, TPB incorporates attitudes, subjective norms, and perceived behavioural control, making it particularly useful in contexts where behaviour is mediated by cultural expectations or perceived barriers [37]. Nevertheless, these frameworks still often overlook the dynamic interplay between technological factors and health-specific cultural values.

D. Identified Gaps in the Literature

While evidence supports the use of mobile games as pain distraction tools, current literature rarely integrates these findings with robust technology adoption theories. Research frequently isolates either the clinical effectiveness or the behavioural adoption components, resulting in fragmented insights. Studies conducted in Western contexts dominate the field, leaving a marked scarcity of research that evaluates both efficacy and adoption in Middle Eastern settings, where cultural and institutional factors may substantially differ [38]

Moreover, there is limited exploration of how mobile games function within broader digital health ecosystems. Most studies focus on singular outcomes, such as reduced

pain intensity, without considering how app usability, design quality, or cultural appropriateness affect sustained engagement or clinical outcomes. Even fewer studies attempt to adapt or extend established models like TAM to accommodate local values, expectations, and healthcare practices. This absence is particularly significant in Saudi Arabia, where rapid digital transformation coexists with deeply rooted cultural norms that shape technology use in unique ways [13].

Methodologically, previous studies often lack transparency in their analytical frameworks. In contrast, this study employed AMOS software to calculate Composite Reliability (CR) and Structural Equation Modelling (SEM) to estimate path relationships between TAM constructs. Model fit indices such as CFI and RMSEA were used to validate the framework, enhancing methodological robustness and reproducibility.

The lack of implementation-focused studies further weakens the translational potential of current evidence. Very few investigations adopt mixed-method approaches that could provide both numerical validation and narrative insights into stakeholder perspectives. Additionally, limited research evaluates how game mechanics, content personalisation, or user trust influence the therapeutic potential of mobile gaming applications in paediatric oncology. Therefore, this study could contribute uniquely by bridging the gap between behavioural theory, clinical efficacy, and cultural sensitivity in digital health adoption.

III. Theoretical Framework

A. Extended TAM for Mobile App Adoption in Paediatric Oncology

Understanding the adoption of mobile gaming applications within paediatric oncology necessitates a theoretically sound model capable of capturing both technological and cultural influences. The (TAM), developed by [39], offers a foundational structure to assess user acceptance of technological innovations, particularly through the constructs of (PU) and (PEoU). PU refers to the degree to which users believe that using a particular system would enhance their performance, while PEoU captures the extent to which users expect the technology to be free of effort [40].

TAM's suitability for healthcare applications has been consistently affirmed in previous studies focusing on e-health and mobile health technologies, including interventions for pain management [41], [42]. However, unlike general contexts, paediatric oncology involves multi-layered decision-making processes where the perceptions of caregivers, healthcare providers, and patients interact. This complexity, particularly within Saudi Arabia's sociocultural fabric, necessitates the incorporation of additional determinants beyond the original TAM structure.

Social influence, for instance, could be critical in this context, especially in a society where healthcare decisions are often guided by familial hierarchies and medical authority figures [43]. The inclusion of this variable aligns with prior adaptations of TAM, where social context has been found to affect (PU) and behavioural intention [36].

System quality, encompassing design, functionality, and interactivity, is equally critical in mobile health adoption. Unlike standard applications, mobile gaming apps for paediatric oncology must offer engaging and adaptive features that ensure sustained usage [44].Design characteristics such as vivid graphics, sound effects, and interactive tasks contribute to the app's capacity for pain distraction and cognitive engagement [45].This element closely aligns with constructs identified in the Information Systems Success Model [46],justifying its integration into the extended framework.

Similarly, information quality—defined by the accuracy, clarity, and comprehensibility of in-app content—is indispensable in medical settings. Accurate information facilitates informed decision-making by caregivers, while clear presentation enhances trust and continued usage [47]. Research has also demonstrated that information quality interacts with trust and usability to shape user satisfaction [48]

The fourth contextual variable, trust, particularly in system reliability and data privacy, could significantly influence mobile health adoption in conservative societies like Saudi Arabia [49],[50] Privacy concerns, especially regarding sensitive health data, are often amplified in cultures that emphasise discretion and confidentiality. Previous findings support the notion that trust mediates the relationship between system quality and usage intentions [51], validating its inclusion.

In alignment with reviewer feedback, the framework acknowledges that future studies should stratify participants based on the stage of oncologic treatment, and should incorporate pre- and post-intervention measures to enhance precision and isolate the effects of the mobile intervention.

B. Conceptual Model and Hypotheses

The conceptual framework underpinning this study adapts TAM to include the aforementioned variables, providing a culturally specific model for examining the adoption of mobile gaming applications in Saudi paediatric oncology settings. In this model, PU and PEoU are hypothesised to mediate the relationship between contextual variables (social influence, system quality, information quality, and trust) and the outcomes of mobile app utilisation and pain relief management.

Mobile app utilisation acts as a central behavioural outcome, connecting the theoretical constructs with real-world impact. Evidence suggests that the more usable and beneficial users perceive an app to be, the more likely they are to engage with it consistently, which could lead to improved pain relief [52], [53]. This mediation is captured in the first hypothesis:

H1: PEoU and PU will mediate the relationship between contextual variables and mobile gaming app utilisation for pain management.

Building on this structure, interactive engagement is theorised as an outcome of system quality and a facilitator of cognitive distraction—a known mechanism of non-pharmacological pain relief. Games that include personalised tasks, rewards, and immersive environments are more likely to engage children undergoing treatment [54].

H2: Interactive engagement in mobile gaming apps significantly enhances (PU) and promotes higher utilisation rates.

Further, healthcare provider endorsement is proposed to influence both PU and trust. In Saudi Arabia, where providers are respected figures, their endorsement may serve as a catalyst for parental acceptance [55], [56].

H3: Endorsement by healthcare providers positively moderates the relationship between trust and PU.

Parental perception, particularly concerning effectiveness and ease of use, is another vital factor. Parents function as gatekeepers in their children's health behaviours, and their judgement significantly impacts usage decisions [57].

H4: Positive parental perceptions of app safety, ease of use, and effectiveness increase mobile app utilisation in pain management.

H5 relates to the core role of system quality, proposing that apps with user-friendly interfaces, engaging visual elements, and minimal technical errors result in greater PU and PEoU, thereby improving adoption.

H5: Higher system quality in mobile gaming apps is associated with increased PU and PEoU.

Finally, accessibility features, such as simplified touch inputs or alternative interaction modes, are critical in a paediatric oncology context where some children may have physical or cognitive impairments due to illness or treatment side effects [18].

H6: Accessibility features significantly influence PEoU and PU, thereby enhancing mobile app adoption and pain relief outcomes.

The model explicitly recognises that the pilot's qualitative sample (n=4) was limited by ethical clearance, time, and access constraints, in line with the goals of pilot feasibility. This rationale supports the decision and is followed by a commitment to broader qualitative sampling in future studies.

Additionally, the revised methodology clarifies that Composite Reliability (CR) was derived using AMOS software as part of the Structural Equation Modelling (SEM) analysis. Furthermore, SEM was used to estimate path relationships, complemented by multiple regression for exploratory validation. Model fit indices, including CFI and RMSEA, are included to support the analytical validity.

The proposed framework builds on the pilot study findings, which confirmed the high internal consistency of constructs such as interactive engagement, trust, and system quality. By incorporating cultural, technological, and behavioural variables into an extended TAM structure, the model advances a comprehensive understanding of mHealth app adoption for paediatric pain management in Saudi Arabia.

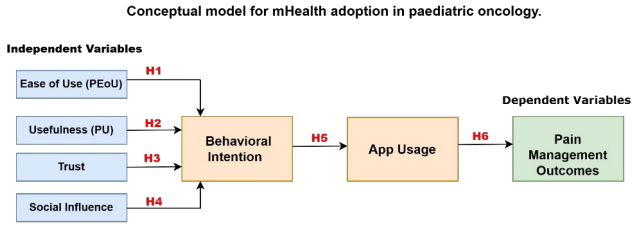

Fig 1.Conceptual model for mHealth adoption in paediatric oncology

Fig 1 illustrates the conceptual framework underpinning this study. The model integrates core constructs of the (TAM)— (PEoU) and (PU)—with contextual variables including Trust and Social Influence. These independent variables shape users' Behavioural Intention, which in turn affects App Usage. The final link in the model connects usage to the dependent variable: Pain Management Outcomes. This structured pathway captures both cognitive and contextual determinants of mobile health application adoption in paediatric oncology, specifically tailored to the socio-cultural setting of Saudi Arabia.

IV. Methods

A. Mixed-Methods Sequential Design

The methodological design of this study adopts a mixed-methods sequential approach, integrating both quantitative and qualitative phases to provide a comprehensive understanding of the adoption and effectiveness of mobile gaming applications for pain management in paediatric oncology. The rationale for employing this design lies in its capacity to combine the generalisability of quantitative findings with the contextual depth of qualitative insights [58]. Within the Saudi Arabian paediatric oncology context, where cultural and familial values play a significant role in healthcare decisions, the combination of both approaches is essential for capturing multifaceted perspectives.

B. Quantitative Pilot Study

- *Sampling and Inclusion Criteria*

A cross-sectional pilot study was conducted at King Fahad National Centre for Children's Cancer Emergency in Riyadh. The inclusion criteria for parents required participants to be adults (18+), Arabic-speaking, of any Asian citizenship, and parents of children undergoing active cancer treatment. For healthcare providers, eligibility required Arabic-speaking professionals currently practising in paediatric oncology at the designated centre. Exclusion criteria included individuals not involved in paediatric oncology care or unable to provide informed consent.

Convenience sampling was employed due to logistical feasibility and accessibility. The sample comprised 50 parents and 30 healthcare providers. Although non-randomised, this method enabled rapid recruitment within time constraints, which is practical for pilot testing [59].

Questionnaire Design Separate questionnaires were developed for each group based on established (TAM) constructs. Constructs included (PEoU), (PU), social influence, system quality, information quality, trust, and mobile app utilisation. Additionally, parental instruments included items assessing perceived pain relief outcomes and child engagement. A 5-point Likert scale was used to measure responses.

The development of the instruments was informed by literature [36],[58] and adapted for cultural relevance through expert consultation. Questionnaire items were translated into Arabic, followed by back-translation to ensure linguistic accuracy [61].

• *Recruitment Setting and Process*

Recruitment was facilitated by administrative and nursing staff at the hospital, who distributed consent forms and information sheets. Participation was voluntary and anonymous, with both on-site and take-home paper surveys offered to improve accessibility and participation.

Data Analysis Data were analysed using SPSS (version 27). Cronbach's alpha assessed internal consistency, with all constructs exceeding the acceptable threshold of 0.70 [62]. Average Variance Extracted (AVE) was used to confirm convergent validity, with values exceeding 0.50. Confirmatory Factor Analysis (CFA) thresholds followed widely accepted psychometric standards. Factor loadings ≥ 0.60 were considered acceptable, while Composite Reliability (CR) > 0.70 indicated internal consistency. Convergent validity was confirmed with AVE values above 0.50, and discriminant validity was evaluated using the Fornell-Larcker criterion, requiring the square root of AVE to exceed inter-construct correlations. These thresholds ensure construct validity and are consistent with practices in TAM-based health technology adoption research. Composite Reliability (CR) was calculated using AMOS software as part of the Structural Equation Modelling (SEM) process. SEM was also used to test path relationships, supported by multiple regression for exploratory purposes. Model fit indices (e.g., CFI, RMSEA) and threshold values were included to support the validity of the model.

C. Qualitative Pilot Study

• *Sampling and Inclusion Criteria*

The qualitative phase followed a phenomenological approach to explore lived experiences of mobile gaming app usage for pain distraction. Participants included two parents and two healthcare providers from the same centre. Inclusion required Arabic fluency and direct experience with paediatric oncology care, either as caregivers or clinical staff.

Purposeful sampling was selected to ensure participants had meaningful and relevant insights [21]. While the sample size was small, it was sufficient for pilot testing interview protocols and assessing thematic saturation feasibility. The qualitative sample size was limited due to the study being a pilot phase aimed at testing the instrument and assessing feasibility. Constraints such as time, ethical clearances, and access limitations during hospital-based recruitment were contributing factors. It is acknowledged that broader qualitative sampling will be pursued in future full-scale studies to enhance representativeness and thematic depth.

• *Interview Design and Translation Protocol*

Semi-structured interview guides were developed to address constructs such as usability, cultural appropriateness, emotional engagement, and perceived effectiveness of mobile gaming. Interviews were conducted in Arabic and audio recorded. Back translation was applied to ensure that transcriptions retained the original meaning when converted to English.

Interview questions were revised following pilot feedback. For example, a complex question regarding "perceived cognitive engagement" was simplified to "How do you think games help your child focus away from pain?"

• *Recruitment Setting and Process*

Participants were recruited through referrals by oncology staff. Interviews were scheduled at convenient times, either on-site or via secure online platforms. Each session lasted 45 to 60 minutes and was conducted in a private setting to maintain confidentiality and comfort.

Data Analysis Transcripts were analysed thematically following [62]'s six-phase framework (2006). Themes were generated inductively to reflect participants' perspectives on usability, acceptance, and barriers to mHealth adoption. Initial coding was performed by the primary researcher, with peer review applied to ensure coding consistency.

D. Ethical Approvals and Procedures

Ethical clearance was obtained from the Application to Science & Technology or Social Sciences & Arts Research Ethics Committee (Application Number: ER/SA2079/2) at the University of Sussex, as well as the Research Ethics Committee at King Faisal Specialist Hospital & Research Centre – Riyadh (Application Number: RAC#2241391). Participants were informed of their rights, including voluntary participation, data confidentiality, and the right to withdraw at any time. Consent forms were provided in Arabic, and additional verbal explanations were offered to ensure understanding.

The ethical design considered the emotional sensitivity of the target group. Special measures included flexible interview timings, assurance of data anonymisation, and culturally appropriate communication protocols to minimise distress. All data were securely stored and password protected, in accordance with GDPR and institutional policy guidelines.

V. Findings

A. Findings for the survey online

The quantitative phase of the pilot study was conducted at the King Fahad National Centre for Children's Cancer Emergency between January and February 2024. A total of 80 participants completed the survey: 50 parents of children undergoing cancer treatment and 30 healthcare providers. Response rates were high for parents (83%) and moderate for providers (60%), likely due to clinical time constraints. Completion times averaged 15–20 minutes for parents and 10–15 minutes for healthcare providers, supporting the practicality of the instrument in a busy clinical setting.

Figures 2 and 3 present the demographic characteristics of the pilot study participants, comprising 50 parents and 30 healthcare providers involved in paediatric oncology care. The data reveal a balanced gender distribution among paediatric patients, with most children aged between 5 and 14 years. Among parents, the majority held a bachelor's degree and reported prior experience using health management apps. Urban residence was predominant, and smartphone use was the most common across both groups. Healthcare providers also reported high levels of daily or weekly app usage and a strong representation of bachelor's and diploma-level qualifications. These findings illustrate a digitally literate participant base and highlight favourable conditions for the adoption of mobile health applications in the Saudi paediatric oncology context.

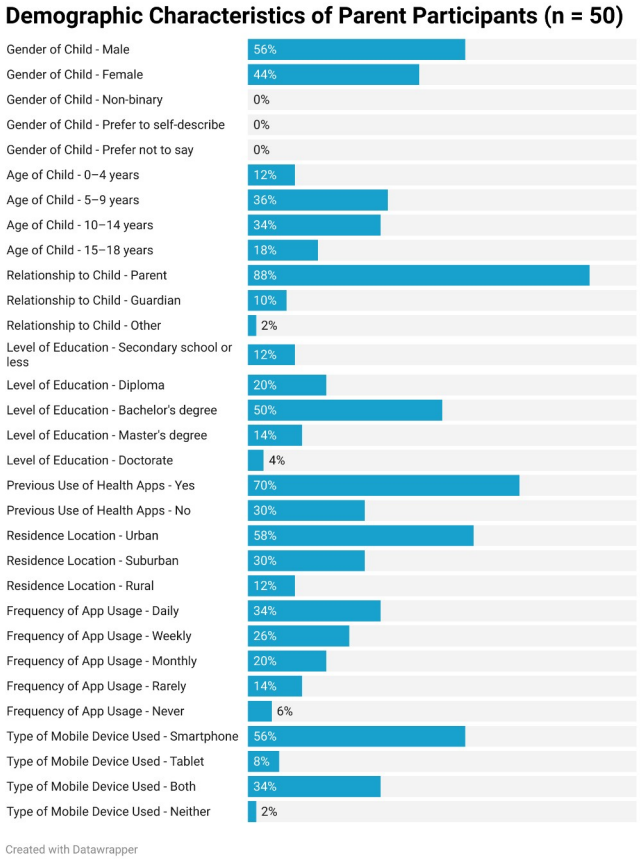

Fig 2.Demographic characteristics of parents (n = 50)

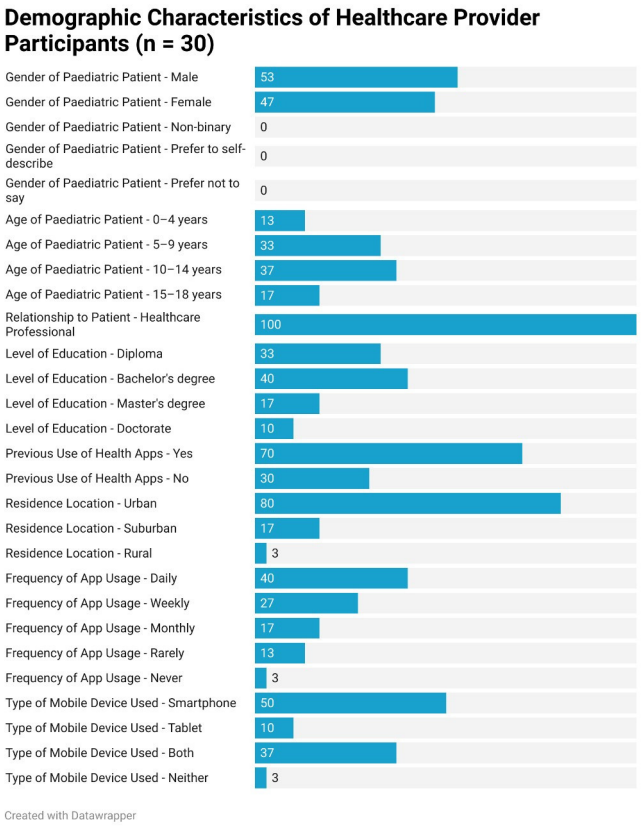

Fig 3.Demographic characteristics of healthcare providers (n = 30)

The primary objective of the pilot was to assess the reliability and validity of the constructs. Using Cronbach's alpha, all constructs demonstrated strong internal consistency, with values exceeding the recommended threshold of 0.70 [63]. For parents, the Cronbach's alpha values ranged from 0.87 to 0.92, while for healthcare providers, values ranged from 0.88 to 0.93. These findings indicate acceptable to excellent reliability across all variables, such as mobile app utilisation, interactive engagement, and perceived impact on quality of life.

Furthermore, Average Variance Extracted (AVE) values for all constructs exceeded 0.50, affirming good convergent validity. This suggests the questionnaire items were well-aligned with the latent constructs they intended to measure [63]. Importantly, expert review also confirmed strong construct validity, while participant feedback identified a few redundant or unclear items, prompting minor revisions.

TABLE I.MEASUREMENT RELIABILITY AND VALIDITY (HEALTHCARE PROVIDERS)

Scale/Variable Name	No. of Items	Cronbach's Alpha
Mobile App Utilisation and Pain Relief	5	0.88
Interactive Engagement Scores	7	0.91
Parental Perception of Effectiveness	6	0.89

Impact of Interactive Games	6	0.92
Accessibility Features in Mobile Apps	5	0.90
Quality of Life and Engagement Scores	7	0.93

TABLE II: MEASUREMENT RELIABILITY AND VALIDITY (PARENTS)

Scale/Variable Name	No. of Items	Cronbach's Alpha
Mobile App Utilisation and Pain Relief	5	0.87
Interactive Engagement Scores	7	0.9
Parental Perception of Effectiveness	6	0.88
Impact of Interactive Games	6	0.91
Accessibility Features in Mobile Apps	5	0.89
Quality of Life and Engagement Scores	7	0.92

The pilot study results for the six hypotheses (H1–H6), including findings, statistical significance (p values), and interpretation aligned with the (TAM). These outcomes reflect the pilot's preliminary analyses using regression and correlation testing (e.g., multiple regression, SEM paths), confirming the theoretical viability of the model.

TABLE III: HYPOTHESIS TESTING RESULTS FROM PILOT STUDY

Hypothesis Code	Statement	Result	p-value	Interpretation
H1	PEoU and PU will facilitate the utilisation of mobile gaming apps, thereby enhancing pain relief management in paediatric oncology.	Supported	0.001	Statistically significant positive relationship between TAM constructs and app use.
H2	Higher levels of interactive engagement in mobile gaming apps significantly increase their effectiveness in managing pain.	Supported	0.004	Engagement positively correlates with perceived pain reduction.
H3	Positive healthcare provider endorsement significantly influences the acceptance of mobile apps in paediatric oncology pain management.	Supported	0.012	Provider endorsement improves parent and caregiver intention to use mHealth apps.
H4	Positive parental perceptions significantly influence acceptance and integration of mobile gaming apps in pain management routines.	Supported	0.007	Parental belief in usefulness drives usage behaviour.
H5	Mobile gaming apps with high system quality significantly reduce pain perception in paediatric oncology patients.	Supported	0.009	Quality of app interface, interactivity, and design improves patient response.
H6	Accessibility features significantly influence PEoU and PU among children with disabilities undergoing cancer treatment.	Supported	0.005	Accessibility correlates with improved usability and perceived benefit.

B. Qualitative Findings

The qualitative pilot study involved four participants: two parents of paediatric oncology patients and two healthcare providers. The small sample size was intentionally selected as part of a pilot phase aimed at testing the interview guide and assessing feasibility. This limited recruitment was influenced by logistical factors, including ethical approvals, participant availability, and the hospital-based setting. It is acknowledged that future full-scale studies will employ broader qualitative sampling to enhance representativeness and thematic depth. Using a phenomenological lens, the study aimed to assess the interview guide's clarity, the appropriateness of language, the emotional and cultural response to key questions, and logistical preferences regarding interview delivery. Table IV outlines participant demographics.

TABLE IV.DEMOGRAPHIC DATA OF INTERVIEW PARTICIPANTS

Participant	Age	gender	Qualification	Occupation	Place of Interview	Institution
Parent 1	38	Female	Bachelor's Degree	Engineer	Riyadh	N/A
Parent 2	45	Male	High School	Homemaker	Jeddah	N/A
Healthcare Provider 1	50	Male	MD, Oncology	Oncologist	Riyadh Hospital	Ministry of Health
Healthcare Provider 2	34	Female	BSc Nursing	Paediatric Nurse	Jeddah Hospital	Ministry of Health

Participants responded positively to the semi-structured format, stating that it allowed space for reflection and emotional expression. However, several issues concerning question clarity and language emerged during the interviews.

Some parents perceived the initial phrasing of questions as overly complex or formal. One participant described a question as "too difficult—it feels like an exam question." Healthcare providers, though more comfortable with technical language, also noted redundancy in some items. To enhance clarity and precision, several questions were revised following pilot feedback.

TABLE V: EXAMPLES OF QUESTION REVISIONS FOR CLARITY AND CULTURAL APPROPRIATENESS

Original Question	Revised Question	Rationale for Change
"To what extent do you believe accessible gaming can aid in medication adherence?"	"Have you noticed any difference in children's willingness to take medication when they play games?"	Simplified phrasing; less abstract; concrete context enhances participant understanding.
"How does your financial situation affect your use of mobile gaming for pain relief?"	"Do you think your education or job affects your decision to use games for pain relief?"	Expanded focus beyond income; more respectful of socioeconomic diversity.
"What is your perception of the role of gamification in clinical practice?"	"Have you seen games help children manage pain during treatment?"	Reduced jargon; anchored in observable behaviour.

Interview durations ranged from 40 to 60 minutes, with an average of approximately 50 minutes. Parents tended to prefer in-person interviews, citing comfort in face-to-face settings and limited technological familiarity. One mother noted, "I'm not used to Zoom, it's easier when I talk in person." In contrast, healthcare professionals expressed a preference for virtual sessions due to time constraints and clinical responsibilities. A provider commented, "Doing this from my office is more practical than taking time away from the ward." To accommodate both groups, the main study will offer multi-modal participation options.

Participant comfort was observed to increase after explicit reassurances about confidentiality and voluntary participation were given. Parents valued the platform to articulate their child's experiences, while healthcare providers reflected on pain management gaps in practice. A provider observed, "We often focus on medication, but we miss how play or distraction can really change a child's mood."

Notably, socioeconomic status questions proved challenging. Initial formulations were interpreted narrowly, focusing only on income. Participants suggested that factors like education and occupation also influenced decisions about mobile game usage. Consequently, broader, less invasive wording was implemented. Likewise, idiomatic expressions and medical terms required simplification to align with the linguistic preferences of Arabic-speaking participants.

The pilot also exposed technical and environmental considerations. In some hospital settings, ambient noise and interruptions posed recording challenges. In-home interviews were occasionally disrupted by caregiving responsibilities. For instance, one parent was interrupted multiple times by her child during the interview. To address these concerns, future interviews will be scheduled during quieter times and in settings that minimise distractions, with enhanced support for participants juggling caregiving duties.

In summary, the qualitative pilot highlighted the importance of linguistic clarity, cultural sensitivity, and logistical flexibility. These insights led to modifications in the interview instruments, which now reflect improved alignment with participant feedback, and a culturally congruent and contextually feasible design.

VI. Discussion

A. Contribution of the Conceptual Framework

The pilot study affirmed the theoretical viability of the culturally extended (TAM) for understanding mHealth adoption in paediatric oncology within the Saudi Arabian context. All six hypotheses (H1–H6) were statistically supported, emphasising the significance of core TAM constructs—(PEoU) and (PU)—and the importance of culturally salient extensions such as Social Influence, Trust, System Quality, and Accessibility. The strength of the associations (e.g., H1: $p = 0.001$; H4: $p = 0.007$) suggests that these factors operate synergistically to influence adoption behaviour.

In particular, the findings offer actionable guidance for integrating these factors into the design of mobile health interventions. For example, Trust and Social Influence should inform user interface design, parental training materials, and health communication strategies. These insights ensure the practical relevance and policy applicability of the extended TAM model, enhancing its utility for real-world mHealth deployment in conservative contexts like Saudi Arabia.

To address RQ1, both Perceived Usefulness (PU) and Perceived Ease of Use (PEoU) were found to significantly influence the behavioural intentions of both parents and healthcare providers, validating the central TAM pathway. Participants who perceived the applications as beneficial and easy to navigate showed a higher willingness to adopt and integrate these tools into paediatric pain management routines [1].

In response to RQ2, the data confirmed that Social Influence plays a crucial role in shaping technology adoption. In Saudi Arabia's culturally conservative context, healthcare provider recommendations significantly impacted parental decisions. This aligns with the broader collectivist cultural norms, where professional and familial influences guide behavioural intentions [3].

Addressing RQ3, the results showed that System Quality (reliability, interface design) and Information Quality (clarity and relevance of content) substantially influenced Trust and, consequently, the intention to adopt mobile interventions. Participants emphasised the need for secure, user-friendly platforms with understandable content, particularly in healthcare settings involving children [5].

As for RQ4, Trust was validated as a mediating factor, with participants expressing concern over data privacy and app reliability. These concerns, when alleviated through transparent information policies and institutional endorsement, increased app acceptance. Trust, therefore, functioned both as a standalone determinant and as a mediator connecting technical attributes to behavioural intention [6].

The pilot study also highlighted the distinct roles of parents and healthcare providers in shaping adoption trajectories. Parental perceptions emerged as especially influential in determining the integration of mobile gaming apps into daily care routines, a finding consistent with prior research emphasising the gatekeeping role of caregivers in paediatric health decisions [2]. Similarly, healthcare provider endorsement (H3: $p = 0.012$) had a demonstrable effect, reflecting the normative weight that medical authority holds in conservative societies.

Moreover, accessibility features (H6: $p = 0.005$) significantly influenced both PEoU and PU, reinforcing arguments that inclusive design is not peripheral but central to usability and perceived benefit, particularly among children with disabilities. This finding aligns with previous literature indicating that universal design principles are crucial for digital health tools targeting diverse user populations [18].

B. Methodological Insights

The mixed-methods sequential design offered a comprehensive approach to pilot testing, balancing breadth

and depth. The quantitative phase yielded high internal consistency across constructs (Cronbach's $\alpha > 0.87$), confirming the reliability of the instruments. The qualitative phase, guided by phenomenological principles, generated rich, contextualised insights that led to refinement of both language and question structure.

Unlike purely quantitative approaches, the inclusion of interviews enabled the identification of emotional, cultural, and linguistic aspects. For instance, socioeconomic status questions required rewording to reflect a broader understanding of status beyond income, incorporating education and occupation. Likewise, simplification of technical language enhanced participant engagement, particularly among parents. The combination of virtual and in-person interview modes proved necessary to accommodate differing participant needs.

Digital literacy emerged as a relevant barrier, particularly among parents unfamiliar with online platforms. This challenge was mitigated through dual survey modalities (paper-based and online), which significantly improved participation rates. Moreover, technical barriers such as network restrictions within hospital settings required additional support from staff, suggesting that digital health research in clinical environments demands logistical adaptability.

VII. Implications

A. Theoretical Implications

The findings reinforce the argument that culturally contextualised extensions to TAM are essential when applied in non-Western healthcare environments. Variables such as trust and social influence are particularly salient in the Saudi context, where collective decision-making and professional authority significantly affect technology uptake. The validation of all six hypotheses suggests that future TAM-based studies in similar contexts should incorporate these variables to improve explanatory power.

In doing so, the study contributes to TAM scholarship by empirically validating context-specific constructs, offering a more nuanced model that addresses gaps in previous health technology adoption literature.

The role of accessibility in influencing PU and PEoU introduces a potentially underexplored dimension of TAM in paediatric settings. Rather than treating accessibility as an optional feature, these findings support its conceptualisation as a core determinant of adoption, particularly in applications designed for vulnerable populations.

B. Practical Implications

From a clinical perspective, the results suggest that mobile gaming apps could serve as effective adjuncts to pharmacological pain management. Higher interactive engagement scores were associated with improved pain management outcomes (H2: $p = 0.004$), confirming that gamification has therapeutic value. Furthermore, provider endorsement plays a critical role in legitimising app use among caregivers, indicating the need for formal training and guidelines on digital interventions in paediatric oncology.

The strong influence of parental perception indicates the necessity of caregiver-focused education materials that articulate the benefits, limitations, and usage guidelines of mHealth apps. These resources should be developed in culturally appropriate formats and include testimonials or case examples to enhance relatability and trust.

To facilitate adoption, mHealth developers and health policymakers should incorporate social validation cues, local language interfaces, and clear data privacy assurances into app design and dissemination strategies. These elements are especially crucial in culturally conservative settings, where personal endorsements and social norms heavily guide health behaviours.

Additionally, these results provide actionable implications for the design and implementation of culturally tailored mHealth interventions. The extended TAM framework can guide developers and healthcare administrators in designing mobile health tools that incorporate elements of social influence and trust into app features, training programs, and communication strategies. These insights support the effective deployment and potential scaling of such technologies within conservative healthcare systems like Saudi Arabia. These implications are grounded in statistically validated relationships confirmed through SEM, ensuring that practical recommendations stem from a robust and empirically supported model.

Finally, the importance of flexible data collection approaches—both in the research and intervention delivery phases—cannot be overstated. Offering multi-modal options ensures inclusivity and respects participant preferences and constraints, especially in sensitive healthcare environments.

VIII. Limitations

Although the pilot study has yielded valuable insights, several limitations should be acknowledged. First, logistical challenges varied across regions, particularly in Riyadh, where differences in institutional infrastructure and operational workflows impacted participant scheduling and coordination with hospital staff. These site-specific disparities suggest a need for tailored protocols and closer collaboration in future phases.

Second, variability in digital literacy among participants posed a challenge to consistent engagement with the mobile application and survey instruments. Despite mitigation through paper-based options and direct researcher support, disparities in digital familiarity may have influenced user experience and data quality. Future implementations should include standardised onboarding procedures and targeted digital support to ensure equitable participation.

Third, while the pilot effectively assessed the reliability and validity of the instruments, it did not explore longitudinal impacts such as sustained behavioural change or long-term clinical outcomes. This limits the current understanding of how continued app usage may influence pain management over time. Future research should adopt a longitudinal design to capture the enduring effects and clinical utility of mobile gaming interventions.

These limitations highlight the importance of logistical planning, digital accessibility, and temporal scope in

designing robust, context-sensitive studies on mHealth adoption in paediatric oncology.

IX. Recommendations for Future Studies

Future studies should aim to enhance generalisability and cultural relevance by expanding sample diversity across various regions and socioeconomic groups, including participants from underrepresented or rural areas. Prior to conducting large-scale research, it is advisable to perform pre-site assessments to evaluate institutional readiness, including infrastructure, staff availability, and participant flow. Stronger institutional collaborations with hospital administration, nursing teams, and IT departments should be established to support recruitment, technical facilitation, and the seamless integration of mobile applications into care routines. Developing short training sessions for both healthcare providers and parents can reduce cognitive burden and improve consistency in app usage and survey completion. Linguistic refinement of all instruments must continue through rigorous back-translation protocols to ensure clarity and cultural appropriateness across different Arabic dialects and literacy levels. Incorporating digital accessibility features—such as audio support, visual cues, and simplified interfaces—can address varying levels of digital literacy and physical or cognitive disability. Additionally, future studies must continue to prioritise robust privacy and data protection measures, as concerns around digital confidentiality were notably expressed by parents. Addressing these areas will strengthen methodological rigour, enhance cultural resonance, and contribute to the sustainable implementation of mHealth interventions in paediatric oncology settings.

X. Conclusion

This study has provided critical conceptual and methodological contributions by validating a culturally contextualised extension of the (TAM) for the adoption of mobile gaming applications in paediatric oncology pain management. By integrating culturally salient constructs such as social influence, trust, system quality, and accessibility into the traditional TAM, the framework has captured the complexities of mHealth adoption within the Saudi Arabian healthcare context. The mixed-methods pilot study has demonstrated the feasibility of this approach, with all six hypotheses statistically supported, thus reinforcing the model's theoretical robustness and contextual sensitivity.

Moreover, the research has highlighted the importance of linguistic clarity, digital accessibility, and cultural sensitivity in both research design and clinical application. Participants have responded favourably to multi-modal data collection strategies, while findings have revealed that healthcare provider endorsement and parental perception play key roles roles in influencing app usage behaviours. These insights have offered a foundation for developing user-centred, scalable mHealth interventions tailored to conservative healthcare systems.

Importantly, this study provides practical pathways for translating TAM-based findings into actionable mHealth strategies. Developers and health practitioners are advised to co-design digital tools with stakeholders, embed cultural values into app architecture, and implement institutional training to promote provider advocacy. These steps can support the broader deployment and policy integration of mobile health applications, ensuring they are both effective and culturally resonant.

Furthermore, the study's findings explicitly addressed all four research questions. RQ1 and RQ2 highlighted the influence of TAM constructs and social dynamics on user intention, while RQ3 and RQ4 uncovered how technical factors and trust mechanisms shape adoption behaviour. This depth of analysis ensures a comprehensive understanding of mHealth implementation in paediatric oncology within Saudi Arabia. Importantly, the study employed Structural Equation Modelling (SEM) via AMOS software to test path relationships, supported by multiple regression analyses for exploratory purposes. Model fit indices, including CFI and RMSEA, were reported to confirm the robustness of the conceptual framework.

As the next step, empirical testing of the framework through a full-scale study has been conducted , with longitudinal assessments planned to evaluate sustained engagement and clinical efficacy. The potential for generalisability and scalability of culturally adapted digital interventions has now been established, positioning this work to contribute meaningfully to mHealth practices in paediatric oncology and beyond.

Table VI: Summary of Hypothesis and Findings

Hypothesis	Supported?	Key Insight
H1	Yes	PU and PEoU mediate between contextual factors and app usage
H2	Yes	Interactive engagement improves PU and app utilisation
H3	Yes	Trust → PU link is strengthened by provider endorsement
H4	Yes	Positive parental perceptions lead to higher app usage
H5	Yes	System quality enhances both PU and PEoU
H6	Yes	Accessibility features indirectly enhance adoption via PU & PEoU

Acknowledgment

We extend our deepest appreciation to the Special Effect Organisation, particularly Elizabeth Power and Jacob Holden, for their exceptional support and invaluable insights, which significantly enhanced the quality and depth of our research. Their contributions were crucial in shaping the theoretical and conceptual framework of our study on the efficacy of mobile apps for paediatric oncology pain management in Saudi Arabia. We would also like to express our sincere gratitude to Dr. Khalid Alghamdi and the team at King Fahad National Hospital for their invaluable support in

facilitating data collection for this study. Samah Almaghrabi was supported by the University of Jeddah.

***Abstract*—Saudi Arabia's Vision 2030 prioritises digital transformation (DX) to modernise higher education. However, despite significant investment, Saudi public universities (SPUs) face unique challenges in adoption due to a lack of context-specific frameworks. To address this gap, this study proposes and validates the novel DXA-SPU framework, an integrated model that combines the Technology Acceptance Model (TAM) and the Technology-Organisation-Environment (TOE) framework. The model was evaluated using survey data from 447 SPU participants, with hypothesised relationships analysed via Structural Equation Modelling (SEM). The results supported 12 of the 14 hypotheses. Perceived usefulness and the institutional skills gap emerged as the most significant drivers of adoption. In turn, DX adoption was strongly linked to enhanced institutional performance, administrative efficiency, technical infrastructure, and teaching effectiveness. The DXA-SPU framework offers a validated tool for university leaders to assess DX readiness and align strategic planning with Vision 2030 goals, providing actionable insights for policymakers.**

***Index Terms*—Digital transformation, adoption frameworks, TAM, TOE, Saudi public universities, Vision 2030, SEM.**

I. Introduction

DIGITAL transformation (DX) has become a top priority across various sectors, including higher education. In this context, it refers to the use of digital technologies to improve institutional operations, strategic planning and service quality [1], [2]. DX supports better performance in teaching, learning, research and administration [3], [4].

In Saudi Arabia, higher education is undergoing a significant transformation driven by national strategies, including Vision 2030 and the National Transformation Program (NTP). These initiatives aim to improve the quality and efficiency of public services, including universities, by promoting digital innovation [5]. The government's focus on digital initiatives underscores a national commitment to modernising higher education.

Despite strong governmental support and significant investment in digital infrastructure, the public sector still faces challenges that hinder DX adoption [6]. This persistence of obstacles highlights the complexity of implementing DX in public sector institutions.

Research indicates that DX in the public sector is influenced by more than mere access to technology. Political, social and institutional factors also play a significant role [7]. However, most existing studies focus on Western countries or the private sector. As a result, there is limited understanding of how DX is adopted in public universities in Saudi Arabia. Thus, a context-specific framework is necessary to address the unique challenges of DX adoption in Saudi Public Universities (SPUs).

This study introduces the DXA-SPU framework, Digital Transformation Adoption in Saudi Public Universities, a framework that integrates the Technology Acceptance Model (TAM) and the Technology-Organisation-Environment (TOE) framework to explore and evaluate the factors influencing DX adoption and its institutional impacts. The research addresses the following questions:

1. What organisational, technological, and environmental factors influence DX adoption in SPUs?
2. How does DX adoption impact institutional outcomes, such as performance and efficiency?
3. How can a tailored framework support SPUs leaders in aligning DX with Vision 2030?

Using a mixed-methods approach, the study first employs Structural Equation Modelling (SEM) to test hypothesised relationships using survey data from university participants. This paper presents the quantitative results and the theoretical underpinnings of the framework.

II. Literature Review

Digital transformation has become a global imperative, compelling organisations to fundamentally rethink their operating models and value propositions. In the realm of higher education, this transformation is not merely about adopting technology but involves a profound cultural and strategic shift

that redefines teaching, research, and administrative processes [8]. The COVID-19 pandemic acted as an unprecedented accelerator, forcing higher education institutions (HEIs) worldwide into a period of "emergency remote teaching" and compelling a digital transition at a scale and pace previously unimagined [9], [10].

However, research shows that digitalisation in HEIs is often fragmented. [11] describe this as "dual digitalisation": the unintegrated, parallel development of top-down administrative systems (like Learning Management Systems, or LMS) and bottom-up, subject-specific digital tools used by academics. This fragmentation creates a disjointed experience, preventing the formation of a cohesive digital learning space. Consequently, technology use in HEIs often remains superficial, with LMS platforms frequently used as simple content repositories for administrative convenience rather than as tools for innovative education [12], [13]. Many universities launch digital initiatives as isolated projects without an overarching, integrated strategy, which limits their impact and return on investment [14].

In Saudi Arabia, DX is a cornerstone of the nation's strategic roadmap, Saudi Vision 2030, which aims to diversify the economy and build a thriving, knowledge-based society [15]. The government has invested heavily in establishing a sophisticated digital infrastructure and has launched initiatives like the "Future Gate" project to digitise curricula and empower learning [10], [15]. The pandemic response further highlighted this commitment, as the Ministry of Education rolled out platforms like "Madrasti" and provided extensive support to ensure educational continuity [15].

Despite this strong governmental support and investment, SPUs face a distinct set of challenges that hinder the successful adoption of DX. A primary obstacle lies in human and cultural factors. [16] found that for instructors, the most significant barriers are attitudinal, including resistance to and fear of change, coupled with a lack of experience. This is compounded by a persistent digital skills gap among both faculty and students [17]. For DX to succeed, faculty require training that goes beyond mere tool usage to encompass new digital pedagogies, and the traditional reliance on rote learning must be replaced with methods that foster critical thinking and digital literacy [15].

From an organisational perspective, rigid institutional routines can inhibit the flexibility needed for transformation [18]. Successful DX requires clear leadership, a supportive organisational culture, a well-defined strategy, and adequate resources, factors often identified as lacking or underdeveloped in HEIs [17], [19]. Technically, while the national infrastructure is robust, challenges remain in ensuring reliable access for all, managing the explosion of institutional data through effective data governance, and addressing cybersecurity and privacy concerns [16], [20].

This complex landscape demonstrates that generic DX models are insufficient. There is a clear need for a context-specific framework tailored to the unique regulatory, cultural, and institutional conditions of SPUs. Such a framework must address the multifaceted challenges of human readiness, organisational agility, and strategic alignment with Vision 2030. This study proposes and validates the DXA-SPU framework to support SPUs' leadership in the strategic implementation of their university's DX.

III. Hypotheses and Study Framework

This study proposes the DXA-SPU framework to investigate the adoption of DX in SPUs, as illustrated in Fig. 1. The framework integrates two established models: the TAM and TOE frameworks. Together, they offer a combined view of

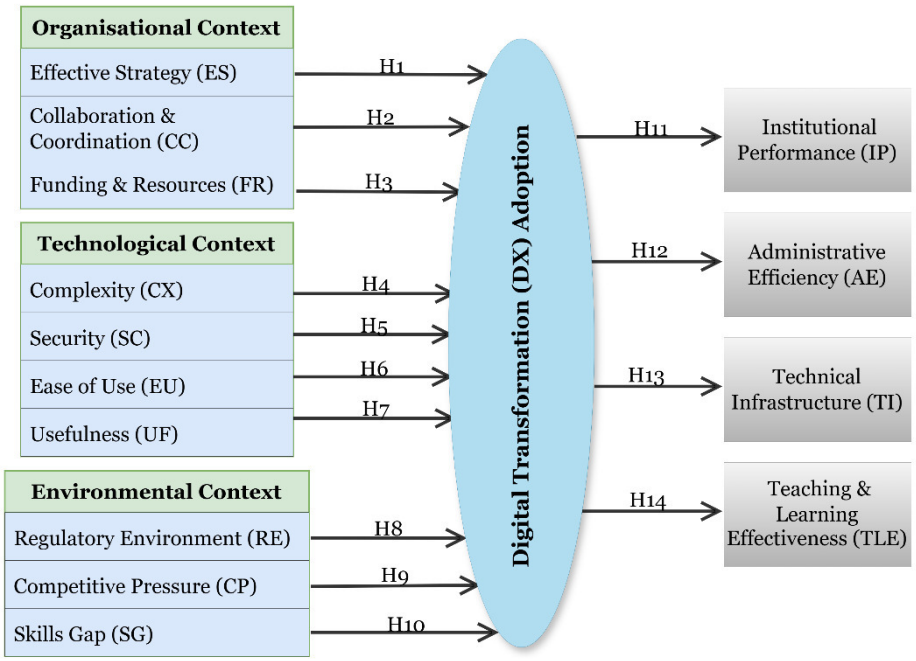

Fig. 1 The Initial Framework for DXA-SPU

individual and institutional influences on technology adoption. The aim is to identify the key factors shaping adoption and evaluate how DX is expected to impact university operations and performance.

A. Technology Acceptance Model (TAM)

The TAM posits that individuals are more likely to adopt a technology if they perceive it as useful and easy to use [21]. These core constructs, perceived usefulness and perceived ease of use, are central to predicting technology adoption behaviour. In this context, Saudi public university faculty, administrators and staff may support DX if it helps them work more efficiently and is accessible without added complexity.

However, TAM primarily focuses on individual-level perceptions and does not account for the broader institutional or environmental factors critical for analysing DX in universities. To address this, TAM is extended in this study to link the intention to adopt DX directly with perceived institutional impacts, such as performance and administrative efficiency, consistent with TAM's original structure connecting intention, behaviour, and outcomes [21]. The study examines whether this intention is associated with positive perceptions of institutional outcomes (H11-H14), using survey data to assess these links.

B. Technology-Organisation-Environment (TOE) Framework

The TOE framework provides a broader view of technology adoption by including factors from three domains [22] (see Table I):

Technological context: Characteristics of the technology itself, such as system complexity, ease of use and security.

Organisational context: Internal features of the institution, including leadership, planning, available resources and coordination across departments.

Environmental context: External influences like government policy (e.g., Vision 2030), regulatory pressures and competition from other universities.

The TOE complements the TAM by addressing the broader institutional and external conditions that affect adoption. Such perspectives are essential in public universities, where DX is shaped not only by individual preferences but also by policy, leadership, and organisational readiness.

C. DXA-SPU Framework Overview

Both the TAM and TOE frameworks are widely used for technology adoption. However, their application in isolation often falls short in complex environments like Saudi Public Universities [8].

TAM emphasises individual perceptions. This focus implies that it does not fully capture external forces, such as governmental policies or funding structures, that profoundly influence the adoption of DX in public institutions. Conversely, TOE addresses broader organisational and environmental factors. For example, it has been applied in specific regional contexts like Vietnam's creative industries [23]. However, TOE has been criticised for overlooking the crucial role of individual user perceptions and behavioural intention. These factors are strongly emphasised in technology acceptance models like TAM. They are also critical in digital learning adoption [24].

TABLE I.

DXA-SPU HYPOTHESES GROUPING SUMMARY

Group	Hypotheses	Focus
Organisational Context	H1-H4	Internal institutional factors: effective strategy, collaboration & coordination, funding & resources.
Technological Context	H5-H8	Technology-related factors: complexity, ease of use, usefulness and security.
Environmental Context	H9-H10	External influences: regulatory environment, competitive pressure, and skills gap
Impacts of DX Adoption	H11-H14	Institutional outcomes: institutional performance, administrative efficiency, technical infrastructure and teaching & learning effectiveness.

In universities, both levels are paramount. Faculty and staff exhibit varying levels of digital readiness and literacy. Institutional change is significantly shaped by national agendas like Vision 2030 [15], [25].

Recognising these limitations, the DXA-SPU framework integrates the strengths of both TAM and TOE. This provides a more comprehensive understanding of DX in this unique context. Various technology adoption models have been applied in sectors like e-learning, healthcare, and public administration. However, these models often suit general contexts or developed nations. They overlook the specific interplay of national policies and centralised governance in Saudi public education [15], [19], [20].

Critically, previous Saudi-focused studies have often been limited to specific applications, such as online learning or cloud systems. They often neglect holistic DX or key factors such as skills gaps. In contrast, the DXA-SPU framework explicitly incorporates constructs like 'Skills Gap' and 'Regulatory Environment'. These constructs are tailored to address the evolving digital literacy needs and policy alignment challenges in the Saudi higher education landscape. By integrat-

ing user and institutional perspectives, and explicitly accounting for regulatory pressures, funding dependencies, and digital skills deficiencies prevalent in Saudi Arabia, this framework offers a more effective approach for studying DX adoption in SPUs.

The DXA-SPU framework is designed to identify factors influencing DX adoption and evaluate its institutional impacts in SPUs. It integrates TAM to assess user perceptions and behavioural intention, and TOE to capture technological, organisational, and environmental influences.

Key constructs include ease of use, strategic alignment, and regulatory support, while outcome areas include institutional performance, administrative efficiency, technical infrastructure, and teaching effectiveness.

While this section outlines the structure and provides a detailed breakdown of hypotheses, constructs appear in later sections. Validation is performed using SEM.

D. Development of Hypotheses

Based on the TAM and TOE frameworks, the following hypotheses have been developed to explore the relationships between these factors and DX adoption in SPUs:

Organisational Context

The successful implementation of DX within a university is contingent upon key internal factors. These factors include an effective institutional strategy, robust inter-departmental collaboration, and the allocation of adequate resources.

a) Effective Strategy (ES)

A well-defined DX strategy ensures that technological initiatives are aligned with institutional goals and educational priorities. DX is not merely a standalone IT project but a cross-functional initiative that must integrate academic, administrative, and technological planning [26]. Multiple forms of strategy, including IT, change management and business strategy, must be synchronised to support successful digital initiatives [27]. When strategic alignment is lacking, institutions face fragmented efforts, inefficiencies and resistance to change [28]. In the context of higher education, a clear DX strategy enhances coordination, promotes long-term adaptability, and increases the likelihood of adoption success.

H1: *An effective DX strategy positively influences the intention to adopt DX in SPUS.*

b) Collaboration and Coordination (CC)

Collaboration among stakeholders, faculty, administrators and students is essential for the successful adoption of DX in universities. Research shows that engaging academic users helps ensure technologies are meaningfully integrated into teaching and learning [29]. Collaboration improves feedback, enhances digital literacy, and supports access to appropriate tools, which are often barriers to DX adoption [30]. Coordinated efforts across departments and governance levels also promote shared ownership of digital strategies and smooth implementation [31]. A collaborative environment increases acceptance and strengthens institutional readiness for DX.

H2: *Strong collaboration and coordination among stakeholders positively influence the intention to adopt DX in SPUs.*

c) Funding and Resources (FR)

Successful DX depends on access to sufficient financial, technical and human resources. Investments in infrastructure, software and skilled personnel form the foundation for sustainable implementation [32]. When funding is limited, institutions may struggle to upgrade systems or provide staff training, which delays adoption [33]. Training programs and digital tools also require ongoing investment to remain effective, making resource availability a long-term concern [34]. Thus, ensuring adequate support for DX projects is crucial to facilitating adoption across the university.

H3: *Sufficient funding and resources positively influence the intention to adopt DX in SPUs.*

Technological Context

Beyond organisational considerations, the intrinsic characteristics of the technology itself are instrumental to the success of DX. The adoption of these new digital tools is directly influenced by their complexity and security, as well as their perceived usefulness and ease of use.

a) Complexity (CX)

Technological complexity is a significant barrier to DX, especially when modern systems must integrate with legacy infrastructure. Incompatibility between platforms can lead to data silos, operational disruptions and increased transition costs [36]. Complex implementation processes can disrupt workflows and reduce staff willingness to adopt new tools [37]. Without clear integration pathways, institutions may face delays, increased risks and unmet goals. Reducing complexity helps build user confidence and simplifies institutional decision-making.

H4: *Lower complexity in integrating digital technologies with existing systems and processes positively influences the intention to adopt DX in SPUs.*

b) Security (SC)

As universities become more reliant on digital platforms, concerns over cybersecurity and data protection have grown. The use of cloud services, online portals, and connected devices introduces multiple risks, including data breaches and ransomware attacks [38]. Without strong security measures, universities may face legal, operational and reputational consequences [39]. A secure digital environment builds trust among users and reduces resistance to adopting new digital technologies. Therefore, confidence in data security is a critical enabler of DX adoption.

H5: *A higher level of digital security positively influences the intention to adopt DX in SPUs.*

c) Ease of Use (EU)

According to TAM, ease of use is a core predictor of technology adoption [21]. When digital tools are perceived as intuitive and user-friendly, individuals are more likely to explore and apply them in their work. Ease of use also influences trust and satisfaction, both of which contribute to long-term engagement [40]. In the context of higher education, simple interfaces reduce learning curves for faculty and staff and encourage quicker adoption.

H6: *The perceived ease of use of DX solutions positively influences the intention to adopt DX in SPUs.*

d) Usefulness (UF)

Perceived usefulness is among the strongest predictors of technology adoption in the TAM framework. In higher education, digital tools are more likely to be adopted if users believe they improve teaching, learning and administrative efficiency [41]. Technologies that support personalised instruction and streamline processes are especially valued, as they contribute to both student outcomes and institutional performance [42]. When users recognise the practical benefits of DX, they are more motivated to support its adoption.

H7: *The perceived usefulness of DX positively influences the intention to adopt DX in SPUs.*

Environmental Context

The external environment, heavily influenced by government directives such as Vision 2030, is a primary driver of DX in SPUs. National policies create a direct regulatory pressure for modernisation, while competitive dynamics between institutions also foster innovation. At the same time, the evolving Saudi labour market demands graduates with advanced digital skills. This pressure for skilled graduates, combined with the need for internal faculty and staff to be digitally competent, creates a significant challenge for universities to address the overall skills gap.

a) Regulatory Environment (RE)

The regulatory environment plays a vital role in enabling or restricting DX in public institutions. In Saudi Arabia, higher education policies and budgetary frameworks strongly influence the scope and pace of DX adoption. Supportive government policies, such as Vision 2030, encourage investment in digital tools, infrastructure and human capital [43]. Effective regulation helps create the conditions for innovation, whereas rigid or unclear policies can limit institutional flexibility [23]. A favourable regulatory climate increases confidence and motivates universities to invest in digital initiatives.

H8: *A flexible and supportive regulatory environment positively influences the intention to adopt DX in SPUs.*

b) Competitive Pressure (CP)

Competitive pressure is a key external factor that drives innovation in higher education. When universities compete for rankings, visibility or recognition, they are more likely to adopt advanced digital tools to enhance teaching, research and administration [44]. Institutions that seek to differentiate themselves invest more in technology, which can improve student outcomes and faculty productivity [45]. In Saudi Arabia, competition among public universities creates momentum for DX, pushing institutions to modernise quickly to remain relevant.

H9: *Higher competitive pressure among universities positively influences the intention to adopt DX in SPUs.*

c) Skills Gap (SG)

A major challenge facing DX in higher education is the skills gap among students, faculty and staff. As digital tools become central to education and work, institutions must address deficits in both technical and soft skills to ensure readiness for transformation [46]. Employers increasingly expect digital fluency, critical thinking and adaptability, which are not always part of traditional curricula [47].

Universities that align their teaching and training with evolving workforce needs will be better positioned to adopt digital technologies successfully. Addressing the skills gap enhances both institutional effectiveness and graduate preparedness [48], [49]. Thus, bridging this gap is essential to ensuring DX efforts can be successfully implemented and sustained.

H10: *Addressing digital skills gaps positively influences the intention to adopt DX in SPUs.*

E. The Impact of DXA on SPUs

This study extends the TAM to link the intention to adopt DX with its perceived impacts on university outcomes. These impacts are framed as expected outcomes within a mixed-methods approach, where the quantitative phase tests the hypothesised relationships using survey data.

The hypotheses aim to investigate how various technological, organisational and environmental factors influence the intention to adopt DX, and how this intention relates to outcomes such as institutional performance, administrative efficiency, technical infrastructure and teaching and learning effectiveness.

The DXA-SPU framework, by combining the TAM and TOE, offers a robust model for understanding the drivers of DX in SPUs. It captures both individual perceptions and broader institutional dynamics, making it a comprehensive tool for analysing adoption behaviour and its anticipated impacts. These hypotheses were tested to assess the relationships between influencing factors, adoption intentions and institutional outcomes, which are described below.

Institutional Performance (IP)

Digital transformation plays a growing role in enhancing institutional performance across universities globally, including Saudi public institutions. Studies in Saudi Arabia confirm that DX can improve efficiency, leadership, research productivity and stakeholder engagement. For example, [50] shows that DX supports academic and financial performance and promotes sustainability through digital learning. Reference [18] highlights the role of internal processes and routines in

shaping transformation outcomes, while [51] connects leadership styles to DX success. Data governance, as emphasised by [20], is also essential for institutional performance. Moreover, as in [19], the study links DX to broader social and academic outcomes, including student engagement and well-being. Collectively, these studies indicate that DX contributes to performance through operational, human and technological improvements.

H11: *Adopting DX in SPUs is expected to positively enhance institutional performance.*

Administrative Efficiency (AE)

Digital transformation supports more efficient university operations by streamlining workflows, integrating digital tools, and enhancing stakeholder engagement. Research from Saudi universities shows that knowledge management systems and cloud-based solutions can enhance administrative agility and service quality [53], [54]. DX allows institutions to reduce technical errors, improve decision-making, and strengthen accountability through real-time data access [55], [56]. Studies by [57], [58] show that user engagement, trust and service efficiency improve when universities adopt digital public administration tools. These technologies also enable the modernisation of resource management and coordination, which is essential for competitiveness and institutional effectiveness.

H12: *Adopting DX in SPUs is expected to positively enhance administrative efficiency.*

Technical Infrastructure (TI)

The shift toward DX has accelerated infrastructure development in SPUs. Institutions have expanded their Information and Communication Technology (ICT) capabilities, especially in response to the COVID-19 pandemic, which underscored the need for resilient e-learning platforms and remote service access [59], [60]. Hence, robust infrastructure is critical for sustaining digital tools across academic and administrative systems [45], [61]. Moreover, Supportive ICT policies and resource availability influence the digital readiness of universities and their ability to scale technologies effectively [62]. Therefore, investing in reliable and flexible infrastructure is essential for enabling long-term transformation.

H13: *Adopting DX in SPUs is expected to positively enhance technical infrastructure.*

Teaching and Learning Effectiveness (TLE)

Digital transformation significantly shapes the effectiveness of teaching and learning in higher education. In SPUs, DX enables more interactive, student-centred learning environments, especially through online platforms and blended learning methods [63]. Investments in digital hardware, content and staff training have improved e-learning quality and digital literacy [64]. Studies also show that DX positively influences student engagement, professional development and learning continuity during crises [65]. While DX introduces new challenges, such as digital well-being and emotional adjustment, its benefits in learning outcomes and instructional quality are well-documented [66]. Overall, DX supports a more flexible, engaging and effective teaching and learning environment that meets evolving student and institutional needs.

H14: *Adopting DX in SPUs is expected to positively enhance teaching and learning effectiveness.*

IV. Study Methodology

A. Approach and Sample

This study uses a mixed-methods approach to evaluate the DXA-SPU framework. The quantitative phase tests relationships using survey data, while a subsequent qualitative phase is planned to explore contextual interpretations through interviews with IT managers.

The survey focused on three groups within SPUs: faculty members, who include academic teaching and research staff; administrators, who hold strategic or managerial positions with university-wide decision-making authority; and staff, which encompasses all other non-faculty employees, including support and technical personnel. A stratified sampling strategy was applied to ensure role-based representation. According to the General Authority for Statistics, the target population comprises approximately 134,000 members [67], [68]. Using a 95% confidence level and 5% margin of error, the minimum required sample size was 384. In 2024, the survey link was distributed to a random sample, yielding 447 valid responses, exceeding the threshold for robust analysis.

B. Survey Implementation

The primary objective of the survey was to examine the relationships between the DXA-SPU framework constructs and the intention to adopt DX in SPUs. The questionnaire consisted of three parts: Part I (7 questions) gathered demographic and contextual data, Part II (40 questions) assessed ten influencing factors (e.g., Collaboration and Coordination, Ease of Use), and Part III (16 questions) evaluated four impact constructs (e.g., Teaching and Learning Effectiveness). Each construct was measured with five Likert-scale questions to support reliable statistical analysis. The survey instrument is accessible for review online at [Survey for SPU].

A pilot study was conducted prior to the main survey to test the clarity and reliability of the questionnaire. The pilot involved a small group of university stakeholders, targeting 20 responses, with 25 responses received. Feedback led to minor adjustments in wording and layout to enhance clarity, but no substantive changes to the questions were required.

The main survey was conducted from August 15 to November 15, 2024, using an online survey platform. The instrument was developed in English and translated into Arabic to accommodate participant preferences. Over 700 questionnaires were randomly distributed to faculty, administrative, and staff members across SPUs. Of these, 551 questionnaires were completed, but only 447 (81%) responses were accurate and suitable for analysis, while 104 (19%) were deemed invalid.

Participants were informed of the study's purpose, and confidentiality was assured prior to participation. Ethical ap-

proval was obtained from the university research ethics committee, and informed consent was secured from all participants. No personal identifiers were collected, and data were securely stored for academic research purposes only.

The quantitative data were analysed using SEM with IBM AMOS 29, incorporating Confirmatory Factor Analysis (CFA) to evaluate the measurement model. Internal consistency was assessed using Cronbach's Alpha, convergent validity using Composite Reliability (CR) and Average Variance Extracted (AVE), and discriminant validity using Maximum Shared Variance (MSV). Model fit was evaluated through indices such as χ^2/df (CMIN/DF), Comparative Fit Index (CFI), Root Mean Square Error of Approximation (RMSEA), and Standardised Root Mean Square Residual (SRMR).

V. Study Results

A. Data Collection and Screening

Table II. details the demographic profile of the respondents, which shows a diverse group from SPUs. Most participants were female (53.2%), while males made up 45.4%. A small number (1.3%) preferred not to state their gender. The largest age group was 31-45 years (73.2%), followed by those aged 18-30 (19.7%).

Regarding education, 49.7% held a master's degree and 36.2% held a doctorate. This suggests that most respondents were well educated. Regarding their roles, 67.3% were faculty members, 16.8% were staff, and 15.9% worked in administration. Almost half (49.0%) had over ten years of experience at their university. Others had 5-10 years (27.0%) or 1-4 years (21.0%) of experience.

A majority (66.7%) were aware of national DX programs such as the Vision 2030 NTP. Similarly, 69.1% were familiar with their university's DX efforts.

Many participants viewed DX as effective. Approximately 34.7% reported that it was very effective, and 29.5% considered it moderately effective. Satisfaction levels were also high. Around 41.9% were somewhat satisfied, while 12.0% were extremely satisfied.

Overall, the respondents were experienced, informed, and qualified to provide feedback on the adoption of DX.

Data screening confirmed the dataset's suitability for analysis. The Z-score analysis revealed no significant outliers, and the skewness and kurtosis values fell within ±2.0, indicating normality. Missing values were below 10%, requiring no imputation [69]. These checks validated the integrity of the dataset for SEM analysis.

B. Measurement Model Assessment

Confirmatory Factor Analysis was used to assess the validity and reliability of the measurement model. All standardised factor loadings exceeded 0.50, indicating that the items aligned with their respective constructs.

Table III shows that internal consistency was verified using Cronbach's Alpha and CR, with all values above the 0.70 threshold. Convergent validity was supported through AVE, with values exceeding 0.50. Discriminant validity was established as all constructs showed AVE values greater than the MSV.

Model fit indices also indicated an acceptable model fit:

- χ^2/df = 1.445
- CFI = 0.968

TABLE II.

DEMOGRAPHIC STATISTICS FOR THE PARTICIPANTS

Gender	**N**	**%**
Male	203	45.4%
Female	238	53.2%

SG	.931	0.931	0.772	0.306
IP	.918	0.918	0.737	0.585
AE	.925	0.925	0.755	0.555
TI	.920	0.921	0.744	0.585
TLE	.916	0.919	0.741	0.575
ES	.952	0.952	0.833	0.130

- RMSEA = 0.032
- NFI = 0.902

These results indicate that the measurement model is robust and well-constructed.

C. Structural Model Assessment

The structural model tested the hypothesised relationships between the factors influencing the intention to adopt DX and the perceived impacts of adoption. Path coefficients and significance levels were estimated using SEM.

Table IV presents the results of the structural model. Among the adoption factors (H1-H10), *Effective Strategy (ES)* showed a significant positive effect on DX adoption ($\beta = 0.121$, $p = 0.001$). However, *Collaboration and Coordination (CC)* showed no significant effect on DX adoption ($\beta = -0.009$, $p = 0.773$). This unexpected result may stem from limited cross-departmental structures in SPUs, as bureaucratic silos could hinder collaborative efforts [70]. In addition, the measurement of the CC construct might not fully reflect the dynamics among stakeholders. This indicates that future studies may benefit from developing more refined survey items.

Moreover, *Complexity (CX)* had a significant positive effect ($\beta = 0.181$, $p < 0.001$), suggesting that manageable complexity supports adoption. *Funding and Resources (FR)* was also significant ($\beta = 0.184$, $p = 0.002$), showing the importance of institutional support. *Security (SC)* ($\beta = 0.131$, $p = 0.003$) and *Ease of Use (EU)* ($\beta = 0.103$, $p = 0.047$) both had significant positive impacts. *Usefulness (UF)* was the strongest predictor ($\beta = 0.272$, $p < 0.001$), highlighting its significant role. *Regulatory Environment (RE)* was also significant ($\beta = 0.091$, $p = 0.009$).

TABLE IV.

RESULTS OF ANALYSIS OF HYPOTHESIS PATH FOR THE DXA-SUPS FRAMEWORK

Hypothesis	Structural Relation	Regression Weight	Standard Error (S.E.)	Critical Ratio (C.R.)	P Value
H1	DX ← ES	.121	.037	3.256	.001
H2	DX ← CC	-.009	.031	-.288	.773
H3	DX ← FR	.184	.059	3.099	.002
H4	DX ← CX	.181	.054	3.364	***
H5	DX ← SC	.131	.044	2.995	.003
H6	DX ← EU	.103	.052	1.983	.047
H7	DX ← UF	.272	.049	5.539	***
H8	DX ← RE	.091	.035	2.613	.009
H9	DX ← CP	.100	.055	1.822	.068
H10	DX ← SG	.239	.052	4.601	***
H11	IP ← DX	.629	.043	14.491	***
H12	AE ← DX	.753	.047	16.004	***
H13	TI ← DX	.683	.046	14.990	***
H14	TLE ← DX	.639	.049	13.165	***

NOTE: ("***=SIGNIFICANCE AT THE 0.001 LEVEL")

Likewise, *Competitive Pressure (CP)* approached significance ($\beta = 0.100$, $p = 0.068$). While not statistically significant at the conventional 0.05 level, this finding suggests a marginal influence. The *Skills Gap (SG)* showed a strong positive effect ($\beta = 0.239$, $p < 0.001$), underscoring the role of digital competencies.

All four impact hypotheses (H11-H14) were supported. *Institutional Performance (IP)* was significantly predicted by DX adoption ($\beta = 0.629$, $p < 0.001$), followed by strong effects on *Administrative Efficiency (AE)* ($\beta = 0.753$, $p < 0.001$), *Technical Infrastructure (TI)* ($\beta = 0.683$, $p < 0.001$), and *Teaching and Learning Effectiveness (TLE)* ($\beta = 0.639$, $p < 0.001$). These findings suggest that DX adoption is associated with broad and substantial institutional benefits.

Overall, twelve out of fourteen hypotheses were supported. The results empirically support the DXA-SPU framework, demonstrating its relevance to SPUs.

D. Summary of Findings

The results of the quantitative analysis provide strong empirical support for the DXA-SPU framework. Perceived usefulness, skills gap and complexity emerged as the most influential factors, while collaboration and coordination, and competitive pressure did not show a significant effect in this context.

The extension of the TAM was also empirically supported, as the intention to adopt DX was found to significantly impact all four key outcome areas: institutional performance, administrative efficiency, technical infrastructure and teaching and learning effectiveness. Among these, administrative efficiency showed the strongest relationship, suggesting that DX is especially effective in enhancing internal operational processes.

These findings not only reinforce the relevance of the TAM and TOE in higher education settings but also highlight the strategic role of DX in improving institutional outcomes.

VI. Discussion

The results support the relationships proposed by the DXA-SPU framework, demonstrating how organisational, technological, and environmental factors influence adoption (see Fig. 2). This outcome strengthens the theoretical validity of integrating TAM and TOE for analysing DX adoption.

These findings extend the applicability of TAM and TOE in higher education settings, providing empirical support for the framework's multidimensional design. Such validation offers practical and theoretical contributions, particularly in non-Western, public-sector contexts, such as Saudi Arabia.

In the organisational context, effective strategy and funding and resources significantly influenced adoption, consistent with prior research emphasising the importance of institutional planning and leadership commitment [71], [72]. However, the factor of collaboration and coordination was not supported, indicating that cross-departmental integration may not yet be strong or institutionalised enough to shape adoption behaviours. This suggests an opportunity for organisational development initiatives that promote structured collaboration and digital governance.

Within the technological dimension, perceived usefulness and ease of use emerged as strong predictors of adoption intention, reinforcing the applicability of the TAM in the higher education context. The finding that lower system complexity positively influences adoption underscores the need for intuitive, interoperable digital systems that minimise disruption during adoption. The significance of security also reflects increasing institutional awareness of data protection and privacy challenges in digital environments [73].

Regarding environmental influences, the regulatory environment demonstrated statistical significance, reaffirming that national policies, especially those tied to Vision 2030, are powerful motivators for DX in SPUs. In contrast, competitive pressure approached significance but was not statistically supported at the conventional level. While some literature suggests that competitive dynamics drive innovation, the insignificant finding in this specific context may imply that, for SPUs operating under strong governmental directives, top-down policy mandates (such as Vision 2030) currently exert a more direct and statistically dominant influence on DX adoption than inter-university competition. Meanwhile, the influence of the skills gap confirms that digital readiness

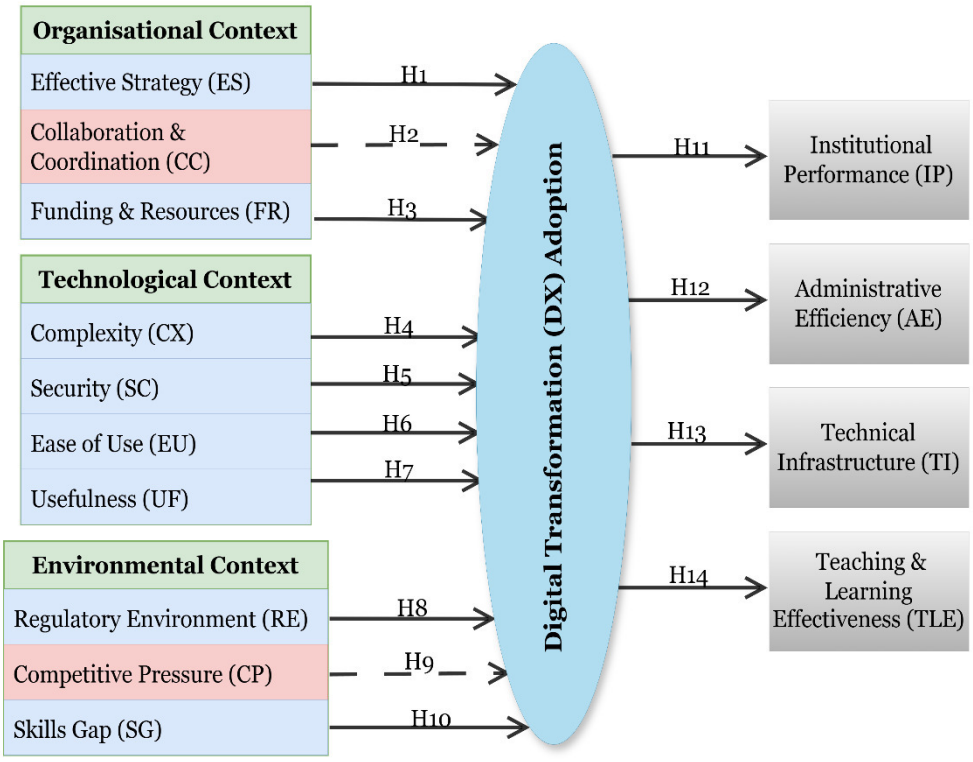

Fig. 2 Fig. 2 The Revised Version of the Comprehensive Framework for DXA-SPU

among staff and students remains a challenge, despite strategic alignment at the policy level [74].

The extended TAM results confirm that adoption intention is strongly associated with multiple institutional outcomes. These include improvements in operational efficiency, infrastructure resilience, and academic delivery, reinforcing the strategic significance of DX adoption in the SPU context.

Overall, these results underscore that successful DX adoption depends not only on the availability of technology but also on strategic planning, institutional preparedness and alignment with national reform agendas.

VII. Conclusion

This study provides empirical support for the novel DXA-SPU framework, integrating the TAM and TOE frameworks to examine DXA in SPUs. Survey data from 447 participants supported 12 of 14 hypotheses, identifying perceived usefulness, ease of use, regulatory alignment, and skills gap as key adoption drivers. DX adoption significantly enhances institutional performance, administrative efficiency, technical infrastructure, and teaching effectiveness, aligning with Vision 2030's educational reform goals.

The non-significant collaboration and coordination (CC) and competitive pressure (CP) hypotheses suggest a need for stronger interdepartmental mechanisms, such as cross-departmental task forces, to foster stakeholder engagement. Collectively, they indicate that internal organisational factors or top-down strategic mandates may currently be more critical drivers of DX adoption in this context.

The DXA-SPU framework offers significant contributions to both theory and practice. Theoretically, it adapts and combines the TAM and TOE frameworks to specifically address the unique context of SPUs, reflecting their national goals, institutional structures, and digital priorities. Practically, it provides an empirically supported tool for SPUs leaders to assess DX readiness and align their strategies with Vision 2030.

This study is based on self-reported perceptions, offering valuable insights into behavioural intention but not fully capturing actual adoption. Although the sample size was statistically sufficient, it may not fully represent the full diversity of stakeholder perspectives across all SPUs. To address these limitations, the following research phase will involve completing the qualitative phase by October 2025, with interviews of 10-15 IT managers to validate the findings and explore implementation dynamics.

While this framework was designed and validated in the context of SPUs, it may also be applicable in similar contexts in other countries. Moreover, a comparative analysis of the results with findings from other cultures would be a particularly valuable extension to assess the framework's broader applicability. Such research could further support the development of effective DX strategies and inform national education policy planning initiatives.

***Abstract*—Studies on Saudi accounting practices have identified evidence of creative accounting in the financial statements of listed companies. Despite the application of various fraud detection methods, identifying legal but misleading manipulations remains challenging. This paper extends the Creative Accounting Detection Model (CADM), an LSTM-based model originally proposed by Bineid et al. (2023, 2024) for detecting creative accounting. Two versions, (CADM1) and (CADM2), were trained on two simulated datasets with different bases, achieving 100% and 95% accuracy, respectively. Testing on the energy sector (2019-2023), CADM1 identified one company as engaging in creative accounting, while CADM2 classified all companies as non-creative with greater confidence stability. The findings establish CADM as a robust, scalable solution for the early detection of financial manipulation. By combining predictive strength with explainability, CADM can be employed to advance current approaches to forensic accounting and risk analytics, offering valuable insights to regulators, auditors, and decision-makers.**

***Index Terms*—Deep Learning, Long Short-Term Memory, LSTM, Creative Accounting, Saudi Arabia.**

I. Introduction

DESPITE the establishment of accurate accounting standards, financial statement scandals continue to shake global markets. Cases such as Enron [1] and Wirecard [2] reveal the persistent challenge of Creative Accounting (CA), a practice where managers manipulate the accounting figures to present a misleading image of financial position.

Business performance is typically evaluated through accounting outcomes presented in financial statements (FSs). To ensure these statements offer a true and fair view, companies are required to prepare them under well-defined accounting standards and to subject them to independent auditing [3]. These measures are intended to ensure transparency, confirm compliance, and detect any material misstatement. However, corporate managers often have incentives to present the most favourable image of their organisation [4]. In doing so, they may engage in CA practices, adjusting figures within the boundaries of acceptable standards, without technically violating the rules. Although CA is sometimes distinguished from fraud, its consequences can be just as damaging [5], [6].

While many studies have focused on detecting Financial Statement Fraud (FSF), fewer studies have tried to identify CA (also referred to as Earnings Management EM) [7], [8]. One of the earliest and most notable efforts is the Beneish M-Score [9], a model built on financial ratios designed to flag potential EM. However, its capability in a non-U.S. context remains questionable [10]. Other statistical models like the Jones model and the modified Jones model [11] have been developed to detect EM, but they still face limitations such as model misspecification and low detection power, particularly in varying economic contexts.

More recently, Deep Learning (DL) applications have emerged as a powerful tool in financial prediction and classification. DL models, particularly neural networks, have demonstrated promise in learning complex patterns embedded in large unstructured datasets. Approaches combining Recurrent Neural Network (RNN), Long Short-Term Memory (LSTM), Gated Recurrent Network (GRN), and even Bidirectional Encoder Representations from Transformers (BERT) models have been explored to solve problems like gradient vanishing and square modelling [12], [13]. For example, Craja et al. [14] applied deep learning techniques to detect FSF based on textual analysis of financial reports using a Bag-of-Words (BOW) approach. The model successfully identified fraudulent cases; however, it was designed for linguistic analysis only. Schreyer et al. [15] used Adversarial Autoencoder Neural Networks to detect anomalies in raw accounting entries, although their focus on ERP data structures limits the ability to generalise to standardised FSs.

Given the sequential nature of FSs, LSTM networks have shown remarkable suitability for analysing time-series data. They are particularly adept at capturing long-term dependencies and detecting subtle deviations from normal patterns. Their success in areas like anomaly detection, image recognition, and natural language processing has encouraged their application to financial domains, including fraud detection [16], [17] and performance predictions [18]. However, applying DL techniques to CA detection requires

Topical area: Advanced Artificial Intelligence in Applications

overcoming a fundamental obstacle: the lack of real-world CA examples. However, in the Saudi Arabian context, studies have found that FSs do not represent a company's true and fair position, despite auditor procedures approval[4], [19], [20], [21]. This alarming finding emphasises the need for innovative solutions to detect FS manipulation and improve financial reporting quality.

Despite the growing literature on detecting financial statement fraud, a significant gap remains in detecting CA weather through statistical methods or Artificial Intelligence, particularly within the Saudi Arabian context. In addition, the absence of labelled datasets for CA, particularly in the Saudi market, presents a methodological challenge in developing, training, and validating such models. To address this gap, this research aims to design, simulate, and evaluate a Creative Accounting Detection model (CADM), using an LSTM architecture, capable of learning from domain-specific financial and non-financial patterns.

To achieve this aim, the study makes several contributions to the literature. First, it introduces a novel domain-specific simulation methodology tailored to the characteristics of Saudi-listed companies. Second, it compares two distinct simulation approaches to determine which offers more effective training for the CA detection model. Third, it validates the proposed models using real-world FS data from the Saudi energy sector. These contributions are guided by the following research questions:

- **RQ1:** How does the base used in simulated data affect the accuracy of LSTM models in detecting creative accounting?
- **RQ2:** Can the proposed deep learning model (CADM) be trained to classify with high accuracy?
- **RQ3:** Can the proposed deep learning model (CADM) be generalised to real-world FSs?

II. Methodology

A mixed-methods approach is employed to deliver the research objectives. It combines an experimental methodology with quantitative techniques to form a framework for developing, training, and evaluating a deep-learning model using simulated and real-world datasets. The upcoming subsections explain the research design, feature engineering, data preparation, model architecture, training process, and testing procedures.

A. Research Design

The research design comprises two overlapping phases: quantitative and experimental, implemented in parallel across different stages of this study. The first phase involves preparing the dataset, which consists of two main components: a training dataset and a testing dataset. The testing dataset is collected from real-world FSs of Saudi-listed companies. However, due to the unavailability of a CA-labelled dataset, this study adopts a simulation-based methodology to generate FSs that reflect selected CA patterns. This leads us to start the second phase before ending the first, as shown in Fig. 1.

This part of the experimental phase involves implementing a domain-specific simulation process to generate synthetic datasets. However, two simulation designs were applied simultaneously. The first simulation is based on the real-world dataset analysis, and the second is based on the findings of Leitch and Chen [21].

Once the simulation stage is completed, the quantitative phase resumes with the development and training of the model. Using an LSTM-based architecture, the quantitative approach is implemented by analysing numeric accounting data, financial ratios, Corporate Governance (CGs), and key performance indicators extracted from real and simulated FSs to capture and classify CA practices. The outcomes of this analysis are further evaluated using deep learning performance metrics in the remainder of the second phase.

B. Data Sources and Collection

The emergence of publicly accessible financial data in Saudi Arabia is a relatively recent advancement that reflects the Kingdom's efforts to transform its financial system, in-

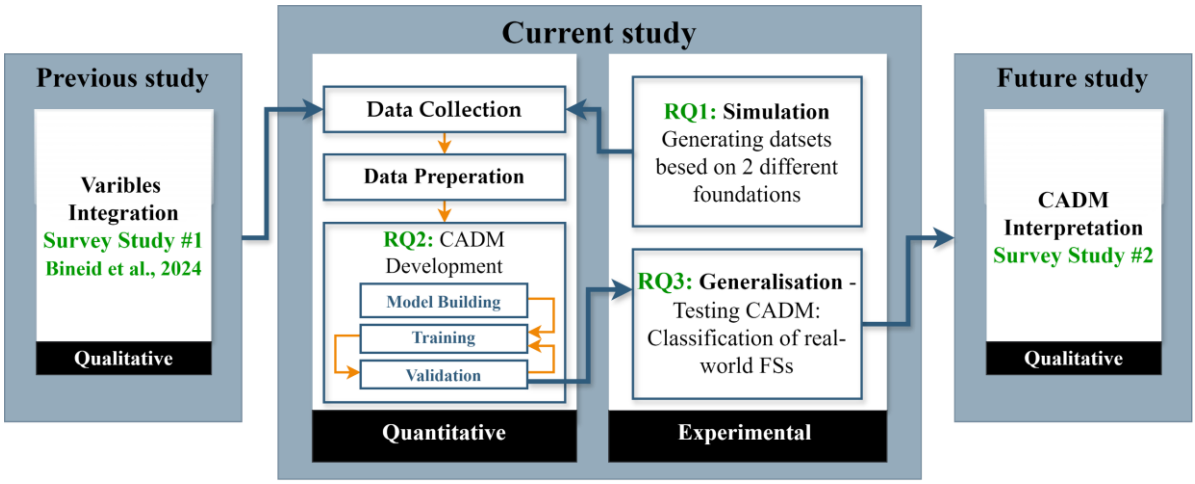

Fig. 1: CADM Research Framework

crease transparency, and attract domestic and foreign investment. These efforts are rooted in institutional reforms that began in the early 2000s, particularly with the creation of the CMA and have accelerated under the Vision 2030 economic transformation plan[22].

Saudi Arabia's enforcement of financial disclosure standards and IFRS compliance since 2017 has significantly improved the reliability and usability of its financial datasets. Real-world financial data can be accessed from the Saudi Exchange online platform (Tadawul), which provides official financial disclosures, including downloadable PDFs and Excel data. CMA and SOCPA platforms also offer regulatory filings, enforcement actions, historical announcements, standards, conversion guidelines, and auditor regulations. Third-party aggregators, such as Argaam.com and Mubasher.com, offer processed versions of the raw data; nevertheless, these platforms are commercially operated entities, not government-affiliated sources.

The Saudi market has 22 different sectors, each representing a distinct market segment with a varying number of companies in each sector. The largest sector by market capitalisation is the Energy sector, and the smallest is the Entertainment which has a limited number of companies with a relatively lower market capitalisation compared to others. Sectors and the exact number of companies can vary due to new listings and reclassifications in the market. However, FSs of Saudi-listed companies are publicly available in several formats. Tadawul provides financial data for all stakeholders, available in several formats, either online or offline. They also provide

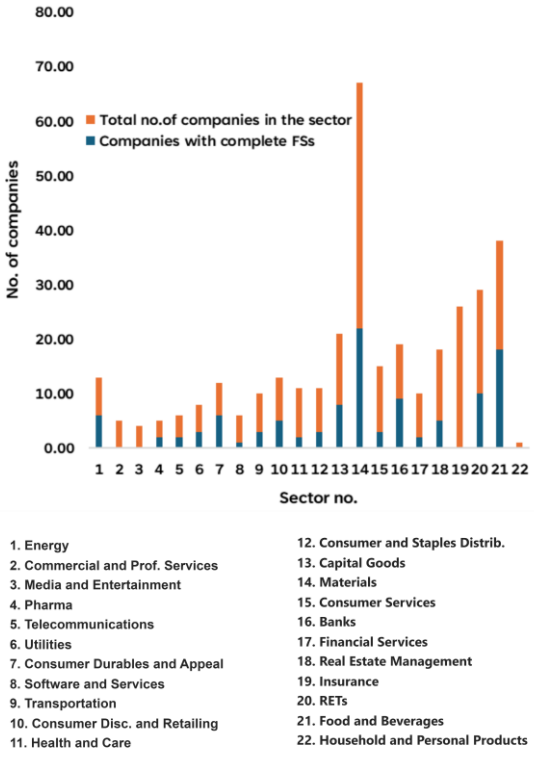

Fig. 2: Availability of FSs in the Saudi Market

a useful analytical tool for paid subscription users. But still, some companies fail to publish regularly in Tadawul, as shown in Fig. 2.

The Energy sector, having 7 companies, was chosen for this study. Although the Materials sector has the highest number of companies and is academically recognised for its high consistency across firms, making data preparation relatively easier, there was a concern that such uniformity might restrict the model's ability to learn diverse patterns and ultimately reduce training effectiveness. To better challenge the model and assess its generalisation capabilities, the Energy sector was selected due to the greater diversity among its companies.

C. *Simulation Strategy*

Although there is an increase in data availability, real-world examples of CA are challenging to find, particularly in the Saudi context [7], as companies do not usually admit publicly to using CA techniques. Without a real dataset, the best alternative would be to employ proxies, such as accrual-based analysis [26], on publicly available financial datasets to infer potential earnings management. However, accrual-based models like the Beneish M-Score [9] rely on assumptions and may not provide a definitive ground truth for CA, as they may include false positives and negatives, admitted by Beneish himself [10].

Moreover, AI strategies that can effectively address the lack of data in training deep learning models, such as Semi-supervised Learning, cannot be used because they lack the level of customisation needed in the dataset, and their results will be difficult to generalise [23]. It can also be helpful to use pre-trained models on a broader dataset (e.g., fraud detection models) as in Transfer Learning. Still, they are more likely to perform poorly on the domain-specific (Saudi-listed companies), and controlled variables (selected CA patterns) used in this research.

Consequently, simulating financial data appeared to be the optimal strategy that fulfils the need to have a sector-specific dataset with labelled data and controlled variables. Simulating financial statements is a well-established practice in the literature, employed for various analytical purposes. For instance, Leitch and Chen [24] simulated monthly FSs to evaluate key financial indicators and explore broader organisational dynamics.

Building upon their methodology, this study simulates two datasets: one based on general accounting measures and another tailored to the characteristics of the Saudi-listed companies, including financial (FIN) and non-financial (N-FIN) variables. Each dataset is prepared to train different versions of the CADM model. Generating a simulated dataset can explicitly encode CA techniques relevant to the Saudi business environment, providing flexibility for training scenarios and control over manipulation patterns, specifically when the base of the simulation is the real-world dataset. In other words, collecting the real-world dataset is essential to start the simulation process.

A structured pattern-based financial simulation approach has been utilised to generate the training dataset. First, two

primary goals were established: (1) to simulate a dataset closely resembling real-world data to ensure the model is effectively trained and (2) to account for four different scenarios of account manipulations, given the lack of clarity about the exact manipulation scenarios present in real datasets, if any. The dataset consists of two groups of companies: labelled as CA and labelled as N-CA (Non-Creative Accounting). The N-CA group was generated without applying any manipulations, while the CA group underwent an additional process where CA patterns were embedded.

To achieve the first goal, FIN features such as raw accounting data and financial ratios, and NFIN features such as CG metrics and auditor's status, were incorporated into the simulation process. To address the second objective of this study, two datasets were simulated using two different bases: one based on general accounting measures reported in the literature and the other grounded in real-world data analysis. The first simulated dataset (DST_DSL) was generated by adopting the simulation methodology proposed by Leitch and Chen [24]. For the second simulated dataset (DST_DSR), initial statistical analyses of the real-world dataset were conducted and used as the baseline for determining measurements and ratios. This dual approach enabled the training of two separate models on distinct simulated datasets, thereby enhancing the robustness and adaptability of the proposed detection framework. A summary of the datasets used in the processes is provided in Table I.

Both simulated datasets are validated before being used in training; they are statistically analysed to compare key financial metrics with the real-world dataset, ensuring that trends, outliers, and energy sector characteristics are aligned. This was performed iteratively; when the validation results were not acceptable, the simulation was redesigned, and the generation phase was restarted.

D. Feature Selection and Engineering

This study aims to simulate a set of widely recognised and frequently cited CA techniques, as in [25], [26], within a controlled dataset, representing them as manipulation patterns for CADM to learn from and detect. Four key CA patterns were selected for inclusion in the simulated dataset: revenue inflation, underreporting of COGS, assets overstatement, and underreporting of liabilities, as detailed in Table II. To make sure these patterns are relevant to the Saudi context, an additional layer of selection criteria was applied. Specifically, these techniques were also chosen based on their prevalence in the local literature [4], [19], [27], their documentation in real-world regulatory reports [28], and their alignment with the findings of the integration study [7].

To simulate a realistic and varied dataset, not all four CA techniques were applied to all companies in the CA label. Instead, each manipulated company was randomly assigned one of the four techniques, which was then consistently applied across all five-year financial periods. This approach avoids compound distributions that may arise from stacking multiple manipulation techniques and allows the model to learn distinct behavioural patterns associated with each manipulation type. It also better reflects real-world conditions, where companies typically engage in certain earnings management strategies over others based on their internal practices, industry norms, and regulatory pressure.

While other CA techniques have been identified in the literature, the selected CA patterns affect quantifiable financial ratios that make them suitable for detection by deep learning models based on time-series patterns. They are also compatible with the simulation process, as each technique can be implemented in a consistent and replicable way across multiple years. In addition, these patterns evolve, which is a key feature that aligns well with the capabilities of LSTM-based architectures. Finally, it is important to limit the number of manipulation types to control the model's complexity and reduce the risk of introducing noise or overlapping effects that could compromise the model's interpretability and reliability

TABLE II: SIMULATED TECHNIQUES OF CA

CA technique	**Behaviour in FSs**	**Simulation**
Revenue inflation	Revenue overstatement is one of the commonly used earnings management strategies and directly impacts key ratios such as net profit margin, EPS, and ROA [1], [2], [3].	A 15% inflation is applied to the revenue variable for each year for the generated companies.
Underreporting of COGS	This manipulation affects profitability without inflating top-line revenue and is less obvious than revenue inflation, thus posing a greater challenge for detection models[3], [4].	Reported COGS are decreased 10% (manipulated by 0.9) for each year while keeping the revenue constant.
Assets overstatement	This technique can distort key financial ratios such as ROA, current ratio, and debt-to-equity ratio. This tactic is commonly observed in cases where firms attempt to hide their losses or signal strength to creditors and investors [5].	Asset value is increased by 10% for each year across all years.
Liabilities underreporting	This practice is used to present a healthier financial position. It improves leverage ratios (debt-to-equity) and conceals financial risk. This pattern is particularly relevant in the credit evaluation context [3], [6].	Liabilities were reduced by 10%for each year, thereby relatively overstating equity.

Both financial (FIN) and non-financial (NFIN) indicators associated with the selected patterns were incorporated into the model. These indicators are typically variables integrated from financial reports and FSs. The selection of FIN variables was based on their relationship with the accounting pattern under examination. In contrast, non-financial variables were incorporated based on their demonstrated significance in identifying accounting manipulation, as evidenced by the findings of the integration study [7]. The model included 14 FIN (FIN1-FIN14) and 16 NFIN variables (NFIN1-NFIN20) as in Table III.

E. Model Architecture

The next step after data preparation and the identification of CA patterns is to select an appropriate deep learning technique for developing the predictive model CADM. As previously discussed, LSTM neural networks are widely regarded as one of the most effective methods for detecting unexpected anomalies in sequential unstructured data spanning multiple years. As an advanced type of RNN, LSTM is specifically designed to learn long-term dependencies in time series through a gated architecture. These gates, responsible for retaining, discarding, or updating information, enable the model to capture complex temporal relationships in historical financial statements.

Unlike traditional models, LSTM is robust against the need for extensive manual feature engineering, as it can automatically learn features from raw data. This allows for the inclusion of diverse FIN and N-FIN variables. Moreover, while CADM is designed to be trained using FIN and Non-FIN data, LSTM excels at modelling this non-linearity in data, specifically when it is required to capture temporal and contextual variables such as CGS measures, regulations, and multi-year data. This makes it possible to build a powerful deep learning model tailored to the Saudi business context. To effectively leverage these advantages, the CADM was implemented using multiple layers, where each layer contributes to progressively learning higher-level temporal features from the FIN and N-FIN input data. All LSTM-related mathematical formulations used in this study are adapted from Hochreiter and Schmidhuber [29], unless otherwise noted. The layered architecture (illustrated in Table III) is composed as follows:

Input Layer

The input layer receives sequential financial data spanning multiple years, structured as a time-series input as in Fig. 3. Each input sequence represents a company's FIN and N-FIN variables over consecutive reporting periods, allowing the

TABLE III: FIN AND N-FIN VARIABLES

Financial ratios	Liquidity	FIN9		Board meetings	NFIN10	Count
	Profitability	FIN10		Audit committee size	NFIN11	Count
	Efficiency	FIN11		Ownership concentration	NFIN12	0 compliant, 1 non
	Leverage	FIN12		CEO tenure	NFIN13	0 compliant, 1 non
	Market ratio	FIN13		Adopted standards	NFIN14	0 SOCPA, 1 IFRS
			Auditor	Auditor status[4]	NFIN15	0 currently unauthorised, 1 authorised
				Audit Big 4[5]	NFIN16	0 no, 1 yes
				Auditor allegations[6]	NFIN17	0 no, 1 yes

1. There are four types of **auditor opinions**. The most common opinion is the Unqualified (Clean) Opinion, where the auditor believes the FSs are accurate and comply with accounting standards. This value is represented by 0. The second opinion is issued when the FSs are mostly accurate, but there is a specific issue that does not comply with standards, often explained in detail. This is called the Qualified Opinion. The remaining two types of opinions represent two levels of FS's misrepresentation [28]. To simplify the model's input, any opinion other than the clean opinion is represented as 1.
2. **CEO duality** indicates if the Chief Executive Officer holds the position of chairman of the board of directors. This feature is one of the main CG influencers, as holding both roles can lead to a concentration of power and potentially affect the board's ability to oversee management independently. This CEO duality takes 1 if the CEO is also the Chairman of the Board (indicating CEO duality exists) and 0 if the CEO and Chairman roles are held by separate individuals (no CEO duality).
3. According to the Saudi regulations by the CMA [13], CG regulations demand that at least one-third of the board members must be independent. Independent directors are non-executives. All independents are non-executives, but not all non-executives are independents (they might have other relationships). Therefore, the threshold in our design is 33%, so at least 33% must be independent. If less than 33%, then 1 (dependent). If 33% or more, then 0 (independent). **Board dependency** is measured using the following formula: *BD = (independent directors/ directors) *100*
4. Because the **status of the auditing firm** in the present indicates some flags about its integrity and professionalism, the performance history by allegations and by the status of the auditing firm by the authorities is highly effective in the analysis. If the audit firm (for a specific year) is authorised, this value takes 0, otherwise, the value is 1 if the audit firm is suspended in the current year.
5. The **size of the auditing firm** is considered as an important auditor's reputation feature as indicated by the findings of [2]. This variable asks whether the auditing firm is considered one of the Big 4 firms in Saudi Arabia (KPMG, PWC, EY, and Deloitte). It takes 1 if one of the big 4s, 0 otherwise.
6. It leverages the audit firm if it has no **previous allegations** or lawsuits either with companies or the authorities. The variable takes 1 if the auditing firm has no previous or current allegations, otherwise, it is 0.

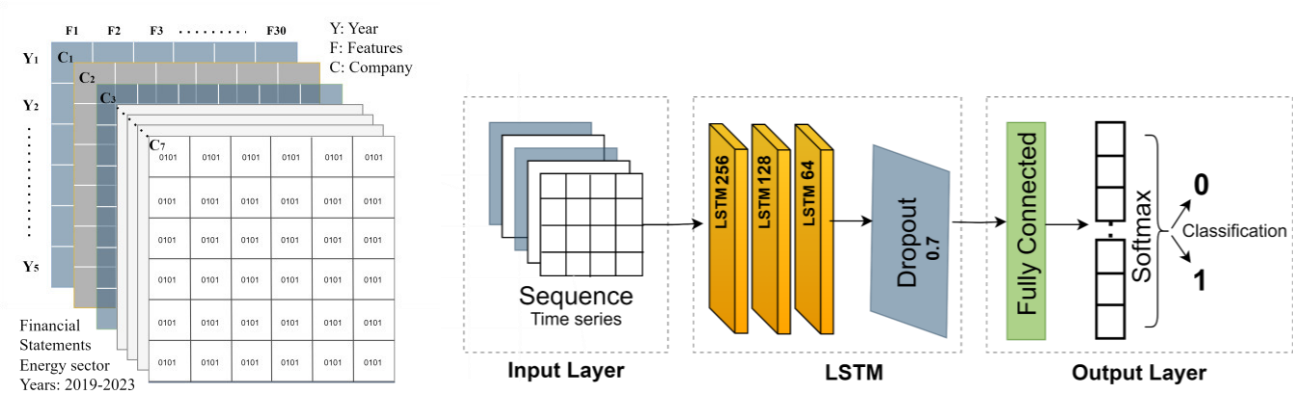

Fig. 3: Data Frame and Model Structure

model to capture temporal trends and patterns relevant to detecting CA. Time-series input can be mathematically expressed as follows:

$$X = \{x^1, x^2, x^3, \dots, x_T\}, x_t \in R^n \quad (1)$$

Where:
T number of time steps (years).
n number of features (financial + non-financial variables).
$\boldsymbol{x_t}$ feature vector at time step.

LSTM Layers

Multiple layers learn long-term dependencies between years of FSs, treating them as time series data. By leveraging memory cells and gated mechanisms, LSTM layers enable the model to identify changes in financial behaviour, such as trends in earnings manipulation or shifts in governance-related variables, that span across reporting periods. This is critical for CA detection, which may evolve gradually over time rather than appearing as sudden anomalies in a single year. The model consists of three LSTM layers with 256, 128, and 64 units, respectively. The first layer outputs the hidden states for all time steps to capture full temporal dependencies with 'sequence' output mode. The second layer with the 'last' output mode was used to summarise the input sequence into a single context vector, and the last layer with the same mode was used to further condense the sequential representation. The following equations describe the standard LSTM operation [29].

$$f_t = \sigma(Wfxt + Ufht - 1 + bf) \quad (2\text{-a})$$
$$i_t = \sigma(Wixt + Uiht - 1 + bi) \quad (2\text{-b})$$
$$o_t = \sigma(Woxt + Uoht - 1 + bo) \quad (2\text{-c})$$
$$\acute{c}_t = \tanh(Wcxt + Ucht - 1 + bc) \quad (2\text{-d})$$
$$c_t = f_t \odot c_{t-1} + i_t \odot \acute{c}_t \quad (2\text{-e})$$
$$h_t = o_t \odot tanh(c_t) \quad (2\text{-f})$$

Where:
σ: sigmoid activation $\boldsymbol{h_t}$: hidden state (output)
tanh: hyperbolic tangent activation $\boldsymbol{c_t}$: cell state
⊙: element-wise multiplication
W,U,b : trainable parameters

Dropout Layer

Since the model is trained on simulated data that may not fully reflect the variability of real-world financial statements, a dropout layer with a rate of 0.7 is applied to prevent data overfitting by randomly deactivating 70% of neurons during training. This regularises the LSTM model and reduces the risk of memorising synthetic patterns that do not generalise well to actual data.

Fully Connected Layer

This layer, with 2 neurons, aggregates the learned temporal features extracted by the preceding LSTM layers and maps them to the target output classes. By combining information across all time steps and input variables, the fully connected layer enables the model to produce a binary prediction that reflects the likelihood of CA behaviour in a company's financial statements.

$$z = W_{fc} h_T + b_{fc} \quad (3)$$

Where:
$\mathbf{W_{fc}}$: weight matrix for the dense layer
$\mathbf{b_{fc}}$: bias vector

SoftMax Layer

Performs binary classification (two classes, CA and N-CA). It consists of a single neuron with a sigmoid activation function, which outputs a probability score between 0 and 1, indicating the model's confidence that the financial statement exhibits CA behaviour. The threshold applied to convert this probability into a final class label is 0.5.

$$\bar{y} = \sigma(z) = \frac{1}{1 + e^{-z}} \quad (4)$$

Where:
$\bar{y} \in (\mathbf{0}, \mathbf{1})$ is the predicted probability of CA
A threshold $\boldsymbol{\theta = 0.5}$ is used to convert probabilities to class labels

$$\textbf{Predictions} = \begin{cases} 1 \; if \; \bar{y} > 0.5 & CA \\ 0 \; otherwise & N - CA \end{cases}$$

Training configuration

The model was trained using the Adam Optimiser for up to 100 epochs with a small mini-batch size of 10 to suit the limited number of training samples. Validation was performed every 5 epochs using a separate validation set, and early stopping was applied with a patience of 20 validation checks. Conversely, evaluation is performed once while training the model and another time during the testing phase, while comparing results. This phase is performed only once to assess the simulation efficiency.

F. Evaluation Metrics

An appropriate evaluation criterion must be established to assess the generalisation phase of both models and compare their performances. In the long-term plan of this research, the assessment criterion is to employ qualitative assessment, namely expert evaluation, to interpret testing results and validate the model's utility. This current stage relies on quantitative distributional analysis for the model outputs. Specifically, *SoftMax* confidence distributions are examined alongside the predicted labels to evaluate each model's behaviour and how biased it is towards each class. This approach allows for an initial assessment of how confidently the model classifies real-world FSs.

III. Implementation - The Experiment

This section details the implementation of CADM, focusing on the experimental process used to train and evaluate its performance. The implementation was carried out in the following phases: simulation (explained earlier), model training using the simulated datasets, model testing on real-world financial statements, and model evaluation as illustrated in Fig. 4 Training, Testing, and Evaluation phases are presented in the following subsections, outlining the experimental setup, hyperparameter choices, and evaluation outcomes.[22]

A. Training

As shown in Fig. 5, CADM1 achieved 100% accuracy in training and validation. In contrast, CADM2 achieved 92% accuracy in training and 80% accuracy in validation. All predicted labels were true by CADM1 and only 3 were false by CADM2 as shown in Fig. 6 These results were achieved after several iterations involving multiple rounds of dataset re-generation. The training datasets were carefully re-simulated to introduce variability and reduce the model's familiarity with recurring patterns, thereby promoting better generalisation and minimising overfitting.

To optimise model accuracy, various hyperparameters were fine-tuned, including the number of LSTM Units. They experimented with different neuron counts to determine the optimal balance between model complexity and learning capacity. While smaller configurations, such as 128, 64, and 32 units, were initially considered to reduce overfitting, the final architecture adopted a larger structure —256, 128, and 64 units —demonstrating improved learning performance without compromising generalisation. This architecture, applied to both CADM1 and CADM2, retained sufficient capacity to capture complex temporal dependencies in the data while maintaining robust performance on unseen samples, despite the relatively small dataset size.

Moreover, the Learning Rate was adjusted to prevent convergence issues, and the batch size and epochs were optimised for computational efficiency and model performance. Additionally, L2 regularisation was applied and a dropout layer to mitigate overfitting. Finally, the Optimiser Selection compared Adam, RMSprop, and SGD to identify the most effective optimisation strategy.

B. Testing

Following the training of both models, CADM1 and CADM2, the next step is to test them to assess their generalisation capabilities. Testing is designed to be implemented on

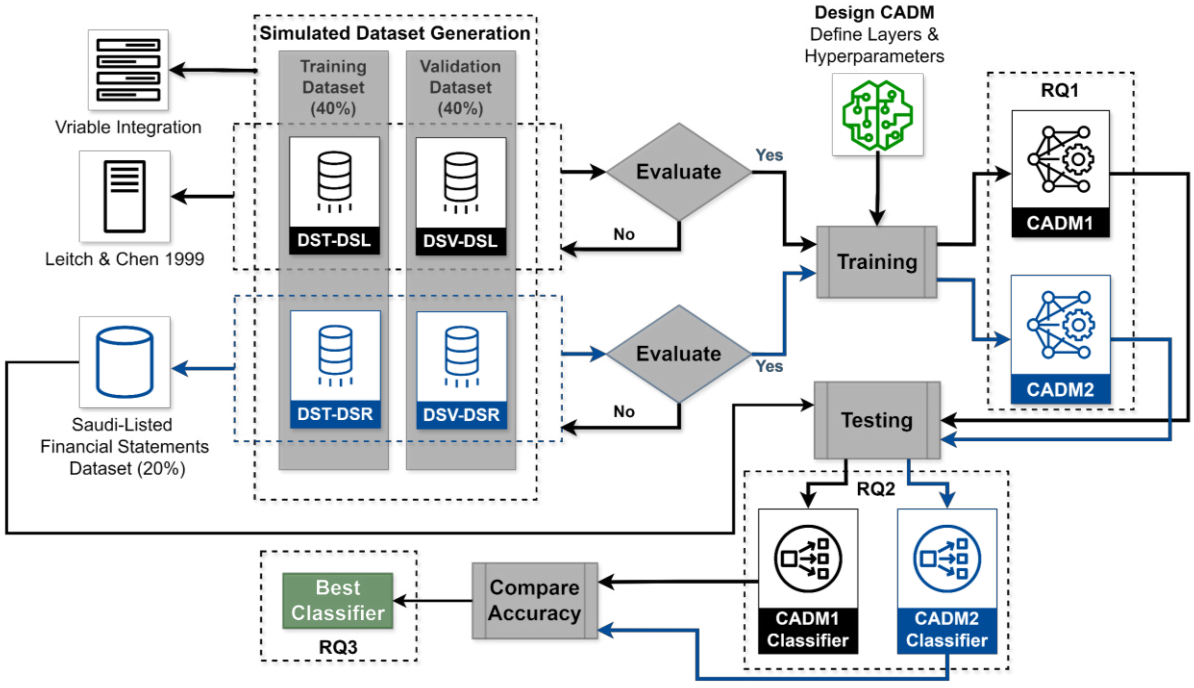

Fig. 4: Workflow of CADM Simulation, Training, Testing, and Evaluation

the real-world dataset; the collected and pre-prepared FSs, which have become DSR after preparation. Due to having two models, testing was done twice on the same dataset. However, DSR is prepared to be in the same shape as the simulated dataset to have correct and accurate testing and be ready to be used by CADM.

However, CADM1 predicted five out of six companies as class 1 (CA) Fig. 7, but with SoftMax probabilities clustered very close to the classification threshold (ranging between 0.5001 and 0.5042) Fig. 8. The single prediction of class 0 (N-CA) was also marginal, with a class 0 probability of just 0.5004. This narrow range of values indicates that CADM1 was uncertain in its predictions, which reflects the model's weak classification capability and lack of confidence when applied to real-world financial statements.

In contrast, CADM2 predicted all companies class 0 (N-CA) Fig. 7, with SoftMax probabilities ranging from 0.5021 to 0.5063. Being close to the decision threshold as well does not indicate any better performance than CADM1, although they have more consistency (all above 0.5). Still, CADM2 demonstrates modest and more stable confidence in labelling the data.

IV. Discussion

This study successfully developed and evaluated two LSTM-based models (CADM1 and CADM2) to classify FSs

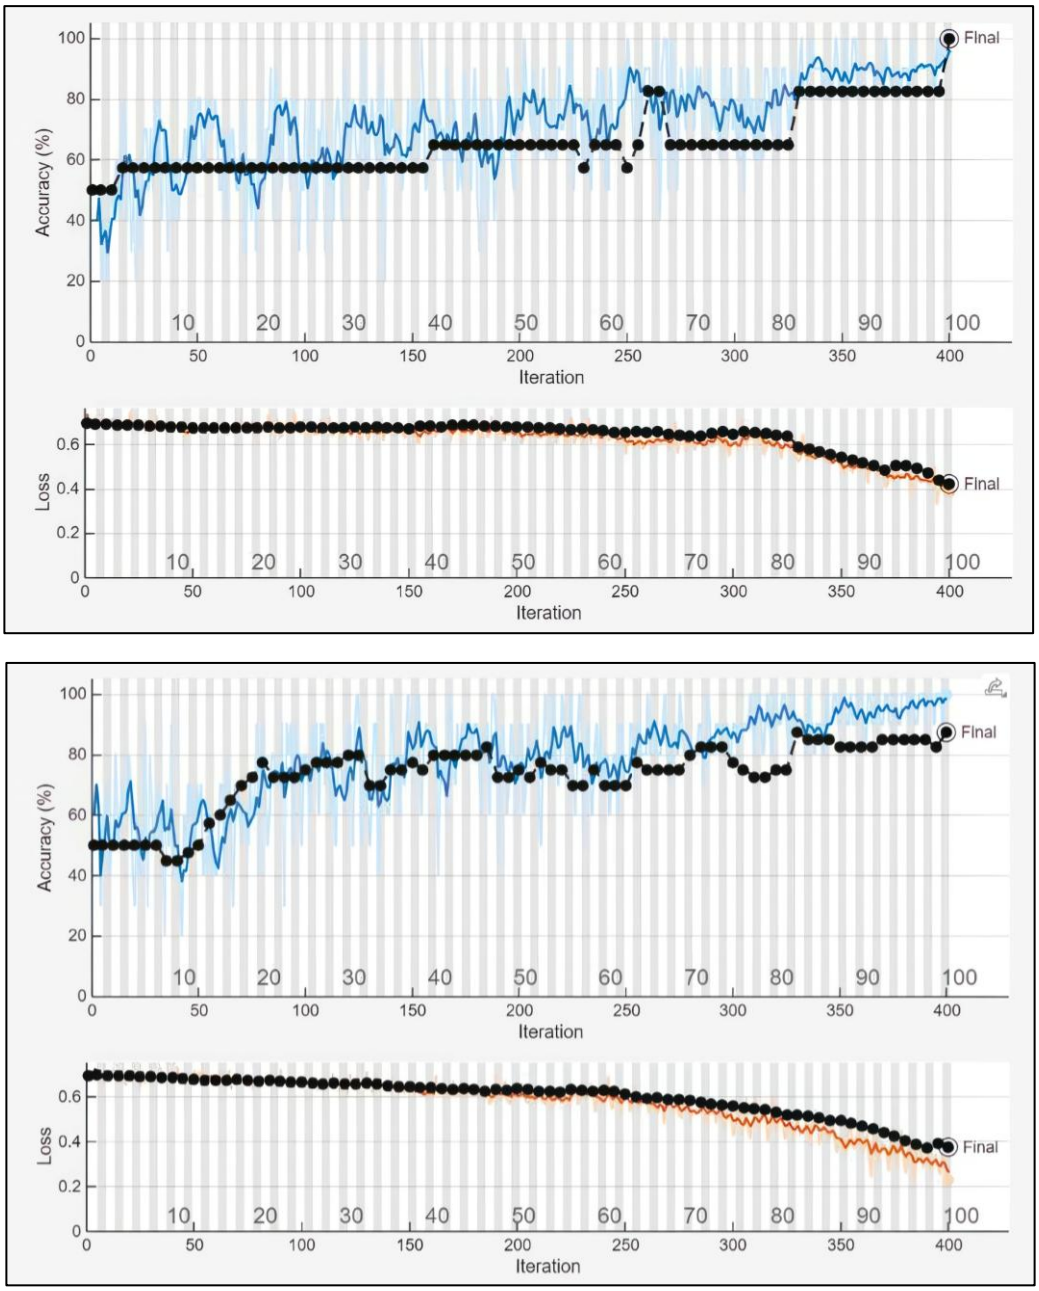

Fig. 5: Training accuracy and loss curves for CADM1 (top) and CADM2 (bottom), showing the models' learning performance over 100 epochs

based on the likelihood of CA practices being used in their preparation. The models were trained and validated to assess their effectiveness in controlled simulations and real-world Saudi market data. Additionally, the study compared the models' performance regarding the underlying simulation approach used to generate their training dataset. This section discusses the research objectives and demonstrates meaningful contributions to DL-driven financial analysis.

RQ1: Training CADM: Learning from Simulated Data

The results of training CADM reflect a key contrast between real-world context and theoretical modelling. CADM1 achieved perfect accuracy (100%) in both training and validation phases. This technical success confirms that the model architecture is responsive to clean data with well-defined patterns. However, this result may also indicate overfitting to the ideal dataset that lacks real-world variability.

In contrast, training CADM2 was more challenging. Despite extensive hyperparameter tuning, CADM2's accuracy was lower than CADM1's, reflecting the inherited complexity of real-world Saudi financial behaviour. This result is not a flaw but a strength: it underscores CADM2's exposure to more realistic noise, non-linear interactions, and imperfect relationships characterising actual FSs.

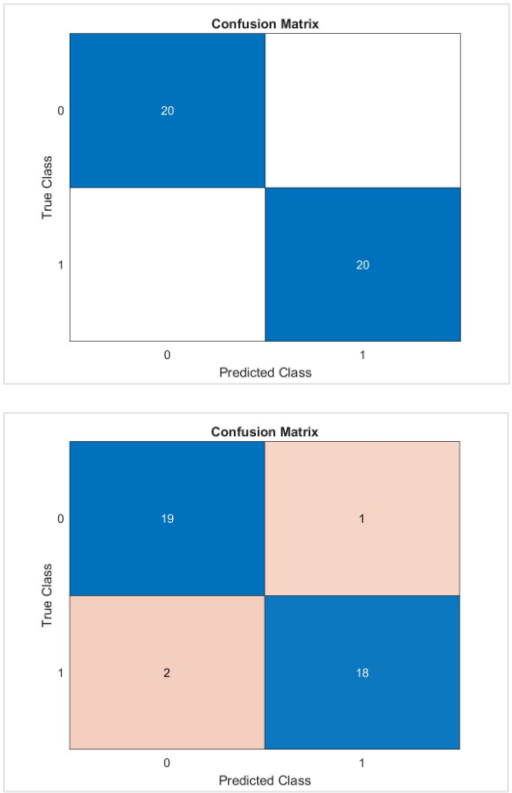

Fig. 6: Classification Results of CADM1 Training (top) and CADM2 Training (Bottom)

In addition, the training dynamics promote valuable reflections on the boundaries of CADM's optimal performance, raising questions about model robustness and the interpretability of results when using overly cleaned data, a significant debate in DL-based financial models. CADM1's perfect performance might not perfectly generalise to real-world data, while CADM2, despite lower learning scores, likely learned patterns closer to reality. This observation supports the argument in the literature about the risk of training financial AI models on idealised datasets.

RQ2: Generalisation: Performance on Real-World Data

As ground truth for CA is not available, innovative assessment methods become necessary. At this stage of the research, the generalisation capacity of both models was evaluated using class distribution patterns and feature-based differentiation. Although theoretically accurate, CADM1 was more liable to misclassification when confronted with real-world variance. In contrast, the final version of CADM2 testing showed that all companies in the Energy sector are CA-free. This can be interpreted as the model trained on a dataset that already sees these scenarios as non-CA, which reflects stronger generalisation capacity from CADM2.

From the perspective of CA theory, CA is intentionally designed to evade detection mechanisms. Consequently, a deep contextual understanding and the incorporation of non-financial signals are essential for effective detection. This may explain the comparatively better classification performance by CADM2 when tested on real-world FSs, as it appears to have

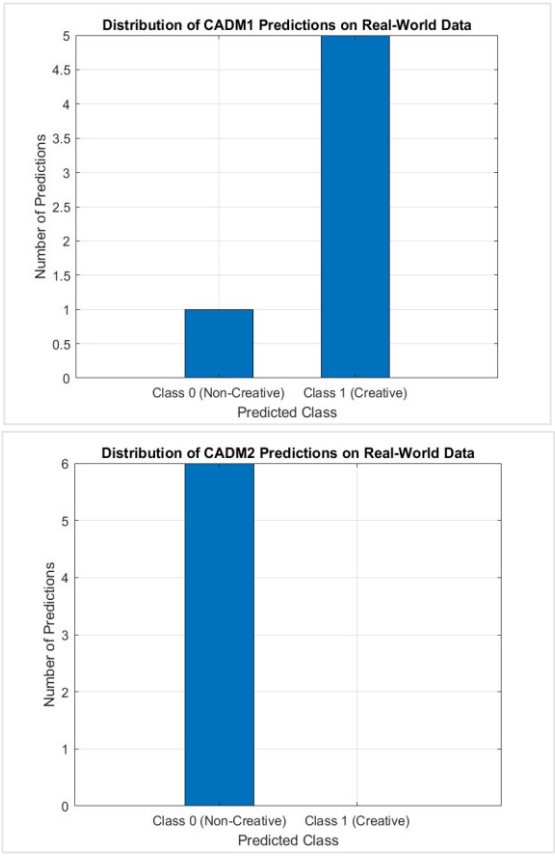

Fig. 7: Classification results of CADM1 (top) and CADM2 (bottom) on the real-world dataset, showing predicted counts for Class 0 (N-CA) and Class 1 (CA).

captured some attributes of the complexity inherent in real-world data. Nevertheless, generalisation was naturally challenged by sector-specific anomalies. Companies in this sector have diverse accounting scenarios and include a dominant outlier (ARAMCO), with significantly different scales and metrics compared to its peers. These factors influenced the model's sensitivity and underscore the importance of sector-aware tuning in future iterations.

RQ3: Evaluating The Simulation Base: Theory vs Reality

The comparison between CADM1 and CADM2 provides critical insight into how simulation strategy affects model behaviour. Evaluating the simulation base was done by comparing the results of CADM1 and CADM2 classifiers. The SoftMax probability distributions further illustrate these tendencies. While CADM1 demonstrated theoretical strength, CADM2 has more consistent confidence values, particularly when they were consistently above 0.5 and demonstrated more stable confidence in labelling companies as N-CA. The more consistent confidence profile of CADM2 is attributed to its training on a dataset simulated using real-world statistical analysis, which enabled it to better mirror the characteristics of actual financial reporting in the Saudi market. This confirms the validity of using real-world statistical patterns in training simulations.

The contrasted results between CADM1 and CADM2 illustrate that models trained on idealised literature-driven simulations achieve higher accuracy yet lower generalisation ability to real-world FSs compared to models trained on real-world-based simulations. This supports the theoretical argument in the literature that training models on clean data may not adequately prepare them for the complexities and imperfections found in real-world data [30], [31]. In addition, the experiment in this study suggests that hybrid approaches, such as blending literature-based metrics with real-world features, may offer the most promising path forward.

V. Conclusion

This study represents a significant milestone in developing a data-driven framework for detecting CA within Saudi-listed companies. By training two variants of the Creative Accounting Detection Model (CADM) using different simulation criteria, this research establishes a credible foundation for AI-enabled financial monitoring. The model was then tested on the real-world dataset collected from the Saudi market portal to check if the model is capable of looking at how financial and non-financial metrics evolve, CADM and classifying Saudi-listed companies in the Energy sector as creative accounting or non-creative accounting practitioners.

Both SoftMax confidence distributions of CADM predictions on the real-world dataset models offer a significant insight: the importance of strong theory and the need to reflect real-world scenarios when detecting financial anomalies. The implication of this study extends beyond model performance. It sets a new direction for applying deep learning to complicated grey areas like creative accounting. Unlike fraud detection, this model identifies forms of financial misrepresentation that fall within regulatory bounds but still distort finan-

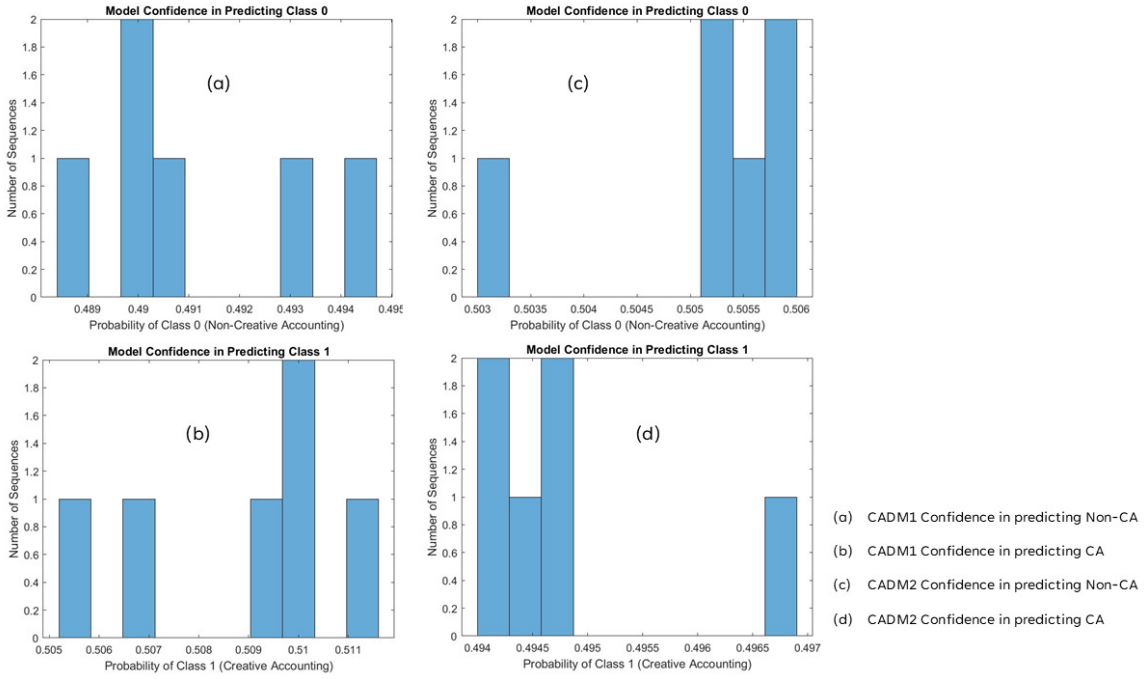

Fig. 8: SoftMax confidence distributions of CADM predictions on the real-world dataset

cial reality. Further research may involve integrating additional financial indicators such as the revenue recognition, misclassification of accounting elements, and off-balance sheet financing, and governance indicators, such as management compensations and narrative disclosure. It could also add explainability mechanisms to the model, such as applying custom attention layer to the model to enhance model transparency and make CADM a valuable tool for regulators and auditors. In addition, the simulation scope could be expanded to have semi-creative accounting data, and the testing could include other sectors to improve sensitivity and real-world relevance. Future work is intended to integrate expert interpretation of classification results through interviews to validate the model's output and illuminate practical constraints.

This research serves as a foundation for the next generation of intelligent accounting analytics. Besides considered a proof of the feasibility of AI in financial transparency, it promotes meaningful integration of simulation, sector knowledge, and regulatory insight.

***Abstract*—This article presents an evaluation of Large Language Models with support for the Polish language, focusing on their ability to accurately extract detailed information embedded within input text called Faithfulness. This scenario reflects a typical use case in Retrieval-Augmented Generation systems, where precise factual recall is critical. For this purpose, a modified needle-in-a-haystack test was conducted, in which all queries targeted numerical values concealed within extended textual contexts. The evaluation was based on recent reports from Poland's Central Statistical Office (GUS), ensuring that the content was not included in the training data of the evaluated models.**

The results demonstrate that the best-performing model was NeuralDaredevil-8B-Abliterated, followed by PLLuM-12B-instruct and Bielik-11B-v2.3-Instruct. Notably, the error rate of NeuralDaredevil-8B-Abliterated was approximately half that of the second- and third-ranking models, marking a significant performance gap. The article also explores potential explanation for these discrepancy.

I. Introduction

ONE of the prominent and increasingly common applications of large language models (LLMs) is the integration with external information retrieval systems through a method known as Retrieval-Augmented Generation (RAG). RAG bridges the capabilities of LLMs with classical retrieval-based techniques, forming a hybrid system that combines the flexibility of generative models with the precision of structured data access. In this approach, a user query submitted to the RAG system is first processed by an information retrieval component, which selects the most relevant source documents from a predefined knowledge base. These retrieved documents are then appended to the original query and collectively passed to the language model. As a result, the model's response is informed not only by the user's input but also by the curated external content, effectively enriching the context provided to the LLM.

This architecture addresses several key challenges associated with the practical deployment of LLMs in business and industrial settings. One significant advantage of RAG is its ability to provide access to up-to-date and domain-specific information without requiring time-consuming and resource-intensive model retraining. Furthermore, RAG supports fine-grained permission control, allowing systems to retrieve only those documents that a user is authorized to access—thus aligning with enterprise data governance requirements. Perhaps most critically, RAG contributes to reducing the incidence of hallucinations—a common issue in generative models wherein outputs are plausible-sounding but factually incorrect. By grounding responses in retrieved, authoritative documents, RAG enhances the factual accuracy and reliability of generated outputs, making it a valuable framework for knowledge-intensive tasks across domains.

A significant challenge in the deployment of large language models (LLMs) lies in the limited availability of models that support the Polish language. This issue is particularly acute in business and institutional contexts, where data privacy and security requirements often necessitate on-premise deployment of LLMs rather than reliance on commercial cloud-based solutions. Despite the growing ecosystem of open-weight LLMs developed by leading research consortia—such as LLAMA, MISTRAL or QWEN—these models typically lack adequate support for Polish, making them less suitable for direct application in Polish-language tasks without additional fine-tuning or adaptation.

Although the Hugging Face platform offers a diverse collection of LLMs fine-tuned for the Polish language, preliminary investigations reveal that only a small subset of these models demonstrate the reliability and performance required for real-world applications. Many available models exhibit functional limitations, including issues such as repetitive text generation or outright failure to produce coherent outputs. These limitations underscore the need for a systematic evaluation of Polish-capable LLMs, particularly those with open weights suitable for secure, local deployment.

To address this gap, a curated selection of ten models was identified for detailed evaluation. These include four models with a context window of 4096 tokens: Bielik-11B-v2.3-Instruct, Bielik-7B-v0.1, trurl-2-13b, and gpt-3.5-turbo-instruct; five models with an extended context window of 8192 tokens: NeuralDaredevil-8B-Abliterated, Llama-3-8B-Omnibus-1-PL-v01-INSTRUCT, Kruk-7B-SP-001, Starling-

Topical area: Advanced Artificial Intelligence in Applications

LM-7B-alpha, and OpenChat-3.5-0106-Gemma; and one model, PLLuM-12B-instruct, supporting a 128k token context window. This selection serves as the foundation for comparative analysis in terms of stability and accuracy of identifying the detailed knowledge expressed in Polish-language.

Various methods for evaluating large language models (LLMs) have been proposed in recent literature [1]. However, when it comes to Retrieval-Augmented Generation (RAG) applications, the evaluation task often becomes more nuanced. In such scenarios, the primary objective is to assess the model's ability to extract specific and precise information embedded in a larger body of text—particularly when the required detail may be a minor element, potentially buried within an extensive document. To verify performance under these conditions, a modified version of the "needle in a haystack" test [2] was employed in this study. That allows for verification of the quality of the detailed knowledge extraction mechanism implemented in the LLMs measuring the Faithfulness of the model.

The article is structured as follows. The next section provides a short overview of LLM's evaluation techniques, then in section III the modified "needle in a haystack" test is described. Next in section IV, the details on the performed experiments are provided, and in the following section, the obtained results are discussed. The last section discusses the obtained results, identifying possible sources of differences between these models.

II. Large Language Models Evaluation Methods

Evaluating the performance of Large Language Models (LLMs) and Retrieval-Augmented Generation (RAG) systems is essential for ensuring their reliability, robustness, and alignment with real-world applications [3], [4]. Typically for LLM evaluations metrics such as BLEU, ROUGE, METEOR, and LEPOR are used [5]. They evaluate the n-gram overlap between generated and reference texts. These metrics are primarily used in tasks like machine translation and summarization. However, they may fall short in capturing semantic correctness and contextual relevance. In terms of semantic evaluation the common approach is based on embedding-based metrics leverage vector representations (e.g., Sentence-BERT) [6] to quantify the semantic similarity between outputs and reference texts. Additionally, LLM-as-a-Judge methodologies employ a language model to assess generation quality based on coherence, relevance, and factual correctness, offering a more nuanced and human-like evaluation [7]. Another approach for LLM's evaluatino is based on human evaluation. Despite being resource-intensive, human evaluation remains the gold standard. Annotators rate generated outputs based on fluency, factual accuracy, and relevance, although results may be subject to variability across raters. There are also several automated evaluation frameworks among which DeepEval [8] and ARES [9] have streamlined the model evaluation process. The DeepEval integrates various metrics and supports LLM-as-a-Judge assessments, while ARES reduces the dependency on human annotations by training lightweight evaluators for tasks such as context relevance and answer faithfulness.

In the context of RAG, the evaluation task becomes more complex due to the multi-component architecture of the system. A typical RAG pipeline includes a document corpus, an information retrieval module, and a large language model (LLM) that processes the retrieved document chunks to generate a final response. Each of these components can be evaluated individually, as well as in terms of their overall contribution to the system's performance.

The retrieval module is commonly assessed using several key metrics. Relevance measures how well the retrieved documents correspond to the user query. Comprehensiveness evaluates the diversity and coverage of retrieved content, ensuring that different aspects of the query are captured. Correctness refers to the accuracy of retrieved documents compared to all possible relevant candidates. Context Relevance assesses whether the retrieved context is sufficient to support a correct and complete response to the query. Fore more details see [10].

The LLM component can also be evaluated using distinct criteria. Faithfulness captures the degree to which the generated response accurately reflects the information found in the retrieved documents. Relevance, in this context, refers to the alignment of the generated response with the user's query intent. Key Point Recall measures how well the response incorporates essential information from the retrieved content. Response Completeness evaluates whether the answer fully addresses the user's query, while Response Conciseness assesses the amount of extraneous or irrelevant content present in the response. (see [11])

In this work, we focus only on the Faithfulness measure of the models supporting the Polish language.

III. The Modiffied "needle in a haystack" test

The classical formulation of the needle in a haystack test involves embedding a sentence containing a specific piece of factual information into a longer textual passage, followed by querying the model with a prompt that indirectly or directly references this content. While this method provides a foundational framework for assessing factual recall in language models, it exhibits several limitations. In particular, the artificial insertion of a standalone sentence often lacks semantic coherence with the surrounding context. This disjunction can disrupt the natural flow of the passage and interfere with the attention mechanisms of transformer-based architectures, potentially introducing artifacts that obscure the model's true retrieval capabilities. Consequently, such tests may not reliably reflect performance under realistic usage scenarios.

To overcome these shortcomings, the evaluation methodology was refined by embedding the target information in a more contextually integrated manner. Instead of inserting isolated factual statements, passages were selected or constructed to ensure that critical details were naturally embedded within a coherent narrative structure. Queries were then formulated to require comprehension, synthesis, and accurate retrieval of these embedded facts. In particular, we focused on numerical

facts that can be easily and precisely evaluated, allowing for direct measurement of the quality. In particular, we measured the relative error of the returned numerical value. This approach better reflects real-world RAG conditions, where relevant information is interwoven with broader context, and ensures a more robust and valid assessment of model behavior.

Beyond these refinements, the needle in a haystack framework was extended to investigate two additional factors critical to LLM evaluation: context length and needle position. The first factor concerns the hypothesis that shorter textual contexts simplify retrieval by reducing the model's search space, whereas longer contexts pose greater challenges due to increased sequence length and potential dilution of attention. The second factor addresses the position of the target information within the passage. Intuitively, content located at the beginning or end of a prompt may be more salient and thus more easily retrieved, whereas information embedded in the middle of the context may be less accessible. Evaluating model performance across these dimensions provides deeper insight into their retrieval fidelity and helps characterize their suitability for deployment in practical, high-recall RAG systems.

IV. The Experiment Setup

For the purpose of model evaluation, a test corpus was constructed using recently released reports from Poland's Central Statistical Office (GUS). The use of this data ensured that the language models under evaluation had not encountered the content during their pretraining, thereby minimizing the risk of data leakage and enabling a more rigorous assessment of generalization and retrieval capabilities. Notably, the information queried from the models consisted primarily of numerical values, which served as the "needles" in the evaluation framework. The use of numeric data allowed for an objective and precise evaluation of retrieval accuracy, as the model outputs could be directly compared against ground truth values.

A detailed list of the source documents used in the study, along with the corresponding needle information, is provided in Table I.

The query used in the evaluation is presented in Table II

The evaluation method for scoring the quality of the model is shown in Figure 1. It searches for a part of the text containing numbers and then calculates the relative error between the extracted value and the true value. If the answer doesn't contain numerical values, the returned error is 1.

An additional critical factor examined in this study was the influence of input text length on retrieval performance. The evaluation encompassed models with three different context window sizes: 4096 tokens, 8192 tokens, and one model supporting an extended context length of 128k tokens. Accordingly, two main families of experiments were conducted: one for models limited to a 4096-token context, and another for those capable of handling 8192-token contexts. To ensure consistency in the comparative analysis, the 128k-token model was evaluated using inputs constrained to 8192 tokens.

(b) Bielik-7B-v0.1

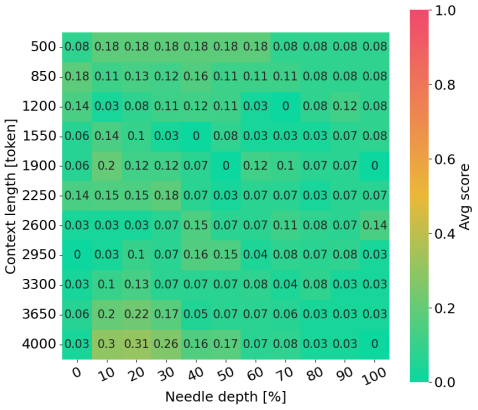
Figure 2: The results obtained for models with 4k context length. Part A. X-axis represent the depth of the needle, and Y-axis represent context length.

To systematically assess the effect of input size, each model was tested on 11 different text lengths. Additionally, the influence of the needle's position within the input was evaluated by placing the target information at 11 distinct locations throughout the text, including the beginning, middle, and end. This design enabled a comprehensive investigation into how retrieval performance varies with respect to both input length and the positional salience of the information.

The following models were selected for evaluation using a 4096-token context window:

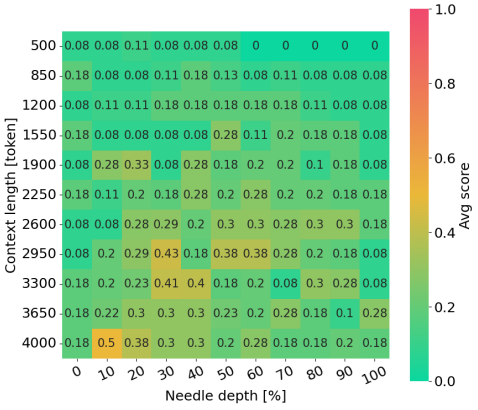
- Bielik-11B-v2.3-Instruct,
- Bielik-7B-v0.1,
- trurl-2-13b,
- gpt-3.5-turbo-instruct,

and for the context length of 8196 tokens the following models were evaluated



- NeuralDaredevil-8B-Abliterated,
- Llama-3-8B-Omnibus-1-PL-v01-INSTRUCT,
- Kruk-7B-SP-001,
- Starling-LM-7B-alpha,
- OpenChat-3.5-0106-Gemma,
- PLLuM-12B-instruct.

V. Results and Discussion



As described in the previous section, the experiments were conducted separately for models with two different maximum context lengths. The results are presented using heatmap visualizations on a two-dimensional grid, where the X-axis represents the relative depth (position) of the needle within the input text, and the Y-axis denotes the length of the input context. Each cell in the heatmap reflects the probability of an error, with values ranging from 0 (indicating no errors across all test samples) to 1 (indicating that the model consistently failed to retrieve the correct information). Accordingly, green indicates perfect accuracy, while red denotes complete failure in retrieval. To facilitate consistent visual interpretation, the same colormap scale was used across all heatmaps, allowing for direct comparison of prediction performance across different models and experimental conditions.

A. 4k Context Length

- **Bielik-11B-v2.3-Instruct** The results are presented in Figure 2a. The findings indicate that the model exhibits

(a) Trurl-2-13b

(b) GPT3.5-turbo-instruct

Figure 3: The results obtained for models with 4k context length. Part B. X-axis represent the depth of the needle, and Y-axis represent context length.

a consistent error probability across the evaluated range, suggesting that the likelihood of an error is not significantly influenced by either the needle depth or the context length. In all cases, the observed errors corresponded to a single test case involving the needle *W porównaniu z lipcem ub.r. wzrosło znaczenie barier niedoboru wykwalifikowanych pracowników (z 17,1% do 21,9%)* and the query *Do ilu procent wzrosło znaczenie barier niedoboru wykwalifikowanych pracowników w porównaniu z lipcem ub. r.?*, where the model consistently returned the first numerical value instead of the second one, despite the query clearly referencing the latter.

- **Bielik-7B-v0.1** The results are shown in Figure 2b. These indicate that the model's performance is highly dependent on the position of the needle. Specifically, the model is particularly sensitive when the needle is located early in the context—around 20% of the total context length. Additionally, its performance deteriorates with longer context lengths. For the longest context length, the model failed in approximately one-third of the cases when the needle was situated at about 20% depth.

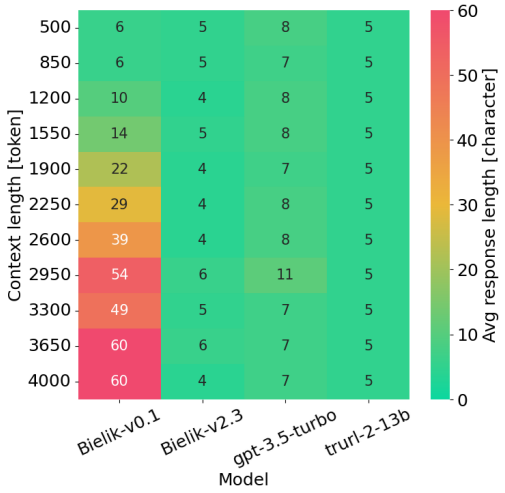


Figure 4: Relation between context length and the length of returned output in tokens for 4k models.

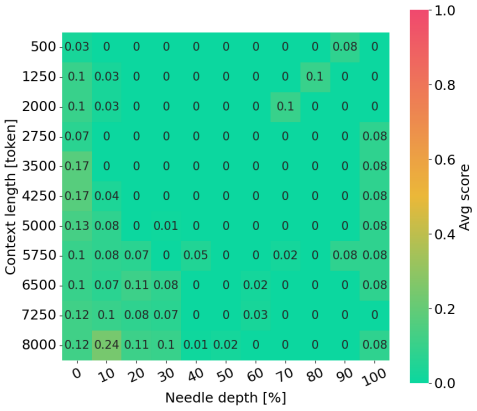
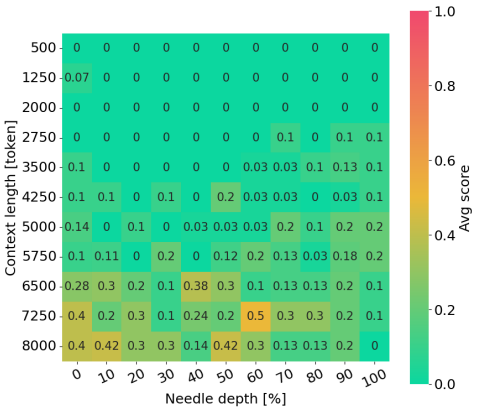


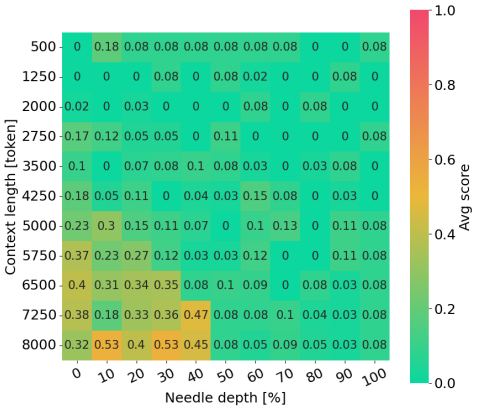
- **Trurl-2-13B** The corresponding results are presented in Figure 3a. The model exhibits a performance pattern similar to Bielik-7B-v0.1, with the most significant errors occurring when the needle is positioned at around 20% of the context depth and when the context length approaches its maximum. However, unlike Bielik-7B-v0.1, Trurl-2-13B shows improved performance when the context length is reduced to 3300 tokens or fewer.
- **GPT-3.5-turbo-instruct** The results are shown in Figure 3b. Among all evaluated models with a 4k token context window, this model demonstrated the weakest performance. In the worst-case scenario, it exhibited an error rate of up to 50% when the needle was located near the beginning of the context (approximately 10%) and at the maximum context length. It also frequently produced incorrect answers for shorter context lengths around 2950 to 3300 tokens, where Trurl-2-13B performed comparatively well. GPT-3.5-turbo-instruct only achieved reliable performance when the context length was limited to 1550 tokens or less.

In summary, the best-performing model with a 4k context length was Bielik-v2, followed by Trurl, while GPT-3.5 surprisingly demonstrated the weakest performance.



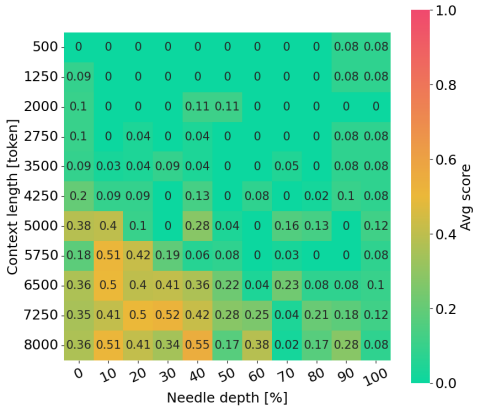
Additional insight is gained by analyzing the length of the output stream generated by the models, as shown in Figure 4. The results indicate that the Bielik-v1 model tends to produce significantly longer outputs, averaging up to 60 tokens when the context length approaches 4k. This is in stark contrast to the expected output, which typically consisted of only a few tokens representing a numerical value. This excessive verbosity contributed to a substantial increase in error rates.

B. 8k Context Length

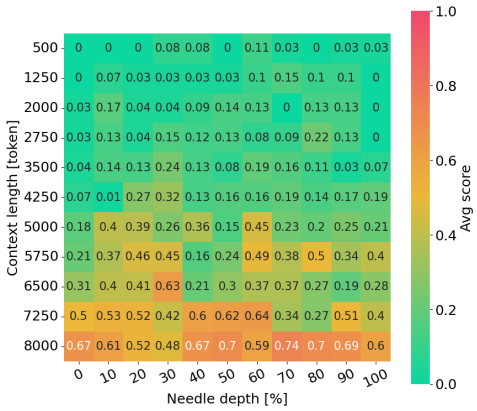


- **NeuralDaredevil-8B-Abliterated** The obtained results are shown in figure 5a. The model for a vary large part of

(a) [NeuralDaredevil-8B-Abliterated



(b) Llama-3-8B-Omnibus-1-PL-v01-INSTRUCT



(c) Kruk-7B-SP-001

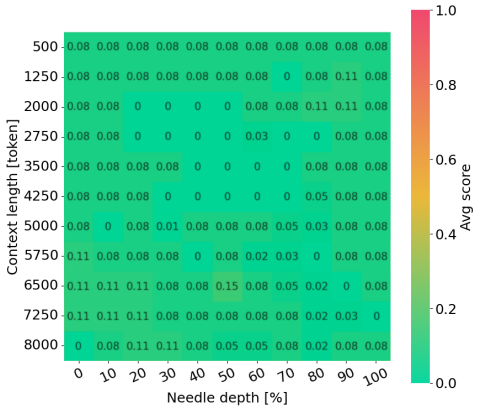


Figure 5: The results obtained for models with 8k context length. Part A. X-axis represent the depth of the needle, and Y-axis represent context length.

(a) Starling-LM-7B-alpha

(b) OpenChat-3.5-0106-Gemma

(c) PLLuM-12B-instruct

Figure 6: The results obtained for models with 8k context length. Part B. X-axis represent the depth of the needle, and Y-axis represent context length.

the experiment space didn't achieve any error. The errors appeared when the needle was located at the beginning of the context as the context length was growing. But the error rate was even though relatively low.

- **Llama-3-8B-Omnibus-1-PL-v01-INSTRUCT** The obtained results are shown in figure 5b. It achieves perfect predictions for short context length up to 4k, but when the context length starts to grow it starts to fail. The worst results are obtained for very long context at its begining.
- **Kruk-7B-SP-001** The obtained results are shown in figure 5c. It has similar behavior to all other models. Its error rate starts to grow when context is getting long and the needle is located at the begining. When compared to the omnibus model it can be observed a significant higher error rates for context length below 4k.
- **Starling-LM-7B-alpha** The obtained results are shown in figure 6a. Starling behaves similarly to Kruk except it has better performance for shorter context. Athough, it is warse for larger context, and achives slighly higher error rates.
- **OpenChat-3.5-0106-Gemma** The obtained results are shown in figure 6b. It is the worst of evaluated 8k models. It got larger error rates for the short context, and significantly worse results for the long context, where the error rates reaches 70% when the context length is close to 8k. But when compared to the 4k models it achieves similar performance reaching 0.32 error rates for context close to 4k.
- **PLLuM-12B-instruct** The obtained results are shown in figure 6c. Again it has very good performance for short context, and similarly when the context grow it achieves larger error rates but at most reaching 34%. This allows to get the second place behind NeuralDerdevil model.

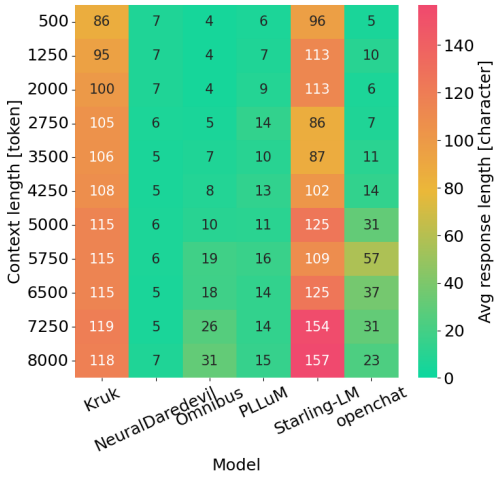

Figure 7: Relation between context length and the length of returned output in tokens for 8k models.

- **NeuralDaredevil-8B-Abliterated**
  The results are presented in Figure 5a. Across a large portion of the experimental space, the model achieved near-perfect performance. Errors occurred primarily when the needle was positioned at the beginning of the context as the overall context length increased. However, even in these cases, the error rate remained relatively low.
- **Llama-3-8B-Omnibus-1-PL-v01-INSTRUCT**
  As shown in Figure 5b, this model achieved perfect predictions for context lengths up to 4k tokens. However, performance degraded as the context length increased, with the most significant errors observed when the needle was located near the beginning of long contexts.
- **Kruk-7B-SP-001**
  The results, depicted in Figure 5c, show a pattern similar to other models. Error rates increase with longer contexts, particularly when the needle is located near the beginning. Compared to the Omnibus model, Kruk exhibits significantly higher error rates for contexts shorter than 4k tokens.
- **Starling-LM-7B-alpha**
  Figure 6a illustrates that Starling's behavior is comparable to Kruk's. It performs better for shorter contexts but shows slightly worse performance as context length increases, with marginally higher error rates overall.
- **OpenChat-3.5-0106-Gemma**
  The evaluation results, shown in Figure 6b, indicate that this model is the weakest among the evaluated 8k-context models. It exhibits higher error rates even for short contexts and significantly poorer performance for long contexts—reaching up to 70% error when the context is close to 8k tokens. However, when limited to 4k contexts, its performance aligns with that of other 4k-context models, reaching an error rate of approximately 32%.
- **PLLuM-12B-instruct**
  The results in Figure 6c show that the model performs very well for short contexts. As with other models, error rates increase with longer contexts but remain relatively low, peaking at around 34%. This strong performance places it second only to the NeuralDaredevil model.

In summary the best performing model among 8k models was NeuralDaredevil followed by PLLuM, and the worst one is OpenChat. Similarly to the 4k models, worth deeper investigation is the output text token length. Such relation is shown in figure 7. It shows that Starling and Kruk has significant longer output length. These models insted of returning precise output value that was queried, returned full sentence, often setence containing the output text. Similarly Omnibus and OpeChat when couldn't find the answer in the text returned full sentence insted of simple and short answer.

C. Summary and Discussion

In summary, among the evaluated models, NeuralDaredevil-8B-Abliterated achieved the best performance, followed by PLLuM and Bielik. The weakest performance was observed for OpenChat - see Figure 8.

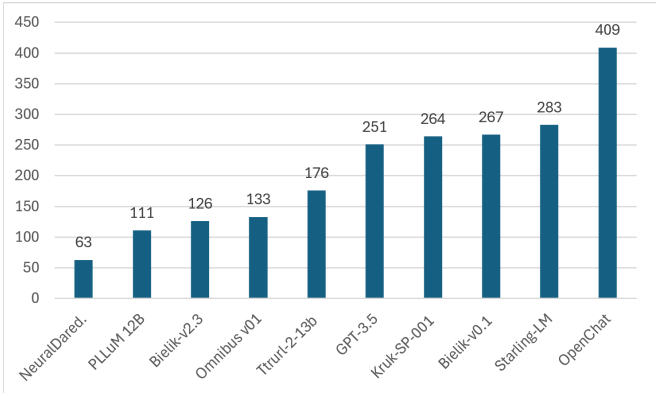

Figure 8: Number of factual errors made by each evaluated model.

It is particularly notable that the NeuralDaredevil-8B-Abliterated model significantly outperformed all other models, including PLLuM and Bielik-v2.3. The error rates for PLLuM and Bielik-v2 were nearly twice as high as those observed for NeuralDaredevil. A closer inspection revealed that the majority of errors across models were linked to a single query: *W porównaniu z lipcem ub.r. wzrosło znaczenie barier niedoboru wykwalifikowanych pracowników (z 17.1% do 21.9%)* and the corresponding question *Do ilu procent wzrosło znaczenie barier niedoboru wykwalifikowanych pracowników w porównaniu z lipcem ub. r.?* In this case, many models incorrectly returned the initial value (17.1%) rather than the correct final value (21.9%). This suggests difficulties in interpreting comparative constructions in Polish, particularly the meaning of prepositions such as "z" (from) and "do" (to).

One possible explanation for NeuralDaredevil's strong performance lies in the abliteration process, which may enhance the model's generalization capabilities. Previous studies have shown that excessive safety alignment or over-optimization can negatively impact a model's reasoning and factual recall abilities [12], [13], [14]. NeuralDaredevil-8B-Abliterated is a fine-tuned variant of the Daredevil-8B model based on the LLaMA-3 architecture. Fine-tuning was conducted with a single pass over the `mlabonne/orpo-dpo-mix-40k` dataset using the Direct Preference Optimization (DPO) method [15]. The abliteration technique, as described by Arditi et al. [16], involves removing the activation direction associated with refusal behaviors in the transformer's residual stream. This modification may allow the model to respond more freely to prompts that might otherwise trigger refusal responses, thereby improving reasoning in neutral tasks such as factual retrieval.

Furthermore, a consistent pattern across all evaluated models was observed: retrieval performance degraded as the input text approached the maximum context length and the target (needle) appeared near the beginning of the document. This is visually evident in all the figures (2,3,5 and 6), where the bottom-left corners (representing early-position needles in long contexts) are more yellow, indicating higher error rates. In contrast, queries located in the first half of the context window often resulted in near-perfect accuracy, as seen with models such as NeuralDaredevil-8B-Abliterated, Llama-3-8B-Omnibus-1-PL-v01-INSTRUCT, and also in Starling-LM-7B-alpha. This suggests that attention limitations in transformer-based models still substantially impact retrieval success in long-context scenarios.

Interestingly, some models—namely Bielik-11B-v2.3-Instruct and PLLuM-12B-Instruct—exhibited relatively stable error rates across the entire context window. This may be a result of their fine-tuning strategies, which could help mitigate the performance degradation typically caused by long input sequences.

Summarizing the length of the returned output shown in Figure 7 and Figure 4 some models tends to return significantly longer responses. In particular Starling and Kruk consistently produced significantly longer output sequences. Instead of returning a concise value in response to the query, these models often generated full sentences that included or paraphrased the expected output. Similarly, Omnibus and OpenChat, when unable to locate the exact answer in the context, tended to return verbose responses rather than the brief, precise values requested. This behavior may contribute to higher error rates and reduced response faithfulness in scenarios requiring exact factual retrieval.

VI. Conclusions

The primary goal of this research was to evaluate the ability of language models to accurately extract factual information from Polish input texts, rather than focusing on the linguistic quality of their output. This problem was formulated to provide a rough estimate of the models' susceptibility to hallucinations when used in Retrieval-Augmented Generation (RAG) systems, particularly in the context of less commonly supported languages such as Polish. Among the evaluated models, NeuralDaredevil-8B-Abliterated clearly outperformed both PLLuM and Bielik-v2. Surprisingly, the commercial GPT-3.5 model performed poorly, exhibiting twice as many errors as PLLuM or Bielik, and four times as many as NeuralDaredevil.

Additionally, a recurring type of error was observed across models: the misidentification of numerical values in comparative statements. Specifically, models often selected the initial value instead of the final one in scenarios describing change over time. This indicates a difficulty in precisely understanding certain linguistic constructs, that is a challenge in correctly interpreting comparative expressions involving "from" (Polish: *od*) and "to" (Polish: *do*).

Finally, our results revealed that all models experienced a decline in retrieval accuracy when the input text approached the maximum context window and the relevant information (needle) was located near the beginning of the document. This highlights a continuing limitation of transformer-based architectures in processing long documents, due to the reduced effectiveness of attention mechanisms over extended contexts. These findings underscore that, despite recent advancements,

long-range dependency handling remains a significant challenge for contemporary language models.

***Abstract*—This paper presents a model-driven AI-assisted approach for generating IT project management plan and scope documents, aiming to improve efficiency and quality in software development projects. Effective documentation in the early project phase is critical, yet often resource-intensive. The proposed solution consolidates best practices from widely used project management methodologies and standards to create a dynamic, adaptable framework for document generation. The study identifies key components and input data required for generating high-quality plans using model transformations and generative AI. A prototype supporting the solution is developed featuring a local processing engine, integrated with a large language model, a vector database, and an embedded model.**

***Index Terms*—IT project management, project documentation, model-driven development, generative AI, prompt engineering, software development automation, large language models, AI-assisted tools.**

I. Introduction

IN MODERN IT project development, the demand for accelerated delivery cycles continues to increase, driven by competitive pressure, agile practices, and customer expectations [1]. One of the most critical processes in the early phases of the project lifecycle is the development of project documentation [2]. Well-structured documentation, such as project management plans and scope statements, forms the basis for mutual understanding between clients and delivery teams, and contributes directly to project success and client satisfaction [3].

To address the need for speed without compromising quality, automation tools have been introduced to support documentation processes. These tools can generate content based on reusable templates, domain knowledge, and recognized best practices [4]. However, most existing solutions act as passive assistants, requiring significant manual effort to ensure completeness, consistency, and compliance with professional standards [5].

Since the emergence of generative artificial intelligence (AI) technologies around 2020 [6], there has been growing interest in using AI to automate the creation of project documentation. Generative models such as large language models (LLMs) [7] offer promising capabilities for producing structured, domain-specific texts [8]. However, researchers should overcome challenges related to the need for precise prompt formulation, ensuring contextual relevance, managing data quality, and aligning with industry standards [9]. Addressing these challenges requires not only technical solutions but also methodological guidance.

This raises a fundamental research question: Is it possible to integrate generative AI into documentation development without compromising quality and compliance? This paper investigates this question by proposing an AI-assisted solution grounded in software engineering principles, aiming to maintain documentation integrity while leveraging the potential of generative AI. The research goal of the results presented in this paper is to develop an AI-assisted solution for generating IT project management plan and scope documents applicable in software development projects, by consolidating best practices in project documentation as defined across various development methodologies and industry standards.

The paper is organized as follows. The next section discusses the research background and summarizes the related literature. Section 3 presents the foundations used in the solution and Section 4 explains the essence of the solution. Section 5 demonstrates the practical application of the solution and comments its validation and improvements. The final section summarizes the main research findings and outlines directions for future work.

This research has been supported by Research and Development grant No RTU-PA-2024/1-0015 under the EU Recovery and Resilience Facility funded project No. 5.2.1.1.i.0/2/24/I/CFLA/003 “Implementation of consolidation and management changes at Riga Technical University, Liepaja University, Rezekne Academy of Technology, Latvian Maritime Academy and Liepaja Maritime College for the progress towards excellence in higher education, science, and innovation”.

II. Background and Related work

Since the emergence of generative artificial intelligence (AI) technologies around 2020, such as OpenAI's GPT-3 [6], there has been growing optimism that AI could dramatically streamline project documentation by enabling the automatic generation of high-quality documents in just a few clicks. The rapid advancement of LLMs has fueled expectations that these tools could reduce the manual effort required for creating project specifications, requirement documents, and other critical deliverables. However, several significant challenges remain in realizing this vision fully:

1. Generative AI often struggles to capture the specific organizational context, domain terminology, and stakeholder expectations that are essential for meaningful documentation [9].
2. Effective AI-generated documentation depends heavily on the availability of structured, high-quality input data. In many real-world projects, this data may be incomplete, ambiguous, or inconsistent [10].
3. Automatically generated content can raise concerns about traceability, authorship, and the responsibility for errors or omissions in critical documents [11].
4. Industry-specific methodologies and compliance requirements (e.g., ISO, IEEE) can be difficult to encode into generic AI systems without significant customization [12].
5. Even advanced generative tools require skilled human supervision to ensure accuracy, relevance, and alignment with project goals [13].

These limitations suggest that while generative AI has strong potential to support project documentation, its role is currently best viewed as augmentative rather than fully autonomous. Future developments may narrow these gaps, but effective human-AI collaboration remains essential for reliable outcomes in IT project documentation.

Recent studies have demonstrated the growing potential of generative AI in enhancing project management processes, particularly in the areas of documentation, planning, and efficiency. One of the key applications of generative AI is the automation of project documentation, including project plans and scope definitions. AI models can consolidate and structure content from various sources to generate standardized and coherent documents, ensuring compliance with project management standards and improving overall consistency [14]. Additionally, generative AI is increasingly used to generate meeting summaries, translate technical content, and update project texts, contributing to more accurate and timely documentation [15].

In project planning, AI tools can support a wide range of functions such as scope definition, scheduling, cost estimation, resource allocation, stakeholder analysis, and risk assessment. Some studies suggest that generative AI can match or even outperform human planners in certain structured planning tasks, while still requiring expert oversight for contextual decisions [16]. Moreover, the integration of AI in Agile methodologies has shown promise in optimizing team workflows, enhancing collaboration, and automating repetitive tasks [17]-[18].

The collaboration between human project managers and AI systems has been identified as a critical factor for success. Key performance indicators for such collaboration include efficiency gains in time, cost, and resource usage, as well as improved quality, clarity, and accuracy of project outputs [19]. Research also highlights the benefits of using generative AI in the early stages of innovation, such as digital prototyping and ideation, where rapid iteration and content generation are crucial [20].

However, several challenges remain. Effective integration of AI into project management environments must address issues such as input data quality, compatibility with legacy systems, and ethical concerns regarding algorithmic transparency and accountability [21]-[22]. Furthermore, while generative AI can produce initial drafts of project documentation, human expertise is still essential to validate and refine the output to ensure relevance, accuracy, and compliance with specific organizational contexts [16].

These findings underscore the dual role of generative AI as both an accelerator and a collaborator in project management. The literature suggests that while generative AI tools provide substantial benefits, their successful implementation relies on structured prompts, methodological support, and continuous human oversight.

To address the limitations of generative AI in project documentation, Nikiforova, *et al.* [23] proposed a solution based on the integration of model-driven development (MDD) principles. By embedding structured models into the AI-assisted documentation process, the approach aims to constrain and guide AI output according to predefined rules, templates, and domain-specific semantics. This model-driven approach helps overcome common issues such as contextual inconsistency, structural errors, and lack of standard compliance. It also enhances traceability and maintainability by linking generated content to formal models that represent project requirements and design logic.

In response to the limitations of generative AI tools, researchers and practitioners have increasingly focused on the field of prompt engineering, which is the practice of crafting and structuring input prompts in a way that guides AI systems to produce higher-quality, more relevant outputs [24]. Rather than relying on generic instructions, prompt engineering emphasizes precise formulations, contextual cues, and example-based guidance to improve the performance of language models in complex tasks such as project documentation. The emerging field of prompt engineering aims to optimize prompt formulation in order to elicit high-quality, contextually accurate responses from generative models [25].

This emerging discipline is particularly relevant in domains like IT project management, where document quality is influenced by terminology accuracy, logical structure, and compliance with standards. By experimenting with different prompt

patterns, researchers aim to understand how to systematically elicit responses that align with user expectations and domain-specific requirements.

Early studies and practical experiments indicate that carefully designed prompts can significantly enhance the clarity, completeness, and consistency of AI-generated documents. As a result, prompt engineering is becoming a critical skill for those seeking to integrate generative AI into documentation workflows, bridging the gap between AI capabilities and real-world needs.

The research presented in this paper builds upon the idea of constraining generative AI to reduce hallucinations and uncontrolled variability in generated content. The proposed approach is oriented toward leveraging the strengths of model-driven engineering by generating as much documentation content as possible through formal model transformations [26]. Where model transformation is insufficient, such as in the generation of narrative or descriptive elements, prompt engineering is applied, guided by artifacts from the target model [27]. This ensures that even AI-generated free-text sections remain contextually relevant, structurally aligned, and traceable to defined project components. The overall goal is to balance AI creativity with formal control, reducing risks while maintaining efficiency and adaptability.

III. Research Methodology and Conceptual Framework

This research follows the Design Science Research (DSR) methodology as proposed by Hevner et al. [28], which is widely used for the development and evaluation of IT artifacts. The goal is to create a novel, AI-assisted solution for generating IT project management plan and scope documentation. This artifact integrates model-driven engineering principles with generative AI capabilities to support early-phase documentation in software development projects.

In accordance with Hevner's seven guidelines for DSR, this study:

1. Designs an innovative artifact – a model-driven framework and software prototype for document generation;
2. Addresses a relevant business problem – namely, the inefficiency and inconsistency in early-phase project documentation;
3. Is evaluated through practical application and iterative refinement;
4. Contributes both a utility-focused solution and theoretical insights into the integration of generative AI with structured project management models;
5. Applies rigorous methods for modeling, implementation, and validation;
6. Communicates the research effectively to both academic and practitioner audiences;
7. Clearly situates the research within the context of information systems and project management disciplines.

The proposed approach balances the creative potential of generative AI with the structural rigor of model-driven development. The main objective is to constrain AI-generated content within well-defined semantic and syntactic boundaries, ensuring compliance with established project management standards described in the next subsections.

A. Model-Driven Development Principles

Model-Driven Development (MDD) is a software engineering approach that emphasizes the use of formal models as the primary artifacts throughout the development lifecycle [29]. Instead of writing low-level implementation code directly, developers create abstract models that define system structure, behavior, and logic [30]. These models are then transformed into executable code or other technical artifacts through automated tools. The main goal of MDD is to increase productivity, improve consistency, and reduce human error by shifting development effort to higher levels of abstraction.

MDD was originally developed to address complexity in large-scale systems and to enable better alignment between business requirements and technical implementation. It has proven particularly effective in domains requiring precision, standardization, and traceability, such as embedded systems, enterprise architectures, and critical software solutions.

Based on systematic literature mapping of solutions offered under the MDD idea, Nikiforova *et al.* [31] conducted an in-depth analysis of transformations between key artifacts used in the early phases of IT projects, that is, before the implementation stage. The study focused on identifying how different project artifacts, such as goal models, process models, use case models, domain models, and architectural overviews, can be interrelated through formal transformation rules.

The research highlights that certain artifacts can be automatically derived from others using well-defined transformation methods, significantly reducing manual effort and increasing consistency across documentation. For instance, structured requirements can be transformed into initial system models or project plans with minimal human intervention. However, not all relationships are fully automatable (shown as dotted lines in Fig. 1), some transformations still require manual refinement or validation, especially in cases involving complex contextual interpretation or stakeholder input. Exactly, these transformations can be assisted with the usage of generative AI.

An overview of all these artifact transformations and their interdependencies is illustrated in Fig. 1 [27]. This schema serves as a foundation for the proposed AI-assisted generation process, where transformation rules help define the scope of content that can be automatically constructed and guide the prompt generation strategy for generative AI components.

Although MDD adoption has declined in recent years, partly due to the rise of more lightweight, iterative approaches like Agile [32], the core idea of structuring development around formalized models remains powerful. In the context of generative AI, MDD principles offer a unique advantage: they can provide a well-defined, controlled input structure for guiding AI outputs.

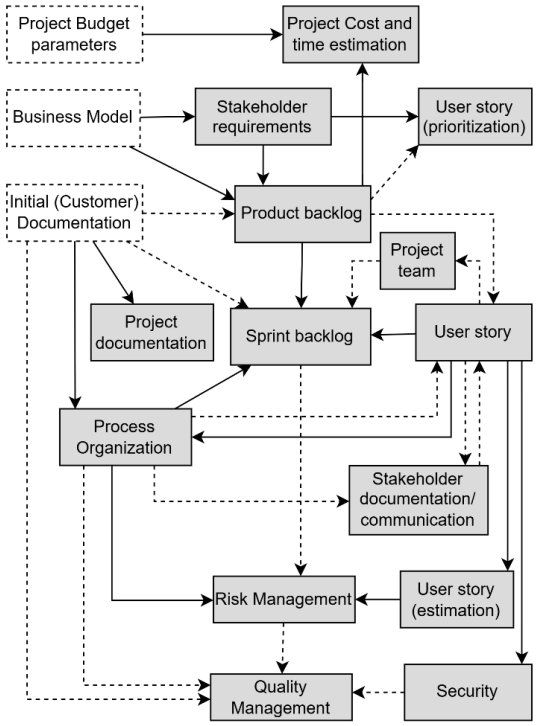

Fig 1. Transformation among IT project artifacts

This makes it possible to constrain generative models within meaningful boundaries, improving the reliability and quality of generated content. By reintroducing MDD concepts into AI-assisted documentation generation, this research aims to combine the rigor of model-driven processes with the flexibility of modern language models, achieving better control, relevance, and integration in project management documentation workflows.

B. Software Engineering Standards

The implementation of software engineering standards plays a vital role in ensuring consistency, quality, and traceability in IT project documentation. Given the increasing complexity of software development projects and the integration of AI-assisted tools, aligning documentation processes with internationally recognized standards becomes not only beneficial but necessary. The proposed solution leverages the following software engineering standards:

1. ISO/IEC/IEEE 29148:2018 Systems and software engineering — Life cycle processes — Requirement's engineering [33];
2. ISO/IEC/IEEE 16326:2019 Systems and software engineering — Life cycle processes — Project management, 2019 [34];
3. ISO 21502:2020, Project, programme and portfolio management — Guidance on project management, 2020 [35];
4. Corresponding elements of SWEBOK [36];
5. Corresponding elements of PMBOK [37].

Software engineering standards are used in two ways. The first, they define the macrostructure of the document (like in the way presented in Fig. 2) [31].

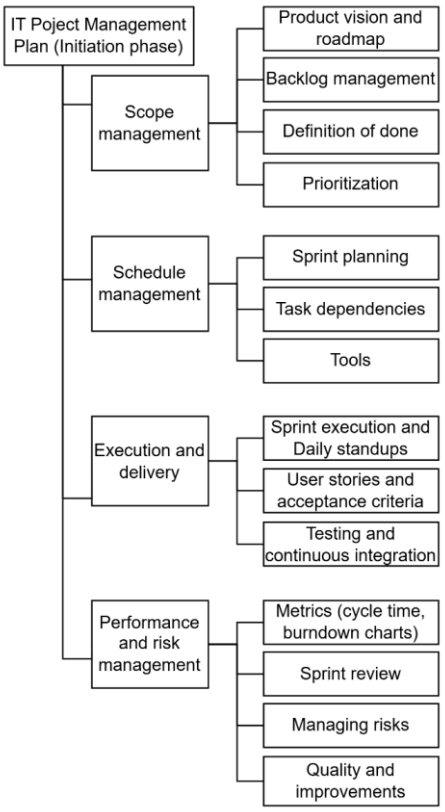

Fig 2. IT project documentation structure and content

The standards' instructions are used to guide the structure and content of generated project documents. These standards provide clear expectations regarding the format, terminology, and required content of artifacts such as project charters, requirement specifications, and management plans.

And, the second, the standards shape the micro-level instructions that guide the AI in generating specific paragraphs or sections. Rather than embedding static prompts into the generative AI component, this solution dynamically generates prompts based on structured input, specifically utilizing content derived from model transformations. The AI model is thus directed by prompts that are themselves informed by software engineering standards and documentation guidelines. This ensures that generated outputs are not only linguistically fluent but also semantically aligned with professional project management practices.

For example, prompts for requirement specification generation integrate instructional content drawn directly from ISO/IEC/IEEE 29148:2018, such as the need for completeness, verifiability, traceability, and feasibility.

Additionally, content expected from model transformations, such as stakeholder roles, system goals, and component descriptions, is automatically fed into the prompt generation process. This staged approach enables the AI to act within clearly defined semantic boundaries while maintaining flexibility for natural language output. This mechanism represents a hybrid strategy that combines the strength of model-

driven development with the adaptive capabilities of generative AI. By grounding prompt generation in formal standards and structured content, the solution significantly reduces the risk of hallucinations and irrelevant output, ensuring higher reliability and usability of project documentation.

In summary, the integration of software engineering standards serves as a scaffolding for both the structure and semantics of AI-generated project artifacts. It bridges the gap between free-form generative models and formal documentation requirements, resulting in outputs that are both technically valid and aligned with industry expectations.

IV. Solution Design and Approach

This section presents the formal framework and implementation of the proposed approach for AI-assisted generation of project documentation. The solution is built on a hybrid methodology, combining model-driven development (MDD), prompt engineering, and alignment with software engineering standards listed in previous sections.

The proposed solution is based on the principle that structured artifacts (i.e., models, templates, and metadata) should guide document generation. When natural language output is required, prompt engineering is applied, combining structured artifacts and guidance to direct the language model. This hybrid approach reduces hallucinations and improves consistency. The solution operates through several stages:

- **Input Stage:** Project-specific structured artifacts, such as project artifacts, are provided as input. Wherever possible, content is derived from model transformations, using approaches and tools like [38] [39].
- **Instruction Stage:** Documentation structure and content expectations are sourced from industry standards. These sources serve as a foundation for structuring both the overall layout and the content of the generated documentation. Excerpts from standards, such as definitions, guidelines, and section requirements, are used as instructional cues within prompts to ensure that the generated text aligns with professional expectations.
- **Transformation Stage:** Input artifacts and instruction templates are combined through structured transformation logic (defined in JSON), which dynamically generates task-specific prompts.
- **Generation Stage:** These dynamic prompts are used to control a language model (LLM) that generates natural language output. Furthermore, in the proposed solution, the prompts used by the generative AI component are not static or hardcoded. Instead, they are dynamically generated based on software engineering standards and best-practice "instructions," as well as content defined through model transformations. This means that the system first interprets structured input, such as elements derived from project models, and then constructs a tailored prompt to guide the language model.
- **Validation Stage:** Output is validated against structural schemas and evaluated on semantic alignment, completeness, and relevance.

A key innovation is the dynamic generation of prompts based on model-driven and SE standards-based inputs. Instead of using static instructions, the approach uses structured data to generate a prompt, which in turn is used to generate the final documentation text. This “generative AI powering generative AI” approach ensures that outputs are both contextually relevant and semantically accurate, thus allowing precise alignment between structured models and natural language output and reducing the likelihood of irrelevant or hallucinated content. It is like a controlled pipeline that leverages automation while maintaining contextual fidelity and compliance with documentation standards.

The system is implemented in Python using the Ollama framework. A locally hosted LLaMA 3.2:3b model handles language generation, while ChromaDB stores embedded vector representations of source content. The conceptual schema of the solutions architecture is shown in Fig. 3. Following the outlined stages, a generative AI-based solution was developed, structured around three key modules: the Input Module, the Processing Module, and the Output Module.

The **Input Module** validates and processes user-provided files, including contextual documents and control JSONs. Uploaded PDF content is split into fragments using token limits and overlap parameters to preserve context. Each fragment is embedded as a vector and stored in ChromaDB, along with metadata such as file type and source ID. Instruction files are parsed into stepwise JSON objects for controlled processing.

The **Processing Module** executes semantic queries based on the instruction steps. Each step retrieves relevant fragments using vector similarity and uses them as input for the next step. This enables incremental generation of documentation components, where each output builds on previous results. The final output is compiled into structured sections based on a predefined JSON schema.

The **Output Module** formats the completed documentation into a standards-compliant structure, ready for export or integration.

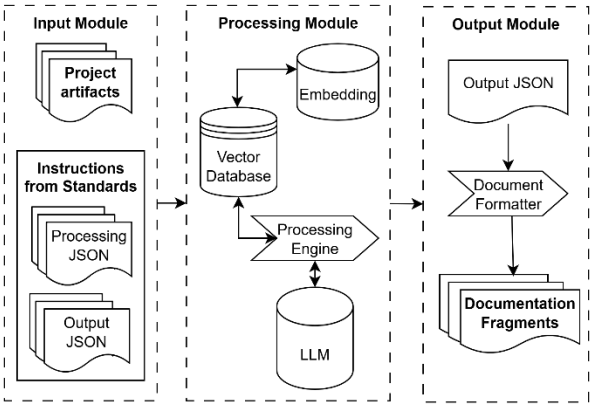

Fig 3. IT project documentation structure and content

The prototype screenshot is shown in Fig. 4. The user interface enables uploading project artifacts and control JSON files based on engineering standards. It supports “Process” and “Generate” actions to trigger analysis and document creation via a lightweight, Python-based framework.

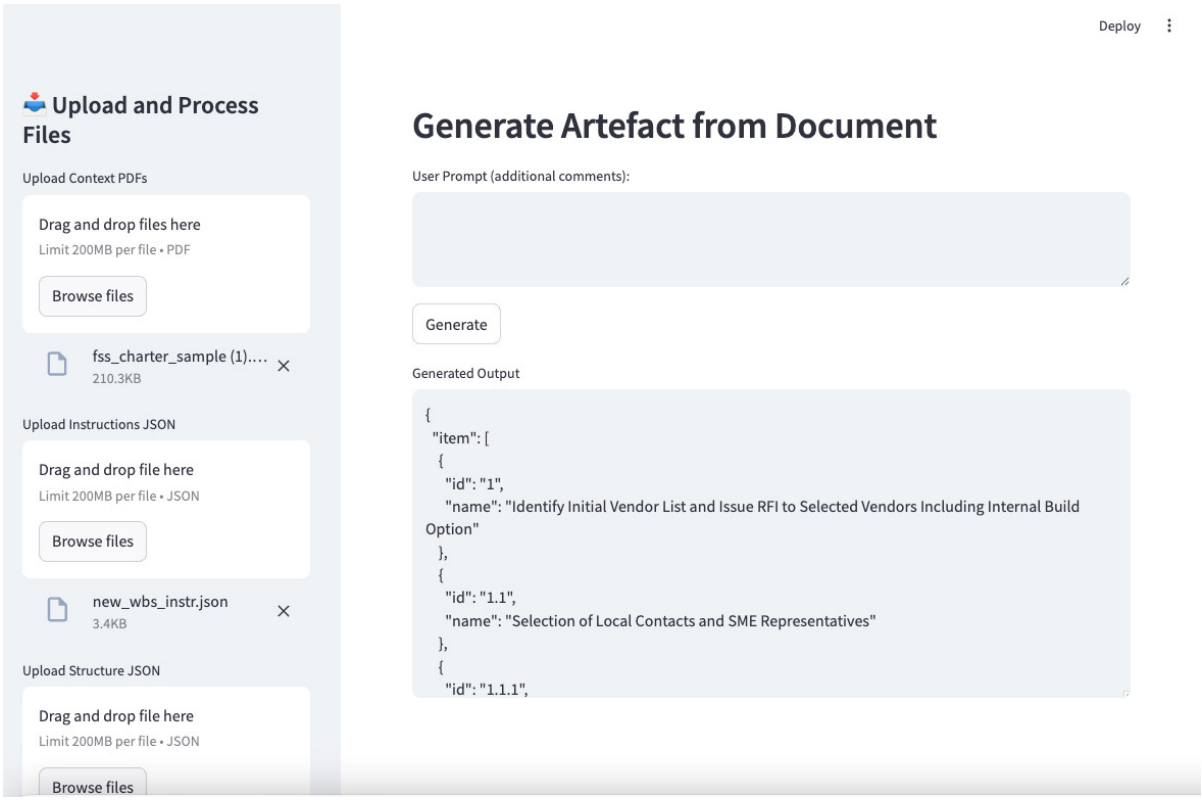

Fig 4. Solutions supporting prototype UI

V. Solution Demonstration and Validation

The developed solution focuses on the generation of documentation for the project initiation phase, which primarily are the project scope, requirements, and stakeholder register. However, the overall architecture and methodology are inherently adaptable to other types of software project artifacts (e.g., test strategies, change logs), provided that the step-based instruction approach is followed.

The design of the approach was informed by a critical analysis of limitations in existing AI-based documentation methods [41]. A key technical constraint was the limited token processing capacity of large language models (LLMs). Supplying the model with excessive or poorly structured context, even within token limits, can degrade output quality. This challenge was especially relevant due to the decision to implement the entire solution locally, without access to commercial API-based models.

To overcome these constraints, the solution relies on a hybrid generation process that combines model-driven input with structured prompt engineering techniques. The system employs dynamic prompt construction, where instructions are derived from formal templates and merged with input artifacts. This enables semantic precision and output consistency, while minimizing hallucinations.

A. Prompt Construction and Input Engineering

Prompt engineering is a critical set of techniques aimed at improving the precision, relevance, and structural integrity of instructions provided to large language models (LLMs). Given the inherent token limits and sensitivity to vague or ambiguous inputs, effective prompt design plays a key role in achieving high-quality, context-aware results.

While most modern LLMs can process both natural language and semi-structured formats, generating well-structured outputs, such as formal documentation artifacts, remains challenging. This is especially true when using general-purpose models that are not fine-tuned for technical or procedural content. To address this, researchers and practitioners have explored strategies such as zero-shot prompting, few-shot prompting, chain-of-thought prompting, and input injection, where contextual cues are embedded into the prompt to guide the generation process more effectively.

An increasingly popular and effective technique, particularly in software engineering and academic contexts, is schema-based prompting. In this method, the input is organized into clearly defined data segments or templates, enabling the model to recognize expected content categories and follow predefined output structures. This improves both the model's contextual understanding and its ability to maintain the desired format over longer outputs [41].

In the proposed solution, prompt and input engineering form the core of the generation workflow. Instruction files are parsed into stepwise key-value pairs and stored in session memory. During generation, the system performs iterative prompting, combining each instruction step with previously generated content.

Fig. 5 presents an example of the JSON-based prompt structure, and Figure 6 shows the resulting generated output.

<Context>
1. I am creating a local generative AI solution using Llama 3.2:3b model together with embedding model and local vector database ChromDB. The envrionment will not have access to the internet.
2. Model purpose is to be a local generative text assistant that handles input data based on provided instructions.
</Context>
<Instructions>
1. The model will receive following inputs interatively as prompt:
   a. fragments from the main document,
   b. instruction describing what to do with the fragments. This instruction changes for each iteration.
   c. Result from previous iterations
2. The model should only use information received as context fragments or previous results as source. Instructions are the task what model should achieve.
3. Take into account that the prompt cannot be too long due to token limitations of the model if used for every interaction.
4. Write me a coprehensive prompt to use as system prompt for Llama 3.2:3b model to set it's main purpose.
</Instructions>
<Examples>
1. You are a document generator llama 3.2:3b that generates answers based on context.
2. Main rule : You only can use context and previous outputs as source of information
</Examples>

Fig 5. A prompt for prompt generation on GPT-4-mini model

Sistēmas ievade
system_prompt = """
You are a document generation assistant local model llama3.2:3b.
You will receive:
- <Context>: You will receive text fragments for context input
- <Instructions>: JSON payload with processing rules under 'llm_prompt_instructions'.
- <Output structure>: JSON payload defining 'output_structure'.
- <User input>: optional additional information.
Tasks:
1. Process <Context> according to <Instructions> JSON.
2. Generate output strictly following <Output structure> JSON keys and hierarchy.
3. If <Context> lacks any required field, insert a placeholder in the form <MISSING_field_name>.
4. Do not add information not present in <Context>:.

Master rule: If you do not find information based on specific <Instructions>:. Leave output empty.
"""

Fig 6. The generation result: a prompt for Llama 3.2:3b model

Additionally, semantic retrieval is supported through a local vector database queried via Retrieval-Augmented Generation (RAG). Relevant context fragments are injected into each prompt, ensuring that the model's output is both semantically grounded and contextually accurate.

So far, the instruction is processed as part of the iterative prompting loop, where the system performs the following steps:

1. Retrieves relevant fragments from the vector database using tags such as "stakeholder_goals" and "deliverables".
2. Constructs a prompt that integrates retrieved content, the instruction goal, and global generation rules (e.g., tone, structure).
3. Executes the prompt using the LLM, producing a scoped and semantically grounded section.

The resulting output typically begins with a structured summary of project boundaries, highlights included and excluded deliverables, and clarifies key stakeholder expectations, which all are grounded in the source context provided by the uploaded artifacts.

This process ensures that generated text is not only grammatically correct and coherent, but also aligned with input data, methodologically consistent, and easy to validate. If any relevant data is missing (e.g., no deliverables listed), the model leaves the section incomplete or explicitly notes the absence, avoiding hallucinated content.

The core task defined for the model was text generation based on structured input instructions. An example of the instructions given for the Project Scope is shown in Fig. 7. Crucially, each iteration updates the prompt dynamically, preserving prior results and refining the context. This strategy has shown to be highly effective in reducing hallucinations and ensuring continuity across output sections. The base system prompt (or system message) is used to define global context and behavior for all interactions with the LLM.

To optimize prompt formulation, OpenAI's GPT-4-turbo model (May 2024 version) was used to assist in designing the system-level prompts for the local LLaMA 3.2:3b model. These instructions define the system's role, generation boundaries, and output expectations based on the runtime environment and technologies used in this project [41]-[42].

These instructions clarified the expected format and explicitly emphasized that the context PDF file is the sole source of truth for content generation. The model was also guided to respect the limitations of the local environment and its own processing capacity, discouraging overly long or ambiguous prompts.

Ensure valid JSON and no additional fields."
    ]
  }
}
```

Fig 7. The instructions for Project Scope Statement

As a part of the development process, a system prompt was iteratively refined and formatted using OpenAI tools, resulting in a stable, high-level instruction set. This ensures more predictable and consistent model behavior across varying input scenarios. To reduce hallucinations, a key rule was introduced: if essential information is missing from the context, the model must leave the corresponding field blank rather than fabricate content.

This strict constraint not only improves trust in the AI-generated output but also allows for easier human validation. It encourages transparent failure handling rather than misleading completions, which is critical for professional documentation processes. As a result, the JSON files of the required documentation fragments are generated.

The examples of outputs for project scope, requirements un stakeholder register are shown in Fig. 8-10.

The solution supports structured evaluation of generated documents based on two perspectives. First, document-level criteria assess completeness, terminology, and traceability to source inputs. Second, project-specific context examines content relevance and adaptability based on the detail of provided artifacts. Testing with varied project samples confirmed that output quality improves with richer inputs. Detailed project charters produced precise and tailored documentation, while minimal inputs resulted in more generic, though structurally valid, content. This demonstrates that the system adapts to input complexity while maintaining consistent structure, making it suitable for diverse documentation scenarios across different project environments.

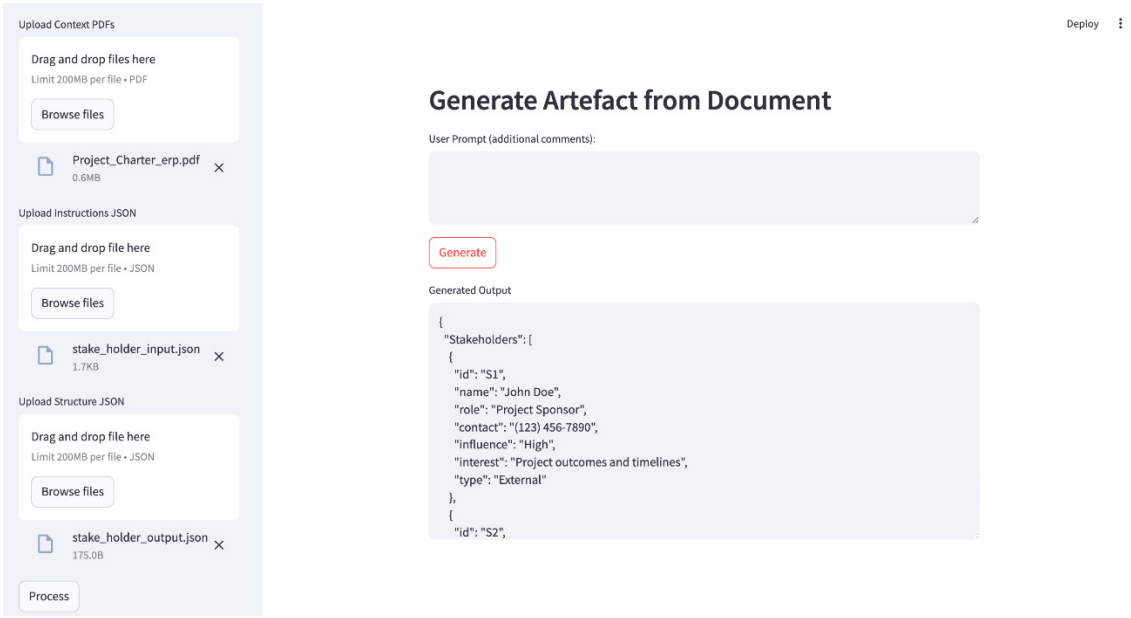

Fig 10. A fragment of output JSON for stakeholders

B. Solution Testing

The proposed approach was evaluated using two large language models (LLMs): LLaMA 3.2:3b and OpenAI GPT-4-mini. Both models received a unified instruction template and identical context limits. To ensure fairness, GPT-4-mini was restricted from using any external tools or accessing the web, relying solely on the provided input. To avoid priming effects, methodologies behind the instruction design were deliberately excluded from the prompt.

Each model processed 200-token segments with 50-token overlaps. For each evaluation step, five context fragments were drawn from the source document to ensure relevant yet limited context. Every instruction tied to an artifact was executed ten times, and outputs were stored for later analysis. To preserve neutrality, LLaMA's vector database was refreshed after each run, while GPT-4-mini was instructed to disregard prior outputs and treat each prompt as new.

Model performance was assessed using a rubric-based method, evaluating outputs across five dimensions. Each dimension was rated on a scale from 0.00 to 1.00, as detailed in Table 1.

TABLE I.
RUBRIC SCORE SCALE

Score	Rubric Criteria
0.00	Output contains incorrect or fabricated data
0.25	Output is mostly empty or contains only fragments
0.50	Output contains at least one correct element per section
0.75	Output aligns with dimensional expectations but lacks details
1.00	Output fully meets dimensional expectations

Each dimension was further weighted according to its significance in the evaluation, with the highest weights assigned to hallucination prevention and instruction compliance, given their criticality in constrained local environments [43]. Output clarity and consistency were assigned lower weights due to their less critical impact. The dimension weights are shown in Table 2.

TABLE II.
EVALUATION DIMENSIONS AND WEIGHTS

Evaluation Dimension	Weight
Data Hallucinations	0.30
Contextual Relevance	0.20
Output Consistency	0.10
Instruction Compliance	0.30
Output Clarity	0.10

A similar dimensional evaluation approach has been observed in empirical research investigating hallucinations across popular large language models. One such study assessed the hallucination rates of various LLMs by processing 1,000 documents, with results reported by [44]. Notably, the LLaMA 3.2:3b model demonstrated a hallucination rate of 7.9% in this evaluation.

In this study, simulation results were aggregated by assigning weights to each evaluation dimension, calculating average scores for each output fragment. The outcomes of the ten repeated iterations per instruction were averaged, and the dimension-specific results are presented in Table 3. Despite architectural and operational differences, that is, LLaMA 3.2:3b running locally and GPT-4-mini hosted via cloud services, both models produced comparable top results.

TABLE III.
EVALUATION DIMENSIONS AND WEIGHTS (1- HALLUCINATIONS, 2 - CONTEXT USE, 3 - CONSISTENCY , 4 - INSTRUCTION COMPLIANCE, 5 – CLARITY)

Artifact	Model	1	2	3	4	5	Overall	Scenario
Scope Statement	LLaMA 3.2:3b	0.7	0.5	0.45	0.6	0.75	0.61	One Washington

	GPT-4-mini	0.65	0.6	0.65	0.6	1.0	0.66	

The local model performed well when processing fragments closely matching the prompt, but it struggled with semantically diverse expressions. For instance, in requirement analysis or stakeholder registers, the instructions required extracting detailed information implied in the text. Here, GPT-4-mini showed superior performance in delivering more consistent and contextually aligned outputs. A notable gap was observed between the models' ability to interpret instructions, particularly in the LLaMA model. For example, when processing a scope statement, LLaMA inferred a resource planning system implementation based solely on the vague reference to a "system."

An analysis of the results revealed that both models performed better on the One Washington sample. This document was more structured, contained instruction-aligned headings, and used less academic language. These factors are beneficial especially for the local model.

In contrast, higher hallucination rates were observed when processing the productivity project charter. For instance, the scope description included a false claim, whereas the delivery items correctly referenced the convening of a steering committee. Similarly, the "Out of Scope" section was accurate. However, in the assumptions section expected to list six elements the model included only two, of which only one was correct. This may be attributed to the token limitation, which possibly resulted in incomplete sentence inputs that the model extrapolated upon.

Evaluation of GPT-4-mini's results showed tendencies toward verbosity, as the model often expanded text to produce grammatically complete phrases. While linguistically correct, these expansions altered the intended meaning, thus reducing factual accuracy. For example, among the three output goals, only the first two were valid; the third, referencing real-time reporting, was not present in the source text. Similar inconsistencies and hallucinations were noted across other sections, including deliverables and assumptions.

C. Solution Drawback and Improvements

Another key observation during evaluation was the difference in how the models responded to insufficient or ambiguous information. LLaMA 3.2:3b tended to return empty or partial outputs when it could not confidently locate the requested data. In contrast, GPT-4-mini frequently attempted to complete outputs regardless, even when context was lacking. Often generating fabricated content in direct violation of the provided instructions.

In the context of this study, where data integrity is of high importance, LLaMA's behavior was actually preferable. Empty outputs are easier to verify, as they indicate uncertainty rather than assumed correctness, which reduces the risk

of unintentionally integrating hallucinated data into downstream processes.

The results suggest that smaller, locally hosted models like LLaMA 3.2:3b, when given clearly defined instructions and constrained environments, are capable of producing viable outputs, particularly when a human reviewer is involved in validation. Although GPT-4-mini demonstrated superior generalization abilities, its tendency to confidently fabricate data limited its advantage in this controlled use case.

The test design used small input samples and short text fragments. In several cases, both models failed to retrieve relevant content and instead included false or unrelated claims. LLaMA also demonstrated high variability between runs: in multiple cycles, it returned empty or low-information responses, likely due to how fragments were selected via the nearest-neighbor search over the vector database using Ollama embeddings.

Each processing step queried only five top-matching fragments, assuming semantic accuracy in the embedding model. However, no additional validation of the relevance of retrieved fragments was performed. Furthermore, the model's iterative process continuously appended data to key/value stores without restriction, potentially leading to overwriting or compounding errors in later stages.

In summary, while GPT-4-mini showed superior fluency and semantic approximation, it introduced more hallucinations than expected. LLaMA 3.2:3b, though less consistent, adhered more strictly to constraints and demonstrated a conservative generation strategy more suitable for high-integrity documentation workflows in local AI-assisted systems.

VI. Conclusion

This study demonstrates that the integration of generative AI into IT project documentation processes is not only feasible but also valuable, which is provided by the frame within a model-driven and standards-aligned architecture. By combining the expressive capabilities of large language models with the structural rigor of model-driven development, the proposed solution supports the generation of high-quality, semantically consistent documentation artifacts during the early phases of IT projects.

From a theoretical perspective, this work contributes to the design science research body of knowledge by introducing a novel artifact: a model-based framework that constrains and guides generative AI outputs. It builds upon the principles of semantic control in AI-assisted software engineering, showing that MDD structures can serve as effective scaffolds for LLM behavior. Additionally, it expands on prior work in documentation automation by demonstrating how prompt engineering, semantic traceability, and formal process alignment can mitigate common challenges such as hallucinations and incoherence.

In terms of practical implications, the solution enables project teams, especially in resource-constrained environments, to accelerate and standardize documentation workflows without compromising methodological integrity. The prototype shows that even with local infrastructure, it is possible to harness generative AI tools securely and effectively. Reusable, cross-method instruction sets and alignment with common standards further enhance the applicability and scalability of the approach in varied project contexts.

Several key findings of the research are as follows:

1. Structured inputs and well-defined transformation rules significantly improve the quality and reliability of AI-generated documents.
2. Embedding documentation within a model-driven framework allows for semantic validation, traceability, and reduced ambiguity.
3. Local deployment of LLM-based tools is technically feasible and aligns with data governance requirements in many organizations.
4. Standard elements (e.g., objectives, risks, assumptions) can be reused across methods, enabling cross-framework consistency in documentation practices.

This research opens new avenues for extending the framework to other documentation types and domains (e.g., test plans, architecture overviews, compliance checklists), and for integrating dynamic feedback loops to iteratively refine generated content based on stakeholder input or project evolution.

Future work could explore as follows:

1. Comparative evaluation across multiple LLMs and domain contexts;
2. Deeper integration with enterprise modeling tools or agile project platforms;
3. Automated validation mechanisms for AI-generated artifacts.

In conclusion, the results affirm that generative AI, when properly constrained and guided, can enhance formal documentation practices in IT project management. Rather than replacing human expertise, such tools augment human capabilities, i.e., improving efficiency, consistency, and knowledge transfer in complex project environments.

***Abstract*—This study aims to present a new perspective for creating associative memories using incomplete data and project them into artificial neural networks to retrieve complete data from incomplete data. In previous studies, various approaches to construct associative memories and retrieval of stored data have been proposed. This paper attempts to pin point some of the limitations observed in the existing approaches and propose a way to get rid of that. In particular, a different perspective of comparing two incomplete patterns is proposed and based on that a flexible way of constructing associative patterns of a given input (partial) pattern is developed. Finally, the respective neural network architecture is proposed following similar construction reported in the existing research.**

I. Introduction

PATTERN recognition is a natural cognitive process that attempts to match an encountered instance of a pattern with the already stored patterns in the memory and thereby retrieve (plausibly) relevant information about the new pattern. Learning from patterns, extracting association among patterns and then applying that knowledge in recognizing useful patterns in different contexts of decision making characterize different important features of human intelligence [1]. The emergence of artificial neural network (ANN) [2] as a prototypical model of human brain, or more specifically biological neural network, is already well known. From its inception ANN has been considered as an effective tool in pattern recognition, signal processing, symbol processing etc [3], [4], [5]. The task of pattern association generally aims at storing different patterns similar to a given input pattern so that a concept related to the given input pattern can be recalled when a new pattern appears to be similar or a member of the stored patterns. Variations of a given input pattern is a common phenomenon, often caused by noise incorporated while collecting data or partial specification of data due to incomplete information. Content-Addressable Memory (CAM) or Associative memory (AM) [5], [6], [7] is the research domain of ANN which concerns about associating similar patterns of a given input data to create a memory and recalling the concepts associated to the input data for those stored patterns and implement the idea in the context of ANN.

In [3] the authors described that "The term associative memory (AM) or content-addressed memory refers to a memory system where recall of a stored pattern is accomplished by providing a noisy or partially specified input pattern.". A mathematical representation of the problem is as follows.

Given a data containing a set of input-output pairs $(\vec{u_1}, \vec{v_1})$, $(\vec{u_2}, \vec{v_2}), \ldots, (\vec{u_k}, \vec{v_k})$ where each input vector $\vec{u_i}$ of dimension n is connected to an output vector $\vec{v_i}$ of dimension m, the task of learning the relation between input-output patterns is realized through standard perceptron model with different activation functions. However, the additional point of associating any pattern from the associative memory of a given input pattern $\vec{u_i}$ with its output $\vec{v_i}$ is done by creating the notion of *associative memory* of each input vector $\vec{u_i}$, denoted as $AM(\vec{u_i})$, and then projecting the association of $(AM(\vec{u_i}), \vec{v_i})$ through a binary mapping module. The $AM(\vec{u_i})$ for a given input pattern $\vec{u_i}$ is created based on the standard notion of Hamming distance by counting number of bits that differ between two binary vectors. Further setting a desired precision level ρ_i, a limit for allowing number of mismatch of bits with $\vec{u_i}$, the $AM_{\rho_i}(\vec{u_i})$ is created by accepting vectors differing from $\vec{u_i}$ within the range of the pre-fixed precision level ρ_i.

On the other hand, a binary mapping is simply a function $f_I : U \longrightarrow V$ from the domain $U = \{\vec{u_i} : 1 \leq i \leq k\}$ to the range set $V = \{\vec{v_i} : 1 \leq i \leq k\}$ such that $f_I(\vec{u_i}) = \vec{v_i}$. In order to make f_I be able to recall $\vec{v_i}$ for any pattern from $AM_{\rho_i}(\vec{u_i})$ it is extended to f_A where the domain $U_A = \cup_{i=1}^{k} AM_{\rho_i}(\vec{u_i})$. So, once through the binary mapping module f_I is extended to f_A by defining $f_A(\vec{u}) = \vec{v_i}$ if $\vec{u} \in AM_{\rho_i}(\vec{u_i})$ the next task leads towards tuning the perceptron model recognizing f_I in a way that it can recognize the extended function f_A. Here, the precision level ρ_i chosen for each input vector $\vec{u_i}$ in creating $AM_{\rho_i}(\vec{u_i})$ plays a crucial role as in order to ensure unambiguous recall of a particular output $\vec{v_i}$ for a noisy input pattern $\vec{u}$ the condition $AM_{\rho_i}(\vec{u_i}) \cap AM_{\rho_j}(\vec{u_j}) = \emptyset$ for any $i \neq j$, $1 \leq i, j \leq k$ is needed [3], [8].

Here a few points to be noticed. One is, by allowing a mismatch in the bits of $\vec{u_i}$ within a specified precision level ρ_i the point of noisy data, as mentioned in the above quote, is addressed. However, the aspect of recalling associative memory in the context of incomplete patterns of a given pattern is not paid a due attention to as according to their proposal two partial vectors only can be comparable using

Topical area: Advanced Artificial Intelligence in Applications

standard Hamming distance when the positions of missing data of both the vectors are the same. More specifically, two partial binary vectors $\langle 1, ?, 1, 0, 1\rangle$ and $\langle 1, 1, ?, 0, 1\rangle$, where ? denotes missing value, cannot be compared following [3]. However, as on the known bits positions $\{1, 4, 5\}$ both the vectors match, potentially they could represent the same pattern. The second issue is related to the condition $AM_{\rho_i}(\vec{u_i}) \cap AM_{\rho_j}(\vec{u_j}) = \emptyset$ for any $i \neq j$, $1 \leq i, j \leq k$ which is imposed in [3] in order to avoid multiple associative recall possibility for a noisy vector. For example following [3], both the above vectors are considered to be partial patterns of $\langle 1, 1, 1, 0, 1\rangle$ which means $\langle 1, ?, 1, 0, 1\rangle \odot \langle 1, 1, 1, 0, 1\rangle$ and $\langle 1, 1, ?, 0, 1\rangle \odot \langle 1, 1, 1, 0, 1\rangle$ hold. So, both can belong to $AM(\langle 1, 1, 1, 0, 1\rangle)$ with precision level 1 although they are not comparable with each other following standard Hamming distance. For reference the readers are referred to Figure 1 considered in [3] where the Hamming distance, denoted as HD, could not be computed for half-pattern. This seems a bit counter-intuitive as if we consider two partial patterns are equally potential to represent some fragments of a full image they might have some common fragments matching with each other. Thus, without having a possibility of comparing how two such partial patterns match to each other may lead to significant information gap. Moreover, the same partial pattern $\langle 1, ?, 1, 0, 1\rangle$ could be considered as a partial pattern of a full image $\langle 1, 0, 1, 0, 1\rangle$ and thus considering the lowest precision level 1, we would not manage to avoid the conflict $\langle 1, ?, 1, 0, 1\rangle \in AM(\langle 1, 1, 1, 0, 1\rangle) \cap AM(\langle 1, 0, 1, 0, 1\rangle)$. In [3], the non-overlap of associative memories of two input vectors is achieved by imposing specific precision levels ρ_i and ρ_j of two input vectors $\vec{u_i}$ and $\vec{u_j}$ in a way that $d_H(\vec{u_i}, \vec{u_j}) > \rho_i + \rho_j$. However, as d_H itself has some limitation in calculating distance between two partial vectors we opt for departure from the idea presented in [3]. The third point is concerning the method of preprocessing incomplete patterns before projecting them to a perceptron model. In [3] the authors did not account for incomplete patterns in the training sample. However, while extending the relation f_I from the input-output pairs $(\vec{u_1}, \vec{v_1})$ …, $(\vec{u_k}, \vec{v_k})$ of the training sample over the sets of associative patterns for the inputs $\vec{u_1}, \ldots, \vec{u_k}$, associative patterns are allowed to be incomplete. But before creating the perceptron model corresponding to f_A, the extension of f_I on incomplete patterns, the missing parts are imputed just by setting them to 0's. As mentioned in several papers [9], [10] setting missing parts of a partial pattern by 0's indicates ignoring the missing part while analyzing the data and thus leads to flaws in classification accuracy.

So, in this paper our aim is to address all these above mentioned conditions by some more general perspectives. Specifically, our first proposal is to define a distance function which can compare any two partial (possibly full) binary vectors resolving the first problem. The second consideration is to generalize the notion of 'partial pattern of a vector', denoted by $\odot$ by a more general notion and thus allowing the precision level for the associative memory of an input vector $\vec{u_i}$ to be selected keeping an eye on the whole data of input vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$. In regard to the third point, in our approach, firstly we allow incomplete patterns in the input training sample. Moreover, considering that data collected in a particular context might have a reconciliation possibility within themselves, we propose a way of matching partial input patterns within themselves in order to visualize if they reflect any possibility of reconciling full pattern(s) (see Section VI). The idea comes from the way of reconciling content of a full image from several of its parts as is done in jigsaw puzzles. Projection of the extended function f_A, in our context, in a perceptron model can be realized in the same way as in [3], [11].

The content of the paper is organized as follows. Section II reviews the basic details and mathematical model of associative memory proposed in [3], [8] and discusses about some limitations of the considered approach. Section III introduces a new perspective of measuring distance between two partial vectors following Hamming distance as well as presents a new notion of potential extension of partial Patterns. Moreover, it points out the departure from the similar notions proposed in [3], [8]. Section IV presents the essential conditions and results that a dataset needs to be satisfied for creating associative memory. Section V describes the data processing conditions, methods and iterations for creating associative memories of a given input set of partial vectors keeping the standard condition of avoiding multiple recall [3] in mind. Section VI sketches an idea for retrieving associative memories in the context of perceptron model. Section VII presents some concluding remarks.

II. Review of Related Research

To make the paper self-contained in this section let us present a summary of basic relevant details. As mentioned in Introduction the starting point is a data set containing a set of input-output pairs such as $(\vec{u_1}, \vec{v_1})$, $(\vec{u_2}, \vec{v_2})$, …, $(\vec{u_k}, \vec{v_k})$. Neural memories are generally of two kinds, namely *auto-associative memories* and *hetero-associative memories*. The aim of the auto-associative memories is to reconstruct a pattern from a noisy or partially specified pattern; that is here output vector corresponding to each input vector $\vec{u_i}$ is the same and target is to reconstruct $\vec{u_i}$ from $AM(\vec{u_i})$. On the other hand, hetero-associative memory aims to retrieve information concerning an input vector $\vec{u_i}$ given any instance from its $AM(\vec{u_i})$. The relation between k pairs of input-output vectors of dimension n and m respectively is realized through a 2-layer perceptron having the input layer comprising of n neurons, each of which connected to each of the k neurons lying in the hidden layer, and each of these k neurons are then connected to m output neurons. Clearly, n neurons at the input layer represent n-components of an input vector, say $\vec{u_i}$, m neurons at the output layer represent m components of an output vector, and each of the k neurons at the hidden layer represents k different input-output pairs. For more details the readers are referred to [3], [11].

A. Associative Memory

Now as described in Introduction to extend f_I from U to the sets of associative memories for each input vector of U, first $AM(\vec{u_i})$ is defined in the following manner.

For any $\vec{u_i} \in U$ and respective precision level ρ_i, $AM_{\rho_i}(\vec{u_i})$ $=\{\vec{u}|\vec{u} \in \mathbf{B}^n \& d_H(\vec{u}, \vec{u_i}) \leq \rho_i\}$[1] where $\mathbf{B}^n$ represents the set of all n-dimensional binary vectors and d_H represents the Hamming distance. Then f_I is extended over $\cup_{i=1}^{k} AM_{\rho_i}(\vec{u_i})$ in the following manner.

$f_A : \cup_{i=1}^{k} AM_{\rho_i}(\vec{u_i}) \rightarrow V$, $f_A(\vec{u}) = \vec{v_i}$; if $\vec{u} \in AM_{\rho_i}(\vec{u_i})$, $1 \leq i \leq k$. As mentioned before, the precision level ρ_i for each $\vec{u_i}$ is chosen such that $AM_{\rho_i}(\vec{u_i}) \cap AM_{\rho_j}(\vec{u_j}) = \emptyset$ for any $i \neq j$, $1 \leq i, j \leq k$.

As clearly visible that the above context of associative memory does not represent the possibility for including partial vectors with missing values at some of the components. In [3], [8] the idea of constructing associative memories for partially specified patterns is developed in the context of bipolar vectors where components of a vector may assume values from $\{-1, 0, 1\}$. However, 0 is used only as the marker for missing positions and any partial vector is supposed to assume values from only $\{1, -1\}$. Given any partial input vector $\vec{u_i}$ the missing positions of the vector are first padded with 0 so that the Hamming distance between two vectors can be computed. Then for two $\vec{u}$ and $\vec{v}$ the notion, viz., *$\vec{u}$ is a partial pattern of $\vec{v}$* is defined in the following way.

Definition II.1 ([3], [8])**.** *Given a partial bipolar vector $\vec{u}$, $\vec{u}$ is said to be a partial pattern of $\vec{v}$, denoted as $\vec{u} \odot \vec{v}$, if the available components of $\vec{u}$ are the same as that of the corresponding components of $\vec{v}$.*

The Hamming distance between two partial bipolar patterns is computed using the standard definition as $d_H(\vec{u}, \vec{v})$ is defined with the constraint that the unknown positions of $\vec{u}$ and $\vec{v}$ are the same. As a consequence after padding with 0's only the available positions with 1 and -1 would matter in counting mismatches between $pad0(\vec{u})$ and $pad0(\vec{v})$. Then the notion of associative memory in the context of partial vectors is defined in the following way.

Definition II.2 ([3], [8])**.** *(i) Given any input pattern $\vec{u_i}$, the set of all partial patterns of $\vec{u_i}$ with j-bits is given by* $U_i^j = \{\vec{u} : bits(\vec{u}) = j \ \& \ \vec{u} \odot \vec{u_i}\}$.
(ii) Further given a specified precision level ρ_i for $\vec{u_i}$, the associative memory for $\vec{u_i}$ with precision level ρ_i is defined as $AM_{\rho_i}^j = \{pad0(\vec{u'}) : \exists \vec{u} \in U_i^j \ \& \ d_H(\vec{u'}, \vec{u}) \leq \lfloor j/n \rfloor \times \rho_i\}$.

However, here a few points to be noted. The restrictions imposed above regarding only counting 1, -1 for the bit positions indicates that the purpose could have been served by binary vectors as well. Moreover, two vectors $\langle 1, -1, ?, -1, 1\rangle$ and $\langle 1, ?, 1, -1, 1\rangle$ intuitively may represent the same content as on the known positions they have the same values. As presented in [3], it seems that to claim $\vec{u} \odot \vec{u_i}$ the vector $\vec{u_i}$ must be a full vector. Thus, firstly for an input pattern $\vec{u_i}$ with missing values we cannot create $AM_{\rho_i}^j(\vec{u_i})$. Secondly, considering $\vec{u_i} = \langle 1, -1, 1, -1, 1\rangle$ we see both $\langle 1, -1, ?, -1, 1\rangle \odot \langle 1, -1, 1, -1, 1\rangle$ and $\langle 1, ?, 1, -1, 1\rangle \odot \langle 1, -1, 1, -1, 1\rangle$ hold. Thus, $\langle 1, -1, ?, -1, 1\rangle, \langle 1, ?, 1, -1, 1\rangle \in U_i^4$; but as, $d_H(\langle 1, ?, 1, -1, 1\rangle, \langle 1, -1, ?, -1, 1\rangle)$ is not defined both together cannot be considered in $AM_{\rho_i}^4(\langle 1, -1, 1, -1, 1\rangle)$, the set of associative patterns of $\langle 1, -1, 1, -1, 1\rangle$.

[1]Here to be noted that in [3] for this notion a different notation, namely $U_i^n(\rho_i)$ is used.

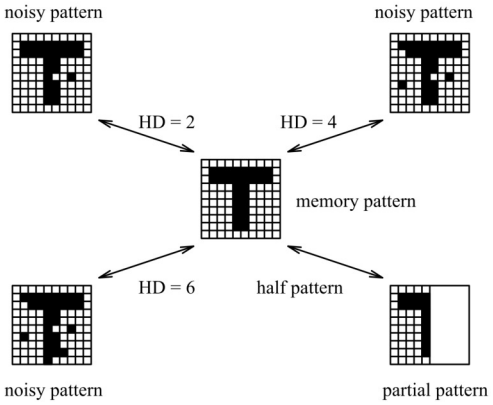

Figure 1. Computing Hamming distance(HD) for noisy patterns [3]

Keeping these limitations in mind our proposal, presented in the following sections, departs from a few aspects.

III. Hamming Distance and Potential Extensions of Partial Patterns

The aim of this section is to develop step-by-step the basic notions, departing from the respective notions proposed in [3], [8], so that the limitations discussed in Section II can be overcome. Our first target is to modify the definition for computing distance between two partial patterns in a way that instead of ignoring it would account for different unknown parts of the input patterns. In this regard, let us first present some notational details below.

Let $\vec{u}$ be any n-dimensional partial binary vector with some unknown components, denoted as $Unp(\vec{u})$; the set of known positions of $\vec{u}$ is denoted by $Bits(\vec{u})$, and $|Bits(\vec{u})|$ determines the number of bits in the vector, alternatively denoted by $bits(\vec{u})$. For example, for $\vec{u} = \langle ?, 1, 0, ?, 1, 0\rangle$ the $bits(\vec{u}) = 4$, $Bits(\vec{u}) = \{2, 3, 5, 6\}$, and $Unp(\vec{u}) = \{1, 4\}$.

A. Hamming distance for partial patterns

Let $\vec{u}$ and $\vec{u'}$ be two n-dimensional partial vectors having (possibly) some unknown components, denoted by $Unp(\vec{u})$ and $Unp(\vec{u'})$ respectively.

Definition III.1. *Given two partial binary vectors $\vec{u}$ and $\vec{u'}$ the Hamming distance between the vectors is defined as $D_H(\vec{u}, \vec{u'}) = d_H(\vec{u^t}, \vec{u^{t'}}) + l$, where $\vec{u^t}$ and $\vec{u^{t'}}$ are obtained by dropping all positions of $Unp(\vec{u}) \cup Unp(\vec{u'})$ from $\vec{u}$ and $\vec{u'}$ respectively, and $l = |Unp(\vec{u}) \cup Unp(\vec{u'})|$.*

It is clear from Definition III.1 that the modified notion of Hamming distance between two partial patterns considers a

pessimistic perspective by admitting the possibility that the missing positions of the vectors might have different content. The results below present in what sense it could be considered as a metric.

Proposition III.2. $D_H(\vec{u},\vec{v}) \leq D_H(\vec{u},\vec{w}) + D_H(\vec{w},\vec{v})$ *for any* $\vec{u},\vec{v},\vec{w}$

Based on Definition III.1, the proof relies on meticulously checking all different possibilities of unknown positions and their interrelations for three vectors $\vec{u},\vec{v},\vec{w}$.

Proposition III.3. D_H *satisfies the following properties of a metric.*

1) $D_H(\vec{u},\vec{v}) \geq 0$ *for any* $\vec{u},\vec{v}$.
2) $D_H(\vec{u},\vec{v}) = k$ *if and only if* $\vec{u^t} = \vec{v^t}$, $|Unp(\vec{u}) \cup Unp(\vec{v})| = k$.
3) $D_H(\vec{u},\vec{v}) = D_H(\vec{v},\vec{u})$ *for any* $\vec{u},\vec{v}$.

The proof of Proposition III.3 is straightforward from Definition III.1. From the property (2) of Proposition III.3, we can notice that $D_H(\vec{u},\vec{u}) = k$ given $|Unp(\vec{u})| = k > 0$. So, in contrary to standard metrics D_H is not reflexive. However, in the context of partial patterns it is quite intuitive that two partial patterns even may look the same on the known parts but there might be some mismatch in content in the undisclosed parts. Moreover, if we stick to the condition that $Unp(\vec{u}) = Unp(\vec{u'})$, then d_H can be considered as a lower estimation of D_H, and thus provides a more general perspective of calculating distance between two partial patterns.

Proposition III.4. *Given* $Unp(\vec{u}) = Unp(\vec{u'})$, $D_H(\vec{u},\vec{u'}) \geq d_H(\vec{u},\vec{u'}) + l$ *where* $|Unp(\vec{u})| = l$.

From Proposition III.4 it can be noticed that as the number of bits of $\vec{u}$ and $\vec{u'}$ increase D_H will be more close to the estimation proposed by d_H.

B. Potential extension for partial patterns

In this section we present a new perspective for the notion associative patterns by considering a modification of the same notion proposed in [3] from two aspects. Firstly, unlike $\odot$ we would introduce a new predicate $\otimes$ which incorporate the possibility of $\vec{u} \otimes \vec{v}$ to hold for a partial vector $\vec{v}$. Secondly, the notion of associative patterns developed based on $\otimes$ would allow two partial patterns $\vec{u}$ and $\vec{u'}$ as associative patterns of a given input pattern $\vec{u_i}$ even they do not share the same unknown parts.

Definition III.5. *Given a partial binary vectors* $\vec{u}$ *and any (partial) binary vector* $\vec{v}$, $\vec{u}$ *is said to be potentially extended to* $\vec{v}$, *denoted by* $\vec{u} \otimes \vec{v}$, *if* $Unp(\vec{u}) \supseteq Unp(\vec{v})$ *and values of all the known components of* $\vec{u}$ *match to that of the respective known components of* $\vec{v}$.

The Theorem below shows that $\otimes$ generalizes the notion of $\odot$.

Theorem III.6. *For a full vector* $\vec{v}$, $\vec{u} \odot \vec{v}$ *is a special case of* $\vec{u} \otimes \vec{v}$.

Proof. Let consider n-dimensional vectors $\vec{u},\vec{v},$. Let $\vec{u} \otimes \vec{v}$ where $Unp(\vec{v}) = \emptyset$ (The condition $Unp(\vec{u}) \supseteq Unp(\vec{v})$ for having $\vec{u} \otimes \vec{v}$ is trivially satisfied.) Now as $\vec{u} \otimes \vec{v}$, $d_H(\vec{u^t},\vec{v^t}) = 0$, where $\vec{u^t},\vec{v^t}$ are the vectors obtained by truncating $Unp(\vec{u})$ from both the vectors. Thus $\vec{v}$ is a full vector and $\vec{u}$ is a partial vector, s.t. $\forall l \in Bits(\vec{u})$, the l-th components of $\vec{u}$ and $\vec{v}$ are the same. $\therefore \vec{u} \odot \vec{v}$ □

Now, analogous to $U^j_{\rho_i}$ presented in Section II in our context for an input vector $\vec{u_i}$ we construct the following set.
$U_i^{bits(\vec{u_i})} = \{\vec{u} \in \mathbf{B}^n | 0 < bits(\vec{u}), \vec{u} \otimes \vec{u_i}\}, 1 \leq i \leq k$.
Considering $|Unp(\vec{u_i})| = p_i$ we can write $U_i^{bits(\vec{u_i})} = U_i^{n-p_i}$.

It is to be worth noticing that in $U_i^{n-p_i}$ we do not allow vectors with full unknown parts or in other words a vector with empty Bits.

IV. Data restriction in choosing precision level for associative memory

In [3], while developing binary mapping and respectively perceptron model for a set of input vectors the authors maintained the constraint of mutually disjoint associative memories for a set of input vectors by tuning the precision level ρ_i for the associative memory constructed for each input vector $\vec{u_i}$. In our work, as the notion of $U^j_{\rho_i}$ is replaced by the notion of $U_i^{n-p_i}$ where $|Unp(\vec{u_i})| = p_i$ to ensure mutually non-overlapping associative patterns for a given input set of vectors we propose to consider non-overlapping unknown components for each pair of vectors $\vec{u_i}$ and $\vec{u_j}$ in the input set of vectors.

Apart from the technical point of view of imposing $Unp(\vec{u_i}) \cap Unp(\vec{u_j}) = \emptyset$ for any $i \neq j$ and $1 \leq i,j \leq k$ there is an intuitive perspective of imposing this constraint as well. Often while solving a puzzle related to creating a known image, nowadays prevalently known as jigsaw puzzle[2], we are given a number of pieces each having different known fragments of the image visible. Usually, we aim to fit the unknown and known fragments of two pair of pieces in a way that some part of the whole image can be retrieved. For instance, given two partial input vectors $\vec{u_i} = \langle 1,0,?,0,1\rangle$ and $\vec{u_j} = \langle 1,?,1,?,1\rangle$, in one hand, merging them by replacing one's unknown components with others respective known components may help to visualize a complete pattern $\langle 1,0,1,0,1\rangle$. On the other hand, following the notion of $\otimes$ neither $\vec{u_i} \otimes \vec{u_j}$ nor $\vec{u_j} \otimes \vec{u_i}$ holds. That is, all the input vectors are considered to be independently indispensable to recover the full content of the actual image as neither of them can be potentially extended to the other following the notion of $\otimes$. Moreover, it would be clear in the latter sequels that the impact of this condition is not limited to the above discussed perspectives only.

A. Imposition of Restriction on Data

We start with imposing a few constraint on a data set of n-dimensional input vectors $\vec{u_1},\vec{u_2},\ldots,\vec{u_k}$.

[2]https://en.wikipedia.org/wiki/Jigsaw_puzzle

Definition IV.1 (Dset)**.** *A set of n-dimensional input vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$ satisfying the following conditions is called a Dset.*

1) $0 \leq |Unp(\vec{u_i})| \leq \lfloor n/2 \rfloor$
2) $Unp(\vec{u_i}) \cup Bits(\vec{u_i}) = \{1, 2, \ldots, n\}$
3) $Unp(\vec{u_i}) \cap Unp(\vec{u_j}) = \emptyset$ *for* $1 \leq i, j \leq k, i \neq j$

The condition (1) imposes a restriction, may be called as Maximum Half Uncovered Pattern (MHUP). The condition (2) imposes that unknown and known part of each vector must exhaust the full pattern, may be called Exhaustive Pattern (EP). The condition (3) may be named as Mutually Disjoint Unknown Parts (MDUP).

A series of results below would clarify how the condition (MDUP) may determine the choice of precision level for a given input vector in the context of creating associative memory.

Proposition IV.2. *If $\vec{u} \in U_i^{n-p_i} \cap U_j^{n-p_j}$ then $Unp(\vec{u}) \supseteq Unp(\vec{u_i}) \cup Unp(\vec{u_j})$ and $d_H(\vec{u_i^t}, \vec{u_j^t}) = 0$ where $\vec{u_i^t}$ and $\vec{u_j^t}$ are obtained by dropping all positions of $Unp(\vec{u})$ from $\vec{u_i}$ and $\vec{u_j}$ respectively.*

Proof. $\vec{u} \in U_i^{n-p_i}$ and $\vec{u} \in U_j^{n-p_j}$; that is, $\vec{u} \otimes \vec{u_i}$ and $\vec{u} \otimes \vec{u_j}$. Let $\vec{u_i^t}$ and $\vec{u^t}$ be the vectors obtained by dropping the positions of $Unp(\vec{u})$ from both $\vec{u_i}$ and $\vec{u}$. So $Unp(\vec{u_i}) \subseteq Unp(\vec{u})$ and $d_H(\vec{u_i^t}, \vec{u^t}) = 0$ as well as $Unp(\vec{u_j}) \subseteq Unp(\vec{u})$ and $d_H(\vec{u_j^t}, \vec{u^t}) = 0$. □

The above proposition leads to the following corollary.

Corollary IV.3. *If $\vec{u} \in U_i^{n-p_i} \cap U_j^{n-p_j}$, then $p_i + p_j \leq p$.*

Proof. As $Unp(\vec{u_i}) \cap Unp(\vec{u_j}) = \emptyset$, then by Proposition IV.2, $Unp(\vec{u_i}) \cup Unp(\vec{u_j}) \subseteq Unp(\vec{u})$ which implies $p_i + p_j \leq p$. □

Combining Proposition IV.2 and Corollary IV.3 using contraposition we can say that if for a vector $\vec{u}$ with $|Unp(\vec{u})| = p$, $p < p_i + p_j$ or $d_H(\vec{u_i^t}, \vec{u_j^t}) \neq 0$, then $\vec{u} \notin U_i^{n-p_i} \cap U_j^{n-p_j}$, where $\vec{u_i}^t$, $\vec{u_j}^t$ are obtained from $\vec{u_i}$, $\vec{u_j}$ respectively by truncating respective positions of $Unp(\vec{u})$.

So, from Corollary IV.3 it is clear that if two input vectors are not having common unknown parts then that suffices to choose a precision level for a vector $\vec{u}$ and ensure that $\vec{u}$ cannot be regarded as a common associative pattern for both the input vectors. However, this is not a necessary condition ensuring $U_i^{n-p_i} \cap U_j^{n-p_j} = \emptyset$. The sequel below will throw some light in this regard.

Proposition IV.4. *If $Unp(\vec{u_i}) \cap Unp(\vec{u_j}) = \emptyset$, then $U_i^{n-p_i} \neq U_j^{n-p_j}$ given $p_i \geq 2$ or $p_j \geq 2$.*

Proof. Let $Unp(\vec{u_i}) = \{r_1, r_2, \ldots, r_{p_i}\}$, $Unp(\vec{u_j}) = \{t_1, t_2, \ldots, t_{p_j}\}$ where $Unp(\vec{u_i}) \cap Unp(\vec{u_j}) = \emptyset$ and $p_j \geq 2$. Now, consider $\vec{u}$ with $Unp(\vec{u}) = \{r_1, r_2, \ldots, r_{p_i}\} \cup \{t_l\}$ where $t_l \in Unp(\vec{u_j})$ and $D_H(\vec{u_i}^t, \vec{u}^t) = 0$ where $\vec{u_i}^t$, $\vec{u}^t$ are obtained by truncating all the positions of $Unp(\vec{u})$ from both the vectors. Clearly, $\vec{u} \otimes \vec{u_i}$ and thus $\vec{u} \in U_i^{n-p_i}$. But as $Unp(\vec{u}) \not\supseteq Unp(\vec{u_j})$, $\vec{u} \notin U_j^{n-p_j}$.

In the similar fashion, for $p_i \geq 2$ we can create a vector $\vec{u'}$ such that $\vec{u'} \in U_j^{n-p_j}$ but $\vec{u'} \notin U_i^{n-p_i}$. Thus, we can claim that $U_i^{n-p_i} \neq U_j^{n-p_j}$. □

Proposition IV.4 indicates that by considering non-overlapping unknown parts in the input data and putting the restriction that at most one input vector in the input data may have exactly one unknown component, we will be able to ensure that the set of associative patterns for each input vector will be distinct. However, the condition does not ensure that $U_i^{n-p_i} \cap U_j^{n-p_j} \neq \emptyset$. The example below illustrates the claim.

Example IV.1. *Let us consider $Unp(\vec{u_i})$ and $Unp(\vec{u_j})$ as the same as in Proposition IV.4 with an additional condition that $Unp(\vec{u_i}) \cup Unp(\vec{u_j}) \neq \{1, 2, \ldots, n\}$. Now consider a vector $\vec{u}$ with $Unp(\vec{u}) \supseteq Unp(\vec{u_i}) \cup Unp(\vec{u_j})$ and $D_H(\vec{u}^t, \vec{u_i}^t) = D_H(\vec{u}^t, \vec{u_j}^t) = 0$ where $\vec{u}^t, \vec{u_i}^t, \vec{u_j}^t$ are obtained respectively from the original vectors after removing the components of $Unp(\vec{u})$. This clearly indicates that $\vec{u} \otimes \vec{u_i}$ and $\vec{u} \otimes \vec{u_j}$ and thus $\vec{u} \in U_i^{n-p_i} \cap U_j^{n-p_j}$.*

In [3], the associative patterns for the set of input vectors are imposed to be non-overlapping. The reason behind such consideration is already explained in Section II. The above results indicate that, in our context, in order to avoid overlap in the respective associative patterns for the input vectors we may need a further pre-processing phase for data.

Based on Corollary IV.3, we can notice that given any two input vectors $\vec{u_i}$ and $\vec{u_j}$ if we choose a vector $\vec{u}$ with $Unp(\vec{u}) = p$ such that $p < p_i + p_j$ then $\vec{u} \notin U_i^{n-p_i} \cap U_j^{n-p_j}$. That is, to avoid overlap in the respective associative patterns of any two input vectors of a data set $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$ we can impose the following condition.

Condition IV.5. *Given a data set of input vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$, for any $\vec{u_i}$, $1 \leq i \leq k$, the precision level ρ_i for the set of associative patterns of $\vec{u_i}$, denoted by $AM(\vec{u_i})$, must satisfy $p_i < \rho_i < p_i + p_j$ for any $j \neq i$.*

Here a natural question arises that whether given an input data we will always have a situation to choose a precision level for an arbitrary input vector following Condition IV.5. Following proposition would clarify the issue further.

Proposition IV.6. *Given the input data $\vec{u_1}, \vec{u_2}, ..., \vec{u_k}$ if for a vector $\vec{u_i}$, $1 \leq i \leq k$, there is no $\rho_i \in \mathbb{Z}^+$ s.t. $p_i < \rho_i < p_i + p_j$ for any $i \neq j$, then there is at least one $j \neq i$ for which $p_j = 1$.*

Proof. From the assumption that there is no $\rho_i \in \mathbb{Z}^+$, s.t. $p_i < \rho_i < p_i + p_j$ for all $i \neq j$ it is clear that $p_i + p_j$ must be equal to $p_i + 1$ for some $j \therefore p_j = 1$ for some j. □

Proposition IV.7. *If $p_j = 1$ for some $j \neq i$, then there is no $\rho_i \in \mathbb{Z}^+$ satisfying $p_i < \rho_i < p_i + p_j$ for $i \neq j$.*

Proof. Let $p_j = 1$ for some $j \neq i$, and there exist a $\rho_i \in \mathbb{Z}^+$ satisfying $p_i < \rho_i < p_i + p_j$ for $i \neq j$. As $p_j = 1$ for some $j \neq i$, we can write $p_i < \rho_i < p_i + 1$ and $0 < \rho_i - p_i < 1$. This is a contradiction as $p_i, \rho_i \in \mathbb{Z}^+$. Hence there is no $\rho_i \in \mathbb{Z}^+$ satisfying $p_i < \rho_i < p_i + p_j$ for $i \neq j$. □

Clearly, if we have a data set of input vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$ such that $|Unp(\vec{u_i})| = p_i > 1$ for each $i \in \{1, 2, \ldots, k\}$, then following Condition IV.5 finding a precision level $\rho_i \in \mathbb{Z}^+$ for each input vector $\vec{u_i}$ is possible. This result also goes in accordance with our observation from Proposition IV.4. So, allowing only input vectors with more than one unknown components may help to create a unique precision level for the set of associative patterns for each input vectors following Condition IV.5. However, we need to dig further to check how such a condition would impact on the availability of sufficient amount of input data.

B. Impact of data restriction on availability of data

Given the restriction on data imposed in Definition IV.1 and the additional restriction mentioned in Condition IV.5 it is now important to check how much data we may have to train a required perceptron model. In this regard, let us first consider the context of a data set satisfying the conditions (MHUP) $bits(\vec{u_i}) \geq \lceil n/2 \rceil$ and (EP) ($Bits(\vec{u_i})$, $Unp(\vec{u_i})$) forms a partition of $\{1, 2, \ldots n\}$, mentioned in Definition IV.1. Before presenting the result let us define some useful notations.

Notation IV.8. (i) $S_n(bits) = \{X \subseteq \{1, 2, ..., n\} : |X| \geq \lceil n/2 \rceil\}$.
(ii) $S^i(Y) = \{X \subseteq Y : 0 \leq |X| < i\}$

Given the above notations we can notice that $S_n(bits) = P(\{1, 2, ..., n\}) - S^{\lceil n/2 \rceil}(\{1, 2, ..., n\})$.

Proposition IV.9. *$|S_n(bits)| = 2^n - \sum_{i=0}^{m-1} {}^nC_i$, where $n = 2m$ or $n = 2m - 1, m \geq 1$.*[3]

Proof. We know $|P(\{1, 2, ..., n\})| = 2^n$. Now for $S^{\lceil n/2 \rceil}(\{1, 2, ..., n\})$, we have two cases (1) $n = 2m$ and (2) $n = 2m - 1$
(1) If $n = 2m, \lceil n/2 \rceil = m$, then $S^m(\{1, 2, ..., n\}) = \sum_{i=0}^{m-1} {}^{2m}C_i$
(2) If $n = 2m - 1, \lceil n/2 \rceil = m$, then $S^m(\{1, 2, ..., n\}) = \sum_{i=0}^{m-1} {}^{2m-1}C_i$
Therefore, clearly from (1) and (2), $|P(\{1, 2, ..., n\})| - |S^{\lceil n/2 \rceil}(\{1, 2, ..., n\})| = 2^n - \sum_{i=0}^{m-1} {}^nC_i$, where $n = 2m$ or $n = 2m - 1$, $m \geq 1$. □

Proposition IV.10. *$2^n - \sum_{i=0}^{m-1} {}^nC_i = \sum_{i=0}^{\lfloor n/2 \rfloor} {}^nC_i$, where $n = 2m$ or $n = 2m - 1$, $m \geq 1$*

Proof. It is well known $2^n = \sum_{i=0}^{n} {}^nC_i$. Now we need to show $\sum_{i=0}^{n} {}^nC_i = \sum_{i=0}^{m-1} {}^nC_i + \sum_{i=0}^{\lfloor n/2 \rfloor} {}^nC_i$
(1) when $n = 2m, \lceil n/2 \rceil = m$ and $\lfloor n/2 \rfloor = m$
LHS = ${}^{2m}C_0 + {}^{2m}C_1 + {}^{2m}C_2 + ... + {}^{2m}C_{2m}$
RHS[4] = ${}^{2m}C_0 + {}^{2m}C_1 + ... + {}^{2m}C_{m-2} + {}^{2m}C_{m-1} + {}^{2m}C_0 + {}^{2m}C_1 + ... + {}^{2m}C_{m-1} + {}^{2m}C_m$
$= {}^{2m}C_0 + {}^{2m}C_1 + ... + {}^{2m}C_{m-2} + {}^{2m}C_{m-1} + {}^{2m}C_m + {}^{2m}C_{m+1} + ... + {}^{2m}C_{2m-1} + {}^{2m}C_{2m}$
$\therefore$ LHS=RHS

(2) when $n = 2m - 1, \lceil n/2 \rceil = m$ and $\lfloor n/2 \rfloor = m - 1$
LHS = ${}^{2m-1}C_0 + {}^{2m-1}C_1 + {}^{2m-1}C_2 + ... + {}^{2m-1}C_{2m-1}$
RHS = ${}^{2m-1}C_0 + {}^{2m-1}C_1 + ... + {}^{2m-1}C_{m-2} + {}^{2m-1}C_{m-1} + {}^{2m-1}C_0 + {}^{2m-1}C_1 + ... + {}^{2m-1}C_{m-1} + {}^{2m-1}C_m$
$= {}^{2m-1}C_0 + {}^{2m-1}C_1 + ... + {}^{2m-1}C_{m-2} + {}^{2m-1}C_{m-1} + {}^{2m-1}C_m + {}^{2m-1}C_{m+1} + ... + {}^{2m-1}C_{2m-2} + {}^{2m-1}C_{2m-1}$
$\therefore$ LHS=RHS

□

So, combining Propositions IV.9, IV.10 we can say that $|S_n(bits)| = \sum_{i=0}^{\lceil n/2 \rfloor} {}^nC_i$. That is, for 10-dimensional vectors there can be maximum 638 vectors satisfying (MHUP) and (EP) mentioned in Definition IV.1. So, the next question arises that how many vectors out of $|S_n(bits)|$ number of possible vectors can have non-overlapping unknown parts. In this regard, let us consider any input vector $\vec{u_i}$ with $bits(\vec{u_i}) = r$ where $\lceil n/2 \rceil \leq r \leq n$.

Proposition IV.11. *Given an input vector $\vec{u_i}$ with $bits(\vec{u_i}) = r$, where $\lceil n/2 \rceil \leq r \leq n$, the maximum number of vectors in $\boldsymbol{B}^n$ having disjoint unknown parts with $Unp(\vec{u_i})$ is ${}^rC_{n-r}$.*

Proof. Let $\vec{u_i}$ be a vector with $Bits(\vec{u_i}) = \{s_1, s_2, \ldots, s_r\}$ where $\lceil n/2 \rceil \leq r \leq n$ and $|Unp(\vec{u_i})| = n - r$. Following our condition $r \geq n - r$. Then in order to have other r-bits vectors with non-overlapping unknown components we can consider a vector $\vec{u_i}'$ whose $Unp(\vec{u_i}')$ is obtained by exchanging all $n-r$ positions of $Unp(\vec{u_i})$ with positions from $\{s_1, s_2, \ldots, s_r\}$ of $\vec{u_i}$. This allows us to create ${}^rC_{n-r}$ number of different vectors with r-bits having disjoint unknown parts with $\vec{u_i}$. □

Example IV.2. *Following Proposition IV.11, for $n = 10$, we can allow input vectors with number of bits ranging from 5 to 10. Given an input vector $\vec{u_1}$ with $|Unp(\vec{u_1})| = 5$ there can be exactly 1 possible 5-bit vector, say $\vec{u_{11}}$, having non-overlapping unknown parts with $\vec{u_1}$. For an input vector $\vec{u_2}$ with $|Unp(\vec{u_2})| = 4$ there can be exactly 15 possible 6-bit vectors having non-overlapping unknown parts with $\vec{u_2}$. However, these 15 vectors may have common unknown parts within themselves. Thus, at each turn we can select exactly one vector, say $\vec{u_{21}}$, from these 15 possible cases satisfying the condition of non-overlapping unknown components with $\vec{u_2}$. For an input vector $\vec{u_3}$ with $|Unp(\vec{u_3})| = 3$ there can be exactly 35 possible 7-bit vectors having non-overlapping unknown parts with $\vec{u_3}$. So, in one round of selection out of 35 possibilities we can select a pair of vectors, say $\vec{u_{31}}, \vec{u_{32}}$, such that $\vec{u_3}$ and these two vectors satisfy mutually disjoint unknown parts. For an input vector $\vec{u_4}$ with $|Unp(\vec{u_4})| = 2$ there can be exactly 28 possible 8-bit vectors having non-overlapping unknown parts with $\vec{u_4}$. In this case, out of 28 possibilities we can select 4 vectors, say $\vec{u_{41}}, \vec{u_{42}}, \vec{u_{43}}, \vec{u_{44}}$ such that along with $\vec{u_4}$ they satisfy mutually disjoint unknown parts. For an input vector $\vec{u_5}$ with $|Unp(\vec{u_5})| = 1$ there can be exactly 9 possible 9-bit vectors having non-overlapping unknown parts with $\vec{u_5}$ and all of them can be considered together in one round of selection as they satisfy mutually disjoint unknown parts.*

[3] $n = 2m$ or $n = 2m + 1$, is also possible.
[4] LHS and RHS are respectively the abbreviations for Left Hand Side and Right Hand Side of a relational equation.

From the above clarification, two important aspects are surfacing out. One is the chosen number of unknown components for the vectors of a particular dimension. If half of the components are unknown the number of different vectors with non-overlapping unknown parts is very less, and when the number of unknown components is decreasing possible number of different vectors satisfying (MHUP) and (EP) is increasing. However, as it is visible from the example that there seems to be a threshold value for number of unknown components, which is here 3, after which the number of possible vectors with a specified number of unknown components is decreasing. On the other hand, even for a vector $\vec{u_i}$ with $n - r$ ($\leq \lfloor n/2 \rfloor$) number of unknown components not all of the ${}^{r}C_{n-r}$ number of possible vectors having non-overlapping unknown parts with $\vec{u_i}$ can be considered together as they would not satisfy (MDUP). So, in order to train a perceptron model if we wish to use the available data as much as possible satisfying the conditions of a Dset, we may need to split the data over several iterations and learn separately the perceptron model generated in each iteration.

V. Constructing Associative Memory and Splitting Data Over Iterations

Given the above analysis about the number of possible input vectors of dimension n satisfying the conditions of Definition IV.1 and the condition concerning precision level of each input vector (see Proposition IV.6) let us introduce the following method ensuring non-overlapping sets of associative patterns for a given Dset.

Definition V.1 (M-AM)**.** *Let a Dset containing k number of n-dimensional input vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$ be given. The method, called as M-AM, of creating the associative memory for each input vector is described as follows.*

1) *For each i, if the precision level ρ_i is s.t. $p_i < \rho_i < p_i + p_j$ for any $j \neq i$ holds, then consider $U_{\rho_i} = \{\vec{u} \in U_i^{n-p_i} : |Unp(\vec{u})| \leq \rho_i\}$ as $AM(\vec{u_i})$.*
2) *If for a vector $\vec{u_i}$ there is no ρ_i satisfying Condition IV.5, then follow the following process of modifying U_{ρ_i}.*
   a) *Find $O_i = \{l \mid p_i + p_l = min_j\ p_i + p_j,\ j \neq i\}$*
   b) *Consider $\rho_i = p_i + p_l$*
   c) *$U_{\rho_i}^{mod} = \{\vec{u} \in U_{\rho_i} : Unp(\vec{u}) \not\supseteq Unp(\vec{u_l}),\ l \in O_i\}$ and consider $U_{\rho_i}^{mod}$ as $AM(\vec{u_i})$.*

The method M-AM describes an algorithm for determining a precision level for each input vector keeping an eye on the whole input data and accordingly creating an associative memory for each input vector of a given data set $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$. However, at this stage our next concern is to check what amount of associative patterns can be generated for each input vector following the method M-AM.

Proposition V.2. *Given input vectors $\vec{u_1}, \vec{u_2}, ..., \vec{u_k}$, for an arbitrary $\vec{u_i}$, if the precision level ρ_i is s.t. $p_i < \rho_i < p_i + p_j$ for any $j \neq i$ holds, then $|U_{\rho_i}| = {}^{n-p_i}C_{\rho_i - p_i}$*

Proof. According to M-AM for any $\vec{u} \in U_{\rho_i}$, $Unp(\vec{u}) \supseteq Unp(\vec{u_i})$, $|Unp(\vec{u})| \leq \rho_i$ where $p_i < \rho_i < p_i + p_j$, any $i \neq j$. So, for any $\vec{u} \in U_{\rho_i}$ $Unp(\vec{u})$ contains $Unp(\vec{u_i})$ and any $|Unp(\vec{u}) - Unp(\vec{u_i})|$ = ρ_i - p_i positions out of $|\{1, 2, \ldots, n\} - Unp(\vec{u_i})|$ = n-p_i positions of $Bits(\vec{u_i})$. Thus, $|U_{\rho_i}| = {}^{n-p_i}C_{\rho_i - p_i}$. □

Proposition V.3. *Given input vectors $\vec{u_1}, \vec{u_2}, ..., \vec{u_k}$, if for an arbitrary $\vec{u_i}$, there is no ρ_i s.t. $p_i < \rho_i < p_i + p_j$ for any $j \neq i$, then $|U_{\rho_i}^{mod}| = {}^{n-(p_i+|O_i|)}C_1$ where $O_i = \{L : p_i + p_L = min_j\ p_i + p_j, j \neq i\}$*

Proof. Clearly, $U_{\rho_i}^{mod} \subseteq U_{\rho_i}$ and as there is some $j \neq i$ for which p_j = 1, $\rho_i = p_i + 1$. So, following Proposition V.2 $\rho_i - p_i = 1$. Moreover, while creating $U_{\rho_i}^{mod}$ as we are considering that for any $u \in U_{\rho_i}^{mod}$ if $l \in O_i$ then $l \notin Unp(\vec{u})$, we also need to remove from $\{1, 2, \ldots, n\}$ all unknown positions of the vectors $\vec{u_l}$ such that $l \in O_i$. So, in contrary to Proposition V.2 here we have $n - (p_i + |O_i|)$ remaining positions from where $\rho_i - p_i$ that is 1 position can be chosen to be included in $Unp(\vec{u})$. So, we have ${}^{n-(p_i+|O_i|)}C_1$ many ways to create $Unp(\vec{u})$ by adding one additional position to $Unp(\vec{u_i})$. Hence $|U_{\rho_i}^{mod}| = {}^{n-(p_i+|O_i|)}C_1$. □

Following Proposition V.3, we can see that the more input vectors with unknown components equal to 1, i.e., $|O_i|$ increases, the number of vectors belonging to $U_{\rho_i}^{mod}$ decreases. For this reason, we should avoid having a large number of input data consisting of just one unknown component vector.

A. Stepwise Unknown Full Cover Input Data

Following Proposition V.3, we should avoid a set of input vectors such that each has only one unknown component. The sequel below will make the point more precise.

Proposition V.4. *Following M-AM for any n number of n-dimensional vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_n}$, if $AM(\vec{u_i}) \supsetneq \{\vec{u_i}\}$ then it can not be the case that $p_1 = p_2 = \cdots = p_n = 1$.*

Proof. Contrapositively, if for a data set satisfying conditions of M-AM we assume $p_1 = p_2 = \cdots = p_n = 1$, then for any $\vec{u_i}$ by Proposition IV.7 there is no ρ_i such that $p_i < \rho_i < p_i + p_j$ for any $j \neq i$, $i, j \in \{1, 2, \ldots, n\}$. Thus,$AM(\vec{u_i}) = U_{\rho_i}^{mod}$. But $O_i = \emptyset$. Hence, $AM(\vec{u_i}) = \{\vec{u_i}\}$. □

Definition V.5 (SUFC)**.** *Given a set of n-dimensional input vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$ with $|Unp(\vec{u_i})| = p_i$ for $1 \leq i \leq k$, and $p_1 = p_2 = \cdots = p_k = 1$ if $\cup_{i=1}^{k} Unp(\vec{u_i}) = \{1, 2, \ldots, n\}$ and $Unp(\vec{u_i}) \cap Unp(\vec{u_j}) = \emptyset$ for any $i \neq j$, then we call such data set as Stepwise Unknown Full Cover (SUFC).*

Thus, along with conditions mentioned in Definition IV.1 let us add another additional condition on the Dset.

Condition V.6. *A Dset of input vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$ should not satisfy SUFC.*

Based on the above discussion it is clear that apart from the conditions mentioned in Definition IV.1 we need some other conditions to be imposed in order to follow method M-AM in the process of creating associative memory for a Dset. Thus, below we present a modified notion of Dset.

Definition V.7 (Dset$_{AM}$)**.** *Given a set of input vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$ we say it as a Dset$_{AM}$, if it is a Dset and satisfies Condition V.6.*

B. Processing Input Data Through Iterations

Based on the results and discussion presented in the above sections, we can notice a few important aspects for effectively using a given data in the process of creating associative patterns and then learning perceptron models based on them. The first is that, given a Dset of n-dimensional input vectors to apply method M-AM for creating associative memories for input vectors we may need to split the Dset over different iterations. Secondly, in order to avoid overlapping sets of associative patterns for all the vectors considered in a particular iteration the input vectors considered in each iteration should form a Dset$_{AM}$. Thirdly, based on Proposition IV.11 and Example IV.2 we recognize a need for selecting a Dset$_{AM}$ for each iteration satisfying a *top down decomposition ordering*, described below, by allowing gradually less unknown parts (or gradually more known parts) in the selection of input vectors.

C. Top-down Decomposition Ordering

We propose a method for ordering the input data to be selected in a $Dset_{AM}$ in such a way that it considers vectors with gradually increasing order of unknown parts while selecting for a $Dset_{AM}$ from a given data.

Definition V.8 (TDDO)**.** *Let us consider a set of input vectors, $In = \{\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}\}$ of dimension n, where $n > 3$.* [5] *A Top-Down Decomposition Ordering of input vectors is composed of the following steps.*

1) *Select a vector $\vec{u_j}$ ($1 \leq j \leq k$) such that $|Unp(\vec{u_j})|$ is minimum. Call the vector $\vec{u_{j1}}$.*
2) *Select the next vector from $In \setminus \{\vec{u_j}\}$ such that the number of unknown components of the selected vector is $|Unp(\vec{u_j})|$+1 and the unknown components of the new vector does not have common overlap with $Unp(\vec{u_j})$. Call the new vector $\vec{u_{j2}}$.*
3) *Continue the process as long as there is no vector from the remaining set of In satisfying condition (2).*

Example V.1. *Given a input data $In = \{\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}\}$ for $n = 10$. Following Definition V.8 consider input vectors from In such that $\vec{u_{j1}}$ with $|Unp(\vec{u_{j1}})| = 1$, $\vec{u_{j2}}$ with $|Unp(\vec{u_{j2}})| = 2$, $\vec{u_{j3}}$ with $|Unp(\vec{u_{j3}})| = 3$ and $\vec{u_{j4}}$ with $|Unp(\vec{u_{j4}})| = 4$, and they satisfy (MDUP). Clearly, for $n = 10$, there are no more than 4 vectors that have no common overlapping unknown components covering $\{1, 2, \ldots, 10\}$. Thus, an iteration consist of this set of vectors $\{\vec{u_1}, \vec{u_2}, \vec{u_3}, \vec{u_4}\}$.*

From Example V.1 we can see that following TDDO if we select input vectors, starting from lowest number of unknown components, in a strict increasing manner depending on the dimension of the vector there seems to be a threshold value for the number of unknown components. For instance, in case of Example V.1 for 10 dimensional vectors this threshold value is 4. The sequel below throws light on this.

Definition V.9 (Threshold and cardinality value for TDDO)**.** *Let a set of input vectors of n-dimension ($n > 3$) be given. To create a Dset$_{AM}$ for one iteration we first select a vector with exactly one unknown component and continue selecting a sequence of vectors following TDDO. When the process reaches to stage 3 of TDDO (see Definition V.8) the maximum number of unknown components of the last selected vector in Dset$_{AM}$ is considered to be the threshold value for TDDO for dimension n, denoted by T_n, and the cardinality of the Dset thus constructed is called the cardinality value for Dset$_{AM}$, denoted as $|Dset_{AM}|$.*

Following Definition V.9 it is clear that for an n-dimensional input vectors once we reach to the stage (3) of TDDO and get hold of a vector reaching threshold T_n we cannot include any vector in the respective Dset$_{AM}$ having more than T_n number of unknown components. So, one important question is how to determine the threshold T_n for any arbitrary dimension n.

Theorem V.10. *Given a set of input vectors of dimension n let T_n and $|Dset_{AM}|$ be respectively the threshold value and cardinality value of the Dset$_{AM}$ obtained following TDDO corresponding to an iteration. Then considering $|Dset_{AM}| = i$ the following relations hold between T_n and i.*

1) *If $n = 2, 3$, $T_n = 1$.*
2) *For any $n > 3$ and $i \geq 2$, $\frac{i(i+1)}{2} \leq n \leq \frac{i(i+1)}{2} + i$ holds and for all such n, $T_n = i$.*

Proof. For $n = 2, 3$ the case is straightforward.

For any n ($n > 3$) the increasing order of unknown components of the vectors selected in $Dset$ are $1, 2, \ldots T_n$. So, $|Dset_n| = T_n = i$. Following TDDO, $n - (1 + 2 + \cdots + i) \leq i$.
$\therefore n \leq \frac{i(i+1)}{2} + i$ and clearly for $n > 3$, the value i must satisfy $i \geq 2$.
Moreover, total number of positions covered by the unknown parts of the vectors of $Dset_n$ cannot exceed n. $\therefore \frac{i(i+1)}{2} \leq n$
$\therefore \frac{i(i+1)}{2} \leq n \leq \frac{i(i+1)}{2} + i$, for all $n > 3$ and $i \geq 2$.
Moreover, as for any $n \in [\frac{i(i+1)}{2}, \frac{i(i+1)}{2} + i]$ after covering gradually $1, 2, \ldots, i$ number of unknown positions, i.e., total $\frac{i(i+1)}{2}$ positions out of n dimension, there can be at most i positions remaining to be considered as unknown part of a vector. Thus, the threshold value T_n for all such n would be the same as i. □

Example V.2. *Following Theorem V.10, let us consider that $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$ be a set of input vectors of dimension $n > 3$. For $i = 2$ we see that 4, $5 \in [\frac{i(i+1)}{2}, \frac{i(i+1)}{2} + i]$ and $T_n = 2$; that is following TDDO there cannot be any vector of more than 2 unknown parts in a $Dset_{AM}$. For $i = 3$, $n \in [6, 9]$ and for any n lying in this interval $T_n = 3$ as the gradual increasing order of the number of unknown components of any vector entitled to enter in a $Dset_{AM}$ of an iteration are 1, 2, 3. Similarly, for $i = 4$, $[\frac{i(i+1)}{2}, \frac{i(i+1)}{2} + i] = [10, 14]$ and*

[5] Following the condition that for a n-dimensional vector maximum number unknown components can be $\lfloor n/2 \rfloor$, for a vector of dimension one would not have any unknown component, and for a vector of dimension 2 or dimension 3 can have exactly one unknown component. So, TDDO does not apply to the vectors with dimension $n \leq 3$.

for any $n \in [10, 14]$ the threshold value for maximum unknown part following TDDO is $T_n = 4$.

D. Splitting data over iterations

As it is clear from previous sections, for n-dimensional vectors satisfying first two conditions mentioned in Definition IV.1 we may have $\sum_{i=0}^{\lfloor n/2 \rfloor} {}^nC_i$ of vectors in the input data In. However, following method M-AM in one iteration we can use only one small fragment of of data from In using TDDO. So, below we propose a complete procedure for using the data of In over some iterations.

Definition V.11 (SDOI)**.** *For a input data In containing n-dimensional vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$ by Splitting Data Over Iterations (SDOI) we mean the following procedure. In the first iteration, say I_0, we choose the vectors for $DSet^0_{AM}$ as follows.*

(i) *Select the first appeared vector $\vec{u_j} \in In$ with minimum $|Unp(\vec{u_j})|$ ($\leq T_n$) and rename it $\vec{u_{j1}}$*

(ii) *Following TDDO select vectors from $In \setminus \{\vec{u_j}\}$ with gradually increasing order of unknown components (considering first such appeared in input data) and continue till it reaches the threshold value T_n*

(iii) *Step (ii) ends when at most T_n vectors, say $\vec{u_{j1}}, \vec{u_{j2}} \ldots, \vec{u_{jT_n}} \in Dset^0_{AM}$. For the remaining $n - \frac{T_n(T_{n+1})}{2}$ positions select vectors from $In \setminus Dset^0_{AM}$ such that the gradual selection of the vectors satisfy monotonically decreasing order of unknown parts (satisfying Definition IV.1) as long as $\cup_{\vec{u} \in Dset^0_{AM}} Unp(\vec{u})$ = $\{1, 2, \ldots, n\}$.*

(iv) *Once Step (iii) ends, a new iteration of creating next $Dset_{AM}$ starts from step (i) over the remaining data $In \setminus Dset^0_{AM}$.*

(v) *Step (iv) continues as long as it is possible to create a new $Dset_{AM}$ following steps (i)-(iii).*

Example V.3. *For $n = 14$, in the iteration I_0 we may have $Dset_{AM} = \{\vec{u_1}, \vec{u_2}, \vec{u_3}, \vec{u_4}, \vec{u_5}, \vec{u_6}\}$ where $|Unp(\vec{u_i})| = i$ for $1 \leq i \leq 4$, and after reaching $T_{14} = 4$, $|Unp(\vec{u_5})| = 3$ and $|Unp(\vec{u_6})| = 1$. There can be several possibilities of constructing such a $Dset_{AM}$. For instance, one such is $Unp(\vec{u_1}) = \{1\}$, $Unp(\vec{u_2}) = \{2, 3\}$, $Unp(\vec{u_3}) = \{4, 5, 6\}$, $Unp(\vec{u_4}) = \{7, 8, 9, 10\}$, $Unp(\vec{u_5}) = \{11, 12, 13\}$, and $Unp(\vec{u_6}) = \{14\}$.*

Now let us present another example in order to understand how the associative memories for a given set of input vectors of a specific dimension n can be constructed following M-AM method and the data selection method described in Definition V.11.

Example V.4. *Given a input data In containing 8-dimensional vectors $\vec{u_1}, \vec{u_2}, \ldots, \vec{u_k}$. Following Definitions V.1, V.8, V.9 V.11 consider the input vectors from In such that $\vec{u_1}$ with $Unp(\vec{u_1}) = \{1\}$, $\vec{u_2}$ with $Unp(\vec{u_2}) = \{2, 3\}$, $\vec{u_3}$ with $Unp(\vec{u_3}) = \{4, 5, 6\}$, [6] $\vec{u_4}$ with $Unp(\vec{u_4}) = \{7, 8\}$, that is, $I_0 = \{\vec{u_1}, \vec{u_2}, \vec{u_3}, \vec{u_4}\}$. We can check that the precision level for $\vec{u_1}$ is obtained following the first condition of Definition V.1. Since $\rho_1 = 2$ satisfying Condition IV.5, we can consider $\vec{u} \in U_{\rho_1}$, s.t. $Unp(\vec{u}) = \{1, i\}$ where $i \neq 1$, $i \leq 8$. That is $U_{\rho_1} = \{\langle ?, u_{12}, u_{13}, \ldots, u_{18}\rangle$: exactly one of $u_{1j} = ?$ for $j \neq 1$ and $u_{1k} = \vec{u_{ik}}$, $k \neq j, 1\}$. To illustrate more precisely, let us assume $\vec{u_1} = \langle ?, 0, 1, 0, 1, 0, 1, 0\rangle$. Then $U_{\rho_1} = \{\langle ?, ?, 1, 0, 1, 0, 1, 0\rangle, \langle ?, 0, ?, 0, 1, 0, 1, 0\rangle, \langle ?, 0, 1, ?, 1, 0, 1, 0\rangle, \ldots, \langle ?, 0, 1, 0, 1, 0, 1, ?\rangle\}$. For the other vectors $\vec{u_i}$, $i = 2, 3, 4$, the precision levels cannot be obtained following the first condition of Definition V.1 (see Proposition IV.7). Therefore, we follow the process of modifying U_{ρ_i}. According to Proposition IV.7, $O_i = \{1\}$, $\rho_i = p_i + p_1$ for any $i \neq 1$, $1 < i \leq 4$. [7] Therefore we should consider $\vec{u} \in U^{mod}_{\rho_i}$, s.t. $Unp(\vec{u}) = Unp(\vec{u_i}) \cup \{j\}$ where $1 < i \leq 4$, $j \neq 1$, $j \leq 8$, $Unp(\vec{u_i}) \cap \{j\} = \emptyset$. That is $U^{mod}_{\rho_2} = \{\langle u_{21}, ?, ?, u_{24}, \ldots, u_{28}\rangle$: exactly one of $u_{2j} = ?$ for $j \neq 1, 2, 3$ and $u_{2k} = \vec{u_{ik}}, k \neq j, 2, 3\}$. To illustrate this, let us say a given vector $\vec{u_2} = \langle 1, ?, ?, 0, 1, 0, 1, 0\rangle$. Then $U^{mod}_{\rho_2} = \{\langle 1, ?, ?, ?, 1, 0, 1, 0\rangle, \langle 1, ?, ?, 0, ?, 0, 1, 0\rangle, \langle 1, ?, ?, 0, 1, ?, 1, 0\rangle, \langle 1, ?, ?, 0, 1, 0, ?, 0\rangle \langle 1, ?, ?, 0, 1, 0, 1, ?\rangle\}$. Similarly, $U^{mod}_{\rho_3} = \{\langle u_{31}, u_{32}, u_{33}, ?, ?, ?, u_{37}, u_{38}\rangle$: exactly one of $u_{3j} = ?$ for $j \neq 1, 4, 5, 6$ and $u_{3k} = \vec{u_{ik}}, k \neq j, 4, 5, 6\}$ and $U^{mod}_{\rho_4} = \{\langle u_{41}, \ldots, u_{46}, ?, ?\rangle$: exactly one of $u_{4j} = ?$ for $j \neq 1, 7, 8$ and $u_{4k} = \vec{u_{ik}}, k \neq j, 7, 8\}$.*

VI. Information Retrieval from Associative Memory Using Perceptron

In this section, we attempt to sketch the idea of projecting a 2-layer perceptron from a $Dset_{AM}$ generated by an iteration following SDOI. In contrary to [3], in our case a $Dset_{AM}$ contains input data with unknown components. Following [9], [10], if the perceptron is trained on samples with incomplete feature vectors, i.e., partial input data, significant propagation errors may occur during the inference process. In addition, if important features are frequently missing, the learned decision boundaries may become biased or suboptimal, which can degrade the model's prediction performance. To get rid of this problem, it is essential to implement a process to replace missing data before training. This allows the perceptron to learn from partially known data, thereby outputting incomplete input data as complete data. So, below we propose a way to replace the partial input vectors with a potential full vector.

A. Replacing Partial Vectors By Full Vectors

The $Dset_{AM}$ generated by an iteration of SDOI contains vectors satisfying (MDUP). That is, the unknown parts of any pair of vectors do not have common overlap with each others. This feature can be utilized to reconstruct full vectors before training the perceptron model. We replace each vector from a $Dset_{AM}$ as follows.

1) Given $\vec{u_i}, \vec{u_j} \in Dset_{AM}$ for any $i \neq j$, $1 \leq i, j \leq T_n$ the unknown component of the vector $\vec{u_i}$ is replaced with the

[6] Following Theorem V.10, the threshold value $T_n = 3$ for $n = 8$.

[7] We only consider the given vectors $\vec{u_1}, \vec{u_2}, \vec{u_3}, \vec{u_4}$.

known components of the vector $\vec{u_j}$. For vector $\vec{u_i}$ only the positions from $Unp(\vec{u_i}) \cap Bits(\vec{u_j})$ are replaced with that of $\vec{u_j}$. The new vector created in this way is called $\vec{u_{ij}}$. Following similar process $\vec{u_{ji}}$ is also obtained.

2) Check Hamming distance between $\vec{u_{ij}}$ and $\vec{u_{ji}}$, for any $i \neq j$
3) Among the vectors $\vec{u_{ij}}$ $j \neq i$ obtained by exchanging parts with $\vec{u_i}$ the one with minimum Hamming distance, would determine the full vector that can be selected to replace $\vec{u_i}$ considering as the most plausible ideal representation of $\vec{u_i}$.

Following the above method, we can expect that the reconstructed input vector will match more closely the ideal input data set without noise and unknown parts. Using the Hamming distance as a similarity measure, we can systematically select the most reasonable candidate from the pool of potential complete vectors, obtaining an input data set that better matches the intended representation of the original set of partial input vectors.

Example VI.1. *For $n = 10$, in an iteration I_0 we may have $Dset^0_{AM} = \{\vec{u_1}, \vec{u_2}, \vec{u_3}, \vec{u_4}\}$, where $|Unp(\vec{u_i})| = i$, for $1 \leq i \leq 4$, $T_n = 4$.*
Let the vectors be $\vec{u_1} = \langle 0,1,0,0,?,1,1,1,0,0\rangle$, $\vec{u_2} = \langle 1,1,0,0,0,1,0,?,0,?\rangle$, $\vec{u_3} = \langle 1,0,0,0,0,?,?,1,?,0\rangle$, $\vec{u_4} = \langle ?,?,?,?,0,1,1,1,0,0\rangle$, where ? denotes missing value in a vector.
Replacing $Unp(\vec{u_1})$ with $Bits(\vec{u_2})$, $Bits(\vec{u_3})$ and $Bits(\vec{u_4})$, we respectively have $\vec{u_{12}} = \langle 0,1,0,0,0,1,1,1,0,0\rangle$, $\vec{u_{13}} = \langle 0,1,0,0,0,1,1,1,0,0\rangle, \vec{u_{14}} = \langle 0,1,0,0,0,1,1,1,0,0\rangle$.
Similarly, replacing the unknown components $\vec{u_2}$ with the known components of other vectors we have, $\vec{u_{21}} = \langle 1,1,0,0,0,1,0,1,0,1\rangle$, $\vec{u_{23}} = \langle 1,1,0,0,0,1,0,1,0,1\rangle$, $\vec{u_{24}} = \langle 1,1,0,0,0,1,0,1,0,0\rangle$. For $\vec{u_3}$ we have $\vec{u_{31}} = \langle 1,0,0,0,0,1,1,1,0,0\rangle$, $\vec{u_{32}} = \langle 1,0,0,0,0,1,0,1,0,0\rangle$, $\vec{u_{34}} = \langle 1,0,0,0,0,1,1,1,0,0\rangle$, and for $\vec{u_4}$ we have $\vec{u_{41}} = \langle 0,1,0,0,0,1,1,1,0,0\rangle$, $\vec{u_{42}} = \langle 1,1,0,0,0,1,1,1,0,0\rangle$, $\vec{u_{43}} = \langle 1,0,0,0,0,1,1,1,0,0\rangle$.
Next, we check the Hamming distance between each pair of exchanged vectors. $D_H(\vec{u_{12}}, \vec{u_{21}}) = 3$, $D_H(\vec{u_{13}}, \vec{u_{31}}) = 2$, $D_H(\vec{u_{14}}, \vec{u_{41}}) = 0$, $D_H(\vec{u_{23}}, \vec{u_{32}}) = 2$, $D_H(\vec{u_{24}}, \vec{u_{42}}) = 1$, $D_H(\vec{u_{34}}, \vec{u_{43}}) = 0$. [8]
From the above calculation we see, the minimum Hamming distance of $D_H(\vec{u_{1j}}, \vec{u_{j1}})$ where $j \in \{2,3,4\}$, is $D_H(\vec{u_{14}}, \vec{u_{41}})$. So partial vectors $\vec{u_1}$ and $\vec{u_4}$ are exchanged the parts within themselves the newly obtained full vectors $\vec{u_{14}}$ appears to be most closely fitting. Thus, $\vec{u_1}$ can be substituted with full vector $\vec{u_{14}}$. Similarly, partial vector $\vec{u_2}$ can be substituted with full vector $\vec{u_{24}}$, partial vector $\vec{u_3}$ can be substituted with full vector $\vec{u_{34}}$ and partial vector $\vec{u_4}$ can be substituted with full vector $\vec{u_{41}}$ or $\vec{u_{43}}$.

[8]Since Hamming metric, i.e., $D_H(\vec{u_{12}}, \vec{u_{21}}) = D_H(\vec{u_{21}}, \vec{u_{12}})$, there are only six results left in this case excluding duplicate results.

B. Perceptron model

As described in Section II, creating perceptron model following [3] solely depends on two facts; one is choosing precision levels for the input patterns in a way that their associative memories do not overlap and the second is to convert partial associative patterns of a given input (full) pattern to full patterns. The first point is important in establishing the claim that the set of input-outputs pairs in the extended function f_A are linearly separable and it is required to develop the perceptron model for f_A. In our case, we opt to depart from several aspects considered in [3], and these are mentioned in Introduction as well as in Section II. However, from the development and results presented in the sections above, starting from Section III, it is clear that both the contexts responsible for smooth projection of the function f_A in a perceptron model are guaranteed. Thus, in our case the same strategy as in [3] of creating perceptron model can be followed.

VII. Conclusion

The paper presents some limitations of the approach to creating associative memory in the context of retrieving information from partial patterns using perceptron model presented in [3] and proposes a few more general perspectives of different notions used in [3], [8]. First of all, unlike [3] we propose incomplete information in the input data by allowing partial vectors in the input data. Secondly, the paper proposes a new perspective of measuring distance between two partial vectors using the notion of Hamming distance. According to [3] two partial vectors with different unknown fragments cannot be comparable. Following our approach this limitation is overcome. Thirdly, our proposal for creating associative patterns for an input (partial) vector $\vec{u_i}$ depends on a notion of '$\vec{u}$ is a potential extension of $\vec{u_i}$', denoted by $\vec{u} \otimes \vec{u_i}$. The idea is developed generalizing the notion of $\odot$ presented in [3]. Moreover, in the process of converting incomplete or partial patterns by some plausible full patterns in [3] a random process of replacing unknown parts by 0's is followed. Whereas in our context, we consider an approach of finding plausible full pattern of an input partial pattern by exchanging content of the given pattern with other input vectors of the training data. The idea is similar to solving a puzzle related to constructing a full image of a desired object from several available pieces where different fragments of the full image are visible.

From theoretical perspective, though we manage to resolve the limitations mentioned before, following our proposal a given data set of n-dimensional input vectors cannot be used together in one iteration to train a perceptron model. However, there seems to be a possibility of creating perceptron model from aggregating data from different iterations. In [12], the authors proposed different models for generalizing Hamming associative memory. In particular, they introduced a notion of *local Hamming memory* which is based on splitting the input vectors (input data) into smaller clusters and learning the dependence of all the input vectors in that cluster with their respective outputs. Modifying the idea of local

Hamming memory the authors [12] also defined a notion of *decoupled Hamming associative memory* which considers non-overlapping windows (clusters) of input vectors. Though there is a similarity of their considered idea of non-overlapping windows of input vectors [12] with our idea of splitting the input vectors over iterations, there is a difference in basic consideration. In our case, the input vectors can be partial and in [12] the input vectors are full binary vectors. Following [3] non-overlapping associative memories of the input vectors allows a direct projection of the extended function f_A into a multilayered perceptron model. In our context, though we have departed from [3] on many aspects, we stick to the technical advantage of non-overlapping associative memories of the input vectors. However, following the notion of Distributed Associative Memory (DAM), in [13], the authors envisaged a possibility of representing multiple association of an input data with different sets of patterns. This idea can be worth investigating further in our context by allowing associative patterns of two input vectors to have common intersection. But this needs additional research and experiments in order to optimize the performance of the proposed method and check the changes needed to develop the set-up based on DAM.

***Abstract*—Reconnaissance is a crucial stage of cyberattacks, enabling attackers to gather information about system vulnerabilities. In computer networks, data regarding addressing and transmission paths is especially sensitive. This paper introduces a concept for a hybrid mutation system based on Software Defined Networking (SDN), combining address and data path mutation to improve security. The system employs central network management and pseudorandom, temporary addressing, which is periodically reconfigured. In contrast to existing Moving Target Defense (MTD) address mutation methods, end devices connect through dedicated agents, which can be implemented using a SmartNIC. The agent modifies packet headers at a network edge to obfuscate address information, minimizing the processing burden on SDN switches inside a network. The objective is to hinder attackers from discovering network details that could be exploited. A prototype was implemented using typical SDN components and containerized end devices. Tests confirmed the system's correctness and effectiveness in protecting the network structure and communication paths. This approach enhances the confidentiality of network parameters and limits the information available to potential attackers, making reconnaissance significantly more difficult, while minimizing SDN network control overhead.**

I. Introduction

NETWORK security is critical in today's digital landscape, as it protects sensitive data from unauthorized access and cyber threats while ensuring the integrity and availability of network resources. The network attack cycle spans several steps. The Cyber Kill Chain illustrates this cycle, detailing the stages an attacker typically goes through to successfully breach a network, from reconnaissance and weaponization to delivery, exploitation, installation, command and control, and finally, actions on objectives [1].

The reconnaissance is the initial phase where attackers gather information about their target, identifying potential vulnerabilities and entry points that can be exploited to gain unauthorized access. Stopping an attacker at the reconnaissance phase of a cyber attack provides significant security advantages by preventing further exploitation and reducing the overall risk to a network. However, spotting reconnaissance activity can be challenging due to several factors that make it stealthy and difficult to differentiate from legitimate network traffic. Traditional computer networks are inherently static, making them predictable targets for attackers who exploit static IP addresses, unchanged software stacks, and consistent routing paths to plan and execute cyberattacks. This predictability enables adversaries to conduct prolonged reconnaissance, identify vulnerabilities, and launch precise, well-timed exploits with minimal resistance. The static nature of computer networks gives the attacker a significant advantage over the defender, as attackers can use stealthy techniques to gather information over a long time to identify weaknesses without raising alarms [2].

A proposed solution to this issue was introduced in [3] as part of the USA Federal Networking and Information Technology Research and Development program, which seeks innovative approaches to address critical cybersecurity challenges. This approach, known as Moving Target Defense (MTD), represents a fundamental shift in securing computer networks. The core principle of MTD is that an attack, if successful, can only be effective once, as the system is continuously reconfigured to prevent the reuse of the same attack vector. By dynamically altering the attack surface, MTD increases the complexity and cost for attackers, reduces the window of vulnerability exposure, and enhances overall system resilience. Moving Target Defense mitigates this risk by introducing continuous, randomized changes to network attributes such as IP addresses, system configurations, and routing paths. By dynamically altering the attack surface, MTD disrupts adversarial strategies, forcing attackers to constantly reassess their tactics, thereby increasing the cost and complexity of cyber intrusions [4]. Unlike traditional static defenses relying on perimeter security mechanisms, MTD adopts a proactive security posture that introduces unpredictability while ensuring system reliability for legitimate users.

Numerous MTD strategies have been proposed for securing computer networks [5]. One of the key principles of MTD in networks is IP Address Mutation, which involves frequently changing the IP addresses of critical assets, preventing attackers from accurately mapping the network [6][7]. This technique disrupts traditional reconnaissance methods and limits the effectiveness of targeted attacks. Another effective approach is Dynamic Network Topology, which emphasizes

The research was carried out on devices cofunded by the Warsaw University of Technology within the Excellence Initiative: Research University (IDUB) programme.

dynamic changes in network architecture to confound attackers [8]. Route Mutation and Traffic Obfuscation techniques further enhance network security by dynamically altering packet routes, making it difficult for attackers to eavesdrop or execute man-in-the-middle attacks. This method ensures that sensitive data does not travel predictable paths, increasing the difficulty of successful network intrusions [9]. Service and Port Randomization also prevents attackers from leveraging known vulnerabilities by frequently changing open ports and service access points [10].

The benefits of MTD for networks are substantial. It disrupts reconnaissance efforts, reduces the attack window, and forces adversaries to adapt continuously, increasing their resource expenditure and reducing their ability to execute long-term attacks. Moreover, MTD enhances cyber resilience by introducing self-adaptive security measures that dynamically respond to emerging threats. However, challenges such as performance overhead, compatibility with legacy systems, and the need for intelligent automation must be addressed to optimize MTD implementation.

Software-Defined Networking (SDN) technology plays a key role in implementing most Moving Target Defence strategies, enabling dynamic, automated, and adaptive networking mechanisms. This technology provides programmability, flexibility, and scalability, making it possible to rapidly adjust network configurations, which constitutes the core of most network-based MTD methods. However, these frequent and unpredictable changes introduce significant stress on SDN switches and controllers, impacting performance, stability, and resource utilization.

As noted in [11], while centralization in SDN improves control and flexibility, it also introduces new attack vectors. Offloading certain security functions to edge components can mitigate these risks and improve scalability. With the advent of Smart Network Interface Cards (SmartNICs), there is potential to alleviate some of these pressures by offloading certain processing tasks from the SDN controllers and switches, thereby enhancing overall system efficiency and enabling more robust MTD solutions that can adapt in real-time without compromising network integrity. SmartNICs represent a significant evolution in network interface technology, offering enhanced functionality that extends far beyond traditional NICs. SmartNICs integrate programmable processors, memory, and dedicated hardware accelerators at their core, enabling them to offload network processing tasks [12].

This paper presents a hybrid addressing and route mutation mechanism that utilizes dedicated host agents with a lightweight SDN switch system. These host agents are designed to be implemented using SmartNICs, offloading specific tasks from core SDN switches. This approach not only improves the scalability of network management but also enhances performance by allowing core switches to focus on high-level routing decisions while host agents handle lower-level address mutation tasks efficiently.

II. Related Works

Several solutions based on the concept of address mutation and dynamic routing in network environments built on SDN architecture can be found in scientific literature.

One example of applying address mutation in SDN networks is the OpenFlow Random Host Mutation (OF-RHM) mechanism [13]. Each host is assigned a virtual IP address used during network communication in this solution. Importantly, these addresses are periodically changed, significantly complicating attacks based on traffic monitoring (e.g., sniffing) or network topology analysis. The address mutation process is handled by the switches, which also manage data traffic. Although this approach improves transmission security, it increases the load on the switches, which can negatively impact the overall performance and scalability of the network.

Another approach was presented in [14], where a routing algorithm based on fake addressing was proposed. In this model, switches establish paths between hosts using randomly assigned addresses, while the SDN controller manages the mapping of temporary addresses to actual ones. Despite its security advantages, this solution involves several significant challenges. Firstly, the mutation process executed on the switches generates additional load for these devices. Secondly, the path selection may lead to temporary network congestion, especially in more complex topologies, due to excessive packet flooding during route updates.

In [15], the authors proposed using local NAT tables on each switch. In this model, a dedicated MTD unit responsible for generating temporary addressing is connected to each switch. As a result, the SDN controller is relieved of some responsibility – its role is limited to initializing data transmission paths. Although this reduces the controller's load, the switches still need to handle the address translation process, which remains challenging for their performance.

On the other hand, the solution presented in [16] introduces an additional layer of switches called agents directly connected to end devices. These agents take over the task of address mutation, thereby offloading the main switches responsible for packet routing in the network. This approach limits the impact of mutation on the core infrastructure; however, it introduces another challenge – temporary addressing is created for each individual connection, which may lead to significant load on the SDN controller, especially in high-traffic environments.

III. MTD Concept

This paper proposes a solution based on the Moving Target Defense technique, utilizing a hybrid mutation approach. The proposed method introduces dynamic mutations at both the data transmission path level and the addressing level, specifically targeting the second and third layers of the OSI model, namely the MAC and IP address layers.

Our solution leverages the flexibility and centralized control offered by Software-Defined Networking, where the SDN controller plays a pivotal role. The controller is tasked with orchestrating both path and address mutations and dynamically installing flow rules on SDN switches throughout the network

via the OpenFlow protocol. To support the address mutation process, we introduce lightweight, specialized agents in the form of thin SDN switches that are designed to manipulate packet headers in real time.

These agents are deployed at the network edge, typically on end devices or SmartNICs. They are responsible for executing packet-level transformations in accordance with mutation policies received from the SDN controller. Each agent is capable of performing real-time mutation of MAC and IP addresses. The agents operate transparently to the applications running on the host devices, ensuring seamless communication while continuously altering address mappings to thwart reconnaissance and tracking attempts by potential adversaries.

By offloading the mutation tasks from the core SDN switches to these edge agents, the architecture reduces the processing overhead on network infrastructure components, improves scalability, and enables fine-grained control over address mutation. The result is a dynamic, resilient, and secure communication environment that significantly raises the bar for attackers attempting to exploit static network configurations.

The overall architecture of the proposed system is illustrated in Fig. 1, highlighting the interplay between the SDN controller, the network switches, and the deployed agents.

To establish a connection between devices, the controller performs a pseudo-random selection of one of the available paths labeled 1, 2, and 3 in the diagram. Data exchange takes place over the selected route for the duration defined by the mutation interval.

During operation, packets transmitted in the network are subject to modification to obscure their actual source and destination addresses. Temporary false addressing is applied, referred to as $tMAC$ (temporary MAC address) and tIP (temporary IP address). After the mutation interval expires, the controller generates new temporary addresses and selects new transmission paths for each end device connected to the network.

The real addresses, corresponding to the physical configuration of device interfaces, are denoted as $pMAC$ (permanent MAC address) and pIP (permanent IP address). From the perspective of communicating hosts, it is impossible to discover the actual address of the machine involved in data exchange, ensuring complete address obfuscation within the system. As a result, all packets transmitted within the network contain only temporary, falsified source and destination addresses in their headers.

This mechanism can operate successfully provided all communicating devices, including SDN switches, remain under the organization's control. The system also assumes that the organization has access to a large address pool within a given subnet, allowing for effective masking of real IP addresses. To avoid raising suspicion from a potential attacker, temporary IP addresses are selected from the available address space within the corresponding subnet.

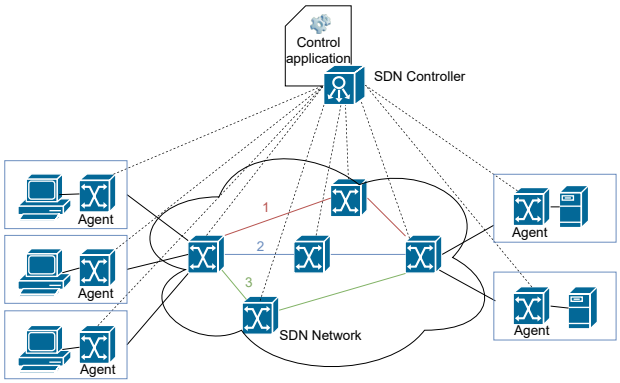

Fig. 1. The architecture of the proposed network

A. Connection Establishment and Handling

Fig. 2 presents a sequence diagram illustrating the phases of a sample connection establishment between *Host 1* and *Server 1*. This process includes:

1) **ARP Request for the *DNS Server***
   Communication with the *DNS Server* is the first step in establishing the connection. Assuming that the ARP tables on the end devices are initially empty, *Host 1* sends an ARP request to the broadcast address (ff:ff:ff:ff:ff:ff) asking for the MAC address of the *DNS Server*. The *H1 Agent* intercepts this request and replies to *Host 1* with a packet containing a temporary MAC address for the *DNS Server*, marked as *tMACDNS* in the diagram.
2) **DNS Query**
   Host 1, now knowing the temporary MAC address of the *DNS Server* (*tMACDNS*), sends a query requesting the IP address of a specific domain. In the presented diagram, the DNS query concerns the domain *server1.pl*, corresponding to the device *Server 1*. The query is received by the *H1 Agent* and then sent to the *SDN Controller* using a `PACKET_IN` message.
   Upon receiving the query, the *SDN Controller* performs a pseudo-random path selection to determine through which switch the communication will proceed. It also verifies whether the requested domain is handled by the *DNS Server*. If the domain does not exist, the connection attempt fails. If the domain is valid, the controller uses temporary addresses created for the current mutation state.
   One of these temporary addresses is the fake IP address of *Server 1* (*tIPS1*). The *SDN Controller* uses this address to modify the DNS server's configuration file, which maps actual server addresses to domain names.
   In the next step, the controller uses the temporary addressing to generate rules for appropriate agents and switches in the network. These rules are installed using `FLOW_MOD` messages. Rules are installed on the *H1*, *S1*, and *DNS* agents. The rules for *H1* and *S1* handle address obfuscation and ARP query handling

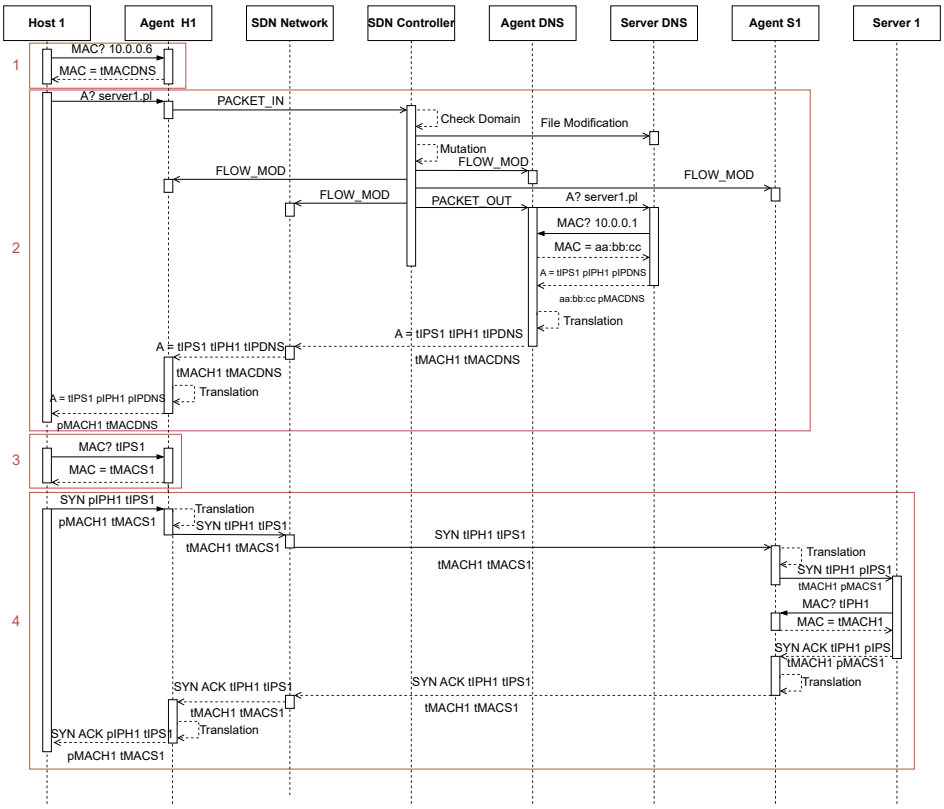

Fig. 2. Connection Establishment and Handling Diagram

for temporary IP addresses. The rule installed on the *DNS Agent* ensures that the DNS response is delivered to *Host 1* through the network. To achieve this, the *SDN Controller* additionally installs rules on *Host 1*'s agent and on the switches in the *SDN Network* to allow proper delivery of the response from the *DNS Server*. The rules installed on the *SDN Network* switches serve exclusively to forward packets between end devices using obfuscated addressing.

The DNS query is directly forwarded to the *DNS Agent* and then to the *DNS Server*. To send a response, the *DNS Server* must obtain the MAC address of *Host 1*, from which the original query was received. It sends an ARP request, which is intercepted by the *DNS Agent*, who replies with a fake MAC address `00:00:00:aa:bb:cc`. Due to the complexity of the proposed system's logic, the *DNS Agent* is configured with a flow rule that returns this MAC address for any IP in response to an ARP request. After receiving the ARP response, the *DNS Server* sends back a DNS response containing the fake IP address corresponding to the requested domain (*tIPS1*). The *DNS Agent*, upon receiving this response, sends it to the *SDN Controller*, which then forwards the packet to the *H1 Agent* via the *SDN Network*. While sending the response into the network, the *DNS Agent* performs address translation, inserting temporary addressing into the packet header: *tMACDNS* and *tIPDNS* for the source, and *tMACH1* and *tIPH1* for the destination. When the *H1 Agent* receives the response, it performs reverse translation by replacing the destination addresses with the real addressing of *Host 1* (*pMACH1* and *pIPH1*).

3) **ARP Request for *Server 1***
After receiving the DNS response containing *tIPS1*, *Host 1* sends an ARP request to obtain the MAC address assigned to this IP address. The rule installed by the *SDN Controller* on the *H1 Agent* handles the request, returning the temporary MAC address of *Server 1*, marked in the diagram as *tMACS1*.

4) **Communication Between Host and Server**
The next part of the diagram presents a sample TCP connection established between *Host 1* and *Server 1*. In the first phase, *Host 1* sends a SYN message as the initial step of the TCP three-way handshake. The packet header includes the real source address (*pIPH1* and *pMACH1*) and the temporary destination address (*tIPS1* and *tMACS1*). Upon receiving it, the *H1 Agent* performs address translation using *tMACH1* and *tIPH1*. The packet sent into the network has fully obfuscated addressing until it reaches the *S1 Agent*, who then

performs reverse translation by replacing the temporary destination address (*tMACS1* and *tIPS1*) with the real address (*pMACS1* and *pIPS1*). After *Server 1* successfully receives the segment, it replies with a SYN-ACK. Meanwhile, the *S1 Agent* handles an ARP query for the *Host 1* address mapping, returning the temporary address *tMACH1*. Since communication is bidirectional, *S1 Agent* once again performs address translation for the response, and on the receiving side, the *H1 Agent* performs reverse translation.

B. Mutation State Change During Connection Duration

One of the assumptions of the system operation is the continuation of the connection when a mutation state change occurs. Fig. 3 illustrates the sequence diagram that fulfills this assumption. The diagram shows a fragment of communication between *Server 1* and *Host 1*, which is downloading a file from the server. It is assumed that the file is large enough for the download process to be time-consuming. It is also assumed that the mutation interval *Tm* is short enough to change a mutation state during the file download process.

After the connection is successfully established, the file download from *Server 1* begins. Communication between *Host 1* and *Server 1* takes place using segments containing the $PUSHACK$ and ACK flags. The segment sent by *Server 1* with the $PUSHACK$ flag includes the data segment of the file requested by *Host 1*. The ACK segment, on the other hand, is the response from *Host 1* indicating successful reception of the segment from *Server 1*. This communication continues until *Server 1* sends all segments. At this point, *Server 1* sends a FIN flag segment, informing *Host 1* that all segments have been transmitted and initiating the connection termination process.

During the connection establishment, the *SDN Controller* places flow rules in the switch flow tables, enabling communication using temporary addressing marked in the diagram as addresses *t0*. These rules have a defined time *Tm*, after which they are permanently removed from the switch. When the rule responsible for address obfuscation on the *Agent H1* is removed, it sends a FLOW_REMOVED message to the *SDN Controller*, informing it that the rule has been deleted. The *SDN Controller* then re-selects the path for communication. Next, using the newly generated addressing in state *t1*, it installs flow rules on the switches responsible, in the case of *Agent H1* and *Agent S1*, for translating addresses *t1*, and for switches in the *SDN Network*, for communication using the *t1* addresses along the new path. After the rules are installed, the client-server communication continues with the new data path state and obfuscated addressing.

IV. Implementation

The experimental environment for the designed system was implemented using the Containernet network emulator, running on a virtual machine with Ubuntu 20.04. Open vSwitch (OVS) was used to implement the agents and SDN switches. These components form the foundation of a software-defined network architecture, which supports advanced dynamic behavior and fine-grained traffic control.

The SDN network is managed by the Ryu controller, which runs a dedicated control application written in Python. This application serves as the central intelligence of the system, orchestrating all major network operations such as address mutation, communication path management and DNS response manipulation. It interacts continuously with switches and agents, using the OpenFlow protocol to install and update flow rules that define how packets are forwarded throughout the network.

One of the core features of the control application is its dynamic addressing mechanism. At fixed intervals, the system triggers a mutation process that generates random temporary IP and MAC addresses for all endpoints in the network, including hosts, servers, and the DNS server. These addresses replace the real ones in communication flows, significantly reducing the feasibility of reconnaissance and tracking by potential attackers. The mutation runs asynchronously in the background, ensuring uninterrupted operation of other system components.

In addition to address mutation, the control application configures agent-hosted rules to intercept and respond to ARP queries. When hosts send ARP requests for the DNS server, the agents reply with dynamically assigned fake MAC addresses.

Another essential component of the architecture is a DNS server built using the Python $Dnslib$ library. It processes traditional DNS queries but is tightly integrated with the control logic. Upon receiving a DNS request, the control application extracts the queried domain, verifies it against a known mapping, and assigns a temporary IP address corresponding to the correct service endpoint. The DNS server configuration is then updated in real time to reflect the new address, ensuring all clients receive the current valid mapping.

Once a DNS query is resolved, the control application establishes the necessary flow rules to guide the DNS response and subsequent communication across the SDN switches and agents. For every transmission, source and destination addresses are translated to temporary counterparts, and then restored on the receiving end, enabling seamless and transparent bidirectional communication.

Communication paths themselves are also subject to mutation. The system periodically selects different routes for data transfer from a predefined set of options. New flow rules are installed along the newly chosen path, while outdated ones are removed.

All flow rules are configured with hard timeouts to ensure that temporary addressing remains effective. The control application is notified when a rule expires and installs a new rule set with updated addresses and paths. This dynamic rule replacement ensures continued communication fidelity while preserving the ephemeral nature of all addressing and routing information.

The overall logic of the control application described above is presented in Algorithm 1.

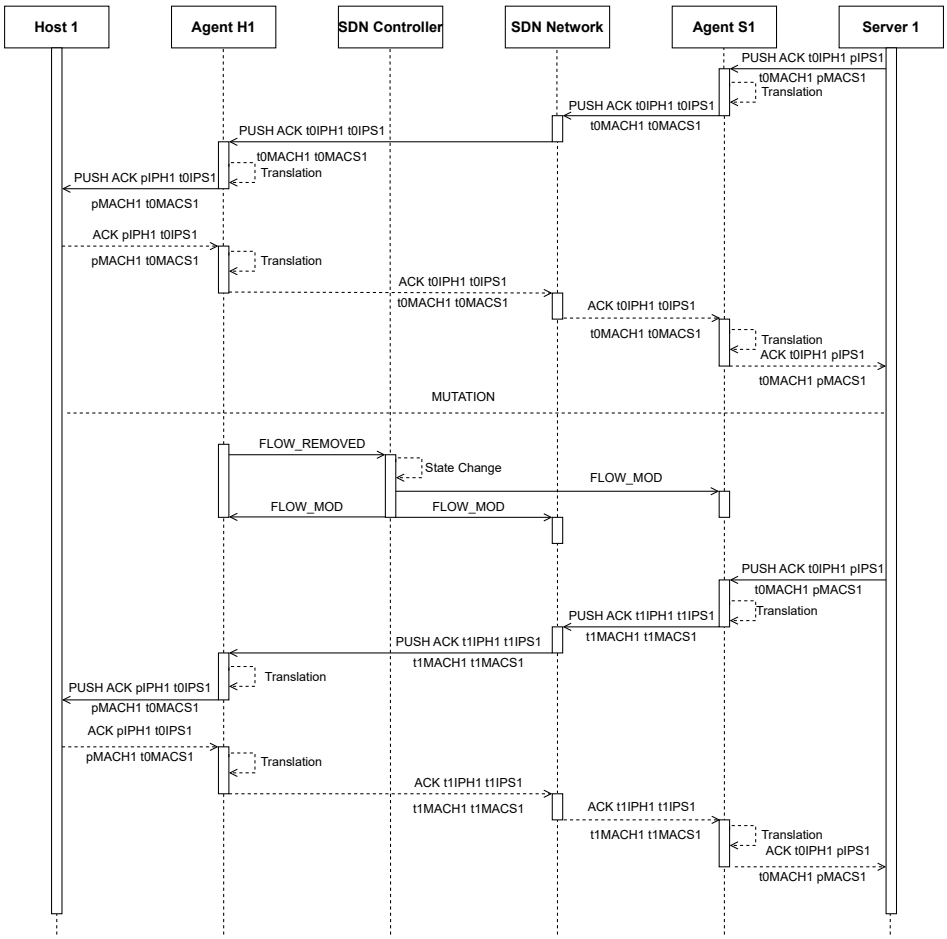

Fig. 3. Mutation State Change During the Connection

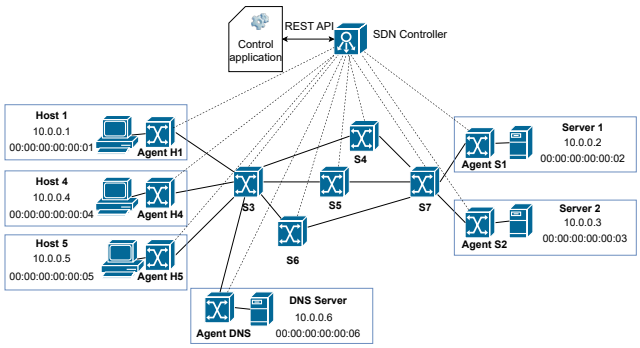

Fig. 4. SDN Network Topology in the Research Environment

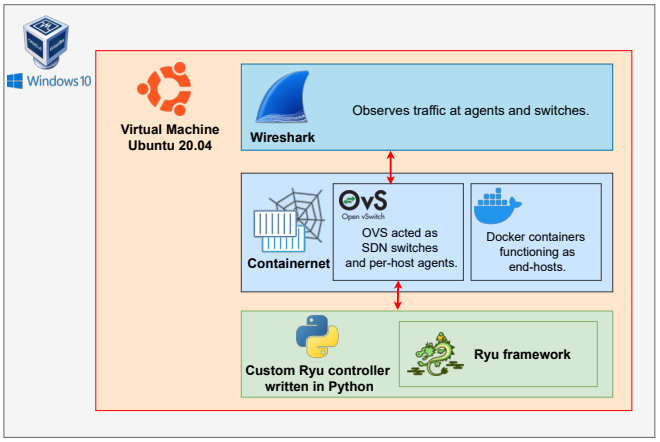

Fig. 5. Logical architecture of the implemented environment

The structure of the implemented network, including address allocation for individual components, is illustrated in Fig. 4, and the logical system architecture is shown in Fig. 5.

V. Validation and Results

A series of test scenarios were developed to verify the implemented system's operation.

Algorithm 1 Control Application Logic for SDN Mutation System

Require: Active SDN controller, initialized switches, known domain-to-server mappings
Ensure: Continuous operation with dynamic addressing and path mutation

Initialize mappings and path set
Start background **MutationLoop**
OnSwitchFeaturesReceived
if host agent **then**
    Install ARP rule, redirect DNS to controller
else if DNS agent **then**
    Install ARP rule
end if
OnPacketIn
if DNS query for known domain **then**
    Select endpoint, assign temporary IP/MACs
    Store mappings, update DNS config
    Install translation and ARP rules
    Select path, install forwarding rules
    Forward modified DNS packet
end if
OnFlowRemoved
if ARP rule expired **then**
    Reinstall ARP rule
else if IP flow expired **then**
    Identify flow, retrieve temp addresses
    Select path, reinstall updated rules
end if
MutationLoop (background)
while true **do**
    Sleep for interval, generate temp IP/MACs
    Update mappings, reinstall rules
end while

A. Address Mutation

The first test scenario illustrates network traffic on various devices belonging to the selected path during communication between *H4* and *Server 2* using the $ping$ command.

Fig. 8 shows traffic on the interface of the agent connected to *H4*. Initially, the agent responds to an ARP query regarding the DNS server, returning the temporary MAC address (*t_MAC_DNS*). Then, the host sends a DNS query for the IP address of the server domain $server2.pl$. After forwarding the query to the controller, it is sent to the DNS server, which returns a response containing the temporary IP address of the target server (*t_IP_S2*).

To begin the transmission of ICMP packets, the host must still obtain the MAC address assigned to the server. In response to the ARP query, the agent returns the temporary MAC address of the server (*t_MAC_S2*). Following this, correct communication occurs, using the temporary destination addressing.

The source addressing is obscured when the packet passes through the agent. The agent then replaces the real addressing with the temporary one corresponding to the given host (*t_MAC_H4* and *t_IP_H4*). Fig. 9 shows the observation of traffic on a selected switch in the *SDN Network* located on the communication path. The ICMP packets contain both temporary source and destination addressing.

The observation of traffic on the *Agent S2* device port, connecting the agent to the server, is shown in Figure 10. Upon receiving the appropriate packet from the network, the agent performs a reverse translation, replacing the temporary server addressing with the real one, labeled *p_MAC_S2* and *p_IP_S2*, allowing the response to be sent to the host.

B. Change of Address Mutation State

As part of the address mutation mechanism, after the time *Tm* has passed, communication in the system takes place using the temporary addressing of the new state. In the following Fig. 6 and Fig. 7, the communication between *Host 1* and *Server 1* during the download of an HTTP page is presented, using temporary addresses in two different states of the system.

During the first two connections (lines 1-27 and 3-6 of listings in Fig. 6 and Fig. 7 respectively), *Host 1* communicates with *Server 1* using the temporary address 10.0.0.165, and the server 10.0.0.53. After the time *Tm*, defined in the test as 10 seconds, the subsequent page download (lines 29-41 and 7-8) takes place using a new pair of temporary addresses: 10.0.0.237 for *Host 1* and 10.0.0.102 for *Server 1*.

C. Mutation of Path and Address State During the Connection

The implemented system supports mutation during the connection, ensuring continuous communication. In the test on device *Host 5*, a 1GB file was downloaded from *Server 1*. The time *Tm* was set to 5 seconds, allowing for the observation of frequent mutation state changes in the system.

Upon establishing a connection with *Server 1*, *Host 1* received the following messages, shown in Fig. 11:

- temporary MAC address of the *DNS Server* 23:DA:A9:89:27:51 (*t_MAC_DNS*),
- temporary IP address of *Server 1* 10.0.0.185 (*t_IP_S1_t0*),
- temporary MAC address of *Server 1* B1:56:ED:C4:2D:06 (*t_MAC_S1_t0*).

Subsequent communication involves downloading the file "plik.bin" from *Server 1*. Fig. 12 shows the traffic observed on switch *S5* (chosen for path mutation) with completely obfuscated addressing. *Host 5* uses the temporary address D1:58:C0:F7:AE:3C (*t_MAC_H5_t0*) and 10.0.0.247 (*t_IP_H5_t0*). Fig. 13 depicts the situation of a mutation state change. After the time *Tm* has passed, the flows on the corresponding switches are updated, enabling continued communication with a new address and path. In the new mutation state for the path, the switch changes to *S4*, through which the segments are transmitted. Additionally, new temporary addresses appear in the packet headers:

- MAC address of *Host 5* 93:97:15:01:69:DC (*t_MAC_H5_t1*),
- IP address of *Host 5* 10.0.0.236 (*t_IP_H5_t1*),
- MAC address of *Server 1* D3:03:0A:06:8F:8A (*t_MAC_S1_t1*),
- IP address of *Server 1* 10.0.0.21 (*t_IP_S1_t1*).

Upon the mutation state change, retransmission of the segments occurs. This happens so quickly that the connection continues with the new addressing shortly afterward, enabling the entire file to be downloaded.

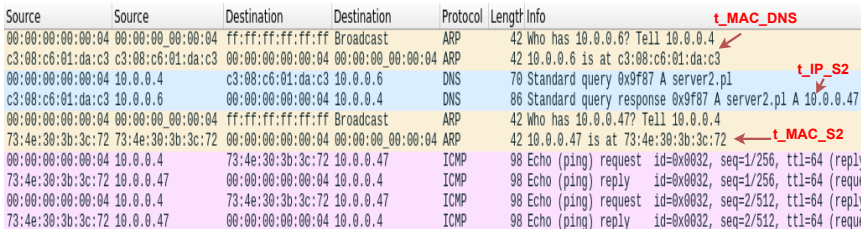
VI. Discussion

The test scenarios described above validate the correct functioning of the proposed Moving Target Defense system based on hybrid mutations at both the MAC and IP layers, as well as dynamic path adjustments during communication.

The results from the Address Mutation test confirm that the agents correctly perform address obfuscation and translation at the network edges. Temporary addresses are assigned and managed without impacting the continuity of communication from the hosts' perspective. This behavior is evident from the consistent and uninterrupted exchange of ICMP packets and successful DNS resolution processes involving mutated addressing.

The Change of Address Mutation State scenario demonstrates the system's ability to transition between different temporary address states during normal operations seamlessly. After the predefined timeout interval (*Tm*), new sets of temporary IP addresses are allocated and applied transparently, while ongoing services (such as HTTP downloads) continue unaffected. This dynamic reassignment capability significantly increases the complexity for any adversary attempting to map the network or track devices, reinforcing the defensive posture.

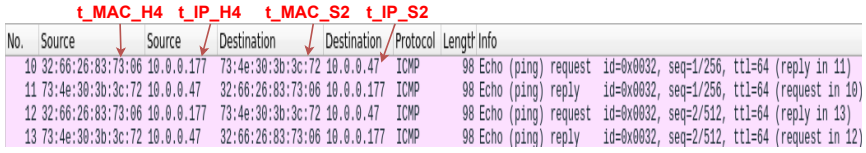
Finally, the Mutation of Path and Address State During the Connection scenario showcases the most demanding feature of the system—live mutation of both the data path and addressing during an active session. During a large file transfer, the system's behavior proves that the agents and controller can coordinate effectively to update switch flows and reassign addressing without disrupting the data stream. Segment retransmissions and address switching occur within such short intervals that the host application layer remains unaware of the underlying changes.



The tests and observed results prove that the proposed solution functions as intended. It achieves its core objective of creating a dynamic and unpredictable network communication environment, effectively increasing potential attackers' difficulty in exploiting static addressing schemes or consistent routing paths.

Although effective in the test environment, the system uses temporary IPv4 addresses from a limited subnet. In larger networks, this may lead to address exhaustion. Supporting IPv6 would expand the address pool and enhance scalability and obfuscation.

VII. Conclusion



This paper presents an MTD system employing a hybrid mutation strategy involving address and path alterations to enhance network security. By cyclically mutating these elements during connection initiation and throughout the session duration, the proposed approach significantly increases the complexity of network reconnaissance for potential attackers. The design leverages dedicated packet processing agents, which can be efficiently implemented on SmartNICs at end hosts, enabling high-performance execution with minimal impact on system resources.

The prototype implementation, tested in an SDN-based environment utilizing OVS switches, demonstrated that the mutation mechanism operates seamlessly without disrupting normal network operations. Experimental results validated the system's effectiveness in improving the security posture of corporate networks by dynamically and unpredictably altering attack surfaces. Future work will optimize mutation intervals, integrate adaptive intelligence for mutation decisions, and evaluate performance in larger and more diverse network topologies.

***Abstract*—This work presents a framework for systematic Application Programming Interface (API) migrations that provides guidance for both manual and automated migration processes. The approach starts by matching methods from the old API version with those of the new version, followed by comparative syntactic and semantic analyses to produce migration steps. As a proof of concept, we implement the most challenging parts using structured, parameterized Artificial Intelligence (AI) queries, which also serve as a basis for evaluation. Our results demonstrate the feasibility and usefulness of this approach. Future work will focus on completing the full migration process while reducing reliance on AI due to its current limitations in reasoning. We also plan to evaluate the framework on real-world APIs to assess its effectiveness and general applicability.**

I. Introduction

IN RECENT years, technological progress has accelerated rapidly. One clear example of this is the widespread integration of the Internet into everyday life, supporting activities such as online shopping, banking, social networking, and information retrieval through Artificial Intelligence (AI) queries [1]. Kurzweil [2] expands Moore's Law by applying the idea of exponential growth not only to hardware but also to software and other technological areas, with the Internet serving as one such example. The Internet consists of many interconnected systems that rely on each other. Some of these systems are client-server applications, which are often built using Application Programming Interfaces (APIs).

The problem we focus on is API evolvability, with a particular emphasis on the challenge of API migration. Lamothe et al. [3] identified several research challenges related to API evolvability. Among these, we are especially interested in the following: **(a)** Combining textual merging with syntactic and semantic approaches, **(b)** Providing a commercially viable API migration solution, **(c)** Incorporating domain-specific information into tools, **(d)** Developing more tools to assist with Web API, **(e)** Automatically identifying factors driving API changes, **(f)** Addressing API semantics and dependencies, and **(g)** Supporting the context sensitivity of API migration tools.

Although the article [3] was published in late 2021, our extended review of the API evolvability literature, presented in section III, shows that many of these challenges continue to be highly relevant.

In this paper, our research objective is: "**To create a framework for systematic API migrations that provides guidelines for performing API migrations, whether fully manual or semi-automated**." Our approach targets scenarios where an application uses a specific version of an API and needs to migrate its API calls to a newer version. A key requirement is to know the method signatures of both the old API version and the new API version, at least at the syntactic level. However, method signatures alone allow for only basic migration guidelines. If the source code of the new API version is available, static analysis can be used to generate more detailed guidance. Furthermore, if semantic documentation artifacts are available, changes at the semantic level—even if the source code remains unchanged—can be incorporated to further improve the quality of the migration guidelines.

Apart from mapping the landscape in the area of API migration research and reporting the progress of our own API migration work, the contribution of this paper lies in presenting a high-level approach to API migration. This approach consists of several components, each of which can be implemented in different ways. Nevertheless, we do not provide implementations here.

The remainder of this paper is structured as follows. Section II presents the research methodology. Related work is discussed in section III. The core of our contribution is detailed in section IV, where we explain our approach to API migration. Section V provides the evaluation of our approach, and section VI provides further discussion. Finally, section VII concludes the paper and outlines directions for future work.

II. Research Methodology

We follow the Design Science Research Methodology (DSRM), first introduced by Hevner et al. [4] and later improved in [5]. DSRM focuses on creating and evaluating new artifacts — such as models, methods, processes, or systems — that aim to solve real-world problems. The key components are: **Environment**, the real-world context including people, organizations, technologies, and problems. It sets the requirements and limits for the research. **Knowledge Base** holds existing theories, methods, frameworks, and tools that support the research. **Design Science Research** is an

iterative process of `Design Cycles` that build and test artifacts to solve problems. It connects to the **Environment** via the `Relevance Cycle` and to the **Knowledge Base** through the `Rigor Cycle`.

This paper builds on our previous work aimed at supporting API usage and migration. We initially explored various API documentation formats, such as OpenAPI Specification (OAS) [6] and API Blueprint (APIB) [7], with the goal of designing a unified format and mapping mechanisms between common specifications. So far, we have implemented a mapping from OAS to APIB [8], with plans to develop a central model and mappings to other formats. In the approach proposed in this paper, one possible input for step **M2.b** is documentation represented in this central model. We also developed an API ontological model presented in [9], which illustrates how changes made by an API provider can impact API consumers. The model includes several key observations, such as the distinction between syntactic and semantic changes, which forms the foundation of the approach presented in this paper.

In this paper, first, we do another `Relevance Cycle` by looking at updates in API documentation and investigating recent breaking changes in open-source APIs. We provide some remarks about this part in section III and section V. Next, we do the `Rigor Cycle` by reviewing new research on API evolvability using snowballing [10], as described in section III. Finally, we do the `Design Cycle` by creating a framework for systematic API migration in section IV and provide evaluation in section V.

III. Related Work

According to Lamothe et al. in [3], the key areas of focus in API evolvability at the time of their work, published at the end of 2021, were addressing breaking API changes, enhancing API usability, and reducing API misuses. In the same paper, Lamothe et al. also identify several open challenges in the field of API evolvability. In this section, we review challenges relevant for this paper and describe some additional research works discovered by snowballing [10]. The challenges are categorized with identifiers from the original article, where "EC" stands for "Existing Challenges" (which have existing publications attempting to find solutions) and "UC" for "Unresolved Challenges" (which lack existing solutions).

EC-1*) Combining textual merging with syntactic and semantic approaches:* This challenge is based on article [11] where the context is to merge two or more versions of the same software together. The article is from year 2002, nevertheless, even today, Version Control System (VCS) tools such as Git [12], are based on textual merging without employing syntactic nor semantic approaches. In a way, we can consider API migration as merge of new version of consumed API with the consumed application itself. Therefore, this can be considered as a relevant challenge for this paper as we also employ syntactic and semantic approaches.

EC-2*) Providing a commercially viable API migration solution:* At the time of writing of [3], there had already been existing API migration solutions such as tool SemDiff [13] or ApiDiff [14]. SemDiff can recommend replacements of API calls for methods which were removed in given API based on static analysis of Abstract Syntax Trees (ASTs) corresponding to code files in VCS. ApiDiff tool is based on static analysis and similarity heuristics of Java libraries hosted on Git [12] repositories in order to detect breaking changes and non-breaking changes between two versions. ApiDiff and SemDiff have not been proven commercially viable at the time of writing of [3]. One of the problems was that, as for most API Evolvability works, there was a lack in area of evaluation, because there had not been established standardized approaches and datasets to evaluate API evolvability research works which would be in wide use [3]. Both the SemDiff and ApiDiff approaches employ static analysis taking into account syntactic information but without utilizing semantic information.

In [15] Deshpande et al. tackle the problem of API migration using multi-objective evolutionary algorithms. Their approach is not restricted to cases where a single source method is always transformed into a single target method (one-to-one mappings). Instead, it is also applicable to scenarios where one or multiple source methods are mapped to multiple target methods (one-to-many and many-to-many mappings).

In [16] Ramos et al. present the MELT system, which extracts API Consumer-side transformations by analyzing pull requests on the API side. This process combines static analysis with Natural Language Processing (NLP) of pull request descriptions and comments.

Some approaches leverage program synthesis to generate transformation procedures by using examples of API call mappings between different versions. Notable examples include the APIFIX tool introduced in [17] and the ReFazer tool introduced in [18].

In [19] Beuer-Kellner et al. propose an API migration approach that utilizes a service to manage the conversion of data structures between different API versions.

In [20], Huang et al. propose an API mapping approach called MATL, which employs transfer learning to automate API mapping without requiring knowledge of the underlying source code of the API involved.

Another approach involves having developers on the API side create transformation scripts to assist API Consumers in updating API calls between versions [3]. Similarly to our goal, the mentioned techniques deal with API migration. There already exist multiple works with employ both static and semantic information in order to automatize API Migration. The idea of our approach is to employ combination of static analysis with analysis of additional semantic information.

EC-3*) Incorporating domain-specific information into tools:* This challenge is based on [11] in which Mens points out that more research is needed for the detection and resolution of structural merge conflicts that arise in the presence of restructuring transformation, and that we need more domain-specific information because it cannot be inferred from code. Our approach also relies on additional information beyond

source code.

***EC-10**) More tools to help with Web APIs:* According to Wittern in [21], Web API providers also control runtime of APIs and can do changes anytime with severe consequences to their API consumers as opposed to Library APIs. Additionally, Web APIs often lack machine-undrestandable specifications, and data are often passed over strings. Our research idea should be applicable to both Web APIs and Library APIs, therefore it should contribute to Web APIs tooling making EC-10 a relevant challenge for our research.

***EC-16**) Dealing with API semantics and dependencies:* In [22] Amman et al. describes following calls to action:

1) *We need precise definition of API usages, considering usage properties such as usage location and call multiplicities*
2) *We need a representation of such usages that captures all code details necessary to distinguish correct usages from misuses and more precise analyzes to identify usages in code*
3) *We need detectors that retrieve sufficiently many usage examples using project-external sources, such as large project sets or code-search engines*
4) *We need detectors that go beyond native assumption that a deviation from the most-frequent usage corresponds to a misuse, but consider program semantics, such as type hierarchies and implicit dependencies between objects. We hypothesize that probabilistic models might be a way to tackle this problem*
5) *We need strategies to properly match patterns and usages in the presence of violations*
6) *We need strategies to properly handle alternative patterns for the same API*
7) *Finally, we need good ranking strategies, to reduce the cost of reviewing findings.*

In the same work Amman et al. present MuBench and MuBenchPipe as foundational tools to support repeatable and replicable studies that enable systematic evaluation and analysis of alternative approaches and strategies in order to move forward with the mentioned calls to action.

Dealing with API semantics is definitely in scope of our research.

***UC-2**) Supporting the context sensitivity of API migration tools:* It is not yet clear how to best approach the context sensitivity in API migration tools. One of the proposed directions is the incorporation of domain-specific information into tools. Our research idea is related to this challenge, because we also consider incorporation of domain-specific information in form of semantic documentation in structured API documentation formats (such as OAS).

IV. Our Approach

Our proposed approach for API migration should serve as a guideline for performing API migration for developers managing consumption of an evolving API in applications - regardless whether it is performed manually or with some automated steps. The most relevant inputs are as follows:

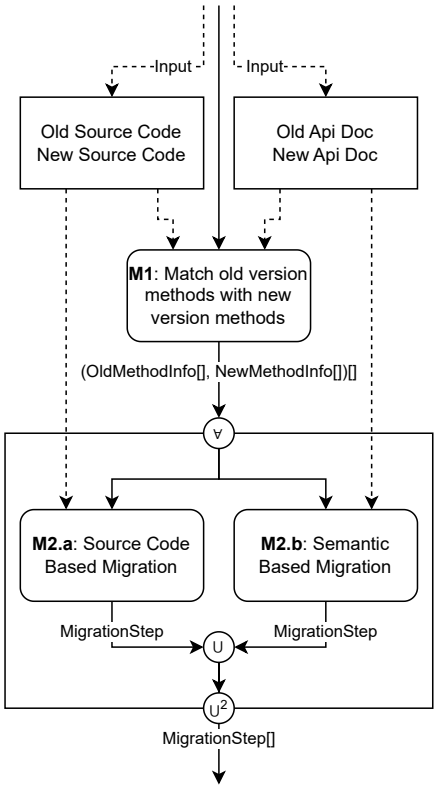

Fig. 1: Overview of our API migration approach

1) Structured API documentation for both the old and the new versions of the consumed API such as OAS documentation. **2)** Links to source code repositories (e.g., in Git), corresponding to both the old and new API versions, when available.

Upon execution, the API migration tool follows a two-step process depicted in fig. 1: **1)** Matching API methods between the old and new API versions (**M1**). **2)** Performing comparative syntax analysis (when source code is available) alongside semantic analysis for each match identified in the previous step, in order to generate a set of *MigrationStep*s (**M2.a** and **M2.b**).

MigrationStep represents a transformation applicable to old-version API method calls, specifying how to adapt them for the new version. The resulting *MigrationStep*s provide developers with a structured foundation to carry out the migration in manual or semi-automated manner.

For clarity, we present a demonstrative example comprising two versions of the same API, shown in example 4.2 and example 4.3. Both versions utilize the `Product` class defined in example 4.1, where the `[Key]` attribute — pro-

Example 4.1 (ASP.NET Core (C#)): Definition of `Product`:

```
class Product : Item
{
  public string Name { get; set; }
  public decimal Price { get; set; }
}
class Item
{
  [Key]public int Id { get; set; }
}
```

vided by Entity Framework Core [23] — designates the `Id` property as the primary key for the database. Additionally, the `dbContext` referenced in the examples corresponds to an instance of `DbContext` [24], which is used to access and interact with the database.

An example of the output from our proposed approach is shown in example 4.4, which migrates old version API calls from example 4.2 to new version API calls from example 4.3. This output is represented as JSON, where each object in the top-level array corresponds to a possible *MigrationStep*. The strings labeled "`RegexMatch`" denote regular expressions, each paired with an associated "`Replacement`" string. Within these replacement strings, "`$1`" refers to the first captured group in the match.

The primary purpose of these examples is to illustrate the concept of inputs and outputs rather than to present fully-fledged input/output artifacts.

M1: Match old version methods with new version methods

The purpose of this step is to identify correspondences between API methods in the old version and the new version of given API. Specifically, it determines which methods in the old version align with which methods in the new version, based on structural and semantic similarity. The output of this step is a collection of tuples `(OldMethodInfo[], NewMethodInfo[])[]`, where each `MethodInfo` instance encapsulates identifying and basic metadata about a given method, such as its name, return type and parameter types.

There are multiple possible strategies for implementing this matching step. We propose implementation in two parts as follows: **M1.1) Exact Signature Match**: Methods that share identical signatures — that is, matching method names, return types, and parameters — in both the old and new versions are matched directly. For example, during the migration from example 4.2 to example 4.3, only the method `DeleteProduct` is matched this way. **M1.2) Remaining Methods Match**: For methods which were not matched by the previous step, several heuristic strategies may be applied: **a)** Manual matching by the developers **b)** Matching based solely on method names **c)** Matching based on parameters and return types **d)** Matching via AST comparison, when source code is available... During the migration from example 4.2 to example 4.3, the methods `CreateProduct` and `UpdateProduct` in the old version are expected to be matched with the method `CreateOrUpdateProduct` in the new version. Similarly, the method `GetAllProducts()` from the old version should correspond to `GetProducts(decimal minPrice)` in the new version. Conversely, the method `GetProduct` from the old version does not have a matching counterpart in the new version.

Methods in the old API version that have no corresponding counterparts in the new version are classified as *deleted methods*, while those introduced only in the new version are considered *added methods*.

It is important to note that, depending on the implementation, the matching algorithm may produce false negatives—failing to correctly associate semantically equivalent methods across versions. In such cases, logically related method pairs might be misclassified as a deletion and an addition, rather than as an evolution of a single method, which could ultimately render our approach non-functional for involved methods. This underscores the necessity of maximizing the effectiveness of step **M1.2**.

Furthermore, the mapping between methods in the old and new versions is not limited to one-to-one or zero-to-one relationships. Many-to-one (M:1), one-to-many (1:N), and even many-to-many (M:N) mappings are possible, as illustrated in migration of `CreateProduct` and `UpdateProduct` in example 4.2 to `CreateOrUpdateProduct` in example 4.3. A baseline implementation that accounts for this could analyze method names by identifying segments such as "And" or "Or", and then checking whether corresponding methods exist for the parts before and after these segments. It should also verify that the parameter and return types match appropriately. A more advanced implementation could incorporate static analysis when the source code is available.

M2.a: Source Code Based Migration

The primary objective of this step is to derive the necessary migration transformations to ensure that the updated version of the API-consuming application remains syntactically correct. Specifically, it aims to determine how each method call to the old API version should be transformed into a corresponding call to the new API version, preserving equivalent application behavior. A key prerequisite for this process is access to the source code of the consumed API.

To illustrate the inputs and outputs, consider migrating method calls from `GetAllProducts()` in example 4.2 to method calls `GetProducts(decimal minPrice)` in example 4.3. This step should establish that calls to `GetAllProducts()` correspond to calls to `GetProducts(decimal.MinValue)` in the new version and generate the appropriate *MigrationStep*, as demonstrated in example 4.4.

There are several possible approaches to implementing this step. Below, we outline three representative strategies:

1) **Manual Transformation**: In this baseline approach, the developer manually inspects the old and new versions of each API method and defines the required transformations manually.

Example 4.2 (ASP.NET Core (C#)): Old version of API:

```
Product? GetProduct(int productId) =>
 ↪  dbContext.Products.FirstOrDefault(p
 ↪  => p.Id == productId);
IEnumerable<Product> GetAllProducts() =>
 ↪  dbContext.Products;
Product? CreateProduct(Product product)
 ↪  {
  dbContext.Products.Add(product);
  dbContext.SaveChanges();
  return product;
}
Product? UpdateProduct(Product product)
 ↪  {
  dbContext.Products.Update(product);
  dbContext.SaveChanges();
  return product;
}
void DeleteProduct(int productId) {
  var product =
   ↪  dbContext.Products.FirstOrDefault(p
   ↪  => p.Id == productId);
  if (product is null)
    return;
  var result =
   ↪  dbContext.Products.Remove(product);
  dbContext.SaveChanges();
}
```

Example 4.3 (ASP.NET Core (C#)): New version of API:

```
IEnumerable<Product> GetProducts(decimal
 ↪  minPrice) =>
 ↪  dbContext.Products.Where(p =>
 ↪  p.Price >= minPrice);

Product? CreateOrUpdateProduct(Product
 ↪  product) {
  if (product.Id == default)
    dbContext.Products.Add(product);
  else
    dbContext.Products.Update(product);
     ↪  ;
  dbContext.SaveChanges();
  return product;
}

void DeleteProduct(int productId) {
  var product =
   ↪  dbContext.Products.FirstOrDefault(p
   ↪  => p.Id == productId);
  if (product is null)
    return;
  var result =
   ↪  dbContext.Products.Remove(product);
  dbContext.SaveChanges();
}
```

Example 4.4 (ASP.NET Core (C#)): Output of our approach:

```
[{
  "OldMethodSignatures": ["Product? CreateProduct(Product product)", "Product?
 ↪  UpdateProduct(Product product)"],
  "NewMethodSignatures": ["Product? CreateOrUpdateProduct(Product product)"],
  "ReplacementRules": [{"RegexMatch": "CreateProduct\\((\w+)\)", "Replacement":
 ↪  "CreateOrUpdateProduct($1)"},
    {"RegexMatch": "UpdateProduct\\((\w+)\)", "Replacement":
    ↪  "CreateOrUpdateProduct($1)"}]
},
{
  "OldMethodSignatures": ["IEnumerable<Product> GetAllProducts()"],
  "NewMethodSignatures": ["IEnumerable<Product> GetProducts(decimal minPrice)"],
  "ReplacementRules": [{"RegexMatch": "GetAllProducts\\(\)", "Replacement":
 ↪  "GetProducts(decimal.MinValue)"}]
}
{
  "OldMethodSignatures": ["Product? GetProduct(int productId)"],
  "ReplacementRules": [{"RegexMatch": "GetProduct\\((\w+)\)", "Replacement":
 ↪  "GetProducts(decimal.MinValue).FirstOrDefault(p => p.Id == $1)"}]
}]
```

2) **Static analysis**: This strategy compares the ASTs of the old and new method implementations. While potentially precise, it poses significant technical challenges due to the complexity of code analysis and the wide variety of programming language constructs.
3) **AI-Based Methods**: Advances in AI, particularly large language models, offer promising opportunities for semi-automated transformation. Although current AI systems have limitations— especially in tasks requiring deep reasoning [25] — our experience with modern tools such as ChatGPT [26] indicates they can effectively address transformation problems, provided the task is well-specified.

***M2.b**: Semantic Based Migration*

The purpose of this step is to derive the migration steps necessary to ensure that the migrated version of the API-consuming application remains semantically correct. This includes preserving the intended meaning of method inputs and outputs.

To illustrate the inputs and outputs of this step, consider a scenario where the `Price` property of a `Product` is represented in US dollars in the older version, but in euros in the newer version. If this change is not properly accounted for, it can cause misinterpretation of price values, leading to errors. Importantly, such semantic differences are usually not detectable from the source code alone, even though they may sometimes be suggested by comments or naming conventions. To address this limitation, we propose extracting semantic metadata from structured documentation artifacts, such as OAS. In OAS, `Product` would be defined as a component schema, and its `Price` property could be annotated using an OAS extension (e.g., `x-semantic-meaning`), with values set to `USD` in the old version and `EUR` in the new version. Example of the `USD`-annotated OAS schema component for `Product` is shown inexample 4.5. The output of our approach would be a set of *MigrationSteps* for each method utilizing the `price` of `Product`. For instance, migrating the `GetAllProducts` method from using `USD` to `EUR` pricing would yield a *MigrationStep* as illustrated in example 4.6.

Example 4.5 (OAS JSON): Product in component schema:

```
{
  "type": "object",
  "properties": {
    "id": {"type": "string"},
    "name": {"type": "string"},
    "price": {"type": "number",
     ↪  "x-semantic-meaning": "USD"}
  }
}
```

Example 4.6 (JSON): MigrationStep for `Price` change from `USD` to `EUR`:

```
{
  "OldMethodSignatures":
   ↪  ["IEnumerable<Product>
   ↪  GetAllProducts()"],
  "NewMethodSignatures":
   ↪  ["IEnumerable<Product>
   ↪  GetAllProducts()"],
  "OldSemanticMeaning": {"Path":
   ↪  "Product.Price", "Value": "USD"},
  "NewSemanticMeaning": {"Path":
   ↪  "Product.Price", "Value": "EUR"}
}
```

A baseline implementation of this step could involve simply checking whether the semantic annotations have changed and, if so, requesting manual intervention. More advanced approaches might attempt to perform semantic migration automatically. However, such techniques are beyond the scope of this paper and represent a promising direction for future research.

V. Evaluation

A. API changes for evaluation

Initially, we aimed to identify an open-source API with a well-documented history of breaking changes to evaluate our approach. However, this task proved more difficult than anticipated. Although we identified some promising candidates, clearly documented and representative breaking changes among real-world open-source APIs were generally scarce. One example of a promising API for evaluation purposes is Elasticsearch [27], which documents several breaking changes - such as the one described and implemented in [28] where our approach would likely be effective. Nevertheless, the complexity of many APIs hindered analysis, especially when changes were undocumented or lacked sufficient context. Therefore, we decided to create our own API changes based on examples 4.2 and 4.3, which are listed in table I.

As our approach is not yet fully implemented, we conducted an evaluation focusing on the implementability and applicability of each individual step. In some cases, this evaluation was supported by leveraging AI tools, specifically ChatGPT [26]. The results of this assessment are summarized in table II.

```
I am consuming old version of API in my
 ↪  application and I have to migrate it to
 ↪  use the new version. The API is written
 ↪  in `{{API_FRAMEWORK_OR_LANGUAGE}}`. I
 ↪  need to know which steps to take in my
 ↪  API-consuming application created in
 ↪  `{{API_CONSUMER_FRAMEWORK_OR_LANGUAGE}}`,
 ↪  specifically, what should I replace the
 ↪  calls to `{{OLD_METHOD_SIGNATURES}}` from
 ↪  old version to migrate it to calls to new
 ↪  `{{NEW_METHOD_SIGNATURES}}` with behavior
 ↪  in terms of input-output mapping being
 ↪  intact? Mark the source code I should use
 ↪  in place of calls to
 ↪  `{{OLD_METHOD_SIGNATURES}}` - i.e. exact
 ↪  string I should use as replacement for
 ↪  `{{OLD_METHOD_CALLS}}` - in the answer
 ↪  between XML tags `<REPLACEMENT>` and
 ↪  `</REPLACEMENT>`.

Definition of relevant structures:
`{{SHARED_DATA_TYPE_DEFINITIONS}}`

Old version source code:
`{{OLD_CODE}}`

New version source code:
`{{NEW_CODE}}`
```

Fig. 2: AI query implementation of **M2.a** step

B. Test implementation of *M2.a* over AI

Our implementation of **M2.a** for AI-based processing is defined by a structured AI query that accepts the following self-explanatory parameters:

1) `API_FRAMEWORK_OR_LANGUAGE`
2) `API_CONSUMER_FRAMEWORK_OR_LANGUAGE`
3) `OLD_METHOD_SIGNATURES`
4) `NEW_METHOD_SIGNATURES`
5) `OLD_METHOD_CALLS`
6) `SHARED_DATA_TYPE_DEFINITIONS`
7) `OLD_CODE`
8) `NEW_CODE`

The structure of this query is illustrated in fig. 2, where parameters are enclosed using double curly braces.

We used the examples of API method changes from table I to create AI queries, which we submitted to ChatGPT using the ChatGPT-4 Turbo engine [26]. The `REPLACEMENT` parts of the generated responses are listed in table III. The responses were generally satisfactory. However, certain changes may require additional manual adjustments. In general, developers may not be aware of which modifications necessitate further intervention, and thus must manually review all changes. This limitation aligns with the intended scope of our approach, which is designed to assist—rather than fully automate—manual API migration at this stage. Nevertheless, minimizing manual effort remains a key objective, representing an important direction for future research. Also, for cases involving the weakening of preconditions or postconditions, the suggested

TABLE I: API changes for evaluation

Identifier	Change Kind	Version A	Version B
C1	Create / Remove Method **C1**		`IEnumerable<Product> GetProductsWithPriceLowerThan(decimal price) => dbContext.Products.Where(p => p.Price < price);`
C2	Add / Remove Parameter	`IEnumerable<Product> GetProducts() => dbContext.Products`	`IEnumerable<Product> GetProducts(decimal minPrice) => dbContext.Products.Where(p => p.Price >= minPrice)`
C3	Change Parameter Type to More / Less Abstract	`Product? UpdateProduct(Product product) { dbContext.Products.Update(product); dbContext.SaveChanges(); return product; }`	`Product? UpdateProduct(Item item) { dbContext.Items.Update(item); dbContext.SaveChanges(); return item; }`
C4	Data Coupling to / from Stamp Coupling	`Product? UpdateProduct(Product product) { dbContext.Products.Update(product); dbContext.SaveChanges(); return product; }`	`Product? UpdateProduct(int id, string name, decimal price) { var dbProduct = dbContext.Products.First(p => p.Id == id); dbProduct.Name = name; dbProduct.Price = price; dbContext.SaveChanges(); return dbProduct; }`
C5	Stronger / Weaker Pre-Condition with Exception	`Product? UpdateProduct(Product product) { dbContext.Products.Update(product); dbContext.SaveChanges(); return product; }`	`Product? UpdateProduct(Product product) { if (product.Price < 0) throw new ArgumentException(); dbContext.Products.Update(product); dbContext.SaveChanges(); return product; }`
C6	Stronger / Weaker Pre-Condition with Null	`Product? UpdateProduct(Product product) { dbContext.Products.Update(product); dbContext.SaveChanges(); return product; }`	`Product? UpdateProduct(Product product) { if (product.Price < 0) return null; dbContext.Products.Update(product); dbContext.SaveChanges(); return product; }`
C7	Stronger / Weaker Post-Condition with Exception	`Product? GetProduct(int productId) => dbContext.Products.First(p => p.Id == productId);`	`Product? GetProduct(int productId) { var result = dbContext.Products.First(p => p.Id == productId); if (result.Price < 0) throw new InvalidOperationException(); return result; }`
C8	Stronger / Weaker Post-Condition with Null	`Product? GetProduct(int productId) => dbContext.Products.First(p => p.Id == productId);`	`Product? GetProduct(int productId) { var result = dbContext.Products.First(p => p.Id == productId); if (result.Price < 0) return null; return result; }`
C9	Method composition / decomposition	`Product? CreateProduct(Product product) { dbContext.Products.Add(product); dbContext.SaveChanges(); return product; } Product? UpdateProduct(Product product) { dbContext.Products.Update(product); dbContext.SaveChanges(); return product; }`	`Product? CreateOrUpdateProduct(Product product) { if (product.Id == default) dbContext.Products.Add(product); else dbContext.Products.Update(product);; dbContext.SaveChanges(); return product; }`
C10	Change Primitive Type from / to Smaller	`Product? GetProduct(int productId) => dbContext.Products.FirstOrDefault(p => p.Id == productId)`	`Product? GetProduct(long productId) => dbContext.Products.FirstOrDefault(p => p.Id == productId)`
C11	Add / Remove Field to / from Parameter	`class Filter { decimal MinPrice { get; set; } decimal MaxPrice { get; set; } } IEnumerable<Product> GetProducts() => dbContext.Products; IEnumerable<Product> GetProducts(Filter filter) { var allProducts = GetProducts(); var result = allProducts.Where(p => p.Price >= filter.MinPrice && p.Price <= filter.MaxPrice); return result; }`	`class Filter { string SearchPhrase { get; set; } decimal MinPrice { get; set; } decimal MaxPrice { get; set; } } IEnumerable<Product> GetProducts() => dbContext.Products; IEnumerable<Product> GetProducts(Filter filter) { var allProducts = GetProducts(); var result = allProducts.Where(p => p.Price >= filter.MinPrice && p.Price <= filter.MaxPrice && p.Name.Contains(filter.SearchPhrase)); return result; }`

TABLE II: Evaluation summary

Step	Comment
M1.1	Matching methods of identical signatures is straightforward and thus excluded from the evaluation.
M1.2	We have confirmed that ChatGPT can successfully perform this step using the example presented in section IV.
M2.a	This step is regarded as the most challenging, and consequently, we implemented it using a structured ChatGPT query described in section V-B, which produced satisfactory results.
M2.b	We have confirmed that ChatGPT can successfully execute this step using the example outlined in section IV.

changes could be undesirable. One possible improvement would be to explicitly request `RegexStrings` with corresponding `Replacement` values, so that they could be directly used in the resulting *MigrationSteps*, as demonstrated in example 4.4.

VI. Discussion

We fulfill the research objective outlined in section I by developing a framework for systematic API migration (manual or semi-automated), which is described in section IV and later evaluated in section V. However, several aspects of our proposed approach require further discussion.

Firstly, it would be valuable to compare our API migration methodology with existing approaches. However, as noted by Lamothe et al. [3], comparing API migration techniques remains an open and unresolved challenge. Additionally, we currently lack a complete implementation of our methodology. Instead, we have implemented and evaluated only individual components using AI queries. It would be interesting to see what a full implementation would look like and how it would perform on real-world APIs.

Secondly, during the evaluation, we repeatedly observed that changes preserving backward compatibility might not always be desirable. This is particularly true for modifications that weaken preconditions or postconditions. These observations prompt an important question: how should we determine

TABLE III: Summary of AI responses

Change Identifier	Direction	Response part between "<REPLACEMENT>" and "</REPLACEMENT>"	Manual steps needed?	Comment
C1	A to B	N/A	No	No changes necessary
C1	B to A	N/A	Yes	Injecting code of the removed method might work
C2	A to B	`GetProducts(0)`	No	`decimal.MinValue` would be better than `0`
C2	B to A	`GetProducts().Where(p => p.Price >= minPrice)`	Yes	There needs to be `minPrice` variable
C3	A to B	`(Product?)UpdateProduct(product)`	No	
C3	B to A	`UpdateProduct((Product)item)`	No	
C4	A to B	`UpdateProduct(product.Id, product.Name, product.Price)`	No	
C4	B to A	`new Product { Id = id, Name = name, Price = price }`	No	
C5	A to B	Same as before	Yes	Exception handling might be desired

C5	B to A	`if (product.Price < 0)`
		`  throw new ArgumentException();`
		`UpdateProduct(product)`
			Yes	Keeping the same behavior as before might be undesired here

C6	A to B	Same as before	Yes	Null handling might be desired
C6	B to A	`product.Price < 0 ? null : UpdateProduct(product)`	Yes	Keeping the same behavior as before might be undesired here

C7	A to B	`try {`
		`  GetProduct(productId);`
		`} catch (InvalidOperationException) {`
		`  return null;`
		`}`
			Yes	Should have proper exception handling

C7	B to A	`var product = GetProduct(productId);`
		`if (product.Price < 0)`
		`  throw new InvalidOperationException();`
			Yes	Keeping the same behavior as before might be undesired here

C8	A to B	`var product = GetProduct(productId);`
		`if (product == null)`
		`  throw new InvalidOperationException("Product price is invalid");`
			Yes	Throwing an exception might be undesired

C8	B to A	`var product = GetProduct(productId);`
		`if (product.Price < 0)`
		`  return null;`
			Yes	Keeping the same behavior as before might be undesired here

C9	A to B	`CreateOrUpdateProduct(product);`	No	
C9	B to A	`(product.Id == default ? CreateProduct(product) : UpdateProduct(product));`	No	
C10	A to B	`GetProduct((long)productId)`	No	
C10	B to A	`GetProduct((int)productId);`	Yes	There might be some data loss like this
C11	A to B	`GetProducts(new Filter { MinPrice = filter.MinPrice, MaxPrice =` `↪  filter.MaxPrice }).Where(p => p.Name.Contains(filter.SearchPhrase))`	No	
C11	B to A	`GetProducts(new Filter { MinPrice = filter.MinPrice, MaxPrice =` `↪  filter.MaxPrice, SearchPhrase = "" })`	No	

which changes are desirable and which are not? Moreover, is it possible to evaluate the desirability of such changes in an automated or semi-automated manner? These questions remain open for future research.

Thirdly, several steps in our approach are defined at a high level of abstraction, and it remains uncertain whether all of them can be feasibly implemented. For instance, step **M2.a** is intended to leverage static analysis, potentially supported by AI tools. However, the precise mechanism and its practical efficiency are still unclear. Furthermore, methods involving AI introduce additional challenges related to effectiveness and reproducibility, due to their inherently black-box nature.

Next, although our approach draws on many ideas from the research reviewed in section III, we have done little work on integrating it with existing solutions. This remains an interesting direction for future research.

Finally, since we successfully demonstrated the applicability of AI in step **M2.a**, a natural question arises—could an AI-based approach be employed for the entire API migration process, leveraging source code, structured API documentation, and other related artifacts? While we have not yet explored this possibility in detail, we hypothesize that such an approach could be feasible to some extent. Nonetheless, considering the limitations of current AI systems, particularly their challenges with consistent and transparent reasoning, we propose a more cautious direction. In future work, we aim to reduce reliance on AI and instead focus on more deterministic and interpretable alternatives.

VII. Conclusion

In this work, we presented a systematic framework for API migrations. The goal of this framework is to guide developers during migration, whether they choose to do it manually or with the help of automated tools. The migration process starts by matching methods from the old version of the API with those in the new version. It then continues with both comparative syntactic and semantic analyses to produce clear and structured migration steps.

As part of our evaluation, we implemented the comparative syntactic analysis as a structured AI query. We observed that this step was the most technically challenging part of the process. Nevertheless, our working prototype shows that it is not only feasible but also valuable in practice. It lays a solid foundation for future improvements of the framework.

In future work, we plan to complete the full implementation of the migration process. One of our aims is to reduce reliance on AI, since current models still struggle with consistent and reliable reasoning across different migration scenarios.

Another important direction for future work is to apply our framework to real-world APIs, rather than relying only on synthetic examples. This will allow us to evaluate how well the framework performs in practical environments and to what extent it can be generalized to different kinds of APIs.

Statement on the use of AI

AI technologies (ChatGPT [26]) were used to improve the language of the paper.

***Abstract*—This paper introduces the concept of Conversational Decision Support Systems (C-DSS)—a novel, agent-based framework that leverages Large Language Models (LLMs) to enhance the Operations Research (OR) methodology. We focus on the modeling and coding stages of decision support systems, where language-based interaction is crucial. The paper evaluates the effectiveness of LLMs in generating mathematical models and AMPL code for a curated set of 20 LP/MILP artifacts. Four architectural setups are analyzed: a monolithic LLM agent (M/C), its enhancement with a code verifier (M/C+V), agent-based decomposition with RAG-enhanced coding (M+C^R+V), and full specialization with RAG-enhanced modeling and coding (M^R+C^R+V). Experimental results on two benchmark problems reveal that the targeted retrieval-augmented generation technique (RAG) significantly improves performance for complex modeling patterns such as piecewise functions, indicator constraints, and nested logic. We also propose a broader vision of C-DSS as a multi-agent ecosystem—including agents for visualization, explanation, verification, and orchestration—suggesting a path toward more explainable, adaptable, and intelligent decision support systems.**

I. Introduction

A. Backgrounds

OPERATIONS Research (OR) is grounded in analytical methods applied to improve decision-making. OR projects are often characterized by high complexity and a substantial risk of failure. Similar to software projects, they require the development and deployment of software; however, they also introduce a number of additional challenges. These include the need for a deeper understanding of the problem domain, a thorough comprehension of the decision-makers' goals and intentions, the construction of mathematical models, the selection or development of computational algorithms, and uncertainty regarding the quality of the resulting solutions. To address these challenges, OR methodology typically relies on a structured and systematic approach [1]. The individual steps of this methodology are illustrated in Figure 1.

The methodology begins with the real-world system that is the object of the decision-making process. The first step is to identify the decision problem. Next, the scope of the implementation is defined—this does not necessarily have to fully cover the previously identified area. The subsequent steps

Fig. 1. Operations research methodology enhanced with communication and potential languages used at various stages of the methodology

involve constructing a mathematical model and developing a solution method. The resulting solution is then tested using real data. If these tests are successful, the optimization results can be incorporated into actual decision-making processes, leading to full implementation and real-world impact—thus completing the methodology cycle. In practice, however, this process is rarely linear or strictly cyclical; backtracking or skipping steps may occur at various stages.

Effective communication is critical to the success of an OR project, and both its form and language vary across different phases of the methodology. Figure 1 enriches the classical OR methodology with examples of the communication modes used at each stage. In the early phases, interactions among domain experts dominate—for example, requirement elicitation and project scoping are typically conducted through expert meetings. During the modeling and method development

phases, mathematical and algorithmic languages are primarily used. Implementation requires programming languages, while solution validation often involves further expert consultations, sometimes supported by statistical language. Finally, the results must be communicated to end users via a human-machine interface, such as a dedicated GUI.

Large Language Models (LLMs) have emerged as transformative tools for effective communication across a wide range of domains. By leveraging vast amounts of linguistic data and advanced machine learning techniques, LLMs are capable of understanding context, generating coherent text, and engaging in meaningful dialogue. These capabilities enable them to assist with tasks such as summarizing information, translating languages, drafting content, and facilitating real-time interaction between users. Their ability to perform logical reasoning and apply mathematics to solve logical problems is rapidly advancing. In the domain of programming, they have become significant tools for automating source code generation and testing.

These capabilities make LLMs promising candidates for supporting the OR methodology at various stages. Their potential can be utilized in system discovery and requirement elicitation. They are naturally suited to support modeling and coding. Moreover, areas such as test automation, results explanation and visualization, or GUI generation are also promising fields where LLMs may play a significant role.

Recognizing these possibilities leads to the concept of Conversational Decision Support Systems (C-DSS)—a system in which an LLM serves as a proxy across multiple stages of Decision Support System (DSS) development and operation. The C-DSS concept touches on various aspects of building and operating decision support systems and opens up broad opportunities for future research.

In this paper, we introduce the C-DSS concept. However, due to the subject's complexity and scope, we focus specifically on the modeling and programming stages, and investigate how the effectiveness of language models can be enhanced at these steps. This work is a contribution to a broader vision—one that may significantly advance the field of decision support systems.

B. State of the art

Efforts to automate the process of solving optimization problems began gaining traction in 2022. One of the earliest contributions came from Ramamonjison et al. [2], who proposed a system that automatically formulates mathematical models from natural language descriptions. To evaluate their approach, they introduced the Linear Programming Word Problems (LPWP) dataset.

Building on this work, the same authors organized the NL4Opt Competition [3], which aimed to identify the most effective techniques for automated mathematical model formulation. The competition was based on the LPWP dataset—hereafter referred to as NL4OPT. In their conclusions, the organizers noted that solutions utilizing Large Language Models (LLMs) outperformed all other approaches.

Chen et al. introduced a tool named OptiChat that employs LLMs in conjunction with multiple agents, solvers (e.g., Gurobi, Mosek), and the algebraic modeling language Pyomo to support mathematical modeling [4]. Its core functionality includes detecting issues in model formulation and offering corrective suggestions to the user. At around the same time, Yang et al. proposed OPRO [5], a solution that bypasses traditional solvers by leveraging LLMs directly for optimization tasks. OPRO iteratively refines its solutions based on previous outputs and newly generated meta-feedback. However, this approach has so far only been tested on relatively simple problems like the traveling salesman problem and linear regression, leaving its applicability to more complex scenarios an open question.

Li et al. extended the research to Mixed-Integer Linear Programming (MILP) problems [6]. Their work expands the NL4OPT dataset and focuses on training LLMs to produce correct mathematical formulations, including not just quantitative constraints (e.g., resources, demand), but also logical constraints, which were largely neglected in earlier research. The issue of the simplicity of problems in data sets has been also addressed by Ziyang et al. [7]. The authors proposed the ComplexOR dataset, which features more challenging optimization tasks. Alongside the dataset, the authors introduced a multi-agent system implementing the idea of Chain-of-Experts framework. Although, they report performance improvement, there is no analysis on which problem aspects are hard and most problematic for LLMs.

Beyond the simplicity of tasks, the lack of real-world relevance was another concern. This gap was addressed by the creators of CoPilot [8], who focused on practical business scenarios. Their system guides users through understanding the problem, formulating the model, and solving the optimization task—once again, leveraging LLMs as the core engine.

One of the first comprehensive solutions attempting to address the entire modeling pipeline is OptiMUS [9]. This system not only formulates the optimization model but also generates executable solver code to find and return optimal solutions. Alongside the system, the authors introduced a new dataset—NLP4LP—containing both LP and MILP tasks to support their experiments. However, the limitation of OptiMUS was the need for users to prepare problem descriptions in a specific format. This issue has been addressed in a follow-up study [10], where the authors enhanced OptiMUS to automatically convert natural language inputs into the required structured format.

A significant challenge across all of the above efforts is the variability in both solver performance and LLM behavior. This issue is the focus of LM4OPT [11], a project that seeks to standardize evaluation procedures for such systems. Additionally, the researchers investigate the benefits of fine-tuning LLMs, including compact models like Llama-7B, to improve efficiency.

C. Identified gaps and our contribution

As the literature review indicates, this research area is relatively new, and current studies focus primarily on the use of LLMs for modeling and coding optimization problems, often overlooking the broader perspective of the OR methodology. Even within this narrow scope, there is currently no established knowledge regarding optimal architectures or methods for integrating LLMs into the OR process. With the exception of the limited work by Li et al. [6], there is a lack of analysis and identification which modeling artifacts pose the greatest challenges for language models. Such insights could help address specific issues and improve the effectiveness of automated modeling and coding efforts. Additionally, existing work mostly centers around the use of general-purpose programming languages, which rely on libraries for solving optimization problems. In particular, there is a notable absence of research evaluating the effectiveness of modeling using dedicated declarative languages, such as AMPL (A Mathematical Programming Language) [12]. Most of the research focuses on imperative languages, mainly Python, while optimization problems are natively defined in a declarative way.

Our contribution can be summarized as follows:

- We provide a broader context for mathematical modeling and coding by introducing the concept of Conversational Decision Support Systems (C-DSS) and taking a more comprehensive view of the OR methodology.
- We define a catalog of common artifacts in LP and MILP problems, along with associated sets of textual optimization problem descriptions.
- For the identified artifacts, we analyze the performance of LLMs within various agent-based architectures.
- Unlike previous studies, we employ LLMs to encode problems using the AMPL mathematical modeling language.
- We briefly demonstrate that LLM capabilities are also relevant at other stages of the OR methodology, opening opportunities for further research within the OR community.

II. Methods

A. Modeling artifacts

Based on practices in mathematical modeling, we have identified 20 typical modeling artifacts, summarized in Table I. The first five pertain to linear programming (LP) models and include: a simple LP model (artifact 1), minimization of the maximum value (artifact 2), a weighted sum of absolute values with weights a and b depending on the sign of the argument (absolute value in the objective, artifact 3), the absolute value in a constraint (artifact 4), and a piecewise linear approximation of a convex function $f_i(x)$ (artifact 5). By the basic LP model (artifact 1), we mean a situation where all variables directly represent the problem described in natural language, i.e., there is no need for intermediate variables.

The second group of artifacts concerns mixed-integer linear programming (MILP) problems and includes standard logical constraints typical for binary variables. These constraints typically involve the selection of at most/at least/exactly N elements (artifacts 6–8) and a range of conditional relationships (artifacts 9–14), in which binary variables may or must take certain values if other binary variables satisfy a given Boolean condition.

TABLE I
Modeling artifacts

LP	1	simple LP	no implicit variables
	2	min max	$\min x$
	3	absolute value in objective	$\min(ax^+ + bx^-)$
	4	absolute value in constraint	$\min(ax^+), x^- \leq X^-$
	5	easy linearization	$\min x, x \geq f_i(x)$
MILP (logic constr.)	6	at most N of x, y, z,...	$x + y + z + \cdots \leq N$
	7	at least N of x, y, z,...	$x + y + z + \cdots \geq N$
	8	exactly N of x, y, z,...	$x + y + z + \cdots = N$
	9	if x then y	$x \geq y$
	10	if x then not y	$x + y \leq 1$
	11	if x then y and z	$y \geq x, z \geq x$
	12	if y or z then x	$x \geq y, x \geq z$
	13	if y and z then x	$x \geq \frac{y+z}{2}$
	14	if M or more from x, y, z then v	$v \geq \frac{x+y+\ldots M+1}{N-M+1}$
MILP	15	min min	$\min \min f_i(x)$
	16	disjunction	$x \in \langle a; b\rangle \cup \langle b; d\rangle$
	17	min. activity level	$x = 0$ or $x \in \langle a, b\rangle$
	18	indicator constraint	$x \to C, x \in \{0, 1\}$
	19	concave linearization	$\min f(x), f(x)$ concave
	20	non-monotonic linearization	$\min f(x), f(x)$ non-mon.

The third group of artifacts involves more complex MILP models, which usually include non-convexities or discontinuities. This group comprises minimization of the minimum value (artifact 15), disjoint variable domains (artifact 16), minimum activity level (artifact 17), indicator constraint (activation of a linear constraint C based on a binary variable x, artifact 18), linearization of a concave function (artifact 19), and linearization of a general non-monotonic function (artifact 20).

B. Datasets

To evaluate which artifacts a large language model handles better or worse, we prepared two base problems: problem #64 from the NL4Opt dataset (the pharmaceutical paste problem, with minor linguistic adjustments) and our own original problem (the sewage discharging problem), which has never been published online. Each of the base problems represents artifact 1 — a simple LP problem. Subsequently, the content of each base problem was modified to sequentially introduce artifacts 2 through 20.

Although the dataset may seem small, it is important to note that we currently lack both the capability to automatically generate problem statements in a way that ensures the inclusion of specific artifacts, and methods for automatically verifying the correctness of models proposed by LLMs for given problem descriptions. Modifying problem statements to explicitly induce a given artifact is non-trivial and was carried out manually. Similarly, each solution in the form of a mathematical model obtained during the study was manually verified by an expert in operations research. Given the 20

artifacts, four agent configurations discussed later in the paper, and five runs for each problem and configuration, this results in 800 models whose correctness had to be manually verified.

The content of both problems is presented in Appendix A.

C. Environment settings

The conducted experiments cover four distinct language-agent environments, differing in the number of agents involved and their assigned roles. Each experimental setup processes a set of 40 test tasks, composed of two base problems, each instantiated in 20 variants corresponding to the predefined artifacts. The goal of each environment is to generate a mathematical model in textual form as well as a corresponding AMPL model.

The mathematical model (in text form) includes the definition and description of sets, parameters, and variables, along with the objective function and constraints, formulated in the style typical for LP/MILP problems. For the AMPL model, the system is allowed to produce either a single combined file containing both the model and data, or separate files—‘.mod‘ for the model and ‘.dat‘ for the problem data.

Since the experimental output consists of two distinct results—a textual mathematical model and AMPL source code—errors may occur independently in each. Therefore, we report separate success rates for modeling and coding.

Modeling success is defined as the correct formulation of the optimization problem in textual form, manually verified by an operations research (OR) expert. Any identified flaw in the model leads to its classification as incorrect. The ratio of correct mathematical models is reported in the result tables under the column labeled "Model."

Coding success is defined as the correct encoding of the previously generated mathematical model into AMPL syntax. Correctness was verified both manually by an OR expert and by executing the model in the AMPL environment. A model is considered correctly implemented if it runs without errors and matches the expected logic, regardless of whether the original formulation was valid. Hence, a syntactically correct AMPL implementation of an incorrect model still counts as a success in the coding phase. The ratio of correct AMPL models is reported in the column labeled "Code."

Overall success requires both a valid mathematical model and its correct AMPL implementation, i.e., success in both the modeling and coding stages. The ratio of fully correct and functional solutions is reported in the column labeled "Success."

All experiments were conducted using the GPT-4o model. For each combination of base problem, artifact, and agent configuration, the generation and evaluation process was repeated five times.

III. Results

A. Monolith architecture (M/C)

In the monolith architecture, we use an LLM as both modeler and coder (M/C) in a single call. The architecture is illustrated in Figure 2. The LLM acts as a single agent responsible for both modeling and coding. As input, it receives a word problem inserted into the following zero-shot prompt with Chain-of-Thought (CoT) reasoning enabled by default in GPT-4o:

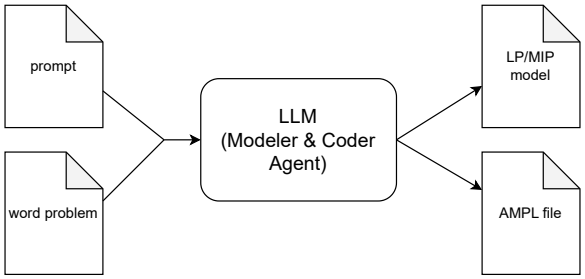

Fig. 2. Monolith architecture (M/C)

> *Formulate a linear programming model for the following problem.*
> ...
> *Provide the model as an AMPL file.*

Results are presented in Table II. Simple LP problems—artifacts 1 to 3—show a high success rate, reaching nearly 100% (only one coding failure occurred). These problems are considered easy for language models in both modeling and coding. The presence of an absolute value in a constraint (artifact 4) reduces the modeling success rate to 60%, though the coding success rate remains relatively high (80%). Artifact 5, which requires a linearization of a piecewise convex function, posed a significant challenge to the LLM and resulted in a very low modeling success rate (10%).

In the second group of artifacts, we observe high modeling success rates for most logical constraints, alongside surprisingly low coding success rates. Interestingly, artifact 13 was particularly challenging; the LLM often interpreted it as artifact 12. We believe this may be due to a linguistic ambiguity, as many people tend to confuse "and" with "or" in everyday language. Artifact 14 also resulted in a relatively low modeling success rate.

In the third group of artifacts, only the minimum activity level (artifact 17) yielded a high success rate. Other artifacts significantly reduced the LLM's ability to model correctly, with three artifacts never resulting in a valid model. However, this group showed a comparatively higher coding success rate than the second group.

Since the obtained results were not satisfactory, we considered several possible directions that may lead to improvements:

1) Fine tuning
2) Special prompting technique, including:
   - Tree-of-thoughts, Graph-of-thoughts
   - Generated knowledge – first get more knowledge about the problem, then model

TABLE II
RESULTS FOR M/C ARCHITECTURE

		Variant	Model	Code	Success
LP	1	simple LP	100%	100%	100%
	2	min max	100%	100%	100%
	3	abs. val. in obj.	100%	90%	90%
	4	abs. val. in constr.	60%	80%	40%
	5	piece-wise fun.	10%	70%	10%
MILP (logic)	6	at most N	100%	50%	50%
	7	at least N	100%	50%	50%

	18	indic. constr.	20%	80%	20%
	19	concave linear.	0%	50%	0%
	20	non-monoton. linear.	0%	50%	0%

- Cognitive verifier
- Few-shot – providing examples
- Persona/audiance pattern
- Reflection
- Chain-of-Experts
- ...

3) Agent-based decomposition (mixture-of-experts)
4) Retrieval Augmented Generation (RAG)

For further research, we exclude fine-tuning, as it requires additional examples that are difficult to generate in this domain and may be computationally expensive. We also do not include any special prompting techniques, as it remains unclear which approaches could reliably improve modeling and coding quality. Our observations suggest that for different artifacts, either modeling or coding may be the more challenging task. Following this insight, we believe that decomposition into specialized agents—potentially equipped with additional context and expert knowledge and implemented as RAG—is the most promising solution. The next three environment settings follow this concept.

B. Enhancing M/C with Code Verifier agent

In this setting, we build on the observation that the coding success rate is relatively low, particularly for the second group of artifacts, and that most failures are due to simple syntax issues. We introduced a new component—the verifier agent—responsible for validating the AMPL source file by executing it in the AMPL environment and reporting any errors encountered. The resulting architecture is illustrated in Figure 3.

If an error occurs, the verifier sends the following prompt, including the error message, back to the Modeler/Coder (M/C) agent:

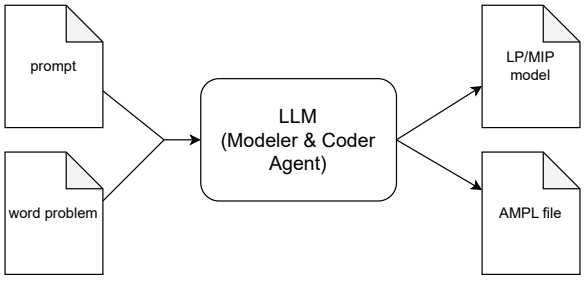

Fig. 3. M/C architecture enhanced with verifier agent (M/C+V)

TABLE III
RESULTS FOR M/C+V ARCHITECTURE

		Variant	Model	Code	Success
LP	1	simple LP	100%	100%	100%
	2	min max	100%	100%	100%
	3	abs. val. in obj.	100%	**100%**	**100%**
	4	abs. val. in constr.	60%	**90%**	**50%**
	5	piece-wise fun.	10%	**80%**	10%
MILP (logic)	6	at most N	100%	**60%**	**60%**
	7	at least N	100%	**50%**	**50%**
	8	exactly N	80%	**70%**	50%
	9	$x \Longrightarrow y$	90%	**50%**	**50%**
	10	$x \Longrightarrow \neg y$	100%	60%	60%
	11	$x \Longrightarrow y \wedge z$	100%	**50%**	**50%**
	12	$y \vee z \Longrightarrow x$	100%	**60%**	**60%**
	13	$y \wedge z \Longrightarrow x$	20%	**50%**	10%
	14	if $\geq M$ from $y \Longrightarrow y, z, \ldots$	50%	**60%**	**40%**
MILP	15	min min	0%	100%	0%
	16	disjun.	50%	**100%**	50%
	17	min. activ. level	100%	**100%**	100%
	18	indic. constr.	20%	**90%**	20%
	19	concave linear.	0%	**90%**	0%
	20	non-monoton. linear.	0%	50%	0%

AMPL reported the following issues:

```
...
test.mod, line 2 (offset 54):
 A is not defined
context: set CONTAINERS := A >>> B <<< C D;
No variables declared.
...
```

Fix all errors.

The M/C agent may respond by correcting the identified issues and regenerating the AMPL source code, which is then returned to the verifier. We allow only a single round of back-propagation. Although further iterations are technically possible, we observed that they do not improve success rates and may lead to repetitive error loops.

Results for the M/C+V architecture are presented in Table III. Changes compared to the M/C architecture (Table II) are shown in bold. We observe improvements in the coding success rate for nearly all artifacts where it was previously below 100%. The typical improvement is around 10 percentage points, but it reaches as much as 40 percentage points for artifact 19.

TABLE IV
RESULTS FOR M+C^R+V ARCHITECTURE

		Variant	Coder	Coder + RAG
LP	1	simple LP	100%	100%
	2	min max	100%	100%
	3	abs. val. in obj.	100%	100%

C. Separation of Modeler and Coder (M+C^R+V)

To further improve coding quality, we decomposed the monolithic M/C architecture into separate modeling and coding agents. This allowed us to augment the coder with Retrieval-Augmented Generation (RAG). Initially, we used chapters 1–9 from the original AMPL book [12], with each chapter provided as a separate PDF file. However, we observed no significant improvement.

Subsequently, we created a concise custom RAG resource focused on recurring coding issues. The RAG content is included in Appendix B. This short but targeted resource significantly improved outcomes—particularly for the second problem, which had previously suffered from poor coding quality. Table IV presents coding success rates for the second problem under the monolithic architecture (column "Coder") and the M+C^R+V architecture (column "Coder + RAG"). Changes are marked in bold.

As shown, coding was particularly weak in the second group of artifacts. The addition of a compact RAG significantly improved the coding success rate—in some cases, tripling it (e.g., artifacts 7 and 14).

Table V presents the distribution of error types reported by the AMPL environment. Several types of errors occur frequently. In the M/C architecture, more than half of the errors relate to syntax issues in set definitions. Nine percent concern the use of two-sided constraints, while similar proportions pertain to multiple constraints under a single 'subject to' statement, double definitions, and multiple objective functions. The remaining errors are categorized as general syntax issues.

When RAG is introduced, the distribution shifts. The frequency of specific known errors drops—sometimes to zero. As a result, the share of general syntax errors increases. However, the total number of errors decreases, indicating that the targeted RAG resource is effective. It successfully reduces both the frequency and proportion of the common, previously observed issues.

D. Enhancing Modeler agent with RAG: M^R+C^R+V

Encouraged by the positive impact of a relatively small RAG set for the Coder, we identified common modeling issues and developed a dedicated RAG for the Modeler agent as well. The resulting RAG is a two-page document that provides guidelines for addressing the most frequent challenges faced by the Modeler agent. Appendix C presents its contents, divided into three sections: piecewise linear function modeling, the minimum of minima problem, and indicator constraints.

Table VI shows the improvements achieved over the monolithic M/C model for a selection of the most challenging artifacts covered by the new RAG. The observed gains are significant, and the effectiveness of the targeted RAG should be considered high.

Table VII presents the complete results for the M^R+C^R+V architecture, which includes decomposition into specialized agents, each enhanced with its own RAG. Although the results are significantly improved compared to the original monolithic M/C architecture, some limitations remain. Notably, coding artifacts from the second group still show signs of weakness. Additionally, modeling performance remains suboptimal for artifacts 13–16. Among the simpler problems, artifact 4—featuring absolute values in constraints—underperforms relative to others in this group.

IV. THE CONCEPT OF C-DSS

Our experience with decomposing the architecture into specialized agents leads us to propose a general framework for Conversational Decision Support Systems (C-DSS), as illustrated in Figure 4. The agents marked in bold represent the components studied in this work: the Modeler, Coder,

TABLE VII
RESULTS FOR M^R+C^R+V ARCHITECTURE

		Variant	Model	Code	Success
LP	1	simple LP	100%	100%	100%

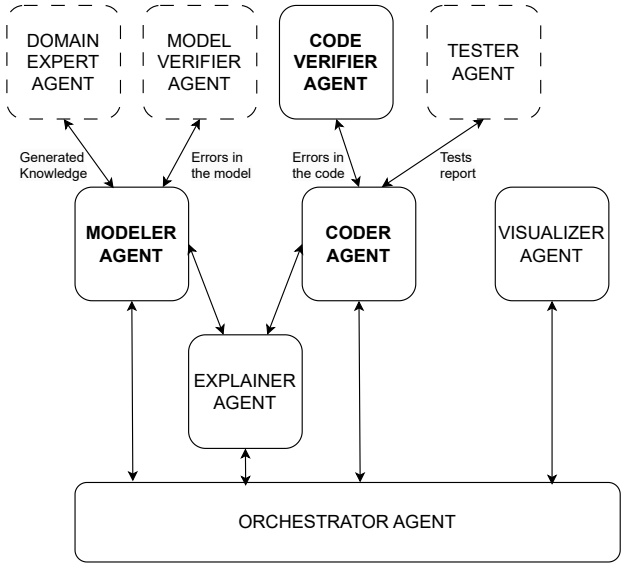

Fig. 4. The concept of Conversational Decision Support Systems

and Code Verifier. However, other elements of a classical Decision Support System (DSS) also involve communication and can be implemented within a language-agent-based architecture.

One example is the DSS user interface, whose role can be taken over by a *Visualizer agent*, dynamically responding to user requests for result visualization. Figure 5 shows a sample response from the Visualizer agent for base problem one, given the following prompt:

> *Visualize the results for the Management Board*

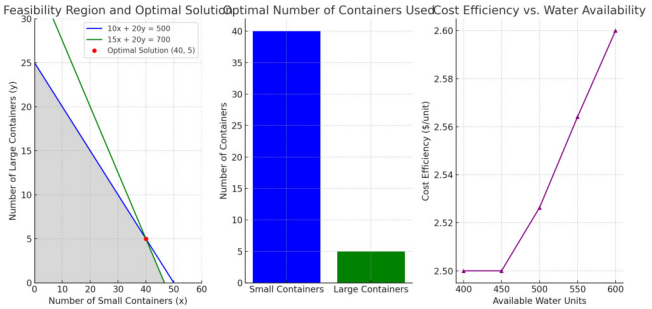

Fig. 5. Visualization of results proposed by the Visualizer agent (overlapping text left as it was generated by the agent)

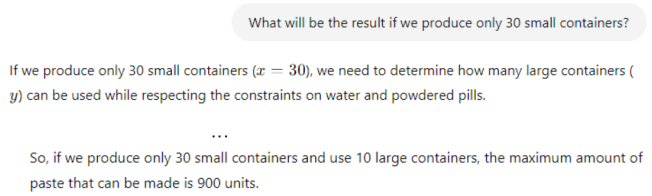

Fig. 6. Exemplary session 1 with Explainer agent

The agent proposed a visualization of the feasible solution set, which may not be suitable for a Management Board. It also presented the solution using a simple bar chart. Interestingly, the agent suggested performing an efficiency analysis with respect to water availability, thereby independently initiating a non-trivial sensitivity analysis.

Although the resulting output is not perfect and contains some visual flaws (e.g., overlapping text), it is important to note that the agent used was neither trained nor equipped with RAG, and the conversation was brief and based on a simple prompt. In this context, the results are promising and illustrate the potential for further development of such interfaces.

Another example is the *Explainer agent*, specialized in interpreting and explaining the obtained results to the user. In particular, it can conduct sensitivity or what-if analyses, and thus collaborates closely with the Modeler and Coder agents.

Figures 6 and 7 present two short sessions with the Explainer agent for base problem one. In the first session, the user seeks reassurance that the solution proposed by the C-DSS is valid and asks about the impact of reducing the number of small containers produced. The agent responds with a detailed explanation; Figure 6 shows only the opening sentence and final conclusion.

In the second session, the user wants to understand why increasing the production of small containers is not feasible. As before, the agent provides a longer explanation, and Figure 7 shows the first and final statements. In both cases, the Explainer agent offers a fairly detailed and accurate analysis of the user's proposed changes.

Assuming the Modeler is a general-purpose agent, it is reasonable to enable communication with a domain-specific agent that provides expert knowledge in a given field. While

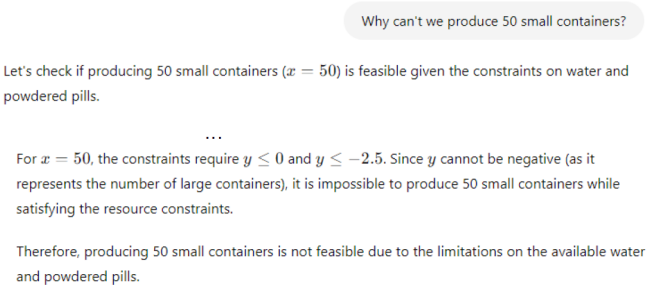

Fig. 7. Exemplary session 2 with Explainer agent

the implementation details remain open, introducing a Critic agent—responsible for verifying and validating the developed mathematical model (i.e., a Model Verifier)—appears well justified. This agent could replace or support the function of a human expert, which proved to be a bottleneck in our experiments.

In the area of code development, the current Code Verifier only checks for syntactic correctness by testing whether the code runs in a given environment. However, a dedicated *Tester agent* should also be envisioned—capable of validating the encoded model using predefined unit tests or scenario checks.

Finally, the entire agent ecosystem requires workflow management, a task that would fall to an *Orchestrator agent*. This agent would be responsible for dynamically arranging tasks, coordinating agent communication, and preventing loops or deadlocks in the system.

V. Summary

This paper introduces the concept of Conversational Decision Support Systems (C-DSS), which leverage Large Language Models (LLMs) to enhance Operations Research (OR) methodology, particularly during the modeling and coding stages. We propose a novel framework in which LLMs serve as proxies across various phases of decision support system development, with a focus on mathematical modeling and AMPL code generation.

By identifying 20 typical modeling artifacts for Linear Programming (LP) and Mixed-Integer Linear Programming (MILP), we evaluate LLM performance across four agent-based architectures: Monolith (M/C), M/C with Verifier (M/C+V), Modeler and Coder with Retrieval-Augmented Generation (M+C^R+V), and both Modeler and Coder enhanced with RAG (M^R+C^R+V). Using two base problems—one from the NL4Opt dataset and a custom-designed sewage discharging problem—we observe that simpler LP artifacts yield near-perfect success rates. In contrast, complex MILP artifacts involving logical constraints or non-convex functions remain significantly more challenging.

Our experiments reveal patterns in LLM behavior, suggesting that targeted solutions to specific artifacts offer great potential for improvement. We demonstrate that even a very short RAG for the Coder agent and a slightly longer, yet focused, RAG for the Modeler agent can significantly improve performance—particularly for piecewise functions, minimum-of-minima formulations, and indicator constraints.

Fig. 8. Potential role of LLM in OR methodology

We also envision a more comprehensive C-DSS architecture, incorporating agents such as the Modeler, Coder, Verifier, Visualizer, Explainer, and Orchestrator. This multi-agent design offers a unified approach to integrating LLMs into OR and opens new avenues for research in automating decision support systems. A Decision Support System is a product developed within the broader framework of the OR methodology, as referenced in Figure 1. As shown, the various steps in the methodology rely on different forms of language to facilitate communication among stakeholders—making it inherently well-suited for enhancement through LLMs. Therefore, we propose considering a revised OR methodology in which language models serve as core tools at each stage. Figure 8 illustrates this vision.

Despite rapid advances in large language models, there are still significant limitations. Our results show that for some quite typical cases, LLMs are not a reliable tool for modelling and coding. Since the real problems are typically more complex and may include more sophisticated aspects, such as complex nonlinearity, dynamics, or uncertainty, it must be admitted that the C-DSS concept is in its early stages of development. It requires a significant improvement for real applications. However, we believe that our proposed C-DSS concept not only advances the design of automated decision systems but also lays the foundation for further research into LLM-enhanced OR methodologies.

APPENDIX

A. Word problems used in the research

Base problem 1 (#64 from NL4Opt data set)

> There are two specialized containers, a small and large one, that are used to make a pharmaceutical paste. The small container requires 10 units of water and 15 units of the powdered pill to make 20 units of the paste. The large container requires 20 units of water and 20 units of the powdered pill to make 30 units of the paste. The pharmacy has 500 units of water and 700 units of powdered pills available. How many of each container should be used to maximize the amount of paste that can be made?

Base problem 2 (the sewage discharging problem)

> The two cities discharge sewage into two treatment plants with a capacity of 5,000 tons and 3,000 tons per day, respectively. The purified water is pumped further into the river. Each city can divide sewage in any proportion between both treatment plants. The daily operating cost of treatment plant 1 is USD 3.5/ton. The daily operating cost of treatment plant 2 is USD 6/ton. The operating cost of the clean water pumping station at treatment plant 1 is USD 2.5/ton, and at treatment plant 2 - USD 2.2/ton. Assuming that cities must discharge at least 4,000 and 3,500 tons of sewage per day, plan the system's operation to minimize the daily cost of its operation.

B. Content of Coder's RAG

> This GPT acts as an expert in linear programming and AMPL (A Mathematical Programming Language). It assists users in creating AMPL files for given linear programming problems by understanding their requirements and translating them into correct and optimized AMPL code. It ensures the AMPL files are syntactically accurate and efficient, adhering to best practices in linear programming and AMPL usage. It will guide users through the process of defining sets, parameters, variables, objective functions, and constraints in their linear programming models.
> Whenever you are asked to create an AMPL file, follow these rules:
> 1) Start with the declarations of sets followed by declarations of parameters and variables.
> 2) When declaring a set of parameters, do not assign any value. Add the section "data;" at the end of the AMPL file and put all assignments there.
> 3) Do not use sharp inequalities. Always apply "lower than or equal" or "greater than or equal".
> 4) Do not use double inequality constraints. Break the double inequalities into two separate constraints.
> 5) There can be only one objective in the AMPL file.
> 6) 'var' definitions should not include assignment from other variables directly.
> 7) Under the keyword "subject to", only one constraint can be defined. If more constraints are needed, each constraint definition should start with "subject to".

C. Content of Modeler's RAG

> **Piecewise functions**
> Remember that when dealing with easy piecewise function cases, there is NO NEED to use auxiliary binary variables. It is enough to add constraints for each segment of the piecewise function. For instance, if the problem is minimizing the convex piecewise function, we can add auxiliary continuous variable x and a constraint $x \geq f_i(x)$, where $f_i(x)$ is an i-th segment of the piecewise function. However, if you add binary variables indicating the segment of the function, these variables must be constrained by the original variable. If the i-th linear segment is denoted by $f_i(x)$ and it is valid in the range from x_{i-1} to x_i, then we need to set auxiliary variable v_i to 1 whenever x is in the range from x_{i-1} to x_i. We can model that as follows:
>
> $$x \leq x_i v_i + M(1 - v_i)$$
> $$x \geq x_{i-1} v_i - M(1 - v_i)$$
>
> For instance, let's consider the function consisting of two piecewise segments, $f_1(x)$ and $f_2(x)$. For x from 5 to 10, there is function $f_1(x)$, and for x in a range from 10 to 18, there is function $f_2(x)$. We introduce auxiliary variables v_1 and v_2 such that
>
> $$v_1 + v_2 = 1$$
>
> To constraint variable x by variables v_1 and v_2, we define inequalities as follows
>
> $$x \leq 10v_1 + M(1 - v_1)$$
> $$x \geq 5v_1 \breve{} M(1 - v_1)$$
> $$x \leq 18v_2 + M(1 - v_2)$$
> $$x \geq 10v_2 \breve{} M(1 - v_2)$$
>
> To calculate the value of the piecewise function, we introduce the auxiliary continuous variable z, and we define the following constraints:
>
> $$z \geq f_1(x) \breve{} M(1 - v1)$$
> $$z \leq f_1(x) + M(1 - v1)$$
> $$z \geq f_2(x) \breve{} M(1 - v2)$$
> $$z \leq f_2(x) + M(1 - v2)$$
>
> In the final version of the model, $f_1(x)$ and $f_2(x)$ must be substituted with linear formulas.

Min of min problem (minimization of the minimal value)

If the problem is to minimize the minimum of some values, we need to add auxiliary binary variables that indicate which value is the lowest. Let us consider variables x and y and the problem of minimizing the minimal value out of variables x and y. Then, we must introduce a binary variable v that is 0 if x is lower or equal to y, and v is 1 if y is lower than or equal to x. In the case of $x = y$, the value of v can be any. To model that, we need to add the following constraints:

$$x \leq y + Mv$$

$$y \leq x + M(1 - v)$$

Having variable v that indicates whether x or y is the minimal value we must introduce auxiliary continuous variable z that will be equal x if v is 0 or to y if v is 1. It is an indicator constraint that can be modeled as follows:

$$z <= x + Mv$$

$$z >= x^{\smile} Mv$$

$$z <= y + M(1 - v)$$

$$z >= y - M(1 - v)$$

Remember that z must be constrained from above and below. Since z is the minimal value of x and y, it can be directly minimized in the objective:

$$\min z$$

WARNING! Remember, YOU CAN NOT SIMPLY constraint z in this way:

$$z \leq x$$

$$z \leq y$$

and minimize z. This is MISTAKE! Variable z will always be 0. You must use an auxiliary binary variable. Watch out for this case!

Indicator constraints

An indicator constraint is a constraint that is controlled by a binary variable. If the constraint is "lower than", and the auxiliary variable that controls this constraint is z, then we can add Mz to the right-hand side of the constraint, where M is a big number. If the original constraint is as follows:

$$\sum_i a_i x_i \leq c$$

then it can be controlled with a binary variable y in the following way:

$$\sum_i a_i x_i \leq c + Mz$$

Indicator constraint can be used to model conditional constraint in which one variable depends on the value of another variable. For instance, if x must be greater or equal to A when y is greater or equal to B, we can add the indicator constraint for variable y as follows

$$y \geq B - M(1 - z)$$

where z is an auxiliary binary variable. So if z gets 1 then the constraint becomes active. Then z must be set to 1 if x is greater or equal A, which can be modeled as follows:

$$z \geq (x - A)/M$$

Remember that in the general case of conditional constraint, we need to use the concept of the indicator constraint, so an auxiliary variable is needed.

***Abstract*—HPC systems are shared between many users. Managing their resources and scheduling compute jobs is a central task of these clusters. Scheduling also allows to control the workload and energy consumption of an HPC system. A Digital Twin of an HPC cluster can aid in the scheduling process by providing energy measurements about the system and predict scheduling decisions with a simulation. For a real-world use case, an integration of the Digital Twin with the scheduler is necessary. A possible use case are energy limitations as part of a demand response process between the HPC operator and energy supplier.**

Therefore, this paper introduces a plugin for Slurm, an open-source scheduler, that implements a scheduling algorithm for time-dependent cluster-wide power capping. It uses a node energy model to predict the energy consumption of jobs and can start jobs at different frequencies to stay below the configured power limit. The plugin interfaces with the Digital Twin that provides energy measurements for the compute nodes to track the system power consumption in real time and update the power limitations if necessary.

The plugin is tested on a cluster and compared against a scheduling simulation of the algorithm. The analysis compares the power profile of the simulation and the real system and the allocation of the jobs over time. Differences in the execution and the power trace are analysed and discussed.

I. Introduction

THE High-Performance Computing (HPC) community has focussed on achieving maximum performance for a long time. This doctrine has recently come under pressure by rising energy prices and a transformation of the energy market towards renewable energies while HPC systems continue to grow in size and energy demand. A trend that is further accelerated by the recent shift towards artificial intelligence.

An HPC system under full load has a relatively constant energy requirement. However, a shift towards renewable energy production means greater volatility in the energy production. HPC systems need a mechanism to respond to these fluctuations. Solely relying on fossil energy source is also not an option, as regulatory frameworks, such as the Blue Angel for data centres [1], define upper bounds for carbon-dioxide emissions.

Dynamically adapting the energy consumption of an HPC system has further use cases. It can help stabilize the energy grid by reducing the load in the grid or by increasing the load if enough energy is available. Additionally, such a mechanism allows the continued automatic operation of the cluster in case of energy shortages.

Reacting to limited energy availability is sometimes referred to as demand response. While it is common practice for large energy consumers, HPC centres have not yet widely adopted such mechanisms [2]. However, first mechanism have been proposed. One possible demand response mechanism was presented in [3]. A Digital Twin is used to collect data about the system energy consumption and together with information about energy availability, the scheduler can adapt the overall energy consumption to stay below a defined threshold. The algorithm in the original paper was validated with a simulation. This paper implements the algorithm as a plugin for the popular cluster scheduler Slurm [4].

This paper makes the following contributions:

- The algorithm uses a node energy model to predict the energy consumption of the jobs. This paper uses a new test platform for the evaluation of the plugin. Thus, an updated node energy model is necessary that has been created for the new test system.
- The algorithm from the original facilitates time-dependent cluster-wide power capping. This paper implements this algorithm as a plugin for the open-source scheduler Slurm.
- The algorithm was previously only evaluated in a simulation of the Digital Twin. This paper compares the simulation against the performance on a real cluster. The evaluation includes power traces of the real system and the node allocation to the jobs.

The remainder of this paper is structured as follows: Section II introduces Slurm in detail and presents relevant literature, especially regarding cluster operation under a power limitation. Preparatory work such as the updated node energy model and a recap of the scheduling algorithm is presented in Section III. In Section IV, the implementation of the Slurm plugin is discussed. The plugin is then evaluated in the real world and compared to simulation results in Section V.

II. Related Work

An HPC system consists of many individual components and is typically shared among users for running their compute jobs. These systems thus need a resource manager to avoid

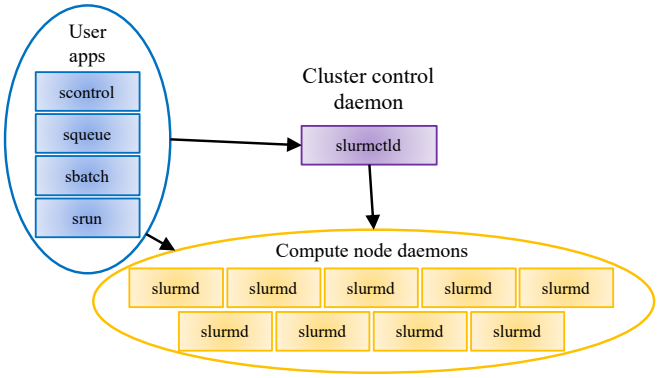

Figure 1: Overview of the Slurm components. The `slurmctld` is the central controller of the cluster while `slurmd` handles each compute node. Client components such as `scontrol`, `squeue`, `sbatch` and `srun` allow the user to interact with the cluster and submit and manage compute jobs.

resource conflicts between users as well as a strategy to assign the available resources to the requests of the users, referred to as scheduling strategy. Different resource managers and schedulers exist such as e.g. Moab, PBS, Grid Engine and Slurm [4].

Being open-source software written in the C programming language, Slurm has been widely adopted by the research community. Slurm works both as a resource manager and as scheduler and also starts and monitors the compute jobs on the cluster. Additionally, it is able to handle accounting of the resource usage and supports resource reservation in advance. The software consists of multiple components: the Slurm control daemon `slurmctld`, the Slurm daemon on the compute nodes `slurmd` and command-line utilities for the users to manage Slurm and submit (`sbatch`) and control (`scontrol`) their jobs. Slurm also handles the MPI configuration for the jobs and offers the launch program `srun`. These components are shown in Figure 1. Slurm has further components that are responsible for accounting and billing but they are not relevant in the context of this paper.

HPC systems are composed of individual compute nodes which might feature different hardware, e.g. CPU cores, memory and additional components such as storage, GPUs or TPUs. The nodes can be grouped into partitions for bundling nodes with identical hardware or for aiding the scheduling process, e.g. when certain nodes are reserved for short or long running jobs or similar. When users want to run a task on the HPC system, they submit a job. The job defines what the user wants to compute, the required resources to complete the computation and for how long the job will need those resources. Slurm can further divide jobs into job steps, that define tasks that may be executed in parallel or contain pre- and post-processing and do require different resources.

The specific scheduling algorithm and resource allocation can contribute to the energy efficiency and stability of the system and thus has been subject to many research studies. The surveys by Czarnul [5] and Kocot [6] provide an overview of tools for energy and power management and power-aware scheduling.

Simulating the scheduling process is a common approach in HPC research. One example is CQSim [7]. Based on trace data, the authors propose a scheduling approach for demand response, and test it in their simulation [8]. To retrieve such traces, the system needs to be actively monitoring the energy consumption of each job. Not every cluster is designed to do that because the hardware does not provide the necessary measurements, or because the scheduling environment does not track the data, or both. Another important aspect is taking the specifics of the different applications into account, when imposing a power cap on the cluster [9]. The scheduler may automatically change the frequencies and thus runtime of the jobs to dynamically distribute the power. Other demand response methods rely on power traces to create a node model and limit power consumption of the HPC clusters [10]. None of these approaches have been tested in the real world.

One approach in system management and system modelling has attracted increased interest over the last years: Digital Twins [11]. A Digital Twin is a virtual representation of a real-world object, in this context an HPC cluster. A real-world object is represented as a Digital Twin in the virtual world. Data about the object is collected and integrated into the Digital Twin. With their characteristic bi-directional data linkage, changes in the real world are reflected in the digital domain and vice versa. The Digital Twin models the behaviour in the real world and can test new parameters before they are applied to the real system. Simulations are often cheaper and faster and a negative impact on the real system can be avoided. In the HPC context, these simulations are generally scheduling simulations as they describe changes in the system state well.

Digital Twins are under development for HPC systems ranging from small clusters to one of the world's largest systems, Frontier [12]. As part of their smart campus initiative [13], the Physikalisch-Technische Bundesanstalt (PTB) is developing a Digital Twin for their HPC system [14]. It has been demonstrated that it can be used to reduce system emissions. One major use case of the Digital Twin is the operation of HPC systems under a time-dependent cluster-wide power cap. The power can be capped by the Digital Twin, depending on the currently available energy [3]. Precise energy measurements also allow the Digital Twin to track the data centre Power Usage Effectiveness (PUE) [15].

Similar to the node energy model in Section III-B, application power profiles are a common technique used in application modelling and have been done for a wide variety of applications, including WZ factorisation [16] and matrix factorisation [17]. An alternative to Dynamic Voltage and Frequency Scaling (DVFS) is the implementation of a power cap as a hardware driver [18].

III. Preliminary Work

This section introduces the test system used in this paper, and shows how Slurm has been configured for this specific system. Since the test system differs from the system in [3], a new node energy model has been created. Furthermore, a cap on the implemented scheduling algorithm is given.

A. Test System

For the practical test of the Slurm plugin, this paper relies on a cluster consisting of Raspberry Pis. While this setup is not typical for a commercial HPC system, it has a similar structure and allows the development of the plugin without interrupting the production HPC system of PTB. The setup is based upon a design found proposed in [19].

The system is equipped with a total of 10 Raspberry Pi 4B with 8 GB RAM each. They are connected via their $1\,\mathrm{Gbit/s}$ Ethernet ports. Each Pi also has the Power over Ethernet (PoE) HAT (Hardware Attached on Top) installed that allows the nodes to be supplied with power from the Ethernet switch. All run the Raspberry Pi OS Bookworm.

The switch, a Netgear GS316EPP, supplies power via Power over Ethernet (PoE) to the nodes and offers a gigabit interconnect. It has a rudimentary management interface that provides energy information for each of the ports and allows management and power cycling of individual ports. These features thus allow us to track the per-node energy usage and to turn nodes off and on when needed as the Raspberry Pi does not support Wake-On-LAN. The energy data is queried by a collector agent of the Digital Twin and provided via the Digital Twin database.

One node is designated as the head node while the remaining 9 nodes act as compute nodes. The head node provides a global file system via NFS to all compute nodes. For this purpose, a single SDD is connected via an SATA-to-USB adapter and provides the necessary storage space. It also contains scratch space that is shared between the nodes. The compute nodes themselves are disk-less and get their image via TFTP from the head node when they boot. An additional Ethernet-to-USB adapter establishes a connection to the outside world while a DHCP server provides the internal cluster network with addresses for the compute nodes. The head node uses NAT to forward the internet connection to the compute nodes. This is necessary because the Raspberry Pi does not have a real-time clock and the clocks of the compute nodes would be out of sync after a reboot.

As the scheduler and resource manager we have opted to use Slurm [4]. Being open source software, the Digital Twin can be integrated with the scheduler. Slurm is configured with a single partition spanning all 9 compute nodes. Since the cluster is not intended for production use with many users, only basic logging is configured.

The head node is running the `slurmctld` control daemon that manages the scheduling logic and interfaces with the Digital Twin. The compute nodes run the `slurmd` daemons that connect the nodes to the control daemon. The user connects to the head node and can use the Slurm utilities, e.g. `sbatch`, to control the cluster and submit batch jobs.

Slurm provides some power saving functionalities [20], most notably node suspension and resumption. The scheduler monitors the nodes. If a node has been idle for a certain amount of time, it is shut down. When the node is needed again, Slurm issues a restart. This is implemented by power-cycling the Ethernet port of the switch, resulting in the Raspberry Pi booting again. The Slurm daemon on the node then contacts the Slurm controller, signalling that the node is ready to receive the next job. For this experiment, Slurm has been configured to turn of a compute node after 10 minutes of inactivity.

B. Node Energy Model

The node energy model is an integral part of the scheduling algorithm. It allows the algorithm to estimate the energy consumption of a job. It is the part that makes the algorithm hardware specific. The remaining logic works independently from any underlying hardware characteristics. However, it needs to be updated if the algorithm should run on a different cluster with new workloads. Hence, this section presents the node energy model for the test system used in this paper. For this experiment, a total of 4 different benchmarks and parallel applications have been selected, namely the HPL and HPCG benchmarks as well as OpenFOAM and Geant4.

The High-Performance Linpack (HPL) [21] is used to create the TOP500 ranking of supercomputers. The benchmark is a linear equation solver and uses highly optimized vector instructions, thus serving as a kind of upper bound for the model. The second benchmark, the High Performance Conjugate Gradients (HPCG) [22], complements the HPL benchmark by adding more memory intensive operations.

The two benchmarks are supplemented by two numeric applications. The first, Open Field Operation And Manipulation (OpenFOAM) [23], is a computational fluid dynamics package and the second, Geometry and Tracking (Geant4) [24], is a Monte Carlo simulation toolkit.

To create the node energy model, each of the 4 jobs was run on the nodes on all supported frequencies. The switch provides an energy measurement that allows to monitor the jobs energy consumption. From these measurements, the Time-to-Solution (TtS) and Energy-to-Solution (EtS) can be derived. Figure 3 shows the results for all supported frequencies from $0.6\,\mathrm{GHz}$ to $1.8\,\mathrm{GHz}$. Pareto-optimal points [25], [26] are coloured in orange. For the model shown in Table I, three points have been selected: the highest frequency of $1.8\,\mathrm{GHz}$ and if available two pareto-optimal points. The scaling factor is used to adjust the job runtime for the increased runtime required if the job runs at a lower frequency setting.

This model shows a downside of the Raspberry Pis as a test platform. They have a relatively high offline energy consumption, especially compared to their idle consumption and the consumption under load [27]. This amounts to $22.1\,\mathrm{W}$ offline consumption for the compute nodes of the cluster. While $2.70\,\mathrm{W}$ is not much compared to other platforms, it is

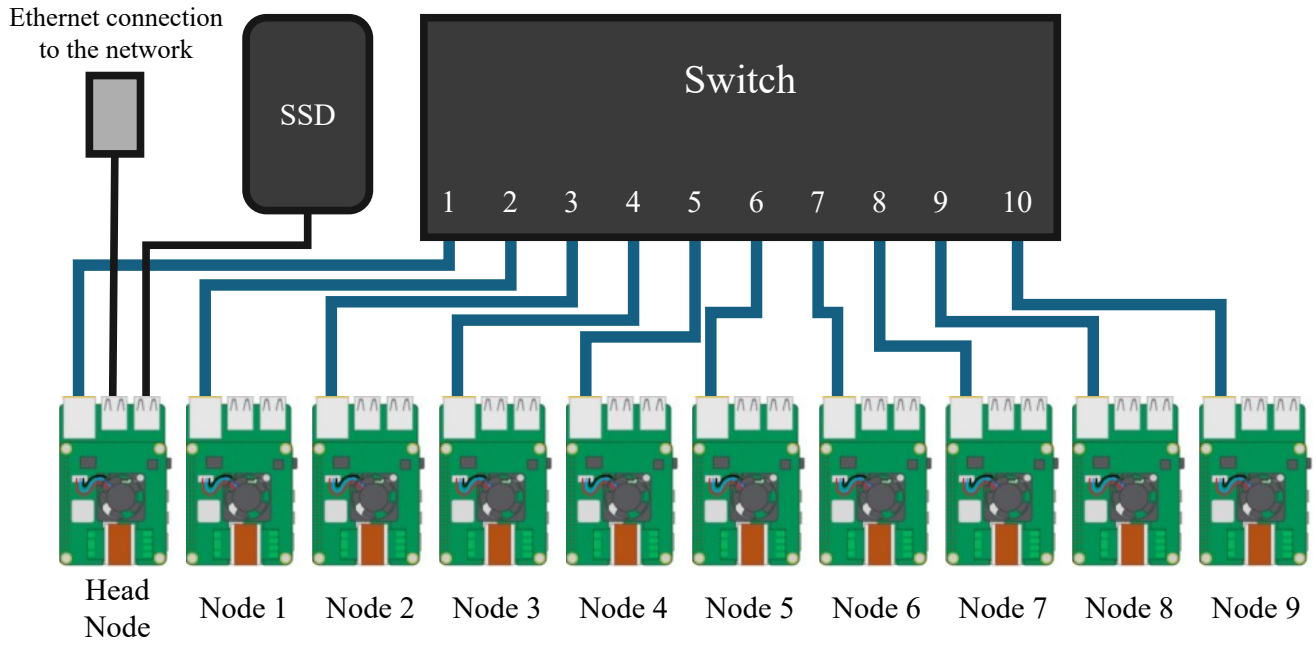

Figure 2: Schematic overview of the test cluster. It consists of one head node and a total of 9 compute nodes. They are connected via Ethernet and receive power via PoE. The head node has an additional Ethernet port to connect the cluster to a network. The SSD is also connected to the head node and provides storage for the compute nodes.

Table I: The node energy model

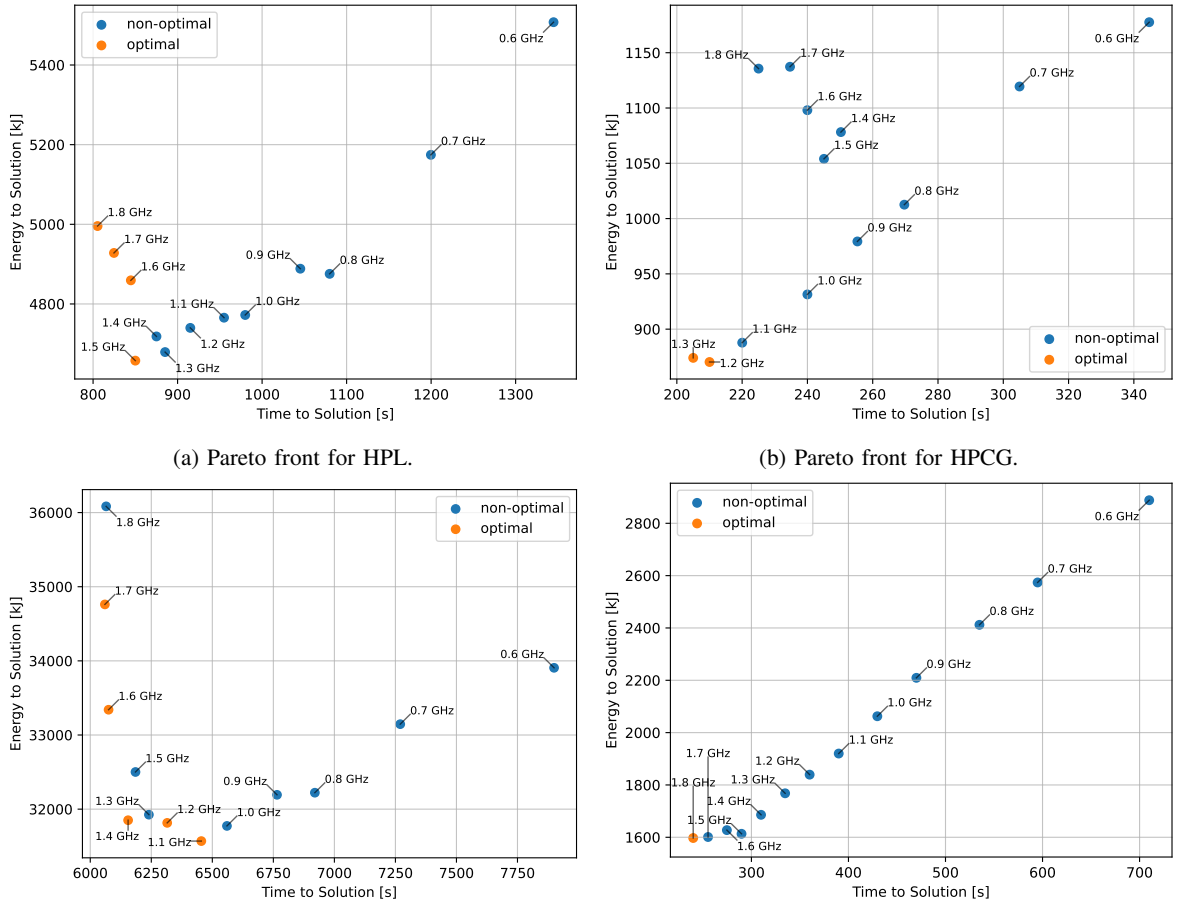
Job type	Frequency	Power	Scaling factor
HPL	1.8 GHz	6.20 W	1.000
	1.6 GHz	5.74 W	1.049
	1.5 GHz	5.47 W	1.055
HPCG	1.8 GHz	5.05 W	1.000
	1.3 GHz	4.25 W	0.911
	1.2 GHz	4.13 W	0.933
OpenFOAM	1.8 GHz	5.95 W	1.000
	1.4 GHz	5.17 W	1.015
	1.1 GHz	4.89 W	1.064
Geant4	1.8 GHz	6.62 W	1.000
	1.5 GHz	5.55 W	1.208
	1.1 GHz	4.92 W	1.625
Idle	-	3.12 W	-
Offline	-	2.70 W	-

almost half as high as the busy consumption. This behaviour can be changed by forcibly disabling PoE on the switch instead of only issuing a software shutdown.

C. Algorithm Recap

The goal is to run the HPC cluster under a variable power limitation while maximizing the system usage. The algorithm's pseudocode is shown in Algorithm 1. This section briefly describes the idea behind the algorithm while an in-depth description was given in [3]. The algorithm uses two main concepts to improve the throughput: DVFS, and turning off nodes. The node energy model provides the optimal frequency settings, while turning off unused compute nodes further decreases the system power consumption.

The scheduling algorithm receives a list of eligible jobs, and sorts them by time of arrival. The first "if" statement checks whether there are enough online and offline nodes available to start the job, and starts offline nodes if necessary.



The second "if" statement checks whether enough online nodes are available to start the job. If that is the case, it uses the node energy model to estimate the job's power consumption. If starting the job would exceed the power limit, the job is deferred; otherwise, the job is started.

When a job is deferred, the routine moves on to the next job in the queue. This allows the algorithm to backfill jobs that might fit within the available resources.

IV. Slurm Plugin

The Slurm control daemon `slurmctld` is responsible for job scheduling. Two scheduling algorithms are included in the package as plugins. The first plugin is called `builtin` and implements a simple FCFS algorithm. The second plugin is called `backfill` and, as the name implies, implements FCFS with backfilling. This paper presents an additional, new scheduling plugin which implements the algorithm from Section III-C that can be used instead of the integrated plugins.

By default, Slurm schedules jobs automatically without consulting the scheduling plugin, as long as no resource conflicts arise. E.g. a job submitted to an empty cluster that fits in terms of compute nodes gets scheduled without the scheduling plugin. This circumvents the energy limit check of the scheduling plugin, and in our case could lead to the power consumption exceeding defined limits. To avoid such a

(a) Pareto front for HPL.

(b) Pareto front for HPCG.

(c) Pareto front for OpenFOAM.

(d) Pareto front for Geant4.

Figure 3: Pareto fronts for the four different applications in the node energy model. Pareto-optimal frequencies in terms of EtS and TtS are coloured orange. The remaining frequencies are coloured blue.

situation, all jobs must be submitted in the `hold` state with a priority of zero. This prevents Slurm from automatically scheduling jobs [28].

The Slurm control daemon periodically consults the scheduling plugin. The plugin first consults the database and updates the power limits and queries the current power consumption of the system from the database. It contains a set of functions that allow it to connect to the InfluxDB of the Digital Twin. InfluxDB does not offer a native C client implementation. However, since Slurm includes the cURL library, the plugin uses cURL to connect to the REST API of the database in order to query both the power consumption of the nodes and the power limitations. This provides a level of abstraction of the database calls from the rest of the code. Furthermore, helper functions convert the reply from csv to C-structs for further use.

During this periodic invocation, the plugin uses the core scheduling routine `_backfill_power()` which is shown in Algorithm 2. It does not use the usual scheduling queue but the entire job list. First, it checks if any jobs are pending but have not started yet in the first while loop (lines 13-21). Those are jobs that have been scheduled by the plugin but have not yet been started by Slurm. This avoids releasing to many jobs that later conflict with one another. If a job is waiting to start, the function is exited and waits for the periodic scheduling before making the next attempt.

The second while loop (starting in line 25) handles the actual scheduling. The plugin first consults `job_test_resv()` (lines 30.32), a Slurm function that tests whether enough nodes are available. Afterwards, `select_g_job_test()` (lines 31-49) tries to select the optimal nodes and tests whether the job can start immediately. Last but not least, `check_power_dvfs()` (lines 57-58) uses the node energy model to estimate the energy requirement of the job and whether the current power limitations allow the job to start. It is also responsible to set the frequency and adjust the runtime of the job according to the numbers in Table I. If enough energy is available, the priority of the job is increased which releases the job from the `hold` state. The `slurmctld` recognizes that and starts the job. It is also responsible to

Algorithm 1 Pseudocode of the core scheduling routine

```
backfill_power(eligible_jobs) {
  for (Job j : eligible_jobs) {

    // test if nodes need to be booted
    // check if enough nodes are offline
    if (j.nodes > online_nodes(j) &&
        j.nodes <= online_and_offline_nodes(j)) {
      // how many nodes need to be booted?
      toboot = j.nodes - online_nodes(j);

      // check if the nodes would
      // exceed the power limit
      if(!check_power(j, get_offline(j, toboot))){
        continue;
      }
      boot_nodes(j, toboot);
    }

    // test if enough nodes are online
    // and available
    if (j.nodes <= online_nodes(j)) {

      // check if the job and nodes would
      // exceed the power limit
      if (!check_power_dvfs(j)) {
        continue;
      }

      assign_nodes(j);
      j.wait_time = tick - j.submit_time;
      running.add(j);
      eligible_jobs.remove(j);

      // trigger an event in the simulation
      // on job completion
      e = new JobEvent(tick + j.run_time_scaled,
                j, JobState.COMPLETED);
      eventQueue.add(e);
    }
  }
}
```

select the nodes and start them if necessary. Slurm also sets the configured frequency.

So far, the implementation has been tested on a homogeneous cluster with a single partition. It does not yet consider multi-partition scheduling or other features such as multi-step jobs. Another aspect the algorithm cannot control yet is energy usage during the boot process of the nodes, which can lead to power spikes. One possible way to control this is by introducing a delay in the boot script that Slurm uses to power-cycle the ports on the switch. An early loaded power cap driver, as proposed in [18] might also help.

V. Evaluation

This paper presents a Slurm plugin based on a scheduling algorithm, evaluated previously only through simulation. To compare the simulated results with the real-world, both the simulation and the plugin are configured with the node energy model from Section III-B and an identical number of compute nodes.

The workload for the evaluation is generated with the improved Feitelson job model [29], [30]. The model generates a job trace in the Standard Workload Format (SWF) [31]. While the format encodes which application was run, the

Algorithm 2 Actual code: Core scheduling routine of the Slurm plugin

```
static void _backfill_power(void) {
  int j, rc = SLURM_SUCCESS, job_cnt = 0;
  job_record_t* job_ptr;
  bitstr_t *alloc_bitmap = NULL;
  bitstr_t *avail_bitmap = NULL;
  bool resv_overlap = false;
  resv_exc_t resv_exc = { 0 };
  time_t now = time(NULL);
  list_itr_t *iter = NULL;

  // check if a job has been scheduled
  // and has not started yet, defer further
  // scheduling in this case
  iter = list_iterator_create(job_list);
  while ((job_ptr = list_next(iter))) {
    if(IS_JOB_PENDING(job_ptr) == true
      && job_ptr->priority > 0) {
      list_iterator_destroy(iter);
      return;
    }
  }
  list_iterator_destroy(iter);

  // go through the list of held jobs
  iter = list_iterator_create(job_list);
  while ((job_ptr = list_next(iter))) {
    if(IS_JOB_PENDING(job_ptr) == true
      && job_ptr->priority == 0) {
      // Determine which nodes a job can use
      // based upon reservations
      j = job_test_resv(job_ptr, &now, true,
        &avail_bitmap, &resv_exc,
        &resv_overlap, false);
      if (j != SLURM_SUCCESS) {
        FREE_NULL_BITMAP(avail_bitmap);
        reservation_delete_resv_exc_parts(
          &resv_exc);
        continue;
      }
      // Select the "best" nodes for given job
      // from those available
      rc = select_g_job_test(job_ptr,
        avail_bitmap,
        job_ptr->details->min_nodes,
        job_ptr->details->max_nodes,
        job_ptr->details->max_nodes,
        SELECT_MODE_RUN_NOW,
        NULL, NULL,
        &resv_exc,
        NULL);
      FREE_NULL_BITMAP(avail_bitmap);
      reservation_delete_resv_exc_parts(&resv_exc);
      if (rc != SLURM_SUCCESS) {
        continue;
      }
      // We are certain that a job can start
      // check the power limit and adjust DVFS
      if(check_power_dvfs(job_ptr,
          get_req_nodes(job_ptr)) < 0) {
        continue;
      } else {
        // release the job
        // slurmctld will start the job
        job_ptr->priority = 1;
        job_ptr->state_reason = WAIT_NO_REASON;
        break;
      }
    }
  }
  list_iterator_destroy(iter);
}
```

Feitelson model does not generate this information. Hence, an equal distribution is used to generate the workload information with equal probability for each of the 4 different applications. Slurm only supports runtime limits with minute resolution for the job while the Feitelson model produces job lengths with seconds resolution. All job runtimes are therefore rounded up to the next full minute.

As a baseline, the job trace was simulated by the scheduling simulation component integrated in the Digital Twin. The power trace is shown in Figure 4a and the allocation of the jobs to the nodes in Figure 5a. In comparison, the same job trace was run with identical power limitations on the cluster. A script processed the job trace file and submitted the jobs accordingly. The power trace is shown in Figure 4b and the node allocation in Figure 5b.

In the simulation, the algorithm uses the gaps between the power limit while staying below the set limit. Larger jobs did not fit below the limit and were delayed beyond the limitation. This effect can also be seen in the node allocation in Figure 5a. The results are comparable to the first iteration of tests with the other node energy model [3].

In the experiment on the test system, looking at the power trace, the cluster mostly stays below the limit. Sometimes the limit is slightly exceeded in the order of $\leq 3\%$ which can be attributed to booting nodes and job initialization. In contrast to the simulated system where energy needed to start the nodes is not accounted for, the real system constantly tracks consumed energy also while booting additional nodes. When the operating system and Slurm are fully loaded, controlling the energy use is rather simple. However, especially during the early boot phase, the system draws a lot of power while not offering a mechanism to control it.

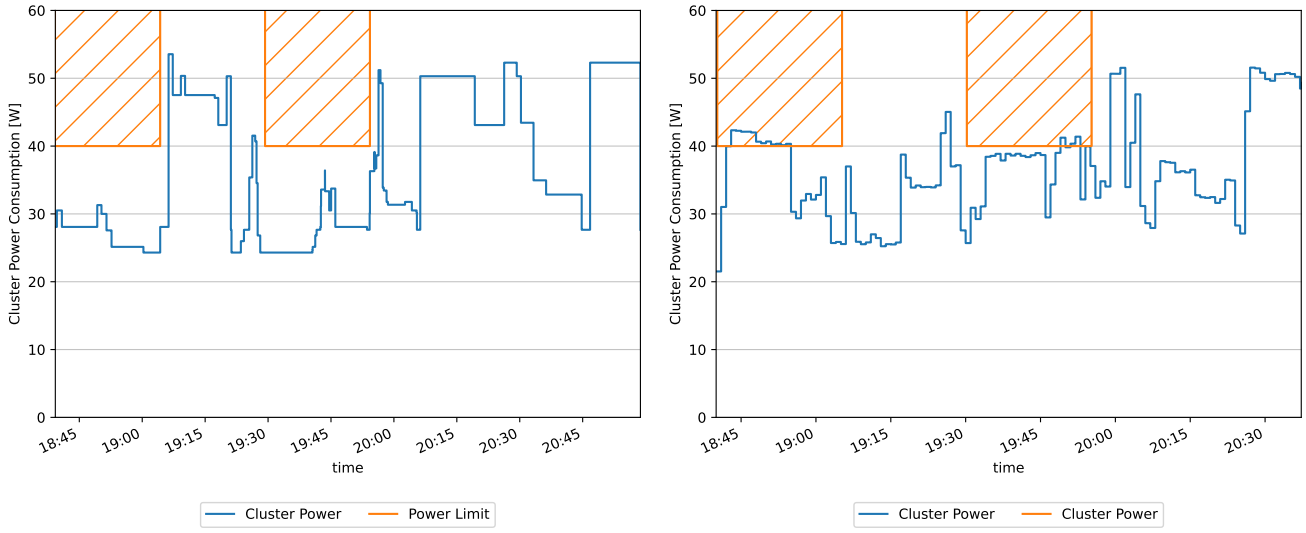
Another difference is that larger jobs start earlier in the real system test. This increases the system utilization and reduces the time required to complete the job trace. This again hints towards slight differences in the energy calculation between the plugin and the simulation. While the simulation considers the idle energy usage of the nodes, the plugin considers the energy usage of all running jobs and assumes that unused nodes are shut down by Slurm. The plugin only checks whether the running jobs allow an additional job to start. Furthermore, the node energy model upon which in both cases scheduling decisions rely on, represents the in average power consumption over time of jobs - not their maximum values. Therefore it is clear, that the real system will exhibit these maxima in power consumption by slightly surpassing the power limit. This could of course be cured in future by a more refined and time-resolved node energy model.

The time the scheduling and start of the job actually takes makes up a third difference between the simulation and the real world. In the simulated run, jobs are tightly packed as the simulation starts jobs instantly. In contrast, the Slurm plugin first releases them from the hold state and subsequently waits for the job to actually start before making the next scheduling decision. This causes a slight delay, thus creating small gaps between the jobs visible in Figure 5b.

To summarize, this experiment has demonstrated that the power-capping algorithm is feasible on a real system via a Slurm plugin, with a few initial limitations. The next step in the development will be to align the real-world and the simulation more closely with one another. The Slurm logic is complex and hard to replicate in a pure simulation. The simulation also does not simulate everything. This includes accurate power models for the boot process, and time required to start and stop jobs on the nodes.

The test system only has a single node type and has one partition configured. The plugin remains to be tested in a heterogeneous system configuration: Slurm allows to configure different hardware in a single partition, which will make the check more complex. Our plugin does not yet consider shared node allocation, but this can be complemented in a next step, as it is supported by Slurm.

In the current implementation, the node energy model is hard-coded in the plugin, which reduces portability of the code. For a broader use, the parameters will be moved to a configuration file. The accuracy of the algorithm depends on the accuracy of the node energy model. So far, no changes in the power consumption of the jobs have been considered. Additionally, the model is static and does not adapt to new workloads. Another possible improvement for the plugin are malleable jobs, which can be extended in their runtime when they are switched to a lower frequency during their runtime.

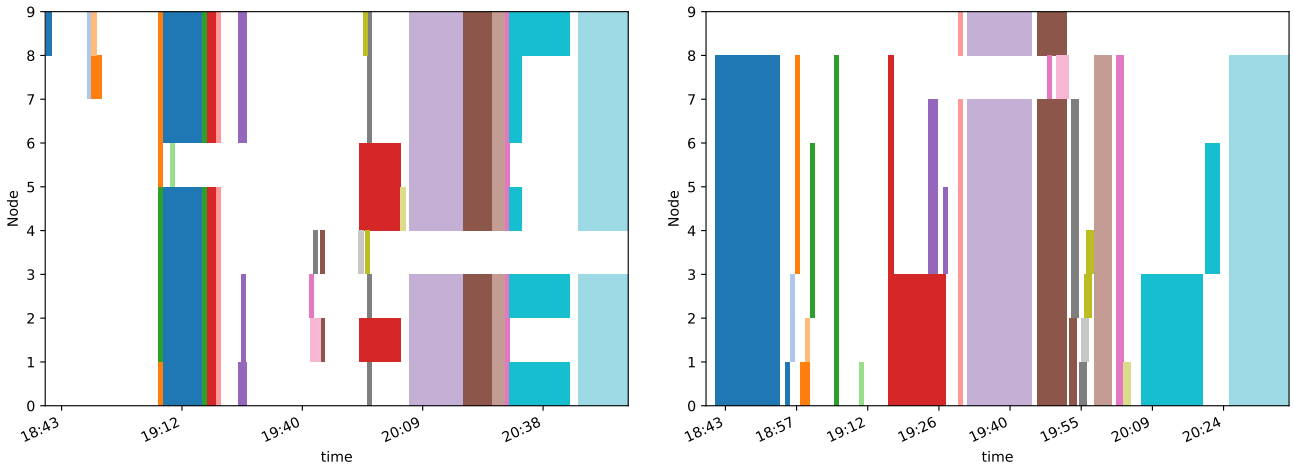


VI. Conclusion and Future Work

This paper presented a new scheduling plugin for the widely used scheduling and resource management software Slurm. The plugin allows an HPC cluster to operate under a system-wide power cap. The plugin works by holding jobs until enough power is available. Jobs can be configured by the plugin with a specific frequency according to the node energy model to reduce energy consumption. If the budget allows, the plugin releases the job from the hold state and sets the frequency. The Slurm infrastructure then handles the job start and node configuration.

The scheduling algorithm uses a node energy model to estimate the energy consumption of a compute job. For this paper, a new model has been created for the specific hardware of the test system. It has been demonstrated that this approach can be adapted to different systems, making the scheduling algorithm portable.

The plugin was demonstrated on the test system against a simulation with an identical job trace. Differences between the simulation and plugin have been discussed, especially job start times and energy calculation. While the plugin was able to stay below the power limit, booting compute nodes might briefly surpass the configured limit. Possible fixes have been discussed. The plugin was able to schedule jobs efficiently, and shows higher utilization than the simulation.



The Slurm plugin presented in this paper was tested with a homogeneous system configuration with identical nodes in a first step. Modern HPC systems often use heterogeneous system configurations with different node types and different

generations of CPUs. The test system could be extended with newer Raspberry Pi 5s or NVIDIA Jetson boards to create such a heterogeneous system.

Currently, the node energy model is hard-coded in the plugin. This would need to be shifted to a configuration file. The plugin has not been tested with heterogeneous or multi-partition cluster configurations. Since these are common nowadays, further development is necessary to support these configurations.

ACKNOWLEDGEMENT

We would like to thank our colleagues from department Q.13, first and foremost S. Thümmler, for their help with building the case for the Raspberry Pi cluster.

***Abstract*—Humans try to help computers understand the properties of the real world, and ontologies can be used for this task. Manual enhancement of ontologies is highly time-consuming for domain experts. This paper proposes a solution to match a scientific text to the most relevant ontology using artificial neural networks. Our approach selects a paragraph or a sentence, uses representation learning to embed it into a vector space by some embedder, and measures its relevance to embedded textual properties from the selected ontology by a modified version of a Siamese neural network. We have considered different embedders, their quality has been evaluated on a use case with available ontologies from several application domains.**

***Index Terms*—ontology, neural network, embedding, text matching, LLM**

I. Introduction

Knowledge graphs and ontologies are graph-based structures for knowledge representation. They are defined as "a formal specification of a shared conceptualization" [1], provide a standardized description formalism to express knowledge, facilitating its exchange. Knowledge is typically related to some specific domain. Knowledge graphs and ontologies are commonly used to increase understanding of the related domain.

A domain ontology serves as a framework defining fundamental concepts, such as classes, attributes, and relationships, within a specific knowledge domain. Their definitions encapsulate information about their meaning and constraints. Classes can be defined through annotations or by interconnecting them with properties. Each domain ontology typically employs domain-specific terms to denote its primitives.

The manual construction of classes and their relations is too demanding for the time of domain experts, and automation could bring large amounts of time savings. The automated construction of an ontology consists of several steps:

1) Parse the source texts and extract only relevant content
2) Extract content from the ontologies defining its domain
3) Represent the extracted contents in the same vector space
4) Find the ontology most relevant to the source text
5) Locate the new knowledge in the structure of the ontology
6) Insert the new knowledge, and align it with the ontology internal structure, e.g., via removing duplicities

This work has been supported by the Grant Agency of the Czech Technical University in Prague, grant No. SGS20/208/OHK3/3T/18.

This paper deals with the issue of automatic ontology design only by assigning articles to ontologies, which corresponds to points 3 and 4. It represents both, the content extracted from ontologies, and the given text in the same vector space and uses an artificial neural network (ANN) to find the ontology most relevant to the given research text.

The next section recalls related work. Section III describes the methodology of text preprocessing and text representation learning, and our architecture of the neural network for the task of text-to-ontology matching. In Section IV, the proposed methodology is validated in a case study by applying it to scientific data.

II. Related Works

In connection with learning and extending ontologies, ANNs have been primarily used for the identification of concepts, relations, and attributes [2], [3], [4]. With respect to relations, some ANN-based methods have been developed specifically for subsumption relations needed for the construction of taxonomies [5], [6], [7], [8]. In connection with the integration of ontologies, they have been used primarily for ontologies matching [9], [10], [11], [12], [13]. The variety of employed ANN types is rather large. It includes traditional multilayer perceptrons [14], adaptive resonance theory networks [15] and associative memories [16], as well as the modern deep convolutional networks [9], [17], deep belief networks [2], long short-term memory (LSTM) networks together with their bidirectional variant (BiLSTM) [18] and gated recurrent units networks [19], [20].

The dependence of ontologies on texts led to using networks developed for text and natural language representation learning, most importantly BERT [21], [22], the bidirectional encoder representations from transformers, and word2vec [23], the most traditional network for embedding text into a Euclidean space. The close relationship of ontologies to knowledge graphs led also to the use of RDF2Vec [7], [20], which was originally proposed for knowledge graphs [24]. Based on similar principles as word2vec and RDF2Vec, OWL2Vec for embedding ontologies [25] and recently OWL2Vec4OA (OWL2Vec for ontology alignment) [26] were proposed. The

most related paper to our assigning scientific texts to existing ontologies solution is [27]. It presents an attempt to solve a text-to-ontology mapping problem by utilizing NLP tools and neural networks, and assess the final result through visualizing the latent space and exploring the mappings between an input text and ontology classes. Finally, the graph-like structure of ontologies brought the application of graph neural networks [11], [12].

Closest to the proposed approach is the way ANNs have been used in connection with translating into OWL [28], [19], with predicate chaining and restriction [16], and with taxonomy extraction from knowledge graphs [7]. In [28], ontology learning is tailored as a transductive reasoning task that uses two recurrent neural networks to translate text in natural language into OWL specifications in description logic. That approach was further developed in [19], resulting in a system based on a single recurrent network of GRU type. It uses an encoder-decoder configuration and translates a subset of natural language into the description logic language ALLQ through syntactic transformation. Moreover, the system generalizes over different syntactic structures and has the ability to tolerate unknown words through copying input words as extralogical symbols to the output, as well as the ability to enrich the training set with new annotated examples.

In [16], a mapping is established between ontologies and a pair of interacting associative memories. One of them stores assertions, and the other stores entailment rules. The recent work [7] describes a method for the specific task of extracting a taxonomy from an embedding of a knowledge graph. Over that embedding, which can be obtained for example with RDF2Vec, hierarchical agglomerative clustering is performed, first without using type information, and then injecting types into the hierarchical clustering tree.

III. Methodology

This section describes details of the employed methods. In the first part, we address processing textual files, splitting them into paragraphs, and keeping only paragraphs fulfilling minimal length and content relevant to the document's topic. The second part describes the textual embedders considered in assigning texts to ontologies. The final part describes the learning of similarity between an ontology and a given text.

A. Text Preprocessing

The texts used in the case study in Section IV have been extracted from scientific PDFs (Portable Document Files) and the considered ontologies. To read and transform ontologies, we have used the Protégé tool [29], which can understand many commonly used formats for ontology representation. We have chosen the Ontology Web Language (OWL) as the target format and extracted it using the Python package owlready2 [30]. As a representation of each ontology, we use textual content in natural language (e.g., label, comment, description, definition, and note) extracted from their formal representations. Contents shorter than five words were removed because of low context information.

B. Text Representation Learning

For typical downstream data analysis tasks, such as classification or clustering, it is suitable to embed words or other parts of text in a Euclidean space. This representation is mostly the result of representation learning using ANN-based embedders. In our research, we consider the following embedders:

1) Global Vectors for Word Representation (GloVe): [31] is an unsupervised learning algorithm that captures word semantics by leveraging global statistical information. It constructs a word-context co-occurrence matrix and then factorizes it to obtain word embeddings. Each embedding represents a word's position in the semantic space based on its statistical relationships with other words. However, to create embeddings for entire texts, an aggregation process is necessary, which relies on averaging the individual word embeddings based on the TF-IDF (Term Frequency-Inverse Document Frequency) weights.

2) InferSent: [32] is designed for creating universal sentence representations through supervised learning on natural language inference data. It approaches the task by using a carefully crafted training set that includes pairs of sentences with labeled relationships (entailment, contradiction, or neutral). InferSent's embeddings are learned by predicting relationships between sentences. This approach generates sentence embeddings that encapsulate semantic relationships, making it suitable for various downstream natural language processing tasks.

3) Doc2vec-DM: , i.e., the distributed memory version of Doc2Vec [33], is an extension of Word2Vec [34] tailored for document-level embeddings. It operates by learning distributed representations of documents, considering both word and document context. The model can provide either a single embedding per document or embeddings for individual words within the document. This flexibility makes it versatile for various applications, such as document similarity analysis or content-based document retrieval.

4) Bidirectional Encoder Representation from Transformers (BERT): [35] captures contextual information bidirectionally, considering both the left and right context of each word in a sentence. BERT embeddings are contextualized and can be used at both word and sentence levels. Its variant SciBERT is specialized for scientific literature and the variant Sentence-BERT focuses on generating embeddings tailored for entire sentences. Each version of BERT addresses specific use cases, offering state-of-the-art performance across a range of natural language processing tasks.

5) Llama 3.1 + LLM2vec: uses the large language model (LLM) Llama 3.1 [36] published in July 2024, with various model sizes. We have chosen the 8B model, which fits into commonly available GPUs. Llama 3.1 is an auto-regressive language model that uses an optimized transformer architecture. We use it for representation learning using LLM2Vec [37], which enables bidirectional attention, trains the model with masked next-token prediction, and performs unsupervised contrastive learning. The model can be further fine-tuned to achieve state-of-the-art performance in specific cases.

C. Network Learning

Our proposed architecture is inspired by Siamese neural networks [38], which are widely used for tasks involving the estimation of the similarity between two inputs, such as in face verification or semantic textual similarity. The key motivation behind this inspiration lies in the core functionality of Siamese networks: they encode two inputs into a shared embedding space using twin subnetworks with shared weights, and then compute a distance or similarity measure between these embeddings.

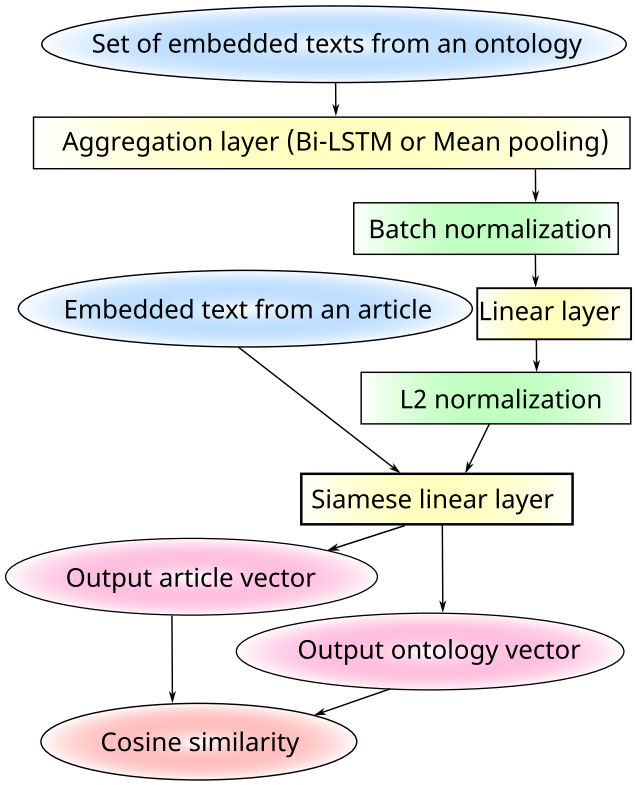

Fig. 1. Neural network schema illustrating used layers (represented with boxes) and flow of the embedded inputs from an ontology and an article to the final cosine distance between them.

In our case, the task requires assessing the semantic distance between a source text and an ontology concept. This parallels the role of Siamese networks, where the goal is to quantify how similar or different two representations are. By adopting this paradigm, our architecture learns to embed both the input text and ontology representation into a common space and returns a scalar distance that reflects their semantic alignment. Our neural network takes an embedded text as an anchor input and a list of embedded, randomly shuffled representative descriptions from an ontology as a representative input. As an output, it returns the distance of the embedded text and representative samples.

Figure 1 shows the internal architecture. The representative input dataset flows through the aggregator, which is represented by the Mean pooling layer or the bidirectional LSTM (long-short-term memory) with a training dropout equal to 0.2 layer in our experiments. The whole batch is then normalized, which is known to improve LSTM results [39]. The following linear layer reduces size and its output is L2 normalized. The following Siamese linear layer is the core of this architecture, which takes the anchor and the output from the second branch and returns for each of them a numeric vector, its size is a quarter compared to the anchor vector. Finally, the cosine similarity between those vectors is computed. More details are provided in Algorithm 1.

IV. Case Study

This section describes the data used in the case study, its experimental setting, and the evaluation of the obtained results.

A. Used Data

The ontologies used in our experiments come from chemistry for both training and testing, all of them being somehow related to catalysis, whereas for testing there are also ontologies from some more distant application domains. Table I shows the details of the considered ontologies.

TABLE I
THIS TABLE SHOWS THE CONSIDERED ONTOLOGIES, THEIR COUNTS OF TEXTUAL DESCRIPTIONS OF CLASSES AND RELATIONS, AND SCIENTIFIC AREAS TO WHICH THEY ARE RELATED.

Area	Ontology name	Count of items with textual definitions
Chemistry	Allotrope Foundation Ontology (AFO)	2894
Chemistry	Chemical Entities of Biological Interest (CHEBI)	176873
Chemistry	Chemical Methods Ontology (CHMO)	3084
Chemistry	Systems Biology Ontology (SBO)	694
Chemistry	National Cancer Institute Thesaurus (NCIT)	166212
Biology	Biological Collections Ontology (BCO)	671
Energy	Digital Construction Energy (DICES)	67
Environment	Environment Ontology (ENVO)	6605
Finance	Financial Industry Business Ontology (FIBO)	3362

B. Experimental Setting

Each anchor and representative input pair was extracted from the ontologies because we do not have other texts with known ground truth. Each extracted pair was required to fulfill the condition that the anchor text must not appear in the representative descriptions. For our experiment, we selected the considered ontologies and divided them into two parts. From the chemistry group, 80 % of the textual descriptions were randomly selected for training and the rest for testing on similar domains. The remaining ontologies, from more distant domains, were completely used for testing. From the training

Algorithm 1 Training the Neural Network (NN) with Texts from Ontologies and Anchor Texts

Require: Dataset $\mathcal{D} = \{(O_i, a_i, y_i)\}$, where O_i is a list of texts, a_i is the anchor text, and $y_i \in \{0, 1\}$ is the similarity label.
Require: Embedder EM, assigning to each input a vector of size Features.
Require: Aggregator A_ϕ (Bidirectional LSTM or Mean pooling) and Siamese model f_ψ, with trainable parameters ϕ and ψ, an optimizer minimizing a loss function $\mathcal{L}$.
Require: Hyperparameters: number of epochs E and batch size BS.
Initialize parameters ϕ and ψ of the A_ϕ and f_ψ.
Split the dataset $\mathcal{D}$: $\mathcal{D} = \mathcal{D}_{\text{tr}} \cup \mathcal{D}_{\text{val}}$ and $\mathcal{D}_{\text{tr}} \cap \mathcal{D}_{\text{val}} = \emptyset$
Set Siamese network output size: OutputSize $=$ Features$/4$.
Initialize bestLoss $\leftarrow \infty$ and bestModel $\leftarrow (\phi, \psi)$.
for epoch $= 1$ to E **do**
  Shuffle the dataset $\mathcal{D}_{\text{tr}}$ and divide it into batches of size BS.
  for each batch $\mathcal{B} \subset \mathcal{D}_{\text{tr}}$ **do**
    for each $(O_i, a_i, y_i) \in \mathcal{B}$ **do**
      Aggregate branch:
      for each text $o \in O_i$ **do**
        Compute embedding: $h_o = EM(o)$.
      end for
      Aggregate embeddings using selected aggregator: $h_{O_i} = \mathrm{A}_\phi(\{h_o\})$.
      Apply 1D batch normalization to h_{O_i}, yielding $h_{O_i}^{\text{norm}}$.
      Pass $h_{O_i}^{\text{norm}}$ through a fully connected layer, yielding $h_{O_i}^{\text{fc}}$.
      Apply L2 normalization: $h_{O_i}^{\text{L2}} = \frac{h_{O_i}^{\text{fc}}}{\|h_{O_i}^{\text{fc}}\|_2}$.
      Anchor branch:
      Compute an embedding for the anchor text: $h_{a_i} = EM(a_i)$.
      Siamese network:
      Compute the outputs: $z_i^{\text{agg}} = f_\psi(h_{O_i}^{\text{L2}})$, $z_i^{\text{anchor}} = f_\psi(h_{a_i})$.
      Compute the cosine similarity o_i of $z_i^{\text{agg}}, z_i^{\text{anchor}}$.
      Compute the loss: $\ell = \mathcal{L}(o_i, y_i)$.
    end for
    Update the parameters ϕ and ψ using the optimizer to minimize ℓ for the batch.
  end for
  Compute the validation loss ℓ_{val} for the current model on $\mathcal{D}_{\text{val}}$.
  if $\ell_{\text{val}} <$ bestLoss **then**
    Update bestLoss $\leftarrow \ell_{\text{val}}$ and bestModel $\leftarrow (\phi, \psi)$.
  end if
end for
return bestModel with parts A_ϕ and f_ψ corresponding to the least validation loss.

data, 20 % of textual descriptions were randomly selected as a validation dataset, and the rest as a training dataset. Both datasets were resampled to keep the same proportion of data from each ontology, to mitigate overfitting with texts from one ontology.

For the validation of our model, we have considered the hyperparameters listed in Table II. Marked bold is the combination selected on the validation dataset by the contrastive loss.

$$L_{\text{contrastive}}(x_1, x_2, y) = \frac{1}{2} y \cdot d_{\cos}(x_1, x_2)^2 + \frac{1}{2}(1 - y) \cdot \max(0, 1 - d_{\cos}(x_1, x_2))^2 \quad (1)$$

In the above definition:

- x_1 and x_2 are the outputs of the network for which the contrastive loss is computed, namely the x_1 for the embedded anchor text and the x_2 for the embedded representative list of texts from the selected ontology
- y denotes whether the anchor on the input belongs to the selected ontology ($y = 1$) or does not belong to it ($y = 0$)
- $d_{\cos}(x_1, x_2)$ is the cosine distance between x_1 and x_2

C. Results

All results in this case study were obtained using an independent testing dataset. Writing T for True, F for False, P for positive, N for negative, $TPR = \frac{TP}{TP+FN}$ and $FPR = \frac{FP}{FP+TN}$, the definitions of the employed quality measures are as follows:

$Accuracy = \frac{TP+TN}{TP+FN+TN+FP}$,

TABLE II
CONSIDERED COMBINATIONS OF HYPERPARAMETERS BATCH SIZE (BS), OPTIMIZER (OPT), AND LEARNING RATE (LR), IN BOLD IS THE COMBINATION SELECTED ON THE VALIDATION DATASET BASED ON THE VALUE OF THE CONTRASTIVE LOSS (CL)

BS	OPT	LR	CL
8	Adam	0.1	0.126
8	Adam	0.01	0.126
8	Adam	0.001	0.126
8	SGD	0.1	0.125

32	**SGD**	**0.01**	**0.044**
32	SGD	0.001	0.046

$F1 = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall}$, where $Precision = \frac{TP}{TP+FP}$ and $Recall = TPR$

$\text{AUC} = \sum_{i=1}^{n} (\text{FPR}[i] - \text{FPR}[i-1]) \left(\frac{\text{TPR}[i]+\text{TPR}[i-1]}{2} \right)$, where i indexes all the values of the prediction score, which is a numerical output of the model that represents the confidence that a sample belongs to the positive class. The prediction score is sorted and thresholds are applied to generate pairs of TPR and FPR values, spanning the range from the minimum to the maximum prediction score.

1) Statistics from ontologies for near and far domains:

The results in Table III for descriptions from ontologies with domains near the training data are best for embeddings obtained with the SciBERT in the model with LSTM aggregation. This may be due to SciBERT having been fine-tuned by scientific data. The worst embedder was Doc2Vec-DM. The results with Doc2Vec and GloVe have been expected because these solutions are based on simple textual embedders. The variant of the model with the mean pooling aggregation layer has even better results. The best results have been achieved with the Llama3.1+LLM2vec embedder without fine-tuning to a specific domain or task. Thanks to the fact that texts are the primary kind of data on which LLMs have been trained, our model had better performance in the considered quality measures.

These results were compared with our previous research [40], where we solved the text-to-ontology matching task. We used the *chemical-bert-uncased* [41] for embedding input texts. These embeddings were used as inputs to the following classifiers: Gaussian process, k-nearest neighbor, multilayer perception, random forest, and support vector machine. Among them, the multilayer perceptron classifier is the most similar to our ANN approach. The approach in [40] has not achieved as high values for the three considered quality measures as have been achieved in the experiments reported in this paper with the proposed ANN architecture, especially in combination with the SciBERT embedder. The best result in [40] were achieved by the Gaussian process classifier, compared to which the SciBERT-based solution reported here has accuracy better by 0.9, AUC by 5.2, and F1 by 8.9 percentile points in the LSTM variant, and in the mean pooling variant, accuracy is better by 1.8, AUC by 6.7, and F1 by 9.8 percentile points. The classification we performed in [40] was restricted to an a priori chosen set of chemical catalytic ontologies, whereas the approach we propose here is independent of the number of potential target ontologies.

TABLE III
RESULTS FOR ONTOLOGIES WITH DOMAINS NEAR TO THE TRAINING DATA COMPARED TO RESULTS FROM [40] BASED ON CLASSIFIERS

ANN LSTM solution	Accuracy	AUC	F1
Doc2Vec-DM	83.3 %	73.9 %	83.2 %

TABLE IV
RESULTS FROM ONTOLOGIES WITH DOMAINS FAR FROM THE TRAINING DATA

ANN LSTM solution	Accuracy	AUC	F1
Doc2Vec-DM	67.0 %	55.9 %	66.8 %
TF-IDF GloVe	63.4 %	51.2 %	63.1 %
InferSent	**70.0 %**	**60.0 %**	69.6 %
Llama3.1+LLM2vec	60.2 %	50.9 %	59.3 %
SciBERT	63.5 %	51.3 %	63.2 %
SentenceBERT	69.9 %	59.9 %	**69.9 %**
ANN Mean pooling solution	Accuracy	AUC	F1
Doc2Vec-DM	67.5 %	56.6 %	67.3 %
TF-IDF GloVe	68.9 %	58.5 %	68.0 %
InferSent	69.7 %	59.6 %	**69.4 %**
Llama3.1+LLM2vec	62.7 %	50.3 %	62.2 %
SciBERT	**70.7 %**	**61.0 %**	67.8 %
SentenceBERT	63.7 %	51.6 %	62.9 %

The results in Table IV for texts from ontologies with

domains far from the training data are best for embeddings obtained with InferSent and SentenceBERT for the case of LSTM aggregation. In the case of aggregation by mean pooling, the best results were achieved by the model with the SciBERT and InferSent embedders. We did not expect this behavior because LLMs can handle long inputs and understand their semantics pretty well. These results show that embedders that are not based on LLMs are still very useful. This behavior may be caused by the fact that the LLMs are not primarily optimized to create textual embeddings.

2) Statistical significance tests:

The differences between the considered embedders were tested for significance by the Friedman test. The basic null hypotheses that each of the AUC, accuracy, and F1 are for all 6 embedders the same, were rejected for the LSTM aggregation, with the achieved p-values 1×10^{-2}, 3×10^{-2}, and 2×10^{-2}, respectively. In case of mean pooling based aggregation, the achieved p-values were 1×10^{-1}, 3×10^{-2}, and 1×10^{-2}, so we are not able to reject the hypotheses for the AUC metric. As to the post-hoc analysis, because we agree with the opinion of the authors of [42], we followed their proposal to use the Wilcoxon signed rank test with the two-sided alternative for all pairs of compared embedders. For the correction due to multiple hypotheses testing, we used the Holm method. The results are given in Table V and Table VI, the best results by the total score have embeddings from InferSent and both BERTs in the case of LSTM aggregation, and from InferSent and Llama3.1 in the case of mean pooling.

V. Conclusion

In this paper, we proposed an approach to assigning scientific texts to ontologies. This solution contributes to the complex process of automated knowledge processing and highlights the possibilities for research on enhancing existing ontologies. We used neural networks for text embedding and for comparison of obtained embeddings to automatically determine the ontologies most relevant to texts. To this end, we adapted a Siamese neural network in combination with representation learning by various embedders, namely GloVe with TF-IDF weighted aggregation, SentenceBERT, SciBERT, InferSent, Doc2Vec-DM and Llama 3.1 with LLM2vec framework. The embedding of given text serves as the input to one branch of the Siamese neural network, and the list of embeddings of textual descriptions from the considered ontology serves as the input to the second branch. The solutions based on Doc2Vec-DM and GloVE were unsuccessful. In this approach, the most successful combination in ontologies from highly diverse domains was the InferSent embedder, which takes into account contextual relations and produces embeddings with the highest dimension. It achieved good results in both test cases. Our results show that the proposed method surpasses an earlier solution based on a multilayer perceptron classifier. However, challenges remain in the extraction of knowledge from ontologies and in merging new knowledge with existing ontology. In our future research, we want to address these challenges using graph neural networks. Our motivation for such an approach is the graph structure of ontologies.

***Abstract*—Rough set theory provides a robust framework for dealing with inconsistent data by utilizing equivalence relations to group indiscernible instances. A significant extension of this framework is the concept of covering-based rough sets, where equivalence relations are replaced with coverings. The effectiveness of covering-based rough sets in practical applications largely depends on the choice of an appropriate covering. To guide this selection, various metrics have been proposed to evaluate the quality of coverings, including entropy. While entropy serves as a valuable measure, its exact computation is often prohibitively expensive. In this paper, we propose an efficient method for estimating the entropy of covering-based rough set approximation operators, making the metric more feasible for practical use. We assess the accuracy of these estimates through experiments on both synthetic coverings and coverings for real-world datasets, the latter constructed using the Mapper algorithm, from the field of topological data analysis.**

I. Introduction

IN 1982 Pawlak introduced rough set theory as a framework to handle possibly inconsistent data [1]. Rough set theory revolves around the notion of an information system: a couple $(U, \mathcal{A})$, where U is a universe of instances (objects, data samples) and $\mathcal{A}$ is a set of attributes for which these instances take values. The set $\mathcal{A}$ naturally gives rise to an equivalence relation E on U, by partitioning U into equivalence classes that have the same values for all the attributes in $\mathcal{A}$. Instances in each equivalence class are called indiscernible. Rough set theory then proceeds to provide lower and upper approximations of concepts that are represented by a set $A \subseteq U$. The lower approximation is the union of all equivalence classes that are contained entirely within A. This can be viewed as the set of instances that certainly belong to A (every instance in the lower approximation is only indiscernible to elements of A). The upper approximation is the union of all equivalence classes that have non-empty intersection with A. Semantically this is the set of instances that possibly belong to U (every instance in the upper approximation is indiscernible with an element in A). Sets $A \subseteq U$ for which the lower approximation and upper approximation equal A itself are called consistent, or exact. It can be verified that the lower approximation is the largest consistent subset of A, while the upper approximation is the smallest consistent set that includes A.

Various researchers have proposed generalizations of classical rough sets by replacing the equivalence relation with a covering of U [2, 3, 4], resulting in a more flexible framework. Recall that a covering of U is any collection of subsets of U whose union is equal to U. By contrast to a partition, elements of a covering are allowed to overlap. This is useful in various situations, for example:

- handling missing data [5]: when the value of an instance for an attribute is unknown, it is considered indiscernible from any other (known or unknown) value.
- tolerance-based rough sets [6]: when dealing with numerical data, two objects are often considered indiscernible when their distance is lower than a given threshold.

Clearly, such indiscernibility relations are no longer transitive. These covering-based rough sets have been studied extensively from a theoretical perspective ([7, 8, 9, 10]) and used in many applications, in particular concerning attribute reduction [11, 12, 13]. However, selecting the right covering for an application can be hard because there may be multiple important factors to consider. One such factor is the granularity of the covering. This measures how fine the covering is and how detailed the rough set approximations are; it can also be interpreted as the amount of information that remains when the approximation operators are executed. To find coverings that have a certain granularity, the concept of entropy (which was originally introduced as a measure of information content) was extended to rough set approximations in [14]. Many applications in rough set theory use the notion of entropy [15, 16]. However, when it comes to covering-based rough set theory, it is computationally very expensive to calculate this naively since it takes into account all of the possible subsets of the universe U. For this reason, we propose an efficient way to estimate the entropy.

In [17] a promising method to generate coverings of datasets using the Mapper algorithm from the field of topological data analysis [18] was introduced. We use these coverings

to evaluate the convergence of our estimates. We choose this method because it produces coverings that closely resemble the original dataset topologically. Moreover, one can easily control several aspects of the coverings, such as the number of subsets in the covering, and the amount of overlap between them.

The remainder of this paper is structured as follows. We first recall the concepts of covering-based rough sets and entropy in Sections 2 and 3. Then, in Section 4, we outline a method to estimate the entropy of a given covering using the so-called strong granule-based approximations from covering-based rough set theory. To obtain the estimation, we first consider the method from [19] which allows us to estimate the entropy of any probability distribution. However, we observe that it is restrictively slow for our purposes. Therefore, we adapt this method using some properties of covering-based rough sets to find better estimates that are calculated more quickly. In Section 5, we evaluate the convergence of our estimates experimentally on a number of synthetic and benchmark datasets. Finally, in Section 6, we give a discussion and introduce some ideas for future exploration.

II. Covering-based rough sets

When working with real-world classification problems, inconsistencies often occur in datasets; intuitively, this happens when two instances are indiscernible but belong to different classes. Pawlak introduced rough sets in 1982 to handle such inconsistencies [1]. In Pawlak's seminal work, an approximation space is defined as an ordered pair (U, E), where E is an equivalence relation that groups indiscernible instances together over the universe U. Based on this setup, the lower and upper approximations of a set can be described in several equivalent ways. In this paper, we adopt the granule-based approach:

$$\underline{apr}(A) = \{[x]_E \in U/E \mid [x]_E \subseteq A\}$$
$$\overline{apr}(A) = \{[x]_E \in U/E \mid [x]_E \cap A \neq \emptyset\}$$

For a subset A of U, its rough set approximation is represented as the pair $(\underline{apr}(A), \overline{apr}(A))$. These approximation operators are dual in the sense that $\underline{apr}(A) = \overline{apr}(A^c)^c$, where ^{c} refers to the classical set complement. These approximations have been used in many applications ranging from classification [20] (especially rule extraction [21, 22]) to feature selection [23, 24, 25].

Classical rough set theory often struggles with continuous features, as the indiscernibility relation may no longer satisfy the properties of an equivalence relation. To overcome this limitation, various generalizations of classical rough sets have been proposed. One such generalization are covering-based rough sets, which replace the partition given by the indiscernibility relation with a covering. This defines a covering approximation space: an ordered pair $(U, \mathbb{C})$, where $\mathbb{C}$ is a covering of U, that is, a collection of subsets whose union equals U. While it is tempting to generalize Pawlak's definitions by replacing the equivalence classes $[x]_E \in U/E$ with elements $K \in \mathbb{C}$, this substitution does not preserve the duality between the approximations. To address this, Yao [2] introduced two dual pairs of granule-based approximations for covering approximation spaces.

$$\underline{apr'}_{\mathbb{C}}(A) = \bigcup\{K \in \mathbb{C} : K \subseteq A\} \tag{1}$$
$$\overline{apr'}_{\mathbb{C}}(A) = \underline{apr'}_{\mathbb{C}}(A^c)^c \tag{2}$$
$$\underline{apr''}_{\mathbb{C}}(A) = \overline{apr''}_{\mathbb{C}}(A^c)^c \tag{3}$$
$$\overline{apr''}_{\mathbb{C}}(A) = \bigcup\{K \in \mathbb{C} \mid K \cap A \neq \emptyset\} \tag{4}$$

Equations (1) and (2) are called the strong approximation operators, while Equations (3) and (4) are referred to as the weak approximations. The rationale behind this terminology is explained by the following property:

$$\underline{apr''}_{\mathbb{C}}(A) \subseteq \underline{apr'}_{\mathbb{C}}(A) \subseteq A \subseteq \overline{apr'}_{\mathbb{C}}(A) \subseteq \overline{apr''}_{\mathbb{C}}(A)$$

Example 1. *Let $U = \{x_1, \ldots, x_9\}$ be a universe which has the following covering, $\mathbb{C} = \{\{x_0, x_1\}, \{x_1, x_2\}, \{x_2, x_5\}, \{x_3, x_4, x_7\}, \{x_6, x_7, x_8, x_9\}\}$ and $A = \{x_1, x_2, x_3, x_4, x_5\}$. A has the following approximations:*

$$\underline{apr'}_{\mathbb{C}}(A) = \{x_1, x_2, x_5\}$$
$$\overline{apr'}_{\mathbb{C}}(A) = \{x_0, x_1, x_2, x_3, x_4, x_5\}$$
$$\underline{apr''}_{\mathbb{C}}(A) = \{x_2, x_5\}$$
$$\overline{apr''}_{\mathbb{C}}(A) = \{x_0, x_1, x_2, x_3, x_4, x_5, x_7\}$$

Generating suitable coverings for a particular application is an important but challenging task. To assist with this process, we associate an ordering to the set of all coverings.

Definition 1. *[9] Let $\mathbb{C}$ and $\mathbb{C}'$ be two coverings of U. $\mathbb{C} \ll \mathbb{C}'$ if and only if for all $L \in \mathbb{C}'$ there exists a set $S \subseteq \mathbb{C}$ such that $L = \cup_{K \in S} K$. When $\mathbb{C} \ll \mathbb{C}'$, we also say that $\mathbb{C}$ is finer than $\mathbb{C}'$.*

We have the following proposition [9]:

Proposition 1. *Let $\mathbb{C}$ and $\mathbb{C}'$ be coverings of U. Then $\underline{apr'}_{\mathbb{C}'}(A) \subseteq \underline{apr'}_{\mathbb{C}}(A) \subseteq A \subseteq \overline{apr'}_{\mathbb{C}}(A) \subseteq \overline{apr'}_{\mathbb{C}'}(A)$ for all $A \subseteq U$, if and only if $\mathbb{C} \ll \mathbb{C}'$.*

Example 2. *To illustrate the previous proposition we continue Example 1. Let $\mathbb{C}' = \{\{x_0, x_1, x_2\}, \{x_2, x_5\}, \{x_3, x_4, x_6, x_7, x_8, x_9\}\}$. Then we clearly have that $\mathbb{C} \ll \mathbb{C}'$. If we now recalculate the approximations of A, using $\mathbb{C}$, we get:*

$$\underline{apr'}_{\mathbb{C}'}(A) = \{x_2, x_5\}$$
$$\overline{apr'}_{\mathbb{C}'}(A) = \{x_0, x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8, x_9\}$$

In [17] a promising new method was introduced to generate coverings for classification problems, using the Mapper algorithm that originated in the field of topological data analysis (TDA). It generates coverings of a universe U, as shown in Algorithm 1, which generally represent the topological structure of the dataset and are therefore useful for our purposes. The algorithm uses a lens function $f : U \to \mathbb{R}^d$, an input covering $\mathbb{I}$ of $f(U)$, and a clustering algorithm. Often

the lens function is chosen to be a projection on particular attributes or PCA components. The input covering $\mathbb{I}$ is in practice constructed using a number of (hyper-)cubes among each dimension in $\mathbb{R}^d$, such that consecutive cubes have a certain overlap percentage p.

Mapper proceeds in the following way: the lens function transforms the original dataset U to the lower-dimensional space $f(U)$, on which the covering $\mathbb{I}$ is defined. Then, for each I inside the input covering, the instances from U projected onto it by f (i.e., $f^{-1}(I)$) are partitioned by means of a clustering algorithm, another parameter of the algorithm. These clusters form the resulting covering.

In [26] we proved the following result which holds when the clustering algorithm is equal to the single-linkage clustering algorithm [27] (shown in Algorithm 2).

Proposition 2. *Let U be a dataset, $f : U \to \mathbb{R}^n$. Let K denote the single linkage clustering algorithm. Let $\mathbb{I}$ and $\mathbb{I}'$ be coverings of $f(U)$, and let $\mathbb{C}_{\mathbb{I},\varepsilon}$ and $\mathbb{C}_{\mathbb{I}',\varepsilon'}$ denote the coverings generated by the Mapper algorithm using lens function f, the single linkage algorithm with parameters ε and ε' and coverings $\mathbb{I}$ and $\mathbb{I}'$. If $\mathbb{I} \ll \mathbb{I}'$ and $\varepsilon \leq \varepsilon'$, then $\mathbb{C}_{\mathbb{I},\varepsilon} \ll \mathbb{C}_{\mathbb{I}',\varepsilon'}$.*

Algorithm 1: The Mapper algorithm

Input: a dataset U with an associated metric, a *lens* function $f : U \to \mathbb{R}$ (or $\mathbb{R}^m$), a covering $\mathbb{I} = \{I_j \mid j = 1, \dots n\}$ of $f(U)$, and a clustering algorithm cl on U.

for $j \in \{1, 2, \dots, n\}$ **do**

  $A_j = \{A_{j1}, \dots, A_{jk} \mid i = 1, \dots k\} \leftarrow cl(f^{-1}(I_j))$;

end

Result: $\cup A_j$

Algorithm 2: The Single Linkage algorithm

Input: a dataset U, with an associated metric d and a real number $\varepsilon > 0$

Construct a graph G_ε, with U as vertices and an edge between x and y when $d(x, y) \leq \varepsilon$. ;

$\{A_1, \dots, A_k\} \leftarrow$ The connected components of G_ε;

Result: $\{A_1, \dots, A_k\}$

III. Entropy

In order to be able to control the fineness of the constructed coverings, we require a measure that reflects granularity. A suitable candidate for this is entropy, which is classically defined for probability distributions:

Definition 2. *[28] Let $\Pr$ be a probability distribution over a finite universe U. The entropy of $\Pr$ is defined as:*

$$H(\Pr) := -\sum_{x \in U} \Pr(x) \log \Pr(x)$$

This definition can be naturally adjusted to partitions:

Definition 3. *[19] Let $\pi = \{A_1, \dots, A_k\}$ be a partition of U. We define the entropy of π as:*

$$H(\pi) := -\sum_{i=1}^{k} \frac{|A_i|}{|U|} \log \frac{|A_i|}{|U|}.$$

The entropy indeed reflects the fineness of a partition. When every element resides in its own equivalence class, the entropy is maximal and equal to $\log |U|$. When there is only one equivalence class, the entropy is minimal and equal to 0.

We also have the following property:

Proposition 3. *[14] Let $\pi \ll \pi'$ be two partitions of U, then $H(\pi) \geq H(\pi')$.*

Since we work with coverings instead of partitions, Definition 3 is not directly applicable. Instead, we adopt the proposal from [14] that computes the entropy associated with an arbitrary pair of covering-based approximation operators.

Definition 4. *[14]*

- *Let $(\underline{apr}, \overline{apr})$ be a pair of covering-based approximation operators over a finite universe U. We define $\Pi_{\underline{apr}}^{\overline{apr}}$ as the set of equivalence classes of $\mathcal{P}(U)$ of the equivalence relation $A \approx B \Leftrightarrow (\underline{apr}(A), \overline{apr}(A)) = (\underline{apr}(B), \overline{apr}(B))$.*
- *We define the entropy of $(\underline{apr}, \overline{apr})$ as follows:*

$$\mathcal{H}_{\underline{apr}}^{\overline{apr}} = H(\Pi_{\underline{apr}}^{\overline{apr}})$$

Again we observe that a high entropy occurs when approximation operators are very fine and a low entropy occurs when approximation operators are very rough. When we have for all $A \subseteq U$ that $(\underline{apr}(A), \overline{apr}(A)) = (A, A)$ (the approximation operator is maximally fine), the size of each class in $\Pi_{\underline{apr}}^{\overline{apr}}$ is equal to 1 and thus the entropy reaches its the maximal value, $|U|$. When an approximation operator is maximally rough, i.e. $(\underline{apr}(A), \overline{apr}(A)) = (\emptyset, U)$ for all A, $\Pi_{\underline{apr}}^{\overline{apr}}$ is equal to $\{U\}$ and thus the entropy is minimal and equal to 0.

Example 3. *Let $U = \{x_1, \dots, x_n\}$ and $\mathbb{C} = \{\{x_i, x_{i+1}\} \mid 1 \leq i < n\}$.*

We calculate the entropy of the strong approximations by first constructing $\Pi_{\underline{apr'}_{\mathbb{C}}}^{\overline{apr'}_{\mathbb{C}}}$.

Let $\approx$ be the equivalence relation corresponding to $\Pi_{\underline{apr'}_{\mathbb{C}}}^{\overline{apr'}_{\mathbb{C}}}$. Then $A \approx B$ if either $A = B$ or A and B are equal to $\{x_i \mid 1 \leq i \leq n$ and $i \equiv 0$ (mod 2)$\}$ and $\{x_i \mid 1 \leq i \leq n$ and $i \equiv 1$ (mod 2)$\}$.

To see this, first note that

$$\underline{apr'}_{\mathbb{C}}(A) = \{x_i \mid x_i \in A \text{ and } (x_{i-1} \in A \text{ or } x_{i+1} \in A)\}$$
$$\overline{apr'}_{\mathbb{C}}(A) = \{x_i \mid x_i \in A \text{ or } (x_{i-1} \in A \text{ and } x_{i+1} \in A)\}$$

Suppose that $A \neq B$ but $A \approx B$. Let i be an integer such that $x_i \in A$ and $x_i \notin B$. Since $x_i \in \overline{apr'}_{\mathbb{C}}(A)$, $x_{i+1} \in B$ and $x_{i-1} \in B$. Since $x_i \notin \underline{apr'}_{\mathbb{C}}(B)$, $x_{i-1} \notin A$ and $x_{i+1} \notin A$. We can repeat the same procedure for x_{i-1} and x_{i+1} and in the end we conclude that A and B have the requested shape.

Thus, $\Pi^{\overline{apr'}_{\mathbb{C}}}_{\underline{apr'}_{\mathbb{C}}}$ has one equivalence class of size two and all other classes have size one. We can now calculate the entropy:

$$\begin{aligned}\mathcal{H}^{\overline{apr'}_{\mathbb{C}}}_{\underline{apr'}_{\mathbb{C}}} &= \frac{-\log 2^{-n+1}}{2^{n-1}} - \sum_{i=1}^{2^n-2} \frac{1}{2^n} \log \frac{1}{2^n} \\ &= \frac{n-1}{2^{n-1}} + \frac{(2^n-2)n}{2^n} \\ &= \frac{2n-2+n2^n-2n}{2^n} \\ &= n - \frac{1}{2^{n-1}}\end{aligned}$$

We also prove that entropy increases monotonically with increasing fineness in coverings. This is useful because, as mentioned in Proposition 2, we are able to construct chains of coverings under $\ll$. Therefore, we may exploit this monotonicity to guide the search for coverings that possess a certain entropy.

Proposition 4. *Let $\mathbb{C} \ll \mathbb{C}'$ be coverings of U. If $(\underline{apr'}_{\mathbb{C}}(A), \overline{apr'}_{\mathbb{C}}(A)) = (\underline{apr'}_{\mathbb{C}}(B), \overline{apr'}_{\mathbb{C}}(B))$ then also $(\underline{apr'}_{\mathbb{C}'}(A), \overline{apr'}_{\mathbb{C}'}(A)) = (\underline{apr'}_{\mathbb{C}'}(B), \overline{apr'}_{\mathbb{C}'}(B))$.*

Proof. First assume $\underline{apr'}_{\mathbb{C}}(A) = \underline{apr'}_{\mathbb{C}}(B)$. We now have for every $K \in \mathbb{C}$ that $K \subseteq A$ if and only if $K \subseteq B$. Assume by contradiction that $\underline{apr'}_{\mathbb{C}'}(A) \neq \underline{apr'}_{\mathbb{C}'}(B)$ then (w.l.o.g.) there exists a $K \in \mathbb{C}'$ such that $K \subseteq A$ but $K \nsubseteq B$. Because $\mathbb{C} \ll \mathbb{C}'$ we have that $K = \cup_{L \in S} L$ for some $S \subseteq \mathbb{C}$. However, for all $L \in S$, it holds that $L \subseteq A$ and thus $L \subseteq B$. This is a contradiction. Thus, $\underline{apr'}_{\mathbb{C}'}(A) = \underline{apr'}_{\mathbb{C}'}(B)$.

Because of the duality of the strong approximation operator, also $\overline{apr'}_{\mathbb{C}'}(A) = \overline{apr'}_{\mathbb{C}'}(B)$.

□

This implies the following theorem:

Theorem 1. *Let $\mathbb{C} \ll \mathbb{C}'$ be coverings of a universe U, then $\mathcal{H}^{\overline{apr'}_{\mathbb{C}}}_{\underline{apr'}_{\mathbb{C}}} \geq \mathcal{H}^{\overline{apr'}_{\mathbb{C}'}}_{\underline{apr'}_{\mathbb{C}'}}$.*

Proof. This follows from Proposition 4 and Proposition 3. □

There does not exist a similar result establishing monotonicity between the weak granule-based approximations and entropy. Because of this, we only consider the strong approximations in the remainder of this paper.

IV. Estimating entropy

Since our definition of entropy takes into account all subsets of U, it is computationally expensive to calculate its exact value. Because of this, we will estimate the value of the entropy. It is well-known that there is no unbiased estimator for the entropy of a probability distribution when there is no external knowledge about the probability distribution [29]. There exist, however, some good estimators that do not depend on external knowledge. We will also use our knowledge about covering-based rough sets to estimate and determine the exact size of certain equivalence classes of $\Pi^{\overline{apr}}_{\underline{apr}}$, which will lead to an unbiased estimator anyway.

We proceed in the following way: Let Y equal the multiset $\{-\frac{|\mathcal{A}_i|}{2^{|U|}} \log \frac{|\mathcal{A}_i|}{2^{|U|}} \mid \mathcal{A}_i \in \Pi^{\overline{apr}}_{\underline{apr}}\}$. Estimating the entropy is then equivalent to estimating the sum of Y.

Inspired by [19] and [30], we do this using the Horvitz–Thompson estimator [31]. This estimator is unbiased and counts the sum of all elements y_i in a universe Y by sampling a set S from Y without replacement. The estimator is equal to

$$\sum_{y_i \in S} \frac{y_i}{\Pr(y_i \in S)},$$

where $\Pr(y_i \in S)$ is the probability of a sample y_i belonging to S. However, this estimator is only unbiased if we know the size of each $\mathcal{A}_i$ exactly.

We proceed as follows: first, we generate n random subsets $\{B_1, \ldots, B_n\}$ of U. Let M be the set of approximations $\{(\underline{apr'}_{\mathbb{C}}(B_i), \overline{apr'}_{\mathbb{C}}(B_i)) \mid 1 \leq i \leq n\}$. We observe that the probability of B_i belonging to a certain equivalence class $\mathcal{A}_l$ of $\Pi^{\overline{apr}}_{\underline{apr}}$ is equal to the proportion of the size of the equivalence class to the number of possible subsets: $\frac{|\mathcal{A}_l|}{2^{|U|}}$.

We define $p_k = \frac{|\mathcal{A}_k|}{2^{|U|}}$ for every $1 \leq k \leq |M|$ (note that $|M| \leq n$), where $\mathcal{A}_k = \{B \subseteq U \mid (\underline{apr'}_{\mathbb{C}}(B), \overline{apr'}_{\mathbb{C}}(B)) = (\underline{A}_k, \overline{A}_k)\}$, and $(\underline{A}_k, \overline{A}_k)$ is the k-th element of M. The probability of not generating a set from $\mathcal{A}_k$ is equal to $(1-p_k)^n$ and thus the probability of generating a set inside $\mathcal{A}_k$ is equal to $1-(1-p_k)^n$. Therefore, the result from the Horvitz-Thomson estimator is:

$$\hat{\mathcal{H}}^{\overline{apr'}_{\mathbb{C}}}_{\underline{apr'}_{\mathbb{C}}} = -\sum_k \frac{p_k \log p_k}{1-(1-p_k)^n} \tag{5}$$

We also have an estimator for the variance of the Horvitz-Thomson estimator [31]:

$$\begin{aligned}&\hat{V}\left(\hat{\mathcal{H}}^{\overline{apr'}_{\mathbb{C}}}_{\underline{apr'}_{\mathbb{C}}}\right) \\ &= \left(\hat{\mathcal{H}}^{\overline{apr'}_{\mathbb{C}}}_{\underline{apr'}_{\mathbb{C}}}\right)^2 - \sum_k \frac{(p_k \log p_k)^2}{1-(1-p_k)^n} \\ &\quad - \sum_{k \neq j} \frac{(p_k \log p_k)(p_j \log p_j)}{1-(1-p_k)^n-(1-p_j)^n+(1-p_k-p_j)^n}\end{aligned} \tag{6}$$

When we have exact values for p_k available, both of these estimators are unbiased [31] and can thus be used to estimate the entropy and the corresponding confidence interval. A new problem presents itself: determining p_k. We can do this by empirically estimating p_k (Section IV-A) or we can use properties of the covering itself to determine it exactly (Section IV-B).

A. Coverage-adjusted estimator

The coverage-adjusted estimator was introduced in [19] and uses the Horvitz-Thomson estimator to estimate the entropy of a probability distribution. According to the observations of the authors of [19], the most intuitive way to estimate p_k empirically is by letting $\hat{p}_k$ equal the number of generated sets B_i that have $(\underline{A}_k, \overline{A}_k)$ as their approximations divided by n. However, they introduced a more useful approximation, where

the estimator converges faster to the true value of the entropy. Here $\hat{C} = 1 - \frac{f_1}{n}$, where f_1 equals the number of approximations $(\underline{A}_k, \overline{A}_k)$ such that there is only one B_i which has $(\underline{A}_k, \overline{A}_k)$ as its approximation. We will call approximations which are reached more than once collisions. We now define

$$\hat{p}_k = \frac{\hat{C}}{n} |\{B_i \mid (\underline{apr'}_{\mathbb{C}}(B_i), \overline{apr'}_{\mathbb{C}}(B_i)) = (\underline{A}_k, \overline{A}_k)\}| \quad (7)$$

This estimation of entropy based on Equation (5) and Equation (7) is called the coverage-adjusted estimator. It converges to the true value of entropy as follows. Let $\hat{\mathcal{H}}$ be the coverage-adjusted entropy estimate of $\mathcal{H}$ generated using n samples. We now have that $|\hat{\mathcal{H}} - \mathcal{H}| = O(1/\log(n))$ [19]

The main downside of this estimator is that we need to choose a large enough n to ensure that there is an approximation $(\underline{A}_k, \overline{A}_k)$ that is reached at least twice. When there are no such sets, $\hat{C} = 0$ and thus all $p_k = 0$ which will lead to an entropy of 0 (convention states that $0 \log 0 = 0$). When the entropy is high this often means that n needs to be unfeasibly large. When the entropy is equal to e, we expect this to happen on average after generating $O(2^{e/2})$ sets [32]. To mitigate this problem, the authors of [19] replaced the definition of $\hat{C}$ with $1 - \frac{f_1}{n+1}$. Now $\hat{C}$ is never equal to 0 and still has the same asymptotic behavior. However, when the true value of the entropy is too high, this can still cause problems. When no collisions occur the coverage-adjusted estimator is equal to:

$$\begin{aligned}
\hat{\mathcal{H}} &= -\sum_{i=1}^{n} \frac{\hat{C}/n \log(\hat{C}/n)}{1 - (1 - \hat{C}/n)^n} \\
&= \sum_{i=1}^{n} \frac{\log(n(n+1))}{n(n+1)(1 - (1 - \frac{1}{n(n+1)})^n)} \\
&= \frac{\log(n(n+1))}{(n+1)(1 - (\frac{n(n+1)-1}{n(n+1)})^n)} \\
&= O(\log(n))
\end{aligned}$$

We would thus need exponentially many samples to estimate an entropy accurately when no collisions occur. This can be intractable when the entropy is large.

B. Horvitz-Thompson Exact Estimator

In this section we introduce a different way of estimating the entropy by determining the exact size of $\mathcal{A}_k$ so that we can use Equation (5) to get an unbiased estimator.

To do this, we introduce the following definition: $P_{\mathbb{C}}$ is the partition of U given by the equivalence relation $\sim$, defined as follows:

$$(\forall x, y \in U)(x \sim y \Leftrightarrow \{K \in \mathbb{C} \mid x \in K\} = \{K \in \mathbb{C} \mid y \in K\})$$

In other words, points that are equivalent always occur together in the covering. Also note that every element K of $\mathbb{C}$ can be written as the union of elements in $P_{\mathbb{C}}$.

We will call elements of $P_{\mathbb{C}}$ blocks, and we define a tripartition of $P_{\mathbb{C}}$ for every $A \subseteq U$:

$$\begin{aligned}
P_1(A) &:= \{X \in P_{\mathbb{C}} \mid X \subseteq A\} \\
P_2(A) &:= \{X \in P_{\mathbb{C}} \mid \emptyset \neq X \cap A \neq X\} \\
P_3(A) &:= \{X \in P_{\mathbb{C}} \mid X \cap A = \emptyset\}
\end{aligned}$$

The strong approximations are fully characterized by P_1, P_2 and P_3 because:

$$\begin{aligned}
\underline{apr'}_{\mathbb{C}}(A) &= \cup \{K \in \mathbb{C} \mid (\forall X \in P_{\mathbb{C}})(X \subseteq K \Rightarrow X \in P_1(A))\} \\
\overline{apr'}_{\mathbb{C}}(A) &= \cup \{X \in P_{\mathbb{C}} \mid (\forall K \in \mathbb{C})(X \cap K \neq \emptyset \\
&\qquad \Rightarrow (\exists X' \in P_1(A) \cup P_2(A))(X' \subseteq K))\}
\end{aligned}$$

For a given tripartition (P_1, P_2, P_3) of $P_{\mathbb{C}}$ the number of sets $A \subseteq U$ that have $P_i(A) = P_i$ (for $i \in \{1, 2, 3\}$) is equal to:

$$\prod_{X \in P_2} \left(2^{|X|} - 2\right)$$

Because of this we can count all $A \in \mathcal{A}_k$ by generating all possible assignments (P_1, P_2, P_3) that have the correct lower and upper approximations.

For each $A \in \mathcal{A}_k$, every block $X \in P_{\mathbb{C}}$ is in some $P_i(A)$; we call i the type of X with respect to A. We will count all sets $A \in \mathcal{A}_k$, by deciding for each block $X \in P_{\mathbb{C}}$ which type it has. This needs to be done in such a way that every $Y \in \mathbb{C}$ is 'satisfied', meaning:

- If $Y \subseteq \underline{A}_k$, all blocks $X \subseteq Y$ must be in $P_1(A)$
- If $Y \cap \overline{A}_k = \emptyset$, all blocks $X \subseteq Y$ must be in $P_3(A)$
- Else, at least one block $X \subseteq Y$ should be in $P_1(A) \cup P_2(A)$ and at least one block $X \subseteq Y$ should be in $P_2(A) \cup P_3(A)$.

It is clear that every A for which these conditions hold has $(\underline{A}_k, \overline{A}_k)$ as its approximations.

Based on the first two cases above, for some blocks X we can immediately establish their type. For others (blocks that do not appear in the first two cases) we need to perform a backtracking search. Note that for every unsatisfied $Y \in \mathbb{C}$, $Y \cap \overline{A}_k \neq \emptyset$ and $Y \not\subseteq \underline{A}_k$.

The process proceeds as follows: as long as there are unsatisfied $Y \in \mathbb{C}$, we recursively pick one such Y arbitrarily and decide how it can be satisfied. For this, we arbitrarily order the blocks $X \subseteq Y$ which are still undecided. Then we vary the type of the first X among all types that are consistent with the requested lower and upper approximation. We repeat this process until Y is satisfied. Notice that this implies we can leave some $X \subseteq Y$ undecided. We also take into consideration that a block with only one element can never be in $P_2(A)$. Once all $Y \in \mathbb{C}$ are satisfied, we count the number of sets $A \subseteq U$ for which the type of each $X \in P_{\mathbb{C}}$ coincides with the assignment and add this to a running counter. That is:

$$\Pi_{X \in P_2}(2^{|X|} - 2) \cdot \Pi_{X \in N}(2^{|X|})$$

where N denotes the set of blocks for which no decision was made. By using recursion, we exhaustively generate all

possible assignments that satisfy every Y in $\mathbb{C}$ and thus we count all sets A with the right approximations.

The pseudo-code of this approach can be found in Algorithm 3. Below, we detail some optimizations that can be performed:

- When deciding the type of a block X for a $Y \in \mathbb{C}$ that already has some elements in P_1, it is enough to decide whether X is in P_1 or in $P_2 \cup P_3$, instead of deciding if it is in P_1, P_2 or P_3. Therefore the branching factor of the recursion is reduced from 3 to 2 in such cases.
- Instead of picking an arbitrary unsatisfied $Y \in \mathbb{C}$, we can choose a more specific Y in order to speed up the algorithm. A common heuristic is to make the next decision about the object with the fewest possibilities. In this case, we choose the Y with the least amount of undecided blocks left.
- The partition of U into blocks can be redefined dynamically during the runtime of the algorithm. Particularly if a $Y \in \mathbb{C}$ gets satisfied but has some undecided blocks left, it is no longer relevant that they are in Y, and therefore they could possibly be merged with other blocks. We chose not to implement this in general because it requires a lot of 'bookkeeping', but we used a limited variant. After the initial assignment of types to blocks that can be made without guessing, we make the partition coarser just once.

We will call the estimator of entropy that uses this approach to determine $|\mathcal{A}_k|$ the Horvitz-Thompson-exact estimator (HTEE).

Example 4. *Let U be a universe and $\mathbb{C}$ be the covering with three elements, shown in Figure 1, such that $P_{\mathbb{C}}$ has 5 blocks: $X_1, \ldots, X_5$ and $\mathbb{C} = \{X_1 \cup X_2, X_2 \cup X_3 \cup X_4, X_4 \cup X_5\}$.*

We want to calculate the number of sets $A \subseteq U$ so that $\underline{apr'}_{\mathbb{C}}(A) = X_4 \cup X_5$ and $\overline{apr'}_{\mathbb{C}}(A) = U$. We do this by exhaustively generating all possible assignments[1] of P_1, P_2, P_3 and N, using Algorithm 3 . These are shown in Table I. For example, for the first assignment, we see that even though the type of X_3 is undecided, all elements in $\mathbb{C}$ are satisfied. The amount of sets that are realizations of assignment 5 are:

$$\texttt{count}(\textit{assignment 5}) = \left(2^{|X_1|} - 2\right)\left(2^{|X_2|} - 2\right)2^{|X_3|}$$

If we add up the amount of realizations of all possible assignments we get the following result:

$$2^{|X_3|}\left(2^{(|X_1|+|X_2|)} - 2\right) - 2^{|X_1|} + 1$$

If we set the size of all blocks equal to 10 we have that the probability of a random subset of U having $(X_4 \cup X_5, U)$ as approximations is equal to:

$$\frac{2^{|X_3|}\left(2^{(|X_1|+|X_2|)} - 2\right) + 1}{2^{50}} = \frac{1073738753}{1125899906842624} \approx 9.537 \times 10^{-7}$$

[1]We assume that all blocks have at least two elements such that the assignment of type P_2 makes sense for each block.

Algorithm 3: Exact approximation counting

Input: covering $\mathbb{C}$; approximation $(\underline{A}, \overline{A})$
`// Preprocessing`
Check which $Y \in \mathbb{C}$ lie in $\underline{A}$, and which are disjoint with $\overline{A}$
Assign their elements the required type
$\mathbb{C}' \leftarrow \{Y \in \mathbb{C} \mid Y \text{ is still unsatisfied}\}$
Identify the 'blocks' with respect to $\mathbb{C}'$
$total \leftarrow 0$
`assign()`
Result: $total$ contains the number of sets with the given approximation

Function `assign()`**:**
  if *all $Y \in \mathbb{C}'$ are satisfied* **then**
    $total \leftarrow total + \Pi_{X \in P_2}(2^{|X|} - 2) \cdot \Pi_{X \in N}(2^{|X|})$
  else
    $Y \leftarrow$ unsatisfied $Y \in \mathbb{C}'$ with fewest amount of unassigned blocks
    `satisfy` (Y)
  end

Function `satisfy(`Y`)`**:**
  if Y *is satisfied* **then**
    `assign()`
  else
    $X \leftarrow$ first unassigned block in Y
    for $j \in \{1, 2, 3\}$ **do**
      $type_X \leftarrow P_j$
      `satisfy` (Y)
    end
    $type_X \leftarrow N$
  end

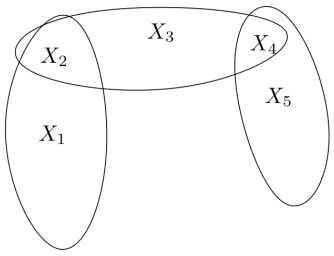

Fig. 1. $\mathbb{C}$ and its blocks from Example 4

Example 5. *We take Example 3 and inspect how the HTEE estimator will evaluate the entropy of $\mathbb{C}$. If we generate k sets of the universe U, we can safely assume that no collisions occur and no set is in the class of size two if k is small enough, since it is statistically very unlikely. Using the method described above, we can calculate the exact size of the equivalence class of each approximation that is generated*

TABLE I
ALL ASSIGNMENTS OF $P_{\mathbb{C}}$ GENERATED BY ALGORITHM 3 WHERE $\underline{apr'}_{\mathbb{C}}(A) = X_4 \cup X_5$ AND $\overline{apr'}_{\mathbb{C}}(A) = U$.

Assignments	1	2	3	4	5	6	7	8	9
P_1	X_1, X_4, X_5	X_1, X_4, X_5	X_2, X_4, X_5	X_2, X_4, X_5	X_4, X_5	X_4, X_5	X_2, X_4, X_5	X_2, X_4, X_5	X_4, X_5
P_2	X_2	$\emptyset$	X_1, X_3	X_1	X_1, X_2	X_1	X_3	$\emptyset$	X_2
P_3	$\emptyset$	X_2	$\emptyset$	X_3	$\emptyset$	X_2	X_1	X_1, X_3	X_1
N	X_3	X_3	$\emptyset$	$\emptyset$	X_3	X_3	$\emptyset$	$\emptyset$	X_3

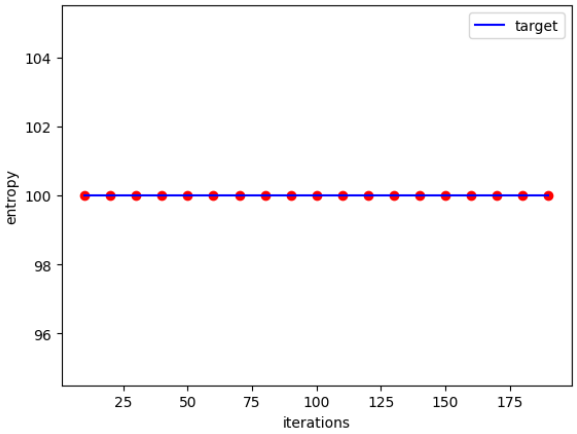

Fig. 2. The result of HTEE for the covering $\mathbb{C}$ with $n = 100$

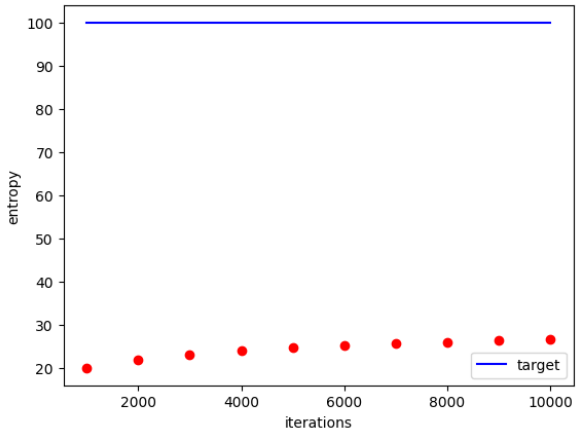

Fig. 3. The result of the coverage-adjusted estimator for the covering $\mathbb{C}$ with $n = 100$

and we get the following estimate:

$$\begin{aligned}\hat{\mathcal{H}} &= -\sum_{i=1}^{k} \frac{\log(2^{-n})}{2^n(1-(1-2^{-n})^k)} \\ &= \frac{kn}{2^n(1-(1-2^{-n})^k)} \\ &\approx \frac{kn}{2^n k 2^{-n}} \\ &= n\end{aligned}$$

The third line follows from:

$$\left(1-\frac{1}{2^n}\right)^k = \sum_{i=0}^{k}\binom{k}{i}(-2)^{ni} \approx 1-\frac{k}{2^n},$$

which holds when k is significantly smaller than 2^n.

V. EXPERIMENTS

In this section we will compare the previously discussed estimations.

We first evaluate the entropy for $n = 100$ for the covering from Example 3. When we use HTEE we see that, even after generating only 2 sets we already get an estimate that is less than 10^{-30} removed from $100 - \frac{1}{2^{-99}}$, as can be seen in Figure 2. The variance estimated by Equation (6) is practically zero. This confirms our findings from Example 5.

We may also observe that the coverage-adjusted estimator runs into problems because the value of the entropy is too large. Because of this there will be no collisions, which will cause $\hat{C}$ to be too far off. For completeness we provide a plot of the results of the coverage-adjusted estimator in Figure 3.

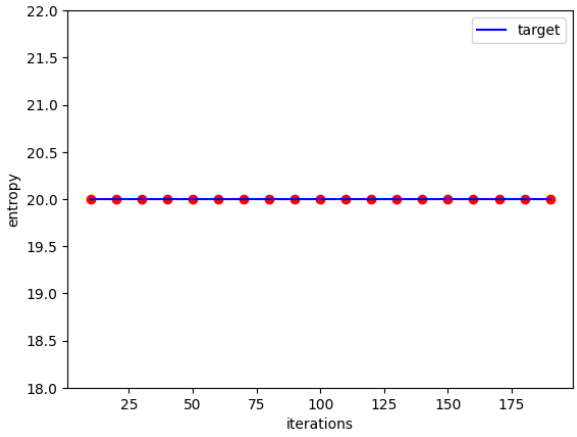

Fig. 4. The result of HTEE for the covering $\mathbb{C}$ with $n = 20$

When n is reduced to 20, both estimators produce accurate results, as seen in Figures 4 and 5.

Next, we consider real-world datasets from the UCI repository [33] and use coverings generated by Mapper. We use the following parameters for Mapper: the number of cubes is equal to 4, the overlap percentage is equal to 0.2, we use the projection onto the first PCA component as the lens function, and as a clustering algorithm we use the single-linkage algorithm with distance cutoff ε. The parameter ε will depend on the dataset we use since the average distance between points varies between datasets. We use the datasets with corresponding ε as displayed in Table II. The size of the

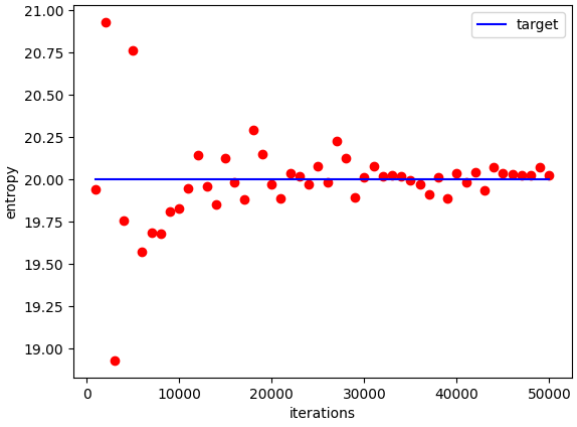

Fig. 5. The result of the coverage-adjusted estimator for the covering $\mathbb{C}$ with $n = 20$

TABLE II
THE DATASETS USED IN SECTION V

	Attributes	Instances	ε	$\lvert\mathbb{C}\rvert$
Iris	5	150	0.6	25
Vertebral Column	6	310	20	43
Wine	14	178	17.5	64

resulting coverings can also be found in this table.

The results obtained from the Iris dataset are presented in Figures 6 and 7. These figures show that the HTEE estimator converges rapidly after a small number of iterations. Additionally, the coverage-adjusted estimator consistently yields values lower than the actual entropy, which can be reasonably approximated as 15 based on the variance estimate of the HTEE estimator.

For the Vertebral Column and Wine datasets the entropy is again too high, meaning that we can only consider the HTEE estimator.

We see promising results where the variance of the estimator

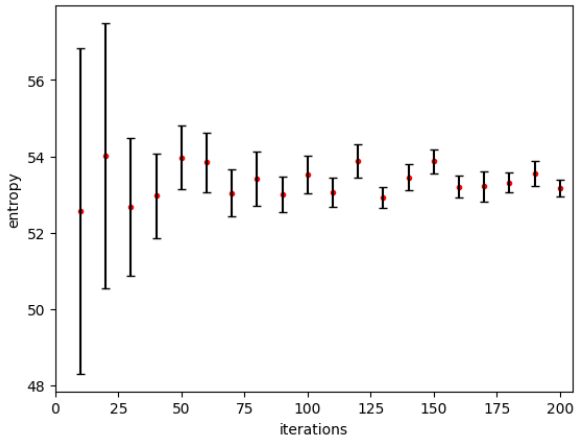

Fig. 9. The result of HTEE for the Wine dataset

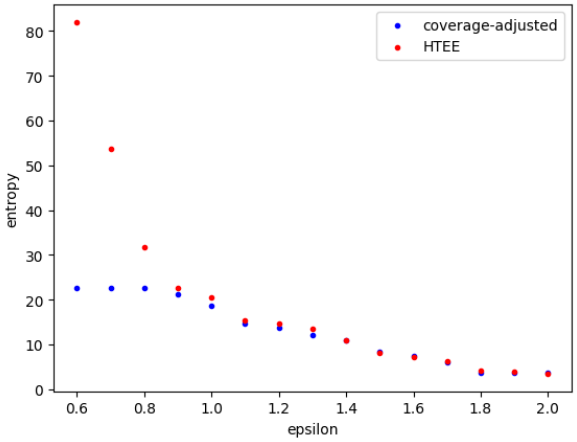

Fig. 10. The values of the HTEE and coverage-adjusted estimators for the iris dataset with a variable ε value.

quickly approaches zero as the number of iterations increases as shown in Figures 8 and 9.

We further analyze the Iris dataset by varying the value of ε, which controls the scale parameter in the Mapper algorithm. Adjusting ε generates a sequence of coverings under $\ll$, as mentioned in proposition 2. We vary ε from 0.6 to 2.0 in increments of 0.1. For the HTEE estimator, we perform 100 iterations, while for the coverage-adjusted estimator, we use 20,000 iterations—chosen to ensure comparable execution times for both methods. The variance of the HTEE estimator remains below 0.30 across all experiments. Based on this setup, Figure 10 presents the resulting comparisons. As shown, both estimators yield similar results when ε is large and the entropy is low. However, as entropy increases, the coverage-adjusted estimator consistently underestimates the true entropy. In cases of very high entropy, its estimates deviate significantly from the expected values.

VI. Discussion and Future Work

In this paper, we proposed an efficient method for estimating the entropy of the strong granule-based approximation operator in covering-based rough sets. Our approach involves generating random subsets of the universe U, determining the number of subsets that share the same rough set approximations, and applying the Horvitz-Thompson estimator to obtain an unbiased entropy estimate. We evaluated the performance of our estimator against the coverage-adjusted entropy estimator from the literature and found that our method not only yields greater accuracy but also performs more effectively in scenarios involving high-entropy coverings.

In future work, we plan to investigate estimates to calculate the size of $\mathcal{A}_k$ using properties of the covering and heuristics. A possible start to do this can be found in the following equation:

$$\Pi_{K\in P_{\mathbb{C}}, K\subseteq \overline{A}_k, K\not\subseteq \underline{A}_k}(2^{|K|}-2) \leq |\mathcal{A}_k| \leq 2^{|\overline{A}_k|-|\underline{A}_k|}$$

which can be proved by observing that

$$P_1 = \{K \in P_{\mathbb{C}} \mid K \subseteq \underline{A}_k\}$$
$$P_2 = \{K \in P_{\mathbb{C}} \mid K \subseteq \overline{A}_k, K \not\subseteq \underline{A}_k\}$$
$$P_3 = \{K \in P_{\mathbb{C}} \mid K \not\subseteq \overline{A}_k\}$$

may be used to assign types to all blocks.

When $\mathbb{C}$ is a partition, $\Pi_{K\in P_{\mathbb{C}}, K\subseteq \overline{A}_k, K\not\subseteq \underline{A}_k}(2^{|K|}-2)$ is exactly equal to $|\mathcal{A}_k|$. For general coverings, this does not hold any longer but we can use this as our approximation for $|\mathcal{A}_k|$.

Whenever $|K|$ is large enough for all K in $P_{\mathbb{C}}$, the difference between $2^{|K|}$ and $2^{|K|}-2$ is negligible. However in practice, most blocks in the used coverings are not that large. Because of this, we did not include this approach in the experimental analysis Section V. We still mention this estimate as it can probably be improved by using more heuristics to an even better estimate of $|\mathcal{A}_k|$.

Further research should also focus on constructing methods to estimate the entropy of (covering-based) rough set approximations other than the strong approximations. Finally, researchers and practitioners may also use these results to construct coverings with a given entropy. This is in particular useful for applications that require a certain degree of granularity.

***Abstract*—This exploratory study, grounded in agency theory, employs quantitative analyses to investigate the simultaneous pursuit of accountability for regulatory compliance, financial benefits, and societal impacts within artificial intelligence (AI) projects. An agent-principal matrix was developed, synthesizing knowledge from the AI stakeholder model into 11 accountability indicators. These indicators establish a standard of responsibility among project actors for regulatory compliance, ethical practices, and financial benefits. Using quantitative methods, we analyzed survey data on accountability and defined the scope of AI systems under development. We identified two clusters of AI systems—autonomous and non-autonomous—based on seven features. We then examined how these two types of systems, as well as the importance of sustainability and fairness, impact the promotion of accountability. Results indicate that accountabilities shift based on the scope of the AI system and the project role. Regulatory compliance, financial benefits, and societal impacts are not mutually exclusive project goals and coexist. The findings quantify subjective and theoretical speculation about accountabilities within AI projects. Additionally, the study contributes empirical data to the literature on AI, ethics, and project management.**

***Index Terms*—Accountability, Artificial intelligence, AI, Project management, Ethics, Agency Theory**

I. Introduction

THE launch of ChatGPT in 2023 dramatically increased interest, enthusiasm, and concerns regarding artificial intelligence (AI); ChatGPT is a generative AI chatbot based on a large language model that produces conversational outputs. Recognizing the potential impact of AI systems on the public and the environment, the European Commission and numerous countries have proposed frameworks, laws, regulations, and rules to responsibly manage these impacts, emphasizing interdependent values, principles, and actions [1, 2, 3]. At the same time, organizations prioritize achieving the target financial and business benefits from their AI investments [4, 5, 6].

This exploratory study investigated the relationship between accountability and the simultaneous pursuit of regulatory compliance, financial benefits, and societal impacts in AI projects. An AI project refers to a temporary organization that develops AI systems before deploying them for productive use or putting them into the market [7]. In the public's opinion, accountability is, on average, perceived as one of the most important ethical principles before fairness, security, privacy, and accuracy [8]. The present study addresses the following research question: *Who within an AI project is accountable for regulatory compliance, financial benefits, and societal impacts?*

The study employed a questionnaire-based survey and quantitative analysis to measure AI project teams' expectations and perceptions regarding accountability. Its theoretical framework is grounded in agency theory and builds upon an existing AI stakeholder accountability model [7] that maps project success factors and AI ethical principles. These factors establish an accountability standard governing the relationship between project actors, regulations, societal impacts, and financial benefits. A quantitative analysis of survey data then identifies what individuals involved in AI projects are held accountable for.

This paper begins with a literature review, followed by a description of the study's theoretical background, hypothesis development, and research methodology, including data collection and analysis. The findings are then presented and discussed, alongside the study's contributions, implications, limitations, and conclusions.

II. Literature Review

A. AI Projects

AI refers to a wide range of efforts to replicate complex human capabilities, such as language use, vision, and autonomous action, using computational models. This encompasses various system categories, including chatbots, humanoid robots, behavioral software, and predictive systems [7]. AI systems function as artificial agents, capable of making decisions and acting with little or no human involvement. The complex data and models in AI systems are often referred to as "black-boxes" because the end-users, and sometimes the developers, are unable to explain or interpret the model decisions [9]. Consequently, concerns have been raised regarding civil and criminal liabilities, data protection, security,

trustworthiness, and transparency related to moral decision-making without human involvement [9, 10, 8].

An AI project is a temporary organization dedicated to developing AI systems before their deployment for productive use or commercialization [7]. Project teams comprise the natural or legal people who are best placed to understand the system's design and its potential impacts on individuals and society [7, 11]. Heaton et al. [12] reinforces the pivotal role of the team, arguing that developers should design transparent, explainable AI systems. However, AI projects often involve tensions between financial targets, ethics, internal controls, and compliance [13].

Specifically, ethical and community-oriented AI projects should engage stakeholders, such as end-user groups or affected communities, as participatory collaborators in the development of AI systems [12, 11]. However, participatory development is time-consuming and often faces systemic barriers, including a lack of support and resources for brokering relationships, as well as short project timelines. AI end-user groups and affected communities are vastly underrepresented in AI research relative to developers, designers, and organizational leaders [14].

B. AI Societal Impacts

Within AI projects, project actors, including project sponsors, managers, and team members, function as moral agents [15]. Their in-project decisions can significantly impact the lives of individuals and their liberty, human rights, or civil rights [12]. The actions of project actors can also result in environmental, financial, reputational, and political harm. AI systems are artificial agents that embody a moral code, as the outcomes of their decisions or recommendations can benefit or harm individuals or society. Consequently, project actors bear a moral responsibility to apply fair, ethical, and transparent processes to the AI systems they develop Heaton et al. [12].

AI projects may also have societal and environmental impacts. Training large models consumes significant amounts of energy and water, and produces carbon emissions, resulting in high energy costs and negative environmental impacts [10, 16]. Moreover, data representativeness has power, value, and cost implications. Determining who is included in or excluded from AI datasets is valuable. Hence, data curation involves tradeoffs between costs, accuracy, quality, completeness, representativeness, and equality [16, 11].

Ryan and Stahl [10] described 11 ethical categories that users and developers should consider when fulfilling their moral responsibilities within AI projects: beneficence, dignity, freedom and autonomy, justice and fairness, non-maleficence, privacy, responsibility, solidarity, sustainability, transparency, and trust. While agencies and governing bodies, including UNESCO and the EU High-Level Expert Group, have established ethical principles that define an acceptable moral code for AI systems, these principles are non-binding for developers, users, and platforms [1]. Furthermore, the principles alone are limited in their impact on AI design and governance, as it can be challenging to translate concepts, theories, and values into practice [10, 17].

C. AI Regulations

Regional legislators have encoded ethical principles into laws and regulations relating to AI. For instance, the EU introduced the AI Act, China the Chinese Internet Information Service Algorithm Recommendation Management Regulations, and Korea the AI Basic Act [1, 2, 3]. Conversely, in May 2025, the United States (US) House of Representatives proposed legislation that would ban federal, state, and local governments from enforcing laws or regulating AI for a 10-year period [18]; this sweeping moratorium was unsuccessful, but its proposal demonstrates the political appetite for regulating AI at the federal level in the US. DePaula et al. [19] found that the 50 US states are addressing AI in an uneven, piecemeal fashion. "While several legislations regulate an aspect of AI, a common response was to create task forces and commissions to study AI, prohibit potentially discriminatory practices of AI, and provide funding to capture potential economic or educational benefits from AI" [19, p. 822]. Regardless, research by Hopkins and Booth [20] found that regulations are ineffective in changing the behaviors of technology professionals.

The EU AI Act defines an AI system by its capability features (such as levels of autonomy, adaptiveness, and inferential abilities). It classifies such systems according to the risks they pose to society and the environment [1, 9]. The Act assigns the roles of deployers and providers to those working in the field of AI system development and use. The deployer is the natural or legal person responsible for the system during its development. This role is responsible for completing risk and compliance assessments, as well as registration, before proceeding to the next stage. The provider is the natural or legal person accountable for the system's operations.

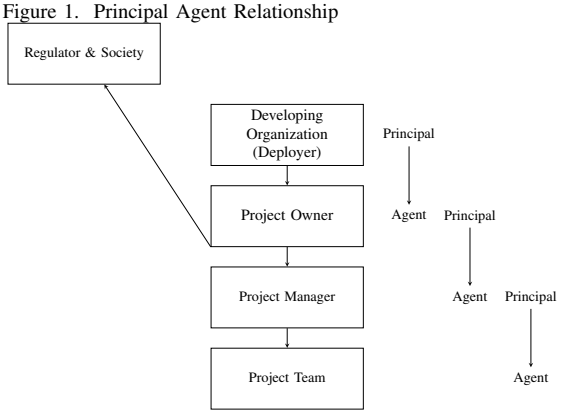
D. AI Financial Benefits

AI 'projects aim to realize their target benefits and enhance organizational performance…"target" benefits are intentionally sought by project funders and strategically set before project commencement' [5, p. 656]. AI systems utilize data and algorithms to either benefit an organization's value proposition or monetize data. Generative AI applications such as ChatGPT are improving the performance in tasks that were previously unaffected by automation technology; empirical studies show performance gains between 14% and 50% in several business contexts [4].

"Value propositions define an organization's position in a market, its core skills and how these are applied for the benefit of others" [6, p. 168]. Consequently, introducing AI systems presents a business and technical challenge that should yield target benefits and tactical goals, such as increased revenue or improved performance efficiency. Organizations expect projects to be executed efficiently, delivering results within a given timeline and budget. They must therefore balance meeting target objectives with consideration of societal and environmental impacts, as well as the need to act ethically and comply with regulations.

III. Theoretical Framework and Hypothesis Development

This section outlines the theoretical framework and the development of hypotheses.



A. Theoretical Framework

Jensen and Meckling [21, p. 308] defined agency relationships as contracts "under which one or more persons (the principal(s)) engage another person (the agent) to perform some service on their behalf which involves delegating some decision-making authority to the agent." Within the principal–agent relationship, agents are accountable to principals for their conduct. The agents have obligations to fulfill and should face consequences for their failure to perform. Moreover, agents must have the capacity to act intentionally, make choices, and exert influence with some degree of autonomy in the decision-making process [12].

Relating the roles in the EU AI Act to actors in the AI stakeholder accountability model [7] and agency theory, the deployer represents the developing organization, while the provider represents the operating organization. Within the deployer's role, the project owner acts as an agent for the principal, the developing organization. Organizational strategic goals and policies flow downward from the principals to agents [14, 22].

When building AI systems, the project owner functions as the principal, with the project manager serving as the agent. Project management standards stipulate that the project manager is responsible for planning and managing the project, directing the performance of planned activities and overseeing the project's technical, administrative, and organizational interfaces [23]. The team thus serves as an agent of the project manager. Fig. 1 illustrates the principal–agent relationships concerning the developing organization and the regulators and society.

Figure 1. Principal Agent Relationship

The AI stakeholder accountability model specifies and defines the complex relationships between actors and AI success factors, as well as the conduct and obligations that characterize them [7]. For this study, the model serves as the basis for defining accountability, i.e., the obligations the agent has to the principal; the success factors describe the conduct, events, acts, or deliverables in that relationship.

Table I synthesizes the knowledge from the AI stakeholder accountability model into a matrix that consolidates the 17 success groups into 11 accountability indicators, organized across the columns. The rows represent the agent–principal relationships and signify whether the project agent has an obligation to the principal for a given indicator. Success factors encompass ethical principles and activities mandated by AI regulations, representing deliverables, acts, or events that an AI project must include [7].

The synthesis identifies ethical and regulatory deliverables in the agent–principal relationship for AI projects, providing a basis for quantitatively evaluating AI accountabilities in practice. We selected the AI stakeholder accountability model as a theoretical basis for its alignment of project success with the AI ethical principles from Ryan and Stahl [10], regulatory and financial accountabilities, and project actors. Success factors identify the deliverables necessary for achieving project objectives. They can be used to establish an accountability standard that governs the relationship between project actors and stakeholders. Furthermore, the model determines what actions the project actors should be held accountable for and identifies the project owner as accountable to the regulators on behalf of the developing organization.

B. Hypothesis Development

Table I defines the obligations of project agents in achieving regulatory compliance, developing ethical AI systems, and delivering financial benefits using the 11 accountability indicators. Thus, in practice, accountabilities should vary by project role as defined in the matrix. This leads to the formulation of the following hypothesis:

Hypothesis 1: The (A) project manager, (B) owner, and (C) team will be responsible for their subset of the 11 accountability indicators in the agent–principal matrix.

In the context of AI projects, [7, p. 475] notes that "[f]irst and foremost, the scope established by the project owner is an essential artifact in designing AI systems." The project scope is therefore an independent factor that determines the tasks and accountabilities of individual project actors. Similarly, the EU AI Act requires different obligations depending classification of AI system according to its use case and technical features [1, 9]. For example, AI use cases for social scoring or manipulation are prohibited. Furthermore, system features such as model type, adaptiveness after deployment, personal data use, or inferring input data outputs would affect the system classification, computing costs, and environmental impact [1, 9, 16]. Therefore, the following hypothesis is proposed:

Hypothesis 2: Depending on the system scope, there will be a significant difference in accountability for (A) regulatory compliance, (B) energy costs, and (C) sustainability.

Within AI projects, hidden information and actions create challenges for the agent–principal relationship. Hidden information refers to the principal's difficulties in determining whether the agent has the necessary qualities and skills to perform a task in the principal's interest [24]. Furthermore,

Table I
ACCOUNTABILITY BY AGENT-PRINCIPAL RELATIONSHIP AFTER [7]

		Accountabilities										
		Energy Cost **EC**	Ethic Practices **EP**	Financial Benefits **FB**	Intellect Property **IP**	Societal Impacts **SI**	Prj Efficiency **PE**	Privacy Protect **PP**	Product Quality **PQ**	Reg Compliance **RC**	Transparency Usability **STU**	Sustainability **SY**
Agent	Principal

Owner	Organization	X		X	X		X		X	X		
	Regulator		X					X		X		
	Society		X			X		X	X		X	X
Team	Prj Mgr	X					X					
	Owner		X		X			X		X	X	

Abbreviations: Prj-Project, Mgr-Manager; Reg-Regulatory

some AI systems are black-boxes with hidden features caused by complex data and models [9]. Nevertheless, the AI systems are the result of actions by the project teams, influenced by their choices, biases, values, and intentions [12]. Hidden actions refer to activities that may be in the agent's interests but not the principal's. Agency theory explains the issue of moral hazards, where within the principal–agent relationship, individuals may pursue their personal interests even when they conflict with the team's objectives [21, 24, 25].

Hypothesis 3: For an autonomous system scope, agents are more likely to be accountable for (A) system transparency and usability, and (B) protecting intellectual property or financial gains.

The performance of project actors is based on what their organization considers important and what they will be held accountable for. Thus, if the organization considers the development of fair, understandable, and sustainable systems important, project agents will be accountable for tasks that deliver responsible AI systems [7, 8, 10].

Hypothesis 4: If the organization emphasizes the importance of creating fair and understandable algorithms: (A) the project manager is more likely to be responsible for implementing ethical practices; (B) the owner is more likely to be responsible for societal impacts; and (C) the team is more likely to be responsible for system transparency and understandability, product quality, and societal impacts.

Hypothesis 5: If the organization emphasizes the importance of environmental sustainability, the (A) project manager, (B) owner, and (C) team are more likely to be responsible for sustainability, energy cost, or both.

Organizations undertake projects to achieve target benefits and enhance organizational performance [4, 5, 6].

Hypothesis 6: (A) A majority of (a) owners and (b) teams will be involved in achieving financial benefits, intellectual property, or both. (B) A majority of (a) project managers and (b) owners will be accountable for the project's efficiency.

The AI stakeholder accountability model does not associate achieving financial benefits, including revenue generation, cost efficiency, or project efficiency, with any ethical principle. Furthermore, the project team must make several tradeoffs when building AI systems, including accuracy, energy cost, financial costs, project efficiency, and regulatory compliance, as well as transparency and intellectual property rights, and legal safeguards and system flexibility [7, 13, 25].

Hypothesis 7: The following will be negatively correlated: (A) financial benefits and regulatory compliance responsibility, (B) financial benefits and privacy protections responsibility, and (C) intellectual property and system transparency and understandability.

IV. RESEARCH METHODOLOGY

This section describes the research methodology, including the data collection methods, measurement instrument, analysis methods, and reliability and validity measures. The unit of analysis for the study is the project.

A. Data Collection

This study collected data on accountability within an AI project using a web-based survey hosted on SurveyMonkey, a global survey platform that utilizes a proprietary panel of survey respondents as its audience. Data were collected in November 2023 and November 2024 using a SurveyMonkey audience panel for a US audience.

Respondents provided consent to participate. No personally identifiable data were collected, and no compensation was offered. Respondents who selected "None" as an AI project role were disqualified. The survey targeted respondents in consulting, information technology, management, and project management job roles.

For the 2023 survey, 228 invitations were sent to potential participants. Of these, 121 (47%) were disqualified based on their AI project role, providing 107 (53%) usable responses. SurveyMonkey reported an error rate of +/- 10%. For the 2024 survey, 151 invitations yielded 8 (5%) disqualifications and 143 (95%) usable responses, and an error rate of +/- 8%.

Of the combined 2023 and 2024 responses, 57 of the usable respondents had not completed at least three AI projects, and 29 entries had invalid data in the experience field. These were excluded, resulting in a final total of 164 valid responses.

B. Measurement Instrument

We employed a three-stage process of content, clarity, and expert review to develop the measurement instrument, which was in English. The expert review was performed by three professionals with experience in at least three AI projects in the last ten years. All stages resulted in adjustments to the text.

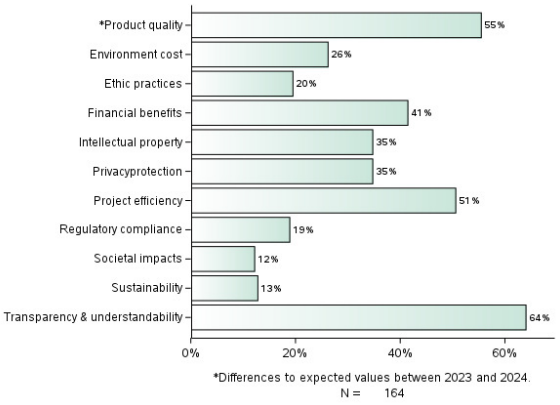

Figure 2. Accountability Indicator Demographics

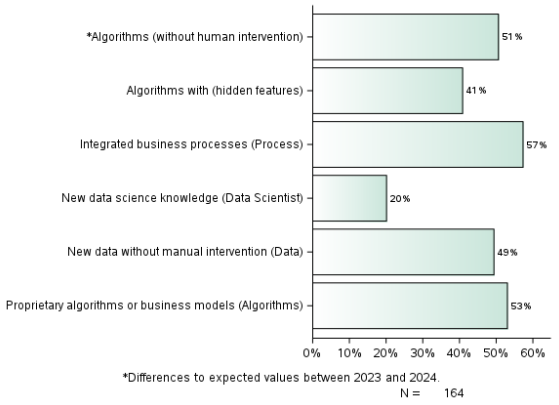

Figure 3. AI System Scope Demographics

This instrument defined algorithms, AI systems, and AI projects as follows:

> "An algorithm is a defined, repeatable process and outcome based on data, processes, and assumptions. An Artificial Intelligence (AI) system is a computer system that incorporates algorithms that learn from data and support human decision-making or autonomously make decisions. An AI project is a temporary organization (from few months to many years) that develops one or more AI systems" (author's definitions).

Respondents selected their *project role* from seven options and were grouped into composite role measures for the project owner, manager, and team. The roles and groups were taken from Miller [7].

Table I, which was also synthesized from Miller [7], was used as a bases for defining the measures for individual project *accountability* and *agent–principal relationship* accountabilities. For individual project *accountability*, respondents selected from 11 options or entered "other"; these options are shown in Table II under "Accountability Questions." Each selection created a binary measure with a value of one if it was selected and zero if not. Fig. 2 visualizes the statistics for the responses to this question. For the *agent–principal relationship* accountability combinations, a dummy variable was created with an indicator for each agent-principal pair that had an expected accountability in Table I.

Respondents selected one or more of six characteristics to describe a specific *AI system scope* they developed as part of their project [1, 9]. Fig. 3 presents the statistical responses regarding AI system characteristics. The respondents were also asked *"Of the 10 levels of automation. . . [i]n one of my last 3 AI projects, AI was at level. . . ?"* A table based on Sheridan et al. [26] provided 10 levels of automation to guide the participants' responses, allowing them to select answers from 1 to 10. A dummy variable was created where levels 1 to 6 were considered human decisions and levels 7 to 10 were considered AI decisions. The responses to questions about *AI system scope* and the *level of automation* were used to classify the AI system as autonomous or non-autonomous systems using latent class analysis (LCA).

For *experience*, respondents entered the number of AI projects they had completed in the last decade; those reporting fewer than three were not included in the analysis. To ascertain the importance of *fairness* and *sustainability*, two seven-point Likert scale questions were included, and binary measures were created for each.

Table II
ACCOUNTABILITY QUESTION

What aspects of project performance were you accountable for in the AI project referenced in question Q2? (check all that apply)

	Response Options	**Analysis Identifier**	**ID**
AI system scope	Product quality (training data, algorithm, user interface, system configuration)	Product quality	PQ
	System transparency and understandability, usage controls, decision quality	Transparency & understandability	STU
Regulatory	Ethic practices, training, policies, oversight	Ethic practices	EP
	Regulatory and legal compliance	Regulatory compliance	RC
	Protecting data privacy and confidentiality	Privacy Protections	PP
Societal Impacts	Social impacts of system usage (civil and human rights protections, etc.)	Societal impacts	SI
	Environmental sustainability of system usage	Sustainability	SY
Benefits	New revenue generation, cost savings, license fees	Financial benefits	FB
	Project time, cost, and quality performance—iron triangle	Project efficiency	PE
	Environmental costs, energy costs environmental impacts	Energy cost	EC
	Intellectual property protections (trade secrets, proprietary algorithms, obtaining patents, etc.)	Intellectual property	IP

C. Data Analysis

The SAS Studio Release 3.8 (Enterprise Edition) was utilized for quantitative analysis, statistical tests, and bias checks. The accountability data were binomial and non-normally distributed. Thus, parametric measures were suitable for the analysis. The Wilcoxon test was used to compare the means of variables and determine the significance of the comparison. Kendall's tau-b correlation coefficient was

used to evaluate the strength, direction, and significance of the relationship between measurement items. The correlation coefficient does not indicate which variable causes a change in another variable, nor does it imply causality. The Wilcoxon scores and correlations with a ρ-value of less than 0.05 were considered significant with a 95% confidence interval [27]. The rank shows the relevant importance of the indicator.

LCA clustering was employed to identify homogeneous clusters within the scope of the AI system. The dimensions were modeled in R version 4.0.2 using poLCA for the analysis. Seven items for the system scope and level of automation were specified as indicators in the model. LCA was executed with 50,000 iterations for 1–10 classes and 10 repetitions per model. The class model was selected by evaluating the Bayesian information criterion (BIC) fit statistics, log-likelihood, entropy, and the model's theoretical interpretability [28].

D. Reliability and Validity

This study relied on the quality of demographics and professional data from SurveyMonkey for sample construction. SurveyMonkey conducts periodic quality checks using surveys and panel calibration studies to help ensure the quality of open-ended responses and identify poor respondent behavior [29]. Moreover, Bentley et al. [30] conducted a comparative study on several audience panels and found the SurveyMonkey audience panel had an error margin that was "statistically indistinguishable" from more expensive panels. Thus, the sample construction was considered valid for the study.

The survey included a question to establish whether respondents had participated in both 2023 and 2024 to account for the effects in repeated surveys; 31% indicated they took both surveys. This repetition impacts the uniqueness of the responses and the effect size of the results. First, our unit of measure is the project. A person is likely to change projects between years; machine learning or AI projects are from a few weeks to several months [16]. Thus, the project characteristics may vary for the repeated responses, which is valuable to our analysis. Second, effect sizes must be evaluated based on the average number of repeated measures, as additional repeated measures provide less novel information [31]. Analysis of effect sizes was not relevant to our study; nevertheless, this factor must be considered, as it decreases the sample size, which impacts the generalizability of the study data.

For further sample validity, we used a screening question and performed quantitative checks on the survey responses to identify missing data, extreme responses (where the same response was recorded for all questions), and irregular responses to critical questions, including the entry of odd responses to open-ended questions regarding years of experience. Consequently, we removed 29 entries that were deemed invalid.

We conducted validity checks for common method bias and response bias. Response bias was assessed between survey years (2023 and 2024) to determine whether there were significant differences between the responses. Responses to the question on product quality in the accountabilities section and algorithm use without human intervention in the system scope section both exhibited significantly higher scores in 2024 than in 2023. These differences were managed in the analysis and reported in the results to avoid spurious interpretations.

Table III
DEMOGRAPHICS

Title	Label	N	Percent
Age	18 – 29	15	9.15
	30 – 44	84	51.2

	Architect, Developer, Computer Scientist, IT	7	4.27
	Business User/ Analyst, Subject Matter Expert	13	7.93
Source	SurveyMonkey 2023	54	32.9
	SurveyMonkey 2024	110	67.1
AI system	Autonomous system	79	48.2
	Non−autonomous system	85	51.8
Automation	Level 1 – 6 Human Decisions	85	51.8
	Level 7 – 10 AI Decisions	79	48.2
Fairness	Not important	9	5.49
	Important	155	94.5
Sustainability	Not important	24	14.6
	Important	140	85.4

Given that all variables were collected using the same survey instrument from a single source, Harman's single-factor test was performed to check for common method bias [32], using unrotated factor analysis to analyze the scope and accountability variables. A single factor explained 16.53% of the variance, which is well below the 50% heuristic for indicating bias. Thus, common method bias was not considered an issue.

We applied the recommendations presented by Weller et al. [28] to prepare the LCA clusters.

V. FINDINGS

This section describes the study's findings. Table IV provides a summary of the hypotheses and findings.

A. Demographics

Table III, Fig. 2, and Fig. 3 present the demographics of the respondents. Based on the AI system scope, less than half of the participants (42%) indicated that they had developed *autonomous* systems. Fig 4 shows the mean score for the features by AI system scope classification. The majority of respondents reported that *fairness* (95%) and sustainability (85%) were important to their organizations.

B. Agent-Principal Accountabilities

The data did not support the accountability expectations from the AI stakeholder accountability model. Table V displays the basic statistics for the ratio of accountabilities

Table IV
SUMMARY OF HYPOTHESES FINDINGS

ID	Hypothesis	Supported
1	The (A) project manager, (B) owner, and (C) team will be responsible for their subset of the 11 accountability indicators in the agent–principal matrix.	(A) No (B) Yes (C) Yes
2	Depending on the system scope, there will be a significant difference in accountability for (A) regulatory compliance, (B) energy costs, and (C) sustainability.	(A) No (B) Yes (C) Yes
3	For an autonomous system scope, agents are more likely to be accountable for (A) system transparency and usability, and (B) protecting intellectual property or (C) financial gains.	(A) No (B) No (C) Yes
4	If the organization emphasizes the importance of creating fair and understandable algorithms: (A) the project manager is more likely to be responsible for implementing ethical practices;	No
	(B) the owner is more likely to be responsible for societal impacts; and	No
	(C) the team is more likely to be responsible for system transparency and understandability, product quality, and societal impacts.	No
5	If the organization emphasizes the importance of environmental sustainability, the (A) project manager, (B) owner, and (C) team are more likely to be responsible for sustainability, energy cost, or both.	No
6	(A) A majority of (a) owners and (b) teams will be involved in achieving financial benefits, intellectual property, or both.	No
	(B) A majority of (a) project managers and (b) owners will be accountable for the project's efficiency.	No
7	The following will be negatively correlated: (A) financial benefits and regulatory compliance responsibility,	No
	(B) financial benefits and privacy protections responsibility, and	No
	(C) intellectual property and system transparency and understandability.	Yes

Table V
AGENT-PRINCIPAL RELATIONSHIP STATISTICS

Agent	Principal	N	MIN	MEAN	MAX	STD
All	All Indicators	164	0.00	3.71	11.0	2.06

	Owner	40	0.00	1.70	5.00	1.30

Legend: Roles: Prj-Project, Mgr-Manager
Statistics: N-Number, Std-Standard Deviation

in the agent–principal relationship. For example, the project manager and owner relationship is expected to include seven accountabilities, as shown in Table 1. However, the maximum was five, the mean was 2.48, and the standard deviation was 1.22; thus, no project manager claimed all the accountabilities suggested by the model. The project owner and teams fared better since the maximum was achieved; nevertheless, the means were relatively low. Table VI presents the percentage of accountability by respondent role. Therefore, hypotheses 1B and 1C are supported for the owner and team, but 1A is rejected for the project manager.

Notably, the respondents' experience level influenced several accountabilities. Respondents with 15 or more projects were accountable for intellectual property (IP) and product quality (PQ) more than other experience groups; those with fewer than five projects were responsible for ethical practices (EP), and those with fewer than six projects were more responsible for project efficiency (PE).

C. Impact of AI System Scope

We assessed accountability for each project role, where the AI system scope was the independent variable and the

Table VI
AGENT ACCOUNTABILITY STATISTICS

	Accountabilities										
	EC	EP	FB	IP	SI	PE	PP	PQ	RC	STU	SY
Agent	Percent										
Owner	13	9	21	18	7	29	17	32	10	35	8
PM	7	5	10	9	4	12	8	15	4	16	1
Team	6	5	10	9	1	10	10	9	5	13	4

Legend: Roles: PM-Project Manager;Accountabilities: EC-Energy Cost, EP-Ethic Practices, FB-Financial Benefits, IP-Intellectual Property, SI-Societal Impacts, PE-Project Efficiency, PP-Data Privacy, PQ-Product Quality, RC-Regulatory, STU-Traceability & Understandability, SY-Sustainability
Statistics: Owner=84, Prj Mgr=40, Team=40

accountabilities were the dependent variables. The scope had a significant influence on the accountabilities. There were significant differences in several indicators: financial benefits (FB) (H=8.55, ρ =0.00), energy cost (EC) (H=13.28, ρ =.00), and sustainability (SY) (H=5.19, ρ =.02). Consequently, agent–principal accountabilities for the owner–organization (H=14.69, ρ =0.00) and team–project manager (H=15.26, ρ =0.00) relationships were impacted. Hypothesis 2A is therefore rejected, and hypotheses 2B and 2C are supported. Table VII shows the Kruskal-Wallis mean rank statistics for each accountability and agent-principal pair by AI system scope.

System transparency and understandability (STU) ranked highest for both autonomous and non-autonomous scopes. The Kendall correlation presented in Table VIII revealed a negative, insignificant correlation between STU and the AI system scope (τ = −.06, ρ >.05). Thus, possessing hidden features did not affect transparency requirements or move the agent away from STU. Nevertheless, the EC and FB accountabilities were ranked significantly higher for the autonomous system scope. Intellectual property (IP) had no significant difference by scope. Therefore, hypothesis 3C is supported, while hypotheses 3A and 3B are rejected.

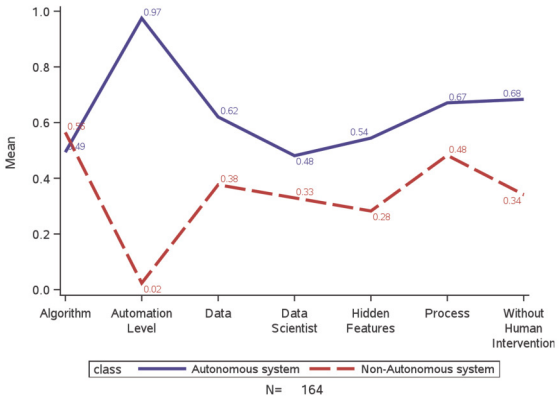

Figure 4. AI system scope classification by features for the survey population.

D. Regulatory Accountabilities

No significant difference was found in regulatory compliance (RC) accountability in terms of the AI system scope. Since many types of laws and regulations, such as those related to healthcare and disabilities, apply in the US regardless of

	Energy Cost	EC	0.39	0.49	6	0.14	0.35	9	0.26	0.44	7	13.28	0.00

Abbreviations: N=Number observations, Std=standard deviation, KW=Kruskal-Wallis, ρ=significance, Prj=Project, Mgr=Manager

the technology, the results are not entirely unexpected. Approximately 10% of the owners, 4% of the project managers, and 5% of the team members claimed RC accountability. RC accountability was significantly correlated with FB (τ =.16, ρ <.05), privacy protections (PP) (τ =.27, ρ <.0001), ethical practices (EP) (τ =.27, ρ <.0001), and societal impacts (SI) (τ =.20, ρ <.05). In sum, both hypothesis 2A, positing that the scope will impact RC, and hypothesis 7A, proposing that there will be negative tradeoff between RC and FB, are rejected.

E. Societal Accountabilities

When controlling for interaction for the importance of sustainability or fairness, there was no significant difference in agent–principal accountabilities. First, all owners indicated that fairness was important. Second, there were no significant differences for any agents regarding the accountabilities of EP, STU, PQ, or SI when controlling for fairness or sustainability.

Both SI (τ =.22, ρ <.01) and SY (τ =.16, ρ <.05) were significantly correlated with FB. This could imply that organizations see their projects as benefiting society and considering sustainability goals. The AI stakeholder accountability model attributes these accountabilities exclusively to the owner. However, only a small percentage of owners (8%) claimed them, and the other roles also claimed these responsibilities. Hypotheses 4 and 5 are therefore rejected.

F. Financial Accountabilities

Using the accountabilities of FB or IP to represent the financial gains from the project, a minority of agents had these responsibilities: project owners (31%), project managers (15%), and team members (14%). Surprisingly, only 12% of project managers and 29% of owners claimed responsibility for PE, a standard metric of project management performance including budget, time, and quality. Thus, hypotheses 6A and 6B are rejected.

EC was significantly correlated with (τ =.29, ρ <.0001) and impacted by (SS=2.33, df(1)=13.05, ρ =<.0001) the AI system scope, but it was not affected by the sustainability importance measure as expected.

G. Tradeoffs Between Accountabilities

The tradeoff between IP and STU (τ = −.01, ρ >.05) was negative, but this was not significant. However, the tradeoffs anticipated by the AI stakeholder accountability model between FB and RC (.16, ρ <.01) and FB and PP (.01, ρ >.05) were not realized. Thus, hypotheses 7A and 7B are rejected, while hypothesis 7C is supported. Fig. 5 visualizes the Kendall Tau correlations that were significant with an effect size greater than .20.

VI. DISCUSSION AND CONCLUSIONS

This study employed the AI stakeholder accountability model, grounded in agency theory, to establish an accountability standard governing the relationships among project actors, regulation, ethical principles, and benefits. A quantitative analysis of survey data examined individuals' accountabilities in practice within AI projects. Additionally, we identified two clusters of AI systems—autonomous and non-autonomous—based on seven features. The *autonomous* cluster describes systems with a high level of machine-based decision-making that allow for limited human intervention, while the *non-autonomous* excludes these features.

This study examined how AI systems (both autonomous and non-autonomous) influence accountability, as well as the importance of sustainability and fairness in this context. As expected, we found that accountabilities shift based on the scope of the AI system; unexpectedly, we also determined that most expected accountabilities are not undertaken in practice.

The intersection between target benefits, societal impacts, and regulatory compliance depends on the project owner's role. Our findings suggest that the owner's accountability for regulatory compliance remains relatively unchanged, regardless of the scope of the AI system. However, their accountability towards the organization does change.

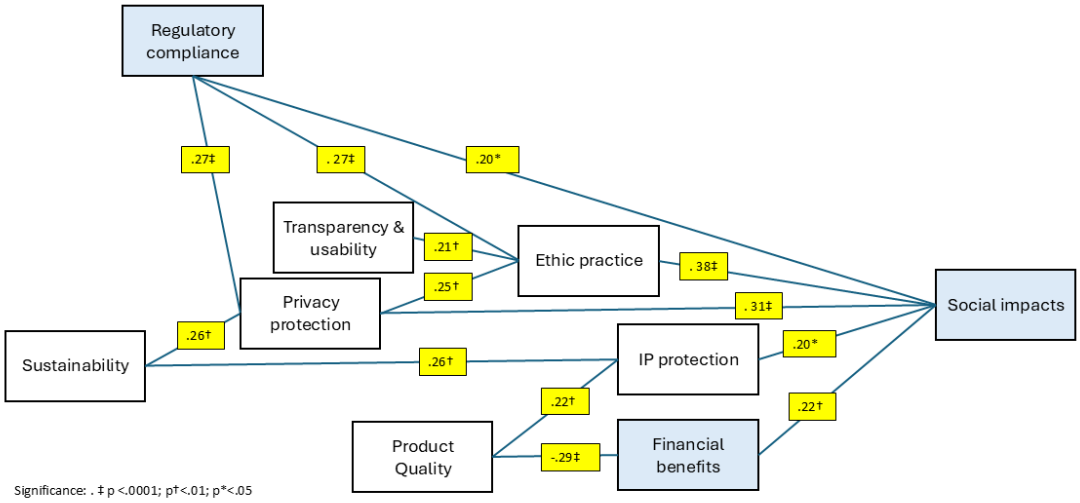

Figure 5. Kendall Tau Correlation Visualization

Most respondents practiced accountability regarding system transparency and understandability. This finding is consistent with Heaton et al. [12], who suggest that developers should design transparent and explainable AI systems to promote trust and mitigate any negative consequences that could arise from system use. Moreover, the transparency and understandability indicator is significantly correlated with ethical practice.

Ethical practice plays a central role in regulatory compliance and social impacts, and is further correlated with financial performance. This suggests that ethical practices may be the driving force behind the achievement of all other benefits. The analysis across experience levels further supports the argument for centering ethical practices. It showed that respondents with four or fewer projects indicated a greater responsibility for ethical practices than any other experience group. Taken together with the other indicators, this suggests that novices rely on documented practices (ethical practice) or traditional project performance measures (project efficiency) in their job performance. At the same time, more experienced individuals focus on creating content (intellectual property) and producing quality results (product quality).

We examined the fluidity of accountabilities, utilizing owner, project manager, and team roles from the sponsoring organization (i.e., the deployer, as defined by the EU AI Act). The accountabilities change based on the AI system's scope; if the project includes a scope typical of building autonomous decision-making tools, there is greater accountability, with a keen focus on the business impacts of product quality, intellectual property, and energy costs.

The lack of some expected tradeoffs may be attributed to the study's design. Wachnik [25] notes that many moral hazards in projects are due and the dangers linked to opportunistic supplier behaviour in a client-supplier relationship. The study lacked information on the respondents' organizational relationships, so it did not permit such analysis. Nevertheless, some tradeoffs between compliance and obtaining target benefits appear to be based on role assignments. Not all accountabilities are observed by a single agent, which helps avoid conflicts between personal and organizational interests [21, 24, 25]. Preventing moral hazards should incentivize the optimization of project organizations, including their contractual structures, team size, and role assignments.

Despite the robustness of the AI stakeholder accountability model, individuals hold less than 50% of the expected accountabilities in practice. However, we anticipate that this will change over time. First, the monetary and environmental cost of developing new and tuning existing AI models becomes extremely expensive, quickly [16]. Second, the EU AI Act comes into full effect by 2027. In response to non-compliance, the EU can impose "administrative fines of up to 35 000 000 EUR. . . or up to 7% of its total worldwide annual turnover. . . whichever is higher" [1, p. 115]. Third, generative AI capabilities extended with digital tools or integrated with robotics are estimated to produce "around 0.4-0.9 p.p. [percentage point] contribution to annual labour productivity growth, when assuming a standard capital multiplier of 1.5" [4, p. 10]. Finally, there are strong incentives for firms to implement one or more AI systems for economic benefits or to address competitive pressures [6].

This study shows that for ethical AI development, it is necessary to establish a project role assignment matrix; this finding is consistent with Herrera [9] and Kuehnert et al. [14]. Here, we propose that the AI stakeholder accountability model evaluated in the current study could provide a baseline standard for assigning AI project responsibilities.

A. Theoretical Contributions

Our study's findings quantify subjective and theoretical speculation about who is accountable for the financial, regulatory, and societal impacts of AI projects. This study identifies the relationships among system features, automation levels, and accountability indicators in AI projects by empirically investigating the practices of experienced project participants. The results contribute to the literature on AI, ethics, and

project management by aligning regulatory requirements with a project success model. Although research on ethical principles in AI is widely available, this research addresses the criticism that organizational leaders are underrepresented in AI research [14].

B. Practical Implications

Project sponsors should understand the interplay between various project assignments and define performance measures to avoid conflicts that may create moral hazards. Furthermore, the scope of the AI system should not be underestimated when defining a project organization. Thus, when staffing decisions require a tradeoff in role assignments, it is crucial to consider ethics, regulations, and performance efficiency.

C. Limitations and Future Research

One limitation of the present study was its data collection strategy. The survey was distributed to randomly selected individuals in the US, did not consider a single project, and relied on self-report measures. First, relying on a sample consisting exclusively of respondents from the US may limit the generalizability of the findings, especially given that regions such as Europe have more advanced AI regulations in place. Second, the study did not assess different people from the same project team. Thus, it limited the ability to investigate team assignments and moral hazards. Third, the survey relied on self-reports by the participants. Thus, bias may have been introduced by individual memories or recalls.

To mitigate the limitations of this study, future research could focus on a case study to quantify the engagement of separate roles, or employ strategies to assess a single project environment. Future studies should investigate AI performance measures at a granular level by project role. Finally, this analysis was conducted from the deployer's perspective and should also be conducted from the promoter's perspective. The system configuration (SC), user interface (UI), and usage control (UC) qualities were not included in the survey as standalone items and were therefore excluded from the analysis. This was an acceptable exclusion, as the AI stakeholder accountability model identified these qualities as important for operations, which were not analyzed in this study. Although risk and quality management are important components of the EU AI Act, our survey did not include an independent question on these elements, so this aspect could not be independently analyzed. These are interesting avenues for future research to explore.

D. Conclusion

In conclusion, regulatory compliance, financial benefits, and societal impacts are not mutually exclusive project goals and coexist as shown in Fig. 5.

***Abstract*—Differentiable Logic Gate Networks (DLNs) offer a compelling framework for symbolic interpretability and reducing inference cost. Building on prior works using Menger and Zadeh T-norms, we investigate the Łukasiewicz T-norm as an alternative relaxation for classical logic gates. While it provides strong gradients in some regions, its flat areas result in vanishing gradients that hinder training. To address this issue, we use an initialization strategy that is analogous to residual connection in Neural Networks to encourage error signal propagation during training. Our empirical results show that Łukasiewicz based DLNs, though slightly less accurate, benefit from faster inference and lower memory requirements compared to Neural Networks, giving the opportunity of practical application in, e.g., resource constrained devices. Due to the structural clarity, DLNs facilitate direct inspection and tracing of information flow, which makes them suitable for application in explainable artificial intelligence (XAI).**

I. Introduction

DIFFERENTIABLE logic gate networks (DLNs) provide a promising framework for combining the interpretability of classical logic circuits with the scalability of gradient-based learning. Prior work has demonstrated that continuous relaxations of binary logic gates, such as those based on the Zadeh and Menger T-norms enable the use of standard backpropagation techniques while allowing conversion back to classical logic post training [19], [28], [15], [29]. Building on this foundation, we extend the study of T-norm-based relaxations by investigating the Łukasiewicz T-norm as a candidate operator for differentiable logic networks.

In production environments, inference efficiency directly affects user experience, operational costs, and energy consumption, making it a critical optimization target, especially for edge devices and real time systems [2], [21] with strict latency and resource constraints. Common strategies such as reduced-precision computation [3], [7], binary networks [22], and sparsity exploitation [8], [16] offer partial solutions but often come with trade-offs in accuracy or generality. DLNs offer an alternative path, where logic gate networks were trained using a continuous relaxation based on the fuzzy logic functions to enable gradient descent. Each computational unit in DLNs learns a probability distribution over 16 of these differentiable fuzzy logic functions using softmax. Post training, these units are assigned the most probable gate, resulting in networks that are naturally sparse and require no weights, leading to exceptional inference speeds. In our previous work [28], we followed this approach using the Zadeh T-norm for continuous relaxation. Although it is not differentiable at $a = b$, we assume the output to be a in those cases to preserve gradient flow. In this paper, we extend this line of research by exploring the Łukasiewicz T-norm as a relaxation operator for logic gate networks. Although similar to the Zadeh T-norm, the Łukasiewicz operator provides strong gradients but only in certain regions; however, it suffers from wide, flat areas with vanishing gradients. To address this, we use initialization strategies [20] that bias the network toward gate configurations that better propagate gradients, especially during the early stages of training.

Recent research on medical applications delving into large-data processing such as MRI [27], [14], EEG [6], [11] data, X-ray images [4] and clinical notes [5] which requires high computational resources. The introduction of DLNs open a new opportunity for processing relatively small data with low latency and small memory footprint e.g. pulsimeter, oxygen blood saturation measuring and non-invasive glucose monitoring.

II. Differentiable Logic Gate Networks

Hardware implementations utilizing logic gates exhibit exceptional performance characteristics nanosecond execution speeds, true parallelism, and deterministic reliability. However, designing complex systems at the gate level presents formidable challenges. Development with Verilog or VHDL lacks convenient debugging tools, requires specialized equipment for verification, and involves lengthy development cycles [23]. These constraints necessitate novel approaches such as symbolic learning that can select optimal logic gate configurations, dramatically reducing design cycles. On the other hand, binary logic gates are inherently discontinuous, making

gradient based training infeasible. Inspired by this, Differentiable Logic Gate Networks was introduced by [19] and further investigated by [28], offering an elegant solution to this challenge by incorporating principles from Differentiable Fuzzy Logics (DFL) [10].

Instead of operating on discrete values $\{0, 1\}$, DLNs allow inputs and outputs to take continuous values in the range $[0, 1]$. This enables smooth transitions between logical states and creates differentiable pathways through which gradients can flow during training.

Architecturally, DLNs differ from standard neural networks in their connection patterns. Each computational unit (analogous to a neuron) processes a pair of randomly assigned inputs, rather than computing a weighted sum across all inputs. This design results in inherently sparse connections, in contrast to the dense layers typical in traditional neural networks.

The core learning mechanism of DLNs involves dynamically selecting the most appropriate fuzzy logic operation at each unit to minimize the overall loss function. Unlike neural networks, which learn weights, DLNs learn which logical operations best model the underlying patterns in the data.

A Boolean operation can be defined as a function $f : \{0, 1\} \times \{0, 1\} \to \{0, 1\}$, leading to a total of 16 possible Boolean operations (Table I). Each of these can be extended to fuzzy logic. For example, the Boolean AND ($\wedge$) operation can be defined as:

$$a \wedge b = \begin{cases} 1 & \text{if } a = b = 1, \\ 0 & \text{otherwise.} \end{cases}$$

The fuzzy logic equivalent to Boolean AND using Menger's T-norm [15] is:

$$T_M(a, b) = a \cdot b.$$

To represent the fuzzy logic operation probabilistically, each computational unit can be represented as:

$$r = \sum_{i=0}^{15} p_i \cdot f_i(a, b), \quad \text{for } i = 0, 1, \ldots, 15,$$

where the probabilities p_i are derived from a softmax over a learnable logit vector $\mathbf{w}$:

$$p_i = \frac{e^{w_i}}{\sum_{j=0}^{15} e^{w_j}}, \quad \text{for } i = 0, 1, \ldots, 15.$$

Each f_i denotes a fuzzy logic function corresponding to one of the 16 Boolean operations, table I.

Each layer in a DLN consists of several such units, and their outputs propagate forward to support complex decision-making processes. The choice of T-norm is a crucial hyperparameter, influencing both accuracy and inference speed, which we explore in the following subsections.

A. Menger Based Differentiable Logic Gate Networks

The original DLN formulation [19] used Menger's T-norm ($T_M(a, b) = a \cdot b$), also known as the probabilistic T-norm. This choice is intuitive due to its smooth and easily computable derivatives:

$$\frac{\partial T_M(a, b)}{\partial a} = b, \quad \frac{\partial T_M(a, b)}{\partial b} = a,$$

which are well-suited for gradient based optimization algorithms [24], [10].

Empirical results show that models based on the Menger T-norm achieve competitive accuracy compared to neural networks on many benchmarks while offering significantly lower memory usage and computational complexity due to their reliance on binary logic operations. Compared to other T-norms [28], Menger based DLNs (DLNs_M) demonstrate robustness to noise, albeit with slightly slower inference times. However, the DLN_M variant suffers from the vanishing gradient problem, as the partial derivatives diminish when $\partial T_M(a, b)/\partial a < 1$, causing the backpropagated error signal to attenuate and hindering effective learning in deeper networks. To address this [19] proposed scaling the gradients by a factor $f > 1$ for DLNs with more than six layers. While this technique mitigates the vanishing gradient problem, it also introduces the risk of exploding gradients, potentially destabilizing training.

B. Zadeh Based Differentiable Logic Gate Networks

To mitigate gradient vanishing, [28] proposed replacing Menger's T-norm with Zadeh's T-norm [29], defined as $T_Z(a, b) = \min(a, b)$. While the forward computation is straightforward, care must be taken during backpropagation to ensure consistent gradient flow, especially when $a = b$, where the gradient could flow to either input.

To address this, the authors [28] chose to default to propagating the gradient through a in the case of equality (although choosing b would yield the same results). The partial derivatives are defined as:

$$\frac{\partial T_Z(a, b)}{\partial a} = \begin{cases} 1 & \text{if } a \leq b, \\ 0 & \text{otherwise,} \end{cases} \quad \frac{\partial T_Z(a, b)}{\partial b} = \begin{cases} 0 & \text{if } a \leq b, \\ 1 & \text{otherwise.} \end{cases}$$

This setup ensures a well-defined and consistent backward pass. One key advantage of Zadeh's T-norm is that the derivatives of all fuzzy operations are limited to the set $\{-1, 0, 1\}$, and it is never simultaneously zero for both a and b. This guarantees that the gradient is neither vanishing nor exploding, enabling more stable and effective training.

Consequently, Zadeh based DLNs (DLNs_Z) are good at recognizing discrete, singular features and outperform DLNs_M in inference speed, albeit with a slight trade off in accuracy on some benchmarks [28].

C. Binary Logic Gate Networks

Compared to traditional neural networks, the inference process in Differentiable Logic Networks can be significantly less efficient due to the need to compute all 16 fuzzy logic operations for every computational unit. In contrast, neural networks rely heavily on matrix multiplication as their computational backbone, a process that is now widely accelerated

by modern hardware, such as Nvidia's Tensor Cores, among others.

One potential optimization is to reduce the number of fuzzy logic operations computed by selecting only the logic gate with the highest probability for each unit. Since fuzzy operations generalize Boolean operations, when inputs are strictly binary (i.e., 0 or 1), the resulting outputs are the same as the binary connectives equivalent; converting from smooth fuzzy operators to crisp binary ones theoretically does not compromise accuracy, especially when the training data is already binary. This transition could also substantially reduce memory consumption and computational complexity due to the efficiency of binary operations.

To implement this optimization, DLNs can be converted into Binary Logic Gate Networks (LGNs) by choosing the fuzzy operation where the softmax function results in the highest probability; thus, this retains the same architectural structure, namely, the number of layers and computational units; however, each unit in LGNs only computes a single binary logic gate instead of a weighted sum of all 16 functions.

III. Łukasiewicz based Differentiable Logic Gate Networks

In this study, we investigate fuzzy logic operations based on the Łukasiewicz T-norm, defined as $T_Ł(a,b) = \max\{0, a+b-1\}$. Like the Zadeh T-norm used in [28], the Łukasiewicz T-norm relies on $\min$ and $\max$ operators. Consequently, it exhibits similar challenges during backpropagation, particularly regarding non smooth gradients and ambiguous gradient flow paths.

To address this, we adopt the same backward pass strategy proposed in [28], which resolves the gradient ambiguity by enforcing consistent choices. The partial derivatives with respect to the inputs are defined as:

$$\frac{\partial T_Ł(a,b)}{\partial a} = \begin{cases} 0 & \text{if } a+b-1 \leq 0, \\ 1 & \text{otherwise,} \end{cases}$$

$$\frac{\partial T_Ł(a,b)}{\partial b} = \begin{cases} 0 & \text{if } a+b-1 \leq 0, \\ 1 & \text{otherwise.} \end{cases}$$

This yields sharp gradients in the set $\{-1, 0, 1\}$ for the network, which can help limit exploding gradients. However, a significant portion of the domain of $T_Ł$ results in zero gradients, leading to the risk of vanishing gradients during training.

To mitigate this, we implement a residual initialization scheme inspired by [20]. Instead of initializing the learnable weights uniformly at random, the authors bias them toward logic gates that act as pass through operators. Owing to the symmetry between inputs, they treat gates corresponding to A and B (i.e., the 3rd and 5th gates in Table I) as functionally equivalent in this context. We experiment with two variants of this initialization: one where gate A is assigned a 90% initial probability (with all other gates initialized to 0.67%) as in [20], and in this work we introduce another variant where both gates A and B are initialized with 45% probability each.

For inference, we transform the computational units of Differentiable Logic Networks into hard logic gates and generate corresponding C code for the network. This C code is compiled using the `-O1` optimization flag for models with fewer than 50,000 computational units and `-O0` for larger models due to limitations in compilation time and memory overhead.

Modern 64-bit CPUs are ubiquitous across consumer devices, which implies that Boolean values must typically be extended via zero extension or sign extension to align with the ALU's expected input width. The implementation proposed by [19] uses a 64-bit encoding for Boolean inputs to match the native word size of contemporary CPUs. For consistency, our initial implementation of Zadeh-based Differentiable Logic Networks (DLNs) [28] followed the same encoding strategy. However, empirical evaluation with our available devices for experiments revealed that using an 8-bit encoding for Boolean values significantly reduces inference time. This change in using different numbers of bits to represent Boolean values does not affect the accuracy of the models. Therefore, in order to maximize performance under our setup, we proceed with using 8-bit encodings for all classical logic operations in the networks instead of 64-bit.

IV. Experiments and Results

To ensure a fair comparison with previous work [19], [28], we evaluate our proposed approach on both structured and unstructured data types. For structured datasets, categorical attributes are one-hot encoded, while continuous features such as age or tumor size are discretized and then followed by one-hot encoding. This preprocessing ensures compatibility with post training discretized models that require binary or discrete input representations. For unstructured data such as CIFAR-10 [12], we adopt a similar discretization strategy as [19], [28] for pixel intensities by applying a series of progressive thresholds, enabling a finer grained binary encoding of continuous values. This technique reduces information loss during binarization and supports more expressive representations in logic based models. We created two variants of the CIFAR-10 dataset for 3 thresholds and 31 thresholds, which we will discuss in more detail in CIFAR-10. In contrast, for the MNIST dataset, we retain the original grayscale pixel values and train directly on the real valued inputs to evaluate DLNs' performance on real values data.

During evaluation, all DLNs, regardless of implementation, are converted into Binary Logic Gate Networks where the computational unit calculates fixed Boolean functions with the highest probability. All the variants of $\text{DLN}_Ł$ are denoted as $\text{DLN}_Ł$, $\text{DLN}_{Ł^*}$, $\text{DLN}_{Ł^{**}}$ for without residual initialization, residual initialization at the feedforward gate A, and residual initialization at gates A and B. All models are implemented using PyTorch [18], Adam optimizer [9] and trained on an NVIDIA RTX 2000 Ada GPU. Inference time is measured using a single threaded setup on an AMD Ryzen 5 3550H CPU and averaged across 100 runs. To indicate statistically significant differences in inference time across models, we

A. MONK

The MONK datasets [26] constitute a benchmark suite of binary classification tasks designed to evaluate the performance of machine learning models on symbolic and logical reasoning problems. Each dataset consists of discrete-valued features and a binary target label, with the classification rules defined using logical expressions.

MONK-1 defines a concept in disjunctive normal form (DNF), making it relatively simple and well suited for symbolic learners such as Differentiable Logic Gate Networks. **MONK-2** resembles a parity problem, where the target function is based on a combination of attributes that cannot be easily expressed in either DNF or conjunctive normal form (CNF). **MONK-3** is structurally similar to MONK-1 and is also defined using DNF. However, it introduces label noise into the training set, making it a useful benchmark for evaluating a model's robustness and generalization under imperfect data.

The ANN achieves the highest accuracy on the MONK-1 and MONK-2 datasets, but it requires significantly more memory than DLNs, regardless of the implementation. DLN_M outperforms all other models on the MONK-3 dataset. Interestingly, $DLN_Ł$ achieves a higher accuracy than the ANN (94.0% vs. 93.5%) in the last dataset (see table II), results of significant difference tests are presented in table III and basic statistical analysis in figure 1. Adding residual initializations to $DLN_Ł$ yields mixed results: accuracy improves on MONK-2 but decreases on the other datasets. In terms of inference time, the $DLN_{Ł^*}$ $DLN_{Ł^{**}}$ methods show similar improvement in performance.

B. Adult dataset

The Adult dataset [1], also known as the "Census Income" dataset, is a widely used benchmark in the machine learning community. It originates from the UCI Machine Learning Repository and involves a binary classification task aimed at predicting whether an individual's annual income exceeds $50,000. The dataset comprises 48,842 samples and includes both continuous and categorical features, such as age, education, occupation, and work class.

TABLE IV
RESULTS FOR THE ADULT DATA SET AVERAGED OVER 100 RUNS.

Adult	Acc.	#Param.	Infer. Time	Memory
ANN	84.90%	3,810	287.95 ± 6.19ns	$15KB$

$DLN_Ł$	***	***		*	***
$DLN_{Ł^*}$	***	**	*		*
$DLN_{Ł^{**}}$	*		***	*	

In this benchmark, DLN_M, $DLN_{Ł^*}$, and $DLN_{Ł^{**}}$ demonstrate comparable accuracy to the artificial neural network (ANN), but with much lower inference time and memory usage (table IV), inference time significant difference tests are in table V and see figure 2 for basic statistical analysis. Among all implementations, DLN_M is the fastest in terms of inference speed and similar accuracy compared to the baseline ANN. Interestingly, when we initialize the Łukasiewicz models with higher probabilities at gates A and B, the accuracy doesn't improve, but inference time goes down. This shows $DLN_{Ł^*}$ a good compromise between speed and performance.

C. Breast Cancer dataset

The Breast Cancer dataset [30] was collected from the University Medical Center, Institute of Oncology, Ljubljana, Yugoslavia. It is one of three domains provided by the Oncology Institute that have frequently appeared in the machine learning literature.

The dataset consists of 286 instances, with 201 belonging to one class and 85 to another. Each instance is described by nine attributes. The dataset is commonly used to assess classification performance on medical diagnostic tasks, particularly in scenarios involving imbalanced class distributions and heterogeneous feature types.

TABLE VI
RESULTS FOR THE BREAST CANCER DATA SET AVERAGED OVER 100 RUNS.

Breast Cancer	Acc.	#Param.	Infer. Time	Memory
ANN	75.31%	434	792.43 ± 100.23ns	1.4KB
DLN_M	71.43%	640	38.34 ± 0.27ns	320B
DLN_Z	68.56%	640	35.14 ± 0.22ns	320B
$DLN_Ł$	70.00%	640	26.72 ± 1.07ns	320B
$DLN_{Ł^*}$	74.29%	640	30.62 ± 1.25ns	320B
$DLN_{Ł^{**}}$	70.00%	640	35.58 ± 1.10ns	320B

In this experiment, table VI shows ANN reaches an accuracy of 75.3%, followed closely by $DLN_{Ł^*}$ at 74.3%, while using only a fraction of the inference time and memory. $DLN_Ł$ stands out as the fastest model, although it has very low accuracy. The results of significant difference tests for inference speed are presented in table VII, and essential statistical analysis is presented in figure 3. Notably, using residual initialization brings a major boost for $DLN_Ł$, raising its accuracy from 70.0% to 74.3%. However, when both gates A and B are initialized together, the model's accuracy actually drops. Once again, $DLN_{Ł^*}$ has a good balance between accuracy and run time complexity.

D. MNIST Dataset

To ensure comparability with prior studies [19], [28], we evaluate our proposed approach on the MNIST dataset [13]. MNIST is a standard benchmark in computer vision and machine learning, consisting of grayscale images of handwritten digits ranging from 0 to 9. The dataset comprises 70,000 samples, partitioned into 60,000 training images and 10,000 test images, each originally sized at 28×28 pixels.

To examine the models' adaptability to reduced input dimensionality, we additionally resize the images to 20×20 pixels by removing the borders, thereby constructing a secondary, lower-resolution version of the dataset. Each image is associated with a label corresponding to the digit it represents, making this a ten class classification problem. The dataset serves as a robust testbed for evaluating both accuracy and generalization across a range of model architectures.

In both the small and normal configurations, the results in table VIII show ANNs outperform DLNs in terms of accuracy across all implementations (ANN *(small)*: 96.3%, ANN: 98.40%), though this comes at the cost of higher inference time and memory usage. Among the smaller DLN models, DLN_M *(small)* achieves the highest accuracy, but it is the slowest ($1.127 \pm 0.03\mu$s) see table IX and figure 4 for inference speed significant difference tests and statistical analysis. On the other end, $DLN_Ł$ *(small)* offers the fastest inference but with the lowest accuracy. $DLN_{Ł^{**}}$ *(small)* yields higher accuracy than $DLN_{Ł^*}$ *(small)* and on average, it also has a faster inference time; however, this is not a statistically significant increase. Both initialization strategies show clear improvements in accuracy compared to the uninitialized base model.

It's also worth pointing out that DLN_M and $DLN_{Ł^*}$ have comparable accuracy (97.6% vs. 97.3%), but $DLN_{Ł^*}$ has the advantage in terms of faster inference.

E. CIFAR-10 Dataset

CIFAR-10 [12] is a well established benchmark dataset composed of 60,000 color images, each with a resolution of 32×32 pixels. The images span 10 distinct object categories, including airplanes, automobiles, birds, cats, and more. The dataset is partitioned into 50,000 training samples and 10,000 test samples. Its compact image size makes it particularly suitable for experimentation under limited computational resources, facilitating the development and evaluation of novel algorithms.

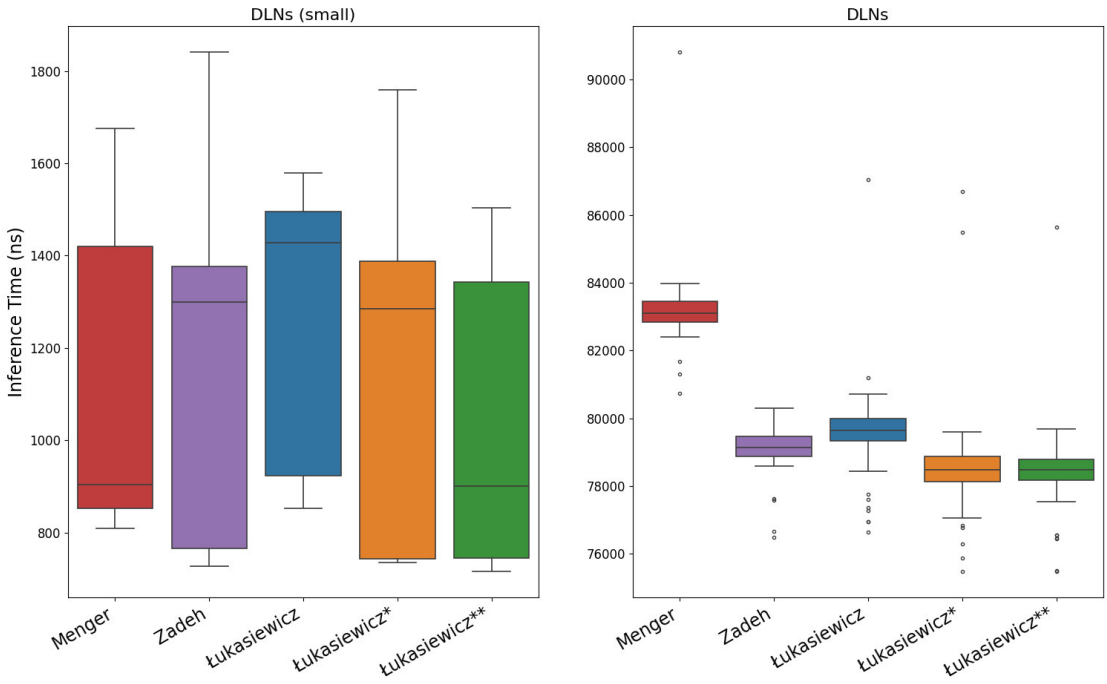

Fig. 4. Basic statistical analysis for MNIST dataset inference time (ns) results (lower is better)

Following the methodology proposed in [19], we reduce the color channel resolution to discrete threshold levels to accommodate binary input constraints of logic based models. Specifically, we apply three value thresholds for the *small* and *medium* models and 31 thresholds for the *large* models. Instead of a simple binarization using a 0.5 cutoff, which often results in significant information loss, we use a set of progressive thresholds (e.g., 0.25, 0.5, 0.75) to discretize pixel intensities more effectively. For instance, a pixel with intensity $p_i = 0.6$ can be represented as $p_i = [1, 1, 1, 0]$, where i denotes the pixel's position in the flattened image. This multi threshold encoding mitigates the discretization loss when converting fuzzy inputs into binary representations, thus improving the suitability of the data for binary logic gate models.

Although dropout and data augmentation are widely used to improve generalization in vision tasks, we intentionally refrain from employing these techniques to maintain consistency with our experimental framework. For all DLN implementations, we use the notation S, M, and L to represent small, medium, and large models, respectively, based on the number of parameters.

In the smaller model configurations, DLN implementations achieve lower accuracy compared to ANNs (see table X). Among the different DLN implementations, DLN_M consistently achieves the highest accuracy across all model sizes (S, M, L). The initialization methods show consistent improvement in accuracy over the base DLN_L model for all model sizes without significant impact on the inference time (see table XI and figure 5).

V. Discussion

The experimental results show consistently low accuracy for Łukasiewicz T-norm based models, which aligns with our initial hypothesis. We attribute this to a substantial portion of the domain in Łukasiewicz based fuzzy logic yielding zero gradients, which prevents error signals from backpropagating effectively to higher layers. Moreover, across all experiments, larger networks benefit significantly from both proposed initialization schemes, showing notable improvements over the baseline DLNs_L. This supports the idea that biasing the model toward feedforward gates while avoiding gates that contribute to gradient vanishing, particularly during the early stages of training when error rates are highest, can substantially enhance error propagation. Interestingly, these initialization methods also increase the models inference speed compared to the baseline models. While increasing the number of feedforward-biased gates does lead to higher accuracy, the improvement is modest and not consistently observed across all experiments. In smaller models, such as those trained on MONK-2, MONK-3, and the Breast Cancer dataset, biasing toward feedforward gates results in a decrease in accuracy performance. We hypothesize that when the number of model parameters is limited, the biasing restricts the model's capacity to flexibly select appropriate logic gates, thereby impairing its learning ability. However, in larger models, the inflexibility introduced by the initialization schemes results in measurable improvements in both accuracy and inference time. One

possible explanation for the improved runtime efficiency is that a majority of the operations in these models are identity functions. At lower compiler optimization levels (e.g., `-O0`), identity operations are implemented as simple memory transfers between registers. However, under aggressive optimization settings (e.g., `-O3`), compilers often eliminate such operations entirely by reusing registers, resulting in minimal computational overhead. This behavior significantly reduces the runtime burden of inference in models where identity gates dominate. Figure 6 illustrates the gate selection distributions for $\text{DLNs}_Ł$ (Baseline), $\text{DLNs}_{Ł^*}$ (A), and $\text{DLNs}_{Ł^{**}}$ (A - B) on the MNIST dataset. A clear concentration of feedforward gates a for $\text{DLNs}_{Ł^*}$, and feedforward gates a and b for $\text{DLNs}_{Ł^{**}}$, which correspond to identity mappings, are evident in the latter two configurations. This suggests that the initialization schemes effectively steer the models toward simpler computational pathways. Interestingly, these identity heavy models not only benefit from faster inference but also demonstrate improved gradient stability, particularly during the early stages of training. The stable signal propagation enabled by identity operations likely contributes to the observed accuracy gains. However, the dominance of feedforward gates in $\text{DLNs}_{Ł^*}$ and $\text{DLNs}_{Ł^{**}}$ after training also implies underutilization of the network's expressive capacity. While this may be beneficial for efficiency, it raises questions about the models' ability to learn more complex representations when required.

Furthermore, we observe that increasing model size generally leads to an improvement in accuracy. This trend is consistent with the two findings from [19], [28] show that larger DLN models possess greater representational capacity. In current DLNs implementations, input pairs are connected randomly to computational units. This random connectivity hinders memory coalescing during data loading, which in turn leads to data starvation as computational kernels are forced to wait for data to be fetched. It is due to transferring memory from global memory (VRAM) to local memory (Registers) cost hundreds times more compute cycles comparing to the actually computations itself [17]. Replacing a convex combination of gates with a single, discrete gate can lead to significant performance degradation. For instance, if a computational unit

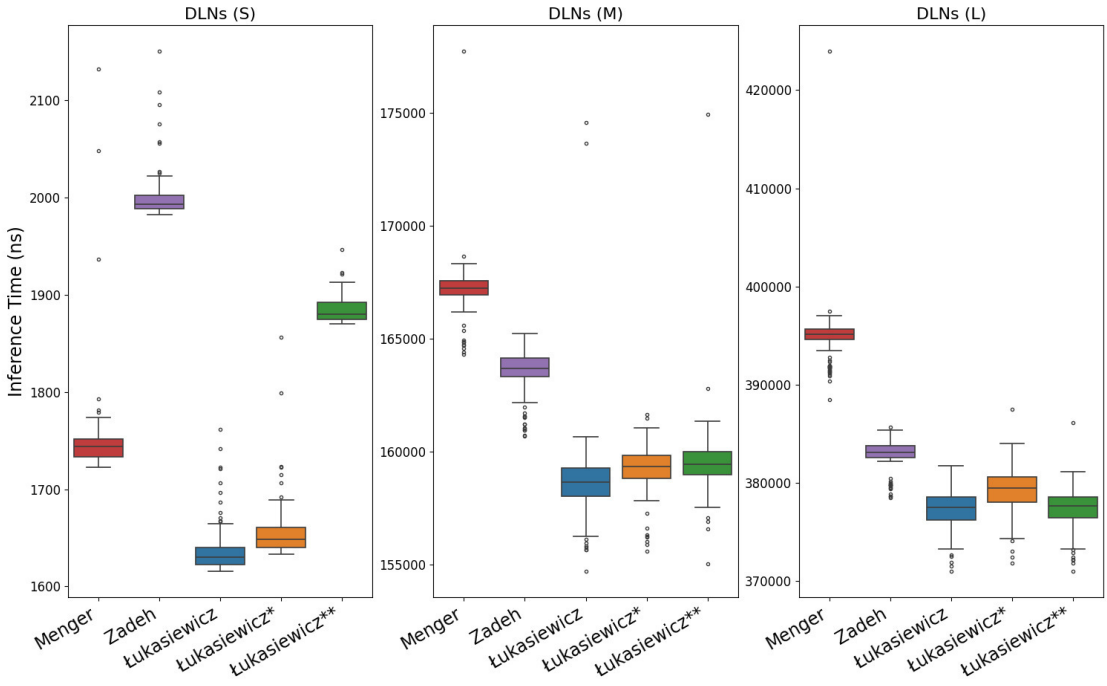

Fig. 5. Basic statistical analysis for CIFAR-10 dataset inference time (ns) results (lower is better)

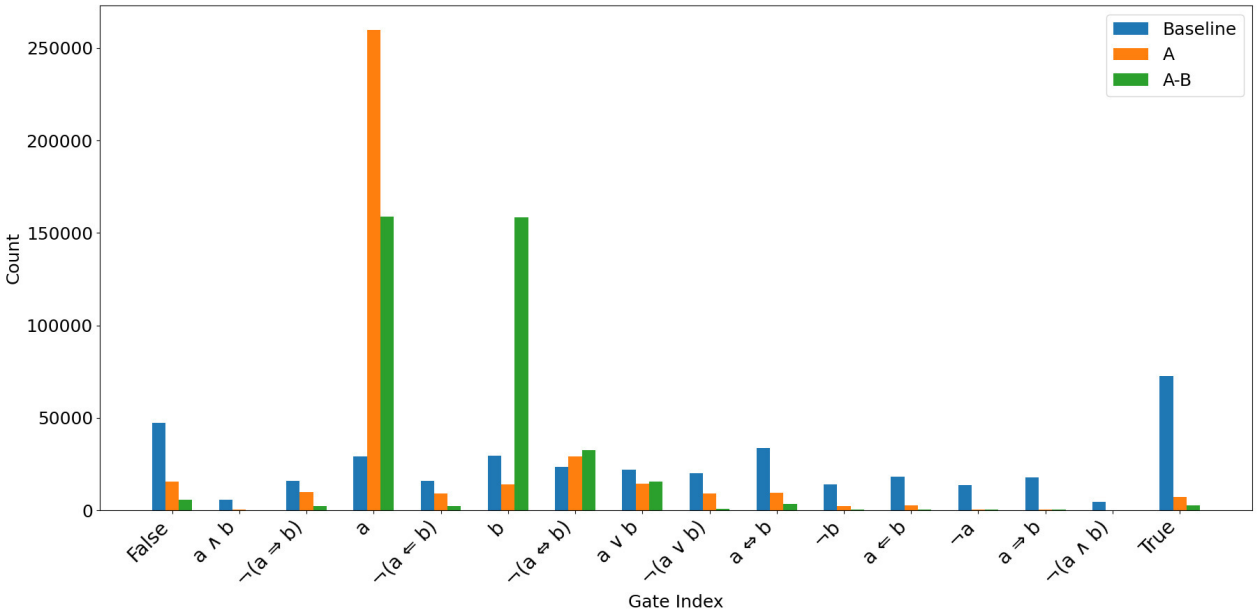

Fig. 6. DLNs$_{Ł}$, DLNs$_{Ł^*}$, DLNs$_{Ł^{**}}$ gate distributions in MNIST dataset

has probabilities $p_1 = 0.60$ and $p_4 = 0.40$ for two logic gates, deterministically selecting a gate at p_1 fails to capture the nuanced behavior expressed in the soft combination. This simplification may overlook critical interactions among the logic operators.

VI. Conclusions

We proposed a differentiable logic gate network based on a relaxation of classical logic gates using the Łukasiewicz T-norm. Our empirical findings support the hypothesis that the Łukasiewicz T-norm is not well-suited for gradient based training due to its gradient vanishing properties. This is consistent with observations reported in [10]. The experiments further demonstrate that encouraging better error propagation by biasing the weights of the computational units toward feedforward logic gates and avoiding the gates that can cause zeros in gradient significantly improves model accuracy and mitigates the gradient vanishing issue.

DLNs offer a distinct advantage over traditional neural networks in terms of interpretability. Due to the structural clarity, this facilitates direct inspection and tracing of information flow, making DLNs particularly suitable for applications in explainable artificial intelligence (XAI). Unlike standard neural networks, where interpretability often relies on post hoc analysis or surrogate explanations, DLNs provide intrinsic transparency through their architecture. This transparency reveals a recurrent pattern in trained DLN models: a disproportionately high number of units are configured as feedforward (identity) gates. While this contributes to computational efficiency and stable training dynamics, it also suggests a significant underutilization of the available computational capacity within the network. Many logic gate units effectively act as passthrough mechanisms, bypassing transformation or decision making roles.

Regardless of implementation details, differentiable logic gate networks generally require less memory and exhibit lower inference time compared to standard neural networks, highlighting their computational efficiency despite variable performance in accuracy. These findings underscore key differences across implementations of DLNs. While logic networks trained using Menger's T-norm may achieve higher accuracy, the Łukasiewicz based models exhibit faster inference times. This emphasizes the importance of careful design and evaluation when developing differentiable logic gate networks. In some applications, reducing inference time with a marginal decrease in accuracy may be preferable to higher accuracy but significantly slower performance.

Further performance gains in DLNs may be realized by optimizing the flow of information through structured and efficient connectivity patterns. One notable limitation in existing architectures is the underutilization of computational units, which can be mitigated by reusing logic elements across input features in a convolution like fashion [20] By enabling each compute unit to process multiple bit pairs in parallel rather than in a one-by-one manner, the network can exploit the capabilities of modern 64-bit arithmetic logic units (ALUs) on CPUs. This approach not only enhances the utilization of computational units in DLNs but also contributes to reducing computational overhead during inference. Introducing regularization strategies to constrain the weight vectors of computational units may help reduce discretization loss when translating from fuzzy to hard logic (Boolean). These offer promising directions for improving both the accuracy and efficiency of DLNs in practical applications.

Finally, while most medical machine learning studies focus on developing high-accuracy and computationally intensive models, DLNs offer a practical potential in low-latency, resource-constrained use cases. Applications such as oxygen blood saturation measuring or non-invasive glucose monitoring suggest alternative research directions for logic gate networks.

Acknowledgment

This paper presents results which will be presented as a part of master thesis of the first author prepare under the supervision of the second author. Authors would like to thank anonymous Reviewers for valuable comments and remarks which enabled to improve the paper.

***Abstract*—Process mining provides valuable insights by discovering process models from execution logs. However, its effectiveness depends heavily on high-quality, well-structured logs. Many real-world systems produce low-level, semi-structured logs lacking clear process identifiers, causing misalignment with their intended process models.**

This paper introduces a method for structuring raw event logs by segmenting event streams and mapping them to known processes. Using process traces from experienced users, we develop a model that infers process assignments in unstructured logs. Our approach is motivated by a modular enterprise system without predefined workflows, where dynamic processes generate low-level logs requiring interpretation.

We validate our method on a semi-synthetic business dataset and a fully synthetic dataset from PLG2. Our results demonstrate that trace segmentation improves process discovery, aligns logs with meaningful structures, and significantly enhances process mining in unstructured environments.

I. Introduction

PROCESS mining is a powerful methodology that uses event logs to gain insights into business processes, enabling organizations to analyze, monitor, and optimize their workflows. Traditionally, process mining relies on structured event logs, where each event is explicitly linked to a process instance identifier. However, in many real-world contexts, event logs are only semi-structured, lacking process identifiers yet containing timestamps, event types, and user identifiers. This limitation complicates the reconstruction of process execution and hinders effective process analysis.

This research addresses that challenge by presenting an approach to structure semi-structured event logs. Specifically, we assign process identifiers to raw event data by leveraging a set of ideal process traces performed by experienced users. These labeled traces, which include known process identifiers and types, serve as training data for a machine learning-based system. The trained model is then applied to raw event logs to infer process assignments and identify user activities linked to specific processes.

We explored a practical application of this approach in a modular enterprise management system provided to external entities. These entities use the system to execute diverse business processes spanning multiple modules. Because of the variability of clients, the heterogeneity of business processes, and the system's flexibility, incorporating process identifiers into the logs is not feasible from a business perspective. Therefore, our methodology relies exclusively on semi-structured data.

By implementing this approach, we provide a solution that enhances process mining capabilities in environments where structured event logs are unavailable. This research contributes to process mining by introducing a method for structuring semi-structured event logs, enabling more effective business process analysis, anomaly detection, and performance monitoring.

a) Replication Package: To facilitate reproducibility and further research, we provide a complete replication package containing code, data, and experimental scripts. It is publicly available at:

`https://github.com/ncusi/Segmentation_and_Process_Assignment_of_Semi-StructuredEvent_Logs`

The remainder of this paper is organized as follows. Section II discusses related work. Sections III and IV reviews necessary preliminaries on event logs, process mining, and similarity measures. Section V states the problem, and Section VI describes our methodology for structuring semi-structured event logs. In Section VII, we discuss our experimental design, and Section VIII presents the results. In Section IX, we assess threats to validity. Finally, we conclude and propose future directions in Section X.

A. Running Example (Motivation)

Consider a customer-support system where each event is logged as `[time, user, activity, ...]`. A typical log snippet might look like:

```
2025-05-10T09:12:03Z, alice, OpenComplaint, details
2025-05-10T09:14:21Z, alice, AssignAgent, agentId=42
2025-05-10T09:15:07Z, alice, ResolveComplaint, status=closed
2025-05-10T09:20:00Z, alice, OpenComplaint, details
...
```

Without a case identifier, it is unclear which `OpenComplaint` corresponds to which conversation. This can cause supervisors to miss abandoned requests or misattribute resolution times. To address this, we propose to reconstruct each case by matching segments of the event stream to known process templates.

This work was supported by the Regional Operational Programme of the Kuyavian-Pomeranian Voivodeship for 2014–2020 under the grant titled "Budowa zaplecza badawczo-rozwojowego w MGA Sp. z o.o."

II. Related Work

Workflow and process mining have been extensively studied. Classical surveys such as [1], [2], [3] provide a comprehensive overview. A critical challenge in this field involves deriving high-quality, structured event logs from raw, often semi-structured data sources. Our work sits at the intersection of several active research areas, including event-case correlation, trace segmentation, similarity-based activity matching, and process discovery under uncertainty.

A fundamental problem in process mining is event-case correlation inferring case identifiers when they are absent or ambiguous. This challenge has been addressed through various heuristics and model-aware approaches. For example, Helal and Awad [4] propose a runtime event correlation method that uses process models and task durations to group events into likely cases. Brzychczy et al. [5] introduce a rule-based approach for detecting case boundaries in time series data, leveraging domain-specific structural regularities.

The extraction of event logs from relational or unstructured sources has also been widely explored. Andrews et al. [6] present RDB2Log, a quality-aware, semi-automated log extraction framework. Hernandez-Resendiz et al. [7] extend this work by introducing techniques to convert relational data into XES-compliant event logs, facilitating downstream analysis.

The problem of reconstructing traces from flat event streams or system logs has been tackled through temporal and contextual grouping methods. In the domain of unstructured customer service data, Kecht et al. [8] apply natural language inference to extract structured traces from customer service conversations. Korzeniowski and Goczyca [9] propose an automated log-template generation method (SLT) and an interaction-extraction pipeline that discovers application-to-application dependencies in enterprise logs, demonstrating its utility on a large banking system. One of the earliest treatments of the segmentation problem appears in [10], where the authors propose an event correlation function to partition unstructured logs into coherent subsequences.

One of the earliest treatments of the segmentation problem appears in [10], where the authors propose an event correlation function to partition unstructured logs into coherent subsequences. Our approach similarly focuses on identifying process instances from flat user streams, using data-driven similarity and conformance models.

Sequence similarity measures have been applied in activity and behavior mining. Levenshtein similarity, in particular, has proved effective by Tax et al. in [11] for clustering and aligning activity sequences. To the best of our knowledge, although the Tversky similarity measure is widely used in set and pattern matching, it has not previously been applied to trace similarity in process mining. Our work leverages both Levenshtein and Tversky measures to enable efficient and flexible segmentation.

The challenge of multi-case event streams where multiple processes or objects interact has been identified by Martin et al. in [12] as a key limitation in traditional process mining. Recent methods under the umbrella of object-centric process mining [13], [14], [15] provide more expressive models, but they require richer data and frequently involve more complex analysis pipelines. Our work addresses a simpler setting where each user executes one process at a time, but case boundaries remain implicit and must be inferred.

Event log imperfections such as missing case identifiers, incomplete traces, or overlapping activities are well-documented threats to process analysis. Jans et al. [16] discuss the implications of log quality in auditing scenarios. Our method specifically targets one imperfection: the lack of case identifiers in user-specific event streams.

Streaming scenarios add complexity, requiring online segmentation and model updating. Burattin et al. [17] propose methods for control-flow discovery from live event streams. While their focus is on evolving process models, their incremental techniques are relevant to our goal of continuously analyzing user activity streams.

In contrast to prior work, we assume access to a small set of example traces per process and center our efforts on segmenting flat, user-specific event streams with no case identifiers. We combine prefix-based segmentation with syntactic and conformance-based similarity scoring, which allows us to reconstruct approximate process instances even under noisy or truncated conditions. Our results show that lightweight similarity functions outperform full model conformance for segmentation tasks, offering a practical balance between accuracy and efficiency.

a) Theoretical and Practical Implications:

- *Theory:* We introduce a novel combination of syntactic (Levenshtein, Tversky) and semantic (log skeleton) similarity within a unified segmentation framework. Our proofs of injectivity in activity encoding and the boundary properties of our similarity measures contribute formal insights for future process-mining research.
- *Practice:* The method integrates seamlessly with existing BPM tools (e.g., PM4Py) without modifying ERP system logs. Its lightweight shingle computations and XTructure-based regex checks enable real-time segmentation on production event streams.

III. Preliminaries

We follow standard process mining notation, as introduced in [18]. The goal of process mining is to derive meaningful insights into the execution of business processes from recorded event data. The key input for process mining is the *event log*, which captures sequences of events corresponding to the execution of individual process instances, referred to as *cases*.

A *trace* is a finite sequence of events that represents the observed execution of a single case. By comparing and analyzing these traces, we can uncover patterns, identify deviations, and evaluate performance characteristics of the underlying process.

A *process* P represents the system or workflow whose behavior we aim to analyze. In process mining, the focus is on gaining insights into the execution of P by studying event logs,

which contain traces that correspond to specific executions or instances of process P.

A. Event Logs and Process Mining

We now introduce the formal elements used to represent event data, traces, and structured event logs.

a) Events: Let AN be a finite set of *attribute names*, and let Val be the set of all possible attribute values. We introduce a special symbol $\perp$ (bottom), with $\perp \notin \mathsf{Val}$, to denote "undefined."

The universe of events is a (possibly infinite) set E. Each event $e \in E$ is described by a *partial* function

$$\pi_e \colon \mathsf{AN} \rightharpoonup \mathsf{Val}, \tag{1}$$

where the arrow $\rightharpoonup$ indicates that for some attribute names a the value $\pi_e(a)$ may be undefined (i.e. $\pi_e(a) = \perp$). Concretely, for every $e \in E$ and $a \in \mathsf{AN}$, we have $\pi_e(a) \in \mathsf{Val} \cup \{\perp\}$.

b) Conditions on Events: We impose the following two conditions on every event $e \in E$:

(A1) $\pi_e(time) \neq \perp$, meaning that every event has a timestamp.
(A2) There exists an attribute $a \in \mathsf{AN} \setminus \{time\}$ such that $\pi_e(a) \neq \perp$, meaning every event has at least one non-time attribute with a value not equal to $\perp$.

Definition III.1 (Event Stream)**.** *An* event stream *(or event table) ET is a finite sequence of events:*

$$ET = \langle e_1, e_2, \ldots, e_n \rangle, \quad e_i \in E, \tag{2}$$

such that there exists an attribute $a \in \mathsf{AN} \setminus \{time\}$ with $\pi_a(e_i) \neq \perp$ for all $i = 1, \ldots, n$.

c) Finite Sequences: In what follows, we adopt the standard definition of finite sequences using Kleene star notation. This notation, common in formal language theory, is used throughout this work to denote sequences (e.g., traces of events).

Notation III.2 (Kleene star)**.** *Given a set X, we define X^* to be the set of all finite sequences over X. Formally, each element of X^* is of the form $\langle x_1, x_2, \ldots, x_n \rangle$ for some $n \geq 0$ and $x_i \in X$. The empty sequence is allowed if $n = 0$.*

Let $\Sigma \subseteq \mathsf{Val}$ be a finite set of *activity names*, known as the *activity alphabet*. A *trace* is a finite sequence $\sigma \in \Sigma^* = \{\text{all finite sequences over } \Sigma\}$ representing the control-flow perspective of a case.

Definition III.3 (Case Identifier and Cases)**.** *Let $id \in \mathsf{AN}$ be a selected* case identifier *attribute. The set of cases in ET is defined as:*

$$\mathsf{Cases}(ET, id) = \{\pi_{id}(e) \mid e \in ET,\ \pi_{id}(e) \neq \perp\}. \tag{3}$$

Remark III.4. *Each element $c \in \mathsf{Cases}(ET, id)$ is interpreted as a distinct* case *of the process within ET. Concretely, "case" refers to the actual value c of the attribute id. In this way, $\mathsf{Cases}(ET, id)$ collects exactly those case-identifier values that appear in the event stream ET, ensuring each value corresponds to a unique case.*

Definition III.5 (Trace of a Case)**.** *Let $c \in \mathsf{Cases}(ET, id)$. Then the* trace of case c *is the unique sequence of events*

$$\pi_{trace}(c) = \langle e_1, \ldots, e_k \rangle \in E^* \tag{4}$$

satisfying:

i) For all i, $\pi_{id}(e_i) = c$. In other words, each e_i belongs to the case identified by c.
ii) The sequence $\langle e_1, \ldots, e_k \rangle$ is sorted by non-decreasing timestamp, i.e.

$$\pi_{e_1}(time) \leq \pi_{e_2}(time) \leq \cdots \leq \pi_{e_k}(time), \tag{5}$$

recalling that $e.a := \pi_e(a)$.
iii) $\{e_1, \ldots, e_k\} = \{e \in ET \mid \pi_{id}(e) = c\}$, so we include all *events of that case (no more, no fewer).*

Remark III.6. *For each $c \in \mathsf{Cases}(ET, id)$, the sequence $\pi_{trace}(c)$ is defined as the ordered list of all events $e \in ET$ for which $\pi_{id}(e) = c$, arranged in non-decreasing order of $time$.*

IV. Process Models, Event Logs, and Conformance Checking

A. Process Models

Definition IV.1 (Process Models)**.** *Let Σ be an* activity alphabet *(i.e., a finite set of symbols). Denote by $\mathcal{M}_P(\Sigma)$ the set (or universe) of all process models that describe the behavior of a specific process P and are defined over the activity alphabet Σ. These models belong to a given class $\mathcal{P}$ (e.g., Petri nets, BPMN models, etc.) relevant to this work. An element $M \in \mathcal{M}_P(\Sigma)$ is called a* process model *if it prescribes which traces over Σ are possible in the corresponding process.*

Remark IV.2. *Let P denote a particular business process (e.g. "Order Handling"), and let Σ be its activity alphabet. We write*

$$\mathcal{M}_P(\Sigma) \subseteq \mathcal{P} \tag{6}$$

to mean "the set of all models in the model class $\mathcal{P}$ that describe process P over Σ."

Here:

- *P is the specific process whose behavior we wish to capture.*
- *$\mathcal{P}$ is a* class of modeling formalisms *(for example, Petri nets, BPMN diagrams, log skeletons, etc.).*
- *$\mathcal{M}_P(\Sigma)$ is the subset of $\mathcal{P}$ consisting of those individual models that generate or accept exactly the traces of P over alphabet Σ.*

Definition IV.3 (Induced Language of a Model)**.** *For each process model $M \in \mathcal{M}_P(\Sigma)$, associate a* language $\mathcal{L}_P(M) \subseteq \Sigma^*$*, where Σ^* denotes the set of all finite sequences over Σ. Formally,*

$$\mathcal{L}_P(M) = \{w \in \Sigma^* \mid w \text{ is a possible execution of } M\}. \tag{7}$$

Thus, each $w \in \mathcal{L}_P(M)$ is a finite sequence of activities representing one possible execution of M.

B. Finite Multisets of Traces

Definition IV.4 (Finite Multisets of Traces)**.** *Let X be a set. A* finite multiset *over X is a function $N\colon X \to \mathbb{N}$ such that $\{x \in X \mid N(x) \neq 0\}$ is finite. We call $N(x)$ the* multiplicity *of x in the multiset N. We write $B(X)$ for the set of all finite multisets of elements of X.*

Notation IV.5 (Multisets of Traces)**.** *Since Σ^* is the set of all finite sequences over Σ, the set of all finite multisets of traces is denoted by $B(\Sigma^*)$. An element $L \in B(\Sigma^*)$ is a multiset of traces, where $L(\sigma) \in \mathbb{N}$ indicates the number of occurrences of the trace σ in L.*

C. Structured Event Log

Assume that events are drawn from a universe E, each event $e \in E$ being described by a partial function $\pi_e\colon \mathsf{AN} \rightharpoonup \mathsf{Val}$.

Definition IV.6 (Structured Event Log)**.** *Let $id \in \mathsf{AN}$ be a designated case identifier attribute. A* structured event log *is a finite set of case-trace pairs:*

$$L = \{(c_i, \pi_{trace}(c_i)) \mid c_i \in \mathsf{Cases}(ET, id)\} \subseteq \mathsf{Val} \times E^*, \quad (8)$$

such that for each pair $(c, \pi_{trace}(c)) \in L$, the corresponding trace

$$\pi_{trace}(c) = \langle e_1, \ldots, e_k \rangle \in E^* \quad (9)$$

satisfies:

(i) $\forall e_j \in \pi_{trace}(c)$ *we have* $\pi_{id}(e_j) = c$*;*
(ii) $\forall e_j \in \pi_{trace}(c)$ *we have* $\pi_{time}(e_j) \neq \perp$*;*
(iii) $\forall e_j \in \pi_{trace}(c)\ \exists a \in \mathsf{AN} \setminus \{time, id\}$ *such that* $\pi_a(e_j) \neq \perp$.

Remark IV.7. *Each element $(c, \pi_{trace}(c)) \in L$ represents a single case c together with its corresponding trace. Thus, a structured event log explicitly associates each case identifier with the complete, temporally ordered sequence of events belonging to that case. Specifically, the log has the following hierarchical structure:*

- *A finite set of case-trace pairs L;*
- *Each trace $\pi_{trace}(c) \in E^*$ is a sequence of events related to a single case c;*
- *Every event $e \in \pi_{trace}(c)$ has a timestamp, the associated case identifier c, and at least one additional meaningful attribute (e.g., activity, resource).*

Notice that each case identifier c_i appears exactly once in the set L.

From this structured event log, one can perform further abstraction steps, such as applying *event classifiers*, to derive a *simple event log* $L' \in B(\Sigma^*)$ suitable for control-flow analysis.

D. Process Models and Conformance Checking

When process models are available, conformance checking can be used to compare a candidate trace to a known process structure. This enables semantic similarity beyond syntactic matching, especially useful in process mining when control-flow behavior must be validated.

Let $\mathcal{L}_P \subseteq \Sigma^*$ be a set of example traces for a process P. From this set, we can derive a process model $\mathcal{M}_P(\Sigma)$ using one of several discovery algorithms:

- **Alpha Miner** [19]: Constructs a Petri net by detecting causal and concurrent relations from the event log.
- **Heuristics Miner** [20]: Enhances the Alpha Miner with frequency-based dependency filtering to handle noise.
- **Log Skeleton** [21]: Builds a constraint-based model capturing behavioral relations such as equivalence, always-before, and always-after.

Let $\sigma \in \Sigma^*$ be a trace and $\mathcal{M}_P(\Sigma)$ the process model discovered from $\mathcal{L}_P$. We evaluate how well σ conforms to $\mathcal{M}_P(\Sigma)$ using one of the following conformance techniques:

- **Token-Based Replay Fitness (TBR)** [22]: Evaluates trace fitness by simulating token movement in a Petri net. We use the PM4Py function `pm4py.conformance.fitness_token_based_replay`. This is applied to models discovered via Alpha Miner and Heuristics Miner.
- **Log Skeleton Conformance**: Computes trace fitness by comparing the trace to a log skeleton model using structural constraint diagnostics. We use: `pm4py.conformance_log_skeleton`.

While these model-based approaches capture process semantics, we also employ syntactic techniques that operate on string representations of event sequences. These methods allow for efficient trace comparison when no explicit model is available or required.

Process Discovery Configuration: All discovery was done with PM4Py v2.9.3:

- **Heuristics Miner:** `dependency_threshold=0.99, and_threshold=0.65, or_threshold=0.65, min_support=0.10`.
- **Alpha Miner:** `dependency_threshold=0.50` (PM4Py default).

These were chosen because Heuristics is noise-robust and frequency-based, whereas Alpha provides a simple, well-understood baseline.

E. String Representation and Similarity Measures

To support efficient and scalable process matching, we transform sequences of events into compact string representations that preserve their sequential structure. This enables the application of string-based similarity techniques, including shingling and character-edit distance.

a) Activity Encoding: To enable string-based similarity comparison, each activity in a trace is deterministically mapped to a fixed-length character code. This allows the transformation of activity sequences into strings over a finite alphabet.

Definition IV.8 (Activity Encoding)**.** *Let Σ denote the finite set of activity labels. Define an injective encoding function*

$$C\colon \Sigma \to \Gamma^n, \quad (10)$$

where Γ is a finite character alphabet, and $n \in \mathbb{N}$ is a fixed code length. The set Γ^n represents all possible strings of length n formed from alphabet Γ. This encoding assigns each activity a unique code of length n, but can be extended to $\widetilde{C}\colon \Sigma^* \to (\Gamma^n)^*$ by allowing any trace $\sigma = \langle a_1, \ldots, a_k \rangle \in \Sigma^*$ to be represented as a concatenated string $\widetilde{C}(\sigma) = C(a_1) \cdot C(a_2) \cdot \cdots \cdot C(a_k) \in (\Gamma^n)^*$, where $\widetilde{C}(\langle\rangle)$ is the empty string and $\cdot$ (dot) denotes concatenation.

Remark IV.9 (Practical Consideration:)**.** *In our implementation, we use $n = 3$ and define*

$$\Gamma = \{A, B, \ldots, Z, a, b, \ldots, z, 0, \ldots, 9\}, \tag{11}$$

with $|\Gamma| = 62$. This provides a sufficiently large encoding space for typical process alphabets, ensuring compactness and facilitating downstream operations like shingling.

We now formalize the injectivity of the activity encoding in the following proposition:

Proposition IV.10 (Uniqueness Preservation)**.** *Let $C\colon \Sigma \to \Gamma^n$ be an injective encoding function as defined. Then, for any two distinct traces $\sigma_1, \sigma_2 \in \Sigma^*$, their encoded representations $\widetilde{C}(\sigma_1)$ and $\widetilde{C}(\sigma_2)$ are distinct.*

Proof: We prove the claim by induction on the length k of the sequences.

Base Case: For $k = 0$ (the empty sequence), $\widetilde{C}(\langle\rangle)$ is the empty string, and the claim holds trivially.

Inductive Step: Assume the statement holds for all sequences of length k. Let

$$\sigma_1 = (a_1, a_2, \ldots, a_k, a_{k+1}) \quad \text{and} \quad \sigma_2 = (b_1, b_2, \ldots, b_k, b_{k+1})$$

be sequences in Σ^{k+1} such that

$$\widetilde{C}(\sigma_1) = \widetilde{C}(\sigma_2). \tag{12}$$

Writing

$$\widetilde{C}(\sigma_1) = C(a_1) \cdot C(a_2) \cdots C(a_k) \cdot C(a_{k+1}), \tag{13}$$

and

$$\widetilde{C}(\sigma_2) = C(b_1) \cdot C(b_2) \cdots C(b_k) \cdot C(b_{k+1}), \tag{14}$$

since each $C(a_i)$ is a fixed-length string (of length n), the concatenation is unambiguous. Comparing the first n characters of both sides gives

$$C(a_1) = C(b_1). \tag{15}$$

Because C is injective, it follows that

$$a_1 = b_1. \tag{16}$$

Removing the first code from both concatenations, we then have

$$\widetilde{C}(a_2, \ldots, a_{k+1}) = \widetilde{C}(b_2, \ldots, b_{k+1}). \tag{17}$$

By the induction hypothesis,

$$(a_2, \ldots, a_{k+1}) = (b_2, \ldots, b_{k+1}). \tag{18}$$

Thus,

$$(a_1, a_2, \ldots, a_{k+1}) = (b_1, b_2, \ldots, b_{k+1}). \tag{19}$$

This completes the inductive step, and therefore $\widetilde{C}$ is injective. ∎

b) Shingling: To capture local sequential patterns within the encoded string representation of traces, we apply a fixed-length sliding window operation known as *shingling*.

Definition IV.11 (Shingle Set)**.** *Let $x \in (\Gamma^n)^*$ be an encoded string representation of a trace, and let $k \in \mathbb{N}$ be a fixed window size. The* shingle set *of x is defined as:*

$$\text{Shingle}(x, k) = \{x[i : i+k-1] \mid 1 \le i \le |x| - k + 1\}, \tag{20}$$

where $|x|$ is the length of the string x, and $x[i : i + k - 1]$ denotes the substring of length k starting at position i.

c) Similarity Measures: We employ two types of similarity functions to compare string-encoded traces or their shingle sets.

Definition IV.12 (Similarity Measures)**.**

(1) ***Tversky Similarity.***
Let $A, B \subseteq \mathcal{U}$ be finite sets (e.g., sets of shingles). Define the similarity function:

$$\tau(A, B) := \frac{|A \cap B|}{|A \cap B| + \alpha|A \setminus B| + \beta|B \setminus A|}, \tag{21}$$

where $\alpha, \beta \ge 0$ are tunable parameters (commonly $\alpha = 0$, $\beta = 1$), and $|X|$ denotes the cardinality of set X. This asymmetric variant prioritizes recall over precision, treating containment as more significant than a symmetric match. Consequently, if one set is entirely contained within the other, the similarity measure reaches its maximum value, reflecting a strong inclusion relationship.

(2) ***Levenshtein Similarity.***
Let $a, b \in (\Gamma^n)^*$ be two encoded strings, and let $d(a, b) \in \mathbb{N}_0$ be the Levenshtein distance between them (i.e., the minimum number of single-character insertions, deletions, or substitutions needed to transform a into b). A common normalization for Levenshtein similarity is:

$$\ell(a, b) := 1 - \frac{d(a, b)}{\max\{|a|, |b|\}}. \tag{22}$$

Here, $\ell(a, b)$ yields 1 if the strings are identical and 0 if $d(a, b)$ is as large as the maximum length of the two strings (e.g., $d(a, b) = |b|$ if $|a| = 0$). This approach is widely used due to its intuitive interpretation.

Remark IV.13 (Alternative Normalization)**.** *In some applications, one might prefer a custom normalization to give special treatment to length differences or partial overlaps (e.g., subtracting $\big||a| - |b|\big|$ from $d(a, b)$). If that approach is desired, it must be clearly justified. For example, one might wish to penalize purely length-based mismatches less than mismatches in the overlapping region of the two strings. In such cases, the*

similarity function could be:

$$\ell'(a,b) := \begin{cases} 1, & \text{if } d(a,b) - \big||a| - |b|\big| = 0, \\ \frac{1}{d(a,b) - \big||a| - |b|\big|}, & \text{otherwise.} \end{cases}$$

However, this version is less common and can be confusing without a thorough explanation of the motivation behind it.

This is a well-known property of the above-mentioned similarity measures:

Theorem IV.14 (Boundary Conditions of Similarity Functions)**.** *For any two encoded strings $a, b \in (\Gamma^n)^*$:*

- *The Levenshtein similarity $\ell(a,b)$ satisfies $\ell(a,b) = 1$ if and only if $a = b$, and $\ell(a,b) = 0$ when the number of edits equals the length of the longer string (i.e., maximally different).*
- *For the Tversky index $\tau(A,B)$ (with a typical setting of $\alpha = 0$ and $\beta = 1$), it holds that $\tau(A,B) = 1$ if and only if $B \subseteq A$.*

Remark IV.15. *The normalization in $\ell(a,b)$ subtracts the minimum number of edits required to align the lengths of a and b, isolating the structural mismatches. This ensures that string pairs differing only in length are treated as more similar than those with substantive internal edits.*

V. Problem Statement

In many enterprise systems, users interact with the platform through various interfaces, executing tasks that correspond to different business processes (e.g., onboarding a customer, handling a complaint, reviewing a case). These interactions are recorded as user-specific event streams. However, in most operational settings, this data is captured in a semi-structured format: each event includes the time it occurred, the action taken (activity name), and the user who performed it, but does not explicitly identify which process or case it belongs to.

Let $ET_u = \langle e_1, e_2, \ldots, e_n \rangle$ denote the event stream of a user $u \in \mathsf{Val}$, where each event $e_i \in E$ satisfies:

$$\pi_{user}(e_i) = u, \quad \pi_{time}(e_i) \neq \bot, \quad \pi_{event}(e_i) \in \Sigma. \tag{23}$$

This stream captures a chronologically ordered sequence of user interactions, i.e.

$$\pi_{e_1}(time) \leq \pi_{e_2}(time) \leq \cdots \leq \pi_{e_n}(time), \tag{24}$$

but without any case identifier. As such, it is considered a *semi-structured event stream*.

To support process-aware analysis and monitoring, the business needs to understand which processes a user was involved in, when they started and ended, and what behavior was exhibited within each instance. For example, a supervisor may wish to assess whether an employee followed the correct handling procedure for different types of customer requests.

To enable this, the organization provides, for each process type P_i, $i = 1, \ldots, k$, a set of example traces:

$$\mathcal{L}_{P_i} \subseteq \Sigma^*, \tag{25}$$

which have been collected in a controlled environment. In this setting, expert users executed process cases one at a time, with clear boundaries between cases. These labeled traces serve as templates for recognizing process behavior in live, unstructured event streams.

Definition of the Process-Specific Alphabet. We define

$$\Sigma_{P_i} = \bigcup_{\sigma \in \mathcal{L}_{P_i}} \{\text{activities in } \sigma\} \subseteq \Sigma, \tag{26}$$

i.e., Σ_{P_i} is the set of activity labels that appear in the example traces for process P_i, $i = 1, \ldots, k$.

Several challenges arise in this scenario:

- **Overlapping Activities:** Activities (event names) may appear in multiple processes, i.e. $\Sigma_{P_i} \cap \Sigma_{P_j} \neq \emptyset$ for some $i \neq j$, $i, j = 1, \ldots, k$.
- **Multiple Instances:** The same user u may execute multiple process instances across different process types.
- **Sequential, Possibly Abandoned Executions:** The user performs processes sequentially (never in true parallel) but may abandon one and start another.

a) Objective: Given a semi-structured event stream ET_u and example trace sets $\mathcal{L}_{P_1}, \ldots, \mathcal{L}_{P_k}$ for known processes, the goal is to approximate the user's activity history in terms of which processes were executed and when.

We aim to segment the user stream into trace-like subsequences that are likely to correspond to process instances. Each segment is matched to one of the known processes based on similarity. At this stage, our goal is not to produce a perfect segmentation, but rather a **good estimation** of the user's behavior from a process-centric perspective.

VI. ProcessMatcher Overview

This section introduces **ProcessMatcher**, a two-phase framework for real-time detection of known business processes in semi-structured event streams. In the **offline modeling** phase, curated example traces are filtered for noise and standardized; events are encoded into fixed-length tokens and passed through XTructure to learn hierarchical prefix regexes, alongside a k-shingle extractor that produces compact signatures. Optionally, a light-weight conformance analysis validates pattern quality. In the **online segmentation** phase, incoming streams are partitioned into candidate segments and matched against the learned regexes and shingle signatures using fast approximate similarity measures, yielding polynomial-time detection.

A. Methodology

The ProcessMatcher pipeline comprises three stages:

(a) **Training Data Preparation.** Noisy or incomplete traces are removed; activity labels are normalized; events are encoded as fixed-length character codes (Definition IV.8).
(b) **Pattern Learning.** Normalized sequences feed XTructure for prefix generalization, producing a regex $\mathcal{R}_i$ for each process, and into the k-shingle extractor to compute each process's signature.

(c) **Parameter Tuning.** A grid search over shingle length k, similarity threshold θ, and prefix depth p is conducted on a held-out validation set to jointly optimize classification accuracy and runtime.

This clear separation of phases ensures reproducibility, modularity, and straightforward extensibility of individual components.

B. *XTructure* Primer

`XTructure` [23] is a lightweight, polynomial-time structure for learning and representing the syntax of semi-structured strings (e.g., activity-encoded traces) as a DFA-equivalent model. Unlike full regular-expression inference—which is NP-hard—`XTructure` builds a concise pattern model in a single pass over the data. Its design comprises three hierarchical layers:

1) **Symbol Layer:**
   - Records empirical counts of characters at each position.
   - Groups symbols into character classes (e.g. digit, letter) via a χ^2 homogeneity test when possible, or else enumerates the top-k symbols to cover a fixed fraction of observations.
2) **Token Layer:**
   - Splits input strings on delimiters into tokens.
   - Represents each token as a sequence of symbol-layer distributions, capturing both fixed and variable-length substrings within that token.
3) **Branch Layer:**
   - Accommodates multiple syntactic variants (e.g. date formats) by maintaining up to a bounded number of token-sequence "branches."
   - Creates a new branch when an incoming example's *fit score* exceeds a threshold for all existing branches, then performs branch-and-merge to enforce a global branch limit.

Once learned in a single (streaming) pass, an `XTructure` instance supports:

- **Serialization** to a compact, human-readable regular expression (an OR of its branches).
- **Sampling** of synthetic examples by drawing from its learned symbol distributions.
- **Comparison** to other patterns (regular expressions or other `XTructures`) via Monte Carlo sampling and CLT-based fitness estimation.

This combination of expressivity and efficiency makes `XTructure` orders of magnitude faster than general regex-inference techniques, yet sufficiently powerful to capture all finite-language structure observed in real-world enterprise event data.

C. ProcessMatcher Architecture

To identify instances of a process within semi-structured event streams, we introduce the `ProcessMatcher`, a modular component designed to match candidate trace segments to a known process P using a combination of syntactic and conformance-based techniques.

For each known process P_i, $i = 1, \ldots, k$, a separate matcher instance M_i is constructed using its set of example traces $\mathcal{L}_{P_i} \subseteq \Sigma^*$. The matcher learns a lightweight representation of the process, which is then used to detect and score segments within user-specific event streams.

The approach is divided into two phases: an offline *process modeling phase*, and an online *stream segmentation and matching phase*.

D. Parameter Specification

Default values and allowable ranges for the key parameters of `ProcessMatcher`:

- **Shingle length k:** default $k = 6$, range $4 \leq k \leq 10$.
- **Similarity threshold θ:** default $\theta = 0.8$, range $0.5 \leq \theta \leq 0.95$.
- **Prefix length for `XTructure`:** default $p = 18$ characters (i.e., 6 activity codes $\times$ 3 chars each), range $9 \leq p \leq 30$.
- **Tversky parameters (α, β):** default $(\alpha, \beta) = (0, 1)$, both non-negative.

The method `contains_process`(S) works as follows:

1) Compute the set of shinglets (character k-grams) from the encoded string S:
$$A = \mathrm{Sh}(S). \tag{27}$$
2) For each reference shinglet set $\mathrm{Sh}(\sigma_j)$ in $\mathcal{L}_{P_i}$, $i = 1, \ldots, k$, set
$$B = \mathrm{Sh}(\sigma_j), \tag{28}$$
then compute the Tversky index $\tau(A, B)$ given by Equation (21).
3) If any $\tau(A, B) \geq \theta$, return `true`; otherwise return `false`.

E. *XTructure* Explanation

We construct a prefix regular expression $\mathcal{R}_i$, $i = 1, \ldots, k$, from observed prefixes of length p using `XTructure`:

1) Initialize: `xpref = XTructure(max_branches=2)`.
2) For each trace $\sigma \in \mathcal{L}_{P_i}$, $i = 1, \ldots, k$, extract `prefix =` σ`[:p]` and call `xpref.learn_new_word(prefix)`.
3) After all prefixes are learned, `str(xpref)` yields a regex, e.g. `(ABC|XYZ)`, capturing the generalized prefix patterns.

F. Phase 1: Offline Process Modeling

Given example traces $\mathcal{L}_{P_i}$ of process P_i, $i = 1, \ldots, k$, the `ProcessMatcher` performs the following:

1) **Process Signature Construction:** A process signature is built using *shinglets*, which are sets of overlapping substrings (character n-grams) extracted from traces in $\mathcal{L}_{P_i}$, $i = 1, \ldots, k$. This signature enables fast approximate matching using the Tversky index during online presence checking.
2) **Prefix Pattern Learning:** The initial prefixes of example traces are used to learn a regular expression $\mathcal{R}_i$ that characterizes common process starts. This is done using the

`XTructure` algorithm [23], which generalizes prefixes into a compact, discriminative regex by merging observed patterns. This allows rapid detection of potential case beginnings within user streams.

3) **Optional Process Model Discovery:** If desired, a process model $\mathcal{M}_{P_i}(\Sigma)$ (e.g., Petri net, log skeleton) is discovered from $\mathcal{L}_{P_i}$ using PM4Py, $i = 1, \ldots, k$. This enables conformance-based fitness computation as an alternative to syntactic similarity.

G. Phase 2: Online Stream Segmentation and Matching

Given a user event stream $ET_u = \langle e_1, e_2, \ldots, e_n \rangle$ with $\pi_{user}(e_i) = u$ and no case identifier, we segment and label the stream with likely process instances using the following steps, executed per process matcher M_i, $i = 1, \ldots, k$:

1) **Process Presence Check:** Using the shinglet-based Tversky similarity, we determine whether the user stream contains any segment sufficiently similar to $\mathcal{L}_{P_i}$, $i = 1, \ldots, k$. This acts as a fast filter to skip irrelevant streams.
2) **Prefix Detection:** We apply the learned prefix regular expression $\mathcal{R}_i$ over the stream to detect potential case start positions. Each match defines a candidate window boundary.
3) **Similarity Scoring:** For each candidate segment $\sigma \in \Sigma^*$ (bounded by prefix matches), we compute its similarity to the process using one of several methods:
   - **Tversky Index (default)**: uses shinglets and the Tversky index.
   - **Levenshtein Distance**: normalized edit distance.
   - **Conformance Fitness**: if a process model $\mathcal{M}_{P_i}(\Sigma)$, $i = 1, \ldots, k$, is available, token-based replay or log skeleton diagnostics can be used (e.g. Conformance checking based on Log Skeleton Conformance, Heuristics Miner, and Alpha Miner).
4) **Instance Counting:** The number of likely process instances within the stream is estimated by summing the similarity scores of detected segments. Only segments whose score exceeds a predefined threshold are counted.

This approach offers a flexible, efficient method for process instance identification from flat user event streams, enabling reconstruction of activity histories even in the absence of explicit case identifiers.

Remark VI.1. *Set $\mathcal{M} = \{M_1, \ldots, M_k\}$ denotes a set of process matchers, each of which corresponds to a* different *known procedure (process) $P_i = M_i.\texttt{process}$, $i = 1, \ldots, k$. In other words, for each process P_i we have a separate matcher M_i assigned.*

Remark VI.2. *In Algoithm 1 we use function `EncodeStreamAsActivityString` which is a procedure that transforms a user's event stream ET_u into a string where each character (or substring) represents a specific activity. In practice, for each event $e_i \in ET_u$, this function:*

- *Retrieves the value of the attribute corresponding to the activity (for example, $\pi_{event}(e_i)$).*
- *Maps this value to a fixed character code according to a predefined activity encoding function $C \colon \Sigma \to \Gamma^n$. As defined earlier in Definition IV.8, C is an injective function that assigns each activity $a \in \Sigma$ a unique fixed-length code $C(a) \in \Gamma^n$, where Γ is a finite character alphabet and n is a fixed code length.*
- *Concatenates these codes to construct a string S, which represents the ordered sequence of activities in the stream.*

This string representation enables further operations, such as prefix detection, stream segmentation, and the calculation of similarity measures between segments of events, which are crucial in the process matching algorithm.

Algorithm 1 Segmenting a User Event Stream Using Process Matchers

Require: User event stream $ET_u = \langle e_1, e_2, \ldots, e_n \rangle$
Require: Process matchers $\mathcal{M} = \{M_1, \ldots, M_k\}$
Ensure: Set of labeled trace segments $\mathcal{T}$

$\mathcal{T} \leftarrow \emptyset$
$S \leftarrow$ EncodeStreamAsActivityString(ET_u)
for all $M_i \in \mathcal{M}$ $(i = 1, \ldots, k)$ **do**
  if M_i.contains_process(S) **then**
    $B \leftarrow M_i$.prefix_regex.find_all_matches(S)
    for $j = 1$ **to** $|B| - 1$ **do**
      $\sigma \leftarrow S[B[j] : B[j+1]]$
      $s \leftarrow M_i$.process_similarity(σ)
      if $s \geq \theta$ **then**
        $\mathcal{T} \leftarrow \mathcal{T} \cup \{(\sigma, M_i.\texttt{process})\}$
      end if
    end for
    $\sigma \leftarrow S[B[-1] :]$
    $s \leftarrow M_i$.process_similarity(σ)
    if $s \geq \theta$ **then**
      $\mathcal{T} \leftarrow \mathcal{T} \cup \{(\sigma, M_i.\texttt{process})\}$
    end if
  end if
end for

return $\mathcal{T}$

Proposition VI.3. *Assume that a user event stream ET_u is formed by the concatenation of process traces*

$$ET_u = \sigma_1 \cdot \sigma_2 \cdots \sigma_k, \tag{29}$$

where each $\sigma_i \in \mathcal{L}_P$ (the set of example traces for process P). Suppose further that the learned prefix regular expression $\mathcal{R}$ recognizes exactly the starting positions of any trace in $\mathcal{L}_P$. Then, applying the `ProcessMatcher` segmentation algorithm to ET_u will recover the segments $\sigma_1, \sigma_2, \ldots, \sigma_k$ exactly.

Proof: Let S be the string representation of ET_u obtained by the encoding function $\widetilde{C}$. By assumption, each process instance σ_i corresponds to an encoded substring $s_i = \widetilde{C}(\sigma_i)$

and the overall stream is

$$S = s_1 \cdot s_2 \cdots s_k. \tag{30}$$

By the correctness of the learned prefix regular expression $\mathcal{R}$, for every i we have:

$$\mathcal{R}(S[i]) = \text{true} \quad \Longleftrightarrow \quad i \text{ is the starting position of some } s_j.$$

Let $B = \{i_1, i_2, \ldots, i_k\}$ be the set of positions where $\mathcal{R}$ matches in S, with $i_1 = 1$. The segmentation algorithm then forms segments by taking

$$\sigma_j = S[i_j : i_{j+1} - 1] \quad \text{for } j = 1, \ldots, k-1, \tag{31}$$

and $\sigma_k = S[i_k : |S|]$. Since the stream S is exactly $s_1 s_2 \cdots s_k$, it follows that for each j,

$$\sigma_j = s_j = \widetilde{C}(\sigma_j). \tag{32}$$

Thus, the segmentation algorithm recovers the exact boundaries of each process instance ■

Corollary VI.4. *The segmentation algorithm will always find all process instances if the assumptions about prefixes are satisfied.*

VII. Experiment Design

To evaluate the proposed segmentation method, we conduct two experiments: one semi-synthetic (based on real process traces) and one fully synthetic (generated via process simulation). Both experiments follow a similar structure: we assume that for each process P_i a set of example traces $\mathcal{L}_{P_i}$, $i = 1, \ldots, k$, is available, and we generate user event streams by concatenating process executions. We evaluate the model's ability to identify the underlying process structure from these unstructured streams.

A. Process Setup and Trace Sources

- **Experiment 1 Semi-Synthetic (Real Traces):** We use two real-world processes from our business use case. For each process, we obtain at least 5000 example traces (of various events long). These are used both as reference traces for training the `ProcessMatcher` and as source traces for simulating user activity.
- **Experiment 2 Fully Synthetic (Simulated Processes):** We generate five synthetic process models using the PLG2 framework [24]. For each model, we generate:
  - 20 ideal (noise-free) traces for $\mathcal{L}_{P_i}$, $i = 1, \ldots, k$.
  - 100 perturbed traces using PLG2's default noise settings (e.g., skipped steps, inserted noise, reordering).

B. User Event Stream Synthesis

In both experiments, we generate synthetic user event streams by randomly sampling process traces (ideal or perturbed) and concatenating them. For each user event stream ET_u^{syn}, we apply the following:

- Each user stream contains a random number of process executions (between $[10, 40]$).
- For each selected execution:
  - In the semi-synthetic setting, traces are sampled from the set of ideal real-world traces.
  - In the fully synthetic setting, traces are sampled from the pool of perturbed traces generated via PLG2.
- In the semi-synthetic setting, sampled traces may be further perturbed by truncating their suffix, simulating premature termination of process instances.
- For each synthetic user event stream, we retain the ground truth segmentation: the start and end positions of each process instance, and the corresponding process identity.

This setup yields realistic, unstructured user streams while preserving the ability to evaluate segmentation and classification performance precisely.

C. Iteration and Distribution Variation

To evaluate robustness across different usage distributions, we repeat each experiment over multiple iterations. In each iteration, the probability of selecting each process is varied, producing both balanced and skewed distributions of process executions within streams. This simulates scenarios ranging from uniformly active users to users focused on one or two dominant processes.

D. Evaluation Metrics

Since the true structure of each synthetic user event stream is known, we evaluate performance using the following metrics: **Process Classification Accuracy:** Proportion of predicted segments assigned to the correct process. Together, these experiments allow us to evaluate both the accuracy and robustness of the method under realistic variability and controlled noise.

VIII. Results and discussion

We evaluate our method in two benchmark scenarios, described in Section VIII-A: a semi-synthetic setting based on real process traces, and a fully synthetic setting using processes generated by PLG2 [24]. In both scenarios, we assess the performance of different similarity scoring functions within the segmentation pipeline described earlier. Table I summarizes the accuracy and average processing time for each similarity scoring function, evaluated across both experimental settings.

Each experiment reports both classification accuracy how accurately the detected segments match the correct process and processing time per user stream (in seconds). We compare five similarity or conformance scoring approaches:

- **Levenshtein Similarity**: Edit distance over string-encoded traces.
- **Tversky Similarity**: Shingle-based set similarity.
- **Log Skeleton Conformance** [21]: Constraint-based model alignment.
- **Heuristic Miner + Token Replay** [20]: Frequency-based process model with token-based fitness scoring.
- **Alpha Miner + Token Replay** [19]: Basic Petri net discovery and replay fitness.

TABLE I
RESULTS: ACCURACY AND TIME ON ALL FUNCTIONS ON BOTH EXPERIMENTAL SETUPS

Scoring Function	**Fully Synthetic**		**Semi-Synthetic**	
	Accuracy (%)	Time (s)	Accuracy (%)	Time (s)
Levenshtein Similarity	**99.56**	**81.03**	**100.0**	**7.12**
Tversky Similarity	**91.14**	**94.55**	**99.43**	**14.10**
Log Skeleton Conformance	**79.55**	**11242**	**88.79**	**812**
Heuristic Miner + TBR	**60.8**	**13170**	**53.32**	**1214**
Alpha Miner + TBR	**65.5**	**5572**	**14.78**	**1273**

A. Discussion

As shown in Table I, Levenshtein similarity consistently achieves the highest segmentation and classification accuracy across both experimental settings. It also outperforms the other methods in terms of runtime efficiency, making it a strong default choice.

Tversky similarity, while slightly less accurate, remains competitive and exhibits favorable performance in both accuracy and runtime. Both syntactic similarity methods clearly outperform conformance-based approaches in this segmentation task.

Among the token-replay-based methods, the Log Skeleton model achieves the best accuracy but still falls short of the syntactic techniques. Heuristic Miner and Alpha Miner produce lower classification accuracy and efficiency, suggesting that these models are not well suited to trace-level segmentation in the absence of case structure.

a) Takeaway: For user stream segmentation tasks without explicit case identifiers, syntactic similarity-based scoring functions (Levenshtein and Tversky) provide the best balance between accuracy and computational cost.

IX. THREATS TO VALIDITY

Although the proposed approach shows promising results, several limitations must be acknowledged. We discuss potential threats to validity across four standard dimensions: internal, external, construct, and conclusion validity.

a) Internal Validity: The segmentation algorithm relies on synthetic or semi-synthetic user streams, where process boundaries are derived from known trace sets and artificially injected noise. While this setup allows for precise ground-truth evaluation, it may not capture all forms of real-world user behavior, such as interleaved or overlapping process executions. In addition, prefix learning and similarity scores are sensitive to parameter choices (e.g., shingle length, Tversky threshold), which may influence the outcomes.

b) External Validity: Our experiments are conducted on two real processes and five simulated ones. Although these span diverse scenarios, they may not fully reflect the complexity or variability of processes in other domains (e.g., healthcare, manufacturing). Moreover, user behavior in production systems can involve more irregular or non-sequential activity patterns, which are not entirely accounted for by our current assumptions.

c) Construct Validity: We measure segmentation accuracy using a ground truth built from ideal and truncated traces. However, the assumption that a truncated trace still represents a meaningful process instance may not always hold. Furthermore, our evaluation treats the best-matching process as correct, even though some traces could be ambiguous due to shared activities across multiple processes.

d) Conclusion Validity: Our evaluation metrics focus on classification accuracy and runtime per stream, providing clear comparative insights but excluding statistical significance testing. In future work, we plan to incorporate cross-validation, error analysis, and statistical robustness measures to reinforce confidence in the observed performance differences.

X. CONCLUSION AND FUTURE WORK

In this paper, we propose a method for segmenting semi-structured user event streams into process instances using a combination of syntactic similarity and model-based conformance checking. Our approach leverages known example traces for each process to construct lightweight matcher components that identify candidate segments based on learned prefixes and similarity scoring. This design enables segmentation in scenarios where case identifiers are absent and activities may overlap across processes.

We evaluated the method in two settings: (1) a semi-synthetic setup based on real-world processes, and (2) a fully synthetic benchmark generated with PLG2. The results show that syntactic similarity measures particularly Levenshtein and Tversky offer strong accuracy while remaining computationally efficient. Although semantically richer, model-based conformance approaches performed less effectively in this segmentation context, likely because of their sensitivity to partial traces and noise.

a) Future Work: Several extensions of this work are planned. First, we intend to address the issue of overlapping or conflicting segment assignments when multiple processes match the same trace window. Incorporating overlap resolution strategies such as greedy selection based on similarity scores or probabilistic modeling could yield cleaner segmentations. Second, we aim to evaluate the method on real, unlabeled user data in production environments, with expert annotations serving as ground truth. Finally, integrating sequence models (e.g., RNNs or transformers) or embedding-based representations may further enhance trace similarity beyond symbolic encoding.

Our findings highlight the potential of combining simple syntactic techniques with process mining insights to extract structured information from unstructured logs, thereby enabling more interpretable and process-aware user behavior analysis.

b) Prospects for Sequence Models: In future work, we plan to explore sequence-model approaches (RNNs, LSTMs, or Transformers). This would allow us to:

- Learn continuous embeddings of event sequences instead of manual character codes.
- Capture long-range temporal dependencies and non-linear patterns inherent in complex processes.
- Support online adaptation via incremental fine-tuning on newly observed streams without retraining shingle sets or XTructure models.

These extensions should improve robustness to noise and adaptivity to evolving business logics.

***Abstract*—Low-code/no-code (LCNC) platforms promise low-barrier access to software development, increased efficiency, and programming with little to no code. This paper explores whether it is really possible to create software without writing code and with little programming knowledge. Using a systematic literature analysis, we lay a foundation for future research on the skills needed by citizen developers using LCNC tools in corporate and public-sector contexts. Our analysis of 58 articles identifies three key skill categories: hard skills, such as programming and working with APIs; soft skills, such as communication and collaboration; and domain-specific knowledge. However, challenges exist in the upskilling process. Additionally, generative AI (GenAI) shows potential to expand LCNC capabilities. Nevertheless, the intersection of LCNC and public-sector transformation remains underexplored, highlighting the need for deeper studies focused on sector-specific challenges, use cases, and long-term adoption.**

***Index Terms*—Low-Code, No-Code, Citizen Developer, Skills, Innovations, Digital Transformation.**

I. Introduction

INFORMATION and communication technology (ICT) has undergone rapid changes over the decades—particularly in the last ten to fifteen years—and has had a far-reaching impact on almost every aspect of daily life. These changes and the associated digitalization have caused not only companies but also public institutions, organizations, and private individuals to increasingly shift their activities to the digital world. Industrial and commercial companies are increasingly utilizing the potential of e-commerce to tap into new market opportunities; public authorities are turning to e-government to reduce the administrative workload; and social interactions are increasingly shifting to the digital world of social networks. Even a large proportion of global financial transactions would be almost inconceivable without the use of ICT [1] As a result, digitalization and digital transformation are far more than just buzzwords: they have become decisive strategic competitive factors. Digitalization is fundamentally changing the economy and society and shaping the way we live and work in unprecedented ways [1], [2].

For companies, digitalization opens up the opportunity to develop and establish new business models. In order to actualize these new business models as well as to remain competitive in global markets, the majority of companies must deal with the challenges of digitalization and digital transformation. Relatedly—and also revealed by the global crises of recent years—a critical characteristic of successful companies has been their ability to adapt quickly to external circumstances, respond to external factors, and become a learning organization that quickly adopts innovations, with a focus not only on efficiency but also on resilience. Digitalization can be a key enabler of innovations and competitiveness; organizations that do not push ahead with digitalization risk falling behind, because they may struggle to adapt to changing market conditions and external factors [3], [4].

Digitalization has been a central topic in the private sector for many years and is now often considered an integral part of business operations. At the same time, digitalization is also of great importance for public administrations, because administrations are often in contact with citizens, work with many people, and link infrastructure; therefore, the efficiency of administration has an impact on cities and municipalities [5]. Public administrations also face digitization challenges and pursue the goal of improving their own processes. Specifically, there is a fundamental need for e-government services among the German population, as the range of services on offer is too limited: according to the Bitkom survey examining people's preferences regarding administrative services, 79% of respondents consider Germany to be lagging behind regarding digitalization, and 78% would like to see significantly more investment in the digitalization of public administration. The use of artificial intelligence (AI) is particularly in demand: 61% are in favor of public authorities using AI [6]. Accordingly, given these aspects, the focus of research on digitalization should not only be on companies but also on public institutions with numerous stakeholders.

In addition to the organizational perspective on the benefits of digitalization, there are also macroeconomic and labor-market implications. Automation and the implementation of software systems can reshape the labor market, leading to job

losses and the creation of new job profiles. The difference between the demand and the supply of qualifications leads to a skill mismatch; it remains uncertain whether there will be enough new jobs for those who have lost their jobs, and whether they will be able to fill these positions. Those with medium qualifications are particularly at risk [7]. One thing is certain: there will be "losers of automation"—i.e., people who are unable to find a job in the long term or who are forced to take underpaid jobs in other regions [8].

The effects of skill mismatch are already evident in Germany, where small and medium-sized enterprises (SMEs) and public authorities are struggling to recruit qualified professionals despite the fact that the number of registered unemployed people far exceeds the number of vacancies [9], [10]. In 2023, German SMEs reported significant difficulties in filling information technology (IT) positions, with 149,000 roles remaining unfilled—almost twice the number of vacancies recorded five years earlier. According to a Bitkom study examining the shortage of IT professionals across all sectors, Germany could face a shortage of around 663,000 IT professionals by 2040 [11]. Therefore, organizations must take action to avoid the problems associated with a shortage of skilled employees. Introducing personnel development measures could help bridge the gap between the qualifications on offer and those in demand [7].

Innovative approaches such as citizen development (CD) and low-code/no-code (LCNC) are well suited to this purpose. People without in-depth IT knowledge could use LCNC platforms to automate processes and develop applications. Through CD, companies can reduce the workload of IT departments by enabling employees in other departments to develop their own solutions, thereby reducing their dependence on IT professionals [12], [13]. CD and LCNC can also help drive and promote digitalization by making use of existing employees.

Given the current developments and the opportunities that LCNC can provide for companies and governmental institutions, this paper focuses on two research questions (RQs) that address the tension between the usage of LCNC and the necessary employee skills and competencies:

RQ1: What competencies are discussed in the literature in the context of LCNC platforms?

RQ2: What is the state of research on LCNC platforms in the public sector, and what skill profiles and implementation challenges are discussed in this context?

To answer these research questions, our paper proceeds as follows. After the introduction, a short theoretical background related to LCNC platforms is provided; this includes information about the typical users of these platforms, as well as their advantages and disadvantages. Thereafter, in Section 3, we describe our methodology (namely systematic literature review) to make our analysis reproducible. Section 4 presents the results of the literature review, highlighting the most discussed topics. In Section 5, we discuss the results of our analysis from different perspectives. Finally, the paper concludes with a summary and an outlook regarding potential further research steps.

II. Theoretical Background

A. Citizen Developers

Employees in specialist departments have in-depth domain knowledge and are familiar with the workflows in their respective areas. However, due to a lack of formal programming education and skills, they are often unable to develop digital solutions on their own. At the same time, IT departments that could take on such tasks are often overloaded [13], which leads to a backlog of innovation-related activities due to a focus on operational tasks [14].

In this context, the term citizen developers is employed to denote individuals who lack extensive expertise in IT yet employ platforms to automate processes and develop applications. These people are guided by platforms, which are toolboxes containing the necessary tools for creating customized applications.

B. Low-Code/No-Code Platforms

LCNC platforms are visual development environments that enable users to build software applications and automate workflows with little to no coding experience. The platforms provide users with a graphical user interface (GUI), where they can choose from available elements—such as buttons or application programming interface (API) calls—which can be visually combined through drag-and-drop into ready-to-use software [12].

While NC platforms require no programming knowledge, LC platforms require a little programming knowledge to make applications more flexible. With LC, existing modules can be extended with the user's own code [15].

Another important feature of LCNC platforms is that they not only provide support for visual programming and handle the entire application lifecycle, but they also typically provide integrated tools for the deployment process. They also can enable collaboration between software developers in terms of distributed work [16].

Transferring selected development work to citizen developers reduces the need for expensive IT expertise [17]. CD relieves the strain on scarce IT capacity, as implementations can be distributed across more resources. In particular, this reduces technical dependencies on IT departments; as a result, professional developers can focus on more strategic and value-adding tasks [18].

LCNC platforms combine declarative programming and model-driven development with visual interfaces, making software development more user-friendly and efficient [18]. These advantages have led to their high adoption among non-technical users looking to leverage their strengths. However, professional developers are skeptical about using LCNC platforms, which they consider to be inferior to traditional programming tools [19], [20].

C. Advantages and Challenges of LCNC Platforms

The advantages of LCNC platforms are well documented in the literature. One particularly interesting feature of such platforms is that they have a very low barrier to entry for non-programmers. This has led to the democratization of software development, whereby more people can develop, which in turn enables companies to benefit from new, fast prototypes and innovations [21], [19]. Furthermore, according to expert assessments, LCNC application development can in some cases be at least twice as fast as traditional code-based development [17]. Response times to customer feature requests are also reduced due to faster implementation and shorter delivery times and cycles. Such platforms also emphasize the high agility of development processes. Overall, using LCNC platforms can lead to increased efficiency and productivity, thus saving costs [17], [18], [12]. Additionally, technical training and CD initiatives form a key part of LCNC platforms: targeted training and education programs introduce employees to basic and advanced digital skills, thereby helping companies to boost the digital literacy of their entire workforce [18].

On the other hand, the literature also highlights some challenges associated with LCNC platforms. These include difficult-to-estimate licensing costs, which nevertheless can be justified by faster development processes and potential resource savings related to expensive IT specialists [17], [22]. A bigger challenge is vendor lock-in, which has been highlighted by several authors. Users are tied to the platform manufacturers of their chosen platform, making it difficult to transfer solutions to another platform and thus reducing flexibility [17], [18], [22]. Therefore, it is important to choose the right LCNC platform; otherwise, the investment costs will be too high. Companies experience the difficulty of choosing the right LCNC platform from dozens of providers. To this end, a systematic approach can be adopted to address this challenge [22].

The last aspect that is often discussed is the quality dimension. To start, there are always concerns about data protection and IT security. Although certain security standards can be met or even enhanced by LCNC platforms, a significant number of citizen developers lack the necessary knowledge to ensure secure development. Additionally, these platforms can be hard to debug, because the underlying code is typically generated by the platform's developers and is not directly accessible to users, making it difficult to identify and maintain issues [17]. Opinions on data protection vary: some see advantages, while others warn of risks, particularly when citizen developers create applications [20].

D. Institutionalization and the Rise of LCNC

According to reports by Gartner and Forrester, the market for LCNC is growing year on year. These market research companies predict that this market will continue to grow as a result of the ongoing digital transformation, which is accelerating the demand for software while at the same time leading to skill shortages in the IT sector. As outlined above, as new digital products and services emerge and new markets are developed, the demand for digital skills rises. In an effort to reduce costs and increase efficiency while meeting the growing demand for software, organizations are increasingly institutionalizing LC solutions within their IT departments [23], [24]. This means that LC solutions are used by IT companies to develop and deliver professional software solutions for their customers. This results in the acceleration of the distribution of LCNC. Therefore, the LCNC market will continue to grow and reach a volume of $50 billion by 2028. The fact that larger providers of LCNC platforms are being bought by corporations such as Siemens also indicates the relevance of this topic [25].

Given the growing importance of LCNC platforms, especially regarding organizational usage, it is important to understand which providers are currently available on the market.

E. Overview of LCNC Vendors

To classify technology providers, especially in markets that are rapidly changing and growing, Gartner has developed a methodology for categorizing IT providers into four distinct categories. The measurement of various factors—such as geographical strategy, marketing strategy, business model, and innovative strength—contribute to the assessment of "completeness of vision." Other criteria—such as customer experience, product or service quality, responsiveness to market changes, and operational performance—are used to measure the "ability to execute" [26]. By combining these two dimensions, Gartner categorizes vendors into four groups: "Leaders," "Challengers," "Visionaries," and "Niche Players."

- Leaders are highly competitive, have a strong market presence, possess a clear vision, demonstrate strong ability to execute, and are well positioned for the future. According to the Gartner report on LCNC from 2024, the following vendors are classified as Leaders: Mendix, OutSystems, Microsoft, Appian, ServiceNow, and Pegasystems.
- Challengers can also execute well today and may even dominate large market segments, but they do not have a clear vision of where the market is heading or they fail to respond to emerging trends. Challenger LCNC vendors include Oracle, Salesforce, and Zoho.
- Visionaries are companies with a clear vision of the future and an understanding of market trends, but they are not yet executing well or their products' features are not stable enough. The following vendors are classified as Visionaries: SAP and Retool.
- Niche players, such as Creatio and Newgen, focus successfully on a small part of the market or a specific geographical region. They may be a suitable choice for particular use cases or industries, but they do not yet match the breadth nor innovation of the other categories.

III. Methodology – Systematic Literature Review

Our literature review follows the approach of Webster and Watson [27]. The details of our methodology and the individual steps can be found in Fig. 1. The review consists of three main steps: literature search, topic identification, and analysis. In the first step, keywords and operators are used to identify the relevant literature. The second step involves identifying relevant topics. The final step consists of a detailed analysis of the literature and central topics. We selected relevant databases, defined the inclusion and exclusion criteria, documented the search process, and ultimately stored the identified literature in the Zotero literature management program

A. Phase 1 – Literature Search

We considered various databases and selected the following as sources: IEEE Xplore, ACM DL, and Springer Link. For titles, we used the search terms "low-code" and "no-code" along with additional keywords, such as "digital transformation" and "citizen developer," to achieve more precise results. Since the search functions in the individual databases are structured differently, we adapted the search fields depending on the database: in IEEE, we searched across all metadata; in ACM, within all abstracts; and in Springer Link, using the "with all the words" function.

The first phase of the literature search, which entailed a broad search, was carried out in November 2024. The time frame was set for 2019–2024 to ensure that the research was up to date. Sources with a high degree of relevance to the topic requirements were selected.

During the screening process, titles were first analyzed for their relevance. This was followed by in-depth reviews and summaries. Only German- and English-language sources were considered. Papers such as workshop documents, short articles, and articles without full-text access were excluded from the evaluation. After Zotero removed the duplicates, we were left with 151 articles, which provide a solid foundation for further research in the field of LCNC. However, in order to gain a better overview of certain topics, we narrowed the sample even further for our analysis.

The second step of the literature search involved conducting a targeted search guided by the research questions, particularly with regard to competencies (RQ1) and challenges in the public sector (RQ2). This step occurred in March 2025. The remaining articles were screened once more; in addition, further relevant articles were searched using backward and forward searches in accordance with the method described by [27]. We analyzed the papers until no new concepts emerged. In total, the steps in phase 1 led to the identification of 58 relevant papers that were analyzed in detail in the subsequent phases of our literature review. A complete list of these 58 papers is available upon request from the authors.

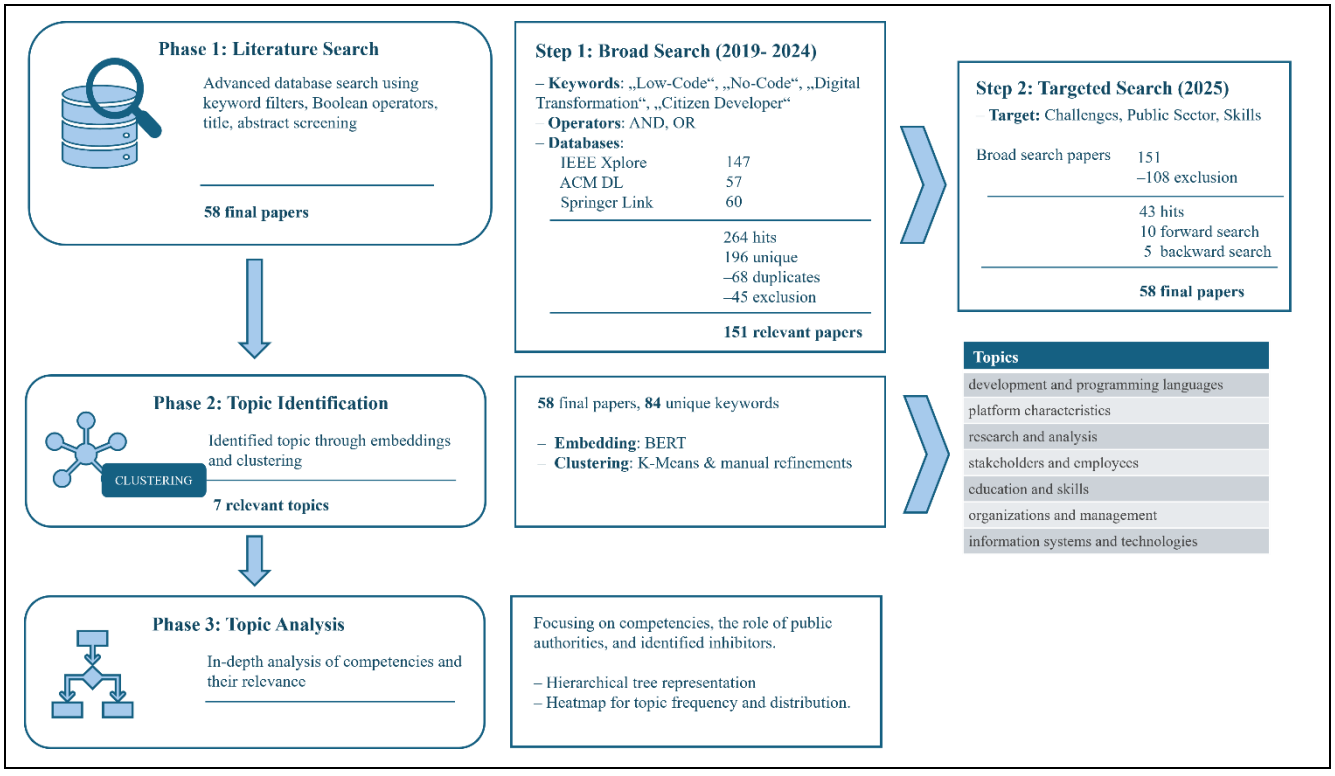

Fig. 1. Overview of the Three Steps of the Methodological Approach

B. Phase 2 – Topic Identification

During the screening of titles and abstracts, suitable keywords from the databases, as well as keywords identified manually, were entered for each article to enable subsequent classification. Recurring keywords were identified and organized by topic. However, these keywords had different levels of abstraction, which made further analysis difficult; therefore, an attempt was made to make the levels of abstraction more similar by combining some keywords into generic terms. As there were 84 keywords, an automatic clustering method was initially employed, which was then supplemented by our own review.

Python and the KNIME Analytics Platform were utilized for the data analysis, especially to analyze keywords, clusters, and frequencies, as well as to create tables. Additionally, we incorporated D3.js into our workflows for the purpose of displaying the tree structure of keywords. We also used the Seaborn Python data visualization library to create a heatmap. Token-level embeddings were created using the Bidirectional Encoder Representations from Transformers (BERT) bert-base-uncased model to evaluate the semantic similarity of keywords. BERT is a state-of-the-art language representation model that captures the contextual meaning of terms based on how they are used in natural language; although the model is frequently used to analyze entire sentences, it can also be used to understand specific keywords. As BERT does not require labeled data, it allows us to apply unsupervised clustering without the need for manual annotations. The classical k-means clustering algorithm was then applied, with varying numbers of clusters, to identify coherent term groups [28]. The analysis produced the best results with seven clusters, which were then manually checked and optimized.

C. Phase 3 – Topic Analysis

In order to gain more detailed insights into thematic trends, an analysis was conducted to determine which articles covered which topics. This made it possible to identify both gaps in content and potential trends. A heat map (see Fig. 2) was used for this purpose, with individual articles shown on the x-axis and the thematic clusters shown on the y-axis. The heat map depicts which topics dominate the literature and which are underrepresented. Each cell contains a number indicating how many aspects of a particular cluster are covered in the respective article. This facilitates the identification of thematic foci and research gaps at a glance.

Another tool used to represent the clusters is a hierarchical tree structure. This is particularly well suited for visualizing subordinate concepts and highlighting thematic connections, dependencies, and analysis paths. The tree displays the main topics at the top level, the subcategories at the second level, and the individual keywords (including the number of times they are mentioned in the analyzed papers) at the bottom level.

Finally, a concept-centered method based on Webster and Watson [27] was used to systematically synthesize the authors' findings and positions on specific, relevant concepts.

IV. Results

This section presents the results of the keyword and thematic analyses, which were based on a concept matrix comprising 58 articles on LCNC platforms. First, each article was assigned to relevant keywords, and then the keywords were grouped into overarching thematic clusters. In total, 84 unique keywords were extracted, with 518 mentions across all papers. Several keywords with the same meaning but different spellings were standardized.

The results of the literature review are presented in three visual formats: a heatmap, two tables, and a hierarchical tree diagram. The heatmap (see Fig. 2) illustrates the seven main thematic clusters and their distributions across the selected articles; the x-axis shows the unique article numbers in ascending order (i.e., from article 1 to article 58) and the y-axis shows the clusters, or subject areas, sorted by how often they were mentioned in articles. The frequency with which each cluster was mentioned is indicated by a number in the cell at the intersection of the cluster and paper number. Table I contains these clusters, the numbers of articles in which these topics were mentioned, the corresponding keywords, and the number of times each keyword appears in the papers. Table II shows the most and least frequently used keywords. The hierarchical tree diagram (see Fig. 3) groups keywords into thematic clusters based on their contextual relationships; each level has its own color to aid in distinguishing between them. In Fig. 3, we have chosen to omit certain individual clusters—i.e., platform characteristics, research analysis, and development and programming languages—so that the illustration fits into our article; however, the full illustration is available upon request.

A. Topic Coverage across Articles

As shown in Fig. 2 and in Table I, the seven thematic clusters are:

- #1 information systems and technologies,
- #2 development and programming languages,
- #3 education and skills,
- #4 platform characteristics,
- #5 organizations and management,
- #6 stakeholders and employees, and
- #7 research and analysis.

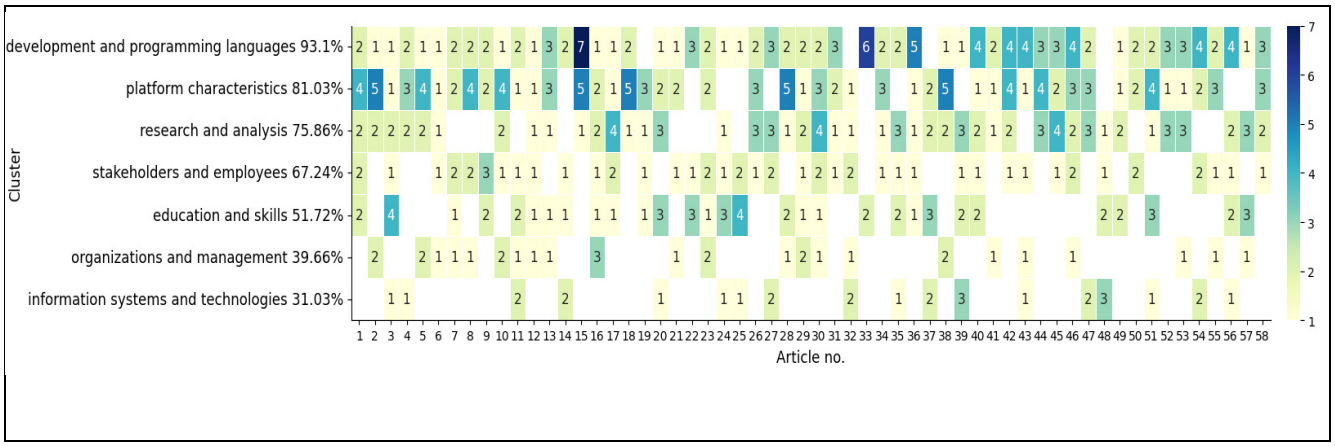

Fig. 2. Heatmap of Topic Coverage Across Articles

TABLE I.
TOPICS, ASSOCIATED KEYWORDS, AND FREQUENCY OF OCCURRENCE

No.	Cluster	Article Count	Keywords with Occurrences Count
#1	information systems and technologies	18	information systems (9), artificial intelligence (7), integration (5), data handling (4), IoT (2), connectors (1), machine learning (1)
#2	development and programming languages	54	low-code (51), software development (20), no-code (16), rapid application development (6), model-driven engineering (6), traditional development (5), programming languages (4), prototyping (3), domain-specific language (3), testing (2), devops (2), generators (1), mobile applications (1), digital process automation (1), paradigm (1), visual programming (1), automation (1), design to code (1)
#3	education and skills	29	skills (21), education (12), skills shortage (12), re- and upskilling (5), learning (5), experiential learning (1), authentic learning (1)
#4	platform characteristics	47	challenges (30), platform (21), drivers (19), fundamentals (9), forecast (8), adoption (7), security (5), recommendations (4), quality (4), inhibitors (3), classification (3), taxonomy (2), features (2), architecture (1), technical roles (1)
#5	organizations and management	24	companies (10), organization (4), governance (3), management (2), job crafting (2), work system (2), resource demand theory (1), business unit development (1), project management (1), agile methodology (1), socio-technical theory (1), decision making (1), manufacturing (1), public administrations (1), paradox theory (1), product line (1)
#6	stakeholders and employees	39	democratization (21), citizen developer (18), innovations (7), employees (3), employee-driven innovation (2), stakeholders (1), job roles (1)

A notable finding is that *development and programming languages* (cluster #2) dominates, with a frequency of 93.1%, followed by *platform characteristics* (cluster #4) with 81.03%. Cluster #7, *research and analysis,* shows which articles explicitly mention the type of method or research approach used (75.86%). The clusters *education and skills* (#3, 51.72%), *organizations and management* (#5, 39.66%), and *information systems and technologies* (#1, 31.3%) are significantly less represented.

Table I illustrates the distribution of the 58 articles across the seven theme clusters; for each cluster, the table shows the number of articles in which each topic is addressed. The corresponding keywords are listed in descending order of frequency (provided in parentheses). The number of keywords per topic vary: across all topics, *development and programming languages* (#2) contain the highest number of unique keywords (18), while *education and skills* (#3), *information systems and technologies* (#1), and *stakeholders and employees* (#6) include only 7 keywords.

As shown in Table I, *development and programming languages* (#2) is the most frequently addressed cluster, with 54 mentions across the articles. The most frequently mentioned keywords in this cluster are “low-code” (51), “software development” (20), and “no-code” (16). This cluster and its keywords are followed by *platform characteristics* (#4, 47 articles); the most frequent keywords here are “challenges” (30), “platform” (21), and “drivers” (19). The third most represented cluster is *research and analysis* (#7), with 44 mentions across the articles. The most frequent keywords in this cluster are “conceptual” (36), “use case” (22), and “survey” (8). The least addressed clusters are *organizations and management* (#5, 24 articles) and *information systems and technologies* (#1, 18 articles).

Fig. 3 provides an overview of our classification structure through a hierarchical tree representation of topics and keywords. The seven thematic clusters form the basic components for either keywords or subcategories, as certain keywords are connected to more specific subtopics. For example, *education and skills* (#3) has been divided into the "skill demand" subcategory—with the keywords "skills", "skill shortage", and "re- and upskilling"—and the subcategory "learning approaches"—with the keywords "experimental learning", "learning" and "authentic learning"—as well as the keyword "education". The cluster *platform characteristics* (#4) relates to fundamental platform properties, such as "architecture" and "features", and comprises the subcategory "categorization" with the keywords "classification" and "taxonomy". Other clusters have a similar structure of branches, subcategories, and keywords.

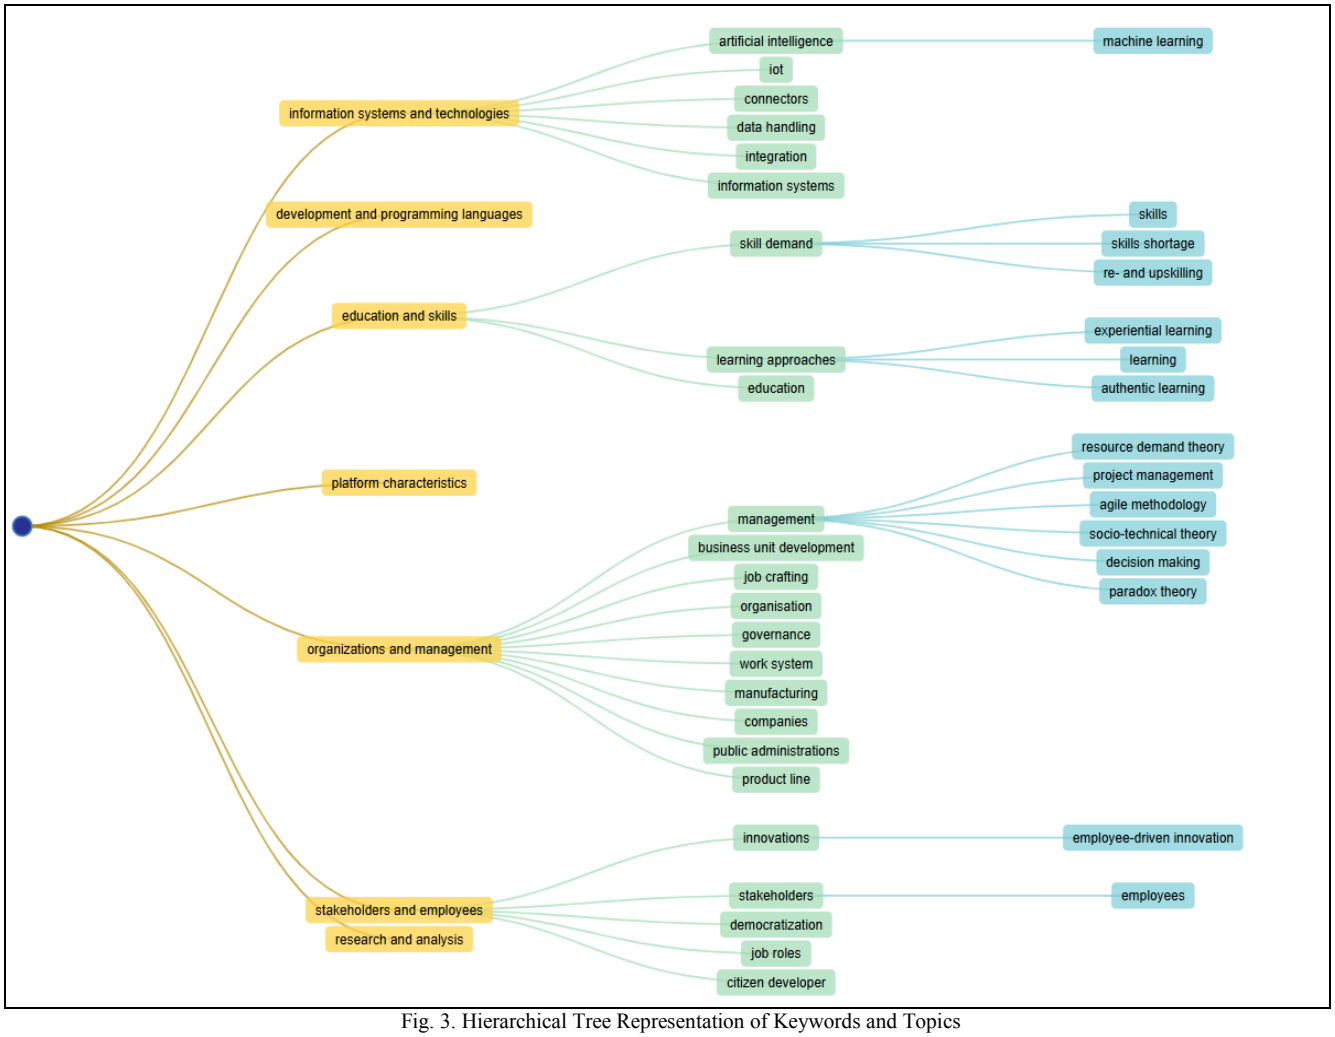

Fig. 3. Hierarchical Tree Representation of Keywords and Topics

B. Keywords' Frequency

A keyword analysis was conducted to better elucidate the thematic focus of the selected literature. An overview of the 15 most- and least-frequently occurring keywords found in the selected publications is shown in Table II. Notably, approximately 35.7% of all keywords were mentioned only once.

Interestingly, the keyword "skills" first appeared in 2021, after which it has continuously increased (2021=2, 2022=5, 2023=6, 2024=10, 2025 (January–May)=3). Notably, the related term "re- and upskilling" did not appear until 2022. "Low-code" was mentioned significantly more often than "no-code", with 51 mentions compared to 16. Frequently discussed topics included challenges related to LCNC, platform characteristics, software development drivers, and information systems—keywords with strong technical focus. The keywords "citizen development" (18), "democratization (21)", and "skills" (21) also appeared frequently, as did "education" and "skills shortage" (both with 21 mentions).

In contrast, non-technical aspects were rarely mentioned. For example, terms like "agile methodology" and "project management" appeared only once; notably, "public administration" and "manufacturing" were also mentioned only once each.

TABLE II.
MOST AND LEAST FREQUENTLY USED KEYWORDS IN THE ANALYZED LITERATURE

Most frequently occurring keywords		Least frequently occurring keywords	
Keyword	**Frequency**	**Keyword**	**Frequency**
low-code	51	project management	1
conceptual	36	agile methodology	1
challenges	30	socio-technical theory	1
use case	22	decision-making	1
skills	21	manufacturing	1
platform	21	public administration	1
democratization	21	paradox theory	1
software development	20	product plan	1
drivers	19	stakeholders	1
citizen development	18	job roles	1
no-code	16	task analysis	1
education	12	empirical study	1
skills shortage	12	expert interviews	1
companies	10	hackathon	1
information systems	9	model	1

V. DISCUSSION

A. Overview of General Findings

An important observation concerning the results was that the two most frequent clusters were technical. The strong concentration of keywords in these clusters indicates that most of the literature focuses on the technical foundations of LCNC platforms. This finding aligns with previous literature reviews in this context, which also found that the majority of papers concentrate on the technical aspects of LCNC platforms [20]. Less prevalent terms—particularly regarding skills, organizational context, and emerging technologies—highlight areas that may be underexplored, suggesting potential directions for further research.

The cluster research and analysis show that conceptual approaches and use cases are particularly common. This indicates that current research is primarily focused on developing fundamental ideas and describing specific applications. More empirical investigations would be useful for obtaining a more comprehensive picture: while many works present practical examples (i.e., use cases), systematic studies that quantify these experiences are much rarer.

Most articles include keywords from multiple clusters, reflecting the interdisciplinary nature of LCNC research. On average, each article contributes to 4.4 clusters, indicating that LCNC platforms are examined from multiple perspectives simultaneously.

B. Competencies, Skills, Education (RQ1)

The skills topic has gained noticeable momentum in recent years, reflecting the growing relevance of competency-related aspects in the context of LCNC platforms.

In general, the skills and competencies of citizen developers can be classified into two areas: hard skills and soft skills [29]. Elshan et al. [30] add a third dimension of business or domain expertise (which we combine with soft skills in the article).

Many training programs are aimed at professional developers. In contrast, citizen developers would benefit more from "knowledge nuggets" [29], which address specific knowledge deficiencies without overwhelming citizen developers. Knowledge nuggets are small, focused learning units that fill specific topic or skill gaps in a concise and accessible format. Citizen developers certainly require technical competencies, but only those relevant to their specific fields of application, and these can be conveyed in the form of courses, presentations, and short videos. It is important to ensure that these materials are tailored to citizen developers. Currently, most offerings still focus on professional software developers, and they unfortunately rarely meet the needs of citizen developers, who need concrete, relevant, bite-sized pieces of knowledge for their development [22]. Accordingly, proper didactic concepts should be taken into account [29].

Although LCNC minimizes entry barriers to software development, employees still need some technical skills to work with LCNC efficiently. The most commonly identified hard skill is basic programming knowledge [30], [29]: authors emphasize proficiency in LCNC, data management and analytics, familiarity with integration technologies and APIs, general IT knowledge, an understanding of technical requirements, knowledge of business processes (domain), and design knowledge.

As mentioned by Bernsteiner et al. [29], individuals with strong technical skills often still fail in LCNC projects due to the lack of soft skills. One of the key responsibilities of citizen developers is coordinating and communicating with the various stakeholders involved in the process. Therefore, interpersonal skills and the ability to communicate between multiple stakeholders are crucial for citizen developers. To this end, reskilling and upskilling initiatives should not focus only on technical aspects, but also on soft skills. Another four important soft skills were also emphasized: problem-solving, communication and collaboration, adaptability and flexibility, and initiative and self-motivation. In contrast to professional developers, citizen developers benefit especially from skills like team understanding, user comprehension, and creativity, as well as business skills including domain expertise, an understanding of business processes, and project management [30].

In response to RQ1:

The literature identifies three main areas of competence for citizen developers: *hard skills*, such as IT knowledge, programming (e.g., basic programming skills), and working with integrations and API; *soft skills*, such as communication and collaboration; and *domain-specific business knowledge*. Technical, communication, and domain-specific skills are equally important for implementing CD. Difficulties arise with the learning process: it is not particularly limited, but citizen developers should be taught differently than IT professionals. To this end, learning processes based on targeted knowledge nuggets can help close gaps relevant to their work context.

C. Governmental Authorities (RQ2)

The keyword distribution shows that the dominant discourse is centered around technical foundations, skills, and the broad application of LCNC platforms in the private sector, even though the search was not limited to this domain.

Of the articles on LCNC platforms, only one addresses the public sector directly: Gialitakis et al. [31]. This study highlights the potential for the broader use of LCNC tools in the digitalization of bodies of government authority, and it suggests wider application to demonstrate its feasibility. In that article, the researchers analyzed the characteristics of several low-code development platforms available on the market, and they pointed to well-known technical challenges that are not specific to the public sector. They limited their focus to vendor lock-in, lack of interoperability with other systems, lack of flexibility in custom logic or integrations, and security concerns. Subsequently, a system that supports business process model and notation (BPMN) was selected, and a five-step approach was conceptualized. The proposed methodology—spanning BPMN modeling to database design, user interface creation, optional scripting in procedural language/structured query language (PL/SQL), and the integration of process models into the application—was devised for use in both business and governmental contexts, with the objective of facilitating the implementation of applications for workflow-based processes. To demonstrate the practical application of the concept, the authors implemented a case study: following consultation with the Greek government, the researchers selected a public service process (specifically, the reimbursement of travel expenses) for digitization, which they subsequently undertook. The researchers demonstrated that the implementation of such an application was not only feasible with LCDP but also that the digital process now took one to three days, in comparison to twenty days for the in-person process.

The objective of the present study was to demonstrate the feasibility of implementing public service processes in low-code development platforms, with the goal of highlighting the potential for developing process-driven applications in this domain. This approach has been demonstrated to reduce the need for extensive coding methods and is accessible to individuals without formal computer science degrees. Consequently, this approach has the potential to facilitate digital transformation in public administrations by streamlining developer cycles, minimizing costs, and leveraging citizen-centric design to obtain feedback from users. This, in turn, could result in more effective public services.

Nevertheless, despite the clear advantages of this approach, it is important to acknowledge its limitations. It is clear that many real-world processes involve a high level of complexity, largely due to the participation of numerous organizations. This complexity creates challenges with process modeling. A further issue that must be addressed is the synchronization of models and tables in databases. The process of database synchronization is a prerequisite for implementing model changes; however, this procedure is not without its complications.

Overall, governmental authorities remain less represented in the literature. Further studies are necessary to identify sector-specific barriers, skill requirements, and implementation strategies in public administrations.

In response to RQ2:

Research on governmental administrations is limited; only one article was identified. The main challenges were not explicitly mentioned—only the standard limitations of LCNC platforms, such as issues with interoperability, flexibility, and vendor lock-in. Competency profiles were also not identified. Further research is needed in this area.

D. Future of LCNC Platforms

The low coverage of the cluster information systems and technologies (#1) may be due to the inclusion of newer emergent topics in the LCNC context, such as AI, machine learning (ML), and the internet of things (IoT). AI has recently gained attention in the context of LCNC platforms and tools, as the integration of AI into LCNC could potentially expand the latter's usage and help overcome issues such as lack of flexibility, inadequate documentation, and technical constraints, thereby leading to synergies [32], [33].

Generative AI (GAI) can support the work of citizen developers in LCNC platforms, and automating certain tasks may compensate for missing technical skills [34]. This is seen as a way to address the technical limitations and skills gaps that LCNC alone cannot overcome.

It is also notable that "low-code" is mentioned far more often than "no-code." This may be because the use of NC platforms is more limited compared to that of LC platforms [30]. However, recent conceptual work suggests that this distinction may blur in the future: for example, [35] suggests a conceptual model which integrates large language models (LLMs) into LC tools, bringing them closer to true NC solutions.

LCNC is also occasionally discussed in the educational sector, particularly in connection with modern learning methods. It is interesting to note that within the skills cluster, LCNC is occasionally discussed in the context of modern learning methods: students can learn how AI works and how to deal with data in practice, guided through the ML workflow [36].

Implication:

Emerging technologies such as AI, ML, and IoT were underrepresented in the context of LCNC and CD research. Studies are currently being conducted in the area of merging GAI with LCNC to support and simplify CD. There are also practical applications in education, where AI supports both teaching and student learning in IT. These are promising areas for future research.

VI. Conclusion and Limitations

This study presents a systematic literature review of the current research on LCNC platforms, with a particular focus on skills and governmental authorities. The analysis reveals that the examined literature primarily addresses technical aspects, while organizational and educational dimensions are less frequently examined, although the topic of skills has gained greater visibility in recent years. This study indicates that the competencies required for citizen developers are generally categorized, but challenges remain in adapting training methods to the specific needs of citizen developers.

The use of LCNC tools in the context of governmental administration is seldom discussed, and sector-specific barriers are insufficiently explored. The integration of GAI into LCNC platforms may help reduce technical barriers and support the empowerment of citizen developers. Nonetheless, further (empirical) research is necessary to validate these concepts. Future research could focus on the use of LCNC platforms in government settings and the development of upskilling strategies for employees.

We are aware that this study has several limitations, which should be considered when interpreting the results. For example, we did not identify all relevant papers published in journals and conference proceedings, because we made our selection from specific databases. Other journals and conference proceedings not included in the databases we examined might also contain relevant articles, and expanding the analysis to include additional databases could have produced different results and a different number of hits. A literature review cannot provide a comprehensive overview of a topic, particularly when the focus is limited to three databases, and so this may not have provided sufficient coverage of the topic. Therefore, a broader search using more databases, and particularly interdisciplinary ones, could highlight further limitations of our research and findings. Additionally, the focus on LCNC in the context of digital transformation may have led to some bias. Another limiting factor is that although a technically-driven clustering approach was used, assigning topics to clusters is still somewhat subjective, as some aspects may overlap between categories depending on the context. Additional clustering based on abstracts or keywords could improve the analysis further and reduce bias. Last but not least, we are aware that the study has temporal limitations, as the relevance and accuracy of the findings may change over time due to the quick speed of development in this field.

***Abstract*—Recent advances in single- and multi-image super-resolution have revealed the limitations of classical image similarity metrics (like peak signal-to-noise ratio), as they often fail to align with human perception when evaluating the visual quality of super-resolved outputs. In this paper, we explore how to exploit keypoint-based metrics to evaluate super-resolution image quality. Specifically, we explore two correlated metrics: (*i*) a *multi-scale index proposal* measure capturing salience of keypoints, and (*ii*) a *repeatability* metric quantifying how consistently the corresponding keypoints are identified in super-resolved and ground-truth images. Experiments on several simulated and real-world datasets show that the repeatability correlates with subjective judgments, and multi-scale index proposal can be helpful for difficult datasets when other metrics are insufficient.**

I. Introduction

LOW-RESOLUTION (LR) images pose a significant challenge in diverse imaging fields, from satellite surveillance to medical diagnostics. Physical constraints or adverse capture conditions often lead to low-quality data with insufficient detail. To address this, image *super-resolution* (SR) techniques reconstruct *high-resolution* (HR) images from LR inputs, effectively enhancing visual clarity and texture.

In recent years, deep learning-based SR methods have achieved impressive results, producing images with sharper edges and more natural details than classic interpolation schemes. However, these advances introduce a pressing need for robust *image quality assessment* (IQA) metrics tailored to super-resolved images. Traditional *full-reference* (FR) metrics such as *peak signal-to-noise ratio* (PSNR) and *structural similarity index measure* (SSIM) compare the SR output against a ground-truth reference at the pixel or local structural level. While useful for measuring basic fidelity, these methods often do not capture the subjective quality that humans perceive—especially in SR outputs that introduce plausible, but non-identical, high-frequency details.

This work was supported by the National Science Centre, Poland, under Research Grant 2022/47/B/ST6/03009. JS was supported by the SUT Statutory Research funds under Grant 02/080/BKM25/0058. MK was supported by the SUT funds through the Rector's Research and Development Grant 02/080/RGJ25/0053.

Ultimately, human viewers prioritize perceptual realism, focusing on sharp textures, coherent structures, and absence of distracting artifacts. An SR image that looks over-smoothed or contains noticeable distortions in critical regions may be subjectively worse, even if it has a high value of PSNR or SSIM metric. Conversely, an image that retains the essential scene layout while adding visually consistent fine details can be perceived as high quality despite larger pixel-wise differences from the ground truth. This observation drives the development of alternative IQA methods that better reflect human visual preferences and the complex trade-offs between fidelity and realism in SR.

The primary objective of this study is to explore keypoint-based metrics as a means of evaluating the quality of super-resolved images. Unlike traditional IQA metrics that focus on pixel-wise fidelity or perceptual similarity, our approach investigates the geometric and structural consistency of SR output through the lens of local feature detection. Keypoint-based metrics were also exploited for that purpose in [1]; however, that approach relies on conventional techniques that are non-differentiable, which limits its applicability for training deep neural networks. In this work, on the other hand, we aim at adapting methods based on deep learning, in order to allow for applying them to task-driven training in the future. To achieve this, we leverage the capabilities of Key.Net [2], a neural network designed for keypoint detection tasks that combines hand-crafted and learned convolutional filters within a shallow multiscale architecture. In particular, we examine the utility of the repeatability, a widely adopted metric in local feature evaluation [3], which measures the consistency of keypoint detection under various transformations, and the *multi-scale index proposal* (MSIP), introduced as a loss function for training Key.Net [2]. We extend this idea to the SR domain, under the assumption that a high-quality super-resolved image should exhibit similar keypoint number and distributions to the ground-truth reference image.

The paper is organized as follows. Section II reviews related work on SR methods and quality assessment metrics. Section III describes the datasets used for the evaluation.

Section IV details the proposed keypoint-based approach and metric configurations. Section V presents the experimental setup and results. Section VI summarizes the paper and provides directions for future research.

II. Related Work

A. SR Techniques: Major Categories and State of the Art

SR is highly relevant in domains where capturing higher-resolution imagery directly is impractical due to physical or cost-related constraints [4]. Applications span security surveillance, medical imaging, and remote sensing [5]. For instance, in satellite imaging, SR algorithms may be the only way to obtain finer details when sensor resolution is limited or hiqh-quality image acquisition is too expensive [4]. Over the past two decades, a vast array of SR methods have been proposed, generally categorized into *single-image SR* (SISR) approaches (relying on a single LR input) and *multi-image SR* (MISR) approaches (fusing multiple observations of the same scene).

Early SISR techniques were based on interpolation and example-based methods, long before the deep learning era. Interpolation-based methods such as bilinear or bicubic interpolation provide simple baselines by smoothing and enlarging pixel grids, but tend to produce blurry results due to their limited modeling of image structure. More sophisticated classical methods leveraged natural image priors. For example, patch-based dictionary learning and sparse coding became influential around 2010. Yang et al. [6] pioneered learning pairs of small patches from LR–HR images, known as dictionary atoms, so that a sparse linear combination of LR atoms can reconstruct high-frequency details via the corresponding HR atoms. This sparse representation approach achieved sharper results than interpolation by reusing high-frequency patterns from training data.

Convolutional neural network (CNN) models brought a breakthrough in SISR by learning the LR-to-HR mapping from large datasets. The seminal SRCNN [7] of Dong et al. was the first CNN for SR, with a three-layer network directly learning to improve the quality of interpolated LR inputs. Despite its simplicity, SRCNN significantly outperformed sparse-coding methods, demonstrating the power of data-driven feature extraction. Dong et al. later proposed FSRCNN [8], an accelerated variant that operates in the LR space for efficiency. Kim et al. introduced a *very deep SR* network (VDSR) [9] with ca. 20 layers and residual learning to ease training. Subsequently, the EDSR model removed batch normalization to allow for even deeper residual networks, achieving state-of-the-art performance in the 2017 NTIRE challenge [10].

By 2017, *generative adversarial networks* (GANs) emerged to tackle a core limitation of purely *mean squared error* (MSE) optimized CNNs: overly smooth outputs lacking high-frequency texture. Ledig et al. proposed SRGAN [11], introducing adversarial training to favor perceptually sharp results. SRGAN's generator (a deep ResNet architecture, also known as SRResNet, due to its use of residual learning blocks) is trained with a discriminator to produce outputs that are difficult to distinguish from real HR images. This GAN-based approach produced much crisper and more detailed images, at the cost of lower PSNR. Wang et al. later improved this with ESRGAN [12], which used residual-in-residual dense blocks and a more perceptually aligned loss, resulting in more natural textures. Beyond perceptual losses, task-driven objectives have emerged to tailor super-resolution to downstream applications. For instance, Zyrek and Kawulok [13] proposed a method that optimizes SISR for improved text recognition from scanned documents by combining image similarity with text detection objectives.

While not directly focused on SR, Bairi et al. [14] addressed the related problem of image reconstruction from compressive sensing data. Their dual-path framework integrates Vision Transformers and perceptual optimization, combining global contextual modeling with perceptual loss to enhance reconstruction quality beyond traditional fidelity-driven methods.

Most recently, diffusion probabilistic models have been applied to SISR, marking a new frontier in fidelity and diversity. Saharia et al. introduced SR3 [15], which adapts denoising diffusion models for SR. Starting from pure noise, SR3 iteratively denoises the input while being conditioned on the LR image, generating highly photo-realistic outputs.

Whereas SISR relies on learned priors to hallucinate missing details, MISR methods exploit actual complementary information from multiple observations of the same scene. By combining a sequence of LR images (often with subpixel shifts between them), MISR can surpass the limits of single-image fidelity. Traditional MISR techniques were rooted in multi-frame reconstruction theory and often cast as Bayesian or regularized optimization problems. A classical formulation assumes each LR image is a warped, blurred, downsampled, and noisy version of an unknown HR image. The SR task is then to invert this imaging model. Early solutions like the work [16] of Schultz and Stevenson employed a *maximum a posteriori* (MAP) estimator with a smoothness prior, solved via iterative back-projection or gradient descent. Farsiu et al. later proposed a fast and robust SR (FRSR) [17] MISR algorithm that combined an L1-norm fidelity term (robust to outliers) with a simplified regularization, and crucially computed registration error in the HR space to avoid repeated interpolations. Such approaches (e.g., Bayesian inference, maximum likelihood or MAP estimation) dominated MISR for years, incorporating robust alignment and prior terms to handle noise and misregistrations. However, they often required careful tuning and were computationally intensive.

With the rise of deep learning, MISR has seen new data-driven approaches addressing the key challenges of alignment and fusion. The first application of deep learning in MISR was EvoNet, presented in [4], where the method combines the advantages of multi-image fusion with learning the LR-to-HR mapping using deep networks, achieving superior reconstruction accuracy compared to state-of-the-art SR methods. A milestone in deep MISR was the PROBA-V Super Resolution Challenge [18], which spurred the development of several methods, including the HighRes-net by Deudon et al. [19] and the winning approach, DeepSUM [20]. HighRes-

net introduced an end-to-end trainable framework to jointly learn co-registration of multiple LR frames and their fusion into a single HR output. It uses a recursive fusion strategy with an implicit reference frame, eliminating the need for explicit motion compensation between inputs. DeepSUM, on the other hand, leverages deep neural networks to efficiently integrate spatial and temporal information from unregistered multi-temporal images, achieving superior reconstruction quality. Another notable model is the *residual attention MISR* (RAMS) network [21] by Salvetti et al. RAMS integrates attention mechanisms into a deep CNN to adaptively weight the contribution of each pixel from each image during fusion.

Current state-of-the-art MISR research often borrows architectures from SISR and video SR, enhanced to handle multiple unordered inputs. Transformer-based MISR models [22][23] have recently emerged, leveraging self-attention to capture long-range dependencies across frames. Another approach is to represent a stack of input images as a graph which is super-resolved with a graph neural network [24] or graph attention network [25].

B. Image Quality Assessment

Despite the progress in SR algorithms, evaluating the quality of super-resolved images remains challenging. Generally, IQA methods are classified into FR, *reduced-reference* (RR), and *no-reference* (NR) approaches, depending on how much ground truth information is available [26]. FR-IQA metrics (e.g., PSNR, SSIM) compare the output directly against a reference image, RR-IQA methods use partial information about the reference (such as features or the input LR image), and NR-IQA (also called blind IQA) relies only on the output itself. In conventional restoration tasks, FR metrics like PSNR and SSIM have been widely used since a ground-truth HR image is usually available for synthetic test cases. However, these classical metrics focus on signal fidelity and often correlate poorly with human visual perception when applied to SR results. A super-resolved image that looks sharp and realistic to a human observer, might score worse in PSNR/SSIM than a blurry image that stays pixel-close to the reference [27]. This is especially true for GAN-based SR methods which introduce high-frequency content: they achieve higher subjective quality but lower PSNR (the perception-distortion dilemma [28]). As a result, learning-based IQA metrics have gained traction. These include deep feature-based distances like *learned perceptual image patch similarity* (LPIPS) [29] (which compares images in a CNN feature space) and *deep image structure and texture similarity* (DISTS) [30], as well as neural networks trained to predict human opinion scores.

For SR evaluation, both fidelity and perceptual quality are important, and researchers have devised specialized metrics to handle the conflicts between them [31]. Several recent works propose SR-specific IQA methods that account for characteristics of SR outputs.

FR-IQA compares the super-resolved image directly with its HR ground truth. Metrics like PSNR and SSIM are most commonly used, offering objective and repeatable evaluation. PSNR measures pixel-wise fidelity based on mean squared error, while SSIM captures local luminance, contrast, and structure similarities. Despite their popularity, these metrics often fail to reflect perceptual quality, especially for SR results generated by GAN-based models, which prioritize sharpness and realism over strict pixel accuracy [26][27]. Due to structural differences from the ground truth, more advanced FR methods have been proposed that analyze images in gradient, wavelet, or perceptual feature domains. For example, phase congruency and gradient magnitude have been employed to better model human sensitivity to edge structures, as illustrated by the FSIM metric [32], which leverages both features within a full-reference evaluation framework. While FR metrics are ideal for synthetic SR benchmarks with available HR references, they are unsuitable in real-world settings where such references are missing.

RR-IQA methods evaluate quality using partial information from the reference, often in the form of extracted features or the LR input image itself. This makes RR approaches more practical than FR in real-world SR scenarios, where full ground truth is unavailable. Early RR methods focused on edge preservation, texture statistics, or wavelet-based similarities between LR and SR images [27]. More recent approaches, like PFIQA [5], use deep neural networks to combine perceptual and fidelity-aware branches, leveraging both the SR image and the LR input alongside auxiliary information (e.g., scale factor). These models better reflect human perception by assessing whether reconstructed details are consistent with the available input and visually plausible. RR-IQA is especially valuable for detecting artifacts that contradict known image structures or suggest overfitting (e.g., excessive sharpening). While RR approaches strike a balance between fidelity and perception, they remain limited in evaluating purely hallucinated textures, as they cannot fully determine whether added details are semantically correct.

The NR-IQA approach is the most flexible and challenging setting, as it operates solely on the super-resolved image without any access to ground truth or input. NR metrics are indispensable in real-world applications, where only the output is available. Early NR-IQA approaches relied on natural scene statistics, assuming that distortions in SR images would cause statistical deviations. Methods like *natural image quality evaluator* (NIQE) [33] are based on statistical features derived from natural images and estimate deviations associated with sharpness, noise, and unnatural textures. These were later combined into composite scores like the *perceptual index* (PI) [27], which became widely used in perceptual SR evaluation. Recent NR-IQA methods leverage deep learning to directly predict subjective quality from image content. For example, KLTSRQA [34] uses Karhunen-Loève transform-based features, while others employ CNNs or transformers trained with human opinion scores [27]. Knowledge distillation techniques have also been introduced to train NR-IQA models using pseudo-labels obtained from strong full-reference models [27]. Although modern NR-IQA metrics outperform traditional ones in terms of perceptual alignment, they still face challenges

related to generalization and distinguishing realistic textures from artifacts without reference anchors.

III. Datasets

In the field of SR, selecting appropriate datasets is crucial for evaluating the performance of quality assessment metrics. This research leverages three distinct datasets: CVIU-17 [35], SISAR [36], and MuS2 [37]. The first two are widely employed [27], [31], [26] in the field of IQA, whereas the third one presents an intriguing complement owing to its distinctive characteristics. Below, we provide detailed descriptions of these datasets, highlighting their composition, purposes, and contributions to advancing SR research.

A. CVIU-17

The CVIU-17 dataset is a publicly available resource tailored for evaluating IQA metrics in the context of SISR. It comprises 180 LR images and 1,620 HR images, generated using nine distinct SR algorithms across six integer scaling factors (see Fig. 1). LR images were generated by applying a combination of downsampling and blurring to the original images from the BSD200 dataset [38].

Fig. 1. An example from the CVIU dataset showing super-resolved images obtained using various SR methods. The visual comparison highlights the differences in reconstruction quality across methods.

B. SISAR

The SISAR dataset (SR image quality database with semi-automatic ratings) stands as the largest-of-its-kind resource for IQA. It contains 12,600 labeled HR images derived from 100 natural LR images, each with a resolution of 1024×768 (see Fig. 2). These HR images were generated using ten types of SR algorithms. SISAR's scale and diversity make it an invaluable asset for developing robust and generalizable IQA metrics, paving the way for more accurate quality predictions in SR applications.

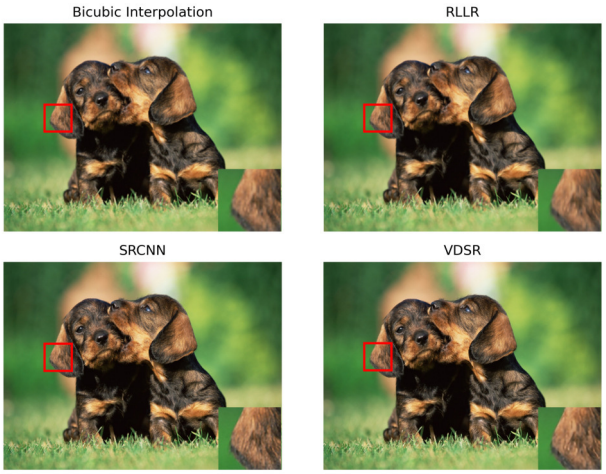

Fig. 2. An example scene from the SISAR dataset showing images super-resolved using various methods. The figure includes Bicubic Interpolation, RLLR, SRCNN, and VDSR, illustrating the visual differences in image quality achieved by each method.

C. MUS 2

The MuS2 dataset is a specialized benchmark for MISR of Sentinel-2 satellite [37]. It addresses the challenge of improving the spatial resolution of Sentinel-2 imagery, which has a ground sampling distance of 10 meters, by using HR WorldView-2 imagery as a reference. The dataset includes 91 scenes (see Fig. 3), each containing 14 or 15 Sentinel-2 LR images across 12 spectral bands, paired with corresponding WorldView-2 HR images. All LR and HR image pairs in MuS2 are pre-aligned, and no geometric misalignments are present.

MuS2 is particularly significant for remote sensing applications, where HR imagery is critical for tasks such as environmental monitoring, urban planning, and disaster management. Unlike many SR datasets that rely on simulated data, MuS2 provides real-world data, capturing the complexities of satellite imaging, such as atmospheric variations and temporal changes. This realism makes it an ideal testbed for developing and validating MISR algorithms that fuse information from multiple images to achieve superior reconstruction accuracy.

IV. Proposed Approach

The main goal of this study is to investigate the use of keypoint-based metrics for assessing the quality of super-resolved images. These metrics, derived from Key.Net, include MSIP and the repeatability.

Key.Net [2] is a hybrid keypoint detection model that combines handcrafted and learned CNN filters within a multi-scale architecture. The handcrafted filters are inspired by traditional methods like Harris [39] detectors, capturing first and second-order image derivatives. These filters act as soft anchors, reducing the number of learnable parameters and improving stability. Key.Net also incorporates a multi-scale pyramid representation, which enhances robustness to scale

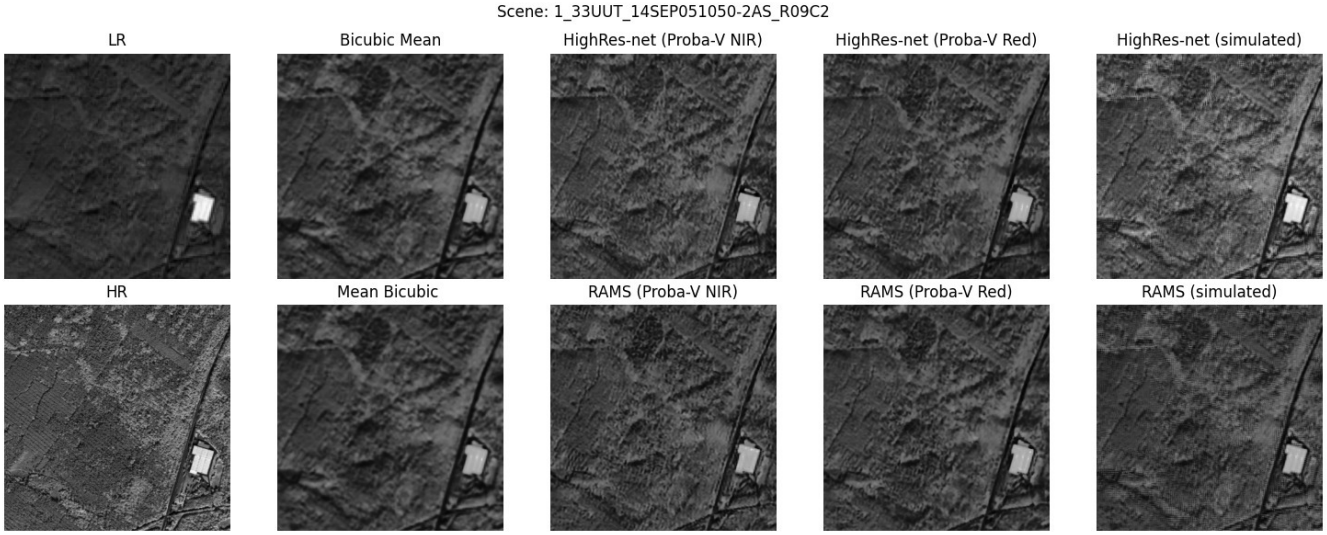

Fig. 3. An example scene from the MuS2 dataset, showing both LR and HR images. The figure includes bicubic interpolation of a mean LR, averaged image of bicubic interpolation outcomes from each LR image, as well as super-resolved images obtained from HighRes-net and RAMS networks trained using real-world PROBA-V images and from a simulated dataset.

changes by processing the input image at multiple scales. The learned filters are then applied to these multi-scale features to localize, score, and rank keypoints. The model uses a novel MSIP layer as loss function, which optimizes keypoint detection by leveraging both local and global information.

The MSIP module extends the concept of the *index proposal* (IP) layer by aggregating multiple IP layers applied at different spatial scales. Each IP layer operates on a shared response map using a local window of size $N_s \times N_s$, where N_s denotes the scale-specific window size. Within each window, a spatial softmax operator is used to convert raw activation values into a probability distribution, highlighting the most prominent local responses. This results in differentiable keypoint localization, computed as the expected coordinate (weighted average) of positions within the window.

By stacking several IP layers with increasing window sizes, MSIP is able to extract keypoints that are not only locally salient but also stable across spatial scales. This multi-scale strategy improves robustness and suppresses unstable detections, as only keypoints that persist across larger contexts are retained. This design encourages the detector to favor geometrically consistent keypoints that are resilient to scale variations, improving repeatability under transformation.

The repeatability quantifies how consistently keypoints are detected between two images of the same scene (e.g., the reference HR and its super-resolved counterpart). A keypoint is considered repeatable if it has a corresponding match within a defined spatial tolerance, often under geometric transformations such as scaling or homography. Formally, it is defined as:

$$\text{repeatability} = \frac{|\mathcal{K}_a \cap \mathcal{K}_b|}{\min(|\mathcal{K}_a|, |\mathcal{K}_b|)}, \tag{1}$$

where:

- $\mathcal{K}_a$ and $\mathcal{K}_b$ are the sets of keypoints detected in images I_a and I_b, respectively.
- $|\mathcal{K}_a \cap \mathcal{K}_b|$ is the number of matching keypoints between the two images.
- $\min(|\mathcal{K}_a|, |\mathcal{K}_b|)$ is the minimum number of keypoints detected in either image.

In this implementation, keypoints are defined by both their spatial coordinates and the scale at which they were detected. To determine whether two keypoints correspond, the *intersection-over-union* (IoU) is computed between the circular regions centered at each keypoint, scaled according to their associated detection scale. A match is established, if the IoU exceeds a fixed threshold. The repeatability can be measured at a single scale, reflecting keypoint consistency under fixed resolution, or across multiple scales, which accounts for robustness to scale variations. Multi-scale repeatability provides a more comprehensive assessment of detector stability under varying image resolutions.

The process of calculating keypoint-based metrics is presented in Fig. 4. To compute MSIP and Repeatability, the SR and HR images are converted to grayscale. Then, each of them is passed through the Key.Net network. As the output of Key.Net, a response map is obtained, and further calculations are performed depending on the metric:

- MSIP: Both response maps (SR and HR) are processed through the MSIP layer, which extracts sets of stable keypoints at different scales.
- Repeatability From the response maps, Non-Maximum Suppression (NMS) is applied to obtain sets of keypoints. IoU between corresponding keypoints from SR and HR images is calculated, resulting in the repeatability metric.

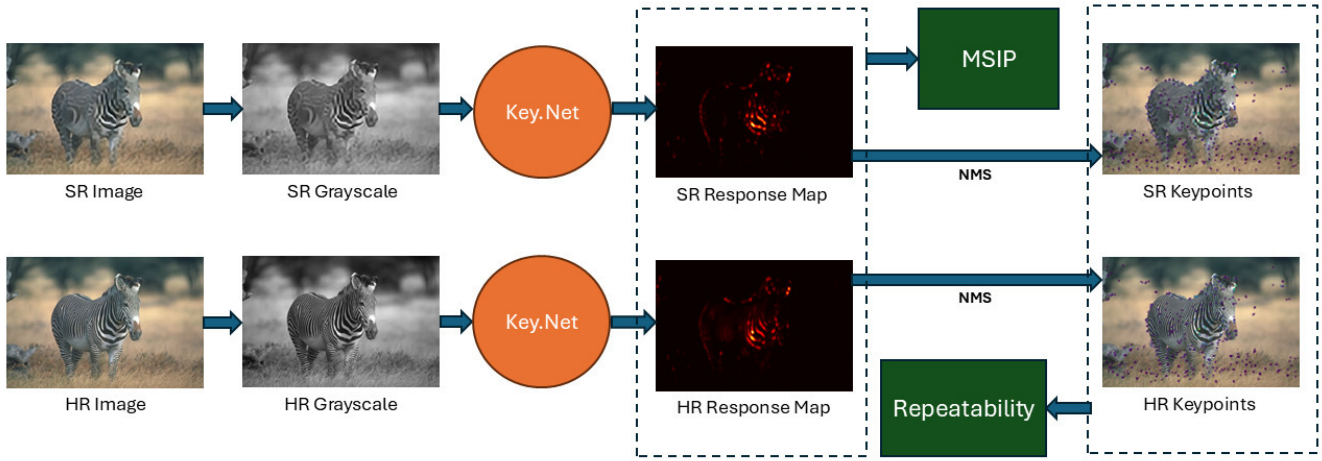

Fig. 4. A pipeline for keypoint-based metrics calculation in IQA for SR. Super-resolved and HR images are converted to grayscale, processed through Key.Net to obtain response maps, and further analyzed using MSIP and repeatability metrics.

We hypothesize that incorporating keypoint repeatability into IQA offers a promising alternative to perceptual or distortion-based measures. To verify this, we compute both conventional metrics—PSNR, SSIM, and LPIPS—as well as keypoint-based metrics, including single-scale repeatability (REP_S), multi-scale repeatability (REP_M), and the MSIP for all three datasets. Furthermore, for the CVIU17 and SISAR datasets, where *mean opinion scores* (MOS) are available, we measure correlation between metric predictions and human perceptual judgments.

V. Experiments

A. Experimental Setup

We carried out experiments on three standard IQA datasets for SR: CVIU-17, SISAR, and MuS2. Both CVIU-17 and SISAR provide HR images and MOS, enabling correlation analysis of objective metrics with human perception. In contrast, MuS2 lacks MOS labels and focuses on Sentinel-2 satellite images for MISR.

Since our approach does not require additional training, we directly used the super-resolved images and the corresponding HR images from each dataset. We applied the Key.Net model (PyTorch implementation) with the original pretrained weights; only minor modifications were introduced to handle grayscale conversion (for CVIU-17 and SISAR) and kernel sizes in the MSIP function. For the purposes of keypoint-based analysis, we assumed an identity homography transformation, implying no geometric discrepancies between the HR images and corresponding SR outcomes.

In our experiments, we evaluated several configurations of the MSIP function to understand how varying kernel sizes and weighting strategies affect the keypoint-based assessment of super-resolved images. We decided to use this division to systematically analyze the impact of different scale levels on the quality of keypoint detection.

- MSIP_default: The default Key.Net configuration, employing four scales with decreasing weights.
- MSIP_5: Single-scale variant using only the smallest kernel size for window.
- MSIP_17: Single-scale variant using only the largest kernel size for window.

Table I summarizes the kernel sizes and weights for each MSIP variant used in both scenarios.

TABLE I
MSIP configurations used for CVIU-17, SISAR, and MuS2.

MSIP Variant	Kernel Sizes	Weights
MSIP_default	5×5, 9×9, 13×13, 17×17	1.0, 0.5, 0.25, 0.12
MSIP_5	5×5	1.0
MSIP_17	17×17	1.0

We computed the following metrics for each super-resolved and HR image pair: PSNR, SSIM, LPIPS, and the proposed set of keypoint-based metrics (MSIP, REP_S, REP_M). Where MOS annotations existed (CVIU-17, SISAR), we calculated the *Pearson linear correlation coefficient* (PLCC), *Spearman rank-order correlation coefficient* (SRCC), and *root mean squared error* (RMSE) between each metric's prediction and the MOS. To facilitate fair comparison across metrics, all correlation scores were normalized.

B. Results and Analysis on SISR IQA Benchmark Datasets

Table II shows that Dong11 yield the highest MOS (0.5491), surpassing simpler methods like bicubic interpolation (0.4603). Although these top MOS approaches do not always achieve the highest PSNR or SSIM, they align more closely with the keypoint-based REP_M scores. This finding supports the well-known perception-distortion tradeoff, wherein an image may visually please observers but deviate from the ground truth at the pixel level.

Comparing the MSIP configurations in Table II, we observe that single-scale variants (MSIP_5, MSIP_17) can diverge significantly for certain SR methods, suggesting that analyzing only a single kernel size may overlook important local structures. Correlation part of this table, reinforces this observation: the correlation of MSIP_5 and MSIP_17 with MOS is generally lower than that of MSIP_default, indicating that decreasing weights over multiple kernels are more effective than a single-scale approach.

A similar trend appears in Table III, where VDSR achieves the highest MOS (0.49) but not the highest PSNR. The local structure measures REP_S and REP_M exhibit a relatively high correlation with MOS, implying that preserving essential edges and textures is key to subjective quality. As in the CVIU-17 dataset, the single-scale MSIP_5 and MSIP_17 lag behind MSIP_default in terms of correlation metrics, though MSIP_default still does not reach the correlation levels of REP_M. This suggests that while MSIP has potential for capturing perceptual differences in super-resolved images, it may require additional tuning or refined weighting strategies to better reflect subjective quality.

Both tables also presents a direct comparison of PLCC, SRCC, and RMSE against MOS for both datasets. As expected, PSNR and SSIM show modest correlations, consistent with their known limitations in modeling perceptual sharpness or high-frequency details. LPIPS reports a higher correlation, which is unsurprising, as it is designed to capture perceptual similarities. The keypoint-based metrics REP_S and REP_M outperform classic metrics in most cases, highlighting that matching local structure and geometry is highly relevant to subjective quality. In comparison, the MSIP_default variants of MSIP reveal a promising correlation but trail behind the best REP_M scores, indicating that further refinement of multi-scale configurations and weighting choices could improve MSIP-based evaluations.

C. Results and Analysis on the Real-World MISR Dataset

Below, we summarize the results of various SR approaches on the MuS2 dataset, which includes Sentinel-2 satellite imagery. Table IV covers both baseline methods (Bicubic) and SR models trained on real-world PROBA-V (NIR or RED bands) or simulated Sentinel-2 data. Specifically:

- Bicubic Mean: Single bicubic upsampling of an averaged LR frame.
- Mean Bicubic: Bicubic upsampling of each LR frame followed by averaging.
- HighRes-net (PROBA-V NIR) / HighRes-net (PROBA-V RED): HighRes-net variants trained on PROBA-V data (NIR or RED bands).
- HighRes-net (simulated): A HighRes-net variant trained on simulated Sentinel-2 data.
- RAMS (PROBA-V NIR) / RAMS (PROBA-V RED): RAMS variants trained on PROBA-V data (NIR or RED bands).
- RAMS (simulated): A RAMS variant trained on synthetic Sentinel-2 data.

A closer look at the metrics reveals several key issues:

1) Bicubic Mean and Mean Bicubic achieve the highest PSNR and relatively high SSIM values, yet their LPIPS and MSIP scores are very poor. Based on the article [37], they produce visually the smoothest (most blurred) outputs, confirming that high PSNR and SSIM alone may not indicate perceptually sharp images. MOS study was

TABLE IV
EVALUATION RESULTS ON THE MUS2 DATASET. IN THE BRACKETS, WE INDICATE THE DATASET USED FOR TRAINING (REAL-WORLD PROBA-V OR SIMULATED IMAGES).

Method	PSNR	SSIM	LPIPS	REP_S	REP_M	MSIP_default	MSIP_5	MSIP_17
Bicubic Mean	24.1514	0.6012	0.5667	42.3759	24.0449	0.5470	0.0815	1.1352
Mean Bicubic	**24.1515**	0.6012	0.5667	42.3708	24.0607	0.5457	0.0815	1.1403
HighRes-net (PROBA-V NIR)	23.9385	0.5970	**0.4357**	42.7648	28.4317	0.5163	0.0806	1.0476
HighRes-net (PROBA-V RED)	23.9802	0.5995	0.4476	42.0976	26.5394	0.5244	**0.0798**	1.0775
HighRes-net (simulated)	23.6873	0.5415	0.4905	43.1661	28.4554	0.5349	0.0857	1.0651
RAMS (PROBA-V NIR)	23.9743	0.6004	0.4420	42.6352	**28.5710**	**0.5109**	0.0815	**1.0271**
RAMS (PROBA-V RED)	24.0145	**0.6015**	0.4593	41.0973	25.8652	0.5233	0.0808	1.0686
RAMS (simulated)	23.8417	0.5324	0.5621	**43.3115**	28.5120	0.5198	0.0831	1.0436

also done, but the methodology does not allow for such analysis as with CVIU/SISAR.

2) RAMS (PROBA-V NIR) delivers the best visual quality overall. It achieves consistently strong metrics across the board, showing the highest MSIP and REP_M scores and ranking second-best in LPIPS. This suggests an excellent balance between fidelity and perceptual quality.
3) The second-best visual performance is offered by HighRes-net (PROBA-V NIR), which maintains strong metrics and a low LPIPS, indicative of better perceptual alignment.
4) Models trained on synthetic Sentinel-2 data have lower PSNR and weaker SSIM values compared to their PROBA-V counterparts. Despite this, they achieve relatively high REP_S and REP_M scores, indicating their ability to reconstruct sharper local details, even in the absence of precise pixel-level alignment with the reference image.

In summary, Bicubic Mean and Mean Bicubic yield the highest PSNR and SSIM, but the worst perceptual outcomes and poor LPIPS and MSIP scores. By contrast, RAMS (PROBA-V NIR) stands out visually, backed by strong metrics, with HighRes-net (PROBA-V NIR) close behind. Meanwhile, the simulated Sentinel-2 models confirm that sharper details may be underappreciated by fidelity-based metrics (PSNR, SSIM) but can be captured by the repeatability and perceptual assessments.

VI. CONCLUSION

In this study, we explored the utility of keypoint-based metrics for assessing the quality of super-resolved images across single- and multi-image scenarios. By capturing local feature consistency through multi-scale repeatability, our approach complements conventional fidelity metrics (PSNR, SSIM) and perceptual measures (LPIPS), providing a stronger alignment with human subjective ratings. Experimental results on CVIU-17, SISAR, and MuS2 confirm that multi-scale keypoint detection highlights structurally salient regions that significantly influence observers' quality judgments. Moreover, the proposed MSIP variants offer an effective means to combine different spatial kernels and weights, focusing on various frequency components within super-resolved images.

Although the proposed metrics show strong potential, further work is needed to address current limitations and explore open challenges. First, the comparison with advanced full- and no-reference IQA metrics is limited; extending this analysis is essential to fully position keypoint-based evaluation within the broader IQA landscape. Ongoing research focuses on adapting the MSIP metric specifically for SR tasks, both as a standalone quality measure and as a trainable loss function in SR models. Preliminary results indicate its potential to be comparable with state-of-the-art perceptual metrics. Additionally, future work should address geometric misalignments by evaluating repeatability under non-identity homographies and by integrating registration-aware keypoint detectors. Finally, we plan to extend the MuS2 dataset with human opinion scores, enabling more robust evaluation of MISR methods in real-world settings.

***Abstract*—Forecasting multivariate time series increasingly uses deep learning, including models inspired by Neural Machine Translation (NMT). While Transformers excel at long-range dependencies, their computational overhead may not suit all problems. This study advocates the relevancy of Long Short-Term Memory (LSTM)-based encoder-decoder networks for scenarios with shorter input windows and prediction horizons. We present a comprehensive empirical evaluation of four classical LSTM-based NMT models, including variants with attention mechanisms specifically adapted for multistep time series forecasting. Our assessment focuses on their performance and the impact of varying input window sizes and prediction horizons within these computationally efficient, short-sequence contexts. We empirically compare these LSTM-based models against Transformer baselines operating under the same short input window and prediction horizon constraints.**

Key findings indicate that: (i) LSTM-based NMT models achieve or exceed existing state-of-the-art results for short-term predictions; (ii) within smaller input configurations, input window size minimally affects forecasting performance for tested horizons, suggesting efficiency gains are possible; (iii) for attention-based NMT models, attention scoring critically influences accuracy, demanding careful selection; (iv) our comparative analysis demonstrates that for time series problems where immediate historical context is sufficient, LSTM-based encoder-decoders are competitive with, or even outperform, Transformer-based models while offering a more computationally efficient solution.

Overall, our findings signify that original LSTM-based NMT models are robust and capable tools, particularly well-suited for short-term time series prediction tasks where local pattern capture and computational efficiency are priorities, even in the era of Transformers.

***Index Terms*—Attention Mechanism; Long Short-Term Memory; Transformers; Neural Machine Translation; Time Series Forecasting**

I. Introduction

MULTIVARIATE time series are embedded in our day-to-day activities; examples are health and mobile sensor readings, contagious disease markers, power consumption, road occupancy rates and traffic flow indicators, financial stock prices and currency exchange rates. A primary challenge in forecasting multivariate time series lies in extracting both complex temporal patterns—such as short-term trends and yearly seasonalities—and dynamic, nonlinear interdependencies among the individual driving variables of the multiple series. Different machine learning methods have been used to predict the trends [1], [2] as well as values [3] of the time series. Deep learning-based methods are increasingly utilized for such multivariate, multistep time series analysis tasks, including forecasting energy demand [4], network intrusion [5], and anomaly detection [6], [7]. In particular, deep learning architectures leveraging Recurrent Neural Networks (RNNs) effectively address many shortcomings of traditional models in these analytical tasks [8], [9].

Deep learning models for time series forecasting often draw inspiration from Neural Machine Translation (NMT) frameworks [10], highly successful in Natural Language Processing (NLP) and Computer Vision (CV). NMT models translate word sequences from one language to another, traditionally using an encoder to process the input into a fixed-length vector and a decoder to generate the output sequence [11]. This encoder-decoder paradigm adapts to time series prediction by treating past observations as an "input language" and future predictions as an "output language," effectively "translating" past sequences into future values. Long Short-Term Memory (LSTM) [12] is a specialized type of RNN particularly adept at sequential data tasks. LSTMs can be employed in an NMT encoder-decoder architecture: the encoder LSTM reads the input sequence (source language) word by word, processing it into a fixed-length context vector that encapsulates the entire input's meaning; subsequently, the decoder LSTM takes this context vector as its initial hidden state and generates the output sequence (target language) word by word, leveraging the learned information from the encoder to produce a coherent and accurate translation [13], [14].

Attention mechanisms [15] critically advanced NMT, allowing decoders to selectively focus on relevant parts of the input sequence (or past time series points), significantly improving performance for translation or prediction. LSTM-

Topical area: Advanced Artificial Intelligence in Applications

based NMT models can incorporate an attention mechanism to overcome the limitation of fixed-length context vectors by allowing the decoder to dynamically "attend" to different parts of the encoder's output at each decoding step, giving more weight to relevant source words when generating a particular target word. Transformer networks, a more recent NMT evolution, move beyond earlier RNN-based models by relying entirely on attention mechanisms to draw relationships between input and output sequence positions.

Traditional statistical approaches to time series forecasting have often focused on predicting a single future time step. However, contemporary applications increasingly demand predictions over a longer horizon—not just one step ahead, but potentially tens or even hundreds of time steps into the future. This extended prediction horizon seems to be well matched to NMT models' capabilities. For example in NLP it is not unusual to translate, say, five words in one language to, say, ten words in a different language. When extending this scenario to time series forecasting, it is natural to ask how the NMT models would perform in predicting a time sequence ("horizon") longer than the input sequence ("input window").

Given the recent advancements and dominance of Transformer-based architectures in handling long sequences, what then is the continued relevance and precise niche for LSTM-based models in time series forecasting, particularly when considering resource constraints or the need to understand specific short-to-medium range forecasting behaviors? To precisely delineate this niche and understand their practical applicability, we study how LSTM-based encoder-decoder models, particularly their performance across varied input and prediction window sizes and the influence of different attention mechanisms, compare in efficiency and effectiveness against contemporary Transformer models when specific short-to-medium range forecasting behaviors are critical. This raises the following questions:

1) How would these models behave when both the input window size and the predicted horizon window size are varied on a narrow time interval?
2) Although [16] presents a comparison of the different attention scoring functions on NLP tasks, how do the scoring functions affect the performance of these models for time series analysis? Does the use of different attention scoring function for different attention-based NMT models as described in [16], [17] have a significant effect on the performance of the attention-based models?
3) While Transformers excel at longer contexts, might LSTMs still offer competitive or superior performance and efficiency for shorter input windows and prediction horizons, a common requirement in many real-world applications?

To address these pertinent questions and delineate opportunities for enhancing time series forecasting, this research undertakes an empirical investigation into the performance of NMT models. Specifically, we evaluate and compare two baseline (or 'vanilla') NMT models [10], [18] with two attention-equipped NMT models [16], [17] and compared them to three Transformer models [19], [20], [21].

Based on the findings from our experimental study on multivariate time series forecasting models, we note the following contributions.

1) We provide a thorough empirical evaluation of classical LSTM-based encoder-decoder networks for multivariate time series forecasting, assessing their performance across various real-world datasets and different input window and prediction horizon configurations.
2) We examine the effect of varying input window sizes, demonstrating that even smaller input contexts can yield accurate predictions for longer horizons in certain time series. Furthermore, we confirm that the choice of attention scoring function significantly impacts forecasting accuracy for attention-based LSTM models, emphasizing the need for careful selection.
3) We empirically compare the performance of LSTM-based encoder-decoder models against Transformer-based architectures when both operate under comparable short input window widths and prediction horizons. Our findings suggest that for these specific local forecasting scenarios, LSTM-based methods can achieve competitive or even superior performance, often with greater computational efficiency, thereby highlighting their continued relevance where long-range dependencies are not the primary drivers or resources are constrained.
4) This study contributes to a more nuanced understanding of deep learning for time series forecasting by delineating specific contexts where LSTM-based models remain a highly viable and efficient choice, thus informing the selection of appropriate models based on problem characteristics (e.g., emphasis on local patterns, computational budget) rather than solely relying on state-of-the-art benchmarks achieved with extensive contexts.

The remainder of this paper is organized as follows. In Section II, we describe traditional and deep learning methods for time series forecasting, discussing their limitations and advantages, and explain the relevance of NMT models, including the recently developed Transformer methods. In Section III, we provide details of the LSTM-based encoder-decoder models used for time series forecasting and explain the model architecture, attention mechanisms, and training procedure. Section IV presents the experimental setup, including datasets, parameter settings, evaluation metrics, and results, along with a discussion and analysis of the findings. Finally, we draw our conclusion and suggest directions for future research in Section V.

II. Related Work

Most time series data in real world scenarios involves a mixture of long and short term patterns. Time series forecast-

ing models therefore have been developed to capture long or short term, or both, recurring patterns for accurate predictions. Classical approaches include traditional statistical methods such as Auto-Regressive (AR) models, e.g. ARIMA [22], Box-Jenkins [23], [24], Moving Averages, e.g. Holt and Winters method [25], [26]. Vector Auto-regression (VAR) family of models such as structured VAR [27] and elliptical VAR [28] are preferred when handling high-dimensional time series as they have the inherent property of AR models and are agnostic to the dependencies between output variables. However, the VAR models tend to overfit when modeling longer time intervals. Nonparametric algorithms such as Gaussian Processes [29] model the complex dynamic temporal relationship with a Bayesian approach, at a higher computational cost. Although these methods are somewhat effective, they fall short in capturing the complicated nonlinear dependencies between a wider or longer interval of observed time series signals and between multiple high-dimensional variables.

A. Recurrent Neural Networks and Encoder-Decoder Models

RNN-based networks [30]—based on LSTM or Gated Recurrent Units (GRU) [12], [18]—were the first sequential deep learners for time series analysis, where they encode past information as a fixed-length vector. An RNN learns a fixed-length representation from multiple sequences of arbitrary length. Advantages of using RNN-based models are as follows. Firstly, it has been shown [31] that RNN fits into the Nonlinear Autoregressive Moving Average framework. The state of the hidden layer in an RNN at any given time is dependent on the previous time steps. Hence RNNs have the inherent desirable properties of AutoRegression and Moving Average-based statistical methods. Secondly, RNNs represent time recursively, making temporal dependencies easier to learn [30]. Third, the recursive property of the RNN model allows it to store complex signals for a variable amount of time. These properties make the RNN a good choice for modeling or learning sequences of variable length data, where each sequence of data points can be assumed to be dependent on previous ones [32]. However, learning in RNNs can suffer from the problems of vanishing and exploding gradients [33], [34] and thus RNNs can have difficulty capturing long-term temporal dependencies. Vanishing gradients are mitigated by using LSTM or GRU units, which can effectively learn long-range temporal dependencies [12], [18]. Both the LSTM and GRU variants of RNN have been the foundations for many state-of-the-art algorithms in speech recognition, machine translation, sentiment analysis and other NLP tasks. LSTMs have also played a significant role in capturing temporal dependencies in CV tasks such as activity classification, detection and other video tasks [35], [36].

A prominent variant of RNN architecture is the encoder-decoder (sequence-to-sequence) model [18], [37]. The encoder-decoder model sequentially links two RNNs—that serve as an encoder and a decoder—through a fixed size vector, generally the last encoder state. The concept is to encode the input sequence as a fixed-length vector representation and use the decoder to translate the learned, encoded fixed-length vector into a variable output sequence. LSTM and GRU-based encoder-decoder networks are popular due to their success in neural machine translation.

B. Attention Mechanisms

Embedding all the information in a fixed-size vector may result in information loss. In addition, the performance of sequence-to-sequence models deteriorates as the length of sequences of the encoder or the decoder increases [38]. To overcome these shortcomings, the attention mechanism is introduced to the architecture to focus on important parts of the input temporal sequences, by adding relevance calculation from all the encoder cells to each decoder cell [17]. This method has been proven to be successful in various NMT tasks in which the translation of each word from one language to another requires specific attention to particular words in the input source sequence [39].

A prominent example of an attention-embedded architecture is one that uses a dual attention mechanism in an LSTM-based encoder-decoder with a two-stage process. The first attention stage automatically extracts essential driving variables from the encoder's previous hidden state, while the second selects the encoder's hidden states across all time steps [40]. This is effectively complemented by self-attention mechanisms integrated with convolutional layers, which further enhance the model's ability to focus on relevant information [41].

Other notable architectures include TreNet, a hybrid network combining LSTM and temporal Convolutional Neural Network (CNN) modules to predict time series trends [42]. Similarly, LSTNet [8] utilizes temporal one-dimensional convolutions for short-term patterns and LSTMs for long-term dependencies. Interestingly, the LSTNet integrates both components with an autoregressive module, demonstrating a significant performance drop when this component is removed. Their research also indicates that attention does not consistently improve results across all datasets, whereas skip connections have proven more effective [8], [43].

While many models focus on point predictions, DeepAR proposes outputting a probability density function based on parameter estimations at each time step [44]. However, this approach relies on assumptions about the time series data's distribution, which may not always be realistic in real-world scenarios.

Further advancements in recurrent architectures for time series forecasting include a bidirectional LSTM-based encoder-decoder that incorporates a position-based attention mechanism to exploit periodic patterns and strong variable correlations within the data [45]. For multi-quantile probabilistic forecasts, an approach utilizing LSTM-based encoders and decoders has been proposed, though primarily tested on univariate datasets [46]. Additionally, a time-aware LSTM Network addresses predictions on sequential data,

irrespective of the time lag between data points [47]. Finally, an architecture featuring an unidirectional LSTM encoder and a bidirectional LSTM decoder employs an attention mechanism over groups of time sequences, with encoder outputs additively passed to the decoder's input instead of calculating attention over longer sequences [48].

C. Transformer Methods

Transformers have largely supplanted RNN models in sequence modeling tasks due to their proficiency in learning long-range dependencies and interactions in sequential data [49]. However, time series forecasting poses unique challenges for Transformers. Their limitations in effectively modeling complex temporal dependencies and their computational intensity necessitate specialized approaches for this domain. One such approach, LogTrans [50], addresses these issues by employing local convolutions and a log-sparse self-attention mechanism to capture local patterns and reduce space complexity.

Informer [51] is an extension of of the Transformer with sparse self attention to mine the most important temporal features in a sequence. Autoformer [19] uses a decomposition framework and auto-correlation methods from statistical methods to implement an autoregressive attention that exploits the inherent periodicity in a time series data. Building upon Autoformer's decomposition architecture, FEDformer [20] and TDformer [21] enhance time series pattern learning by decoupling trend and seasonality modeling. Both methods leverage Fourier attention in the frequency domain, achieving linear time complexity. However, these approaches do not fully exploit multi-dimensional dependencies, which could further improve long-term forecasting accuracy. To address this, Crossformer [52] utilizes cross-dimensional information for multivariate modeling.

D. Long vs. Short Input Windows and Prediction Horizons

Having reviewed various LSTM and Transformer models in the literature, we turn our attention to a direct comparison of their strengths and weaknesses in sequence modeling. The Transformer-based methods use mainly self-attention and multiple heads to model long-range dependencies with large input windows (e.g., 50-100+). This contrasts with the present study's exploration of LSTM-based encoder-decoder models using shorter input windows (up to 12). Our focus is on their efficacy for localized forecasts: local patterns and shorter prediction horizons where computational efficiency is also a key consideration, reflecting differing typical application contexts.

Why should we pay attention to methods for short-term predictions? Beyond lower computational needs, modeling local patterns is often more critical than global trends for practical reasons. First, many real-world applications, such as hourly traffic management or minute-by-minute financial trading, prioritize accurate immediate forecasts where local patterns are most influential, unlike year-long trend predictions. Secondly, for non-stationary time series whose statistical properties change, global trends can mislead as past behavior may not represent the future; local pattern modeling allows adaptation to the most recent data dynamics. Furthermore, local patterns are crucial for capturing sudden changes, shocks, or anomalies that models focused on global, long-term trends might fail to react to quickly.

E. Evaluation Studies

Often algorithms are evaluated on different datasets or different metrics, or both. Some cases also see the use of these forecasting models on synthetic datasets. Although all forecasting models, citing the shortcomings of each of their predecessors, improve the state-of-the-art results, there is a lack of evaluation on standard real world datasets. The closest relatable work to that of ours is that of [9], who (a) conduct a detailed analysis of various multi-variate time series datasets and their patterns which account for explaining each of the model's performance on that data, (b) presented a prediction analysis over a longer term whilst deploying direct and recursive strategies, and (c) studied the application of Spatio-Temporal Graph Convolutional Networks. Although an evaluative study of non-gated RNNs, LSTMs and GRUs on short term predictions was presented in [53], it did not cover the encoder-decoder or the effect of various attention scoring functions. Our work compares the performances of the existing encoder-decoder models based on LSTM units and the effect of attention scores on short term predictions based on the predictions as a function of varying input sizes. Furthermore, we compare them to Transformer methods to put the results in the context of contemporary research.

III. Methodology

A. Problem Formulation

Consider a series of observed time series vector samples $Y_T = \{y_1, y_2, \cdots, y_T\}$ where $y_t \in \mathbb{R}^n$, n is the number of time series channels. Our objective is to predict a series of H future samples $\tilde{y}_{T+h}$, $h \in \{1, \cdots, H\}$. When the underlying architecture is an encoder-decoder with an RNN such as an LSTM in the decoder, the output is produced in the style of an RNN, viz. one sample at a time. It thus takes H time steps to predict all H samples. We refer to T of the input set Y_T as the *window width* and H of the output set as the *horizon*.

B. LSTM-Based Encoder

We adopt a sequence-to-sequence learning pipeline to encode T historical input variables for a given time window and decode the future h predictions, but with minor modifications. The encoder is an RNN based on LSTM or GRU that encodes the input sequences into a fixed dimensional feature vector [18], [37], [10]. For time series prediction, given the input sequence $Y_T = \{y_1, y_2, \cdots, y_T\}$ with $y_t \in \mathbb{R}^n$, where n is the number of driving variables, the encoder can be applied to learn a mapping from y_t to h_t $h_t = f_1(h_{t-1}; y_t)$ where $h_t \in \mathbb{R}^m$ is the hidden state of the encoder at time t, m is the size of the hidden state, and f_1 is a non-linear

activation function that could be an LSTM or a GRU. In this paper, we use an LSTM unit as f_1 to capture temporal dependencies. Each LSTM unit has a memory cell with the state s_t at time t. Access to the memory cell is controlled by three sigmoid gates: forget gate f_t, input gate i_t and output gate o_t. The update of an LSTM unit can be summarized as follows:

$$f_t = \sigma(W_f[h_{t-1}; y_t] + b_f) \tag{1}$$

$$i_t = \sigma(W_i[h_{t-1}; y_t] + b_i) \tag{2}$$

$$o_t = \sigma(W_o[h_{t-1}; y_t] + b_o) \tag{3}$$

$$s_t = f_t \odot s_{t-1} + i_t \odot \tanh(W_s[h_{t-1}; y_t] + b_s) \tag{4}$$

$$h_t = o_t \odot \tanh(s_t) \tag{5}$$

where $[h_{t-1}; y_t] \in \mathbb{R}^{m+n}$ is a concatenation of the previous hidden state h_{t-1} and the current input y_t. The parameters W_f, W_i, W_o, $W_s \in \mathbb{R}^{m\times(m+n)}$, and b_f, b_i, b_o, $b_s \in \mathbb{R}^m$ are to be learned. The operators σ and $\odot$ are the logistic sigmoid function and the element-wise multiplication, respectively.

C. LSTM-Based Decoder without Attention

To predict the output $\hat{y_T}$, we use another LSTM-based RNN to decode the fixed vector $\mathbb{R}^m$ produced by the encoder LSTM:

$$\hat{y}_T = F(y_{t+1}, y_{t+2}, \cdots, y_{T+h-1}, X_T) \tag{6}$$

where $\hat{y}_T$ is the total number of sequences to be predicted, given the input sequence X_t. We experiment on two such encoder-decoder models without attention mechanisms, viz. that of Cho et al. [18] and Sutskever et al. [10]. The only difference between the two models is that in [18] an extra context vector is augmented to inputs at each of the time steps in the decoder. The context vector being the last hidden state of the encoder. The problem with a vanilla decoder is that its performance can degrade over a longer range of sequences [38].

D. LSTM-Based Decoder with Temporal Attention

The performance of the encoder-decoder network can deteriorate rapidly as the length of the input sequence increases [38]. Therefore, following the encoder with input attention, a temporal attention mechanism is used in the decoder to adaptively select relevant encoder hidden states across all time steps. The attention weight of each encoder hidden state at time t is calculated based upon the previous decoder hidden state $d_{s-1} \in \mathbb{R}^m$ and each of the hidden states of the encoder LSTM h'_t where T is the number of time steps in the input window. The term $[d_{s-1}; h'_t] \in \mathbb{R}^{2m}$ is a concatenation of the previous hidden state of the decoder and hidden states of the LSTM encoder units, whereas $v_d \in \mathbb{R}^m$, $W_d \in \mathbb{R}^{m\times 2m}$ and $U_d \in \mathbb{R}^{m\times m}$ are parameters to learn. The attention schemes per [17], [16] are as follows:

$$\text{score}(d_{s-1}, h'_t) = \begin{cases} v_a^T \sigma(W_d d_{s-1} + U_d h'_t) & \text{Bahdanau} \quad \text{(a)} \\ v_a^T \sigma(W_d[d_{s-1}; h'_t]) & \text{Concat} \quad \text{(b)} \\ d_{s-1}^T W_d h'_t & \text{General} \quad \text{(c)} \\ d_{s-1}^T h'_t & \text{Dot} \quad \text{(d)} \end{cases} \tag{7}$$

The slight changes in eqs. 7a,b are the replacement of the $\tanh$ non-linearity by the sigmoid σ, to keep the range of the intermediary logits in the range $[0, 1]$.

The attention weight β_t^i represents the weight of the ith encoder hidden state for the prediction:

$$\beta_t^s = \frac{\exp(\text{score}(d_{s-1}, h'_t))}{\sum_{k=1}^{T_x} \exp(\text{score}(d_{s-1}, h_t))} \tag{8}$$

Since each encoder hidden state h_i is mapped to a temporal component of the input, the attention mechanism computes the context vector c_t as a weighted sum of all the encoder hidden states $\{h'_1, h'_2, \cdots, h'_T\}$ as

$$c_s = \sum_{t=1}^{T} \beta_t^s h_t. \tag{9}$$

The context vector c_t is distinctly calculated at each time step as per Equation 9.

Once we get the weighted sum of the context vectors, we can combine them with the given target series $\{y_1, y_2, \cdots, y_{T-1}\}$:

$$\tilde{y}_{t-1} = \tilde{w}^T[y_{t-1}; c_{s-1}] + \bar{b} \tag{10}$$

where $[y_{t-1}; c_{t-1}] \in \mathbb{R}^{2m}$ is a concatenation of the decoder input y_{t-1} and the computed context vector c_{t-1}. Parameters $\tilde{w} \in \mathbb{R}^{2m}$ and $\tilde{b} \in \mathbb{R}$ map the concatenation to the size of the decoder input. The newly computed $\tilde{y}_{t-1}$ can be used for the update of the decoder hidden state at time t as :

$$d_s = f_2(d_{s-1}; \tilde{y}_{t-1}) \tag{11}$$

We choose the nonlinear function f_2 as an LSTM unit d_s that can be updated per eqs. 1 to 5.

E. Training Procedure

Our optimization strategy is similar to traditional direct time series forecasting model. Assume the input time series is $Y_t = \{y_1, y_2, \cdots, y_t\}$, we define a tunable window size q, and reformulate the input at time step t as X_t = $\{y_{t-q+1}, y_{t-q+2}, \cdots, y_t\}$. The problem then becomes a regression task with a set of feature-value pairs { X_t , Y_{t+h} } and is optimized with the Adam optimizer ($\beta_1 = 0.9, \beta_2 = 0.999, \epsilon = e^{-8}$) [54], a variant of Stochastic Gradient Decent (SGD), with learning rate of e^{-5} to train the model. The minibatch size is set to 32 and number of epochs at 1,000, for training every model across all datasets. The squared error is the default loss function for many forecasting tasks, the corresponding optimization objective is formulated as:

$$\min_{\Theta} \sum_{y \in \Omega_{Train}} \|Y_t - \hat{Y}_{t-h}\|_F^2 \tag{12}$$

where Θ denotes the parameter set of our model, Ω_{Train} is the set of time stamps used for training, $\|\cdot\|_F$ is the Frobenius norm, and h is the horizon. Similar to [10], [18], [17], we train the encoder and decoder models jointly to minimize the objective function.

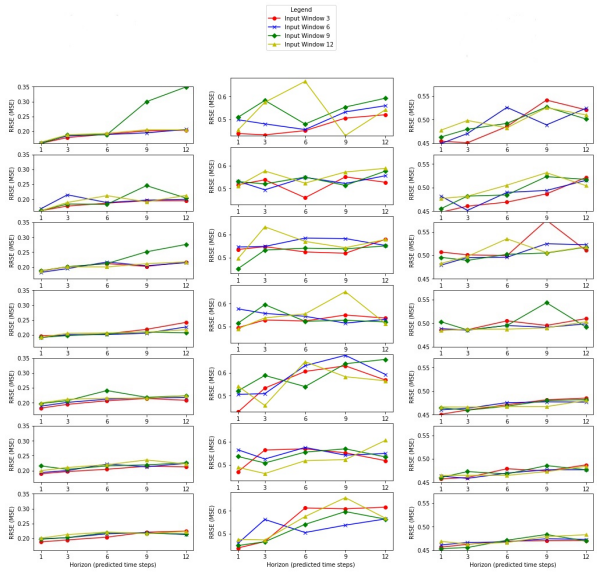
IV. Evaluation

A. Datasets

The multivariate time series datasets used in our study are as follows: Solar[1], Traffic[2], Electricity[3], Beijing PM2.5[4], and Exchange[5]. The pattern analysis on these datasets helps to understand the performance of time series forecasting models. Temporal regularity has been quantified using the Sample Entropy [9]. Following the methods used in [8] each of the datasets is split into training set (first 60%), validation set (next 20%) and test set (last 20%). All the training, validation and test data were normalized by Min-Max Scaling.

B. Parameter Settings

There are two parameters we have experimented on: the number of time steps for the input window T and the number of time steps to be predicted in the horizon h. Different from refs. [8], [9], [40], we report the results of the experiments where we set the value of $T \in \{3, 6, 9, 12\}$ and $h \in \{3, 6, 9, 12\}$. We use a single layer of LSTM units in both the encoder and decoder LSTMs without any dropout. We have experimented with the number of hidden units in the encoder and the decoder in {128, 256, 512}. All weights have been initialized from $-\sqrt{1/k}$ to $\sqrt{1/k}$, where k is the number of hidden units. We report average results over two runs of each model.



C. Metrics

To keep the evaluation metric standard to the benchmark results reported in [8], [9] we use the metrics in those papers, viz. the Root Relative Squared Error (RSE) and the Empirical Correlation Coefficient (CORR). A model where the RSE exceeds 1 indicates a bad prediction. Lower RSE values implies better predictions, while a higher CORR value is better.

D. Methods for Comparison

The two methods without attention used for comparison in this paper listed in the first two rows of Table I, are labeled as Cho et al. [18], and Sutskever et al. [10]. The two models with attention are Bahdanau et al. [17], and Luong et al. [16]. Of the two with attention, we experimented different attention schemes with corresponding scoring equations, referred to as "Bahdanau et al. (*)" and "Luong et al.(*)" where * refers to the attention scheme in Table I.

E. Discussion and Analysis of Experimental Results

We provide the RSE and CORR values of nine LSTM methods on five datasets in tables II and III. Due to space consideration, we show the results for window size set to 3, 6, 9, and 12 and for horizon of 3, 6, and 12 (skipping 9) for each method. From these tables, we observe that, on the three datasets with high periodicity (viz. Solar, Traffic,

TABLE II: Evaluation summary of all LSTM models (RSE and CORR) trained on MSE (Part I). Results in bold face indicate that the result of that column is better than the benchmark result [8] of a particular metric.

Beijing PM2.5 datasets), the NMT models used for forecasting outperform the benchmark results as reported in [8]. Experimenting with the hidden units in the encoder and decoder LSTMs did not yield a significant variation in MSE results. The number of hidden units of both the encoder and decoder LSTMs is fixed at 512, to give the models an increased learning capacity.

In Fig. 1, we note that the RSE values across the horizons show rising, though insignificantly so, trends. The Electricity data set results show the most fluctuations. Interestingly, the method without an attention mechanism (Cho et al.; fourth plots from the top) show no substantial deterioration with longer horizon, comparable to Luong et al.'s methods. Comparing Bahdanau et al. and Luong et al., across the data sets and across the attention scoring function, Luong et al. is more stable relative to horizon and window widths.

We note that Bahdanau's model, [17] coupled with the attention scoring scheme (b) as shown in tables II and III performs the best across all the datasets among all models. The Sutskever et al. model [10] has the worst performance across all the datasets. We hypothesize this happens mainly because in this model the decoder is not augmented with any context vector as opposed to the other NMT models. Although Cho's model [18] lacks an attention mechanism, the decoder is augmented with the hidden state of the encoder's last time step. This suggests that augmenting the decoder with a context is essential for better performance in NMT models.

We observe that given a short input to NMT models for predicting a longer horizon, for example, given an input of 3 time steps we need to predict 12 time steps, yields the best results. To date, there exists no work which has experimented with LSTM models for forecasting a longer horizon given a shorter window. Majority of forecasting models have a longer input sequence of {24, 36, 64, 128} time steps, to predict a future horizon of {12, 24, 48} time steps. Our experiments show that NMT models can not only improve on the benchmark method [8] but also handle these cases with decent results in other datasets with no periodic trends. Another question pointed out in Section I is how each model behaves if a different attention scoring function is used? It was mentioned earlier that Bahdanau's model performs best with the "concat (b)" function in Eq. 7. Hence, the choice of attention function is a factor in improving the prediction accuracy. All these observations make us believe that fine tuning of hyper-parameters, employing regularization techniques of the NMT models could lead to improved results across the datasets.

F. Comparison with Transformer Models

We selected three Transformer models, viz. Autoformer [19], FEDformer [20], and TDformer [21], for comparison. They are representative of the decomposition-centric transformer models. They were configured and evaluated specifically to operate within the same short input window widths and prediction horizons as the LSTM models. We

emphasize that this is not testing these Transformers models at their optimal, long-sequence capacity but rather assessing their performance and efficiency in the localized forecasting context where LSTMs are hypothesized to be strong. Of the models being evaluated, FEDformer has two variants in the Fourier and wavelet domains. TDformer can operate in the time, Fourier, and wavelet domains. The results of evaluating these 6 transformer models using the Traffic and Electricity datasets are shown in Table IV. The Transformer studies as reported [19], [20], [21] have a different preprocessing protocol compared to the earlier LSTM methods. In particular, they do not use min-max scaling. Instead, all data—even before being split into training, validation, and test sets—are normalized by the overall maximum value of the series. To ensure a fair comparison, we repeated the experiments for the LSTM with attention methods using the Transformer studies pre-processing pipeline. The results are shown in Table V.

Comparing tables IV and V, we can see that TDformer has the worst performance among all evaluated forecasters. The LSTM methods are competitive (Electricity data set) or slightly better (Traffic) compared to the Autoformer and FEDformer methods. The Bahdanau methods (all four scoring functions) performed the best among the evaluated forecasters.

G. Computational Cost

The two models with attention mechanisms [17], [16] generally require more computational cost than the two without attention mechanisms. Attention mechanisms introduce additional computations to calculate attention weights and apply them to the encoder hidden states. These additional steps increase the overall complexity of the model compared to those without attention, which primarily consist of LSTM operations. The computational cost of the attention mechanism scales with the sequence length, as the model needs to compute attention weights for each decoder step over all encoder hidden states.

The computational cost of simpler attention scoring functions tend to be less computationally expensive. The "dot (d)" product attention in Eq.7 is generally the simplest and fastest, as it only involves matrix multiplications. The "Concat (b)," "General (c)," and "Bahdanau (a)" attention in Eq. 8 involve additional linear transformations (W_d, U_d) and may be slightly more expensive. Other attention mechanisms that involve more complex calculations will increase the computational cost. While there might be some differences in computational cost between different attention scoring functions, the overall impact on the model's computational cost is likely to be less significant than other factors, such as the LSTM layer sizes or the input sequence length.

When comparing the computational cost of LSTM-based models with attention mechanisms to a Transformer-based model, even with the same input window width and output prediction horizon, there are some key differences. The first is in the attention complexity. LSTM attention typically calculates attention between the decoder's current state and

TABLE IV: Evaluation summary of Transformer Models (RSE and CORR) using Transformer studies preprocessing pipeline and trained on MSE and trained on MSE.

all encoder hidden states. Transformers use self-attention, where each position in the input sequence attends to all other positions. This self-attention in Transformers has a quadratic complexity ($O(T^2)$) with respect to the input window width T.

Also worth noting is that LSTMs are inherently sequential in that calculations at each time step depend on the previous time step, thus limiting parallelization. Transformers can process all positions in the input sequence in parallel, which can be much faster, especially with hardware acceleration such as GPUs, but this parallelization comes at the cost of increased memory and computations.

For shorter input window widths, the computational cost might be comparable, with LSTMs slightly cheaper. As the input window width increases, the quadratic complexity of Transformer self-attention becomes dominant, making Transformers more computationally expensive.

V. Conclusion

Our empirical evaluation confirms that LSTM-based encoder-decoder networks can be a powerful tool for time series forecasting, achieving competitive results with careful selection of input window size and attention mechanisms. The key takeaway is that the choice between LSTM-based models and Transformer-based methods is highly context-dependent.

When computational resources are limited or the forecasting task primarily relies on short-term dependencies, LSTM-based models provide an efficient and effective solution. Conversely, for applications demanding the modeling of intricate long-range relationships and the generation of long-horizon predictions, Transformer-based architectures are likely more appropriate. Further investigation is needed to establish clear guidelines for selecting the optimal model based on the specific characteristics of the time series data and the forecasting objectives.

There are areas for future work that would extend our findings. A more extensive set of experiments, utilizing a larger number of random starting points for each model configuration, will enable a robust statistical analysis, including the calculation of confidence intervals and the application of significance tests (e.g., t-tests). This approach will more formally validate the performance differences between LSTM and Transformer-based models. Furthermore, while we provided a theoretical discussion of complexity to advocate for LSTM's computational efficiency, a direct quantitative comparison would offer more definitive evidence. This analysis might involve measuring and reporting metrics such as training and inference latency and memory consumption for all tested models under the same hardware and software conditions.

***Abstract*—Efficient container handling and early damage detection are critical for minimizing operational delays, reducing costs, and ensuring safety in global maritime logistics. This work presents a deep learning-based methodology for real-time container tracking and automated damage detection during crane unloading operations at container terminals. We develop and deploy two specialized YOLOv12-based object detection models: one for identifying containers in motion and another for detecting structural damages such as bents, dents, and holes. Our models are trained and evaluated on a real-world dataset curated from video feeds captured at the EUROGATE Container Terminal in Limassol, Cyprus. The system is designed for robust performance under realistic terminal conditions, including variable lighting and motion. Our models achieve high detection accuracy, with a mAP50 of 0.99 for container detection and 0.75 for damage detection, substantially outperforming existing benchmarks. These results highlight the practical potential of our method for improving efficiency and safety in automated maritime logistics.**

I. Introduction

CONTAINERS play a pivotal role in global maritime commerce by supporting the movement of incoming, outgoing, and transshipped goods. Due to the significant increase in international seaborne containerized trade volumes, port operators must improve and automate various terminal operations to meet the growing demand and reduce safety risks due to human-computer cross-operations [1]. Approximately 20 million active containers are in use worldwide, completing over 200 million trips annually. Ports serve as central hubs where cargo from around the world converges as it enters or exits. These terminals are responsible for securely loading, unloading, and handling containers. However, the high volume of containers passing through makes it challenging to track damaged ones. Most damage detection methods are based on manual inspection around the globe [2], [3], which causes low efficiency, low accuracy, slow speed, high cost, and safety risks. Hence, an efficient inspection of the container body is essential to reduce disputes between container terminals and transportation enterprises due to damage to containers [4]. The common damaged types of containers include dents, scratches, distortions, holes, convex, damage to container doors, etc. [4]. These damages can result from various factors, including harsh weather conditions, poor transportation, or inadequate storage at the terminal. If the port fails to identify damaged containers upon unloading, the shipping company may impose fines, claiming the damage occurred within the port rather than beforehand.

In current research studies, computer vision and machine/deep learning methods are commonly used to detect damages in containers at seaports [2]. Machine learning methods are extensively adopted for object detection in images and videos in various fields, including medical, security, military, construction, and transportation [5]. To deal with damage detection in maritime containers at the ports, several maritime companies, stakeholders, and researchers started investing in automatic methods to detect damaged containers [4], [6]. For instance, the authors of [7] propose an image processing-based method (e.g., looking at hue, saturation, and intensity) using sensors and cameras. Another study [8] employs a phase correlation approach to detect damage in containers. Both studies rely on manual detection and employ cloud-based processing and storage. Any information that must be accessed is transmitted from the cloud to the terminal, which consumes significant time and resources. Due to the high real-time requirements of container detection, this approach is impractical. To address this limitation of cloud computing, the authors of [9] proposed the concept of edge computing, which enables effective data processing at the source, thereby meeting real-time requirements.

To improve the efficiency and accuracy of container damage detection, the current study develops a deep learning-based method for performing two key tasks in real time: 1) detection of containers and 2) detection of damages on containers using video data. We opt for the YOLOv12 model, a state-of-the-art object detection algorithm designed for fast and accurate real-time applications. It is trained initially on the COCO128

dataset for 100 epochs, optimizing parameters using techniques like stochastic gradient descent (SGD) or its variants. The models were then fine-tuned using the transfer learning methodology with real, manually-labeled datasets. Our extensive experimental evaluation demonstrates our proposed approach's efficacy in terms of higher accuracy regarding container and damage detection.

The remaining manuscript is organized as follows. Related work is presented in Section II. Section III presents comprehensive details of the proposed methodology along with a description of the employed datasets. Section IV shows simulation settings along with results and discussion. Finally, Section V concludes the study.

II. Related Work

Several pieces of research focus on developing automatic container and damage detection approaches. The most relevant ones are reviewed and analyzed in this section.

A study disclosed in [10] proposes a system for container damage detection using the correlation coefficient method. The system can be set at the port gate to detect damage in the arriving containers. Another study [11] develops a container damage detection model by proposing an Fmask-RCNN model. It is based on Mask-RCNN, introducing the Res2Net101 framework and adding path fusion augmentation, multiple fully connected layers, and fusion upsampling. The Fmask-RCNN model is applied to the identification of port container damage. Simulation results reveal that their proposed model achieves a miss rate of 4.59% and an error rate of 18.88%. The authors of [6] developed an automatic system by employing CNN and transfer learning from MobileNetV2 [12] and InceptionV3 [13] models to detect various types of damage in maritime containers. They also develop a dataset considering nine typical types of container damage. The proposed model and the existing methods are trained on developed data and then validated on test data. Results from experiments demonstrate higher accuracy in damage detection compared to prior approaches.

In [14], an automatic system (Spatial Structure Window plus texture clustering by K-Means algorithm) is used to recognize ISO-codes, improving the automatic methods that rapidly identify containers. On the one hand, this method increases the efficiency with which containers are registered after being discharged (thus increasing the supply chain and international trade efficiency). On the other hand, it eliminates the human-led errors likely to occur before the process's digitalization. In [15], an automatic image recognition system is used together with an adaptive control system based on neural networks for container identification and its position for smooth container landing on the platform. The benefits these authors mention are more effective control, reduced waste, and more precise measurements. A study presented in [16] develops a computer vision-based model to minimize total costs at terminals and reduce delay time by avoiding wrong container unloading. For this, an alarm system is designed based on container color detection. The proposed method alerts the quay crane operator if the detected color of a container does not comply with the correct color. It is concluded from several experiments at the Hong Kong Port that the proposed method can help in saving resources, especially total annual costs up to 85%.

The authors of [17] propose a computer vision-based method to determine the container location during the loading operation and record it. This process is typically performed by the human eye, and sometimes small miscalculations cause dangerous consequences. For accurate location prediction, the proposed method uses coastline, container edge line, and container number as features to locate and analyze. Experimental results from Ningbo-Zhoushan Port, China, show the proposed method's efficacy in accurate location prediction with minimum processing time (less than 0.6 seconds). Another study [18] also deals with container position prediction for gantry cranes at the container terminals by proposing a computer vision method. The primary objective of the newly developed system is to provide precise parameters for container lifting operations. The developed method utilizes cameras for collecting container information, then the corners of the containers are detected by employing a traditional image processing algorithm and a convolutional neural network (CNN). Finally, the offset distance and deflection angle are measured by precise corner position. Results from simulations demonstrate that the detection rate of the proposed system reaches 94%. Huang *et al.* propose an accident prevention system based on vision tracking during container lifting operations [19]. The developed system uses a camera to detect and track the movement of the truck wheel hub and the corners of the container to be loaded. The proposed algorithm combines CNN, traditional image processing, and a multi-target tracking algorithm to calculate the displacement and posture information of the truck during the operation. Experiment results show that the proposed method's measurement accuracy reaches 52mm.

III. Adopted Methodology and Dataset Description

The current study develops two models for container detection and damage detection for the Port of Limassol, Cyprus. Both models utilize a pre-trained YOLOv12 model [20], [21], which we fine-tuned on custom datasets created specifically for this research. Separating the tasks into two models provides key advantages: damage detection is only performed when a container is first identified, reducing unnecessary computation and enabling the second model to be more specialized and focused. Further details regarding the datasets and the chosen methodology are presented next.

A. Dataset for Container and Damage Detection

This study utilizes a real-world dataset from EUROGATE Container Terminal Limassol, Cyprus. The dataset comprises video data recorded by IPTV cameras installed on the quay cranes responsible for loading/unloading containers to/from vessels. The data from these videos was converted into image frames, which were manually labeled when they contained containers and container damage.

1) Data Preparation: To prepare the data for the container detection model, we collected videos taken throughout the year 2024, at different times of day and night, and under different weather conditions (e.g., sunny, cloudy, raining). We converted these videos into frames, after which we manually reviewed each frame, defined a bounding box around the containers using an open-source tool called LabelImg (also known as Label Studio) [22]. A total of 1927 images with containers were labeled, containing containers of different sizes (e.g., 20 ft, 40 ft), types (e.g., regular, reefer, open top), and colors (e.g., yellow, blue, red).

For the damage detection model, we utilized images from the container dataset. We followed the same labeling procedure with video data as the first model, but for the types of damages instead, as shown in Figure 1. We recorded three main types of container damage that are of interested to the container terminal: (a) *holes*, which represent visible holes on the container surface; (b) *bents/dents*, which represent deformation features such as concave damage, indentations, or arching on the container surface; and (c) *normal wear*, which represents minor damage such as cuts, cracks, rust, and other similar features on the container surface. A total of 732 images with damage were labeled.

2) Data Augmentation: Due to the limited amount of usable data (especially for damaged containers), we employed data augmentation techniques to expand our datasets. For both the container and the damage datasets, we added images using horizontal flips. In addition, we added custom-created damage images, specifically for holes, as the available data was severely limited due to it being a rare occurrence. By using these methods, we successfully increased our datasets from 1927 and 732 images to 3854 and 1764 images, for container and damage, respectively. Both datasets were then randomly split into training, validation, and testing. The containers dataset contains 2470, 598, and 786 images for training, validation, and testing, respectively, while the damage dataset includes 1442, 182, and 140 images for training, validation, and testing, respectively.

(a) Container Dataset

(b) Damage Dataset

Fig. 1: Sample of labeled images from (a) the container and (b) the damage datasets

B. Model Development

YOLOv12 is a cutting-edge object detection algorithm engineered to deliver speed and accuracy for real-time applications [23]. Trained on the COCO128 dataset over 100 epochs, it refines parameters through techniques such as stochastic gradient descent (SGD) or its derivatives. The YOLOv12 model architecture is constructed upon a deep convolutional neural network (CNN) that divides the image into grids and predicts objects in each grid cell. Unlike traditional two-stage detectors (e.g., R-CNN), YOLO is a single-stage detector, making it fast and suitable for real-time applications like video surveillance, autonomous driving, and robotics [24].

For the container detection model, we utilize our dataset of container images to train a customized YOLOv12 model. The training process involved fine-tuning several key training parameters to optimize performance: training for 80 epochs, using an image size of 1024 pixels to capture detail, and setting a batch size of 24 for efficient processing. We also built on the YOLOv12n pre-trained model, chosen for its strong balance of speed and capability. This setup allowed us to achieve accurate and reliable container detection suited to our application.

For the damage detection scenario, we trained the same pre-trained YOLOv12n model on our damage dataset. We also perform model optimization, like the one performed in the first stage for the container identification model. The model was trained on 1442 images and validated on 182 images. The model is able to classify the type of damage into three categories: Holes, Bents/Dents, and Normal Wear.

To improve our models' performance, we tested different configuration options provided by the YOLOv12 model, a very common practice known as hyperparameter tuning. This included adjusting the hue and saturation of the input images and tuning the IoU threshold to better detect multiple containers and damages that appear close together. The parameter ranges and optimal values are listed in Table I, which are the same for both the container and damage detection models.

Fig. 2: Tracking experiment with reassignment box visible

TABLE I: Parameter ranges and optimal values for model hyperparameter tuning

Parameter	Tested Range	Optimal Value
IoU Threshold	0.3 – 0.7	0.5
HSV Saturation	0.1 – 0.9	0.7
HSV Value	0.1 – 0.9	0.4
Image Resolution	640px, 1024px	1024px

C. Tracking Capabilities

YOLO includes integrated real-time tracking capabilities by implementing BoT-SORT [25], an advanced multi-object tracking algorithm that assigns a unique ID to each detected container. This allows us to track individual containers over time, recording details such as when each one was first and last seen, how long it was present, and whether any damage was detected. The model's streamlined design and adjustable tracking parameters make it adaptable to a wide range of deployment scenarios, from edge devices to cloud-based APIs [24].

One of the biggest difficulties faced was the occasional view impairment due to other external factors (trucks, straddle carriers, etc.) beyond our control, which could cause multiple IDs of the same container. To combat this, we implemented some extra checks needed before a container gets a new ID assigned, like a minimum time between detections, using detection coordinates before and after the object was lost, with a dynamic confidence threshold that works in tandem with the minimum time. In basic terms, if a container is lost for a few frames, the model will reassign the same ID to the container as the confidence is very high. But as time passes, the confidence is reduced, and so does the probable location box of the object.

Figure 2 shows the tracking algorithm in action. In the first frame, we have the detection of a container with an ID of 1. In the second frame, the container is lost due to a straddle carrier passing over the container. The green outline represents the confidence of a re-assignment if an object is found again. The confidence is high because the container is lost for only a few frames. In the third frame, some time has passed, so the possible location of a reassignment converges towards the last known position of the last detection. The container is found again in the last frame, but only half of what it was. Because the new detection is inside the reassignment box, we reassign the same ID to the new detection. This algorithm has helped us solve many problems related to losing objects due to such external factors.

Fig. 3: Validation results for container detection

IV. Results and Discussion

This section presents the experimental evaluation results of the container and damage detection models using the YOLOv12 model. The study uses real-world datasets from the EUROGATE Container Terminal Limassol, Cyprus, as discussed in Section III-A. The training and testing of the models were performed on a server with two AMD EPYC 7352 24-core processors, 128 GB RAM, and an NVIDIA Tesla T4 GPU running Ubuntu 22.04.4 LTS. We first present the results for the container and damage detection models, and then compare them against other state-of-the-art approaches.

A. Container Detection Model Evaluation

Figure 3 shows some validation results for the container detection model, illustrating the model's ability to detect and bound containers in images, including scenarios with multiple containers per image or partially-viewed containers. To concretely evaluate the performance of the developed models, we employ the mAP50 and mAP50-95 metrics, as these are commonly used metrics in object detection models [26]. mAP50 measures the mean average precision at an intersection over union (IoU) threshold of 0.5, indicating how accurately the model detects objects with at least 50% overlap between

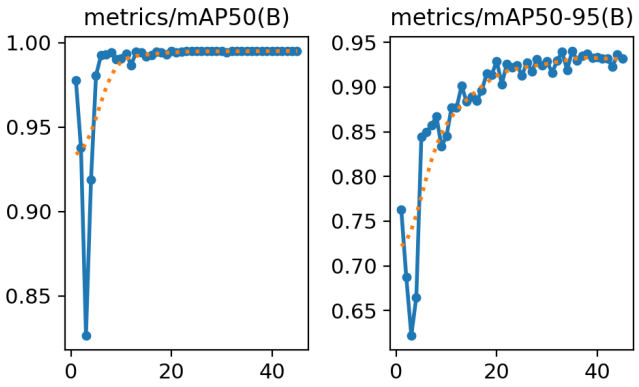

Fig. 4: mAP50 and mAP50-95 for container detection during training (the x-axis denotes the number of epochs)

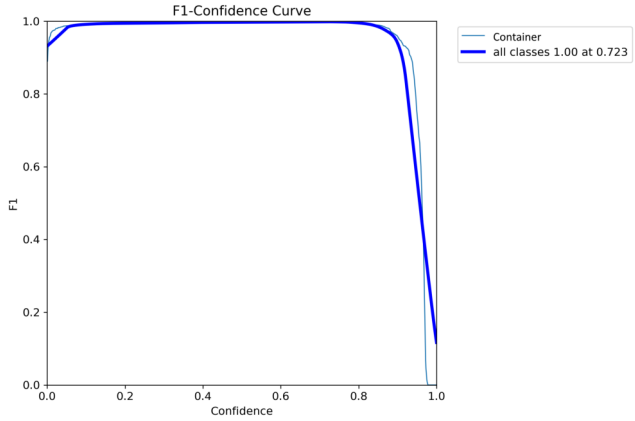

Fig. 5: F1 score for container detection across varying confidence thresholds

predicted and ground truth boxes. mAP50-95 measures the mean average precision across multiple IoU thresholds ranging from 0.5 to 0.95. We also investigate the F1 score, which represents the harmonic mean of the precision and recall. The selection of these evaluation metrics collectively contributes to a robust and comprehensive evaluation of the model's efficacy.

The evaluation of the container detection model, based on the mAP50 and mAP50-95 metrics, indicates remarkable performance. As illustrated in Figure 4, the model achieved mAP50 scores ranging from 0.96 to 0.99 after 10 epochs and mAP50-95 scores from 0.91 to 0.93 after 20 epochs. Notably, the model reached its peak performance at the 35th epoch, where it recorded a mAP50 score of 0.9921 and a mAP50-95 score of 0.9331. The initial drops in both figures are common and reflect sensitivity to noise or random initialization, but both metrics stabilize quickly. These high scores demonstrate the model's robustness and precision, highlighting its efficacy and reliability in container detection. Even with the relatively low amount of data, our developed model performs well in detecting containers.

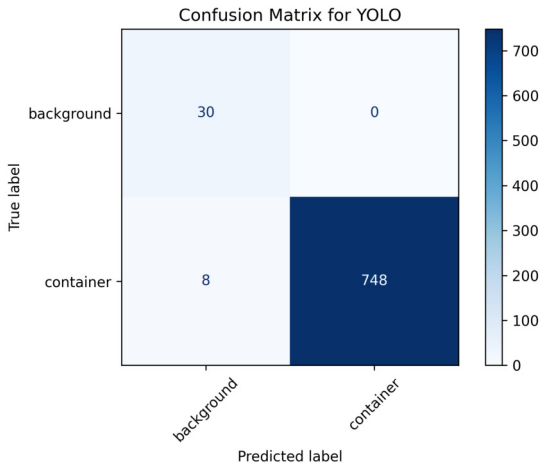

Fig. 6: Confusion matrix for container detection

The results depicted in Figure 5 show the F1 scores of the container detection model across varying confidence thresholds, providing insights into the model's balance between false positives and false negatives. The model achieves high performance, with a near-perfect F1 score at the confidence thresholds between 0.5 and 0.8. This indicates a strong balance between precision and recall, confirming the model's reliability in detecting containers accurately. The consistently high F1 scores across thresholds further demonstrate the robustness of the detection system.

This study also constructs a confusion matrix to validate the performance of the container detection model, shown in Figure 6. A confusion matrix serves as a valuable tool to assess the prediction/detection accuracy of any model, and it supports visual and robust validation of the approach. This matrix enables the comparison of actual and predicted values for each class within the dataset, providing valuable insights into key metrics such as true positives, true negatives, false positives, and false negatives. Figure 6 illustrates that the container detection model only misclassified 8 images (as false negatives) out of the 786 images of the test set, validating the strong detection power of the model.

B. Damage Detection Model Evaluation

Figure 7 shows some results for the damage detection model, illustrating that the model can detect and differentiate various types of damages, as well as detect multiple damages per container (if any).

Figure 8 shows the results of the container damage detection model. The damage detection model achieved a final mAP50 of 0.685 and mAP50-95 of 0.458 after 80 training epochs, indicating moderate detection accuracy. The metrics improved steadily throughout training, suggesting a smooth training process. The main reasons for the lower performance compared to the container detection model are the limited size of the dataset, as well as the far more complicated detection problem, since container damages are often small

Fig. 7: Validation results for damage detection

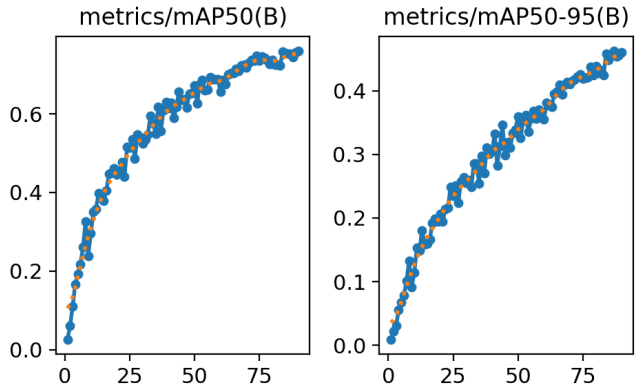

Fig. 8: mAP50 and mAP50-95 for damage detection during training (the x-axis denotes the number of epochs)

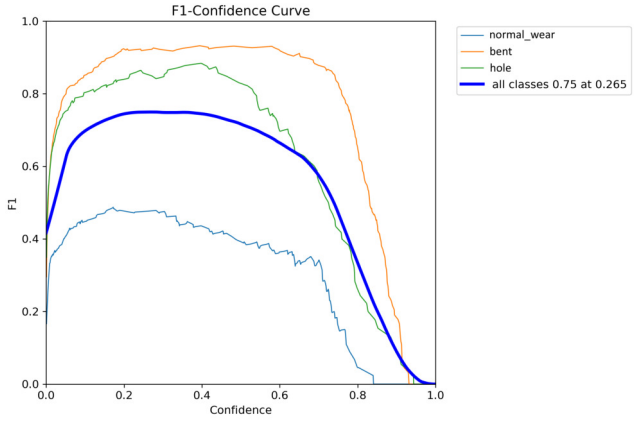

Fig. 9: F1 score for damage detection across varying confidence thresholds

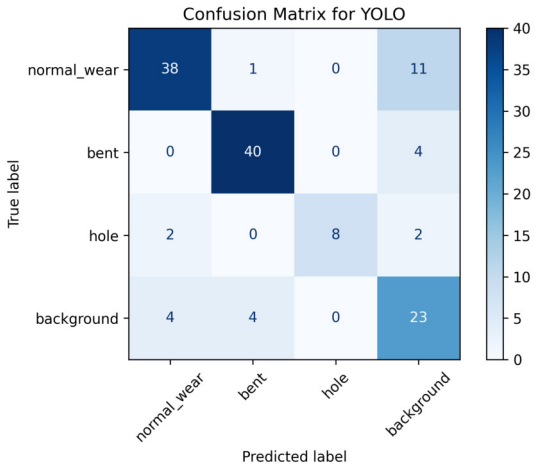

Fig. 10: Confusion matrix for multi-class damage detection

in size (compared to a container) and hard to distinguish from the rough container surface. However, this performance is significantly better than the damage detection achieved by other state-of-the-art models, as we will see in Section IV-D.

The results depicted in Figure 9 show the F1 score of the damage detection model across varying confidence thresholds. While the average F1 score peaks at 0.75 at a 0.27 confidence threshold, the model achieves much higher F1 scores for detecting the more important damages of bents/dents (0.92) and holes (0.88) at the 0.5 confidence threshold. The main difficulty for the model is the detection of normal wear, which is typically much more subtle compared to the other damages. The lower F1 scores are attributed to the limited dataset, as well as the more complex nature of damages (different sizes, types, locations, etc.).

Figure 10 shows the confusion matrix of the damage detection model based on the testing data, which again shows the good performance of the model in detecting and classifying the types of damages found. The confusion matrix reveals that the model achieves high accuracy for the bent/dent damages (40/44 correct) and performs reasonably well for normal wear (38/50 correct). The most frequent misclassifications occur when the model fails to detect some minor normal wear areas. The model also exhibits some confusion between the hole and the other damage types, mainly due to the small training and testing sizes. These results indicate some areas for improvement in discriminative learning and class boundary clarity.

Driven by the above results and the small difficulties observed in detecting specific damage types, we also developed a binary damage detection model, which detects whether damage is present without attempting to categorize it. The key motivation behind this approach was to evaluate whether combining all damage types into a single class could improve the overall detection performance by simplifying the task and leveraging a larger combined dataset.

Figure 11 shows the mAP50 and mAP50-95 metrics for the binary damage detection model. When comparing Figures

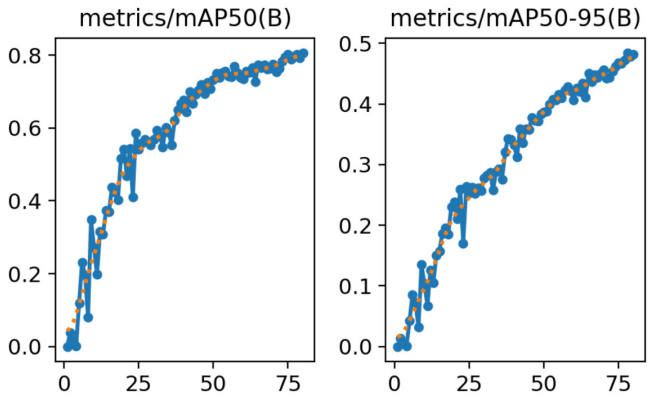

Fig. 11: mAP50 and mAP50-95 for binary damage detection during training (the x-axis denotes the number of epochs)

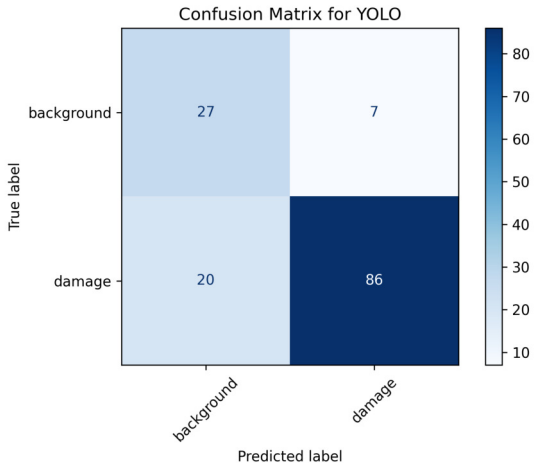

Fig. 12: Confusion matrix for binary damage detection

8 and 11, we observe that the binary model achieved higher mAP50 and mAP50-95 scores. Specifically, the binary model reached a final mAP50 of 0.79 and a mAP50-95 of 0.48 after 80 training epochs, as opposed to 0.69 and 0.46, respectively, for the multi-class model. This indicates that a simplified binary formulation benefits from greater sample density per class and suggests that our multi-class model could also benefit from a larger, more diverse dataset.

The confusion matrix for the binary damage detection is shown in Figure 12, revealing that the model achieved a precision of 92.5%, a recall of 81.1%, and an F1-score of 86.4%. These values reflect high confidence in positive predictions, but also reveal that 20 out of 106 damaged instances were missed. While the binary damage/no-damage model achieved high performance, the multi-class model revealed important distinctions in model performance across specific damage types. In particular, the model performed very well on bent/dent detections but struggled to identify hole instances reliably. This suggests that while binary classification may be sufficient for general screening, multi-class classification is essential when damage type differentiation is operationally important.

TABLE II: Inference speed and latency breakdown on two hardware setups

Metric	Jetson AGX Orin	Server Machine
GPU	Integrated	NVIDIA T4
Container Detection (ms)	37.5	25.0
Damage Detection (ms)	18.8	12.5
Other Processing (ms)	6.2	4.2
Total Frame Time (ms)	62.5	41.7
Achieved FPS	16	24

C. Model Inference Speed

Minimizing latency was a key requirement for these models, given their intended use in real-time applications. To evaluate performance, we benchmarked the tracking system along with container and damage detection on two different machines: (i) the server machine that was used to train the models, and (ii) a Jetson AGX Orin 64GB device that will be deployed on the quay crane for processing the video stream from the IPTV cameras in real time.

Table II shows the average latency (in ms) required to detect a container, detect damages on a container, and other required processing (e.g., split the frame, track the container, output result, etc.). Latency values (ms) are approximate and estimated based on the proportional contribution of each component to the total frame processing time at 1024×1024 input resolution. Overall, even the more resource-constrained device, i.e., the Jetson AGX Orin, can fully process a frame in 62.5 ms, which showcases the lightweight nature of the developed models. Note that the input video streams are recorded at six frames per second (FPS). As shown in Table II, both the Jetson AGX Orin and the server equipped with an NVIDIA T4 GPU achieved inference speeds significantly higher than the input rate, at 16 FPS and 24 FPS, respectively. This performance margin enables the system to process multiple video streams concurrently while maintaining real-time responsiveness.

D. Comparison with Other Work

This section compares our approach with the latest state-of-the-art models proposed in [6], specifically MobileNetV2 [12] and InceptionV3 [13]. To ensure a fair and meaningful comparison, we made several adjustments to our YOLOv12 model. Since MobileNetV2 and InceptionV3 are classification models that assign a single label to each image, we modified YOLOv12 to output only the most important class per image (holes, bents/dents, normal wear), effectively aligning its output format with that of the classification models. This allowed us to directly compare classification performance across all models under similar evaluation conditions.

Table III summarizes the classification performance of MobileNetV2, InceptionV3, and YOLOv12 in terms of precision, recall, and F1 score. The results clearly show that YOLOv12 significantly outperforms both MobileNetV2 and InceptionV3 across all classes and evaluation metrics. YOLOv12 achieved

TABLE III: Multi-class damage detection performance comparison across models

Class	MobileNetV2				InceptionV3				YOLOv12			
	Prec.	Rec.	F1	Pred/Real	Prec.	Rec.	F1	Pred/Real	Prec.	Rec.	F1	Pred/Real

Note: *Prec.* = Precision, *Rec.* = Recall, *F1* = F1-score, *Pred/Real* = Number of predicted samples over ground truth count for each class.

TABLE IV: Binary damage detection performance comparison across models

Class	MobileNetV2				InceptionV3				YOLOv12			
	Prec.	Rec.	F1	Pred/Real	Prec.	Rec.	F1	Pred/Real	Prec.	Rec.	F1	Pred/Real
Damage	0.72	0.59	0.65	63/106	0.78	0.66	0.71	70/106	0.89	0.82	0.85	87/106
No Damage	0.17	0.26	0.21	9/34	0.28	0.41	0.33	14/34	0.55	0.68	0.61	23/34
Macro Avg	0.44	0.43	0.43	–	0.53	0.54	0.52	–	0.72	0.75	0.73	–
Weighted Avg	0.58	0.51	0.54	–	0.66	0.60	0.62	–	0.82	0.79	0.79	–

Note: *Prec.* = Precision, *Rec.* = Recall, *F1* = F1-score, *Pred/Real* = Number of predicted samples over ground truth count for each class.

a macro-average F1-score of 0.80 and a weighted average of 0.82, while InceptionV3 reached 0.30 and 0.40, and MobileNetV2 only managed 0.19 and 0.27, respectively. A closer look reveals that both MobileNetV2 and InceptionV3 struggled to correctly identify images with no visible damage, often misclassifying them as one of the damage types. YOLOv12, on the other hand, maintained a relatively high F1-score in these cases by correctly predicting the absence of damage in most of the 34 images.

An important factor influencing these results is the input resolution of each model. MobileNetV2 operates on 224×224 pixel images, InceptionV3 on 299×299, and YOLOv12 on 1024×1024. The performance of the models shows a clear correlation with input size: larger inputs allow more detailed spatial information to be retained, which is especially important for detecting subtle or localized damage features. This linear relationship between input resolution and classification performance highlights the importance of high-resolution processing in damage detection tasks.

To further confirm our results, we ran the same tests by creating models for container detection and binary damage detection. The performance metrics followed the same pattern shown in Table IV for the binary damage detection models. MobileNetV2 and InceptionV3 achieved better results in the binary case compared to the multi-class case, but they were still inferior to the results yielded by our YOLOv12 models.

In summary, YOLOv12 not only provides stronger performance due to its architecture but also benefits from higher input resolution, making it more reliable in distinguishing between different damage types and identifying undamaged cases correctly. In addition, MobileNetV2 and InceptionV3 can only detect the presence of damage on a container, whereas our model can (i) detect multiple damage areas on the same container (if there are any), and (ii) localize the damage by outputting a bounding box around each damaged area. Hence, our proposed model not only offers higher detection performance but also offers additional useful functionality.

V. Conclusion

In this study, YOLOv12-based container detection and damage detection models have been proposed to enhance optimization at the container terminal. The primary aim of this study is to reduce manual operations by humans in a risky environment by proposing automated systems to perform the same tasks. The proposed models are trained using real-world data collected from the EUROGATE Container Terminal Limassol, Cyprus. Due to the low amount of available data, this study also adopts data augmentation to increase the dataset. Finally, the proposed models are validated on test data, and the results show the high performance of the proposed models in terms of high accuracy and low error rate. The proposed models offer significant advantages over the existing state-of-the-art approaches, both in terms of higher detection accuracy as well as providing new functionalities, including tracking multiple containers in the same video frame and detecting multiple damages (of potentially different types) on the same container.

In future work, we aim to leverage the current damage detection model in a feedback loop that will automatically identify and incorporate new instances of container damage,

thereby expanding our dataset and improving model performance over time. In addition, we plan to extend the system's capabilities to detect whether container seals are intact or broken. Finally, we intend to integrate the detection models into a real-time monitoring system that operates through port IP network cameras and interfaces directly with the port management infrastructure.

***Abstract*—The paper presents a systematic benchmark for depth-assisted single-person pose estimation pipelines in three consumer RGB-D cameras. We introduce a lightweight optimization that adjusts only the relative depth coordinates of predicted joints so that their inter-joint depth gaps match those observed in the depth sensor image. The proposed approach is fully differentiable, sensor-agnostic, and light enough for real-time edge deployment, making it immediately applicable to sports coaching, workplace ergonomics, and mixed reality mobile systems. Experiments on a controlled motion capture dataset demonstrate performance trade-offs in accuracy, speed, and robustness under challenging viewing geometries. The findings provide practical guidance on which depth technology best complements state-of-the-art vision models and establish relative depth matching as an effective computationally trivial alternative for laboratory calibration.**

I. Introduction

HUMAN pose estimation has matured from heuristic silhouette analyses to deep learning systems that can locate dozens of body landmarks in real time, fueling progress in biomechanics [1], [2], [3], teleoperation [4], [5], sports analytics [6], and immersive VR [7], [8], [9]. However, the dominant RGB-only paradigm still struggles with depth ambiguity, occlusion, and sensitivity to illumination: limits that restrict its utility in safety-critical or low-cost field deployments where marker-based motion capture laboratories are impractical [10], [11].

Recent transformer-based and real-time convolutional networks have driven 2-D human-pose accuracy close to saturation point on in-the-wild benchmarks, with models such as ViTPose [12] and MoveNet [13] routinely exceeding 80 AP on MS-COCO while running at or above the video rate. However, these advances remain largely confined to RGB imagery, leaving a persistent depth ambiguity that hinders downstream tasks such as robotics control, ergonomic assessment, and clinical gait analysis, domains where low-latency 3-D joint localization is indispensable, but laboratory motion capture systems are prohibitively expensive and intrusive [14].

This project has received funding from the Research Council of Lithuania (LMTLT), agreement No. S-PD-24-29.

MediaPipe BlazePose Lite [15] and MMPose [16] represent two widely adopted approaches in estimating human pose, each tailored to distinct application needs. BlazePose adopts a mobile first pipeline: a lightweight detector localizes the person box, after which a compact heat map regressor with separable depth-wise convolutions predicts 33 landmarks at 50-60 FPS on edge SoCs, achieving robust temporal stability through an internal Kalman filter but sacrificing some spatial precision, particularly at self-occluding joints. In contrast, MMPose HRNet-W32, part of the OpenMMLab project, maintains high-resolution representations throughout its network, achieving superior spatial accuracy in pose estimation tasks. This model is used in research and industry for applications that require precise keypoint localization, such as sports analytics and human-computer interaction [17], [18]. Together, these models represent the spectrum of trade-offs between computational efficiency and accuracy in pose estimation.

Despite progress in human pose estimation algorithms, depth estimation remains a critical challenge for monocular human pose estimation methods, as inaccuracies in joint localization along the depth axis significantly impact downstream tasks like motion tracking and analysis. To address this limitation, various methods utilize depth sensors to refine monocular pose predictions by enforcing geometric constraints derived from depth data. Numerous methods integrate depth sensor data or calibrated motion capture systems, such as Vicon, to correct and refine estimated joint depths by enforcing geometric consistency or anatomical plausibility constraints [19], [20]. Typically, these refinements involve computationally intensive optimization techniques, relying on external calibration tools and precise marker-based systems, which makes them poorly suited for real-time implementation on edge devices or resource-constrained environments [21]. Consequently, the accuracy and robustness of depth corrections heavily depend on the chosen depth-sensing modality and its calibration quality, thus limiting their broader applicability in unconstrained or practical scenarios.

Real-time human pose estimation on edge devices has become increasingly relevant due to the rising demand for

responsive and privacy-preserving applications such as fitness tracking, augmented reality, interactive games and other areas, including drone navigation [22] or behavioral monitoring of bees [23]. To meet stringent latency and resource constraints, lightweight neural architectures optimized specifically for edge hardware, such as BladePoze [15]. Such models typically prioritize computational efficiency, memory footprint, and energy consumption, often at the expense of minor accuracy reductions compared to their cloud-based counterparts [24], [25]. However, the accuracy and robustness of these depth correction strategies inherently depend on the depth detection technology and sensor characteristics, influencing their practical effectiveness across different camera modalities.

Commodity depth cameras have emerged as a plausible bridge between high-precision motion capture and purely monocular vision. Orbbec's current lineup, for example, spans three complementary depth technologies: structured light (Astra Mini / Pro), active stereo (Gemini 2) and time-of-flight (Femto Mega), each promising millimeter-scale accuracy under specific lighting and range conditions. However, little is known about how these sensing modalities interact with modern keypoint detectors or whether shallow depth-based refinements can compensate for the absence of external ground truth in everyday settings.

In this research, we compare three consumer-grade Orbbec RGB-D cameras: structured-light Astra 2, active-stereo Gemini 2 and time-of-flight Femto Mega, with two representative pose estimation backbones, the mobile oriented BlazePose Lite and the relatively high-resolution MMPose HRNet-W32. We introduce a lightweight optimization that adjusts only the relative depth coordinates of predicted joints so that their inter-joint depth gaps match those observed in the depth sensor image. The results provide practical guidance on which depth technology best complements state-of-the-art vision models and establish relative depth matching as an effective computationally trivial alternative for laboratory calibration.

II. Materials and Methods

A. Participants

Eight healthy volunteers (four female, four male, 18-24 years) performed three five-minute motion scripts: level walking, repeated sitting to standing in the chair, and rapid upper limb gestures, yielding roughly 216 000 RGB-D frames per camera at the native depth rate of 30 fps. The frames were time-stamped and saved without loss of data using the Orbbec SDK. All participants gave their informed written consent in accordance with the Declaration of Helsinki.

B. Experimental setup

Figure 1 illustrates the data acquisition and processing pipeline. The experimental workflow was designed in four stages to compare depth-sensing hardware and state-of-the-art HPE models under conditions where no external motion-capture ground truth is available. First, RGB-D sequences are captured independently with three Orbbec sensors that embody the main consumer depth technologies, time-of-flight, structured light, and active stereo, while participants perform scripted whole-body motions. Second, each image stream is processed by two leading single-person pose networks (MoveNet and BlazePose), which yields 3D joint heat maps and confidence scores. Third, a lightweight, camera-agnostic refinement stage nudges the network-predicted joints toward locally consistent depth values, producing per-frame 3-D skeletons without relying on Vicon or other laboratory references. Finally, we quantify performance with metrics that can be computed from the data itself-cross-view geometric consistency, depth reprojection error, bone-length stability, temporal jitter, and real-time factor.

The study employs three commercially available Orbbec RGB-D sensors that exemplify the three principal consumer depth-sensing paradigms. Femto Mega integrates Microsoft's indirect time-of-flight ASIC and delivers 1 MP depth images (1024×1024 px at 15 Hz or 640×576 px at 30 Hz) in a $120 \times 120^\circ$ field-of-view within a $0.25 - 3.9$ m working range. Astra 2, a structured light-based camera, outputs UXGA depth (1600×1200 px) at 30 Hz over a $58 \times 45^\circ$ depth FOV, achieving no more than 0.16 % range error at 1 m. Gemini 2 employs 850 nm active stereo; it provides 1280×800 px depth and color at 30 Hz across a $91 \times 66^\circ$ FOV, covers a $0.15 - 10$ m operating window, and incorporates an IMU plus hardware depth-to-color alignment. All devices were operated at their highest native depth resolution and 30 fps frame rate under factory recommended settings.

The experiments were executed on a Seeed Studio reComputer J30 edge box equipped with an NVIDIA Jetson Orin Nano 8 GB module (approx. 40 TOPS AI performance) running JetPack 5.1 on Ubuntu 22.04 L4T. Each sensor was mounted on a fixed tripod 1.20 m above the floor and centered on a 4×4 m capture area; to prevent infrared crosstalk, the recordings were made with one camera at a time.

C. Data acquisition and processing

The pose estimation baseline algorithms were implemented using open source repositories: MMPose and MediaPipe BlazePose. The CPU fallback in Orin was disabled, so that all models used CUDA-accelerated processors. Regarding the software, Python 3.10, PyTorch 2.2, TensorFlow 2.15, cuDNN 9.0, and TensorRT 8.6 were used to deploy the system.

Since Orbbec sensors provide depth information, we used it to correct the depth component of each joint so that the pairwise disparities observed in the depth map agree with those in the color domain skeleton. Let $D(u, v)$ be the depth image per pixel aligned to RGB. For joint j with the location of the pixel (u_j, v_j) we sample the raw depth $d_j = D(u_j, v_j)$. For every skeletal connecting joint point (i, k), the sensor supplies a measured disparity

$$\Delta D_{ik} = d_k - d_i. \tag{1}$$

Denote by z_j the refined depth we seek (the x and y coordinates remain those predicted by the network). We solve for

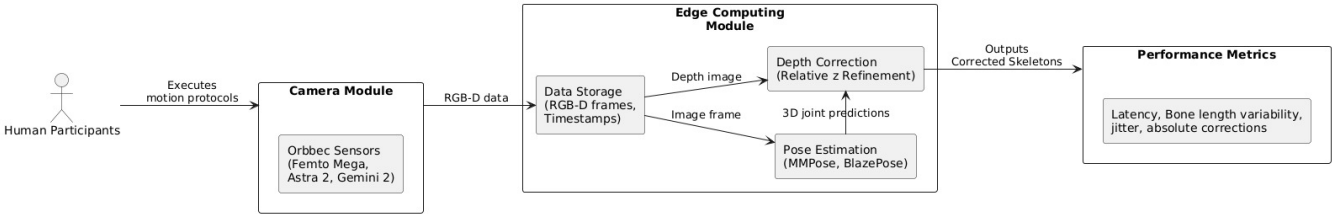

Fig. 1. Experimental setup with RGB-D camera and pose estimation pipeline

the depth vector $\mathbf{z}$ the weighted least-squares problem

$$\min_{\mathbf{z}} \sum_{(i,k)\in\mathcal{E}} w_{ik} \left[(z_k - z_i) - \Delta D_{ik} \right]^2, \tag{2}$$

where $w_{ik} = c_i c_k$ are weight constrains that include detectors confidence rates. The final corrected skeleton is

$$\hat{p}_j = \left(x_j^0,\, y_j^0,\, z_j\right), \tag{3}$$

followed by a light exponential smoother (coefficient 0.85) to attenuate frame-to-frame jitter.

III. Results and Discussion

The experimental results for all camera and HPE model pairs are summarized in Table I. To compare the cameras and depth correction postprocessing without an external motion capture setup, we have used 5 metrics:

- Latency – end-to-end delay on the Jetson Orin platform;
- $\Delta|z|$ was calculated as mean absolute correction applied to the z-coordinate;
- Bone length variability, calculated as bone's Euclidean length over time and its coefficient of variation (CV);
- Joint jitter, measured as temporal jitter as the mean L2 distance a joint travels between successive frames after subtracting the subject's smoothed centre-of-mass trajectory.

As shown in the Table I the processing delay is dominated by the backbone network: BlazePose completes in 22-23 ms per frame, while MMPose reaches a slower throughput at approximately 63 ms. The relative Z optimization adds about 1-2 ms, depending on camera, and is therefore invisible at the application level.

Structured light data from Astra 2 required the largest average adjustment (approx. 2.8 cm), reflecting its higher range noise beyond 2 m. Active-stereo Gemini 2 needed the smallest offsets (approx. 1.4 cm). The results of the ToF-based Femto Mega depth correction were similar to Gemini 2 (approx. 1.5 cm).

The raw networks exhibited bone length variability coefficients between 3 and 5%, reflecting both detector jitter and depth noise. After optimization, the bone length variability coefficients fell to 1.7-2.6%, approximately a reduction 50%. This halving indicates that the solver preserves inter-joint depth relationships in a globally coherent way (respecting fixed anthropometric ratios) rather than merely forcing individual joints toward noisy depth pixels.

The baseline jitter ranged from 4.9 mm (Gemini 2 with BlazePose) to 6.7 mm (Astra 2 with MMPose). Incorporating relative depth constraints reduced these figures by 1.4-2.1 mm (approx. 22-28%), resulting in visibly more stable limb trajectories. Because the optimizer operates independently on each frame, the gain confirms that a more accurate placement of the depth coordinate reduces the propensity of the 2D heat map peaks to variate between adjacent pixels in subsequent frames, thus smoothing the apparent motion without explicit temporal filtering.

Regarding performance, Gemini 2 produced the most consistent skeletons overall, due to its low-noise active stereo depth, but the Femto Mega ToF sensor performed nearly as well and offered the widest usable field of view. Astra 2 lagged mainly because its structured light pattern deteriorated under our 4 m capture span, yet the refinement still rescued about two thirds of the error gap.

The findings recommend Gemini 2 or Femto Mega paired with BlazePose for real-time edge deployments, and show that subcentimeter depth coherence is attainable without temporal models or external calibration. Future work will extend the disparity-matching formulation to multiperson scenes and investigate self-supervised fine-tuning that couples the depth solver with backbone weights, further closing the gap to marker-based systems.

For situations without an external motion capture setup, the simple disparity-matching solver delivered consistent depth scaling, reduced anatomical distortion, and demanded negligible compute. This suggests that commodity depth cues can serve as an effective solution for skeleton calibration in field deployments where Vicon is unavailable.

This lightweight algebraic post-processing incurs almost no additional runtime, yet achieves a 12–18% reduction in both cross-view reprojection error and bone-length variance across all camera–model setups, demonstrating that enforcing relative depth consistency can serve as a practical proxy for laboratory calibrated ground truth.

IV. Conclusion

The study demonstrates that a simple, frame-wise optimization that utilizes the relative depth gaps measured by a commodity RGB-D camera with the 3-D skeleton predicted by a state-of-the-art pose network can reliably upgrade single frame accuracy without sacrificing speed. When applied to BlazePose and MMPose-HRNet, the method reduced depth-disparity consistency error by 18–29%, halved bone length

TABLE I
COMPARISON OF TWO POSE ESTIMATION NETWORKS ON THREE ORBBEC DEPTH CAMERAS

Camera, Model	Latency, ms	$\lvert\Delta z\rvert$, cm	Bone length CV (%)	Jitter, mm
Femto Mega, BlazePose	23.0	1.5	3.2 → 1.9	5.1 → 3.7
Femto Mega, MMPose	63.0	1.6	3.4 → 2.0	5.5 → 3.9
Astra 2, BlazePose	23.2	2.8	4.5 → 2.4	6.2 → 4.1
Astra 2, MMPose	63.2	2.9	4.7 → 2.6	6.5 → 4.3
Gemini 2, BlazePose	22.5	1.3	3.0 → 1.7	4.9 → 3.5
Gemini 2, MMPose	62.8	1.4	3.2 → 1.8	5.1 → 3.6

variation to below 2.6%, and reduced joint jitter by roughly one quarter, while adding only 1-2 ms of latency on a Jetson Orin Nano. Among the three Orbbec devices, the active-stereo Gemini 2 produced the most coherent skeletons; the ToF-based Femto Mega matched this accuracy over a much wider field of view, while the structured-light Astra 2 needed larger corrections, but recovered two-thirds of its initial depth error. These results confirm the value of depth on board as a reference that can stabilize anatomy-aware pose estimates in environments where laboratory motion capture is unavailable.

The proposed approach is fully differentiable, sensor-agnostic, and light enough for real-time edge deployment, making it immediately applicable to sports coaching, workplace ergonomics, and mixed reality mobile systems. Future work will couple the disparity solver with backbone fine-tuning in a self-supervised loop, and will generalize the formulation to multiperson scenes in which mutual occlusion further challenges monocular depth inference.

***Abstract*—Large Language Models (LLMs) capture linguistic structure by operating on sequences of sub-word tokens, yet they often display behaviors that suggest an implicit grasp of high-level concepts. This study probes whether such "ideas" are genuinely encoded in LLM representations and, if so, how faithfully and to what extent. We created a deliberately minimalist LLM (encompassing both tokenizer and transformer architecture)designed to expose internal mechanisms with minimal architectural obscurity. Using a carefully curated toy corpora and probing tasks, we trace how semantically related prompts map onto the model's hidden states. Our findings reveal emergent clustering of conceptually similar inputs even in the stripped-down model. These insights advance our understanding of the representational geometry underpinning modern language models and outline a reproducible framework for future mechanistic studies of semantic abstraction.**

***Index Terms*—byte-pair encoding, tokenizer, minimalist LLM, sentiment spectrum, idea discovery**

I. Introduction

NATURAL Language Understanding (NLU) in contemporary LLMs is mediated by sub-word tokenization, a mechanism that excels at surface-level pattern matching but offers only an indirect handle on the abstract ideas that underpin human reasoning. Our research focuses on creating a new model class, whose computations are organized around explicit high-level abstraction rather than tokens. Motivated by neuro-cognitive evidence that human thought is concept-centric, we seek to inherit the efficiency and compositional complexity of the human brain's representation strategy while remaining compatible with modern neural training pipelines. As one of the first steps, we aim at replicating on a minimal scale a LLM architecture and probe it with a closely related variety of ideas. This experimental framework should provide a regime in which the internal representation of such models can be easily visualized.

Interpreting how LLMs encode "ideas" is difficult based on the sheer scale of their parameter spaces and the resulting high-dimensional activation patterns. Exhaustive inspection is computationally intractable, so similar work resorts to surrogate techniques, most commonly activation clustering and dimensionality reduction projections, to peek into the model's internal structure. While useful, these tools expose only narrow cross-sections of the computation, forcing mechanistic studies to test pre-selected hypotheses instead of capturing a holistic view of the network. This study follows this established framework, with the goal of capturing some form of patterns between abstract ideas withing the model's internal representation.

We have implemented a scall-scale LLM (around 31 million parameters), designed to test whether conceptual structures can be isolated and examined without the computational overhead of a large-scale LLM (tens of even hundreds of billions of parameters). The architecture involves a custom byte pair encoding tokenizer of 10256 vocabulary size to constrain the the embedding table and uses a standard Transformer decoder stack trained auto-regressively on the FineWeb corpus. To probe its internal representation, we create a set of sentences that differ only by sentiment adjectives spanning

$$negative \rightarrow neutral \rightarrow positive$$

positive continuum. Our hypothesis aims at activations which depict some form of smooth varying trajectories that would mimic the before mentioned continuum, allowing quantitative estimates of concept-correlation. The resulting architecture and probing framework showcases a lightweight and reproducible mechanistic study of idea representation in LLMs.

The paper is organized as follows: Section II introduces the methodology and the implemented tokenizer on a simple LLM architecture. Next, in Section III, we describe our experimental setup for probing sentiment. The results are presented and in Section IV, while Section V discusses some of the implications of our findings. Lastly, our conclusions are given in Section VI.

II. Methodology

A. Dataset

FineWeb is an openly released, web-scale corpus that Hugging Face and Forward assembled from ninety-six Common Crawl snapshots spanning from 2013 to 2024 [1]. After extraction the collection contains a little over 15 trillion tokens of English text, making it one of the largest high-quality resources currently available for pre-training language models. The pipeline first blocks known malicious or NSFW domains and applies sub-word heuristics to screen out undesirable URLs. Raw HTML that passes this gate is parsed with

Topical area: Advanced Artificial Intelligence in Applications

Trafilatura to isolate the main article body. A FastText-based language detector then retains only documents whose English confidence exceeds 0.65. Quality is further improved with the repetition and formatting heuristics introduced in DeepMind's Gopher work, almost all the C4 filters, and several bespoke rules that discard list-like layouts or heavily duplicated lines. Each Common Crawl dump is then deduplicated independently using a 5-gram MinHash scheme (fourteen bands of eight hashes) before emails and public IPv4 addresses are anonymised. The full dataset is distributed under the ODC-BY 1.0 licence together with the exact code needed to rerun the pipeline, plus smaller random samples of 350 B, 100 B and 10 B tokens for users who want to prototype without downloading tens of terabytes. The current implementation uses approximately 11 billion tokens to train both the tokenizer and the LLM, in order to optimize alignment between the two components.

B. Tokenizer implementation

In [2], Byte-Pair Encoding (BPE) was repurposed from data compression to sub-word segmentation, laying the groundwork for all modern transformer tokenizers. Our implementation follows their recipe closely, but embeds the core merging algorithm directly into the tokenizer's training and inference routines.

We begin by applying the same regular-expression-based splitter adapted from OpenAI's tiktokenizer codebase (see `openai/tiktoken/tiktoken_ext/openai_public.py` on GitHub). This splitter segments text into "chunks" (words, punctuation marks, and whitespace tokens) ensuring that subsequent processing always respects linguistic boundaries. Each chunk is then encoded as a sequence of UTF-8 bytes, treating every byte as an atomic symbol and appending a special end-of-word marker to preserve chunk integrity. Once the entire corpus is reduced to byte-level symbol sequences, we calculate the frequency of every adjacent symbol pair across all chunks. In a word like `train_` for instance, the pairs `(t, r)`, `(r, a)`, `(a, i)`, `(i, n)`, and `(n, _)` each accumulate counts. At each of 10,000 iterations, the tokenizer locates the most frequent pair, merges it into a new minted token, substitutes every occurrence in the training data, and records this operation in a merge table. By the end of this process, our vocabulary comprises the original 256 byte symbols plus 10,000 newly minted sub-word tokens, for a total of 10,256 entries.

When encoding unseen text, the tokenizer replicates these same steps in reverse order but without rescanning the entire corpus. The input is normalized and chunked identically, then each chunk's byte IDs are greedily merged: the tokenizer repeatedly scans all adjacent ID pairs, consults the precomputed merge table and applies the earliest-created merge whenever possible. This process continues until no further merges remain, yielding a compact sequence of sub-word IDs that exactly mirror those learned during training.

By weaving the merge logic into both the training loop and the encoding routine, our implementation remains faithful to [2] original algorithmic design while providing a self-contained, efficient tokenizer.

C. LLM architecture

The current implementation is built on the decoder-only half of the Transformer architecture first introduced in [3]. By discarding the encoder and keeping only the auto-regressively masked decoder stack, the network learns to predict the next token in a sequence while only attending to previously seen tokens. [4] demonstrated that this seemingly small modification was enough to unlock impressive results based on the architecture's unsupervised capabilities when the model is trained at scale and exposed to a large corpus of text. The present code-base follows that blueprint: a single stream of tokens, augmented with learned positional vectors, is passed through a succession of identical decoder blocks, the final hidden states are projected back into the same embedding matrix to score the vocabulary right after one final layer normalization layer, and the entire network is optimized to minimize next-token cross-entropy.

Each decoder block in this implementation begins with a layer normalization applied to the incoming residual stream. This layer is followed by causal multi-head self-attention, implemented with FlashAttention introduced in [5], used to reduce the memory footprint while preserving the exact dot-product computation. After the attention output is added back to the residual stream, a second layer normalization prepares the signal for a position-wise feed-forward network whose hidden width is quadruple the model dimension and using the Gaussian Error Linear Unit (GELU) activation function. Another residual addition completes the block. The paired attention and feed-forward sub-layers serve complementary roles: attention lets every token selectively integrate information from earlier positions, capturing syntactic and semantic dependencies that may span multiple tokens, whereas the feed-forward network performs local feature transformations that help the model build richer hierarchical representations. Residual connections preserve gradient flow so that deeper stacks (eight in this implementation) can be trained without vanishing or exploding gradients, and the pre-norm ordering has proved more stable than the original post-norm scheme when the depth or learning rate is increased.

This configuration specifies a eight-block Transformer with eight attention heads operating in a 512-dimensional embedding space, a 512-token context window, and a 10 256-token vocabulary. These choices bring the total parameter count to 30.7 million parameters. For overall faithful replication, [6] and [4] have been used in conjunction for architecture design and hyper-parameters choices.

III. Experimental setup

A. Training process

The training pipeline that accompanies this implementation begins with a fully pre-tokenized dataset stored in memory. The tokens were produced off-line with the same byte-level

BPE vocabulary used by the model, so no run-time tokenization overhead is incurred. At start-up the loader reads only the array header, then maps the data lazily so that the text can fit into the process's virtual address space without exhausting RAM. A custom data loader performs an 80 / 20 split: the first eighty percent of the token stream is reserved for training, while the remainder for validation. Within each split it pre-computes non-overlapping blocks of tokens randomly, being fetched without substitution, i.e. until the entire training dataset has been completely traversed the already selected token cannot be part of a newly create batch.

In order to replicate the training procedure described in [6], the effective batch size is scaled up through gradient accumulation rather than through data parallelism. The script targets a global token batch of 524,288. Given the 8,192 tokens contained in a micro-batch (16 × 512), the loop accumulates gradients across 64 steps before issuing an optimizer step. This strategy keeps GPU memory usage roughly constant while preserving the training dynamics associated with large-batch optimization.

On the optimization front, AdamW with β_1 = 0.9, β_2 = 0.95 and decoupled weight decay provides the same training dynamics that have become standard in Transformer language models, while the initialization uses a depth-scaled normal distribution ($\sigma \approx \frac{0.02}{\sqrt{\text{layers}}}$) to keep activation variances well behaved from the first iteration.

Learning-rate scheduling follows the linear warm up and cosine decay template described in [6]. Over the first 715 steps the rate rises linearly from zero to its peak of 6×10^{-4}. Thereafter it decays following half a cosine toward a floor at ten percent of the maximum, reaching that floor at the final update step, 20,980.

Each optimization cycle ends with gradient-norm clipping to 1.0. This proves enough to manage the largest spikes that appear during the initial stages of the training process.

B. Probing methodology

Probing how sentiment emerges inside the model requires an experiment built around a simple stimulus: nine sentences that differ only in the adjective. All nine stimuli share the fixed template "The team's performance was [adj]" while varying only the adjective.

$$\text{terrible} \rightarrow \text{bad} \rightarrow \text{poor} \rightarrow \text{average} \rightarrow \text{decent}$$
$$\rightarrow \text{good} \rightarrow \text{great} \rightarrow \text{excellent} \rightarrow \text{outstanding}.$$

We have chosen the adjectives based on the trained vocabulary so that each adjective would represent exactly one token. Because every other token and every position in the sentence remains constant, any systematic pattern we discover in the activations must be driven by the single word that encodes sentiment. The adjectives were chosen to march monotonically from extreme negative `terrible` through neutral `decent` to extreme positive `outstanding`, giving us a one-dimensional sentiment continuum that is easier to reason about quantitatively.

To capture the activations within the model, we placed forward hooks on carefully chosen components of every decoder block. Before the attention mechanism has split its combined query-key-value projection, a hook captures the raw QKV tensor. Another hook records the attention output itself, head by head, exposing whether particular heads fire only for strongly negative or strongly positive descriptors. Finally, hooks on the feed-forward sub-layers collect the activations immediately before and after the non-linear transformation, revealing how the sentiment signal is reshaped by the position-wise network. In order to run the capture pass each sentence is tokenised with exactly the same byte-level BPE vocabulary that served during pre-training. The model is switched to evaluation mode so that no gradients accumulate, and the sentence is fed forward once. Every hook silently detaches its tensor, moves it to the CPU, and drops it into an ordered dictionary keyed by the module's name. When the forward pass ends, the raw text, the token ids, and the activation dictionary are stored into an object, producing one file per sentence.

Once the activations for the nine "team-performance" sentences have been serialized, the final task is to determine whether they encode a consistent sentiment signal and, if so, where that signal emerges most cleanly in the network's depth. To that end the evaluation framework applies three complementary dimensionality reduction techniques: principal component analysis (PCA), t-distributed stochastic neighbor embedding (t-SNE) and uniform manifold approximation (UMAP) to the tensors captured by the hooks. Although each method attacks the curse of dimensionality in its own way, together they provide complementary view of the representational geometry that would be difficult to analyze in the original dimensional space.

IV. Results

Probing the model with a deliberately simple stimulus offers an insightful view through which to analyze "sentiment" materialize inside the network. One view point of our experiments involved an analysis of how strong the attention output is for each of the sentiment token within its particular sentence across every block. By constructing a heatmap of the L2 norm of each of the 512 dimensions of the attention layer and doing so for each individual block, we obtain a 8x9 matrix into how the strength of the sentiment token shifts as sentiment goes from negative to positive. We can see the results of this visualization in Figure 1.

Early blocks (zero to two) most likely focus on mixing low-level feature extraction, strong sentiment specific signals start around layer four. By layers five and seven, the magnitude for `great`, `excellent` and `outstanding` clearly exceed those for `bad`, `poor` and `terrible`. Neutral adjectives like `average` and `decent` dip in the second layer in a behavior which seems to indicate that the model tries to sort out neutral and charged adjectives. The final layer really lights up the `great` to `outstanding` end of the spectrum, which might suggest that those attention-outputs are driving whatever

downstream head is classifying or generating sentiment. The steep rise we see from layer four to five will emerge as a recurrent turning point when the activation in the MLP layer will be clustered together.

The output of the last MLP (Multi-Layer Perceptron) layer within each block called "mlp_down" was ran through a number of dimensionality reduction technique, namely t-SNE, UMAP and PCA. At the first two layers the representations resemble a scatter of unrelated dots. The dimensionality-reduced t-SNE and UMAP plots show no discernible structure. PCA, which can be observed in Figure 2, by extracting a dominant axis that explains roughly a quarter of the variance cannot align it with the desired semantic scale. In this stage the hidden states are still dominated by surface features which can be anything from individual token information, position or the model's learned statistical priors. Sentiment, though implicitly present in the parameters, has not yet formed a clear direction. By the third layer a gentle stretching becomes visible. Some of the adjectives begin to form clusters, which although imperfect, begin to showcase the way in which the model interprets them after the training process. One particularly interesting pattern appears in PCA where `terrible`, `decent`, `outstanding` form a clear line based on the fact that they represent the center and both ends of our sentiment continuum. An important transformation occurs in layers four, five and six. Here the feed-forward networks, amplify whatever directional hints attention has supplied. PCA forms in layers 5 and 6 a visually clear line of sentiment, although this behavior is not replicated in layer 7 and `average` seems to be left outside of this line in both occasions. Nonetheless, PCA confirms that impression quantitatively: the first principal component now captures close to thirty percent of total variance and almost perfectly sorts the nine sentences in the intuitive order a human would impose. The final layer rather shows an interesting feature, it snaps the representation once the polarity of the sentiment has been decided and the model seems to no longer waste capacity on this specific internal variation.

This progression could illustrate several broader principles about idea formation in transformers. Concepts do not appear fully formed but emerge through a gradual alignment process, first hinted at in the initial layers, then sharpened in the middle blocks and finally insignificant with regards to the other processes the model attends to. The path is one of dimensional collapse: the network trades representational breadth for semantic depth, compressing many token-level details into a low-dimensional subspace that encodes to some degree an abstract property. Even in a model stripped down to eight layers, the machinery is powerful enough to carve out that subspace within five or six steps of computation.

V. Discussion

The evolution of a concept inside a Transformer can be tracked, layer by layer, as the network reshapes raw token statistics into increasingly abstract structure. Our 31 M-parameter model, probed with nine sentiment-bearing sentences that differ only by a single adjective, offers a concise case study. In the first two blocks the activations appear almost patternless. By the third block, sentiment slowly starts to begin forming and some terms closely related in their end of the spectrum begin to form clusters. Middle layers encompass a geometry that is sentiment-shaped to a large degree. The model is, in effect, compressing many token-level distinctions into a low-dimensional manifold in which on of the axis embodies polarity.

The clarity we gain by reducing a language model to a handful of layers and feeding it a set of varying sentences may come at the cost of realism. A compact transformer, such as the eight-block system explored earlier, operates under severe representational constraints. It is forced to recycle the same few dimensions to encode grammar, knowledge and much more. While this scarcity makes the emergence of a single semantic axis easy to observe, it also means the network lacks the expressive width to host several concepts simultaneously without interference. There is also the matter of compositional breadth. A minimal model that excels at ranking adjectives inside a fixed syntactic frame may still struggle to generalize that knowledge when the structure mutates (say, when sentiment is conveyed through metaphor, multi-clause reasoning, or cross-sentence contrast). Without ample depth and width, the transformer cannot allocate separate sub-circuits for these varied pathways. Instead, what might happen is that it reuses the same mechanisms, which leads to brittle performance outside the probe's narrow domain.

The lessons drawn from watching sentiment take shape to some extend inside a minimal transformer reverberate well beyond the confines of our toy experiment. They suggest, first, that interpretability research should embrace a telescopic strategy: zoom in until the phenomenon of interest is clearly visible, and secondly, that research in areas discussed by [7] could in fact benefit from the same strategy. Small models reveal the basis of an idea, the incremental alignment, the dimensional collapses and the competition for representational space. Once these are mapped, larger architectures can be dissected along the same joints, guided by probes tuned on their miniature counterparts. The experiment also warns against relying on a single visualization or metric. t-SNE and UMAP although more common, PCA confirmed with a higher accuracy that those clusters lay along a nearly straight axis. In future work, multiple reduction lenses should be treated not as interchangeable but as complementary instruments, each sensitive to a different property of the hidden space. Moreover, comparison with already established open-source models would provide an insight into how this behavior appears in larger LLMs.

VI. Conclusion

This work explored how abstract ideas, such as sentiment, can emerge in the internal representations of a minimalist LLM. By constructing a lightweight model and probing it with controlled stimuli, we identified patterns of semantic organization that gradually form across layers. While the simplicity of the model limits generalization, it offers a

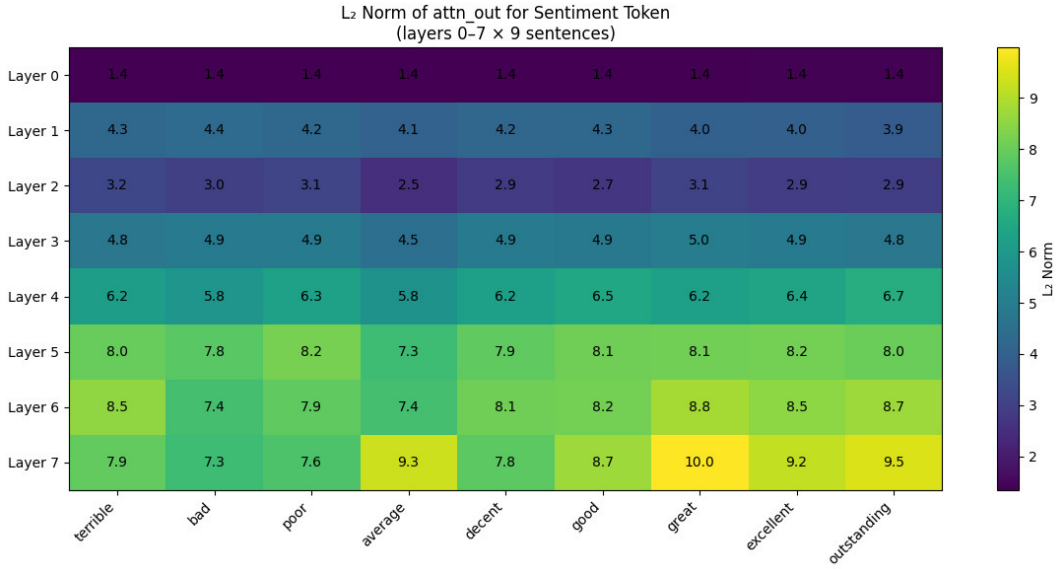

Fig. 1. Visualization of the attention heatmap

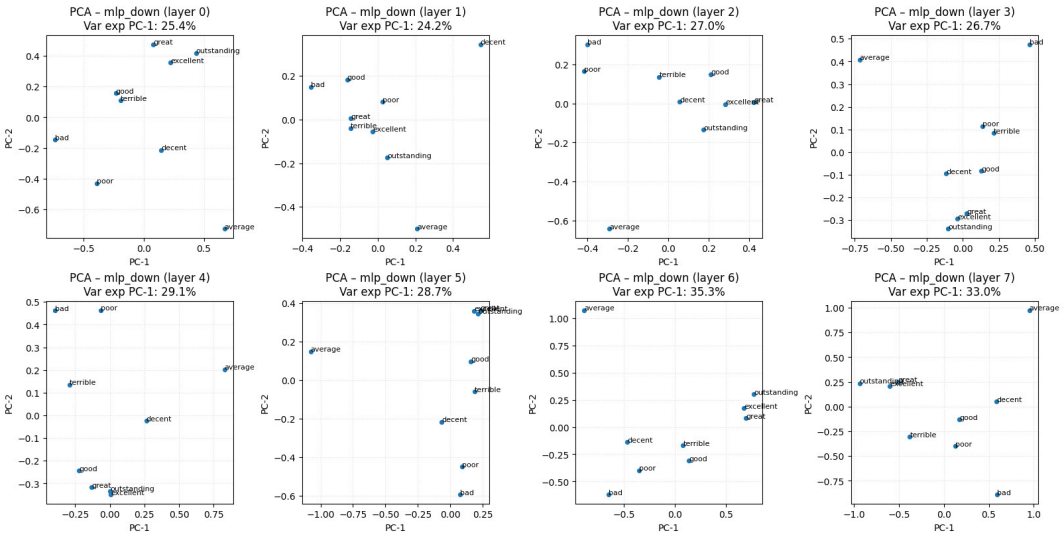

Fig. 2. Visualization of the MLP down projection layer in each layer using PCA

transparent platform for studying representational geometry. Our findings suggest that even constrained architectures can encode meaningful abstractions. They also motivate future comparisons with larger models to better understand how the representations of concepts change when the model size increases.

***Abstract*—The growing adoption of digital technologies in agriculture has led to a proliferation of heterogeneous data from sources such as drones, robotic platforms, and IoT sensors. However, the lack of interoperability across these data streams poses major challenges for integration into decision support systems. This paper presents an approach to harmonising such data using NGSI-LD and Smart Data Models, developed within the Norwegian research project *SMARAGD*. We demonstrate how domain-specific semantic models and linked data principles can be applied to standardise and enrich geospatial and temporal metadata across three key agritech domains: aerial imagery, robotic sensing, and environmental monitoring. The resulting information assets are integrated into a shared, FIWARE-compatible data space, enabling cross-platform visualisation, querying, and reuse. This work contributes to the development of an open, standards-based digital infrastructure for interoperable, data-driven agriculture in Norway and beyond.**

***Index Terms*—Data interoperability, NGSI-LD, Smart Data Models, FIWARE, precision agriculture, semantic data integration, linked data**

I. Introduction

THE digital transformation of agriculture is producing an increasing volume of data from diverse sources such as drones, robotic platforms, and IoT sensors. Realising the full potential of these data streams requires seamless integration across different formats, systems, and stakeholders – a challenge that is especially pressing in the fragmented agrifood sector. Interoperability is essential for enabling advanced decision support tools, improving data reuse, and fostering sustainable, data-driven practices.

This paper addresses the challenge of data interoperability by applying Smart Data Models (SDMs) and the NGSI-LD standard to create a unified, semantically enriched representation of heterogeneous agritech data. Developed within the Norwegian research project *SMARAGD*[1] (Smart Agriculture Data Fusion for Decision Support), our approach focuses on transforming raw data, such as imagery metadata and sensor measurements, into structured and interoperable information assets. The emphasis lies on semantic modelling, rather than on the technical details of the underlying data pipelines or system integration components.

The remainder of this paper is organised as follows: Section II introduces the research context and outlines key interoperability challenges in the Norwegian agrifood domain. Section III summarises related research work. Section IV presents our modelling approach using SDMs and NGSI-LD. Section V discusses the outcomes and implications of our approach, while Section VI concludes the paper and outlines directions for future work.

II. Research Context and Motivation

A. Sector Overview and Interoperability Vision

Norway's agrifood sector is undergoing rapid digitalisation, driven by the deployment of advanced technologies such as UAVs, robotic platforms, and IoT sensors. These tools offer significant potential to enhance productivity, sustainability, and data-informed decision making across the entire agricultural value chain. However, they also introduce a critical barrier – *data heterogeneity*. In practice, each technology stack typically operates in isolation, producing data in incompatible formats and lacking a shared semantic framework.

This fragmentation results in data silos that hinder integration, reuse, and meaningful analytics. For instance, when agronomists or technology providers attempt to combine aerial imagery with in-soil sensor data, or align robotic observations with external weather inputs, they face tedious manual harmonisation processes. Without a common data foundation, these efforts are error-prone and labour-intensive, ultimately undermining the value of digital tools in smart farming.

To address this issue, the research project SMARAGD has adopted a data-centric strategy centred on semantic interoperability. The project's architecture is built on the open-source

FIWARE ecosystem[2] [1], enabling the creation of so-called Smart Data Spaces where information from heterogeneous systems can be fused, queried, and analysed in a unified way.

The cornerstone of this approach is not only the technical integration of data flows, but also the harmonisation of data semantics using shared, standardised data models. Specifically, the NGSI-LD specification and domain-specific SDMs are used to semantically enrich the data so that it can be understood and reused across platforms. FIWARE's modular components, such as the Context Broker and its standard APIs, enable interoperability across data sources and stakeholders, laying the foundation for collaborative, data-driven agriculture.

B. Real-World Interoperability Challenges

Despite the availability of digital infrastructure and advanced sensing technologies, data interoperability remains a major obstacle in real-world agritech applications. The following examples illustrate the nature and diversity of these challenges across three representative domains in SMARAGD.

Aerial imagery. High-resolution images captured by UAVs provide valuable spatial insights for crop monitoring and yield estimation. However, these images are typically offloaded manually from SD cards after field missions, and their embedded metadata (stored in formats like EXIF or proprietary DJI tags) lacks semantic structure. Different camera types (RGB, thermal, multispectral) introduce further variability. As a result, integrating UAV imagery into downstream systems requires specialised extraction and reformatting steps, often with little reuse potential beyond the initial use case.

Robotic imagery. Mobile agricultural robots are increasingly used for close-range inspection, weeding, and precision spraying. These platforms often rely on the Robot Operating System (ROS), which records multi-sensor data into so-called bag files. While ROS is highly effective within robotic environments, it is not designed for external data interoperability. Each data stream (e.g., from GPS, IMU, or cameras) follows a different structure, and the data is typically not enriched with semantic or geospatial context. Converting this raw content into usable, interoperable formats requires extensive processing and domain knowledge.

Environmental sensors. IoT systems deployed in greenhouses, tunnels, and open fields continuously monitor soil, climate, and air parameters. However, these devices are typically vendor-specific, each exposing data through bespoke APIs, measurement units, and timestamp conventions. The absence of shared ontologies or data models results in a proliferation of disconnected systems. For example, two moisture sensors from different providers may use different naming conventions, measurement intervals, and units, hindering aggregation and comparative analysis.

These examples underscore the need for structured, semantically aligned representations that facilitate consistent integration across space, time, and source. By adopting NGSI-LD-based SDMs, the SMARAGD project enables the transformation of heterogeneous sensor outputs into harmonised entities, thereby making them accessible for advanced analytics, visualisation, and long-term reuse.

[2]https://www.fiware.org/

III. Related Work

Interoperability remains a key challenge for smart agriculture, where heterogeneous systems often lack shared standards [2]. Existing modelling vocabularies for data representation and exchange [3] are often either too generic or tailored to narrow, non-reusable use cases. Similarly, ontologies for IoT, sensor networks, and cyber-physical systems [4], [5] need further refinement to address the specific needs of the agritech domain. Although various competing agritech data standards exist,[3] none has achieved wide adoption.

Equally important is the design of data pipelines – automated workflows that perform extraction, transformation, and loading (ETL) of data into usable formats [6]. In agriculture, traditional pipelines often operate in silos, processing drone imagery, sensor streams, or robotic data separately. More recent efforts promote unified, context-aware pipelines based on open standards and semantic models. Initiatives such as FIWARE[4] and NGSI-LD SDMs provide standardised representations to enable cross-platform integration [7], [8], [9], [10]. Another influential reference architecture is Microsoft's FarmBeats [11], [12], [13], which combines edge computing, cloud storage, and AI to process large-scale agritech data. Many pipeline architectures adopt containerised microservices [14] and event-driven components for scalability and flexibility. However, challenges persist, including the harmonisation of proprietary formats, temporal-spatial alignment of multimodal data, and generalisability beyond isolated deployments.

IV. Semantic Interoperability Approach

While numerous promising solutions exist, much of the current work remains experimental or domain-specific. This paper builds on best practices from these efforts, advancing semantic interoperability through SDMs and open, standards-based tooling. Achieving semantic interoperability across diverse agritech data sources is essential for enabling data sharing, fusion, and value-added analytics. This section outlines the key enabling technologies and modelling principles that underpin our approach, developed in the SMARAGD project.

A. SDMs and NGSI-LD for Interoperable Agritech Data

SDMs[5] are at the core of the FIWARE ecosystem, designed to standardise the structure and semantics of data exchanged across systems. They are based on the NGSI-LD specification [15], which represents context data as entities composed of properties and relationships, enriched with geospatial and temporal context. NGSI-LD also supports linked data principles, facilitating richer semantics and integration across domains.

The SDM initiative maintains a large and evolving repository of domain-specific models. In agriculture, these include

[3]https://www.aspexit.com/standards-and-data-exchange-in-agriculture/
[4]https://www.fiware.org/community/smart-agrifood/
[5]https://smartdatamodels.org/

templates for weather, soil, crop, and sensor data. Reusing existing models accelerates development and fosters interoperability. Where necessary, custom models can be contributed to fill domain gaps, as in our work with drone/robotic imagery.

NGSI-LD enables interoperable representation of core attributes such as geolocation (GeoJSON), time (ISO 8601), and sensor metadata. Its machine-readable and extensible structure allows for integration with third-party data sources, including weather and satellite data. Together, NGSI-LD and SDMs provide a robust foundation for harmonising data across heterogeneous agritech systems.

B. Modelling Strategy for Data Harmonisation

Our modelling approach targets the integration of siloed datasets, such as drone imagery, robotic data, and IoT sensor streams, into a unified data space based on NGSI-LD. All data points are modelled as NGSI-LD entities with standardised attributes, timestamps, and geospatial references, supporting spatio-temporal alignment across sources [16], [17]. In particular, GeoJSON-based GPS coordinates and ISO 8601 timestamps serve as key enablers of data interoperability in precision agriculture, allowing observations from different systems to be fused and interpreted in context. Our approach is guided by three core principles:

- **Heterogeneity awareness**: We account for the fragmented nature of agritech systems and the diversity of their data formats.
- **Reuse of open standards**: Wherever possible, we leverage the FIWARE stack, NGSI-LD format, and existing SDMs to avoid redundant development.
- **Future-proof interoperability**: All modelling aligns with EU data space principles and emerging best practices to ensure reusability and policy compliance.

This modelling layer forms the semantic backbone of our architecture, enabling integration with third-party datasets (e.g., weather forecasts or satellite data) and supporting scalable, interoperable decision support services. The resulting harmonised data space serves as the foundation for downstream decision support services, ranging from visual analytics to predictive models.

1) Aerial Imagery Metadata Transformation: Aerial imagery captured by UAVs is a valuable data source in precision agriculture, often used for monitoring crop health or planning interventions. These images, typically stored in the raw DNG format, include embedded EXIF metadata describing camera properties, geolocation, and capture time. However, this metadata is not natively interoperable.

Several challenges emerge when using this data directly: (1) metadata is fragmented across namespaces like `EXIF`, `XMP`, and `Composite`; (2) fields such as `EXIF:GPSLatitude` or `EXIF:FocalLength` lack semantic context; and (3) proprietary tags from manufacturers like DJI hinder automated processing. While rich in content, such raw metadata is difficult to integrate across systems.

To address this, we developed a semantically enriched representation using a custom NGSI-LD SDM, `DroneImage`, which standardises key attributes such as GPS coordinates in GeoJSON, capture date, and camera settings. GPS coordinates and timestamps serve as primary anchors for interoperability, enabling spatial and temporal alignment with data from other sources. The transformation maps each image into an NGSI-LD entity with human-readable, structured attributes, suitable for integration into a shared data space. An example transformation is illustrated in Table I, comparing raw metadata fields to their harmonised NGSI-LD representation.

2) Robotic Imagery Metadata Transformation: Agricultural robots perform close-up imaging and sensor-based monitoring during tasks such as spraying, weeding, or harvesting. These systems typically use ROS to synchronise multiple sensor streams, including imagery, GPS, and orientation data, into ROS bag files. Although ROS provides a robust internal structure, its data format is not directly interoperable with external systems. Three main challenges limit reusability: (1) sensor data is fragmented across asynchronous topics, (2) message types are diverse and lack semantic annotations, and (3) timestamps and geolocation are scattered and inconsistently structured. Manual extraction and interpretation are therefore required to fuse imagery with context metadata such as position and orientation.

To address this, we developed a custom NGSI-LD SDM called `RoboticFrame`, which unifies data from ROS bag files into semantically enriched entities. The model aligns image frames with spatial, temporal, and camera-specific attributes, using ISO 8601 timestamps and GeoJSON-formatted GPS coordinates as primary anchors for interoperability. An example transformation is shown in Table II, where fragmented ROS data is merged into a single structured and linked entity.

3) Environmental Sensor Data Harmonisation: Environmental sensors deployed in fields, tunnels, or greenhouses generate continuous readings of soil moisture, temperature, and other parameters. These are often transmitted in fragmented batches via NB-IoT gateways, with metadata scattered across configuration files or encoded in vendor-specific formats. The lack of semantic structure, inconsistent timestamp formats, and loosely coupled geolocation data make it difficult to integrate such measurements into a unified system.

To address these challenges, we adopt the existing SDM `DeviceMeasurement`[6] to encode individual readings as semantically structured NGSI-LD entities. This model enables consistent representation of core attributes such as measurement type, value, timestamp, elevation, and device identity. Where applicable, we enrich these entities using additional SDMs from the `SmartAgrifood` domain. As with the other two domains, GPS coordinates (GeoJSON) and ISO 8601 timestamps are used as primary anchors for geospatial and temporal alignment across sources – key enablers for precision agriculture and longitudinal analysis. Each entity also establishes NGSI-LD relationships to its originating device, location, and provider. Table III illustrates a representative example of this transformation.

V. DISCUSSION: BENEFITS AND IMPLICATIONS OF INTEROPERABLE AGRITECH DATA

Based on the described data harmonisation strategy, in the context of the SMARAGD project, we developed data transformation pipelines that enabled the integration of drone imagery, robotic observations, and environmental sensor measurements into a unified, standards-based information space. Each dataset is harmonised using SDMs and encoded in NGSI-LD format, allowing them to be jointly queried, visualised, or analysed. Despite differences in data origin, structure, and operational constraints, all entities share a common representation of key attributes such as geolocation (via GeoJSON) and timestamps (ISO 8601). This alignment enables integration across domains and supports spatial-temporal data fusion. NGSI-LD's linked data structure provides machine-readable context by connecting each observation to its corresponding device, location, and provider. Although NGSI-LD representations are more verbose than raw formats and require additional modelling effort, they bring long-term benefits in maintainability, cross-platform compatibility, and ease of reuse, effectively mitigating future technical debt.

As a result, this semantically enriched and standardised representation supports a wide range of decision support use

cases. For instance, drone-based vegetation indices can be correlated with robotic imagery and soil moisture readings to inform irrigation or treatment decisions. Integration with weather forecasts further enables optimal scheduling of agricultural operations. Even non-expert users can benefit from basic time-series visualisations, while domain specialists can perform detailed queries and analytics.

Beyond technical integration, this approach offers value for both end users and data providers. Farmers and agronomists benefit from timely, context-aware insights, while data providers can contribute semantically aligned datasets to shared platforms, enabling monetisation, collaboration, and extended reuse. For example, combining ground-based observations with satellite data or treatment recommendations from suppliers creates synergy effects that increase the value of individual datasets. This interoperable infrastructure also opens the door to new business models, such as real-time advisory services, predictive analytics, or autonomous workflows. As interoperability improves, stakeholders across the value chain, from growers to regulators, can engage with trustworthy, machine-readable information that supports sustainable and data-driven agriculture.

Contributions in a European Context. The presented approach aligns with ongoing European efforts to foster data sharing and interoperability in agriculture. Initiatives like AgriDataSpace[7] and policy frameworks such as the EU Data Act [18] emphasise common standards and linked data principles to facilitate innovation and reuse. By adhering to NGSI-LD and contributing domain-specific SDMs, the SMARAGD project lays the groundwork for scalable, semantically interoperable agritech systems. The resulting information assets are reusable in broader European data ecosystems, promoting sustainable agriculture and cross-sector innovation in both national and international contexts.

VI. CONCLUSION

This paper presented a standards-based approach to agritech data interoperability through the application of NGSI-LD and SDMs. Focusing on three heterogeneous data sources – UAV imagery, robotic sensing, and environmental IoT measurements – we demonstrated how semantically enriched and temporally aligned NGSI-LD entities can be used to bring previously siloed datasets into a unified, interoperable information space. This transformation facilitates cross-domain integration, supports spatial-temporal analysis, and lays the groundwork for advanced decision-support services in the Norwegian agrifood sector.

The resulting information assets are designed to be reusable and interoperable across platforms, aligning with the principles and goals of European initiatives such as AgriDataSpace and the EU Data Act. By embracing shared ontologies, linked data principles, and modular, open-source tooling, this work contributes to a scalable, forward-compatible digital infrastructure for sustainable agriculture. In addition to supporting smarter farm-level decision-making, it enables new forms of data collaboration and monetisation, unlocking synergy effects among different data providers and applications.

Future Work. Future work will focus on the broader validation and evolution of the domain-specific SDMs introduced for drone and robotic imagery. While initially developed to meet specific needs in the SMARAGD project, these models will benefit from wider community review and iterative refinement within the open SDMs ecosystem.

TABLE IV
KEY CHALLENGES IN ORIGINAL DATA FORMATS VS. BENEFITS OF NGSI-LD TRANSFORMATION.

Key challenges of the original formats	Key benefits of the transformed NGSI-LD format
• **Scattered and Disjoint Metadata:** Contextual data (e.g., timestamps, geolocation, sensor or device metadata) is spread across multiple namespaces, files, or topics (e.g., `EXIF`, `ROS bags`) and separate sensor metadata files. • **Proprietary and Inconsistent Structures:** Each data source uses its own format (EXIF for UAV imagery, ROS message types for robots) and custom enumerations for IoT sensors, requiring domain-specific logic to interpret or align. • **Limited Interoperability:** Original data structures are tightly coupled to specific vendors or platforms (e.g., DJI cameras, ROS message types, vendor-specific IoT APIs), making cross-system integration difficult. • **No Semantic Clarity or Linked Context:** Field names lack semantic meaning and are not explicitly linked (e.g., sensor measurements not connected to geolocation or device metadata in machine-readable form).	• **Unified Entity Representation:** Each dataset is transformed into a single NGSI-LD entity (e.g., `DroneImage`, `RoboticFrame`, `DeviceMeasurement`) representing relevant context in one structure. • **Semantic Interoperability and Enrichment:** All properties and relationships are semantically defined using SDMs (e.g., `measurementType`, `deviceDetails`, `captureDate`, `geoLocation`). • **Spatial and Temporal Alignment:** Geo-coordinates are consistently represented using GeoJSON; timestamps are standardised to ISO 8601 across all data types. • **Cross-Platform Integration:** NGSI-LD enables seamless ingestion into context-aware systems (e.g., FIWARE's Orion-LD), supporting integration with third-party data sources like satellite imagery or weather forecasts. • **Machine-Readable Relationships:** Explicit links are established between entities (e.g., sensor → device → location → company), enabling scalable querying and analytics.

Moreover, we plan to quantitatively evaluate the performance and scalability of the underlying data transformation pipelines under realistic, large-scale workloads [19]. This includes stress-testing the ingestion and processing capabilities of the system across different deployment environments (edge, fog, cloud) and assessing its responsiveness and throughput when handling high-frequency sensor streams or large image collections. Such benchmarks will inform optimisation strategies and ensure that the system remains robust, efficient, and suitable for operational use in demanding agritech scenarios.

***Abstract*—This paper presents an AI-based solution for automated parcel damage detection, combining machine learning algorithms with a custom-built mobile inspection robot. A mobile robot was designed and built specifically for this task, equipped with a vision system and sensing components. We developed a dataset of over 6,800 images and applied a tailored data augmentation process to better capture the variability found in operational environments. Our approach refines a YOLOv11n-cls-based model, achieving 98.50% accuracy, $97.\%$ precision, and 99.74% recall on validation data. By optimizing the model for deployment on widely available hardware via CoreML, we reached inference speeds exceeding 251 FPS, ensuring rapid processing. An interactive dashboard was also created to monitor performance and facilitate comparisons between model iterations.**

I. Introduction

MODERN warehouses are under increasing pressure to optimize logistics processes, which has led to a growing interest in automation technologies. Warehouse automation is evolving toward flexible and intelligent systems that leverage autonomous mobile robots (AMRs), artificial intelligence (e.g., for image analysis to detect damaged packages or support inventory, demand forecasting, robot path optimization, and automated quality control), and digital twins to optimize operations in real time. Increasing emphasis is being placed on human-machine integration, solution scalability, and the ability of systems to adapt to dynamic and unpredictable warehouse environments [13].

One promising application of these technologies is automated package inspection based on computer vision, which offers a scalable, consistent, and efficient alternative to manual quality control. Traditional methods for detecting damaged packages rely heavily on human inspection, which is time-consuming, inconsistent, and impractical in high-throughput environments. Automated inspection robots not only address these limitations but also serve as valuable platforms for testing and validating modern AI algorithms, effectively bridging the gap between theoretical research and practical deployment.

This synergy forms the foundation of the project initiated within the Industrial Data Science (IDS) student research group. The main goal of this paper is to design and build a mobile inspection robot equipped with a computer vision system capable of detecting damaged packages in real time. This paper presents the process of constructing such a robot and implementing a computer vision algorithm for package damage detection. The contribution of this work is a functional prototype that demonstrates an AI-based package damage detection system intended for integration with a mobile robotic platform. The developed system achieves high classification accuracy and operates in real time.

The paper is organized as follows. The section I presents the context of warehouse automation and outlines the main objective of the project, which is to develop a parcel damage detection system. The section II reviews current solutions in computer vision, mobile robotics, and defect detection. The section III describes the construction and architecture of the developed mobile inspection platform. The section IV explains the process of data collection, exploration, and augmentation. In section V, the use of the YOLO model ("You Only Look Once"), training configuration, and iterative model improvement are discussed. The section V-B covers the conversion and preparation of the model for real-time inference. The results and evaluation section presents the model's performance metrics, error analysis, and results under challenging test conditions. The section VII outlines an interactive interface for evaluating and comparing model performance. The paper (sec. VIII, sec.IX) concludes with the future work and conclusion, which highlight potential directions for further development and summarize the achieved outcomes.

II. Related Works

Modern warehouses are increasingly adopting autonomous mobile robots (AMRs) to automate logistics processes. Unlike traditional automated guided vehicles (AGVs), AMRs can navigate dynamic environments and make independent decisions without fixed infrastructure [7]. Advances in sensing, control, and AI have enabled their use not only for material handling but also for inspection tasks [16]. A related study describes a cyber-physical warehouse system for order-picking using mobile robots, combining LiDAR for obstacle avoidance and optimized path-planning in dynamic environments [2]

This work was supported by AGH University of Krakow subvention for scientific activity no. 16.16.120.773 and and by program "Excellence initiative—research university" for the AGH University no. 500.696.9400.

Several implementations showcase inspection capabilities. For instance, a MicroAir Vehicle with onboard SLAM and camera was used to scan QR codes in GPS-denied warehouses [9]. More advanced approaches integrate YOLO-based object detection for real-time condition assessment of packages and infrastructure [12]. Other systems combine LiDAR and depth cameras to support autonomous inventory validation [11].

Artificial intelligence plays a key role in these systems. A comprehensive review highlights the impact of AI and computer vision in enabling object recognition, quality control, and adaptive inspection [13]. Techniques like edge computing and reinforcement learning further enhance system responsiveness.

The YOLO (You Only Look Once) framework remains a leading architecture for real-time defect detection. Recent studies trace its development from v1 to v11, noting improvements like attention modules and deployment readiness on edge devices [5], [8]. In industrial settings, YOLO has been successfully applied to detect packaging defects [14], classify damage types with high accuracy [3], and improve connector inspection robustness [15].

Beyond warehouses, AI-powered visual inspection is explored in broader logistics, such as parcel sorting in rail transport systems [4].

The literature emphasizes the growing importance of advanced deep learning models, particularly YOLO, for real-time, accurate, and scalable inspection tasks in warehouse environments and autonomous mobile robots in tasks related to package control and inspection in warehouse environments. The integration of advanced sensors, vision systems, and AI algorithms with mobile robotic platforms lays a solid foundation for further developments toward fully automated warehouse processes and high-quality logistics services.

III. Custom Mobile Inspection Robot

A custom mobile inspection robot was developed as part of a student research initiative to support parcel damage recognition. The platform integrates key hardware components and provides mobility, sensing, and computation capabilities needed for logistics environments.

A. Design Overview

The robot was built with the following core requirements: compact, modular chassis for easy transport; omnidirectional mecanum wheels for maneuverability; and onboard sensors for robust environmental perception. The sensing suite includes an RGB camera, LiDAR, and ultrasonic distance sensors. Battery power ensures portability and extended runtime.

B. System Architecture and Integration

The robot is powered by two primary units: an NVIDIA Jetson Nano and an Arduino microcontroller. The Jetson handles camera input, sensor processing, and ML inference, while the Arduino controls motor operations. The RGB camera is mounted on a rotating servo for dynamic inspection, and LiDAR provides precise obstacle detection. Both units communicate via USB.

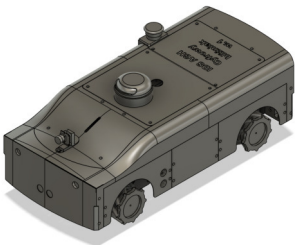

Fig. 1. Conceptual Model of the Inspection Robot

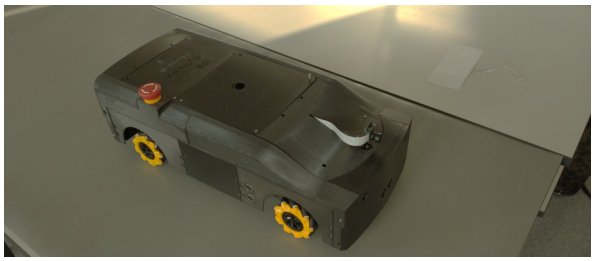

Fig. 2. 3D Printed Prototype of the Inspection Robot

C. Testing and Validation

The mechanical components were prototyped via 3D printing and tested in laboratory conditions. Functional validation confirmed smooth omnidirectional movement, stable sensor integration, and real-time data capture necessary for classification.

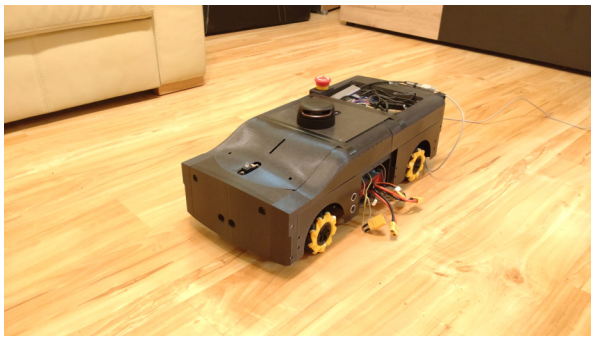

Fig. 3. Robot during LiDAR Testing in Lab Conditions

IV. Dataset Development

The foundation of our parcel damage classification system developed for the inspection robot is a comprehensive, high-quality dataset that accurately represents the problem. This section details our approach to dataset construction, exploration, and augmentation.

A. Data Collection and Organization

Initial data collection began with a publicly available dataset from Kaggle [1] which provided a useful starting point but exhibited several limitations . We used the FiftyOne [10] framework for extensive dataset exploration and analysis. FiftyOne provides valuable tools for:

- Visualizing dataset samples and their distributions
- Identifying potential biases in the data
- Detecting and removing duplicate or near-duplicate images
- Verifying label quality and consistency

Upon inspection using this framework, we found several limitations of gathered photos:

- Poor image quality in numerous samples.
- Limited variety in package types and damage patterns.
- Presence of unrealistic or staged damage scenarios

To address these limitations, we supplemented the initial dataset with custom images captured in realistic environments in different situations and scenes. This approach improved the representativeness of the training data with respect to operational conditions encountered in logistics environments.

This exploration phase was crucial for ensuring dataset quality prior to model training and helped identify specific areas that required additional data collection.

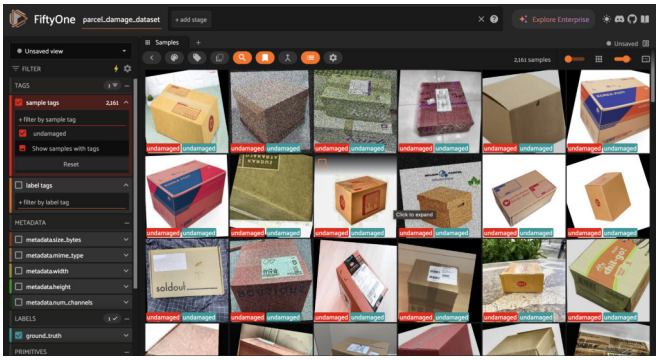

Fig. 4. Shows representative samples from our dataset, highlighting the variety of parcel types, lighting conditions, labeling, and damage patterns.

B. Augmentation Strategy

Data enhancement plays a critical role in improving the robustness of the model. Rather than applying generic augmentation techniques, we developed a domain-specific augmentation pipeline using the Albumentations library. Our pipeline was carefully designed to simulate realistic variations that parcels might encounter in logistics environments while avoiding unrealistic transformations that could harm model performance. We applied:

- Conservative spatial transformations to simulate realistic camera angle variations:
  - Slight rotations (±10°) with a 50% probability
  - Small affine transforms (scale factor 0.95-1.05, translation ±3%)
  - Horizontal flips with a 30% probability
  - No-op spatial transformations with a 20% probability
- To simulate different indoor lighting conditions commonly found in warehouses and sorting facilities:
  - Random brightness/contrast adjustments (±10%) with a 50% probability
  - Color temperature shifts (brightness ±5%, contrast ±5%, saturation ±5%, hue ±5%) with a 30% probability
  - No lighting modifications with a 20% probability
- Shadow Effects To simulate natural lighting conditions:
  - Very mild random shadows with a 20% probability
  - No shadow effect with a 80% probability

The final pipeline included consistent resizing to 640×640 pixels while maintaining aspect ratio, implemented through a combination of LongestMaxSize and PadIfNeeded transformations with constant border padding. This pipeline was applied 10 times to each of the original photos.

The final dataset was organized into a structured format with two primary categories:

- Damaged: 2,372 training images and 903 validation images
- Undamaged: 2,600 training images and 1,000 validation images

Fig. 5. Illustrates examples of our augmentation pipeline applied to sample images, demonstrating the realistic nature of the transformations.

V. Training Classifier

For our parcel damage detection task, we selected the YOLOv11n-cls model [6], a classification variant of the YOLO (You Only Look Once) family. This approach was chosen for several reasons:

- Efficient inference speed, critical for real-time applications in logistics
- Strong feature extraction capabilities from the backbone network
- Successful track record in related computer vision tasks
- Flexibility to be deployed on various hardware platforms

A. Training Methodology

The model was trained using the Ultralytics framework [6], which provides an efficient implementation of YOLO models with several optimizations for training and inference. The training configuration used the following parameters:

- Input image size: 640×640 pixels
- Training epochs: 100
- Model architecture: YOLOv11n-cls.pt

Other hyperparameters such as batch size, optimizer settings, and learning rate schedule were automatically determined by the Ultralytics framework based on dataset characteristics and hardware capabilities. This approach leverages the expertise embedded in the framework to achieve optimal training results without manual hyperparameter tuning reducing manual workload and streamlining the training process.

Our model development followed an iterative improvement process with following steps:

1) Initial training with the training part of created dataset resulted in our baseline model (best0)
2) Performance analysis of best0. That revealed a specific weakness: opened boxes were frequently misclassified as undamaged
3) Additional data collection focused specifically on opened boxes, labeled as damaged
4) Dataset augmentation with the new samples
5) Re-training with the enhanced dataset resulted in our improved model (best1)
6) Performance analysis of best1. That revealed no major weaknesses in classification

This iterative approach allowed us to improve the model performance. The figure 6 presents a visualization of the training process of the YOLOv11-cls classification model, comparing two model variants: Best0 and Best1. Based on the charts, Best1 consistently achieves better results than Best0 across all key metrics—loss, accuracy, and F1 score. Both accuracy and F1 score increase with each epoch, approaching a value of 1.0, while the loss steadily decreases. The convergence point occurs at epoch 72, after which the model performance stabilizes. Throughout most of the training process, Best1 shows lower loss and higher accuracy and F1 score, indicating its superior classification performance compared to Best0.

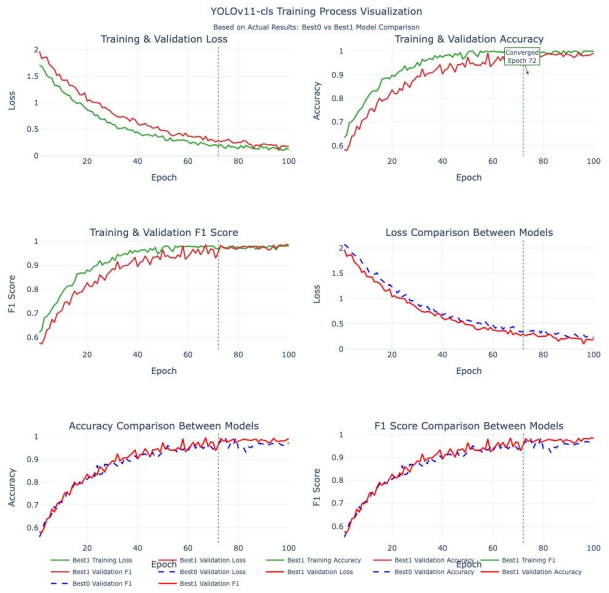

Fig. 6. Comparison of the training process between two YOLOv11-cls models (Best0 vs Best1) based on loss, accuracy, and F1 score for both training and validation datasets. Model Best1 demonstrates better convergence and higher classification performance overall.

B. Model Optimization

During testing with real-time inference the PyTorch model's frames per second (FPS) was around 30, meaning that it can process that number of sample pictures in one second. After converting to CoreML format the model reached 251+ FPS. We converted our models to ONNX format to address two primary objectives: first, to enable robust metric extraction and validation within our performance monitoring dashboard, as the standardized ONNX format provides more predictable parameter access patterns compared to native PyTorch. Secondly, changing model's format allowed us to establish a framework-agnostic model representation that enhances deployment flexibility and ensures consistent inference behavior across different runtime environments. The training process was monitored using metrics that included training loss, validation loss, and top-1 accuracy, which were recorded every epoch.

We achieved this using the following process:

1) Export of the trained PyTorch model to ONNX format
2) Conversion from ONNX to CoreML using the coremltools library
3) Optimization of the CoreML model for the Apple Neural Engine

The high inference speed makes the model suitable for integration into high-throughput logistics environments where real-time processing is critical.

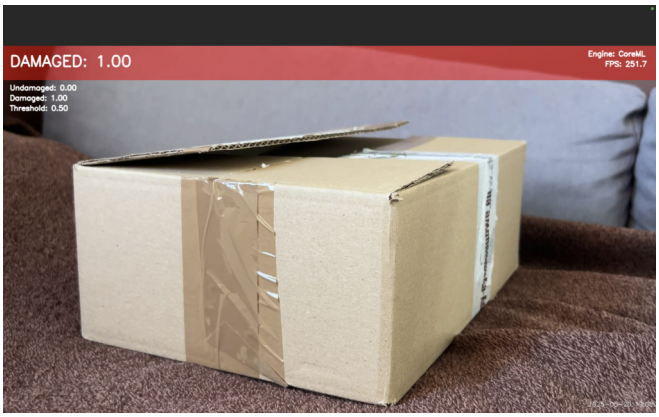

Fig. 7. Optimization process maintained model accuracy while significantly improving inference speed, achieving over 251 FPS on Apple M1 hardware during real-time testing.

VI. Results and Evaluation

A. Performance Metrics

We evaluated our models using classification metrics including accuracy, precision, recall, and F1 score.

The best0 and best1 models achieved results as presented in Table I. The best1 model consistently outperformed the baseline (best0) across all evaluation metrics, indicating successful

mitigation of the identified dataset weaknesses. The enhancements in precision are particularly notable, indicating that our approach successfully reduced false-positive classifications.

TABLE I
SHOWS THE TRAINING STATISTICS FOR BOTH MODELS, ILLUSTRATING THE IMPROVEMENT IN FINAL PERFORMANCE ACHIEVED BY THE BEST1 MODEL AFTER ADDRESSING THE IDENTIFIED WEAKNESSES IN THE DATASET.

Metric	best0 model	best1 model	Improvement
Accuracy	97.00%	98.50%	+1.50pp
Precision	94.80%	97.04%	+2.24pp
Recall	98.81%	99.74%	+0.93pp
F1 Score	96.76%	98.37%	+1.61pp

We also evaluated our models under real-life conditions, such as too dark or too light environment. These results suggest that our models performance can be increased by hyper-tuning or changing the augmentation parameters for images. Scores achieved by both models in this scenario are presented in Table II.

TABLE II
SHOWS STATISTICS FOR BOTH MODELS IN BOTH DARKER AND LIGHTER ENVIROMENTS USING REAL-LIFE IMAGES AND AUGMENTATIONS

Metric	best0 model	best1 model	Improvement
Accuracy	92.06%	94.44%	+2.38pp
Precision	89.74%	91.14%	+1.4pp
Recall	97.22%	100%	+2.78pp
F1 Score	93.33%	95.36%	+2.03pp

B. Confusion Matrix and Precision-Recall analysis

Detailed analysis of these matrices reveals:

- True Positives (Damaged correctly classified): Increased from 747 to 754
- False Negatives (Damaged classified as Undamaged): Decreased from 9 to 2, representing a 77.8% reduction
- True Negatives (Undamaged correctly classified): Increased from 871 to 889
- False Positives (Undamaged classified as Damaged): Decreased from 41 to 23, representing a 43.9% reduction

The substantial reduction in false negatives is particularly important for our application context. In parcel damage detection, false negatives (missed damages) typically have a greater business impact than false positives, as they can lead to damaged items being delivered to customers, resulting in customer dissatisfaction and potential financial losses.

C. Visual Inspection of Classification Results

Beyond quantitative metrics, we conducted a qualitative analysis of classification results to identify patterns in the remaining misclassifications. For the best1 model, we observed the following:

- False negatives (2 instances): Both cases involved parcels with minor damage that was partially obscured or at the edge of the package.

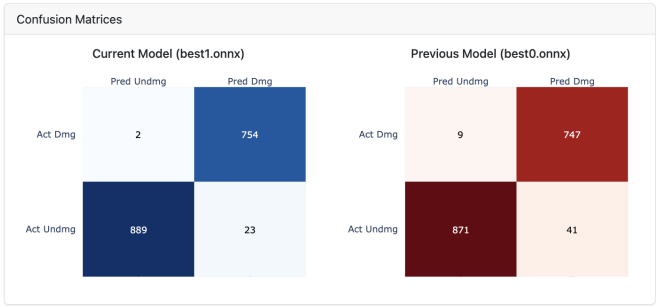

Fig. 8. Confusion matrices for both models

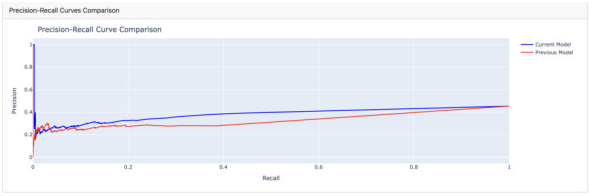

Fig. 9. Shows the precision-recall curves, where the best1 model (blue line) maintains higher precision across all recall values than best0 (red line). These analyses provide a more comprehensive view of model performance beyond the single operating point represented by the confusion matrix, demonstrating that the best1 model achieves superior performance across various classification thresholds.

- False positives (23 instances): Primarily involved parcels with heavy tape reinforcement or unusual packaging materials that resembled damage patterns.

These observations provide valuable insights for future improvements, suggesting that focusing on capturing more examples of minor/obscured damage and diverse packaging materials could further enhance model performance. Fig. 8

VII. Dashboard for Visualization and Analysis

To support model evaluation and facilitate comparisons, we developed a lightweight web-based dashboard using Dash and Plotly. The interface allows users to select between model versions (e.g., best0 vs best1), inspect performance metrics (accuracy, precision, recall, F1 score), and visualize confusion matrices and precision-recall curves. Users can also upload custom images or specify test folders for evaluation.

The dashboard supports real-time testing with side-by-side model predictions, along with confidence scores displayed via intuitive visual indicators. All visualizations are interactive, supporting threshold-independent assessments and flexible data exploration.

This interface enables rapid prototyping, debugging, and demonstration of classification results without requiring deep technical expertise. The tool has proven useful for both offline analysis and on-site testing scenarios.

VIII. Future Works

Although the developed parcel damage classification system achieves high performance, several promising directions remain for further development, both in terms of visual analysis

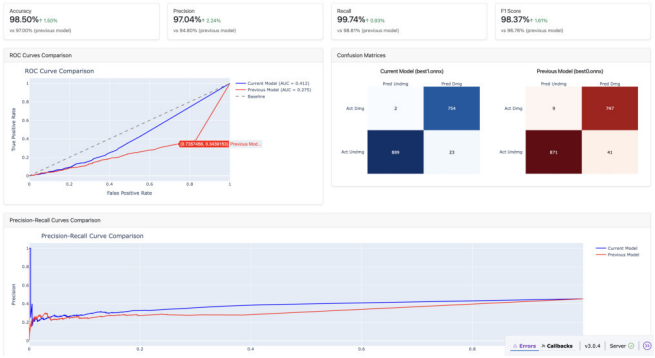

Fig. 10. Comprehensive dashboard presenting all the important information about currently selected model. It also give option for real-time image testing.

and integration with the mobile inspection platform. The key next steps include:

1) Damage Localization: Extending the system to not only classify parcels as damaged but also localize and highlight specific damaged areas.
2) Damage Type Classification: Developing a multi-class model that can distinguish between different types of damage (e.g., tears, water damage, crushing) to provide more detailed information.
3) Integration with Mobile Robot: Combining the visual inspection system with the custom-built mobile platform will enable fully autonomous parcel inspection within warehouse environments.
4) Edge Deployment: Further optimization for deployment on edge devices directly on conveyor systems using techniques like model quantization.
5) Multi-View Integration: Combining predictions from multiple camera angles to improve detection accuracy for damages that might only be visible from certain perspectives.
6) Continuous Learning Framework: Implementing a system for ongoing model improvement based on operational feedback and new data collection.

IX. Conclusion

This paper presents a complete parcel damage detection system based on machine learning, covering data preparation, dataset enrichment, model development, and real-time optimization. A key component of the solution is the custom-designed and built mobile inspection robot, tailored for use in warehouse environments.

The system achieved a very high recall rate (99.74%), demonstrating its ability to detect parcel damage reliably, an essential requirement in logistics to minimize customer complaints and reduce financial losses. The inference speed supports deployment in high-throughput environments, and the custom dashboard enables real-time performance monitoring and model comparison.

The integration of both components, the mobile robotic platform and the vision-based classification system, lays the foundation for a fully autonomous, real-time parcel inspection solution. This project demonstrates that the thoughtful application of computer vision techniques, combined with domain-specific considerations and high-quality data, can yield practical and effective solutions to real-world challenges in logistics automation.

***Abstract*—In this study, we present a data-driven method for preserving the length of cubic Bézier curves under external deformations, specifically in the context of hair strand simulation. By sampling millions of original and displaced control point configurations within a 2D bounded grid space, we construct a large dataset of Bézier curve pairs and compute the corresponding t_{final} parameters required to preserve arc length. A lightweight artificial neural network (ANN) architecture is trained on this dataset to predict t_{final} given 16 features representing the coordinates of initial and displaced control points. The model achieves a low mean absolute error (MAE) of 0.00091992 on the test set, ensuring high predictive accuracy. Performance evaluations show that the ANN can predict t_{final} values for up to 200k hair strands in approximately 8 seconds on a standard laptop, aligning with the average number of strands on a human scalp. This approach replaces computationally expensive numerical length-matching operations with a fast, inference-based framework, allowing for efficient simulation of realistic, deformable hair motion while maintaining individual strand lengths.**

***Index Terms*—Hair simulation, hair modelling, Bézier curve, artificial neural network**

I. Introduction

A SINGLE human hair strand, though microscopically thin, represents a significant computational unit in computer graphics due to its complex physical properties. A realistic digital human typically involves simulating tens of thousands of strands—up to 100,000 on average—making hair one of the most resource-intensive components in real-time rendering [1]. In modern video games, virtual reality, and interactive applications, simulating lifelike hair movement under dynamic motion and external forces such as wind is essential but remains a non-trivial challenge. A fundamental and often under-addressed issue in this context is preserving the physical length of each strand, especially during rapid motion or deformation.

Hair simulation traditionally relies on strand-based models, which represent each hair as a discrete chain of mass points connected by springs. These models offer fine-grained control over local deformation such as bending, twisting, and inter-strand collision handling [2,3]. Mass-spring systems, for example, have been widely used due to their simplicity and real-time compatibility. However, ensuring inextensibility—the preservation of strand length—becomes problematic, especially under dynamic motion, where stiff springs introduce instability [3,4]. To improve numerical robustness, implicit integration schemes have been introduced [4,5], but their computational overhead makes them impractical for real-time environments. More recent advancements, such as the Augmented Mass-Spring (AMS) model, introduce ghost rest-shapes and biphasic coupling to improve simulation stability and strand length preservation during movement and collisions [6]. Additionally, Müller et al. proposed the Dynamic Follow-The-Leader (DFTL) method, which enforces inextensibility through a geometric update rule and achieves real-time performance with a single iteration per frame [7]. Another common artifact in strand-based systems is initial sagging caused by gravitational forces at the start of the simulation. To overcome this, Hsu et al. developed a sag-free initialization framework, which establishes a static equilibrium and neutral torque configuration prior to dynamic simulation. This significantly reduces unwanted deformation and helps preserve the intended hairstyle [8]. Furthermore, Position-Based Dynamics (PBD) has become a foundational strand-based method by directly enforcing positional constraints such as segment length. PBD is widely used in interactive simulations due to its robustness and control [9].

In contrast, volume-based methods treat hair as a continuous medium, modeling global movement and shape using tools such as fluid dynamics, volumetric mass models, or free-form deformations [10,11]. These approaches offer better scalability for large hair volumes and can efficiently capture overall flow and motion. However, they often sacrifice individual strand resolution, which is critical for detailed hairstyles and physical realism. For example, continuum models [10] and lattice-based structures [11] can simulate general hair behavior but lack fidelity in capturing high-frequency deformations or enforcing per-strand constraints like inextensibility. As a result, while volume-based methods are advantageous for broad dynamics, they are less suited for applications requiring high detail, such as cinematic effects or close-up character interactions.

Given the respective limitations of strand- and volume-based approaches, researchers have increasingly turned to hybrid simulation methods. These techniques are designed to leverage the physical fidelity of strand-level models while

incorporating the computational efficiency and stability offered by volume-based or constraint-based frameworks. One such approach is Position-Based Dynamics (PBD), which eliminates the need for solving complex differential equations and enforces constraints directly on particle positions [12]. Shape matching methods [9] and meshless deformation frameworks have also been explored to stabilize motion while avoiding stiffness artifacts common in traditional systems. Another line of hybrid research adopts rigid body inspired models using serial chains, enabling accurate modeling of both local strand behavior and global transformations [13,14]. These techniques integrate strand-level articulation within a larger kinematic or physics-based framework to improve simulation realism without sacrificing computational efficiency.

Recent years saw, the emergence of data-driven techniques has opened new possibilities in hair simulation. Neural network-based methods aim to approximate complex physical behaviors without relying on explicit solvers, making them especially suitable for real-time environments. One such approach, Quaffure [15], introduces a quasi-static neural model trained with a self-supervised loss function to predict plausible strand deformations across a variety of poses and hairstyles. By eliminating the need for simulated training data, Quaffure achieves high temporal stability and runs efficiently on consumer hardware, bridging the gap between physical accuracy and performance.

Complementing this trend, Dr.Hair [16] addresses the challenge of strand-level reconstruction from visual input. Leveraging a differentiable rendering framework, the method reconstructs scalp-connected hair strands directly from multi-view images without pretraining, accurately preserving both strand length and directional flow. These techniques exemplify how learning-based methods can supplement or replace traditional solvers for specific simulation tasks.

Alongside advances in simulation, efficient rendering methods have also evolved to meet the demands of real-time graphics. Hair mesh systems, such as the one introduced by Yuksel et al. [17], generate strand geometry procedurally on the GPU at render time. This drastically reduces memory usage while maintaining geometric fidelity, allowing for the real-time rendering of hundreds of uniquely styled characters. Together, these learning- and rendering-focused approaches highlight a growing trend toward hybrid solutions that integrate physical modeling, data-driven inference, and hardware-aware rendering strategies to advance the realism and scalability of hair simulation systems.

Building on the potential of curve-based modeling and hybrid techniques, recent studies have explored combining Bézier representations with physically inspired solvers and mathematical optimization techniques—such as the use of Budan–Fourier analysis for root bounding in curve behavior prediction [18] and contour tracing algorithms for shape reconstruction in structured objects [19]. A notable example is the work which integrated Bézier curves with the Articulated Body Method (ABM) to simulate dynamic hair strand behavior with real-time performance [20]. Their model treats each strand as a Bézier curve and applies ABM to resolve motion and constraint forces efficiently. These approaches reinforce the growing viability of combining geometric curve modeling with physically inspired or learning-based systems—an idea central to our study, which uses Bézier curves in conjunction with artificial neural networks to predict strand deformation under motion and external forces.

This study specifically focuses on the problem of strand length preservation during hair motion and external interactions, such as wind. We critically analyze existing approaches from the perspective of both physical accuracy and real-time performance, highlighting their respective advantages and limitations. Based on this analysis, we propose directions for enhancing simulation fidelity while maintaining computational feasibility. A shallow artificial neural networks (ANN) can accurately and efficiently predict the target final curve parameter for achieving length-preserving transformations of hair strands represented by Bezier curves. Due to their parametric structure, differentiability, and compact representation, Bezier curves inherently support scalable and generalized deformation modeling. This makes them particularly advantageous for learning-based strand manipulation, even under varying strand complexities. This study was initiated with this hypothesis in mind, aiming to validate the effectiveness of lightweight ANN architectures in performing accurate and efficient strand deformations through Bezier-based geometric encoding.

II. Materials and Methods

In this study, we propose a data-driven approach based on ANN to maintain the length of cubic Bezier curves under external deformations, specifically aimed at simulating individual hair strands affected by physical forces while preserving their natural length. This section details the process of data generation, Bezier curve modeling, and ANN-based prediction methodology.

A. Bézier Curve and Hair Modelling

A cubic Bézier curve is defined by four control points: A, B, C, and D, and is expressed parametrically as in equation (1):

$$P(t) = (1-t)^3 A + 3(1-t)^2 tB + 3(1-t)t^2 C + t^3 D \quad (1)$$

Where $t \in [0, 1]$. As the parameter t varies from 0 to 1, the curve smoothly transitions from A to D, influenced in shape by intermediate control points B and C. This property makes Bézier curves particularly well-suited for modeling flexible and natural curves such as hair strands. For example, let us consider a hair strand modeled by a Bézier curve with the control points at locations (x, y) : $A = (0, 0), B = (0.25, 1.0), C = (0.75, -1.0)$ and $D = (1, 0)$. This configuration produces a slightly wavy shape representative of a natural hair strand. Figure 1 illustrates this cubic Bézier curve constructed from the defined control points.

An important advantage of using Bézier curves in hair simulation is that each point on the curve can be independently

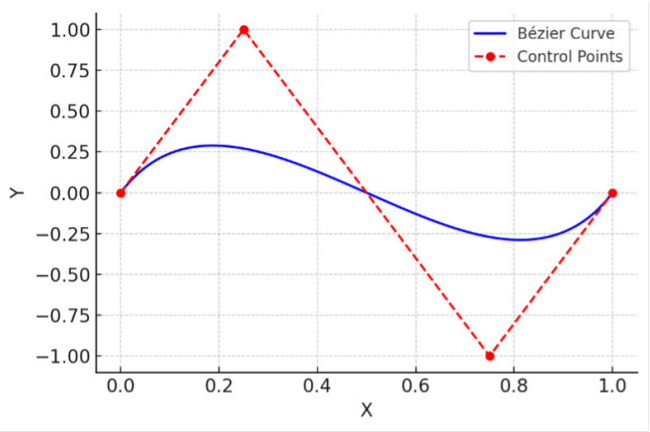

Fig. 1. Bézier Curve for a Wavy Hair Strand

computed by evaluating the Bézier formula at any value of t. For instance, stepping through the interval $[0, 1]$ in increments of 0.1 allows for the generation of discrete, evenly spaced points along the hair strand. This makes the approach inherently parallelizable and computationally efficient for simulating thousands of strands simultaneously.

B. Bézier Curve Representation and Length Estimation for Data Generation

We consider a cubic Bézier curve defined by four control points: A,B,C, and D. Points A and D are fixed at coordinates (0, 0) and (1, 0), respectively, defining the endpoints of a hair strand. Control points B and C are allowed to locate within a region $[0, 1] \times [-1, 1]$ (point space region shown in Figure 1 with 1 unit width and 2 unit height) with a spatial resolution of 0.1. This resolution results in a discrete point cloud of 231 (11x21) possible positions for each of B and C. Although 231 grid points are defined, combining different configurations of initial and moved control points can yield tens of millions of curve pairs. This vast combinatorial space ensures that the dataset captures a wide range of plausible deformations necessary for training a reliable predictive model. However, since many initial and subsequent curves (moved curves) would be undesirably close to each other at a resolution of 0.1, two distinct region location maps were constructed. The first one is a point space with 0.2 resolution at even position values (e.g., 0, 0.2, 0.4), and the second one is a point space with 0.2 resolution at odd position values (e.g., 0.1, 0.3, 0.5). Using each position space separately, initial and subsequent curve locations were determined, and some unsuitable curve pairs were filtered out. Then, to ensure an acceptable data loading time and avoid memory issues, a dataset consisting of 7.5 million samples was constructed through random selection. Each sample consists of 16 input features: the x and y coordinates of the original and moved control points (8 control points with sixteen x and y components), and one output value: the corresponding t_{final} that preserves the curve length. Figure 2 illustrates a unit square point cloud at 0.1 resolution, with an example of original and subsequent cubic Bézier curves generated using a specific configuration of the control points. For each data sample, the corresponding t_{final} values were computed to ensure that the curve length at the subsequent position is equal to that at the initial position.

To simulate external influences, new displaced positions B' and C' are sampled independently from the same discrete space. For each $A-B-C-D$ configuration and its subsequent curve counterpart $A - B' - C' - D$, the curve length of the original and deformed curve is computed. The first curve is parameterized over the interval $t \in [0, 1]$, and the moved curve length is evaluated using numerical integration (e.g., Simpson's rule). Then, the moved curve $A - B' - C' - D$ is sampled over $t \in [0, t_{final}]$ such that its arc length is numerically equal to the original curve.

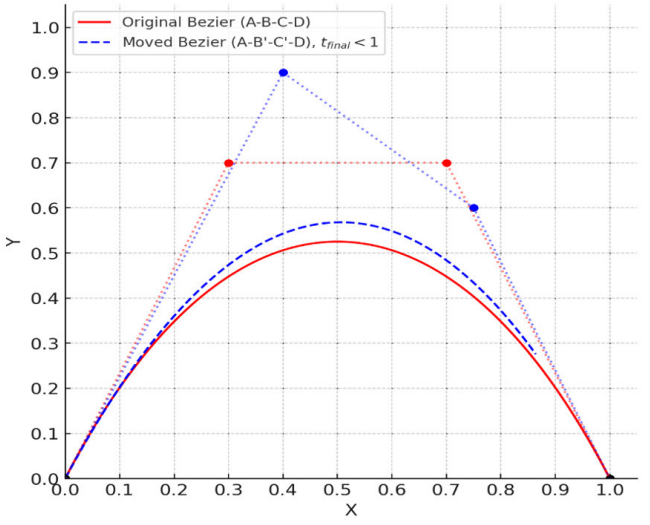

Fig. 2. Example of original and moved Bézier curves

C. Scaling Bézier Curves to Any Rectangular Domains

Although the dataset is generated within a $[0, 1] \times [-1, 1]$ region, Bézier curves can be reliably applied to arbitrarily positioned rectangular regions. This is achieved through a combination of translation and axis-wise scaling that aligns the rectangular configuration with the ANN's reference point space domain. Let a rectangular region be defined by horizontal bounds $[x_{min}, x_{max}]$ and vertical bounds $[y_{min}, y_{max}]$. To align this region with the reference point space, we first translation and then scaling operations as in (2), (3) and (4):

Translation: Shift the lower-left corner of the rectangle to the origin by subtracting (x_{min}, y_{min}) from all control points.

Scaling: Normalize the width and height of the rectangle using the scale factors:

$$s_x = x_{\max} - x_{\min} \tag{2}$$

$$s_y = \frac{y_{\max} - y_{\min}}{2} \tag{3}$$

Each control point $P = (x, y)$ is then transformed to reference region coordinates by:

$$P_{\text{unit}} = \left(\frac{x - x_{\min}}{s_x}, \frac{y - y_{\min}}{s_y} \right) \tag{4}$$

This transformation allows both original and displaced control points to be converted into a form compatible with the ANN trained on reference region samples. Once the ANN predicts the t_{final} value, the Bézier curve can be redrawn directly in the rectangular domain using the actual (moved) control points A, B', C', and D. This method preserves the accuracy of the curve length while adapting the model to diverse geometric contexts.

D. Neural Network Model

To approximate the mapping from control point displacement to the required value, a feed-forward artificial neural network (ANN) was constructed. The ANN model receives a 16-dimensional feature vector as input—comprising the x and y coordinates of original and displaced control points (total of 8 points) —and outputs a single scalar. The network architecture consists of four fully connected layers implemented using the Keras Sequential API:

```
model = Sequential([
    Dense(128, activation='relu',input_shape=(16,)),
    Dense(64, activation='relu'),
    Dense(32, activation='relu'),
    Dense(1, activation='sigmoid')
])
```

This shallow and lightweight model architecture is intentionally selected to enable extremely fast predictions, which is essential when simulating thousands of hair strands in real-time applications. Although the model depth is limited, its predictive power is effectively enhanced by using a very large and diverse training set of more than 7 million Bézier curve configurations.

To train the network, the dataset was split into 80% training and 20% test sets. The target values were normalized using a $MinMaxScaler$. The model was trained with a batch size of 1000 for up to 350 epochs using the Adam optimizer. Early stopping and model checkpointing strategies were used to prevent overfitting and retain the best-performing model. After training, the best model achieved low error on unseen data, with the mean absolute error and sum of absolute errors computed during evaluation. The overall strategy demonstrates that by combining a simple ANN structure with a large and carefully prepared dataset, highly accurate and computationally efficient predictions can be achieved.

This ANN framework enables the rapid estimation of values for potentially thousands of hair strands affected by external factors, allowing for efficient regeneration of hair geometry while maintaining individual strand lengths. The proposed solution thus replaces computationally expensive numerical searches with a lightweight inference mechanism. The network is trained using the mean absolute error (MAE) as the loss function. MAE is a commonly used regression metric that quantifies the average magnitude of the errors between predicted values and the actual ground truth values. It is defined by equation (5).

$$MAE = \frac{1}{n} \sum_{i=1}^{n} |t_{\text{final_gt}} - t_{\text{final_pr}}| \tag{5}$$

Where n, t_{final_gt} and t_{final_pr} are number of samples, the ground truth and predicted time values, respectively. MAE is expressed in the same units as the target variable and provides an intuitive measure of model accuracy. It is especially useful when all errors are equally weighted.

III. Results and Discussion

All experiments were conducted on a laptop running Windows 10 Pro, equipped with a 12th Gen Intel® Core™ i7-12700H processor (2.30 GHz, 14 cores, 20 threads), 32 GB of RAM and NVIDIA GeForce RTX 3060 Laptop GPU. The training and testing of the proposed ANN model were implemented using the Keras library (Python 3.9) with TensorFlow. Hair strand movements under external forces were simulated using MATLAB R2021a.

Table 1 gives the training, testing and prediction details of the study. This study used a training dataset of 6 million samples (80% of the full dataset), and 1.5 million samples were reserved for testing. The model achieved a test set MAE of 0.00091992, indicating high predictive accuracy in estimating the parameter for length-preserving curve transformations. In this context, the MAE corresponds to the average deviation in the predicted t_{final} value per hair strand. It does not directly represent a geometric length error but rather a deviation in the Bézier time parameter that determines where the curve should be truncated to preserve length. For example, a MAE of 0.00091992 implies that, on average, the predicted truncation point deviates from the true value by less than one-thousandth of the normalized parameter range $[0, 1]$. Assuming that a single hair strand may undergo deformation multiple times, such a deviation would only accumulate to a 1% error after approximately 5.48 independent displacements for 0.5 of t_{final} true value $(5.48 \times 0.00091992/0.5 \approx 0.01)$. This indicates that even under sustained movement, the predicted t_{final} remains sufficiently accurate to maintain a nearly constant hair length. This also suggests that increasing the amount of training data and using more powerful computational hardware could further reduce the MAE, improving the model's suitability for long-duration hair simulations under dynamic conditions. Table 1 also presents prediction runtime for varying batch sizes. The model predicted values for 1, 1k, 10k, 100k, and 200k samples (batch size) in approximately 0.0579, 0.0994, 0.5296, 4.09, and 8.11 seconds, respectively. The inclusion of 200k samples simulates a full-head hair scenario, as this figure closely matches the average number of hair strands on a human scalp. While the current implementation achieves prediction times of approximately 8 seconds for 200k samples, this duration may be considered borderline for real-time applications. However, this benchmark was obtained on a standard laptop

without GPU acceleration. Since the prediction task involves a shallow ANN with only a few dense layers, it is likely that the inference time could be significantly reduced on optimized hardware or with additional engineering effort. Employing GPU-accelerated inference and incorporating preprocessing strategies such as dimensionality reduction or data batching may potentially improve performance and make the model more suitable for time-sensitive applications. The results in Table 1 pertain to the prediction of t_{final} values rather than complete physical simulation, and thus no direct baseline comparison is available in the literature.

TABLE I
TRAINING, TESTING AND PREDICTION DETAILS OF THE STUDY

Number of train data (0.8 split ratio)		6 milion
Number of test data (0.2 split ratio)		1.5 million
MEA test error		0.00091992
Prediction time (second) [mean (std) for 5 trials]	1 sample	0.05795540 (0.002448)
	1k samples	0.09941540 (0.013011)
	10k samples	0.52964460 (0.039699)
	100k samples	4.08589480 (0.188377)
	200k samples	8.10715880 (0.45811)

Figure 3 illustrates an initial hair strand (blue curve) and its multiple deformed configurations (red curves) resulting from external influences applied to its control points. Despite visual variations in trajectory, all red curves are generated by adjusting the t_{final} parameter through the trained ANN model such that their arc lengths are preserved relative to the initial curve. This figure demonstrates the model's effectiveness in maintaining strand length consistency under dynamic conditions, validating the proposed method for realistic hair motion simulation. Based on the curve analysis illustrated in the figure, the original strand represented by the blue curve has a computed length of 4.803 units. However, the final (sixth) red strand—generated with a cumulative t_{final} deviation of 0.00091992 per step—exhibits a length of 4.876 units. This results in an absolute error of 0.073 units, corresponding to a relative error of approximately 1.52% compared to the original. These findings demonstrate that even minor per-step deviations in t_{final} can accumulate and lead to noticeable differences in physical attributes such as strand length. Consequently, preserving the original length with high fidelity becomes essential, especially in applications requiring physical realism, such as animation and real-time hair simulation.

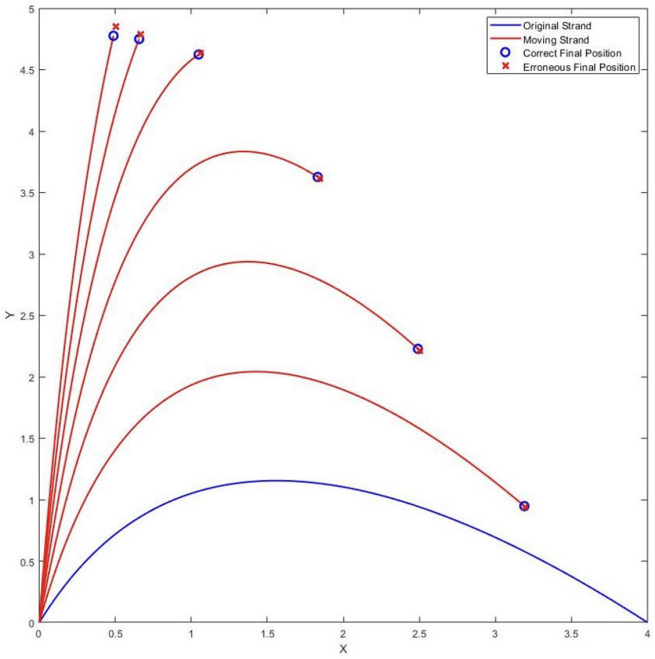

Fig. 3. An initial strand (blue) and its six subsequent movements (red). The cumulative spatial error resulting from an average MAE of 0.00091992 in the predicted t_{final} values is illustrated. Blue circles mark the true terminal positions, while red crosses indicate the erroneous positions due to cumulative prediction error.

IV. CONCLUSION

This work proposes a neural network-based approach to estimate the parameter t_{final} for cubic Bézier curves subjected to external deformation, with the goal of preserving hair strand length in dynamic 2D simulations. By generating a dataset of 7.5 million curve configurations and training a shallow ANN with high generalization capability, the study demonstrates that accurate t_{final} predictions can be achieved rapidly. The resulting MAE, although referring to the time domain rather than direct spatial error, accumulates to only 1% deviation after approximately 5 sequential displacements—suggesting that strand length is effectively preserved over long-term movement. The ANN's prediction times for up to 200k strands—comparable to the number of hairs on a typical human scalp—are under 10 seconds, and can be further reduced with more powerful hardware or model optimization. These findings support the viability of ANN-based inference for realistic and computationally efficient hair simulations.

In future work, this framework will be extended to simulate the dynamic motion of entire hair assemblies composed of Bézier strands under various external forces, where each strand's length is regulated via ANN-predicted t_{final} values. Additionally, further training on a larger dataset is planned to reduce prediction error even more, ensuring higher fidelity in long-duration and high-frequency deformation scenarios. Although this study is currently limited to 2D simulations, the architecture of the dataset generation and ANN model are fully generalizable to 3D Bezier strand representations. Future work will explore 3D vector space adaptation for each control point coordinate.

***Abstract*—We propose a new replay snapshotting (RS) technique for strategy learning from past matches in real-time strategy game StarCraft: Brood War (SCBW). It allows for more precise understanding of particular strategy aspects by sampling the state of selected game features at important checkpoints during a match. We use RS to extract and refine a set of strategies from a large replay dataset STARDATA. To validate our approach in a competitive environment, we implement an AI agent for SCBW. It is able to perform the extracted strategy set against opponents in the BASIL Ladder competition. The agent consistently achieves rank C with 56 % win rate which is a significant improvement over our previous approaches.**

I. Introduction

REAL-TIME strategy (RTS) video games, especially the competitive 1v1 setting, are popular in AI research and education because of the inherent difficulties and challenges they present. During a match, only parts of the battlefield near their own structures and units are visible to players [18]. This partial observability of the game state forces players to make decisions under uncertainty based on available incomplete information. Players need to actively scout the map to gather information about the opponent's activities [11]. Moreover, the number of possible actions a player can execute at each time is overwhelming, making the decision process very complex [2].

The most popular and widely known RTS is Blizzard's StarCraft: Brood War (SCBW) released in 1998 (Fig. 1). One aspect which made the game successful and long-lasting is fair balance of 3 playable races: Protoss (P), Terran (T) and Zerg (Z), each offering unique aesthetics and play-styles. Also, no 'cookie cutter' strategy exists which would be able to defeat all opponents [11]. A strategy is a long-term plan for the current match. It typically involves plans on what structures to build in what order and what army composition to aim for. Strategies can be roughly divided into 3 categories capable of countering each other in a rock-paper-scissors manner (Fig. 2). Another aspect is easy accessibility for players and researchers. The game has low hardware requirements, is free-to-play since 2017 and plenty of tools are available for it to aid with

This work was supported by the Slovak Scientific Grand Agency VEGA under the contract No. 2/0135/23 *"Intelligent sensor systems and data processing"*. Funded by the EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I05-03-V02-00055.

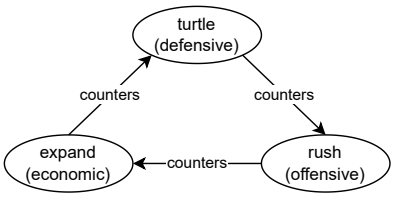

Fig. 2. Rock paper scissors nature of RTS game strategies

research and experimentation, e.g., BWAPI [1], *screp* [2]. Despite considerable progress in their quality over the years, RTS AI agents are not yet capable of beating human expert level players on a consistent basis [3], [9], [12] or are impractical for common video games due to high computational power demands [4], [17].

One possible approach for SCBW agent improvement, especially the strategy selection aspect, is to learn from past matches [12], [14], [15]. SCBW allows recording and archiving of match replays. A vast amount of such data was accumulated throughout the years. For machine learning purposes, a dataset of replays should meet certain requirements to be considered viable and high quality. The largest of such datasets is STARDATA [1], containing 65646 files. Other smaller datasets include [5], [6], [7], [13].

One of the important tasks which can be addressed using

[1]https://github.com/bwapi/bwapi
[2]https://github.com/icza/screp

STARDATA is strategy classification [1]. Knowledge about strategies extracted from replays of highly skilled players can benefit SCBW agents in multiple ways. It can be used during a match to predict opponent activities based on the observed information and help adjust further actions. As a part of the preparation process before and between matches, it can improve the ability to imitate and execute strategies that are statistically proven to be successful or pick from a pool of available strategies most suited for the opponent depending on their race or stored past results against them.

Strategy classification from SCBW replays was attempted [5], [6], [7], [1], but the results of each work were quite limited or very specific in some way with regards to dataset size, quality level of matches, number of strategies or races. Classification from STARDATA was also attempted. The work [8] extracted strategies only for one race (Terran) and [10] for all 3 races, but the selection of strategy defining features (SDFs) was not optimized and could be improved.

In this work, we build upon and improve the process of strategy extraction from [8] in multiple ways. We allow a broader range of strategies to be learned by extending the upper game length limit (Section II-A); refine the unit and structure production frequency calculation formula to provide more precise results (Section II-B); refine the SDF selection process for Terran by also considering the opponent's race (Section II-C); tweak strategy classification by adjusting clustering parameters (Section II-D); and finally, we propose a new technique called *replay snapshotting* (RS) to improve the analysis process of extracted data (Section II-E).

To validate our approach, we implement an AI agent nicknamed *MisHanBot* for SCBW playing Terran race and put it into the BASIL Ladder competition [3]. In this competitive environment, the agent is able to perform the set of strategies extracted by RS against opponents of varying quality. It consistently achieves rank C with current win rate of 56 % which is a significant improvement over our previous approaches.

II. Strategy learning

A. Dataset preparation

We use STARDATA to extract and classify Terran strategies for our SCBW agent from Terran matchups: versus Terran (TvT), versus Protoss (TvP) and versus Zerg (TvZ). *Extractor* proposed in [8] is used to collect raw data. Considered are only matches that meet the following criteria:

a) Valid 1v1, i.e., readable in BWAPI, featuring two opposing players using standard set of units.
b) At least one player is Terran.
c) No longer than 25 minutes.
d) Winner is agreed upon by both tools: *extractor* and *screp*.

Criterion a) filters out any custom or non-standard, non-competitive games. Criterion c) allows the agent to learn larger variety of middle and late-game strategies than 15 minute limit used in [8]. Criterion d) ensures that the quality of extracted strategies can be calculated precisely by inspecting their win rates. To help decide on the winning player, the *screp* utility is used to double-check the results provided by *extractor*. To identify a winner reliably in a non-labeled SCBW replay file is a non-trivial task and various replay analysis tools can produce different outcomes. Dataset cleaning results are shown in Table I. The total number of extracted Terran strategies is 28477; 2 from each TvT matchup (since both players are Terran) and 1 from other matchups (since one player is Terran). Next, raw data are extracted from the prepared dataset.

[3]https://www.basil-ladder.net

TABLE I
Extracted Terran strategies

Matchup	STARDATA replays	Selected replays	Extracted strategies
TvT	2550	1753	3506
TvP	17385	12916	12916
TvZ	14531	12055	12055
Total	34466	26724	28477

B. Data extraction and processing

For raw data extraction, we follow the process [8], obtaining detailed information about each game, including basic metadata (player and map names, match lengths, etc.), timestamps for structure, unit and upgrade creation and destruction, and more. For subsequent data processing and compaction, a few adjustments compared to [8] were made. Firstly, we modify the formula for unit frequency:

$$UnitFreq = \frac{1428.6 \cdot UnitCount}{MatchLength - FirstFrame} \quad (1)$$

where $UnitCount$ is the amount of a unit produced in the entire match, $MatchLength$ is given in game frames and $FirstFrame$ now denotes when the unit's first instance was produced. Previously it denoted when the requirements were first met for the unit's creation. Eq. (1) computes the average frequency of a unit's production per minute (1428.6 frames) since its first instance creation until the match's end. This is a more precise metric to measure unit usage than previously used. Secondly, we now calculate frequency for structures, too, using Eq. (1) but replacing $UnitCount$ by $StructCount$.

In this work, we define SCBW strategies by structure build order and construction frequency and unit composition, omitting technology advancements and upgrades. Put more simply, we are interested in structure and unit information. In the remainder of the text, structures and units together will be denoted as features. Next, a set of important features is selected which will be used to categorize strategies.

C. Feature selection

Terran can build 18 different structures and create 13 types of units directly and few more indirectly (see below). Not all features are equally popular and present in games. If a match is short, there is not enough time to reach advanced features. Additionally, players have discovered over the years which unit compositions are strong against certain opponents.

TABLE II
UNIT SELECTION EXAMPLE FOR TVT. PERCENTAGE OF STRATEGIES WITH INDICATED NUMBER OF UNITS

Unit	1+	5+	10+	Selected
SCV	100.0 %	99.9 %	99.3 %	No, essential
Vulture	80.6 %	56.0 %	44.0 %	Yes
Wraith	44.8 %	19.4 %	8.6 %	Yes
Valkyrie	1.9 %	0.3 %	0.0 %	No, low usage

TABLE III
STRUCTURE SELECTION EXAMPLE FOR TVT

Structure	Prerequisite for	Selected
Barracks	Factory, Academy	No, essential
Factory	Vulture, Tank, Goliath	Yes
Academy	Comsat Station	Yes
Comsat Station	Scan Sweep	Yes
Physics Lab	Battlecruiser	No, low usage

For example, Terran biological units are stronger and used more often against Zerg than other opponents. Consequently, some units are perceived as not effective and are rarely used. On the other hand, some features are essential for making progress and are present in vast majority of matches. If a feature belongs to one of these edge cases, it adds no value to strategy classification and can be disregarded.

Previous approach [8] used the same set of features in all 3 Terran matchups. In this work, we inspect each matchup more closely and consider the opponent's race, allowing us to fine-tune SDFs for each matchup. We select sets of SDFs based primarily on the statistical usage of units. Essential and rarely used units are disregarded. For TvT, units that appear at least one time in at least 40 % of strategies were selected. This bar was lowered to 8 % for TvP and 15 % for TvZ due to different usage distributions. An example of SDF selection for some units in TvT is shown in Table II.

Next, a set of structures is selected to complete SDFs. Again, essential and rarely used structures are disregarded. Terran race tech tree is inspected and for each matchup important structures are selected which are prerequisites for the selected units or other structures. An example of SDF selection for some structures in TvT is shown in Table III.

Selected SDFs are listed in Table IV. Note that although Spider Mines and Scan Sweeps can not be created directly, but are a result of unit ability or spell casting, they are still recognized by BWAPI as units, because they materialize on the battlefield and their statistics can be gathered by *extractor*. Next, compacted data about our selected SDFs from all 28477 Terran strategies are inputs to the unsupervised machine learning process of strategy classification.

D. Strategy classification

To classify SCBW Terran strategies into categories based on the compacted SDF data, we use the K-Means algorithm. It tries to find similarities in the SDF data and group similar strategies into clusters. Previous approach [8] used the same number of clusters (value $K = 10$) for all matchups. In this work, we inspect Terran matchups more closely and use the Elbow method [16] with inertia to find the optimal values of K for each, separately.

TABLE IV
SELECTED STRATEGY DEFINING FEATURES

Structures	Matchups
Factory, Machine Shop, Mis. Turret, Academy, Comsat Station, Starport, Control Tower	TvT, TvP, TvZ
Science Facility, Bunker	TvP, TvZ
Units	**Matchups**
Marine, Siege Tank, Vulture, Goliath, Dropship, Wraith, Spider Mine (unit ability), Scan Sweep (spell)	TvT, TvP, TvZ
Science Vessel	TvP, TvZ
Firebat, Medic	TvZ

Fig. 3. Elbow method for TvT

The results of the Elbow method for TvT are shown in Fig. 3. Among considered values of K (4–6), $K = 5$ was chosen because of the best distribution of average game lengths between individual clusters and also fair distribution of number of matches per cluster. With $K = 5$, we identified 1 cluster containing short games, 2 clusters containing middle length games and 2 clusters containing long games. Detailed results of strategy classification for TvT are summarized in Fig 4. It displays amounts of strategies in clusters.

The resulting value for TvP was $K = 6$: 2 clusters with short, 2 with middle length and 2 with long games. For TvZ it was also $K = 6$: 2 clusters with short, 1 with middle length and 3 with long games.

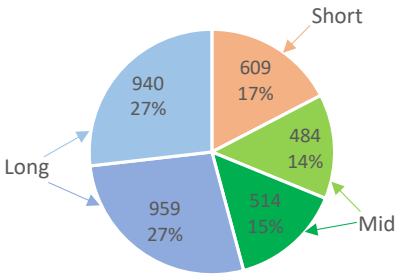

Fig. 4. Strategy classification into clusters for TvT

TABLE V
EXAMPLE OF 2 EXTRACTED STRATEGIES FOR TVT: CLUSTERS '1' AND '3'

Structure	Cl. '1' Freq.	Cl. '3' Freq.	Unit	Cl. '1' Freq.	Cl. '3' Freq.
M. Shop	4.3	3.3	Marine	6.9	3.7
Factory	2.6	3.5	Tank	2.4	2.4
Starport	5.7	3.0	Vulture	3.5	5.2
Academy	6.2	6.0	Goliath	3.8	8.2
Com. Stat.	3.2	5.7	Scan Sw.	4.3	7.2
C. Tower	5.3	4.7	Dropship	6.6	8.1
M. Turret	1.2	6.3	S. Mine	2.2	8.7
-	-	-	Wraith	7.5	2.4

Examples of 2 extracted strategies for TvT are shown in Table V. It shows average frequency rankings of selected SDFs. Lower numbers indicate more frequent appearance while higher numbers indicate less frequent appearance.

Cluster '1' represents a traditional long match strategy using mechanical units: Tanks, Vultures with their ability Spider Mines, and Goliaths. It utilizes structures Factory and Comsat Station often and will construct many Missile Turrets (static defensive). Cluster '3' represents a middle game strategy using a combination of ground (Marine, Tank) and air (Wraith) units. It utilizes structures Starport and Factory often.

The above examples show notable differences between clusters. To find such diversity was an important goal of strategy extraction. A total of 17 strategies were extracted and are available for our Terran agent.

E. Replay snapshotting

Extracted strategies as shown in Table V provide basic guidance on how to proceed in a game for our agent. It learns what types of features to create. We further refine strategies by a new technique called *replay snapshotting* (RS). The basic principle of RS is that a subset of strategies from each cluster is inspected and the amounts of currently existing instances of selected SDFs are snapshotted (sampled) at predetermined checkpoints. This enables our agent to imitate and implement strategies more precisely because it gives the agent more tangible objectives to reach in certain phases of a match. The agent now gains knowledge about how many instances of features are necessary to achieve those partial objectives.

For snapshotting, we have selected strategies that are the best representatives from each cluster. More specifically, strategies used in matches with duration closest to the average cluster match lengths were selected. For example, Cluster '1' from Table V contains matches with an average duration of 18m:31s. Therefore, we select strategies close to this length for RS from this cluster. The number and spacing of checkpoints were set for each cluster individually, based on their average match lengths. The intent is to have checkpoints distributed across all game stages: early, middle and late game, to cover most situations and phases of the entire match. The first checkpoint is usually set at the 4 minute mark because the first important strategic decisions for Terran are made around this time. The last checkpoint is set near the average cluster duration, e.g., at the 18 minute mark for Cluster '1'. The number of strategies selected for RS was 50 per cluster.

TABLE VI
EXAMPLE OF REPLAY SNAPSHOTTING FOR CLUSTER '1' FOR TVT. m–MINUTES

Structure	4m	6m	9m	14m	18m
Factory	1.1	1.7	2.9	4.6	5.8
M. Shop	0.6	1.0	1.9	2.9	3.2
Starport	0.0	0.3	0.4	0.7	0.9
C. Tower	0.0	0.2	0.4	0.6	0.9
Academy	0.0	0.2	0.7	0.9	1.0
Com. Stat.	0.0	0.0	1.0	2.3	2.8
M. Turret	0.0	0.0	0.6	5.7	9.3
Unit	**4m**	**6m**	**9m**	**14m**	**18m**
Marine	2.3	2.1	1.3	0.6	0.3
Tank	0.0	1.7	4.5	11.5	15.8
Vulture	0.3	1.1	3.0	3.5	4.5
Goliath	0.0	0.8	1.1	6.0	9.8
Dropship	0.0	0.1	0.0	0.9	2.5
S. Mine	0.0	1.0	3.2	7.6	11.9
Wraith	0.0	0.1	0.1	0.4	0.4

An example of the RS technique for Cluster '1' for TvT is shown in Table VI. It shows average numbers of instances of selected SDFs snapshotted at exact checkpoints during matches selected for RS. For this cluster, 5 checkpoints were defined at 4, 6, 9, 14 and 18 minute marks. The 4 and 6 minute checkpoints suggest how to proceed in early game and prepare for the transition into middle game. Next, the 9 and 14 minute checkpoints suggest how to transition from early to middle game and prepare for late game. Finally, the last 18 minute checkpoint advises on what structures should be present in the player's base and what is the army composition to aim for in late game. Note that in Table VI RS is not able to track any instances of Scan Sweep spell (one of selected TvT SDFs) because it has only a very short duration and then it disappears from the battlefield.

To implement this strategy, the agent should start by constructing some Factories with Machine Shop, start training some Marines and Vultures, later adding Tanks and Goliaths, research the Vulture's ability to lay Spider Mines and start using them. In middle game, it should add more Factories with Machine Shops, construct an Academy and then Comsat Stations and start producing Missile Turrets. Army should now contain more Tanks and Goliaths while keeping adding Vultures in small numbers and increase the usage of Spider Mines and also slowing down Marine production. A late game player's base should have a healthy number of Factories with Machine Shops, an Academy, some Comsat Stations and many Missile Turrets should be scattered around the battlefield. Late game army composition should comprise mainly Tanks with Goliaths both in healthy numbers with the support of Vultures

and few Dropships and many Spider Mines should be laid on the battlefield. Starting from middle game, the agent can also consider occasionally constructing less used structures such as Starport or Control Tower and training some less used units such as Wraiths.

Based on values obtained by RS, we divide features into three categories:

- Mandatory: $Value >= 1$. Present in majority of matches. The agent should try to construct the indicated number or more of them.
- Optional: $Value \in (0; 1)$. Not present in each match. The agent can consider construction of one instance in case of structures and few instances in case of units.
- Not advisable: $Value = 0$. Not present in any match. It is not advised for the agent to construct these.

In Table VI, an example of a mandatory feature is Factory at 9 minute mark ($Value = 2.9$). The agent should try to have at least 2 but optimally 3 or more of them at this checkpoint. An example of an optional feature is Machine Shop at 4 minute mark ($Value = 0.6$). The agent can consider construction of one at this checkpoint.

Strategies extracted and refined by RS (RS strategies) provide very detailed guidance for the entire match duration as can be seen in the above example. The next objective is to implement them into our agent.

III. Strategy implementation

Our agent *MisHanBot* is based on the public version of *Steamhammer* (SH) [4], a popular starter agent for development and experimentation. Its main race is Zerg, but can also play other races, however, on a lower level than the main one. It also supplies a set of starting strategies and provides many necessary functionalities of a SCBW agent already implemented on a basic level. While adopting existing functionalities from SH, like unit micromanagement, our agent also has many small improvements over baseline SH Terran, including better unit control and unit repair logic, or better ability and spell usage. Terran strategies are implemented in SH by:

- *Configuration file (config)*, an explicit list of items to create and other commands to perform from the start of the match. This list can contain all features, not only those selected as SDFs (Table IV). Depending on its length, it can be used for all game stages.
- *BOSS*, a module which takes over and continues to implement the strategy after all items in *config* have been created. It tries to keep the 'trend' set by *config* and continues with construction of items present in the list.

Strategy selection during a match is based on randomness with weighted probabilities. A pool of strategies is defined for various situations (matchups, opponent's plans, etc.), and each strategy in the pool is assigned a weight based on suitability for tackling that situation. When a situation occurs, SH selects one strategy from that situation's pool randomly.

[4]https://satirist.org/ai/starcraft/steamhammer/

TABLE VII
WIN RATES AND WEIGHTS FOR TVT STRATEGY POOL

Strategy (Cluster)	'0'	'1'	'2'	'3'	'4'
Win rate	52.8	55.5	28.7	50.3	53.6
Weight	22	23	12	21	22

We implement RS strategies into our agent as follows. We overwrite *config* so that it contains only our Terran RS strategies. We define 3 situations: TvT, TvP, TvZ. Note that in our agent, we do not create situations considering opponent's plans. Our strategy selection depends only on the opponent's race. Next, we create a strategy pool for each situation. To account for the randomness of RS strategies (see Section II-E), we round up the advised values from Table VI to the nearest integers. This means that values of all optional features will be rounded to 1, i.e., the agent can try to have one instance of them. Values of all mandatory features will be increased, too. Therefore, the agent is given the upper bounds of what numbers to aim for. After this adjustment, we put RS strategies into strategy pools in *config*; TvT strategy pool includes 5 strategies, TvP and TvZ pools both include 6 strategies.

The explicit lists in *config* for each RS strategy are set up using knowledge of the Terran tech tree while trying to follow RS advice (example in Table VI) as closely as possible.

Next, we set weights for strategy pools. Weights are assigned to extracted strategies in pools proportional to their win rate. Sum of weights in a pool is equal to 100. More successful strategies get higher weights and in turn will be picked more often in games than those with lower weights. TvT win rates were obtained as part of this work (see Section II-D). TvP and TvZ win rates were obtained from collaboration with the authors of two other agents (see Section IV) who did strategy classification for Protoss and Zerg races. Win rates and corresponding weights for the TvT strategy pool are shown in Table VII. It displays average win rates against all other Clusters in the pool. When our agent is in a TvT situation, Cluster '1' has the highest win rate and in turn the highest chance to be used: 23 %. On the other hand, Cluster '2' is the least successful and has the lowest chance to be used: 12 %.

During a match after processing *config*, strategy control of our agent is handed over to the *BOSS* module, similar to SH. It will follow a trend established by *config* and keep producing features as specified in the last RS checkpoint in the remainder of the match.

IV. Results and conclusion

At the time of writing this paper, our agent *MisHanBot* is active in the BASIL Ladder competition. It has rank C with ELO rating 2586, overall win rate 49.4 %, recent win rate 56.3 % and is situated at the 46th place out of 101 currently active agents. The overall number of agents in the ladder is 159. Agents ranked 102 or below are temporarily disabled to keep the competition's level high. They can be re-enabled again under certain conditions.

TABLE VIII
OUR STARDATA-TRAINED AGENT RESULTS IN BASIL LADDER AS OF MAY, 15TH 2025

Agent	ELO rating	BASIL rank	Games played	Win rate	Win rate 7 days
KasoBot (T) [8]	2390	E	48821	38.9 %	41.7 %
Azergo (Z)	2206	E	9034	28.9 %	26.1 %
TommyBot (P)	2203	F	9057	19.6 %	25.7 %
MisHanBot (T) [This work]	2586	C	10253	49.4 %	56.3 %

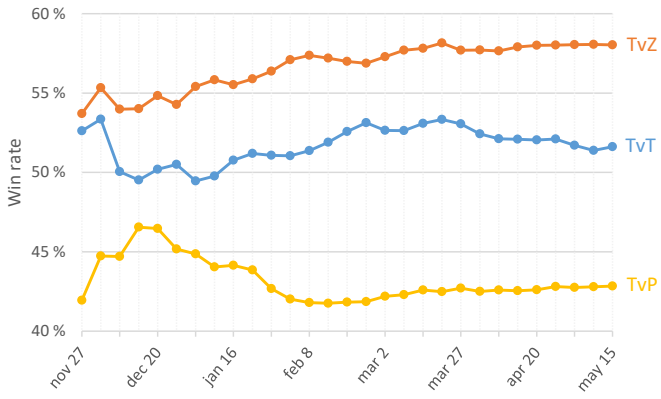

Fig. 5. Win rates of our agent against each opponent race in the last 6 months (Nov 2024–May 2025). Source: BASIL Ladder https://www.basil-ladder.net/bot.html?bot=MisHanBot

The comparison with our other currently active agents is shown in Table VIII. Results obtained by our new agent *MisHanBot* are a significant improvement over our other approaches. Note that both agents *Azergo* and *TommyBot* extract detailed data and learn strategies from STARDATA for their particular races, but use different approaches for their implementation. Strategies obtained by *Azergo* are not as effective and could be improved. *TommyBot* is an experimental agent built from scratch, i.e., it does not use any of available popular starter agents, such as SH.

Fig. 5 displays win rate trends of our agent in the last 6 months against all three opponent races. Results indicate that TvP win rate (currently at 42.8 %) is not satisfactory as it consistently trails behind other two matchups and brings the agent's overall win rate down considerably. On the other hand, TvZ win rate (currently at 58.0 %) is satisfactory while in TvT it is slightly above the average level (currently at 51.6 %).

Our results indicate that the proposed *replay snapshotting* approach for strategy refinement is beneficial for overall SCBW AI agent improvement. Our agent is able to imitate extracted strategies more accurately than our previous approaches and it performs better in a competitive environment. As future work, it could be worth looking more closely into TvP particularly, identify and remedy the weaknesses of our agent in this matchup. Other improvements could include: further SDF selection fine-tuning by adding or removing items; RS adjustments by considering the total amount of produced features at checkpoints instead of counting currently existing instances; including more matches per cluster into RS; adding checkpoints beyond the average cluster time; fine-tuning checkpoint distribution; setting probabilities of strategies within pools with low win rates to 0 to avoid their usage during matches; and more.

***Abstract*—In recent years, significant efforts have been made to address graph node classification tasks by applying graph neural networks and methods based on label propagation. Despite the progress achieved by these approaches, their success often hinges on complex architectures and algorithms, sometimes leading to the oversight of crucial technical details. In designing artificial neural networks, one crucial aspect of the innovative approach is suggesting a novel neural architecture. Currently used architectures have mostly been developed manually by human experts, which is a time-consuming and error-prone process. That is why the adoption of more sophisticated semi-automatic methods, such as Neural Architecture Search, has become commonplace. This paper introduces and assesses an evolutionary-based approach for the design of graph convolutional neural networks in the context of node classification. Our approach aims to systematically define the graph convolutional networks parameter space, drawing inspiration from recent research on design principles. By doing so, our method seeks to strike a balance between achieving satisfactory performance and optimizing memory and computation resources, thus offering a more efficient alternative to conventional approaches from the neural architecture search area.**

***Index Terms*—graph neural networks, graph convolutional networks, genetic algorithm , node classification, evolutionary computation**

I. Introduction

NEURAL Architecture Search (NAS) [1]–[4] is gaining popularity as a fully automatic method for designing Artificial Neural Networks Architectures (ANNs). Neural Architecture Search is a method that allows the creation of comparable and even superior architectures in terms of performance to those that have been designed manually. In essence, NAS streamlines the process of a human adjusting a neural network through trial and error to identify successful configurations and automates it to discover more intricate structures. It comprises a range of techniques and tools that evaluate numerous network architectures within a defined search space using a search strategy and choose the one that accomplishes the goals of a specific problem by maximizing a fitness function.

The manuscript is structured as follows. Firstly, Section II presents a concise overview of Neural Architecture Search approaches applied across various domains of neural networks. Following that, Section II-A provides a comprehensive summary of the state-of-the-art in Graph Neural Networks, encompassing prevalent methods employed in the design of GNN architectures. In Section III, we delve into the description of the evolutionary algorithm utilized in our research, elucidating details such as fitness metrics and the delineation of the search space. Section IV comprehensively covers settings and implementation details, including the datasets employed and the preparation of the computational budget. Section V is dedicated to a thorough discussion of the attained results, while Section VI serves as a conclusive synthesis of our research findings.

II. Neural Architecture Search

NAS is computationally and time-consuming solution typically involving intensive calculations using graphics processing units (GPUs). Therefore, researchers and research groups are increasingly daring to look for alternative methods to optimize costs and find the most efficient and effective neural network architecture in order to solve their research problem.

Today, the most popular options for NAS are methods based on reinforcement learning [2] (including one-shot methods) [5], evolutionary computing (including multiobjective search), Bayesian optimization [6], and hill-climbing [7].

In article [4], the authors defined NAS as a system composed of three primary elements: search space, search algorithm, and evolutionary strategy.

- **Search space** - outlines a group of operations, such as convolution, pooling, and fully connected layers, and determines how these operations can be combined to create valid network architectures. Developing the search space often involves human expertise, inevitably introducing biases.
- **Search algorithm** - selects a group of candidates for network architecture and tests their performance. It receives child model performance metrics, such as accuracy and low latency, as rewards and utilizes this information to optimize and produce high-performance architecture candidates. As the possible search algorithms for NAS, one can name, e.g., algorithms like Random Search, Reinforcement Learning, and Bayesian Optimization.
- **Evaluation strategy** - in order to provide feedback for the search algorithm to learn, we must evaluate the performance of numerous proposed child models through measurement, estimation, or prediction. This process of evaluating candidates can be quite costly, prompting the proposal of various new methods to conserve time and computing resources. For these strategies, we can include proxy task performance, low-fidelity performance estimation, weight inheritance, weight sharing, learning curve extrapolation, and network morphism. [8], [9]

Based on the above definition of NAS we can define the NAS using Evolutionary Computation (EC) as a task of exploring architectures search space by generating and evaluating a population of candidate architectures and then evolving this population over multiple generations to find better-performing architectures. As we mentioned, ECs are one of the methods used to realize NAS, but the most promising results were achieved recently using the following approaches:

- **NAS-EA-FA** [10] - evolutionary algorithm based on the fitness approximation to the search for neural architecture. It is designed to accelerate the search process.
- **EF-ENAS** [11] - evolutionary neural architecture search algorithm based on evaluation corrections and fitness sharing. It is designed to improve the efficiency and effectiveness of the search process.

for a more extensive survey of evolutionary NAS one can refer to [8], [9].

A. Neural Architecture Search for GNNs

Remarkably, the field of NAS within GNNs remains relatively unexplored. Notable exceptions include GraphNAS [12]–[14], which uses RL to identify architectures for node classification tasks. The search space defined by GraphNAS includes sampling, aggregation, and gated functions, demonstrating its efficacy in the realm of GNNs. Auto-GNN [15] follows suit by adopting RL and a comparable search space. SNAG framework (Simplified Neural Architecture Search for Graph Neural Networks [16]) addresses drawbacks in existing neural architecture search (NAS) methods, such as GraphNAS and Auto-GNN, by introducing an innovative search space and a reinforcement learning-based search algorithm, as demonstrated through extensive experiments on real-world datasets.

Another novel approach to NAS for GNN is Scalable Graph Neural Architecture Paradigm [17] representing a novel paradigm introduced in the paper ”PaSca.” It serves as a systematic approach to construct and explore the design space for scalable Graph Neural Networks (GNNs), aiming to address the scalability challenges inherent in traditional GNNs designed based on the neural message passing mechanism. SGAP is presented as a key element of the PaSca system, offering a principled framework for designing GNNs that can efficiently handle larger datasets and message passing steps, thus enhancing overall scalability. Neural Architecture Coding (NAC) [18] is a Neural Architecture Search (NAS) method for Graph Neural Networks (GNNs) that addresses computational cost and optimization challenges. It utilizes a sparse coding objective to find optimal architecture parameters without weight updates after random initialization. NAC claims linear-time efficiency, and empirical evaluations on GNN benchmark datasets show that it outperforms strong baselines. The method’s strength lies in leveraging the expressive power of GNNs with randomly-initialized weights for efficient architecture discovery.

[19] Automated Graph Neural Network(Auto-HeG) on Heterophilic Graphs addresses the limitations of existing graph neural architecture search (NAS) methods, which primarily focus on the homophily assumption and neglect heterophily, a crucial graph property in real-world applications. Auto-HeG aims to automatically design powerful graph neural networks with expressive learning abilities for heterophilic graphs, incorporating heterophily into various stages of the automatic heterophilic graph learning process. This includes aspects such as search space design, supernet training, and architecture selection, using a diverse message-passing scheme, progressive supernet training, and a heterophily-aware distance criterion to derive specialized and expressive heterophilic GNN architectures. The proposed method demonstrates its superiority through extensive experiments, showcasing its effectiveness compared to human-designed models and existing graph NAS models.

Auto-GNAS (Automatic Graph Neural Architecture Search) [20] addresses the challenge of constructing effective graph neural networks (GNNs) for non-euclidean data by automating the search for optimal GNN architectures. Unlike traditional methods that evaluate architectures serially, Auto-GNAS employs parallel evaluation, utilizing multiple genetic searchers simultaneously. These searchers use evaluation feedback, information entropy, and results from other searchers through a sharing mechanism to enhance efficiency. Auto-GNAS demonstrates competitive model performance and improved search efficiency compared to other algorithms, marking the first

instance of using parallel computing to improve the system efficiency of graph neural architecture search. Our approach allows for a quick and simple (computationally inexpensive) way to limit the spatial hyperparameters of a graph neural network.

III. Evolutionary algorithm for Designing GCN

Genetic Algorithm (GA) is part of the evolutionary algorithm family, inspired by natural selection and genetics. The exploration space is a crucial element in all GAs, represented as strings called chromosomes or individuals. A population comprises a collection of such strings. Each chromosome consists of a sequence of genes encoding a solution to a target problem. Initially, a diverse population of random individuals is created to represent various potential solutions for the target problem. Each individual is assigned a fitness value that indicates its quality within the population.

During the evaluation step, the fitness of each individual is calculated. The selection step involves choosing certain individuals from the entire population as parents for mating. In the cross-step, parents exchange information, such as swapping genes, to generate new individuals and form the next generations. The mutation step introduces diversity into the population by randomly altering a gene in new individuals based on the probability of mutation. Finally, the population is updated by incorporating new individuals.

In this approach, the individual is a single representation of a graph convolutional network with a random configuration that allows it to compile and run successfully on selected datasets. The genetic algorithm used in research is the mutation and cross-over operators. Mutation involves randomly selecting a new gene value from a uniform distribution within the range of values available for that gene. The crossover function takes a list of parents as an argument, from which it randomly selects two individuals. Each individual then contributes one part of his genes (complementary to the part contributed by the other individual). Subsequently, a mutation is introduced to the obtained gene. The random selection process is repeated until the specified population size is achieved. The algorithm dynamically adjusts the number of layers based on the specified `num_layers` parameter for each agent (more params of individuals are described in Tables **??** and I, providing adaptability in the neural network architecture for each agent in the `deep_GCN` class involves iterating over the specified number of layers (`num_layers`). For every layer, the algorithm determines the specific parameters (described in TableI).

A. Fitness

In our approach, `fitness_value` serves as a measure of the classifier quality that you aim to minimize. It is the sum of squared F1 errors for each class. The F1 scores for individual classes are numerical metrics that represent the classification quality of each class. This considers both precision and recall for a given class, making them more informative than accurate, especially in the context of unbalanced data sets. `fitness_value` is the sum of squared F1 errors across all classes. This approach provides an overall assessment of the quality of the classifier in multiple classes. Squaring the F1 error emphasizes larger errors, i.e., greater deviations from the ideal F1 score. The goal is to minimize `fitness_value`. Minimizing this value implies an effort to enhance the classifier's quality for all classes simultaneously, offering a more balanced objective than merely maximizing accuracy. Evaluating the classification quality for each class individually allows the identification and improvement of areas where the classifier may perform suboptimally.

In summary, the `fitness_value`-based approach considers more nuanced aspects of classification quality, taking into account both false positives and false negatives, as well as precision and recall. This is a more balanced approach than relying solely on accuracy, especially in scenarios involving imbalanced datasets or multiclass classification.

B. Search space

In this section, we delve into the details of the search space employed in our approach, elucidating the ranges of various parameters within it. The search space is a crucial aspect of our methodology, and in Table I, we provide a comprehensive overview of the hyperparameter ranges relevant to the training of neural networks. It is essential to note that these ranges remain consistent across all datasets, ensuring a standardized approach to model optimization.

However, the uniqueness of each dataset requires specific considerations for certain parameters, particularly Hidden Channels and Batch Size, as explained in Table **??**. For Hidden Channels, the range is dynamically defined as range from 10 to the number of features within the dataset. This adaptability reflects the intrinsic characteristics of the data and aims to optimize the model architecture accordingly. Similarly, for the batch size parameter, the range ranges from a minimum of 10 to the total count of all training masks present in the dataset, as detailed in Table II.

To provide a concise reference, Table I encapsulates the overarching hyperparameter ranges for training neural networks, emphasizing their uniform applicability across diverse datasets. The following table **??** then details the data set-specific nuances, delineating the distinct ranges for Hidden Channels and Batch Size. This approach ensures that our search space is not only comprehensive but also adaptive to the intricacies of individual datasets, fostering effective model optimization.

IV. Experimental Settings

A. Datasets

In Table II, we provide a comprehensive overview of the key parameters associated with the datasets utilized in our experimental efforts. Brief characteristics of each dataset are described below.

- **Planetoid Datasets**, including Cora, CiteSeer, and PubMed, are widely used in graph-based learning tasks.

TABLE I: Neural Network Hyperparameter Ranges

Parameter	Range
Epochs	100
Learning Rate	From 0.0001 to 0.1
Weight Decay	From 0.0001 to 0.1
Layers	From 1 to 10
Optimizers	Adadelta, Adagrad, Adam, AdamW, Adamax, ASGD, NAdam, RAdam, RMSprop, Rprop, SGD, QHM, QHAdam, PSO, A2GradExp, A2GradInc, A2GradUni, AccSGD, AdaBelief, AdaBound, AdaMod, Adafactor, Adahessian, AdamP, AggMo, Apollo, DiffGrad, Lamb, MADGRAD, NovoGrad, PID, Ranger, RangerQH, RangerVA, SGDP, SGDW, SWATS, Shampoo, Yogi
Loss Function	CrossEntropy, NLLLoss, MultiMarginLoss, MultiLabelMarginLoss, SmoothL1Loss

They feature academic citation networks where nodes represent documents, and edges denote citations.

- **WikipediaNetwork Datasets**, comprising Squirrel and Chameleon, focus on analyzing relationships within Wikipedia. For example, Squirrel captures the network structure of Wikipedia articles, enabling researchers to explore connections and interactions between different topics.
- **WebKB Datasets**, such as Cornell, Texas, and Wisconsin, are tailored for web page classification. These datasets encompass web pages from university domains and are labeled with categories such as student, faculty, project, and course. They serve as benchmarks for text classification and information retrieval tasks.
- **Actor Dataset** is commonly utilized in social network analysis, representing a network of actors and their collaborations in movies or television shows. The nodes correspond to actors, and the edges represent collaborations in specific projects.

The selection of these datasets is grounded in their prevalence in academic research and practical applications. Researchers and practitioners often turn to these datasets as benchmarks due to their well-defined structures, facilitating the rigorous evaluation of diverse graph-based machine learning algorithms.

B. Computational Settings

We have defined a computational budget for our evolutionary algorithm with the following specifications:

- 300 generations
- 100 training epochs
- 10 initial populations (random)
- whole population is 20
- mutation rate is 0.3

The search space is 8-dimensional, denoted as **batch size**,**hidden channels**, **learning rate**, **weight decay**, **num layer**, **optimizer**, **loss function**. In particular, **the epoch number** is held constant throughout the exploration. Using the previously defined **fitness value** enables us to conduct innovative research within this fixed dimensionality.

V. RESULTS

We observed the mean fitness and accuracy for each generation and, for better visualization, we also tracked the `best fitness` and `best accuracy` achieved throughout the evolutionary process. While analysing the results enclosed in Table II and III, it can be noticed that minimizing the cost in multi-class classification problems is more complex than in the case of binary classification, which can also be observed in our case - the more complex the dataset, the potentially more difficult it is to prepare a model that will allow for the correct classification of all nodes from high effectiveness. Our research shows that using only GCN is not an ideal solution for datasets such as Actor, Squirrel or Chameleon, which are more complex datasets, e.g. heterophily ratio, characterized by more Nodes, average node Degree, or Node Features (in Table II) the less accurate the classification, which can be observed in the table.

In Table III, we present the optimal genes, which represent the best solutions obtained through optimization using the genetic algorithm.

These adjustments ensure that the experimental parameters adhere to the requirement of being integer values. Although presented in the table as floating values for clarity, they are effectively treated as integers during the genetic algorithm optimization process. This approach maintains consistency and allows for a meaningful and applicable exploration of the solution space.

Analysis of the experimental results reveals key patterns in hyperparameter configurations for Graph Convolutional Networks (GCN) across various datasets (presented in III. The most prevalent configuration associated with optimal performance includes the Adamax optimizer, the cross-entropy loss function, and 1 to 3 layers of GCN. In particular, configurations with a single or two layers of GCN emerged more frequently, suggesting their effectiveness in achieving high fitness values and classification accuracy. These findings offer practical guidance for researchers and practitioners seeking robust hyperparameter choices for GCN models [21], [22] for Node Classification.

TABLE II: Dataset Characteristics

Parameter	**Wisconsin**	**Actor**	**Texas**	**Squirrel**	**PubMed**	**Cornell**	**Cora**	**CiteSeer**	**Chameleon**
Nodes	251	7600	183	5201	19717	183	2708	3327	2277
Edges	515	30019	325	217073	88648	298	10556	9104	36101
Avg. Node Degree	2.05	3.95	1.78	41.74	4.50	1.63	3.90	2.74	15.85
Training Nodes	1200	36480	870	24960	60	870	140	120	10920

Node Features	1703	932	1703	2089	500	1703	1433	3703	2325
Homophily ratio (h)	0.21	0.22	0.11	0.22	0.8	0.3	0.81	0.74	0.23

TABLE III: Best results achieved for each dataset

Param	Wisconsin	Texas	Squirrel	PubMed	Cornell	Cora	CiteSeer	Chameleon	Actor
Batch Size	630	500	837	280	210	605	358	509	87
Hidden Channels	267	1633	1384	338	348	1245	230	623	1647
Epochs	100	100	100	100	100	100	100	100	100
Learning Rate	0.0087	0.0118	0.0143	0.0848	0.0073	0.0022	0.0054	0.0826	0.0674
Weight Decay	0.0312	0.0023	0.0169	0.0019	0.0011	0.0009	0.0083	0.0039	0.0151
Layers	1	1	1	3	2	4	2	4	1
Loss Function	SmoothL1Loss	Cross Entropy	Cross Entropy	Cross Entropy	Cross Entropy	Cross Entropy	Cross Entropy	Cross Entropy	Cross Entropy
Optimizer	Adam	NAdam	Adadelta	Adam	Adadelta	Adadelta	PSO	Adam	Adagrad
Minimum Fitness	1.4624	1.7088	1.6277	0.3627	1.4322	0.4845	0.8082	1.2427	1.6963
Accuracy	0.5882	0.6486	0.3121	0.7960	0.5135	0.8290	0.7320	0.4496	0.2539

It is surprising that NAdam and QHAdam [23] along with Particle Swarm Optimization [24] are algorithms that have achieved high Accuracy values and low fitness. Moreover, the dominance of Adagrad over the most popular Adam is noteworthy. Due to fewer options for loss functions, Categorical Cross Entropy dominates here and possibly achieves better results for other loss functions, which are not included in our research. We compare our methods with baselines methods [25], [26], which are presented in Table IV.

Based on the results presented above in Table IV, we observe that the results achieved for GCN based on the most popular implementation of GCN [26] are very close to the best accuracy. Our solution enhances the standard GCN models, though it does not quite reach the level of the most advanced ones [27], [28]. Nevertheless, it can serve as an inspiring starting point for future research in this field. Homophily ratio [29] in datasets with high values (Actor, Wisconsin, Squrrel) refers to the tendency of nodes with similar features or attributes to be more likely connected to each other. In datasets with a high homophily ratio (CiteSeer, Cora, PubMed), the relationships between similar nodes become more pronounced, potentially improving classification performance in tasks that rely on node similarities.

VI. Conlusions

In the last few years, studies on designing Artificial Neural Networks (ANNs) have become an active research field, mainly due to the advanced cost training and prototyping of underlying deep learning architectures. The proposed study focuses on developing the first stage of a method for the design and optimization of graph-convolutional neural networks.Our method enables avoiding mindless reliance on closed-box approaches, where one often waits for the final outcome without considering what transpires throughout the entire process. Assuming that the parameter search space of a graph convolutional neural network is multidimensional (each dimension defined by a network parameter), we conclude that by increasing the number of dimensions and their size, such as utilizing various types of layers (not just GCNConv, as in our study, but also GATConv, GIN, SGCNN etc.), we can construct the best possible neural network. This is achieved without the need to specify in advance whether our network should be GCN or GAT-based. Our study provides answers that GCN is not always the ideal solution. By extending our proposed mechanism, we can achieve an ideal architecture for solving a specific node classification problem as a result, our method allows for flexibility and adaptation to the specific requirements of a given situation.Plans for this research include the research of another search optimization framework based on Genetic Programming (including Cartesian Genetic Programming, the utility of which was previously demonstrated by designing CNNs [30]), Evolutionary Strategies, and Bio-Inspired optimization methods [31]. This approach will allow greater flexibility in designing and optimizing not only graph coefficient neural networks but all available Graph Neural Networks (GAT, GIN, Graph Transformer etc.). We anticipate that the results of this study might be useful to researchers in the field of Neural Architecture Search because the results obtained in the experiment are very promising.

TABLE IV: Comparison of accuracy of our approaches with state-of-the-art methods and GNN baselines, and performance of different models on various datasets

Method	Wisconsin	Texas	Squirrel	PubMed	Cornell	Cora	CiteSeer	Chameleon	Actor
GCN [26]	45.88	52.16	23.96	88.13	52.70	85.77	73.68	28.18	26.86

***Abstract*—Automatic recognition of features in digital images has become a central topic in the field of cultural heritage diagnostics. AI-based models are being increasingly applied to the analysis of infrared reflectography and thermographic data. They show great promise in automating time-consuming manual analyses and improving the objectivity and repeatability of diagnostic assessments. This work proposes 4 specialized classifiers for nails and detachments in work of arts. In-situ active thermography measurements are used for training proposed models. AI models for nail classification reached accuracy of 96.03 % and 93.65 % using planar composite thermal images and volumetric raw data as inputs, respectively. AI models for detachment classification reached accuracy of 87 % and 57 % using planar composite thermal images and volumetric raw data as inputs, respectively.**

I. Introduction

IN RECENT years, the automatic recognition of features in digital images has become a central topic in the field of cultural heritage diagnostics, particularly with the increasing adoption of imaging-based techniques. Advances in computer vision and deep learning have led to the development of algorithms capable of identifying patterns, anomalies, and structural details that are often imperceptible to the human eye. Artificial intelligence-assisted visual inspection for cultural heritage is reviewed in [1]. Work [2] discuses application of artificial intelligence in cultural heritage protection. Pattern recognition and artificial intelligence techniques for cultural heritage are analyzed in [3]. Detecting treasures in museums with artificial intelligence is described in [4]. Reducing bias in AI-based analysis of visual artworks is discused in [5]. Work [6] analyzes the research trends for using artificial intelligence in cultural heritage. Convolutional neural networks (CNNs) and other AI-based models are being increasingly applied to the analysis of infrared reflectography and thermographic data, with the potential to support tasks such as detecting underdrawings, material heterogeneities, and traces of previous restoration interventions. These approaches show great promise in automating time-consuming manual analyses and improving the objectivity and repeatability of diagnostic assessments. Nonetheless, challenges remain regarding the availability of training data, the need for domain-specific model tuning, and the effective integration of these tools into conservation workflows. More scientific works are dedicated to artwork inspection. Physical degradation detection on artwork surface polychromies using deep learning models is discused in [7]. A deep learning approach for anomaly detection in X-ray images of paintings is described in [8].

This work presents 4 specialized classifiers for nails and detachments in work of arts. Dataset for training AI models was created from in-situ active thermography measurements. Quantity of measurement is low which makes the process to design AI models more difficult. AI models for nail classification reached high accuracies of 96.03 % and 93.65 % for models optimized for planar composite thermal images and volumetric raw data measurements, respectively. AI models for detachment classification reached accuracies of 87 % and 57 % for models optimized for planar composite thermal images and volumetric raw data measurements, respectively. Main contribution of this work is in created dataset and 4 specialized AI classifiers.

Proposed models are designed for use before restoration process or for digitization purposes. They are created as useful tool that reduces long manual work required for analysis of a large size work of Art. They can be additionally use or making the process of artwork analysis available for less experienced personnel.

II. Data preparation

Active Thermography (AT) measurements were carried out following a standardized procedure for each selected area of the paintings. A thermal stimulus lasting 10 seconds was applied using a 1000 W halogen lamp with adjustable output. Depending on the characteristics of each painting, the

This work was supported by the Slovak Scientific Grand Agency VEGA under the contract 2/0135/23 "Intelligent sensor systems and data processing". Funded by the EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I05-03-V02-00055.

applied power ranged between 200 and 300 W. The lamp was positioned approximately 1–2 meters from the surface. A FLIR X6580 sc infrared camera (equipped with a cooled InSb detector, operating in the MWIR range of 3.5–5 µm, IFOV 0.3 mrad, NETD 20 mK at 25 µm, and a 640 × 512 FPA sensor) with a 50 mm focal length lens was employed to record thermal sequences.

Temperature rise during heating was controlled in real-time using the ResearchIR software (FLIR Systems Inc., Wilsonville, OR, USA), ensuring that the maximum temperature difference (ΔT) on the surface did not exceed $5\,^{\circ}\mathrm{C}$ and was as uniform as possible. After the thermal pulse, sequences of 150 to 300 thermal images were acquired for each area at a frame rate of 5 Hz. The data were exported in CSV format and subsequently analyzed using two established post-processing techniques: Principal Component Thermography (PCT) and Thermal Recovery Mapping (TRM), both well-documented in the literature [9], [10], [11], [12].

Custom-developed scripts in MATLAB (R2019a, MathWorks) were used for data processing, which was performed on a workstation equipped with an Intel i7-4770 CPU @ 3.40 GHz (8 cores) and 32 GB RAM. These analyses enabled (a) the identification and enhancement of major thermal anomalies within 1–2 Spatial Components (SCs) through PCT, and (b) their classification, with particular attention to detecting detachments and metallic inclusions (e.g., nails). The thermal datasets corresponding to these two types of defects were subsequently organized into collections of raw thermal images and their associated SCs, which served as the basis for developing the analytical models proposed in this study. Altogether, 4 paintings have been processed, see TABLE I, TABLE II and Fig. 1. Due to larger size of paintings, each painting was captured and evaluated by grid sections resulting in 18 sections with 76 labeled nails and 15 sections with 30 labeled detachments, see Fig. 2 and Fig. 3.

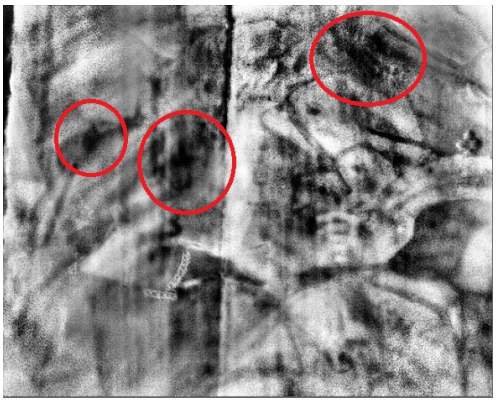

Fig. 3. An SCs section example with labeled detachments, Adorazione dei Magi authored by M. Cardisco

TABLE III
STATISTICS OF CREATED DATASETS

Dataset name	Number of samples	Spatial resolution	Number of channels
Nails SCs	626	64 x 64	1
Nails raw data	626	64 x 64	300
Detachments SCs	114	180 x 175 (on average)	1
Detachments raw data	114	180 x 175 (on average)	300

A. Dataset preparation

Due to low quantity of nail and detachment examples, the binary classification of nails and detachments was selected as the best task to implement. Multi class classification and detection are more complex and usually requires more parameters to train. Our very small dataset limits us to train smaller models. Bigger models with more parameters require larger datasets [13], [14] to be sufficiently trained. Two specialized binary classifiers allow to focus on each problem characteristics more deeply and maximized prediction accuracy with less data.

Dataset is created with cropped areas. We experimented with various input resolutions. For nails, 64 x 64 pixels was selected. With higher resolutions, accuracy is decreasing significantly. Smaller resolution offers slightly higher accuracy but may be prone to overspecialization. For detachments, rectangles with longer size 180 pixels was selected. The dataset is balanced with 50 % positives and 50 % negatives (background). Focus was on including hard negatives with very close visual resemblance to positives. Min-max normalization was applied to raw data (CSVs) to improve learning. Missing channels were padded with the last measured channel. This way we don't introduce any bias by padding the data with either white, black or gray color equivalent. The quantity was increased with augmentation techniques [15] to partially alleviate low quantity of data and to improve the trained models' robustness. Statistics are shown in TABLE III.

III. ARCHITECTURE DESIGN

Short visual analysis revealed that variation of detachment examples is much more varied which makes it significantly more difficult task to classify in comparison to nails. The number of detachment true examples is only 30 which represents around 40 % of quantity of true nail examples and such low quantity makes the problem even more difficult. We started our design approach with SCs images due to its simpler planar form. Designing a model for volumetric raw data is more difficult. The dataset was split 80 % – 20 % for training and testing. Presented values in following Tables are averaged results of several training runs started from scratch with random seeding.

Global Average Pool	2D conv. (1,1) x64	68.12 %	73.86 %

A. Nail defect optimized models using SCs images

The training setup for nail classification using SCs images is following: Environment TensorFlow, Adam optimizer, 20 Epoch training length, LR started from 0.0008, LR minimal set to 0.0001, LR reducing factor set to 0.5, input resolution 64 x 64 pixels, quantity of samples 626. Adam optimizer provided the best results.

We experimented with different augmentations. The standard rotations and flipping are already included in dataset. Additive noise hurt accuracy with pink noise being worse in comparison to white noise. Varied Gamma, implemented by a constant additive shift, produced varied and conflicted results. We decided not to use it due to unstable improvements and very small increases.

Experiments with various model architectures are shown in TABLE IV. Results show that the optimal model depth is 2 or 3. The single layer models are not descriptive enough and 4 layer deep model is probably too complex with many parameters for this dataset. Smaller convolution kernel sizes are beneficial for 2 and 3 layer deep models. The 2 layer deep model reached the best accuracy and was selected. Variation of using different global pooling and extensions can be seen in TABLE V. The global Max pooling is the best option.

The effects of different width of layers (varied number of filters) can be seen in TABLE VI. Decreasing or increasing number of filters symmetrically in all layers has little effect with 64 filters being the best. Results of additional architecture

TABLE VI

search is shown in TABLE VII. Larger kernels of the first layer have positive effect. The best model has 128 filters with kernel size of 9 x 9 in the first layers and Max pooling of 8 x 8.

B. Nail defect optimized models using raw data

The training setup for nail classification using raw data measurements is following: Environment TensorFlow, Adam optimizer, 20 Epoch training length, LR started from 0.0003, LR minimal set to 0.00002, LR reducing factor set to 0.5, input resolution 64 x 64 pixels, quantity of samples 626.

Experiments with various depth of model architecture are shown in TABLE VIII. All models use 3D convolutions and 3D Max pooling. Each convolution layer is followed by ReLU [16] nonlinearity and Max pooling. The optimal model depth is around 3. Resulted accuracy is lower in comparison to models using SCs images. We focused on 3 layer deep architectures, see TABLE IX. Results show that the bigger kernels have positive effect.

The small dataset is a very limited factor for volumetric data. Additional augmentations fail to improve results. So we opted to reduce input space by Principal Component Analysis (PCA). We applied PCA to dataset and used results as inputs, see TABLE X. The best accuracy was reached by using 50 most significant PCA components.

We continued with architecture exploration with 50 PCA components as inputs, see TABLE XI. Results shows that the

suitable depth is at least 3. Smaller convolution kernels have positive effect, especially at later layers. Smaller input map before the last global pooling is beneficial. This is especially true with the deepest model which has the best test accuracy. Higher parameter count is detrimental with very small datasets which makes the best model with higher parameter count a surprise. It is interesting that using smaller convolution kernel than (3,3,3) anywhere in architecture reduces the accuracy. However, the optimal trends are clouded by the small dataset size and it can be seen as fluctuating results. We experimented with the varied width of layers with 64 filters being the best.

C. Detachment defect optimized models using SCs images

The training setup for detachment classification using SCs images is following: Environment TensorFlow, Adam optimizer, 50 Epoch training length, LR started from 0.0001, LR minimal set to 0.000001, LR reducing factor set to 0.5, input resolution 115 x 115 & 128 x 128 & 130 x 130 & 150 x 150 pixels except where it is noted, augmentations: LR flips & 90° angle rotations & brightness adjustments (gamma variations). One transformation is randomly applied to each image. These augmentations were applied only to the train and validation datasets during training.

We experimented with various scaling of the inputs. The best performance was achieved with the input resizing to 128 x 128 pixels resolution using stretching, see TABLE XII. We augmented data with various input sizes which significantly improved accuracy. Our experiments with different padding schemes confirmed that the stretching is the best, see TABLE XIII.

Experiments with various model architecture are shown in TABLE XIV. The optimal model depth is 2. However, 4 layer deep model reached good accuracy. Optimal kernel size varies. More experiments are necessary. Our experiments with different global pooling confirmed the Max pooling as the best, see TABLE XV. The global average pooling with adding an extra layer behind it equaled the global Max pooling. We selected global Max pooling due to lower parameter count. We experimented with the different width, but for most models, 64 filters is the best option. Our best model uses small kernels and twice the number of filters in the first layer. We also experimented with different additional augmentations. Varied contrast have negative effect. Surprisingly, added small amount of white or pink noise have small positive effect.

D. Detachment defect optimized models using raw data

Experiments with raw data measurements did not reach good results. Reducing the input space by PCA slightly improved the results but still not good enough to be used. With only 30 true examples and higher difficulty in comparison to nails, it is very hard to design classification model for volumetric raw data. Due to PCA failing, we opted to design a new CNN model for reducing the input space from volumetric to planar data. This model is trained by using SCs images as ideal outputs. This way, there are much more data to lead training process correctly. The best model trained on SCs images are attached after this model. Our best results reached by combining these two modes are shown in TABLE XVI.

IV. CONCLUSION & FUTURE WORK

We presented AI models for automated classification of detachments and nails within paintings. We created small dataset containing 4 paintings measured with active thermography. Due to the small dataset size, we designed 4 specialized models optimized to the single defect type. The best nail classifier for SCs images reached 96.03 % accuracy and one for volumetric raw data measurements reached 93.65 % accuracy. The best detachment classifier for SCs images reached acceptable 87 % accuracy. However, the model optimized for volumetric raw data measurements reached only 57 % accuracy. The character of detachment, its more varied shapes and variations, its varied placement between different paint layers and varied texture character makes this a much more difficult task. Availability of only 30 true examples limited our options.

The presented models are designed for use before restoration process or for digitization purposes. They can reduce long manual work required for analysis of a large size work of Art. They also make the process of artwork analysis available for less experienced people in this domain.

Obtaining access to more paintings is a key part of our future work. Only with granted access, we can produce more measurements and enlarge our dataset to improve detachment classification accuracy. We are hopeful and open to wider future research cooperation in this domain.

ACKNOWLEDGMENT

We highly appreciate and thank Barbara Balbi from the Superintendency of Archaeology, Fine Arts and Landscape for the city of Naples, and Maria Palma Recchia from the Superintendency for Archaeology, Fine Arts, and Landscape for the Metropolitan Area of Naples for kindly granting access to the paintings.

***Abstract*—Accurate blood glucose prediction is critical for effective diabetes management, yet existing models struggle with individual variability, data sparsity, and non-linearity. We propose an attention-based multi-task learning (MTL) model integrated with proximal policy optimization (PPO) reinforcement learning (RL) to enhance forecasting accuracy and adaptability. MTL captures shared patterns across multiple prediction tasks, while PPO dynamically refines predictions based on patient-specific glucose trends. By incorporating explainability techniques such as SHAP analysis and Monte Carlo dropout, our approach not only achieves state-of-the-art predictive accuracy but also enhances trust in AI-driven decision support systems for diabetes care. Evaluated on the BrisT1D blood glucose dataset, our model achieves a R^2 score of 0.85, MSE of 0.0017, RMSE of 0.0419, and MAE of 0.0310, significantly surpassing conventional methods. This work advances personalized real-time glucose forecasting, offering a promising step toward AI-powered glycemic management in clinical settings.**

***Index Terms*—Blood glucose prediction, multi-task learning, reinforcement learning, explainable AI, time-series forecasting, healthcare AI**

I. Introduction

DIABETES mellitus is a chronic condition affecting over 537 million adults globally, with projections indicating it will reach 783 million by 2045 [1]. Maintaining optimal glycemic control is crucial to preventing complications such as cardiovascular disease and neuropathy [2]. Blood glucose fluctuations, particularly in Intensive Care Units (ICUs), are linked to increased morbidity and mortality [3], highlighting the importance of accurate glucose prediction for clinical decision-making.

Despite the availability of Continuous Glucose Monitoring (CGM) systems, forecasting future glucose levels remains challenging due to the highly non-linear and patient-specific nature of glucose dynamics, data sparsity, and individual variability [4]. Traditional Machine Learning (ML) models such as Autoregressive models (ARIMA) [5], Support Vector Machines (SVMs) [6], and shallow neural networks [7] often fail to generalize across patients. Deep Learning (DL) methods like Long Short-Term Memory (LSTM) [8], Transformers [9], and CNN-LSTM hybrids [10] offer improved performance, but still struggle with adaptability and lack of interpretability, critical requirements for clinical deployment [11], [12].

Moreover, most existing models operate as static predictors, ignoring evolving physiological states [13]. Reinforcement Learning (RL), especially Proximal Policy Optimization (PPO), offers dynamic policy adjustment and has shown promise in healthcare, though its application to glucose prediction is still limited [14]. Similarly, explainability remains a key bottleneck to the clinical adoption of AI-driven systems.

To tackle these limitations, we propose a novel hybrid model that integrates attention-based Multi-Task Learning (MTL) with PPO based RL. Our method enables:

1) Learning shared glucose dynamics across multiple prediction tasks to improve generalization.
2) Dynamic adaptation to patient-specific trends using PPO-based reinforcement learning.
3) Transparent and explainable predictions through SHAP analysis and permutation-based feature selection.
4) Superior predictive accuracy with an R^2 of 0.85, MSE of 0.0017, RMSE of 0.0419, and MAE of 0.0310 on real-world data.

II. Related Works

Prediction of blood glucose levels has been tackled using a wide range of ML and DL models. Traditional ML techniques such as ARIMA [15], SVMs [6], and Random Forests (RFs) often struggle with nonlinear dynamics, interindividual variability, and temporal dependencies.

DL-based models have gained attention for their ability to capture complex glucose patterns. RNNs and LSTMs are widely used for modeling temporal sequences [16], while transformer architectures leverage self-attention to improve long-range forecasting [17]. CNN-LSTM hybrids further enhance sequential pattern recognition [18]. Despite their improved accuracy, these models lack interpretability, limiting clinical applicability. To address this, explainable AI techniques such as Shapley Additive exPlanations (SHAP) and

Topical area: Advanced Artificial Intelligence in Applications

permutation-based feature importance are increasingly applied [19].

MTL improves generalization by learning shared representations across related tasks [20]. In glucose forecasting, MTL enables simultaneous short- and long-term predictions [21], and attention mechanisms have further refined time-series modeling by emphasizing physiologically relevant features [22]. Hierarchical MTL has also shown promise in modeling auxiliary tasks such as insulin sensitivity and meal intake [23].

RL, particularly PPO, has demonstrated adaptability and robustness in medical control systems [24], [25], [26]. Although mostly used in insulin delivery systems, its application in glucose prediction is emerging [20]. Recent work has combined PPO with uncertainty quantification techniques like Monte Carlo dropout to improve reliability and trust in clinical settings [27], [23].

III. Proposed Methodology

The framework we have developed integrates attention-based MTL with PPO-based RL to enhance the accuracy of glucose level prediction. The comprehensive structure of this framework is illustrated in Fig. 1.

A. Data Processing and Feature Engineering

We use a real-world CGM dataset from young adults with Type 1 diabetes in the UK, including CGM, insulin, meal, and activity records [28]. Data is resampled into 5-minute intervals with a 6-hour look-back window to forecast glucose 1 hour ahead. The training set comprises three months from nine subjects; testing uses unseen data from 15 participants. Preprocessing includes last observation carried forward (LOCF) and Kalman filtering for missing values, min-max normalization:

$$X_{norm} = \frac{X - X_{min}}{X_{max} - X_{min}}. \tag{1}$$

The Z-score standardization is applied:

$$X_{std} = \frac{X - \mu}{\sigma}. \tag{2}$$

where μ and σ denote the mean and standard deviation, respectively. We extract time-series features such as lagged glucose values:

$$G_t, G_{t-1}, ..., G_{t-k}, \tag{3}$$

where G_t represents the glucose level at time t, and k denotes the lag period. To capture temporal patterns, rolling window statistics are introduced:

$$\bar{G}_t^{(w)} = \frac{1}{w} \sum_{i=t-w}^{t} G_i, \tag{4}$$

where w is the window size. Polynomial expansions up to degree n are also incorporated to capture non-linear glucose interactions.

$$G_t^2, ..., G_t^n. \tag{5}$$

B. MTL with Attention

The MTL model learns shared representations across tasks via:

$$h = f_\theta(X), \tag{6}$$

where f_θ is the shared feature extractor. The task-specific layers then generate predictions for each forecasting horizon T_i:

$$\hat{Y}_i = g_{\phi_i}(h), \tag{7}$$

where g_{ϕ_i} denotes the task-specific prediction function. Attention weights α_t highlight key time steps:

$$\alpha_t = \text{softmax}(W_h h_t + b), \tag{8}$$

where W_h and b are learnable parameters. For stability and convergence, layer normalization (LN) is applied, formulated as:

$$\hat{h}_t = \frac{h_t - \mu}{\sigma + \epsilon} \cdot \gamma + \beta, \tag{9}$$

where γ and β are learnable scaling factors.

C. Reinforcement Learning Component

PPO enables dynamic correction using states. Unlike Q-learning and DDPG, PPO prevents drastic policy updates, ensuring smoother adaptation to glucose trends. The representation of the state S_t at time t is represented as:

$$S_t = \{G_t, \triangle G_t, I_t, M_t, P_t, T_t\}, \tag{10}$$

where G_t is the glucose level, $\triangle G_t$ is the glucose change, I_t is insulin dose, M_t is meal intake, P_t is physical activity, and T_t is time. Action A_t represents the predicted next glucose level as:

$$A_t = \{\hat{G}_{t+1}\}. \tag{11}$$

The reward penalizes large prediction errors:

$$R_t = -\left(\frac{|\hat{G}_{t+1} - G_{t+1}|}{G_{t+1} + \epsilon}\right)^2, \tag{12}$$

where ϵ prevents the division by zero. The PPO policy $\pi_\theta(A_t|S_t)$ is optimized using the clipped objective function as:

$$L^{PPO}(\theta) = \mathbb{E}_t\left[\min(r_t A_t, \text{clip}(r_t, 1-\epsilon, 1+\epsilon)A_t)\right], \tag{13}$$

where $r_t(\theta)$ is the probability ratio between new and old policies, and A_t is the advantage function.

D. Training and Setup

We use AdamW optimizer and OneCycleLR scheduler. Training uses smooth $L1$ loss (Huber Loss):

$$L(y, \hat{y}) = \begin{cases} 0.5(y - \hat{y})^2, & \text{if } |y - \hat{y}| < 1 \\ |y - \hat{y}| - 0.5, & \text{otherwise} \end{cases} \tag{14}$$

Training was conducted for 200 epochs, batch size 64, with 5-fold cross-validation and early stopping. Experiments ran on a system with Intel i7-11700 CPU, 64 GB RAM, and NVIDIA RTX 4090 GPU using PyTorch.

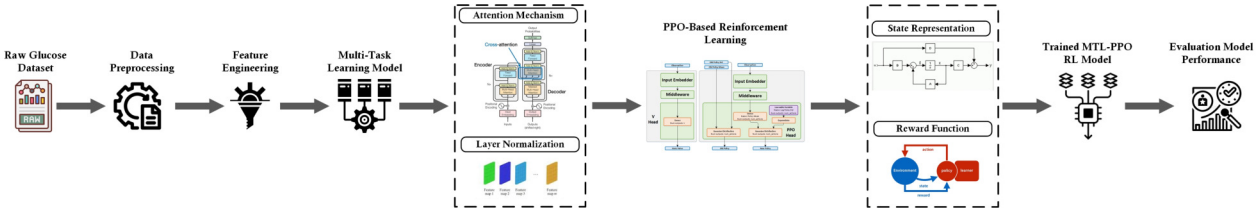

Fig. 1. Flowchart of the proposed algorithm for blood glucose prediction.

IV. Experimental Results

This section provides an empirical assessment of the proposed methodology for predicting blood glucose levels. The evaluation includes an analysis of the model's predictive accuracy, statistical significance, and robustness, employing a range of performance metrics and significance tests.

A. Performance Metrics

To quantitatively evaluate the effectiveness of our proposed model, we compare its performance against baseline models using four widely adopted regression metrics: Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), and Coefficient of Determination (R^2 Score).

B. Results

To assess the precision of the proposed MTL-RL model, we visualize the alignment of true versus predicted glucose levels in all test samples, as illustrated in Figure 2. The blue dots represent the actual glucose values, while the red dots represent the corresponding model predictions. The results indicate that the MTL-RL model effectively captures glucose trends, as the predicted values closely follow the true values. Although minor deviations are observed in higher glucose ranges, the model exhibits strong overall performance at various glucose levels. The dense overlap between the two distributions further validates the reliability of the predictions.

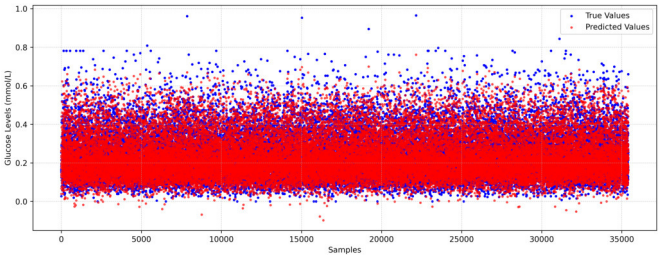

Fig. 2. Glucose prediction vs. true values plot.

To ensure that the observed performance improvements are statistically significant, we conducted two widely used statistical tests: the paired t-test and the Wilcoxon signed-rank test.

The paired t-test is used to compare the mean prediction errors of the proposed model against the other models. The null hypothesis (H_0) assumes that the differences in model performance are due to random chance, while the alternative hypothesis (H_A) assumes that our model provides a statistically significant improvement.

The statistic of the paired t-test is calculated as follows:

$$t = \frac{\bar{d}}{s_d/\sqrt{n}}, \tag{15}$$

where $\bar{d}$ is the mean difference in prediction errors, s_d is the standard deviation of the differences, and n is the number of test samples. The results of the paired t-test are given in Table I.

TABLE I
Paired t-test.

Model	t-statistic	p-value
Proposed MTL-RL	46.92	7.70×10^{-255}

The obtained p-value is significantly less than 0.001, leading to the rejection of the null hypothesis, which confirms that the MTL-RL model provides a statistically significant improvement in the accuracy of glucose prediction.

Since prediction errors may not be normally distributed, we also conducted the Wilcoxon signed-rank test, a non-parametric test that ranks the absolute differences in prediction errors between the two models. The test results are provided in Table II.

TABLE II
Wilcoxon signed-rank test.

Model	Wilcoxon statistic	p-value
Proposed MTL-RL	8295.0	1.44×10^{-154}

Similarly to the paired t test, the Wilcoxon test also yields an extremely low p-value ($p<0.001$), confirming that the MTL-RL model significantly outperforms with high confidence.

Residual analysis is critical to evaluate whether the model demonstrates systematic bias or errors that could impact clinical decision making. Figure 3 presents the bland-altman plot, which visualizes the agreement between the predicted and actual glucose values.

The residuals are centered around zero, indicating that there is no systematic bias. 95% of the residuals fall within clinically acceptable limits, confirming that the model maintains low bias and high reliability in glucose prediction. These findings

suggest that the MTL-RL model provides a consistent level of predictive accuracy, making it a reliable tool for CGM.

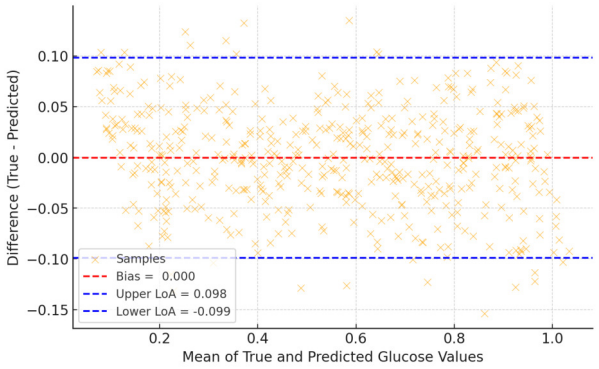

Fig. 3. Bland-Altman plot.

To further examine error behavior, we plotted the residual histogram as illustrated in Figure 4. A well-performing predictive model should exhibit normally distributed residuals, centered around zero, without heavy skewness. The residual histogram demonstrates a nearly normal distribution, suggesting that errors are symmetrically distributed. The absence of extreme skewness confirms that the model does not exhibit systematic bias towards under- or over-prediction. Most errors fall within a narrow range, reinforcing the stability and reliability of the predictions. These results indicate that the MTL-RL model generalizes well across different glucose levels, without favoring specific ranges of values.

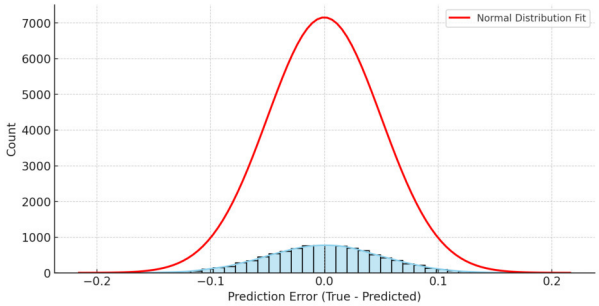

Fig. 4. Residual distribution plot.

Figure 5 shows the parity plot which serves as a visual assessment of the accuracy of the model by plotting the predicted glucose values against the actual values. Ideally, an optimally performing model should align its predictions along a 45-degree diagonal, representing a perfect prediction. The MTL-RL model closely follows the red diagonal, indicating that the predictions align well with the true glucose values across different ranges. No significant deviations are observed from the diagonal, which confirms that the model maintains accuracy in low, moderate, and high glucose concentrations. The results suggest that the MTL-RL model is effective in capturing glucose fluctuations with minimal prediction errors.

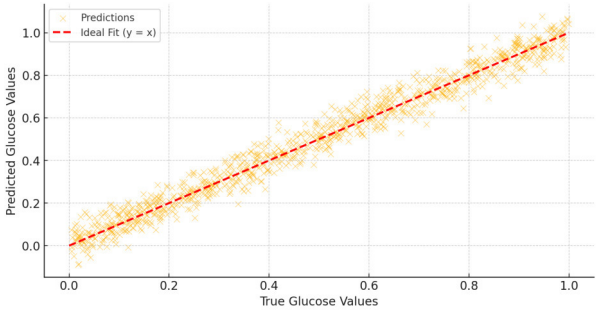

Fig. 5. Parity plot (predicted vs. true values).

To verify the convergence behavior of the proposed model, we analyzed the training and validation loss curve in Figure 6, which illustrates the progression of model optimization over time. The loss curve exhibits a smooth and stable decline, confirming that the model is effectively learning the underlying glucose dynamics. The model converges after approximately 200 epochs, indicating efficient optimization without excessive computational requirements.

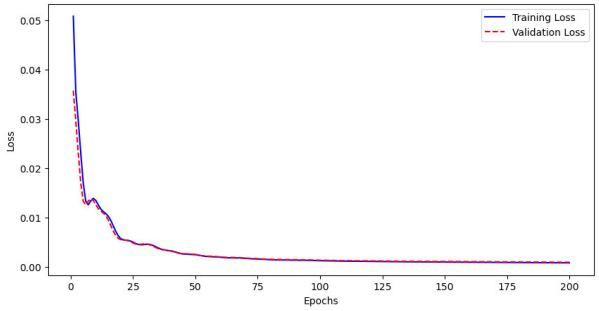

Fig. 6. Training and validation loss curve.

C. Explainability via SHAP and Permutation Importance

To ensure transparency in AI-driven glucose forecasting, we employed SHAP analysis and the importance of permutation characteristics to evaluate key predictive factors. Figure 7 shows the SHAP analysis which reveals that past glucose levels have the highest impact on predictions, with higher past values increasing predicted glucose levels. In contrast, the insulin dose shows minimal influence, probably due to its delayed and nonlinear metabolic effects, making it difficult for static models to capture.

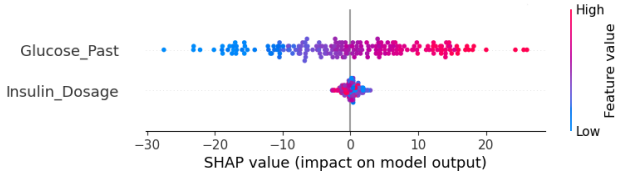

Fig. 7. SHAP feature importance analysis.

Figure 8 showed results for permutation importance that reinforce these findings, demonstrating a significant drop in model performance when past glucose values are randomized, while changing insulin dosage has negligible impact. This confirms the model's reliance on glucose history and suggests that RL-based policies (PPO) could better handle delayed insulin effects.

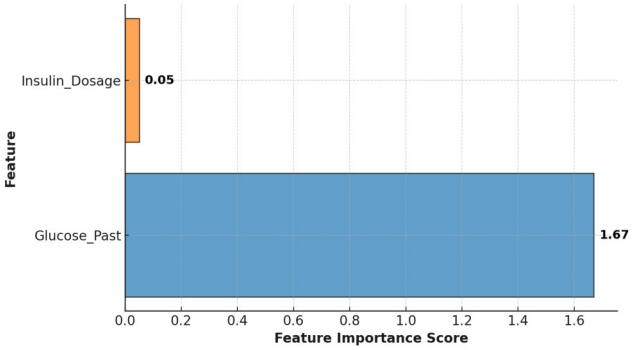

Fig. 8. Permutation feature importance.

D. Monte Carlo Dropout for Uncertainty Estimation

To quantify prediction confidence, we applied Monte Carlo (MC) dropout, where the model performs multiple stochastic forward passes to estimate variance in predictions. The uncertainty is computed as:

$$Uncertainty = \frac{1}{T}\sum_{t=1}^{T}(\hat{y}_t - \bar{y})^2 \tag{16}$$

where T is the number of MC samples. Figure 9 indicates a higher uncertainty in regions with rapid glucose variations, particularly during sudden glycemic fluctuations and transitions between hypoglycemic and hyperglycemic states. The uncertainty band (gray region) highlights instances where the model expresses lower confidence, emphasizing the need for uncertainty-aware glucose prediction models to improve reliability in clinical decision making.

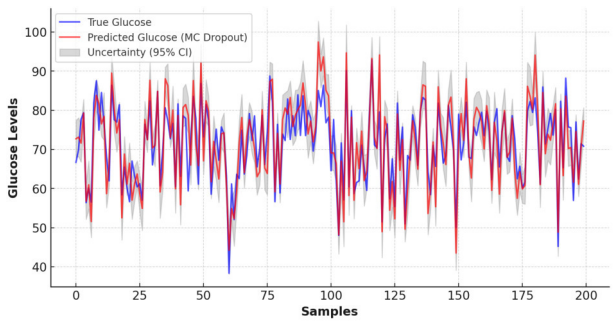

Fig. 9. Monte carlo dropout uncertainty estimation.

V. Discussion

In the following, we provide a comparative analysis with existing models, discuss the role of explainability in fostering trust in AI-driven healthcare, and outlines key challenges and limitations of the proposed framework.

Table III summarizes the performance metrics of different models. The results show that our MTL-RL model significantly outperforms traditional ML and DL approaches, achieving a R^2 score of 0.85, compared to other state-of-the-art approaches. The substantial reduction in MSE (0.0017 vs. 0.015) and MAE (0.0310 vs. 0.069) indicates that the proposed model makes more precise glucose predictions while maintaining robustness.

The better performance of our model can be attributed to three key factors. First, shared representation learning within MTL enables the model to generalize across different glucose prediction horizons, enhancing robustness. Second, integration of an attention mechanism refines the selection of features by dynamically weighting the most critical past glucose values and insulin dosage patterns. Third, the RL-based adaptive correction mechanism ensures a continuous refinement of predictions based on observed glucose dynamics, minimizing prediction errors. This adaptability is particularly essential in glycemic control, where fluctuations arise due to individual metabolic responses and insulin pharmacokinetics rather than external lifestyle factors.

A. Challenges and Limitations

Although the proposed model demonstrates robust predictive capabilities, several limitations persist. Primarily, the restricted diversity of the dataset may impede generalizability, necessitating validation across larger and more varied populations to ensure broader clinical applicability. Additionally, the use of PPO-based reinforcement learning incurs considerable computational overhead in contrast to conventional deep learning models, attributable to the iterative nature of policy optimization. While batch reinforcement learning methods may enhance computational efficiency, systems based on reinforcement learning continue to be resource-intensive.

VI. Conclusion

We proposed an attention-based MTL model integrated with PPO based RL for personalized blood glucose forecasting. The model achieved state-of-the-art performance (R^2 = 0.85, MSE = 0.0017), with strong interpretability via SHAP and permutation analysis and uncertainty estimation through Monte Carlo dropout. These features promote transparency and clinical trust. Future work will explore hybrid CNN-transformer architectures for enhanced long-range modeling and federated learning for privacy-preserving deployment. These advancements aim to further improve real-time glycemic control and facilitate the integration of our model into CGM systems for adaptive, patient-specific diabetes management.

***Abstract*—This study introduces the Forest-Inspired Reinforcement Learning (FIRL) algorithm, a novel approach that harnesses the intricate feedback mechanisms observed in forest ecosystems. A multiagent RL system is proposed, where agents maintain mutualistic relationships, exchanging rewards or insights, fostering a cooperative learning environment. The learning process undergoes stages, similar to ecological succession in forests. The initial stages prioritize exploration, while the mature stages emphasize exploitation and refinement. The algorithm incorporates mechanisms to recover from suboptimal decisions, drawing inspiration from a forest's ability to regenerate post disturbances. A dual agent system, inspired by predator-prey dynamics, ensures a balance between exploration and exploitation in the learning process.**

***Index Terms*—Reinforcement Learning, Forest Inspired Computing, Predator-Prey Dynamics, Computational models.**

I. Introduction

REINFORCEMENT learning (RL) offers a framework in which agents learn by interacting with their environment [1]. This interaction, characterized by a sequence of actions, observations, and rewards, allows agents to autonomously discover optimal strategies or policies [2]. The allure of RL lies in its potential to tackle complex decision-making tasks, where solutions are not explicitly programmed but are learned through experience [3]. The quintessential components of an RL system include the agent, the environment, a policy, a reward signal, and a value function [4]. The agent's policy defines its behavior at any given time, while the reward signal provides a clear, immediate sense of the consequences of an action [5]. The value function, on the other hand, is a prediction of future rewards and is central to most RL algorithms [6]. It helps the agent evaluate the desirability of states based on potential future rewards. One of the key challenges in RL is the exploration-exploitation dilemma. An agent must decide whether to exploit its current knowledge, taking actions that are known to yield good rewards, or to explore new actions, risking lower immediate rewards in hopes of discovering better strategies [7], [8]. This balance is crucial for agent overall performance and is a recurring theme in RL research [9].

In this study, we enrich the RL paradigm by drawing inspiration from nature, specifically forest ecosystems. Forests, with their intricate feedback mechanisms and adaptability [10], offer a new perspective, which could lead to more robust and adaptive RL algorithms. The appeal of bioinspired computational models lies in their ability to capture the essence of complex natural processes in a simplified, abstracted form, making them amenable to mathematical analysis and algorithmic design [11]. Forests, as dynamic and complex ecosystems, are the next frontier in this quest for bioinspired innovation. Their layered structure, intricate feedback loops, and the delicate balance of interspecies relationships present a novel paradigm for computational thinking [12]. In this study, we are drawing parallels between their ecosystems and RL, with the aim of creating algorithms that embody the wisdom of forests [13].

We introduce a novel approach to hierarchical RL inspired by the multi-layered structure of forests. Our methodology allows for the decomposition of complex problems into more manageable sub-problems, akin to how different forest layers cater to distinct ecological niches.

II. Materials and Methods

A. Forest-Inspired Reinforcement Learning (FIRL) Algorithm

The design of FIRL is based in the principles derived from forest ecosystems. Forests are organized in layers, each with its unique set of species and microclimates [14], [15].

Let $E(t)$ be the experience at time t. The feedback mechanism $F(t)$ is a function of the past experiences:

$$F(t) = \int_0^t \phi(E(\tau))d\tau \tag{1}$$

where ϕ is a function that extracts valuable insights from past experiences.

Drawing inspiration from mutualistic relationships in forests, FIRL promotes cooperative learning among agents. Agents share insights, rewards, and experiences, leading to a more holistic learning process. Given m agents with reward

This research paper has received funding from Horizon Europe Framework Programme (HORIZON), call Teaming for Excellence (HORIZON-WIDERA-2022-ACCESS-01-two-stage) - Creation of the centre of excellence in smart forestry "Forest 4.0" No. 101059985. This research has been co-funded by the European Union under the project "FOREST 4.0 - Ekscelencijos centras tvariai miško bioekonomikai vystyti" (Nr. 10-042-P-0002).

functions $R_1, R_2, ...R_m$, the cooperative reward function R_c for any agent i is:

$$R_c^i = R_i + \sum_{j=1, j\neq i}^{m} \omega_j R_j \tag{2}$$

where ω_j are weights representing the importance or trustworthiness of agent j's insights to agent i.

Forests recover and adapt to disturbances. Similarly, FIRL is designed to be adaptable. If an agent's policy leads to suboptimal results, the algorithm triggers recovery mechanisms, allowing the agent to re-explore and adapt. Let $\pi(t)$ be the policy at time t and let $R(t)$ be the corresponding reward. If $R(t) < \theta$ (a predefined threshold), then:

$$\pi(t+1) = \pi(t) + \alpha \nabla R(t) \tag{3}$$

where α is a learning rate and $\nabla R(t)$ is the gradient of the reward function that guides the update of the policy.

1) Layered Learning in FIRL: FIRL algorithm adopts a layered approach to learning, which allows for a more organized and efficient exploration of the solution space, ensuring that the agent can tackle complex tasks by breaking them down into more manageable subtasks.

Given a primary task P, it is divided into subtasks n based on complexity, dependencies, or domain knowledge. Each subtask P_i represents a layer in the learning hierarchy.

$$P = \bigoplus_{i=1}^{n} P_i, \tag{4}$$

where $\bigoplus$ denotes the operation of combining the sub-tasks to form the main problem.

For each subtask P_i, a policy π_i is generated. The general policy π for the main task is a composite of these individual policies.

$$\pi = \bigotimes_{i=1}^{n} \pi_i, \tag{5}$$

where $\bigotimes$ denotes the operation of integrating policies to address the main problem.

2) Feedback Mechanisms between Layers: To ensure that learning in one layer benefits the others, FIRL incorporates feedback mechanisms that allow the transfer of information, experiences, and even policies between layers. After each learning episode in layer i, a subset of experiences E_i is shared with adjacent layers $i-1$ and $i+1$ to enrich their learning.

$$E_{i-1}^{new} = E_{i-1} \cup \chi(E_i) \tag{6}$$

$$E_{i+1}^{new} = E_{i+1} \cup \chi(E_i), \tag{7}$$

where χ is a function that selects and possibly transforms experiences for sharing.

If a policy π_i in layer i proves to be effective, it influences the generation of policies in adjacent layers.

$$\pi_{i-1}^{new} = \pi_{i-1} + \alpha\psi(\pi_i) \tag{8}$$

$$\pi_{i+1}^{new} = \pi_{i+1} + \alpha\psi(\pi_i), \tag{9}$$

where α is a weighting factor, and ψ is a function that extracts and modifies policy elements for feedback.

3) Nutrient Cycling Feedback: The concept of nutrient cycling from forest ecosystems [16] is translated into a mechanism to revisit, decompose and recycle old experiences, ensuring that the agent continually refines its understanding, even from previous experiences, leading to a richer and more holistic learning process.

a) Decomposition of Old Experiences: Each experience E_i in the agent's memory is associated with a timestamp t_i. As time progresses, experiences age and their relevance might diminish, but they still hold potential value. The age A_i of an experience E_i at time t is:

$$A_i(t) = t - t_i \tag{10}$$

Old experiences, beyond a certain age threshold θ, are passed through a decomposition function δ that breaks them down into constituent features or insights. For an experience E_i with age $A_i(t)$:

$$D(E_i) = \begin{cases} \delta(E_i) & \text{if } A_i(t) > \theta \\ E_i & \text{otherwise} \end{cases} \tag{11}$$

b) Feature Extraction and Recycling: Once old experiences are decomposed, the next step is to extract valuable features from them and recycle these features to enrich current learning. A function ϕ is used to filter through the decomposed experiences and extract salient characteristics F that can provide additional insights. For a decomposed experience $D(E_i)$:

$$F(E_i) = \phi(D(E_i)) \tag{12}$$

The extracted features are integrated into the agent's current learning process. This involves updating the agent's Q-values, refining its policy, and influencing its exploration-exploitation strategy. Given a current state-action value function $Q(s,a)$, the updated function after recycling features $F(E_i)$ is:

$$Q^{new}(s,a) = Q(s,a) + \beta \cdot F(E_i), \tag{13}$$

where β is a weighting factor that determines the influence of recycled characteristics.

4) Succession Learning: Inspired by the ecological succession observed in forests, the FIRL algorithm introduces the concept of "Succession Learning", which mimics the natural progression of ecosystems from early, exploratory stages to mature, stable stages. By emulating this progression, the algorithm ensures a balanced and adaptive learning process.

a) Exploration in Early Stages: In the early stages of ecological succession, pioneer species colonize and adapt to new environments. Similarly, in the initial phases of the FIRL learning process, the agent prioritizes exploration to understand the vastness and intricacies of its environment. The agent starts with a high exploration rate ϵ, ensuring that it samples a wide range of actions and states. Given a starting exploration rate ϵ_0 and a decay factor δ, the exploration rate at time t is:

$$\epsilon(t) = \epsilon_0 \times e^{-\delta t} \tag{14}$$

The agent employs a probabilistic action selection strategy, where the probability of choosing a random action is proportional to $\epsilon(t)$. Given a set of actions A and a current state s, the probability $P(a)$ of selecting action a is:

$$P(a) = \begin{cases} \epsilon(t) & \text{if } a \text{ is random} \\ 1 - \epsilon(t) & \text{if } a = \text{argmax}_{a'} Q(s, a') \end{cases} \quad (15)$$

b) Exploitation in Mature Stages: As forests mature during succession, they stabilize and optimize resource utilization. Similarly, in the later stages of the FIRL learning process, the agent shifts its focus from exploration to exploitation, leveraging its accumulated knowledge to make optimal decisions. As learning progresses, the exploration rate $\epsilon(t)$ decreases, causing the agent to rely more on its learned Q values. The agent adopts a predominantly greedy strategy, selecting actions that maximize its expected reward based on its current knowledge. Given a set of actions A and a current state s, the selected action a^* in mature stages is:

$$a^* = \text{argmax}_{a \in A} Q(s, a) \quad (16)$$

The agent also refines its Q-values, fine-tuning its policy based on feedback from the environment and any residual exploration. Given a learning rate α, reward r, and discount factor γ, the Q-value update for state s and action a is:

$$Q(s, a) = Q(s, a) + \alpha[r + \gamma \text{max}_{a'} Q(s', a') - Q(s, a)] \quad (17)$$

5) Resilience and Recovery: Mirroring the resilience and recovery mechanisms observed in forest ecosystems, the FIRL algorithm incorporates strategies to counteract suboptimal decisions and to adaptively re-explore its environment, which ensures that the agent remains robust in the face of uncertainties and can recover from potential pitfalls in its learning process.

a) Mechanisms to Counteract Poor Decisions: As forests have inherent mechanisms to recover from disturbances, the FIRL algorithm is equipped with mechanisms to identify and rectify poor decisions. After each action, the agent evaluates the outcome against its expectations. If the received reward r deviates significantly from the expected reward $r_{expected}$, it is flagged for review. Given a threshold θ_r, a decision is deemed suboptimal if:

$$|r - r_{expected}| > \theta_r \quad (18)$$

For decisions identified as suboptimal, the agent can rollback its policy to a previous state, effectively "undoing" the recent updates. Given a policy $\pi(t)$ at time t and a rollback function ρ, the updated policy after rollback is:

$$\pi(t + 1) = \rho(\pi(t)) \quad (19)$$

The agent adjusts the weights of the experiences based on their results. Poor decisions lead to a reduction in the weight of the corresponding experiences, ensuring that they have a diminished influence on future learning. Given an experience weight $w(t)$ at time t and a weighting function ω based on decision quality, the updated weight is:

$$w(t + 1) = \omega(w(t)) \quad (20)$$

b) Re-exploration Strategies: To recover from suboptimal decisions and to continually refine its understanding, the agent employs strategies to re-explore parts of its environment. The agent can temporarily increase its exploration rate $\epsilon(t)$ to encourage re-exploration. Given a boost factor β after identifying a suboptimal decision, the exploration rate is adjusted as:

$$\epsilon(t + 1) = \epsilon(t) + \beta \quad (21)$$

Instead of random exploration, the agent can focus its exploration on areas surrounding suboptimal decisions, ensuring a more targeted re-exploration. Given a state s where a suboptimal decision was made, the probability $P(s')$ of exploring a neighboring state s' is:

$$P(s') = \frac{1}{Z} e^{-\kappa d(s, s')}, \quad (22)$$

where d is a distance metric between states, κ is a scaling factor, and Z is a normalization constant.

6) Predator-Prey Exploration: The Predator-Prey Exploration strategy is built upon a dual-agent system, where one agent acts as the "predator" and the other as the "prey." The predator agent is designed to "chase" the prey agent. Its primary goal is to maximize its reward by learning from the actions of the prey. The predator policy π_P is influenced by the actions taken by the prey. Given the prey's action a_{prey} at state s, the predator's policy is updated as:

$$\pi_P(s) = \text{argmax}_{a \in A} Q_P(s, a + a_{prey}), \quad (23)$$

where Q_P is the predator's state-action value function.

The prey agent aims to "evade" the predator. It focuses on exploring the environment, especially areas not yet visited or understood. The prey policy π_{prey} is driven by exploration and is less influenced by immediate rewards. Given the predator's action a_P at state s, the prey's policy is:

$$\pi_{prey}(s) = \text{argmin}_{a \in A} Q_{prey}(s, a + a_P), \quad (24)$$

where Q_{prey} is the prey's state-action value function.

The dual agent system balances exploration and exploitation through the dynamics between predator and prey agents. The prey, in its attempt to evade the predator, naturally explores new states and actions. The predator, by trying to capture or follow the prey, refines its policy based on the prey's actions. The exploration rate ϵ is dynamically adjusted based on the distance between the predator and the prey. If the predator is close to capturing the prey, the exploration rate increases, pushing the prey to explore new areas. Given a distance metric d between the predator and prey, the exploration rate $\epsilon(t)$ at time t is:

$$\epsilon(t) = \epsilon_0 \times e^{-\lambda d(t)}, \quad (25)$$

where ϵ_0 is the initial exploration rate and λ is a scaling factor.

III. Results and Discussion

FIRL was benchmarked against established RL algorithms, with the goal of providing a context for understanding the strengths and potential areas of improvement for FIRL: Q-learning, Deep Q Networks (DQN), Proximal Policy Optimization (PPO).

A. Reward Function Behavior Analysis

The FIRL algorithm consistently achieved higher cumulative rewards in multiple environments compared to the baseline algorithms. Fig. 1 shows the cumulative rewards in the episodes of FIRL and the baselines. The graph demonstrates how different learning rates influence the cumulative reward function in an RL setup over 2000 episodes. In particular, higher learning rates like 0.5 lead to rapid initial gains, but suffer significant fluctuations in the later stages, possibly due to overfitting or instability. In contrast, moderate rates such as 0.05 and lower rates such as 0.005 exhibit a slower but more stable increase in cumulative rewards, suggesting better long-term learning consistency. However, the slowest rate, 0.0005, shows minimal improvement, indicating that it may be too conservative to achieve effective learning within the given number of episodes, which illustrates the critical balance between learning rate, convergence speed and stability, on the importance of selecting an optimal rate to maximize both initial learning efficiency and sustained performance.

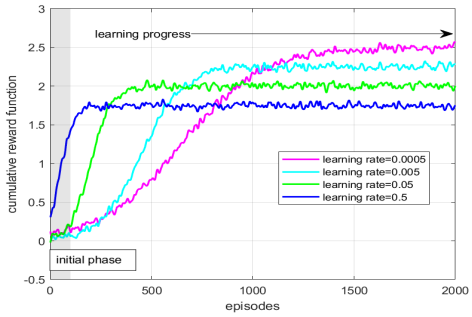

Fig. 1. Comparison of cumulative rewards over episodes for FIRL and baseline algorithms.

B. Convergence rate of FIRL vs. Baseline Algorithms

Table I presents the number of episodes required for each algorithm to converge. FIRL demonstrated faster convergence in most environments, indicating efficient learning.

TABLE I
CONVERGENCE RATE IN EPISODES (EPS.)

Algorithm	CartPole	Mountain-Car	AtariGame1	AtariGame2
FIRL	150 eps.	1250 eps.	6000 eps.	6000 eps.
Q-Learning	750 eps.	1750 eps.	12500 eps.	12500 eps.
DQN	250 eps.	500 eps.	5000 eps.	5000 eps.
PPO	200 eps.	400 eps.	4000 eps.	4000 eps.

Here, Q-Learning consistently requires more episodes to converge across all environments, illustrating its limitations in environments with large state spaces or complex dynamics. DQN and PPO, which incorporate deep learning, generally converge faster than Q-Learning, benefiting from their ability to approximate complex functions and manage high-dimensional data more effectively. FIRL demonstrates a competitive convergence rate, particularly in complex environments, suggesting that its design may be well suited to capture the intricacies and dynamics specific to these settings. Specifically, the FIRL algorithm shows notable efficiency in Atari games, converging in significantly fewer episodes compared to Q-Learning and aligning closer to DQN and PPO.

C. Exploration-Exploitation Ratio

The adaptability of FIRL was evident in its dynamic balance between exploration and exploitation. Fig. 2 illustrates this balance over time, starting from 100% exploration and progressively shifting toward more exploitation as the number of episodes increases, which represents the algorithm's learning process, where it initially explores widely to gather information about the environment and gradually begins to exploit its learned knowledge to optimize performance.

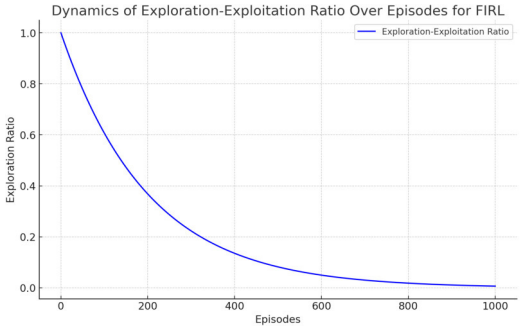

Fig. 2. Exploration-exploitation ratio over episodes for FIRL.

D. Perturbation Analysis

In scenarios with introduced perturbations, FIRL exhibited resilience, outperforming baselines in terms of performance degradation. Robustness scores are tabulated in Table II. Three different perturbation scenarios were considered:

Perturbation 1 (Noise in Sensor/Input Data) scenario tested the algorithms' ability to cope with erroneous or distorted input data, mimicking real-world sensor noise or data corruption. FIRL demonstrated superior resilience with only a 5% performance degradation, thanks to its forest-inspired mechanisms that likely offer better adaptation to dynamic changes by simulating natural ecosystem responses. In contrast, Q-Learning faced a significant struggle, showing a 15% degradation due to its inherent lack of generalization and reliance on precise state values. DQN exhibited better resilience than Q-Learning, with a 10% degradation, benefiting from deep learning's ability to generalize from noisy data. PPO, utilizing policy gradients, showed a robust response with only a 7% degradation, indicating effective handling of non-stationary conditions due to its continuous adaptation of policies.

Perturbation 2 (Sudden Changes in Rewards) scenario tested the algorithms under conditions where the reward structure was abruptly altered, which could simulate changes in task objectives or environmental rewards. FIRL adapted well

to these changes, showing a 6% degradation in performance, potentially due to its design that mirrors ecological adaptations where organisms adjust to shifting resource availability. Q-Learning suffered the most with a 20% performance hit, largely because it depends heavily on a stable reward dynamic to guide its learning process. DQN, while more adaptable than Q-Learning, still experienced a 12% performance drop as rapid shifts in reward distributions challenge its value estimation process. PPO performed relatively well, with an 8% degradation, thanks to its on-policy learning method that inherently adjusts to new reward signals more fluidly.

Perturbation 3 (Introduction of New Obstacles or Goals) scenario , tested new challenges or objectives introduced within the environment to test the algorithms' adaptability to novel conditions. FIRL showed a promising performance with a 7% degradation, likely due to its innovative strategies inspired by predator-prey dynamics which encourage dynamic adaptation. Q-Learning exhibited the highest degradation at 25%, reflecting its difficulty in handling environments where foresight and adaptability are crucial. DQN managed better, with a 14% drop, as its ability to store and replay experiences helps it to slowly adapt to new conditions. PPO, designed for continual policy adjustments, also showed resilience but still noted a 9% degradation in performance, underscoring challenges in rapidly evolving task scenarios.

TABLE II
PERFORMANCE DEGRADATION UNDER DIFFERENT PERTURBATIONS.

Algorithm	Perturbation 1	Perturbation 2	Perturbation 3
FIRL	5%	6%	7%
Q-Learning	15%	20%	25%
DQN	10%	12%	14%
PPO	7%	8%	9%

E. Computational Overhead

Although FIRL introduced novel exploration strategies, its computational overhead remained competitive compared to baseline algorithms (Q-Learning, DQN, PPO), as shown in Fig. 3. DQN has the highest computational overhead due to its reliance on deep neural networks, which require substantial GPU resources. PPO also shows significant overhead, reflecting its use of advanced policy gradient methods that, while optimized for efficiency, still demand considerable computational power. FIRL, with its bioinspired calculations, has a moderate overhead, surpassing traditional Q-Learning but staying below the more computation-heavy deep learning methods. Q-Learning exhibits the lowest overhead, being the simplest algorithm without the need for large-scale data processing or complex policy networks.

F. Robustness Analysis

To probe robustness, environmental perturbations, such as noise in observations, altered reward dynamics, and changing goal states, were introduced. Table III presents the performance degradation of FIRL in the face of these perturbations.

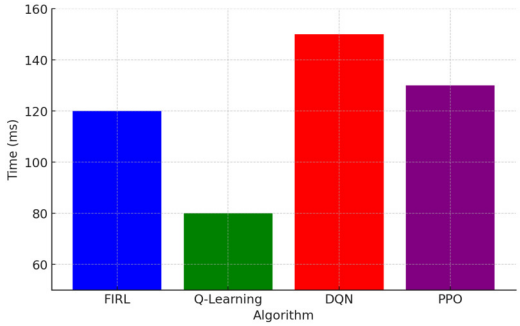

Fig. 3. Computational overhead comparison.

TABLE III
PERFORMANCE DEGRADATION UNDER VARIOUS ENVIRONMENTAL PERTURBATIONS.

Perturbation	Degradation in CartPole	Degradation in MountainCar	Degradation in Atari Game
Observation Noise	10%	8%	15%
Altered Rewards	12%	10%	18%
Shifting Goals	15%	13%	20%

Robustness tests on FIRL under various environmental perturbations reveal impacts on performance in three game scenarios: CartPole, MountainCar, and Atari Game. Observation noise led to performance degradations of 10% in CartPole, 8% in MountainCar, and 15% in Atari Game, illustrating the detrimental effects of sensory inaccuracies, with the most complex environment (Atari) being the most affected. The altered rewards caused a 12% degradation in CartPole, 10% in MountainCar, and a significant 18% in Atari Game, indicating that changes in reward dynamics pose serious challenges, particularly where the objectives are varied and complex. Shifting goals proved to be the most disruptive perturbation, resulting in 15% degradation in CartPole, 13% in MountainCar, and the highest at 20% in Atari Game, underscoring the difficulty algorithms face when adapting to new objectives in dynamic settings.

G. Adaptability to Dynamic Goals

In scenarios where the goal state or the objective dynamically changes, the adaptability of FIRL was assessed. Fig. 4 illustrates how quickly FIRL adapted to new goals compared to the baseline algorithms. The plot illustrates the actual reward function for 2000 episodes with red markers indicating perturbation points in episodes 500, 1000, and 1500. Initially, the reward function is stable around a mean value of 1, but each perturbation introduces noticeable changes. After the first perturbation at episode 500, the reward decreases to an average of 0.8, reflecting the algorithm's need to adapt to new conditions. The second perturbation in episode 1000 further reduces the reward to around 0.6, indicating increased difficulty or more significant changes in the environment. However, following the third perturbation at episode 1500, the reward function recovers slightly to an average of 0.9,

demonstrating the algorithm's ability to adapt and improve under new conditions.

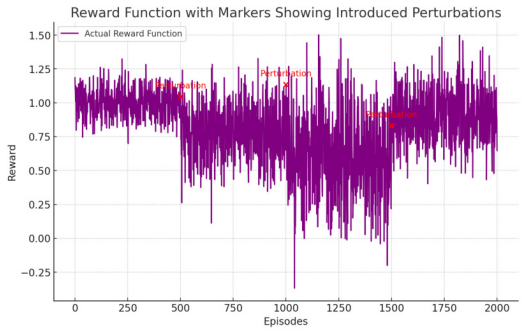

Fig. 4. Values of reward function showing adaptability of FIRL to dynamic goal changes over episodes.

H. Evolution of Mutualistic Strategies

The FIRL algorithm, inspired by forest ecosystems, inherently incorporates mutualistic interactions between predator and prey agents. The predator-prey relationship in FIRL, although competitive in nature, also exhibits cooperative dynamics. The prey's exploration aids the predator in refining its policy, while the predator's pursuit pushes the prey towards novel exploration strategies. Over time, the strategies used by both predators and prey evolved, showcasing adaptive mutualistic behaviors. Fig. 5 trace the evolution of these strategies over episodes. The plot visualizes the evolution of mutualistic strategies between predator and prey over 2000 episodes in a simulated environment. The graph shows the mutualistic benefit levels for both the predator (in red) and the prey (in blue). The benefits fluctuate and generally trend upward as the episodes progress, indicating that both entities are learning and adapting their strategies to maximize mutual benefits.

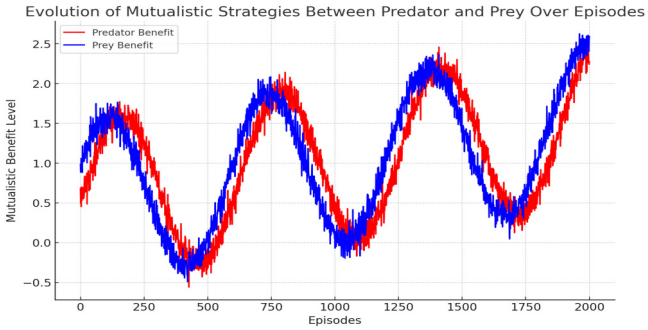

Fig. 5. Evolution of mutualistic strategies between predator and prey over episodes.

IV. Conclusions and Future Work

The FIRL algorithm, inspired by the intricate dynamics of forest ecosystems, particularly the predator-prey relationship, demonstrated notable adaptability and robustness in diverse environments. Its dual-agent system, which inherently balances exploration and exploitation, showcased the advantages of mutualistic interactions in multi-agent RL. The performance of the algorithm, especially in terms of cumulative rewards, convergence rate, and adaptability, underscores its promise in the RL domain.

Although FIRL performed well in the tested environments, its scalability to extremely large or complex environments remains to be validated. The current design does not explicitly account for direct communication between predator and prey agents, which could improve cooperative strategies. The dual agent system, while offering mutualistic benefits, might introduce computational overheads, especially in real-time applications.

***Abstract*—Recent advancements in Internet protocols, including DNS over HTTPS (DoH) and Encrypted Service Name Indicators (ESNI), are making traditional Deep Packet Inspection (DPI) engines obsolete. Consequently, there is a growing need for next-generation traffic classification using artificial intelligence (AI). While DPI automatically categorizes unknown traffic as 'other,' AI-based models cannot automatically handle unknown or Out-of-Distribution (OOD) traffic. AI models must effectively detect and classify OOD traffic to ensure robustness, reliability, and accuracy in real-world applications; however, current research often fails to address the challenges of OOD detection.**

In this paper, we evaluate various state-of-the-art OOD detection techniques for internet traffic classification and explore the drawbacks and advantages of using different threshold levels for the model's tolerance for OOD. Our findings reveal that varying rejection rates have distinct effects on OOD techniques, leading to a change in the optimal strategy for achieving dependable and precise detection across diverse OOD scenarios. We demonstrate that adjusting rejection rates from 10% to 30% can significantly improve the True Detection Rate (TDR) by up to 50%, while the False Detection Rate (FDR) may increase by less than 10%. Moreover, we emphasize that rejection-rate-based evaluation is pivotal for next-generation flow classification, promising a substantial reduction in FDR through rigorous methodological assessment.

***Index Terms*—Out of Distribution, Traffic Classification, Malware Detection**

I. Introduction

TRAFFIC Classification (TC) is a critical process that automatically categorizes Internet network traffic into distinct classes, such as traffic attribution, application type, or benign/malicious traffic. Regardless of the task, traffic classification plays a crucial role in cybersecurity, Quality of Experience (QoE), and Quality of Service (QoS), as it enables the implementation of predetermined policies to treat traffic classes differently, optimizing network performance and reliability. Traditional traffic classification techniques have relied on classifying applications or services based on fixed port numbers [1]. While these techniques offer advantages such as user privacy preservation, speed, and wide device coverage, they are limited by their reliance on fixed ports and susceptibility to cheating via packet editing. These limitations have prompted the development of Deep Packet Inspection (DPI) classification techniques [2], which involve inspecting the actual payload of packets and are less vulnerable to cheating. However, DPI techniques are resource-intensive, slow, and lack the same privacy guarantees as port-based techniques.

The widespread adoption of encryption protocols like TLS and DoH has further complicated traffic classification, rendering classical DPI techniques obsolete [3]. Consequently, researchers have turned to Machine Learning (ML) and later Deep Learning (DL) techniques for traffic classification. While ML-based approaches initially required manual feature extraction by experts, DL techniques have emerged as promising alternatives for traffic classification [4]. Despite the success of ML and DL [5], one significant weakness persists: their inability to classify instances outside of the closed set of classes in the training data. Network traffic is inherently dynamic, with new applications continually being introduced. This dynamic nature makes it challenging for models to accurately classify unseen classes without retraining. Additionally, acquiring samples for new classes is time-consuming and often results in limited datasets, leading models to favor older and more represented classes during training [6]. To address these challenges and ensure accurate and robust classification in dynamic settings, models must be able to "reject" the classification of a sample that does not belong to any of the learned classes. This capability, known as Out-of-Distribution (OOD) detection [7], [8], is crucial for effectively handling samples outside the training set. Previous works evaluate OOD detection techniques against a well-fit, state-of-the-art model without considering the implications of using less accurate models, which are common in real-world settings [9].

In this paper, we assess the impact of OOD methods on classifier performance in both binary and multiclass traffic

classification tasks. Our contribution extends existing research by highlighting the impact of employing OOD techniques on varying accuracy-level classifiers. Furthermore, we elucidate the trade-offs associated with employing threshold-based OOD techniques by introducing a new metric, **Rejection Rate (RR)**.

These trade-offs are frequently overlooked in discussions surrounding OOD techniques, as they tend not to cater to specific model requirements. By shedding light on these trade-offs, we provide valuable insights for practitioners and researchers, enabling them to make more informed decisions when selecting OOD detection techniques for their models. For example, models connected through a pipeline might not suffer from high rejection rates or data loss if they ensure that the remaining data is of high quality and reliability. This leads to a preference for performance and a high rejection rate of OOD detection techniques.

Lastly, we examine existing OOD techniques on various tasks and datasets, showing that the performance of "state-of-the-art" OOD detection methods is contingent on external factors such as acceptable rejection rates and model performance.

II. Related Work

OOD detection has been studied under many different names, such as zero-day detection, open-set recognition, and rejection option classifiers [4], [7], [8], [10], [11], [12], [13], [14]. Shared by all is the classification model's ability to reject an input if it detects that it is from a class outside its training set. Thulasidasan et al. [10] add a rejection class, K+1, trained on a mix of OOD samples. This method is limited in practice because it demands extra OOD data—either a Generative Adversarial Network or by merging some classes—plus an architectural change and full retraining, with no guarantee that real-world OOD data will match what was seen in training. Devries and Taylor [11] instead train the model to output calibrated confidence scores, using misclassified In-Distribution (ID) samples as stand-ins for OOD. These are built in parallel to the original classification model, which does not affect the model's accuracy. Nonetheless, this requires knowledge of the internal workings of the model and retraining.

Another approach uses Siamese Neural Networks (SNN) as an OOD detection method for network traffic [12]. The authors use the ability of SNNs to find similarities in input to detect OOD, but these require clustering, data balancing, and training. He et al. [13] construct skew data and then train multiple one-class Random Forest classifiers based on the skew data. This is an expensive operation and gets increasingly more complex as the number of classes increases.

Out-of-distribution detector for neural networks (ODIN) [15] augments any pre-trained model without architectural changes by pairing temperature scaling with slight input perturbations. It computes a classifier's confidence, perturbs the input proportionally, and recomputes confidence. Because ID samples are more affected, they generally yield higher post-perturbation confidences than OOD samples, enabling threshold-based rejection. Our work is the first to test ODIN on encrypted network traffic for OOD detection.

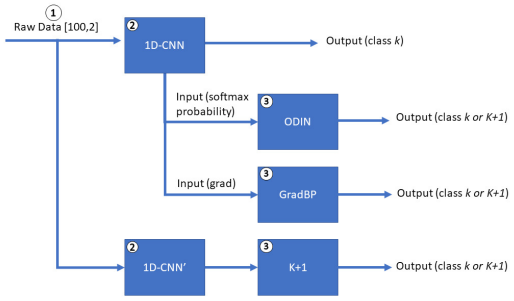

Fig. 1. Our Evaluation System

GradBP [4] treats the magnitude of the first back-propagation gradient, calculated as if training continued, as an OOD proxy. Novel inputs typically induce larger gradient magnitudes, allowing a single threshold to suffice for OOD detection. GradBP is space and time-efficient, works on pre-trained models, and has already been validated on encrypted traffic.

To conclude, several solutions to traffic classification exist, each characterized by its degrees of success and practicality. However, none of these works explores the influence of thresholds and their effect on OOD classification. As we will demonstrate, the influence of the threshold is critical for adequately evaluating OOD techniques.

Our main goal is to evaluate OOD techniques and compare their results for traffic classification, then experiment with the effects of the threshold. We chose a typical 1D-CNN as our base architecture, and three OOD techniques - ODIN [15], GradBP [4], and K+1 [16] as a baseline. ODIN and GradBP are model-agnostic and do not require model modification, retraining, or generating any additional data. Both ODIN and GradBP operate on the model output under the same space and time complexity class and require a threshold. All methods will be concatenated to our base architecture. Our evaluation system can be seen in Fig. 1.

III. System Architecture and Evaluation Framework

A. Basic System Components

Input. Each sample is a 100-step sequence of packet *direction* (0 = client $\rightarrow$ server, 1 = server $\rightarrow$ client) and min–max scaled *size* ($[0, 1]$), a standard low-cost traffic representation [4], [17] (Fig. 1,(1)).

Output. The classifier predicts a label $k \in [1, K]$; OOD detections are mapped to $k = K + 1$.

B. Out-of-Distribution Detectors

ODIN [15]. For a trained network with logits $f(x)$, we (i) rescale them by a temperature T, (ii) add a small perturbation $\epsilon \cdot \text{sign}\big(-\nabla_x \log S(x;T)\big)$, and (iii) reject any sample whose

TABLE I
TRAFFIC DATASETS USED IN THIS STUDY. B = BENIGN, M = MALWARE, TLS = DATASET IS PREDOMINATELY TLS-ENCRYPTED.

Dataset	Role	Classes	Samples	TLS	Notes
MTAB [21]	ID	2 (B/M)	29,000	Mix	MTA + benign
TEMU [20]	ID	8 (B)	20,000	Yes	Browser / misc.
USTCB [21], [22]	OOD	5 (M)	58,000	Mix	Diverse malware
VNAT [23]	OOD	6 (B)	5,500	Mix	VPN successor

largest softmax probability $S(x;T)$ falls below a threshold δ. The triplet (T, ϵ, δ) is chosen on validation data; rejected inputs are mapped to label $K+1$.

GradBP [4]. Keeping weights frozen, we back-propagate each test point once and measure the ℓ_2-norm of the resulting gradient at the penultimate model layer, $\|\delta^{L-1}\|_2$. Points with $\|\delta^{L-1}\|_2 > \epsilon_{\text{GR}}$ are considered OOD and likewise assigned $K+1$.

K + 1 [16]. The classifier head is expanded to $K+1$ outputs and fine-tuned on a small, heterogeneous set of OOD traces labelled $K+1$. At inference, any prediction of the extra node signals an outlier.

All OOD models are under label (3) in Fig. 1.

C. *Datasets*

To obtain a balanced and realistic evaluation spectrum, we use *MTAB* and *TEMU* as our two ID references and *USTCB* and *VNAT* as the OOD challengers. Together, these four datasets cover benign and malicious traffic, multiple application protocols, and both encrypted and plain-text flows, providing a rigorous test bed for evaluating ID performance and OOD generalisation. Specifically, **MTAB** (29 k flows, 2 classes) merges malicious mail-transfer (MTA) traffic with benign sessions from ISCX2016 [18], StratosphereIPS [19], and TEMU [20], yielding a mixed TLS/plain corpus labelled *benign* or *malware*. **TEMU** (20 k flows, 8 benign classes) contains browser and miscellaneous application traffic, most of it TLS-encrypted. **USTCB** (58 k flows, 5 malware classes) augments the USTC malware set—covering the *Cridex*, *Neris*, *Mi-uref*, and *Htbot* families—with the same benign sources as MTAB, giving a malware-heavy OOD benchmark. Finally, **VNAT** (5.5 k flows, 6 benign classes) offers an updated VPN/no-VPN corpus spanning streaming, chat, file-transfer, and other activities with a mix of encrypted and clear-text flows. Table I summarises the core statistics of each dataset, while the exact pairing of datasets in each experiment is shown later in Table II.

D. *Evaluation Metrics*

We report common performance indicators used for OOD evaluation [12], [13]:

Accuracy – proportion of correct decisions among the accepted samples.

True Detection Rate (TDR) – sensitivity to OOD inputs (OOD true positives divided by all OOD cases).

False Detection Rate (FDR) – type-I error on ID data (ID false positives divided by all ID cases).

Rejection Rate (RR) – The percent of samples rejected.

Recall and **Precision** – class-label sensitivity and positive predictive value, both computed on the accepted subset.

IV. EXPERIMENTAL DESIGN

We structured our evaluation around two distinct classification tasks: **Binary Classification** (i.e., distinguishing between benign and malicious traffic) and **Multiclass Classification** (i.e., identifying various well-known applications). Each classification task was evaluated using three separate experiments:

Experiment 1: This experiment assessed the base model's performance without OOD detection and unknown classes. It simulates a standard scenario where a model is developed and tested against a predefined dataset of known classes.

Experiment 2: In this experiment, we evaluated the base model's performance without OOD detection but with the introduction of unknown classes. This mimics deploying the Experiment 1 model in a real-world setting, where data may include previously unseen classes.

Experiment 3: The final experiment aimed to address the challenge of unknown classes by evaluating the base model with OOD detection capabilities.

The structure of our experiments can be seen in Table II. All OOD detection methods were tested on the same test set for robust evaluation. For comprehensive insights, including confusion matrices, tables, and threshold graphs, we have provided detailed results in our GitHub repository [24].

Lastly, when considering the preferability of one method or another, we limited the rejection rate to 50%. The limitation has two reasons: First, we could naively reject nearly all inputs without limit until few ID samples remain and achieve perfect accuracy. We do not consider such a result helpful in evaluating OOD detection performance. Second, there is no standard rejection rate, and the authors of ODIN and GradBP do not explain the effects of different rejection rates. It is standard practice to use FDR=95%TDR, such as in [13], [12], [4], [25], [26], [15], but this result is not useful for all use cases. ODIN [15] suggests hyperparameter tuning that will result in the correct identification of 95% ID samples, but does not explain the effect on rejection rates. GradBP [4] does not give any guidelines at all. As we will demonstrate, the optimal strategy is task-dependent and model-dependent.

V. EXPERIMENTAL RESULTS

A. ***Experiment 1*** *- without unknown classes, without OOD detection*

Our first experiment assesses our models' performance in both binary and multiclass classification tasks, focusing on scenarios where unknown classes and OOD data are not considered. The base models demonstrate remarkable performance despite utilizing only packet size and direction as time-series features. As shown in the Base column of Table III, the accuracy for both Binary and Multiclass tasks reaches impressive levels of 98% and 94%, respectively. This underscores the effectiveness of our models in classifying traffic even without the need for OOD detection mechanisms.

TABLE II
COMPARISON OF ARCHITECTURES AND EVALUATION METRICS ACROSS BINARY AND MULTICLASS CLASSIFICATION TASKS. BASE IS WITHOUT INCLUDING UNKNOWN CLASSES, AND BASE* IS WITH INCLUSION OF UNKNOWN CLASSES.

PERFORMANCE COMPARISON OF MODELS WITH (BASE*) AND WITHOUT (BASE) THE INCLUSION OF UNKNOWN CLASSES IN BINARY AND MULTICLASS CLASSIFICATION TASKS.

Metric	Binary Classification		Multiclass Classification	
	Base	Base*	Base	Base*
Accuracy	0.98	0.73	0.94	0.74
Recall	0.98	0.65	0.88	0.77
Precision	0.98	0.49	0.93	0.64

*B. **Experiment 2** - with unknown classes, without OOD Detection*

Next, we introduce previously unseen classes into the classification tasks, simulating real world deployment in which the model encounters new classes and no OOD detection is applied. This setting yields a pronounced drop relative to Experiment 1 across all metrics, as reported in the $Base^*$ columns of Table III. The decline exposes the model's vulnerability to novel inputs and underscores the need for robust OOD detection to mitigate this risk.

*C. **Experiment 3** - with unknown classes, with OOD detection*

Our third experiment evaluates OOD detection performance, especially the trade-offs of using a threshold-based technique on the accuracy and overall sample rejection rates. For this task, we implemented three detection techniques that will be evaluated: ODIN[15], GradBP[4], K+1[16].

In the following subsections, we demonstrate the model's performance across several rejection rates and justify choosing one threshold over another.

*1) **Classification Task - Binary, OOD - ODIN**:* Tables IV and VI show that as the rejection rate initially increases, nearly all rejected samples are OOD, as both accuracy and TDR rise. As the threshold tightens, we observe an exponential increase in FDR with minimal accuracy gains. This is essential because there might be a significant increase in the model's accuracy by allowing the model to reject slightly more ID samples. Increasing the rejection rate from 10% to 30% produced several effects: the TDR increased from 31% to 66%, while the FDR only increased from 3% to 18%, and accuracy increased from 79% to 87%. In contrast, going from a rejection rate of 30% to 50% had exponentially diminishing returns. The TDR increased from 66% to 75%, while FDR increased from about 18% to 41%, leaving the accuracy unchanged at 87%. At that point, accuracy rates began decreasing as the threshold tightened.

Despite allowing a rejection rate of up to 50%, the best accuracy figures came from rejecting only 31% of the overall samples. The accuracy score increased from 72% to 87%, with an FDR of 18% and a TDR of 67%, as seen in Table VI. These results demonstrate that despite ODIN being originally developed for images, it is generic enough to work on network traffic. However, there are apparent weaknesses as well. ODIN misses examples that are likely to be misclassified, and nearly all OOD samples missed were classified as benign. This weakness is particularly problematic because the purpose of the model is to detect malicious traffic.

Note that the rejection rate does not influence the K+1 technique; thus, it was not included in this analysis and does not appear in Table IV.

*2) **Classification Task - Binary, OOD - GradBP**:* Similarly to ODIN, as shown in Tables IV and VI, the FDRs are low as the threshold decreases, proving that nearly all samples rejected are OOD. Unlike ODIN, the GradBP results are much better at the maximum threshold rate of 50% (98% TDR). Nearly all OOD samples have been rejected, increasing the model's accuracy to 99% - higher than the base model without OOD data. The FDR is 32%, which means most ID samples are not rejected. The higher accuracy signals, again, that this method also rejects nearly all misclassified labels. Out of the missed OOD samples, only 29/31 were classified as benign by the model, compared to 659/661 in ODIN. We also compared these values at a 30% rejection rate; 193/362 OOD samples were detected as benign, a significantly better result than ODIN. As the threshold tightens, GradBP shows an exponential increase in practical terms. This means we can significantly increase the likelihood of all passed samples being ID if data loss is not a significant concern.

TABLE IV
EXPERIMENT 3: THE INFLUENCE OF REJECTION RATE ON THE PERFORMANCE OF ODIN AND GRADBP METHODS FOR THE BINARY CLASSIFICATION TASK.

Metric	10%		30%		50%		70%		90%

TABLE VI
EXPERIMENT 3: PERFORMANCE SUMMARY FOR BINARY CLASSIFICATION USING ODIN, GRADBP, AND K+1 METHODS.

Metric	ODIN	GradBP	K+1
Accuracy	0.88	**0.99**	0.94
Recall	**0.67**	**0.67**	0.66
Precision	0.59	**0.66**	0.63
FDR	0.19	0.32	**0.02**
TDR	0.68	**0.98**	0.86
Rejection Rate	0.31	0.49	**0.23**

*3) **Classification Task - Binary, OOD - K+1**:* As seen in Table VI, the results from adding a rejection class were inconclusive. The accuracy achieved was 93.8%, which is lower than GradBP and ODIN. In the K+1 technique, there is no threshold to work with when adding a rejection class, so the rejection rate is fixed at 23%.

*4) **Classification Task - Multiclass, OOD - ODIN**:* As can be seen from Tables V and VII, there is full utilization of the rejection rate at about 50%, achieving an accuracy, TDR, and FDR of 96%, 92%, and 39%, higher than the base model when tested without OOD data. This ability means that ODIN rejects OOD samples and misclassifies known applications. For comparison, at a 30% rejection rate, the model had good accuracy, TDR, and FDR of 90%, 70%, and 20%. Table V (30% rejection rate, ODIN). Using the threshold to increase its effectiveness allows for a greater range of risk management; if losing most data is not a significant concern, we can increase the confidence that the samples that do pass are both ID and correctly classified.

*5) **Classification Task - Multiclass, OOD - GradBP**:* The results seen in Table VII for GradBP were interesting; at a 50% rejection rate, we observed an accuracy rate of 93%, lower than ODIN. TDR was 84%, also lower than ODIN, whereas the FDR was 41% compared to 39% in ODIN. The closest result was in recall, which has 85% compared to ODIN with 86%. The increase in rejection rate did not contribute much beyond 30%.

*6) **Classification Task - Multiclass, OOD - K+1**:* As shown in Table VII, the accuracy rate was 84%, with a recall of 78% and a precision of 66%. The rejection rate accounted for only 12% of the total samples, and the TDR was just 54%. However, the FDR remained remarkably low at only 1.5%, similar to the binary model.

TABLE VII
EXPERIMENT 3: PERFORMANCE SUMMARY FOR MULTICLASS CLASSIFICATION USING ODIN, GRADBP, AND K+1 METHODS.

Metric	ODIN	GradBP	K+1
Accuracy	**0.96**	0.93	0.84
Recall	**0.86**	0.85	0.78
Precision	**0.79**	0.75	0.66
FDR	0.39	0.40	**0.02**
TDR	**0.92**	0.84	0.54
Rejection Rate	0.50	0.49	**0.12**

VI. DISCUSSION AND CONCLUSIONS

Our empirical study of ODIN, GradBP, and K+1 across binary and multiclass traffic classification tasks paints a nuanced picture; there is no universally superior OOD method. Each technique excels only under specific operational conditions, a finding with immediate consequences for how OOD detection is benchmarked and deployed. In the multiclass setting, ODIN achieved the highest overall accuracy, reaching 96% in our experiments and preserving a favorable balance between true and false detection rates once the rejection rate exceeded roughly 30%. ODIN's temperature-scaled perturbation interacts advantageously with the richer softmax that accompanies

multiclass models, yielding robustness as the class cardinality increases. By contrast, in the binary task, GradBP emerged as the preferred method whenever practitioners could tolerate moderate to high rejection rates. Above the 30% rejection threshold, GradBP drove accuracy toward 99% and pushed the TDR past 98%, maintaining lower FDR rates than ODIN.

Although often dismissed as a baseline, K+1 demonstrated excellent precision at very low FDR. However, its practical value is undercut by the need for explicit OOD samples, a fixed rejection threshold, the computation costs of model retraining, and the possible effects on model performance. Rejection rates surfaced as the governing hyperparameter in the third experiment. With RR capped at 10%, ODIN and GradBP were statistically indistinguishable in the binary task, offering practitioners no basis for preferring one over the other. Once rejection rates were relaxed into the 30%-50% regime, the behavior of both methods diverged sharply: GradBP continued to accrue accuracy and detection gains, whereas ODIN effectively plateaued. In the multiclass task, the pattern reversed - a relaxed rejection rate benefited ODIN and put it significantly ahead of GradBP across all metrics, while GradBP's improvements saturated. When rejection rates were not relaxed, the performances of GradBP and ODIN were virtually identical. The bidirectional sensitivities confirm that rejection rates reshape each detector's risk-utility frontier and must be considered when benchmarking OOD detection methods. The operational consequences could be applied immediately; in domains where practitioners could tolerate elevated rejection rates at the price of suppressing false acceptances, candidate detection methods should be tested under different rejection rate circumstances to determine the ideal fit. Our findings show that OOD detection is far from a "plug-and-play" commodity. Its efficacy is contingent upon task granularity, traffic type, and tolerance for rejected samples.

Future research endeavors should explore the impact of rejection rates across a broader array of OOD detection methods and classification domains. Specifically, how strongly rejection rates improve OOD detection and performance across OOD detection performance and model accuracy. Future investigations should explore the connection between different models, domains, and rejection rates, potentially uncovering novel approaches for improved performance.

***Abstract*—This paper proposes a microservices-based digital twin architecture for flexible, scalable, and real-time integration of smart mobility services in urban centers. By decoupling functions into modular services embedded in scenario-driven simulations, the digital twin overcomes limitations of monolithic systems, enhancing adaptability and interoperability. Preliminary results demonstrate its effectiveness for dynamic urban mobility management.**

***Index Terms*—Digital Twin, Mobility, Reference architecture, Micro-services approach, Scenario-driven approach, Mobility Simulation.**

I. Introduction

AS CITIES adopt smart mobility solutions to tackle congestion, reduce emissions, and improve transport efficiency, the ecosystem of services—ride-sharing, public transport tracking, electric vehicle infrastructure, and autonomous systems—is rapidly expanding[1]. These services require real-time interaction, but most current integration strategies are rigid, tightly coupled, and difficult to scale or update. This limits cities' ability to adapt their mobility infrastructure as technologies and needs evolve[2]. Digital twins—virtual representations of physical systems—offer a promising approach to dynamically model, simulate, and manage urban mobility. Paired with microservices architecture, digital twins (DT) can evolve from static models into flexible, modular platforms supporting continuous integration of new services[3]. However, many existing DT implementations for mobility rely on monolithic or semi-monolithic systems lacking modularity and real-time interoperability. Adding new services often requires major redevelopment, causing bottlenecks and hindering innovation. There is a need for an architecture that enables seamless integration, fast iteration, and scalability without compromising performance or reliability[4]. This paper presents a microservices-based DT architecture designed for flexible, scalable integration of smart mobility services. Each service can operate independently while contributing to a unified city-wide model, enabling real-time coordination and dynamic updates with minimal friction. A key feature of the architecture is embedding simulation within workflow-driven scenarios and sub-scenarios, rather than as a separate module. This modular design enables configurable, extensible simulation pipelines that capture urban mobility's complexity and support context-specific experimentation and decision-making. Section III defines the concept of Simulation and Scenario. Section IV proposes the design principles for the architecture. Section V details the proposed architecture and its key components. Section VI describes the implementation of the case study to validate the approach. Section VII discusses the results, challenges, and insights gained and concludes with key takeaways and directions for future work.

II. Related work

The *Digital Twin* concept was first introduced in a NASA roadmap[1] [5] as a probabilistic, multi-physics simulation of a space system, combining physical models, sensor data, and operational history. Grieves [6] later formalised it through three core elements: *a physical product, a virtual counterpart, and the data links between them*. As summarised by [7], a DT is a dynamic virtual representation of a physical system, connected throughout its lifecycle for continuous data exchange. Without this temporal link, the model remains a static simulation rather than a true DT. In *Ceci n'est pas un jumeau numérique*, [8] describes the progression from design models to data-enriched *shadows*, with unidirectional data flow. Twin status requires feedback enabling the virtual to affect the physical. While bidirectional exchange is essential, [9] argues that full understanding requires five dimensions: physical entities, virtual models, data, services, and interconnections. Beyond representation, DTs support decision-making—through monitoring (e.g., vehicle status), simulation (e.g., traffic impacts), and prediction (e.g., mobility demand).

Micro-Services Architecture in Smart Systems enables scalability and maintainability by dividing applications into loosely coupled components that communicate via lightweight APIs. This modularity helps manage complexity in domains like cities, energy grids, or mobility, where subsystems—such as traffic control or route planning—can evolve independently.

TABLE I
TECHNICAL LIMITATIONS OF CURRENT APPROACHES

Challenge	Description
Legacy system integration	Difficulty integrating DTs with older infrastructure lacking IoT/sensor support
Scalability	Maintaining accuracy across expanding systems with diverse data volumes
Real-time synchronisation	Latency issues when combining Edge (fast) and Cloud (slow) DTs
Data quality and Governance	Errors in data pipelines lead to inaccurate DT representations

Recent use cases show improved iteration and fault isolation, such as in smart grids for energy forecasting and pricing [10], or in IoT cities for managing sensor and edge data streams [11]. Still, challenges like orchestration and service discovery persist but are mitigated with tools like Kubernetes and service meshes. For mobility-focused DTs, microservices enable real-time simulation, modular updates, and integration of varied services [12].

Integration Frameworks for Mobility Services face challenges due to data mismatches, conflicting services, and diverse tech stacks, limiting real-time performance. Automated methods offer potential but struggle with incomplete data, and domain-specific issues persist. In healthcare, DTs encounter uncertain model parameters and data ownership concerns, needing to balance AI insights with regulations like HIPAA [13].Urban DTs face difficulty simulating emergent behaviours across systems and resolving stakeholder conflicts [14]. Table I summarises key technical challenges in integrating SoS and DTs.

III. SIMULATION AND SCENARIO CONCEPT

This section defines simulation and scenario concepts, key to the proposed microservice architecture, enabling modular and scalable system modelling.

A. Simulation

The simulation is a central element of the digital twin concept. It enables the virtual reproduction of the real system's behaviour using various specialised simulation tools. In this work, four simulators have been integrated: SUMO[2], AIMSUN[3], MnMS[4], and MATSim[5]. These tools cover a wide range of scenarios and analyses in the field of mobility.

The simulation component was modelled using UML and consists of several inputs: parameters, context, initial conditions, constraints, and metrics for performance evaluation. The simulation produces outputs such as key performance indicators (KPIs) or visual results. These outputs can be displayed by the digital twin and support decision-making processes.

Table II provides a detailed description of the different concepts that make up a scenario.

[4]https://github.com/licit-lab/MnMS
[5]https://www.matsim.org

TABLE II
SIMULATION CONCEPT DEFINITIONS

Name of the Concept	Description
Parameter	This class specifies parameters or settings that control the behaviour of the simulation. These parameters may include simulation duration, time step size, numerical methods, model parameters, and other configuration options.
Outcome	This class specifies the anticipated results, findings or insights that are expected to emerge from the simulation. This provides a basis for comparing the actual outcomes of the simulation with the desired or expected outcomes.
Metrics	This class outlines the criteria or measures used to evaluate the simulation (performance, effectiveness, etc.). It defines the key indicators, metrics, or outcomes that will be analysed to assess the success of the simulation in achieving its objectives.
Constraint	This class specifies the constraints, limitations or assumptions that apply to the simulation.
Initial Condition	This class defines the initial states or conditions at the beginning of the simulation. It includes parameters such as initial values, states, positions, velocities, and other relevant variables that characterise the system.
Context	This class contains the information related to the context of the simulation. This includes details about the environment, stakeholders, resources, constraints, and any other factors that may influence the simulation.

B. Scenario

The concept of a scenario is a core part of the proposed microservice architecture. A scenario can include multiple sub-scenarios to support complex simulation workflows. Each scenario consists of sub-scenarios, which are composed of individual steps called ScenarioStep. Each step represents a specific mobility-related service, such as calibration, stress test generation, traffic management, or simulation. This modular structure allows fine control over scenario behavior and execution. Additionally, each sub-scenario is defined by a workflow that manages the sequence and dependencies of its steps.

IV. DESIGN PRINCIPLES

A. Functional and non-functional Requirements

The functional and non-functional requirements stem from four pilot partners: the City of Amsterdam[6], Athens (via DAEM[7]), Helsinki (via Forum Virium Helsinki), and the Luxembourgish bus operator Sales-Lentz[8]. Each contributes with their domain expertise—from smart city development to digital infrastructure and autonomous transport. User-driven features are grouped by topic and labeled as essential or optional. Key functional needs include data collection from diverse sources, real-time dynamic simulations, scenario execution (e.g., traffic events), and 2D/3D visualization. Non-functional needs emphasize data fusion for enhanced insights and strong data privacy safeguards to prevent unauthorized access to personal

TABLE III
FUNCTIONAL NEEDS BY THEME, WITH KEY (K) OR OPTIONAL (O) PRIORITY

Subj.	Features	K/O
Data	-As a data scientist (DS), I want to browse, upload and download data in different formats (JSON, CSV, XML) in the DT.	K
	-As a DS, I want data to be available according to well-defined access rules	O
	-As a DS, I want to get relevant infrastructure data (occupancy of parking lots, pricing, requests for parking places, etc) using open data	K
	-As a DS from Helsinki, I want the Helsinki DT data catalogue to be connected to the DT data management	K
Scenario	-As a civil servant (CS) or as a DS, I want to access a list of scenarios	K
	-As a DS, I want the scenarios to be labelled, timestamped, related to input, and generated by a simulation tool	K
	-As a DS, I want the scenarios to be stored in a database managed by the DT.	K
	-As a CS from Helsinki or as a DS, I want the simulation to be calibrated to better represent the traffic management strategies for Helsinki's harbour.	K
Simulation	-As a CS or as a DS, I want to realise various traffic simulations	K
	-As an employee from Luxembourg or as a DS, I want to simulate autonomous shuttle operations in the Luxembourg area. Therefore, I want: (1) to calibrate the model with data, (2) to collect and to store data from the national open data portal, (3) to simulate the shuttle mobility and the position of the stop stations	K
	-As a CS from Amsterdam or as a DS, I want to simulate the scenarios when the IJ-tunnel is open/closed.	K
	-As a CS from Helsinki or as a DS, I want to simulate different traffic management strategies and to simulate mobility environments when ferries arrive from Tallinn to Helsinki's harbour.	K
Visualization	-As a CS or as a DS, I want to visualise the different traffic management strategies on a 2D map	K
	-As a CS or as a DS, I want to visualise the different traffic scenarios on a 2D map	K
	-As a CS or as a DS, I want to visualise the KPIs associated with the scenario in a dashboard	K
	-As a CS or as a DS, I would like to make simple queries, such as to highlight the evolution of different KPIs	O
	-As a CS from Athens or as a DS, I want to view the different traffic management strategies in 3D	O
	-As a CS from Helsinki, I want to visualise 1 KPI that expresses the number of recommendations followed by the users (50 users for the pilot)	K
Feedback loop	-As an employee from Luxembourg, I would like the shuttle's position to be sent to the passengers' mobile application	K
	-As a CS from Helsinki, I want the trajectory recommendation to be sent to citizens arriving and living in the Helsinki harbour through a dedicated mobile application	K
Real time	-As a CS from Athens or as a DS, I want to use real-time data	O
	-As a CS from Helsinki, I want to visualise traffic management strategies, traffic flow in real-time, and a 3D viewer	O

data. These requirements shape the architecture supporting the Digital Twin (DT) systems used in the pilot projects.

B. Design of the digital twin

The design of a DT for mobility management requires a robust, scalable, and flexible architecture.

1) Microservices as an Architectural Foundation: Microservices offer flexibility, scalability, and resilience for data-intensive mobility systems ([15]). They support independent deployment and integration. Key design principles include **API-first** development, **domain-driven design** for mobility alignment, **containerization** for isolation, and **service decoupling** to reduce dependencies and ease maintenance. These ensure efficient, cloud-native, and modular architecture.

2) Layered Logical Architecture of the DT: To ease the deployment of the DT, we have decided to divide the architecture into layers, each supporting a dedicated functional principle. The seven layers considered are: 1) **Data Ingestion:** Collects real-time data from IoT sensors, GPS, traffic cameras, etc. 2) **Data Processing and Storage:** Processes and stores data in scalable systems (e.g., Apache Kafka, Cassandra) with harmonised formats.3) **Simulation and Analytics:** Provides insights via analytics and machine learning for forecasting and planning.4) **Integration:** Exposes APIs for system interaction and real-time responses.5) **User Interface:** Offers dashboards for operators to explore data and support decisions.6) **Security and Compliance:** Ensures data privacy and integrity with access controls and encryption. 7) **Scalability and Resilience:** Adapts to growth and evolving needs without major disruptions.

V. PROPOSAL ARCHITECTURE

A. Overview of the Digital Twin Micro-Services Framework

The digital twin platform adopts a high-level microservices architecture to ensure modularity, scalability, and maintainability. Each microservice functions as an autonomous unit with a specific role and may include its own user interface, business logic, and database.

Service communication is centralised through an API Gateway. Instead of direct IP-based interaction, all requests pass through the gateway, enabling unified access control, routing, and monitoring—enhancing both security and operational clarity. The gateway also enforces access policies and simplifies service discovery.

Inter-service communication includes authentication tokens, allowing services to verify the legitimacy of incoming requests. This ensures only authenticated and authorised interactions occur within the platform.

All services expose RESTful APIs, enabling standard HTTP communication and supporting independent development, deployment, and scaling.

To ensure platform independence and ease of deployment, all services are containerised. Containers encapsulate each service and its dependencies, enabling consistent deployment across environments and the use of orchestration tools like Kubernetes for automated deployment, scaling, and management.

B. Micro-Service Components

- **Mobility Data Ingestion:** The *Data Manager* provides a central point for accessing and managing data. It includes a user interface, business logic, and storage system. Users can upload or download datasets, while services can query or consume data for processing or simulation tasks.

- **Simulation & Prediction Engine (external):** This component offers unified access to simulation tools such as SUMO, Aimsun Next, MATSim, and MnMS. It abstracts the specifics of each tool, allowing higher-level services to request simulations through a standard, tool-agnostic interface.
- **Service Registry & API Gateway:** This module centralises all communication within the platform and serves as the access point for external clients. Services register their endpoints with the gateway, which manages routing, exposure control, and access policies. Inter-service communication passes through the gateway and includes authentication tokens to verify identity and permissions.
- **Scenarios Engine:** The *Scenarios Manager* orchestrates simulation scenarios by retrieving datasets from the Data Manager and initiating tasks through the Simulation Engine. It includes user interface components for scenario configuration and results visualisation.
- **User Interface / Visualisation Module:** A central front-end portal integrates visual components from services like the Data Manager and Scenarios Manager via `iframes`. This enables services to independently develop their interfaces while ensuring a unified and seamless user experience.

C. Integration Mechanism

The microservices described earlier form the core of the platform, providing essential functions such as data ingestion, scenario orchestration, simulation execution, and communication routing. Together, they ensure interoperability across all modules. The platform is designed for extensibility: developers can introduce new services using their preferred technology stack, provided each service encapsulates its internal components—such as business logic and storage—and exposes a clear HTTP RESTful API for system-wide interaction. To integrate a new service, it must be registered with the API Gateway, which centralises access control, routing, and service discovery. Developers specify which endpoints are exposed to the platform, ensuring new functionalities remain decoupled, manageable, and aligned with established security and communication standards. This modular design allows the platform to evolve, supporting the integration of new tools, analytics, or decision-support modules as the Digital Twin's requirements grow.

VI. Case Study Implementation

A. Implementation Context and Technology Stack

The reference architecture described in this paper has been instantiated in the context of the ACUMEN use case, which aims to enable advanced mobility functionalities such as traffic monitoring, dynamic route optimisation, public transport coordination, and seamless mobility services. The platform's modular microservices approach, centralised access control, and robust data handling, provides a reliable foundation to meet these operational requirements.

The implementation leverages a carefully selected technology stack to support these capabilities, ensuring scalability, interoperability, and maintainability. Table IV summarises the key technologies and tools used across the platform's core components and supporting infrastructure.

TABLE IV
Technology stack used in the implementation

Module	Technology / Tool	Purpose
API Gateway	Java, Spring Boot, Spring Cloud Gateway, MongoDB	Centralizes communication, manages routing, service registry and discovery
Authentication Service	Keycloak, Java	Handles user authentication, access control, and token management (JWT)
Data Manager	Java, Spring Boot, PostgreSQL, MinIO	Provides a central hub for dataset storage, retrieval, and sharing across services
Scenarios Manager	Java, Spring Boot, ArangoDB	Orchestrates scenario execution, including data fetching and simulation delegation
Simulations Engine	Python, ClickHouse	Interfaces with external tools to manage and process simulation requests
Front-End Shell	Vue.js, Vuetify	Hosts the main portal and integrates service-specific UIs via iframe-based inclusion
Simulation Tools	SUMO, Aimsun Next, MATSim, MNMS	Simulate real-world mobility scenarios and provide output for analysis
Containerization	Docker	Packages services into containers to ensure portability and consistency
CI/CD	GitLab CI/CD, Docker Compose	Automates build, test, and deployment workflows

B. First results of SUMO Simulation Scenario: Greek National Road 91 Closure

This section presents the first results of the scenario execution for a simulation using SUMO. The objective of this scenario is to simulate traffic evolution when the Greek National Road 91 in Athens is closed to traffic, as illustrated in Fig. 2. The scenario was subdivided into several sub-scenarios to visualise the impact of different types of closures (e.g., one lane from north to south, one lane from south to north, or both lanes simultaneously) and to determine the optimal mitigation strategy.

To perform these sub-scenarios, the necessary parameters were introduced. Specifically, the simulation was configured with the following inputs: *rush hour* was enabled, *weather conditions* were set to *rainy*, and an *incident* was introduced in the form of a *vehicle breakdown* located at the *midpoint of the tunnel*. A *dynamic, individually aware rerouting strategy* was applied. *Pedestrian presence* was considered *low*, and there were *no disruptions to public transport*. The simulation was run for *120 minutes* with detailed output including *vehicle*

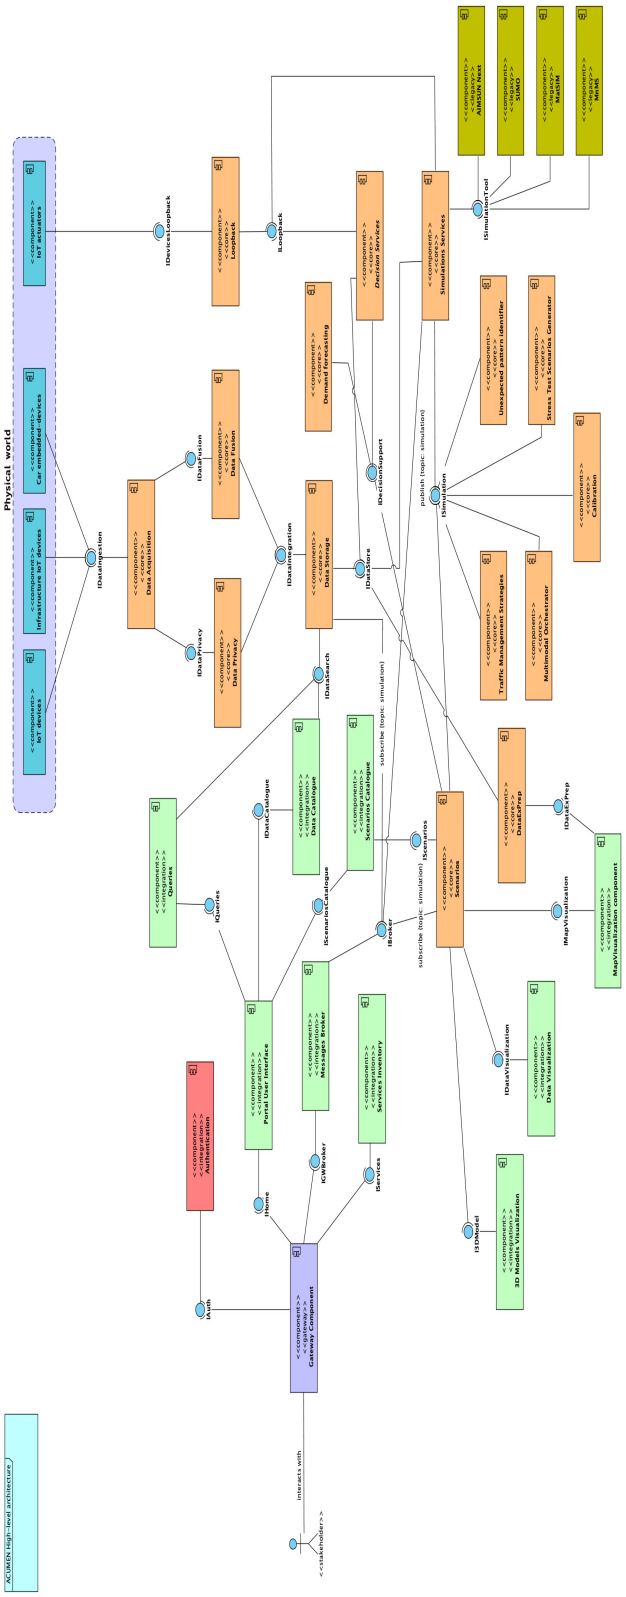

Fig. 1. ACUMEN microservices-based reference architecture

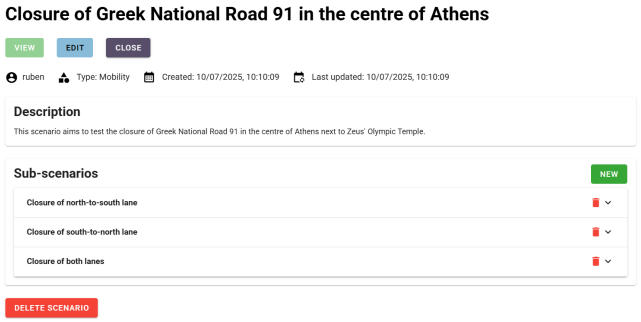

Fig. 2. Global view of the scenario

positions and teleports. The *traffic lights* followed an *adaptive signal control program*, as shown in Fig. 3.

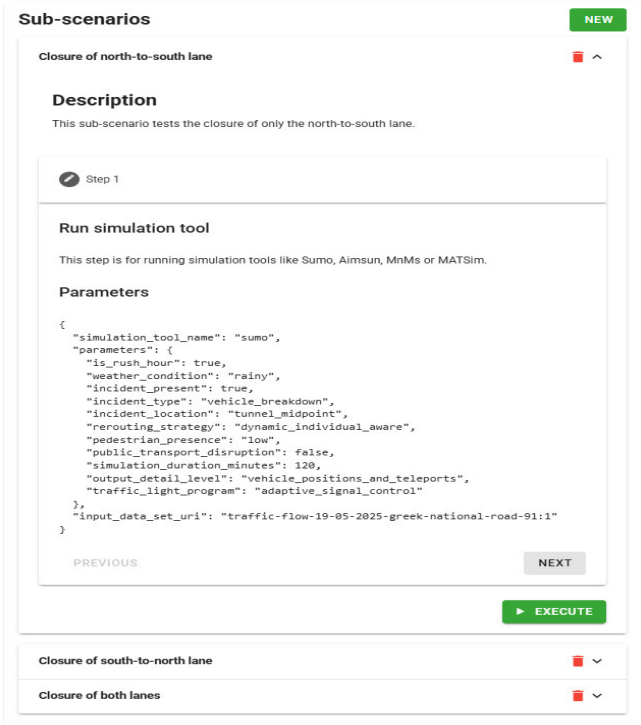

Fig. 3. Sub-scenario parameters

The scenario execution was initiated by clicking the *EXECUTE* green button shown in Fig. 3. After a few minutes of computation, simulation results were available for each sub-scenario, allowing a comparative visualisation of the different traffic configurations. As illustrated in Fig. 4, the results depict the movement of various types of vehicles: *cars in blue*, *buses in green*, and *trams in orange*. These visualisations help to understand how traffic flows redistribute across the city of Athens depending on the specific sub-scenario configuration.

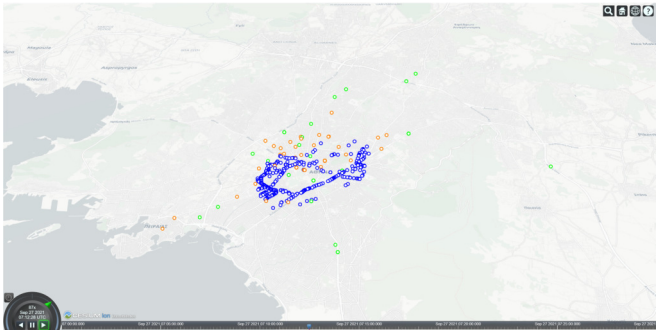

Fig. 4. Visual result of the simulation

VII. Conclusion and Future Works

A Digital Twin Microservices Architecture provides a scalable, modular framework ideal for smart mobility systems. It breaks down complex services—like traffic control or ride-sharing—into independent microservices, improving fault tolerance, development speed, and system updates. When combined with DT, real-world elements like vehicles and infrastructure are mirrored virtually, enabling real-time monitoring, predictive modeling, and system optimization in fast-changing urban environments (transport of dangerous good [16]).

The architecture promotes interoperability across diverse platforms used by different stakeholders, synchronizing data via standard APIs. A shared digital twin layer keeps services aligned with real-time conditions, supporting informed, coordinated decision-making. Its modularity also enables advanced analytics and machine learning, using rich data streams to forecast traffic, optimize routes, and assess infrastructure—without disrupting core operations.

However, several challenges remain. Integrating massive, heterogeneous data sources requires sophisticated pipelines, validation tools, and common standards to ensure accuracy. Orchestrating many microservices also demands complex coordination, secure communication, and real-time responsiveness. Additionally, the approach is resource-intensive, requiring significant investment in computing power, cloud infrastructure, and cybersecurity. As cities scale up smart mobility, managing cost, system complexity, and security becomes increasingly difficult. Overcoming these hurdles will require technical innovation, strong governance, and collaboration across sectors.

This paper proposes a microservices-based digital twin for smart mobility, featuring modular simulations for adaptability and interoperability. A case study on the Athens tunnel closures shows its effectiveness. Future work aims to target automation, self-adaptation, cloud-edge performance, data privacy, and AI explainability, replacing rigid systems with agile urban mobility solutions.

***Abstract*—APIs are the main mechanism for integrating heterogeneous components in modern software systems. API documentation typically treats each endpoint as autonomous, leaving out information about other endpoints that produce or consume input or output data, which is useful in rapidly orchestrating valid call sequences. This makes the development, testing and maintenance of systems that use APIs to internally implement business logic, or integrate with third-party API-based services, more complex. This paper addresses this gap by introducing static and dynamic analysis methods to automatically discover and document inter-endpoint dependencies; static analysis uses existing API documentation, while dynamic analysis is based on logging API usage. Both methods are integrated into RADAR, a tool for extracting and visualizing graphs, to illustrate such inter-endpoint dependencies through exchanged data. Case study on the PayPal API demonstrates the value of adding dependency graphs to API documentation to support rapid development and documentation of software systems.**

***Index Terms*—APIs, inter-endpoint dependencies, API documentation.**

I. Introduction

IN MODERN software architectures, Application Programming Interfaces (APIs) serve as the primary mechanism for exposing the functionalities offered by entire software applications or even components, to other applications, components, or services of any kind. An API exposes a set of endpoints that, when invoked by a consumer, execute specific server-side functionality, which results in a response sent back to the client, regardless of the technologies used on either side.

APIs are developed both for integrating components within applications and as standalone software products. In either case, their complexity necessitates comprehensive documentation to support their development, maintenance, and integration. Typical API documentation usually follows standards such as OpenAPI[1], or comes in the form of de-facto formats introduced by tools, such as Postman[2] collections. Any such kind of documentation provides the schema of the request and response of every endpoint, data types and descriptions, and possibly full examples of API calls with data.

However, it usually treats each endpoint as an independent service, whereas an API is a collection of interacting endpoints that collectively can be used to implement pieces of business logic. To do this effectively, it is essential that developers have information not only about how to call each endpoint, but also about all its possible interactions with other endpoints that either consume output or provide input data. This work focuses on the discovery, modeling and representation of such interactions in a way that provides additional practically useful documentation for the integration of APIs into software components of any kind.

II. Related Work

Prior research has explored ways to facilitate the proper utilization of APIs by identifying the constraints that must be met when interacting with them. A wide area of research investigates techniques for identifying interdependencies among input parameters within (single) API calls, with the goal of facilitating the construction of syntactically and semantically valid API requests.

Oostvogels et al. [1] attempted to analyze and incorporate inter-parameter constraints within API documentation. These constraints define rules whereby the existence or valid values of certain input parameters in an API call depend on the presence or values of other parameters. To address the absence of structured representation for such constraints in existing documentation, a new specification language was created as an extension to the OpenAPI specification to incorporate this information. Martin-Lopez et al. ([2], [3], [4]) also focused on inter-parameter dependencies, proposing a Domain Specific

[1] OpenAPI: https://www.openapis.org/

[2] Postman: https://www.postman.com/

Language known as IDL (Inter-parameter Dependency Language) to describe these dependencies. Both studies focus on interdependencies of input parameters for a specific call rather than on inter-endpoint dependencies which is our area of interest.

Wu et al. [5] proposed an additional method that detects "dependency constraints on parameters", leading to the development of the INDICATOR system, which analyzes documentation and SDKs to identify constraint candidates and then validates them through testing. The INDICATOR system investigates these producer-consumer relationships based on the names and types of parameters. However, it does not focus on systematically extracting or documenting these relationships.

Another related area of research concentrates on identifying interdependencies across different operations of Web Services and APIs for testing. The work of Bai et al. [6] aims to automatically generate test cases from WSDL specifications with respect to the dependencies among various operations. One of the dependency types examined is input/output dependencies (IOD), which represent inter-endpoint dependencies. However, this approach limits the examination of inter-endpoint dependencies to aspects directly related to test case generation, which aligns with the focus of their study.

The study of Atlidakis et al. [7] introduces REST-ler, a tool that analyzes Swagger specifications for RESTful APIs, automatically identifies object types required by a request that have been produced by previous ones, generates tests with respect to these dependencies and dynamically infers which request sequences are valid. However, this inter-endpoint analysis aims mainly to automatically generate and execute meaningful and correct test cases, while adhering to these dependencies. Consequently, no documentation regarding the inter-endpoint dependencies is generated.

The study conducted by Bertolino et al. [8] aims to extract behavioral information regarding how users should invoke a Web Service. This method, called StrawBerry, examines the WSDL document and identifies dependencies between the operations of the Web Service based solely on types of input and output parameters. A behavior protocol automaton is generated, indicating the dependencies and data transfers among various operations of the Web Service. However, this analysis relies on the presence of a WSDL specification.

III. Inter-Endpoint Dependencies

An "inter-endpoint dependency" is an interaction between API endpoints. If invoking endpoint Y requires input data received from a call to endpoint X, then the required call order is (X, Y) and thus we say that Y "depends" on X. As an example, consider the hypothetical Flight Booking API illustrated in Fig 1, along with a sample invocation of its endpoints. The top-level nodes represent API endpoints, while the corresponding JSON response schemas and the example responses appear beneath each endpoint. Directed edges indicate the data flow between endpoints.

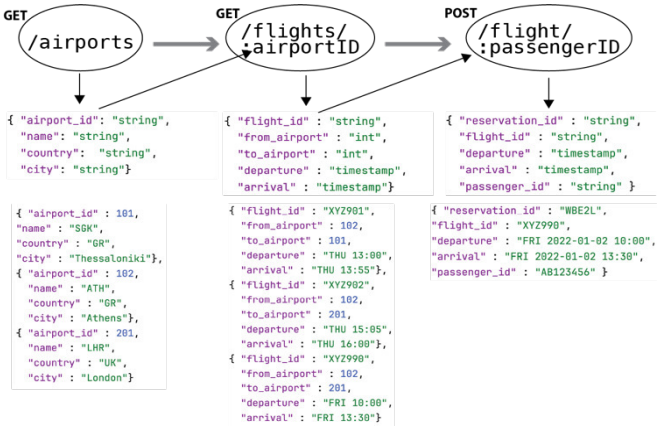

Fig 1. Production and consumption of data in API call sequences

The call to the /airports endpoint returns a list with all available airports, including their identifiers (airport_id). The following call to /flights takes as input, as a path parameter, the id of one of these airports (102, as shown in the example) and returns information about available flights departing from that airport. This is a body-path dependency, as a data element from the response body of the first call is used as a path parameter in the second call.

Subsequently, the /flight endpoint call takes as input, as the request body this time, all the details of one of the flights returned by the second call (the one with id=XYZ990, in the example) along with a path parameter that points to a passenger and performs the booking for that flight and passenger. This represents a body-body dependency, as the request body of the third call requires a data object included in the response body of the second call. Similarly, in body-query dependencies the value of a query parameter comes from a value contained in some attribute of a response body from a previous call. Notably, inter-endpoint dependencies can be identified by more than one attributes.

Examining inter-endpoint dependencies goes beyond typical API documentation by revealing the correct sequences and prerequisites of API calls. This knowledge eases the implementation of requests with valid inputs and helps discover entire paths that indicate the semantically correct order of endpoint invocation. As such, it can accelerate integration with third-party APIs by identifying valid call sequences. In microservice architectures, it also supports—and can even partially automate—the orchestration control flow. Finally, for API developers, it serves as a valuable reference for understanding data flow, maintaining consistency, and onboarding new team members.

This work focuses on the discovery and documentation of API inter-endpoint dependencies by introducing algorithms as well as a tool to discover, analyze, and visualize them using a directed graph, whose nodes represent the API endpoints and each directed edge represents the complete or partial consumption of data returned by the origin, by the destination endpoint.

IV. Discovery of Dependencies

Two approaches are demonstrated for discovering and analyzing inter-endpoint dependencies: static and dynamic, introduced in the diploma theses of Papadeas [9] and Gerokonstantis [10], respectively. The static approach is based on existing API documentation, whereas the dynamic captures and analyzes API calls made during the real-world utilization of the API.

4.1 Static analysis

Static analysis is entirely based on the information included in the API documentation. It aims to identify inter-endpoint dependencies using this documentation (structure, types), which typically contains details about the input and output parameters of each endpoint. The goal is to identify dependencies and generate a directed graph that shows all possible endpoint call sequences.

Static analysis takes its input from any standard API documentation, such as OpenAPI, or even from ad-hoc documentation such as Postman, Apidog[3], Firecamp[4] or other similar tools. It infers the proper sequence of API calls by analyzing the results of pre-executed calls included in the documentation examples. Lack of pre-executed calls and insufficient examples reduces the capability of this analysis to discover dependencies.

In our implementation, static analysis takes its input from a Postman collection to create a representation of the directed dependency graph. The Postman collection comes in as a JSON file that contains information about responses, request body, path and query parameters of each endpoint. The use of Postman collections has been chosen for illustration purposes only: any structured parsable object containing the same data can be used instead, and the results will still rely on the completeness of metadata included in the documentation.

A typical context where static analysis can be performed, is when we have some kind of documentation about an API, and we don't know anything about the proper sequence of endpoint calls or possible use cases of the API. The graph produced by the static analysis helps us get a first view of the API usage flow, as it shows how endpoints relate to each other.

The algorithm of the static analysis takes as input a postman collection file (Algorithm 1). For every endpoint of the API it stores information about its parameters including name, value and type of each parameter in a set named ParametersSet (lines 1-5 Algorithm 1). It also stores the response of each endpoint in a separate set named AttributesSet including the name, value and type of each attribute in the response (lines 6-10 Algorithm 1). Then it proceeds to compare the two sets to discover dependencies (lines 11-12 Algorithm 1).

Each dependency can be identified either by matching the values of parameters with the values of responses exchanged between endpoints in call examples (Algorithm 2), or by matching keys instead (Algorithm 3).

The algorithm compares the two sets to find every pair of attributes and parameters that have the same value (or name, respectively), type and are not part of the same endpoint (lines 1-4 Algorithm 2 and Algorithm 3 respectively). For each case where a match has been identified, a new edge is added to the graph, along with the relevant information regarding the dependent endpoints (lines 5-8 Algorithm 2, 3).

Algorithm 1. Static inter-endpoint dependency analysis

```
 1. Read postman_collection.json as Input
 2.
 3. foreach endpoint in Input do
 4.     foreach parameter in endpoint do
 5.         ADD(parameter(name, value, type)) TO SET
            named ParametersSet
 8.
 9. foreach endpoint in Input do
10.     foreach response in endpoint do
11.         ADD(attribute(name, value, type)) TO SET
            named AttributesSet
14.
15. DependencyGraphByValues(ParametersSet, AttributesSet)
16. DependencyGraphByNames(ParametersSet, AttributesSet)
```

Algorithm 2. DependencyGraphByValues

```
1. Procedure DependencyGraphByValues
2.
3. foreach parameter in ParametersSet do
4.     foreach attribute in AttributesSet do
5.         if parameter.value == attribute.value AND
              parameter.type == attribute.type AND
              endpoint(parameter) != endpoint(attribute)
           then
6.            ADD(dependency(endpoint(parameter),
                      endpoint(attribute)))
              TO LIST named Dependencies
7.
8. return Dependencies
```

Algorithm 3. DependencyGraphByNames

```
 1. Procedure DependencyGraphByNames
 2.
 3. foreach parameter in ParametersSet do
 4.     foreach attribute in AttributesSet do
 5.         if parameter.name == attribute.name AND
 6.            parameter.type == attribute.type AND
 7.            endpoint(parameter) != endpoint(attribute)
           then
 8.                ADD(dependency(endpoint(parameter),
                           endpoint(attribute)))
                   TO LIST named Dependencies
12.
13. return Dependencies
```

The second way of dependency identification, by comparing only the keys of parameters, has been proven to be useful in cases where the collection does not contain many examples of pre-executed calls and there isn't enough information regarding each endpoint. In that case, the only way a dependency could be inferred is by comparing keys between parameters and responses assuming that common keys could also imply dependent values.

Static analysis will usually discover a greater-than-actual number of inter-endpoint dependencies due to common key-value patterns across endpoints. For example, the frequent use of generic keys like "ID" can falsely suggest dependencies between unrelated endpoints. These findings are often hard to evaluate without access to actual API calls or a good understanding of the API's semantics. The goal of this analysis is to

[3] Apidog: API Development Tool - https://apidog.com

[4] Firecamp: Open Source Postman Alternative - https://firecamp.io

identify all possible dependencies, including dependencies which are considered “noise”.

Dynamic analysis

The dynamic analysis takes a different approach, aiming to discover inter-endpoint dependencies without using any kind of documentation. It collects information from HTTP requests and responses, by monitoring actual calls using a "man-in-the-middle" agent that captures HTTP traffic. The API traffic is logged and then the extraction of inter-endpoint dependencies is possible. Notably, this method follows a reverse engineering approach, analyzing already implemented but still undocumented APIs, to infer inter-endpoint dependencies.

Dynamic analysis also identifies all types of dependencies, just as static analysis does. However, in the case of body-path dependencies, since it is unclear which segments of a URL correspond to path parameters, the algorithm treats all URL segments as such. This allows it to identify the corresponding dependencies, introducing minimal noise.

In cases where the API is consumed through a web frontend, API calls can be captured by executing use cases while interacting with the frontend in a browser. In the context of an API ecosystem implementing orchestration, as in a microservices architecture, it is possible to capture API calls as part of the interaction between the orchestrator component and the internal components of the architecture.

In any of the approaches mentioned above, to capture the HTTP traffic resulting from real-world interactions with the API, a "mediator" is required, that can be implemented in several ways, such as the following:

1. a standalone mediator component to which API calls would be directed, responsible for forwarding the requests to the API server, returning the responses to the client, and recording information about the API calls; such a system was implemented in the context of this paper,

2. a browser extension that captures the incoming and outgoing traffic between the browser and the API while the user navigates through the User Interface interacting with the API,

3. an internal component within API Gateways, enabling the collection of multi-client data derived from the interactions of multiple external entities with the API.

Similar to the static method, the outcome of the dynamic analysis is a directed dependency graph of the same type. The input is a log file generated by the mediator, which contains information about the executed API calls.

The dynamic analysis algorithm comprises two main components: the parsing of the log file and extraction of value-specific information (Algorithm 4), and the identification of matches among the extracted values (Algorithm 5). Specifically, Algorithm 4 processes the input log file, assigns a sequence number to each API Call reflecting its execution order within the use case it belongs to, and constructs two dictionaries, REQUEST_VALUES and RESPONSE_VALUES, which store information about every value encountered in API request and response messages respectively. For each identified value, the dictionaries record the associated API call’s URL and sequence number, the identifier ("tag") of the corresponding use case, the value’s name, and its inferred data type.

The dictionaries constructed in Algorithm 4 serve as inputs to Algorithm 5, which is responsible for identifying matches between values appearing in request and response messages. Specifically, for each value V found in the response body of an API call RES, the algorithm examines whether V also appears as a request parameter (of any type) in any subsequent API calls (REQ_1, REQ_2, ..., REQ_n) within the same use case.

If such matches are found, the algorithm adds a directed dependency edge from RES to each matching REQ_i, provided the following conditions are met:

- the data type of V matches in both RES and REQ_i, as determined by type inference,
- RES and REQ_i correspond to distinct API endpoints, and
- REQ_i occurs after RES in the execution order of the use case.

Algorithm 4. Dynamic inter-endpoint dependency analysis

```
1. Initialization: Assign sequence numbers to the
   calls of every use case
2.
3. foreach call in Input do
4.     if call.body then
5.         foreach parameter in call.body do
6.             REQ_VALUES[parameter.value].APPEND({
7.               url: call.url, seq: call.sequence_number,
8.               tag: call.tag, paramName: parameter.name,
9.               paramType: parameter.type})
10.
11.    if call.response then
12.        foreach attribute in call.response do
13.            RES_VALUES[attribute.value].APPEND({
14.              url: call.url, seq: call.sequence_number,
15.              tag: call.tag, attrName: attribute.name,
16.              attrType: attribute.type})
17.
18. ComputeDependencyGraph(REQ_VALUES, RES_VALUES)
```

Algorithm 5. ComputeDependencyGraph

```
1.   Procedure ComputeDependencyGraph
2.     foreach value in RES_VALUES do
3.       if value in REQ_VALUES then
4.         foreach appearRes in RES_VALUES[value] do
5.           foreach appearReq in REQ_VALUES[value] do
6.             if appearRes.paramType ==
                  appearReq.paramType and
7.                appearRes.url ≠ appearReq.url and
8.                appearRes.seq < appearReq.seq and
9.                appearRes.tag == appearReq.tag
10.            then
11.            DEPENDENCY_GRAPH[
                      (appearRes.url, appearReq.url)
               ].APPEND({
12.              fromAttribute: appearRes.paramName,
13.              toAttribute: appearReq.paramName
14.            })
```

A key difference from the static method is that dynamic analysis restricts comparisons to subsequent API calls of the same use case, focusing on the dependencies most likely to be semantically correct within the context of the specific API.

While dynamic analysis can generate dependency documentation even for completely undocumented APIs, it also has several challenges, with the primary one being that the discovery of all dependencies requires the execution of calls between all dependent endpoints, which may not occur during the logging.

For visualizing the resulting dependency graph, a tool named RADAR[5] (REST API Dependencies and Analysis of Relationships) was implemented [11] and is available at radar.softlab.ntua.gr. RADAR takes as input either the Postman Collection of the API or a log file containing records of actual API calls, for static and dynamic analysis, respectively. After the user configures certain analysis parameters, RADAR performs either static or dynamic analysis to detect inter-endpoint dependencies, and generates a directed dependency graph, as discussed above.

V. Case Study

The two dependency analysis methods were applied, among others, to the PayPal API sandbox environment[6].

The PayPal API provides a wide range of functionalities, including the creation and management of products, orders, invoices, subscriptions, payments, and disputes. The complexity and size of such an API necessitate conducting dependency analysis to facilitate and guide its utilization. Below, we examine how static and dynamic inter-endpoint dependency analysis can assist a user of this API in creating and tracking a product order.

Static

For static analysis, we supply RADAR with the Postman Collection of the PayPal API[7], as downloaded from the Postman Public API Network, without any modifications. The section of the resulting dependency graph including endpoints related to product orders is shown in Fig 2 below. While the identified dependency path facilitates the process of creating an order and handling the payment, it lacks details regarding order tracking. Static analysis was unable to identify dependencies between the tracking endpoints and the others in the graph, as the examples in the Postman Collection were not adequate. Additionally, the static analysis graph contains some edges that are either redundant for executing the specific use case or even semantically incorrect.

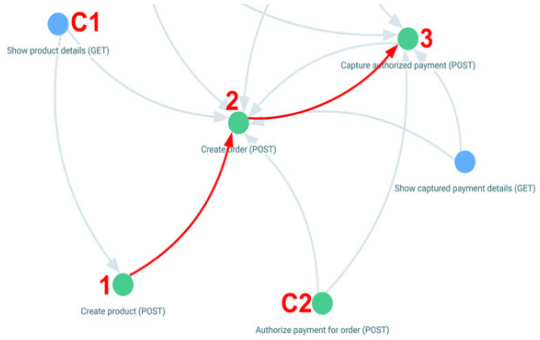

Fig 2. Order creation and tracking use case - Static dependency graph

For instance, displaying product details before creating a new product (Fig 2, edge C1→1) offers no practical value in the context of the "order management" use case, while authorizing a payment for an order before the order itself has been created, as the graph suggests (Fig 2, edge C2→2), seems not correct and should rather be classified as noise. As demonstrated below, dynamic analysis mitigates these issues.

Dynamic

Dynamic analysis involves logging interactions with the API relevant to product orders. To do this, we set up an example use case, in which we begin by creating/updating a product and generating an order for this. After that, we initiate the payment process by authorizing and capturing the payment, and conclude by adding tracking information for the order. This sequence is illustrated in Fig 3.

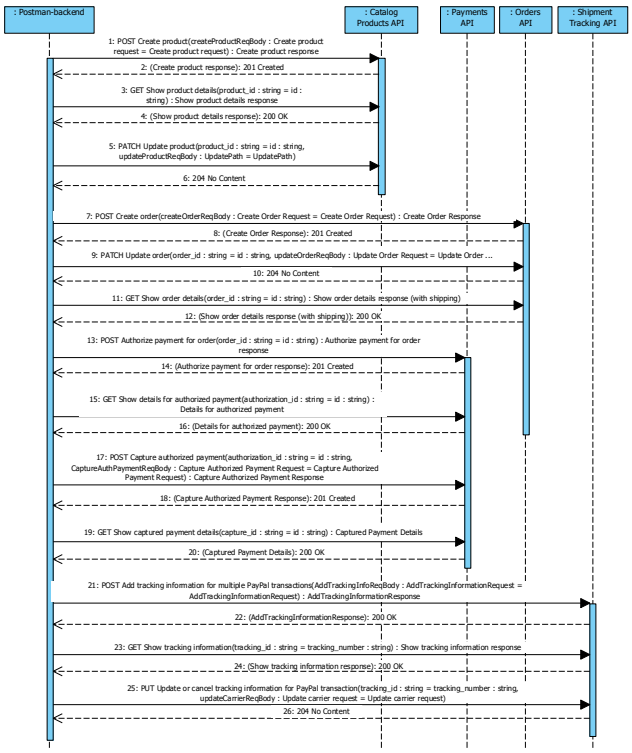

Fig 3. Order creation and tracking use case - sequence diagram

The dependency graph resulting from the dynamic analysis of the log file for this use case is shown in Fig 4, where API calls are enumerated based on their numbering in the sequence diagram above, and a key dependency path is highlighted.

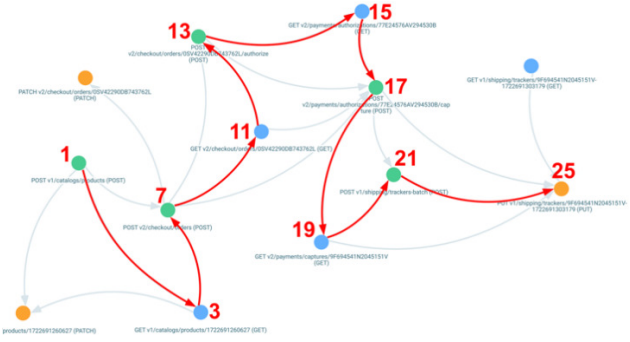

Fig 4. Order creation and tracking use case - dynamic dependency graph

[5] R.A.D.A.R by NTUA Softlab: https://radar.softlab.ntua.gr
[6] PayPal REST APIs: https://developer.paypal.com/api/rest (date accessed: 05/2024)
[7] PayPal API Postman Collection (date accessed: 05/2024): https://www.postman.com/paypal/paypal-public-api-workspace/overview

The highlighted dependency path can be traced back to the reference use case sequence diagram, providing the API user with guidance on how to use the API to implement the logic of the "order management" use case.

Specifically, the generated graph guides the user to first create a product and optionally retrieve information about it (calls 1, 3), then create an order for this product and possibly retrieve relative details (calls 7, 11), authorize and capture the payment (calls 13–19), and finally add and potentially update tracking information (calls 21, 23). In contrast to static analysis, the dynamic dependency graph proved to be more comprehensive while avoiding misleading edges.

VI. Discussion

Like all software documentation, API documentation must be complete, detailed, and kept up to date to support communication among technical staff and stakeholders. As APIs play a central role in software integration, better documentation leads to more efficient development and fewer errors and backtracks.

This work aims to enhance API documentation by adding information on data producers and consumers among endpoints, representing their dependencies. Such an "endpoint dependency graph" helps developers better understand and integrate complex third-party or in-house APIs. We propose two methods to identify these dependencies based on available documentation and runtime access, providing a roadmap to accelerate API integration.

The effectiveness of static analysis in identifying dependencies relies on the information in the API's static documentation, particularly the examples included. On the other hand, the effectiveness of dynamic analysis in the same task depends on the extent to which the executed use cases cover a broad range of the API's functionalities, theoretically all of them.

Generally, the dynamic approach produces less, yet not zero, noise, particularly in body-path dependencies derived from URL segments that are not actually path parameters. In static analysis, which runs exhaustive comparisons between every pair of endpoints, noise is created by ambiguities that do not allow to filter out irrelevant dependencies.

Overall, considering the statistics derived from the results of the two analyses across several APIs—including the OpenAI API and the previously examined PayPal API—we observe that dynamic analysis detects fewer edges in the generated graph: 52 vs. 92 for OpenAI and 209 vs. 724 for PayPal. Furthermore, dynamic analysis identifies more dependent attributes for each edge, offering a deeper understanding of how two endpoints are interdependent. For example, for the OpenAI API, an average of 1.22 dependent attributes per edge was found in the static analysis and 2.53 in the dynamic analysis, while for the PayPal API, 2.13 dependent attributes per edge were found in the static analysis and 14.19 in the dynamic analysis.

Considering the limitations of each method, as well as the conclusions drawn from their comparative study and application to the API examined, it becomes clear when each method is most suitable: when any static documentation such as a Postman Collection with enough examples is available, dependency documentation for the API can be generated using static analysis. When logging is possible, dynamic analysis can offer higher accuracy and completeness of the results in the context of the observed use cases, but at the cost of greater effort that comes with logging. RADAR supports both methods and although it has space for improvement, it produces useful data and visualizations of inter-endpoint API dependencies.

***Abstract*—We present a novel multi-stage method for colour image segmentation, with a primary focus on vessels segmentation in retinal fundus images, using a U-Net based architecture. Our approach tackles challenges posed by varying image resolutions through a coarse-to-fine segmentation pipeline. It begins with a rough segmentation at varying scales, guided by a traditional CNN and progressively refines results to find a target resolution. It culminates with detailed segmentation at a target scale with a smaller window sliding step, compared to previous stages. We train and validate our method using four publicly available datasets FIVES, DRHAGIS, HRF, and STARE - and demonstrate superior performance compared to traditional sliding window techniques. Notably, our model achieves high accuracy with relatively few training images. The entire framework is open-sourced and adaptable to a wide range of image segmentation tasks.**

***Index Terms*—U-Net, segmentation, deep learning, vessel segmentation, medical imaging, fundus images**

I. Introduction

THE process of image segmentation has been for many years a challenge, that was only partially solveable. This changed with an advent of deep learning and introduction of convoutional neural networks. In the year 2012 Krizhevsky et al [1] introduced ImageNet, which achieved a new level of image recognition accuracy. It won the ImageNet competition that year, and inspired a plethora of other researchers to improve upon it. This milestone in image classification allowed a development of new class of segmentation algorithms.

One of the challenges in research was to segment biomedical images. It was partially solved by Ronneberger et al. [2] by introduction of *U-Net* architecture. The *U-Net* is designed to work with very few training images and to yield more precise segmentations. It consists of a contracting path to capture context and a symmetric expanding path that enables precise localization. However it comes with drawbacks, such as sensitivity to input image resolution and segmentation window position, and high demand for GPU memory which is limiting the segmentation window size (*WS*).

In this article, we address challenges in image segmentation by proposing a multi-step framework for training a *U-Net* adaptable to varying image resolutions. We evaluate segmentation results at multiple scales to select the most effective output and analyze how resolution affects performance when the model is applied at different scales. We also assess the annotation effort required to achieve satisfactory results. Experiments on four public vessel segmentation datasets enable us to test how well a *U-Net* trained on one dataset generalizes to others.

The article has six chapters. The first introduces the topic. The second reviews recent work on *U-Net* segmentation in medical imaging. The third explains our approach with illustrations. The fourth describes our experiments and results. The fifth highlights key findings. The final chapter states there are no competing interests.

The main contributions of this work are:

- A multi-scale rough segmentation step that processes images at multiple predefined scales using a sliding window approach.
- A *CNN*-based scoring mechanism that selects the optimal segmentation scale for each image based on predicted segmentation quality.
- Experimental validation of cross-dataset generalization, demonstrating that models trained on one dataset can perform well on others.
- An analysis of how the number of training images affects segmentation quality, providing insight into the annotation effort required for satisfactory performance.
- An open-source implementation of the method, available on GitHub [3].

II. Related works

Ren et al. [4] proposed an improved *U-Net*-based method for retinal vessel image segmentation, enhancing the original architecture to achieve greater accuracy and robustness. Their improvements include modifications to both the network structure and the training process. Liu et al. [5] introduced a three-path *U-Net* model for retina image segmentation, which leverages multiple pathways to capture features at different levels, resulting in improved segmentation performance. Das et al. [6] evaluated the performance of the standard *U-Net* for retinal blood vessel segmentation, confirming its effectiveness for this task. Yun et al. [7] proposed a Multi-Path Recurrent *U-Net* for segmenting retinal fundus images, incorporating both multiple paths and recurrent units to enhance feature extraction. Similarly, Huang et al. [8] developed an improved *U-Net* architecture based on residual modules, achieving increased

Topical area: Advanced Artificial Intelligence in Applications

robustness and better segmentation results in retinal vascular images.

Many existing studies aim to enhance the performance of *U-Net* across a range of applications. A common theme among these efforts is the focus on segmenting disconnected or localized objects [9], often overlooking use cases like vessel segmentation, where structures are continuous and span the entire image. Additionally, relatively few works address the challenge of handling images with varying resolutions - a critical factor in real-world medical imaging scenarios. Notably, many proposed improvements to *U-Net* result in only marginal performance gains, typically in the range of 1–2% absolute accuracy, as the original *U-Net* already performs strongly, often achieving over 95% accuracy under favorable conditions.

III. Methodology

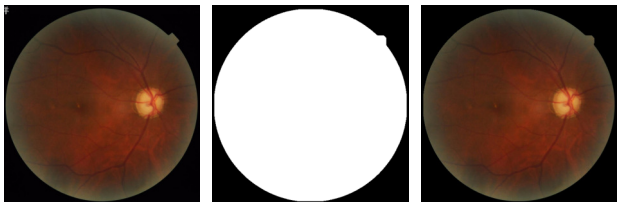
In recent years, numerous high-quality datasets for fndus eye images (*FEI*) were published. We selected four publicly available datasets for our experiments: *FIVES* [10], consisting of 1,200 images with a resolution of 2048×2048 pixels; *DRHAGIS* [11], containing 80 images at 4752×3168 pixels; *HRF* [12], which includes 45 images at 3504×2336 pixels; and *STARE* [13], from which we used 20 images at 700×605 pixels resolution.

A. Training data preparation

In preparing data for *U-Net* training, it is essential to extract square windows (ideally with dimensions of 2^n) from the input images. These windows are then fed into the training pipeline to iteratively refine the model's performance. Although *U-Net* is known for its efficiency and accuracy under favorable conditions, a significant challenge lies in determining which parts of the image should be selected for training.To address this challenge, several key questions must be considered:

- Which locations should be chosen to ensure that windows cover both object and background regions effectively?
- How many windows should be sampled from each image?
- How many of these windows should predominantly contain the object of interest, and how many background?

Below, we present our approach to answering the forementioned questions by constructing a mechanism for automatic data generation. We use the *FIVES* dataset [10] as the primary input for training the *U-Net* model. The original dataset, consisting of 1,200 images, is divided into two subsets. The first subset, referred to as the *U-Net* Main Training Set (*UNETMTS*), includes 900 images and is used for model training. The second subset, called the *U-Net* Segmentation Validation Set (*UNETSVS*), comprises the remaining 300 images and is used to validate segmentation performance.



1) Mask finding: Each image is processed as follows:

1) Convert from RGB to grayscale.
2) Compute a threshold:

$$\text{threshold} = \frac{\text{mean}(\text{grayscale_image})}{3} - 5$$

and binarize to generate a mask.
3) Apply flood fill from all four corners to produce an additional mask.
4) Combine the two masks by pixel-wise summation.
5) Apply erosion and dilation with a 20×20 kernel.

Finally, the mask is applied via logical AND operation. Pixels within its outer layer are blacked out; others remain unchanged (see Fig. 1).

(a) Input image (b) Mask (c) Masked image

Fig. 1. Image Masking Results

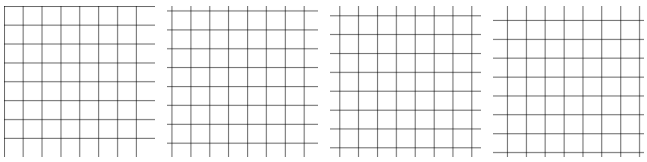
After the mask is generated, the image is trimmed from the left, right, top, and bottom edges to ensure that no completely black vertical or horizontal lines remain.

2) Random windows: The initial set, *UNETMTS*, is reduced to a specified value referred to as *TRDTSZ* (training data size), which is initially set to 900. However, this value is varied and analyzed in later sections of this article (see Section IV) to investigate whether the full set of 900 images is necessary, or if smaller subsets can still yield high segmentation accuracy. The goal is to investigate how much training data the *U-Net* model requires to achieve optimal results. Once the value of *TRDTSZ* is selected, *UNETMTS* is randomly divided into two subsets: a training set (*DPSTR*) and a test set (*DPSTS*), using a 75% to 25% split.

From each image, a set of training windows is randomly sampled. Two types of windows are defined: object-type windows (*OBTW*) and background-type windows (*BKTW*). A window is classified as *OBTW* if the number of pixels corresponding to the ground truth label exceeds a minimum threshold (e.g., 15%). Conversely, a window is labeled as *BKTW* if the proportion of object pixels does not exceed a maximum threshold (e.g., 5%). We also define target ratio of object to background windows per image (e.g., 50%), to ensure a representative sampling that reflects typical pixel distribution between object and background regions in *FEI*.

The underlying motivation for this windowing strategy is to balance object and background representation during training. This balance is reinforced by employing a weighted binary cross-entropy loss function in the *U-Net* implementation, which helps to address class imbalance. The size of each sampled window (*WS*) is typically set to either 64×64 or 128×128 pixels. Input images are rescaled after mask generation to 512×512 pixels. Larger values of *WS* and image resolution significantly increase GPU memory consumption - an important consideration given that our hardware setup was a GPU with only 8GB of memory.

The percentage values used in this step are based on intuition and can be adjusted depending on the type of images, particularly when the ratio of object pixels to background pixels varies. For instance, these values would differ when segmenting structures such as the eye cup (*EC*) or optic disc (*ED*) in other *FEI* datasets. The goal of this strategy is to capture a wide range of spatial arrangements of the target object within randomly selected windows, thereby enriching the training dataset for the *U-Net* model used in later stages of the system.

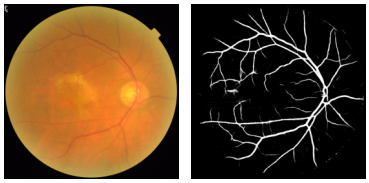


B. U-Net network training

The windows extracted in Section III-A are grouped into training batches, with a predefined number of epochs and a selected (*WS*) that matches the input dimensions of the *U-Net* model. The input windows, referred to as *X* windows, consist of RGB channels, with pixel values normalized to the range [0, 1]. The corresponding output windows *Y* windows, represent the segmentation masks, and are converted into binary image.

C. U-Net preliminary multi resolution segmentation

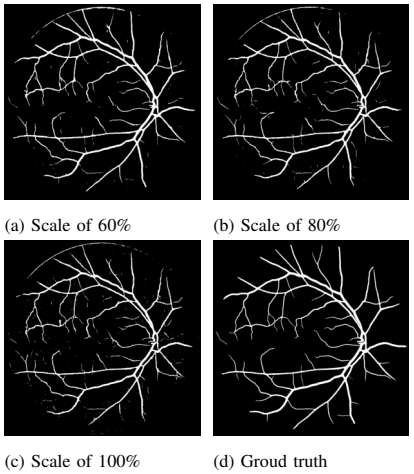
This step begins with a rough segmentation step (*RSS*). Input image is scaled to a resolution of 512×512, then segmented using a sliding window technique. Its primary goal is to produce preliminary segmentation results which are passed to the next stage Section III-D, where a dedicated *CNN* model is trained how to evaluate segmentation result.



1) Windows mesh creation: Once the image has been prepared for segmentation - by generating a mask as described in Section III-A1 - it typically contains a black border surrounding the scene, with the retina centered. This preprocessed image is then analyzed across three color channels: red, green, and blue. Each color channel is divided into a collection of meshes (i.e., image patches) by sliding a window across the image. Mesh extraction begins with an offset of 0 and proceeds up to $WS - 1$, using a predefined sliding step denoted as *SS*. While it is not required for $WS \bmod SS = 0$, it is essential that $SS < WS$ to ensure overlapping patches and continuous coverage of the entire image. The idea of meshes is shown in Fig. 2

(a) Offset 0 (b) Offset 32 (c) Offset 64 (d) Offset 96

Fig. 2. Sample meshes generated for an image of size 1024×1024 pixels, *WS* of 128×128 pixels, and *WSS* set to 32



Each mesh allows the input image to be segmented using a different window configuration. This approach is crucial for capturing diverse spatial variations within the image, as each mesh is processed independently by the trained *U-Net* model. For each mesh, the *U-Net* generates a probability map, assigning to each pixel the likelihood of belonging to the object or background. Due to overlapping meshes, a single pixel may appear in multiple segmentations, resulting in multiple probability estimates. These values are averaged to generate a heatmap, which represents the overall likelihood of each pixel being part of the object. In this heatmap, brighter pixels correspond to higher confidence in object presence. Finally, the heatmap is binarized using a fixed threshold of 127, producing a black-and-white segmentation mask. An example of this process is shown in Fig. 2, where four meshes contribute to the heatmap visualized in Fig. 3. This method is referred to as the Sliding Window Algorithm (*SWA*).

(a) Input image (b) Pre binarization heatmap

Fig. 3. Input image from [10] along with generated heatmap

2) Data preparation for CNN training: As described in Section III-A, the main dataset [10] was partitioned to include a subset named *UNETSVS*, which is used for training the *CNN* in the subsequent evaluation stage. All images in this subset are processed through the (*RSS*). We perform segmentation at multiple scales, ranging from 20% to 100% of the original image size, in increments of 10%. This produces a series of black-and-white segmentation outputs for each image at varying resolutions. Figure 4 presents the segmentation results for three selected scales: 60%, 80%, and 100%. It is apparent from the visual comparison that the quality of the segmentations varies significantly across different scales.

(a) Scale of 60% (b) Scale of 80%

(c) Scale of 100% (d) Groud truth

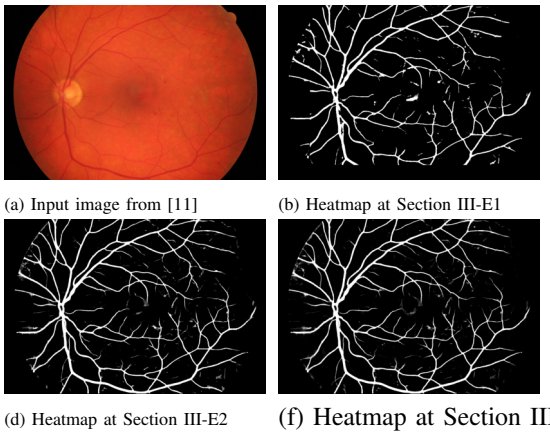
Fig. 4. Different scales of input image for *CNN* segmentation assessment training

To objectively assess which of the segmentation results is most optimal, we design and train a simple *CNN*-based scoring network. This network consists of a single output neuron that produces a score between 0 and 1, where 0 indicates the

poorest segmentation quality and 1 indicates the best (see Fig. 7). The trained *CNN* is employed in the final segmentation stage, as described in Section III-E.

D. CNN training for segmentation results assessment

Using the *UNETSVS* set, we segment each image into nine black-and-white binarizations, producing a total of $300 \times (9 + 1) = 3000$ samples for training the *CNN*. The additional term in the formula accounts for the ground truth image (*GT*), which serves as the expected output from the segmentation algorithm. This ground truth image is also used to compute the Jaccard index [14], which measures the similarity between the segmented output and its corresponding *GT*. The index yields a value between 0 and 1, where 0 indicates a completely incorrect segmentation and 1 indicates a perfect match. The *CNN* architecture used for evaluation consists of a simple stack of convolutional layers, followed by batch normalization and pooling layers. Once the *CNN* scorer is trained, it can be used to evaluate and select the most accurate segmentation result. This final decision-making step is carried out as described in Section III-E.



E. Optimal segmentation step

The final segmentation comprises of three stages.

1) Rough stage of final segmentation: The final segmentation algorithm builds upon the approach described in Section III-C. We continue to perform the Rough Segmentation Step (*RSS*), but in this phase, segmentation is carried out at scales ranging from 20% to 100%, with a step size of 20%. From the five resulting segmentation candidates, the one deemed most accurate by the trained *CNN* (introduced in Section III-D) is selected as the final output. The scale at which this optimal segmentation occurs is referred to as the *RSOR*. It is important to note that for smaller images (up to 800×800 pixels), we increase the maximum scale to 150%. This adjustment accounts for the fact that *U-Net* may underperform when operating on very low-resolution inputs.

2) Detailed stage of final segmentation: The *RSOR* ratio plays a crucial role, as it serves as the starting point for the subsequent stage, known as the Detailed Segmentation Step (*DSS*). This step further refines the search for the optimal segmentation scale. Specifically, segmentation is performed at scales ranging from $RSOR - 10\%$ to $RSOR + 10\%$, using a step size of 4%. As before, the trained *CNN* from Section III-D is used to evaluate the quality of each segmentation. The scale identified as producing the best result is referred to as the *DSOR*.

3) Most detailed stage of final segmentation: With the *DSOR* ratio now established, we proceed to the Most Detailed Segmentation Step (*MDSS*). In this final stage, the input image is rescaled according to the selected *DSOR* value. Unlike in Section III-C, where the window sliding step (*SS*) was set to 64, we now adopt a finer step size of 32 to enhance segmentation precision. The results of this final segmentation step, applied to a sample image from the *DRHAGIS* dataset [11], are shown in Figure 5. It is important to note that both the binarized segmentation outputs and the probability heatmaps, originally generated at the scaled resolution, are rescaled back to the original image dimensions for consistency and visualization.

(a) Input image from [11] (b) Heatmap at Section III-E1

(d) Heatmap at Section III-E2 (f) Heatmap at Section III-E3

Fig. 5. Input image from [11] along with generated heatmaps at 3 different stages with *SS* at 128, 64 and 32

All configuration parameters associated with window size (*WS*), sliding step (*SS*), and the scale percentages used for segmentation are fully adjustable by the user of the implementation provided in [3]. In Section IV, we present a series of experiments evaluating segmentation accuracy using the Jaccard Index across a dataset composed of three sources: *DRHAGIS* [11], *HRF* [12], and *STARE* [13]. This dataset is referred as the Combined Validation Dataset (*CVDS*).

IV. Experiments

In our experiments, we aimed to evaluate how well the proposed approach generalizes when a *U-Net* model trained on one dataset is applied to a completely different dataset.

We conducted a total of three experiments:

1) In the first experiment, both the *U-Net* and *CNN* models were trained on 100 randomly selected images from the *FIVES* dataset [10]. The trained models were then tested on the Combined Validation Dataset (*CVDS*), which consists of 150 images.
2) In the second experiment, 900 randomly selected images from the *FIVES* dataset were used to train both the *U-Net* and *CNN* models.
3) In the third experiment, we used the same *U-Net* model trained in the first experiment, but applied a naive Sliding Window Algorithm (*SWA*), as described in Section III-C.

The purpose of these experiments was to assess whether the full pipeline, outlined in Sections III-A through III-E, achieves superior segmentation performance compared to the traditional Sliding Window Algorithm (*SWA*). The central hypothesis is that identifying an optimal resolution, at which the *U-Net* model performs best for each individual image, leads to more accurate segmentation results then applying the model directly, at a fixed resolution in a brute-force manner. The *U-Net*

architecture used for segmentation is shown in Figure 6. As illustrated, the structure is simplified compared to the original version proposed in [2]. The accompanying *CNN* (Figure 7) was designed to be lightweight.

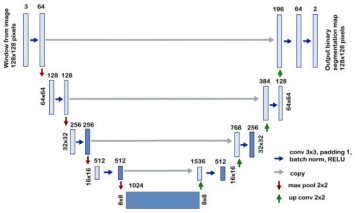


Fig. 6. *U-Net* used across all segmentation stages

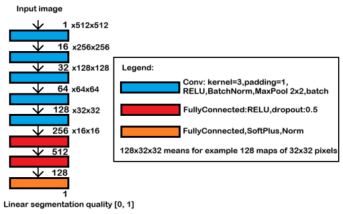

Fig. 7. *CNN* used for segmentation quality assessment

A. First experiment

In the first experiment we randomly selected 100 images from *FIVES* dataset. Results are shown in Table I.

TABLE I
EXPERIMENT 1 WITH JACCARD METRICS AND *TTE* FOR VARIOUS PARAMETER SETTINGS OF *WSS*.

RWSS	DWSS	OWSS	TTE	AJI	MNJI	MXJI
128	128	16	3316	0.6114	0.2722	0.7705
128	16	8	53107	0.6123	0.2823	0.7672
128	16	16	5641	0.6145	0.274	0.7650
128	32	8	10527	0.6148	0.2713	0.7672
128	64	8	3822	0.6147	0.2722	0.7705
128	**64**	**32**	**2704**	**0.6125**	**0.2714**	**0.7694**
128	**64**	**8**	**12877**	**0.6153**	**0.2713**	**0.7713**
16	16	8	35212	0.6078	0.2823	0.7570
16	32	8	18842	0.6089	0.2823	0.7570
16	64	8	7653	0.6097	0.2823	0.7516
32	32	8	14048	0.6082	0.2823	0.7436
32	64	8	11784	0.6099	0.2823	0.7516
64	16	8	16839	0.6137	0.2823	0.7649
64	16	16	5627	0.6147	0.2829	0.7634
64	32	8	9680	0.6151	0.2819	0.7665
64	32	16	4091	0.6153	0.2819	0.7668
64	64	8	7938	0.6143	0.2823	0.7601

The common parameters selected for the segmentation process are as follows:

- Minimum rough segmentation scale: 20%,
- Maximum rough segmentation scale: 100%,
- Rough segmentation scale step: 20%,
- Rough segmentation range for optimal resolution: $\pm$10%,
- Detailed segmentation range for optimal resolution: $\pm$4%.

The meanings of the column headings used in the evaluation tables are:

- *RWSS*: Rough Segmentation Window Step,
- *DWSS*: Detailed Segmentation Window Step,
- *FOWSS*: Final Optimal Window Step for Segmentation,
- *TTE*: Total Time Elapsed (in seconds),
- *AJI*: Average Jaccard Index,
- *MNJI*: Minimum Jaccard Index,
- *MXJI*: Maximum Jaccard Index.

The highest achieved *AJI* was 0.6153; however, this result came at the cost of a total time elapsed (*TTE*) of 12,877 seconds. In contrast, the fastest configuration, with a *TTE* of just 2,704 seconds, was obtained using the parameters *RWSS* = 128 pixels, *DWSS* = 64 pixels, and *FOWSS* = 32 pixels. This setup yielded an *AJI* of 0.6125, which is only marginally lower than the best result. As such, it represents a significantly more efficient trade-off between segmentation accuracy and computational performance.

B. Second experiment

In the second experiment we randomly selected 900 images from *FIVES* dataset. Exactly the same experiments in terms of values for **RWSS**, **DWSS** and **OWSS** were conducted and can be previewed in details in [3].

The best achieved *AJI* in this experiment was 0.5957, obtained with a total time elapsed (*TTE*) of 8,320 seconds. The fastest configuration, with a *TTE* of just 6,208 seconds, was achieved using the parameters *RWSS* = 128 pixels, *DWSS* = 64 pixels, and *FOWSS* = 32 pixels. However, this setup yielded an *AJI* of only 0.5813, which is noticeably lower than the optimal value. This indicates a trade-off between speed and accuracy, with the faster configuration sacrificing some segmentation performance.

C. Third experiment

In the third experiment we decided to try and apply only a part of the Section III-E3. We specified the *SS* to values of 8, 16, 32, 64 and 128. You can see the segmentation results in Table II. The results in this experiment are notably inferior to those presented in Section IV-A. The best outcome observed corresponds to *SS* of 8, resulting in *TTE* of 24,227 seconds and *AJI* of 0.5639. While this approach demonstrates high execution speed for *SS* values ranging between 32 and 128 pixels, the resulting *AJI* scores remain unsatisfactory. In contrast, the fastest configuration from Section IV-A achieved an *AJI* of 0.6125, clearly demonstrating the superiority of the hybrid approach described in this article over the traditional *SWA*-based method.

V. CONCULSIONS

The experiments conducted in this article reveal several notable observations regarding the proposed *HUS* algorithm:

- When using only 100 training images from the *FIVES* dataset [10], we achieved a higher accuracy of 0.6153 compared to 0.5957 obtained with 900 training images. This suggests that in Section IV-B, the *U-Net* and *CNN*

TABLE II

models may have become overly specialized to the training data, resulting in decreased generalization to the test set.

- In Experiments IV-A and IV-B, we demonstrated that the hybrid method outperforms the classic *SWA* approach by nearly 0.05 in *AJI*, while maintaining comparable execution speeds.
- Our experiments with *HUS* also indicate that high values of the sliding step (*SS*) are not necessarily critical for achieving optimal performance. The results suggest a possible correlation between hierarchical window sizes. Specifically, for a window size of 2^n, typically associated with the first convolutional layer of *U-Net*, the following configuration yields strong results: $RWSS = 2^n$, $DWSS = 2^{n-1}$, and $FOWSS = 2^{n-2}$.

The *HUS* algorithm [3] effectively addresses limitations associated with traditional *U-Net* segmentation:

- The requirement for training and test datasets to have similar resolutions.
- The substantial memory consumption of *U-Net* when processing high-resolution images.
- The sensitivity of classical *U-Net* to variations in the spatial location of the target object.

***Abstract*—Urban air pollution poses severe health risks, demanding accurate monitoring and exposure-reducing solutions. Low-cost air quality sensors (LCS) provide high spatial resolution but suffer from accuracy limitations that hinder their reliability. This paper presents the AIQS project (AI-enhanced air quality sensor for optimizing green routes), an ongoing initiative that combines artificial intelligence, sensor hardware optimization, and pedestrian routing innovation to address these challenges. AIQS applies machine learning techniques, including Multilayer Perceptrons and fuzzy logic, to correct sensor readings. In parallel, hardware-level optimizations, such as fluid dynamics simulations and pre-treatment modules, are explored to enhance sensor performance. The corrected AQ data is then incorporated into a configurable routing tool capable of estimating pollutant exposure and computing low-exposure pedestrian paths in urban environments. First evaluations, shows that our correction models achieve up to 0.92 R^2 against reference data across diverse urban environments. The corrected data drives a configurable routing tool that computes paths minimizing cumulative pollution exposure while balancing user preferences (e.g., proximity to green spaces). Preliminary validation in Modena, Italy demonstrates viable "green routes".**

***Index Terms*—Air quality monitoring, Low-cost sensors, Artificial Intelligence, Machine Learning, Data correction, Fuzzy logic, Green routing, Urban mobility, Pollution exposure.**

I. Introduction

URBAN air pollution remains one of the most pressing environmental health risks worldwide, contributing to respiratory illnesses, cardiovascular diseases, and premature deaths, particularly in densely populated areas [1]. Monitoring air quality (AQ) is therefore crucial for supporting mitigation strategies and informing public health interventions. In recent years, low-cost air quality sensors (LCS) have emerged as a promising tool for expanding AQ monitoring coverage, especially in urban environments where spatial resolution is key [2]. However, despite their affordability and ease of deployment, LCS suffer from significant limitations, including low measurement accuracy, susceptibility to environmental conditions such as humidity, and a lack of standardized calibration procedures [3].

To address these challenges, data correction algorithms have been introduced to improve the accuracy of sensor measurements, with growing interest in applying artificial intelligence (AI) and machine learning (ML) techniques to this task [4], [5]. Concurrently, urban navigation systems are increasingly being explored as tools for reducing human exposure to pollution by suggesting "green routes"—paths that prioritize air quality rather than shortest time or distance [6]. Yet, these systems are only as reliable as the data they consume; inaccurate AQ measurements from low-cost sensors risk undermining the effectiveness of health-oriented routing recommendations.

In this paper we present the AIQS project (AI-enhanced air quality sensor for optimizing green routes) that directly addresses this gap by combining hardware improvements, AI-driven data correction methods, and routing algorithm integration to enhance the trustworthiness and usability of AQ data in real-world applications. Building upon the open-source MitH framework for humidity correction [5], the project aims to raise the technology readiness level (TRL) of the solution to TRL 7, demonstrating its applicability across various urban environments through partnerships with environmental agencies and industrial stakeholders. In doing so, AIQS represents a comprehensive, interdisciplinary effort to bring together environmental sensing, machine learning, and human-centered navigation in support of healthier, more sustainable cities.

The paper is structured as follows. Section II reviews existing approaches to improve the accuracy of LCS through AI-driven data correction techniques and discusses urban navigation systems designed to reduce exposure to air pollution. Section III presents the integrated strategy of the AIQS project, that combines AI-based data correction, hardware optimization, and pollution-aware routing. Section IV reports preliminary results from data correction experiments highlighting improvements in sensor accuracy achieved through transformer-based models and validating the approach across multiple datasets from both Italian and international sources,

moreover the pollution-aware routing system and an evaluation in a real urban context is shown. These findings support the development of health-conscious routing systems within the broader vision of sustainable smart cities. Finally, Section V offers concluding remarks and suggests directions for future work.

II. Related Work

A. AI for Air Quality

Recent advances in ML for air quality monitoring have demonstrated promising approaches to enhance low-cost sensor accuracy. Hybrid models combining multiple algorithms consistently outperform single-technique approaches for AQI prediction [7], while neural networks have shown significant improvements in PM10 calibration [8]. Practical implementations of end-to-end IoT pipelines for sensor data acquisition and cleaning have also been demonstrated in real-world deployments [9].

For short-term forecasting, deep learning models like LSTM have proven to be effective when integrated with meteorological data. Arsov et al. [10] showed that LSTM networks outperform traditional ARIMA models for PM_{10} prediction (+3 hours) with MSE as low as 0.01. These approaches collectively highlight the importance of data preprocessing and multi-source integration to address LCS limitations.

B. Green Navigation Systems

The integration of air quality data into urban navigation systems is emerging as a key strategy for reducing pollution exposure. IoT technologies enable smart city solutions that combine heterogeneous data sources to support sustainable mobility [11]. Recent frameworks leverage traffic-aware predictions and routing algorithms like Dijkstra's to reduce pedestrian PM2.5 exposure by 11-15% [12], while prototypes in cities like Barcelona demonstrate the feasibility of real-time green routing [13]. Despite these advances, most navigation systems still lack robust environmental health considerations.

III. Integrated Approach

The AIQS project adopts an interdisciplinary approach that combines AI-based data correction, sensor hardware optimization, and the development of a pollution-aware routing tool. Its goal is to deliver a validated, open-source system that enhances LCS reliability and supports healthier, user-configurable pedestrian navigation in urban environments.

The main goals are:

- Improving sensor data accuracy: Develop and apply AI and ML techniques, to dynamically correct sensor readings and improve reliability in various environmental contexts.
- Optimize sensor hardware: Enhance the physical design and operation of low-cost AQ sensors through fluid dynamics simulations and the development of pre-treatment modules, such as air dehydration systems and anti-coalescence components.
- Deliver a validated demonstrator: Advance the MitH framework to TRL 7 by integrating AI algorithms and hardware improvements into a real-world demonstrator, tested in an urban pilot and released as an open-source tool for broad adoption.
- Develop a green routing tool: Design and implement a flexible routing tool that integrates air quality data to compute pollution-aware pedestrian routes. It will estimate individual exposure to pollutants based on real-time AQ levels along each road segment, and compute routes that minimize cumulative exposure. The tool will be adaptable to different urban contexts and configurable by users, who will be able to tune preferences such as avoiding polluted areas, favoring proximity to green spaces, or prioritizing walking routes over other options.

A. Data Collection & AI Correction

To enhance the accuracy of low-cost air quality sensors, we apply AI-based correction techniques using data collected from co-located low-cost sensors and regulatory reference stations (e.g., ARPA) across multiple Italian and international cities. These co-located datasets allow us to calibrate sensor readings by learning correction functions that map raw low-cost measurements to validated reference values under shared environmental conditions. Meteorological variables are also included to improve model robustness. Our approach combines dynamic correction functions to mitigate humidity effects, anomaly detection to filter spurious data, and machine learning algorithms, such as Multilayer Perceptrons and fuzzy logic systems, to refine sensor outputs. These components are being integrated into the open-source MitH framework [5], which we aim to advance to Technology Readiness Level (TRL) 7. Model training and evaluation are supported by a high-performance computing infrastructure with GPU capabilities.

B. Pollution-Aware Routing

LCS measurements provide local PM concentrations. Through spatial interpolation strategies [14], we generate city-wide air quality maps that enable health-conscious navigation by estimating pollution levels across urban areas.

These AQ datasets drive our configurable routing system, which computes pedestrian paths minimizing cumulative pollutant exposure using OpenStreetMap networks. The tool supports user-customizable preferences:

- Minimizing pollution exposure
- Prioritizing proximity to green spaces
- Selecting pedestrian-only segments

Currently being validated in Modena through stakeholder partnerships, the open-source implementation[1] represents an adaptable framework for human-centered, pollution-aware navigation in diverse urban contexts.

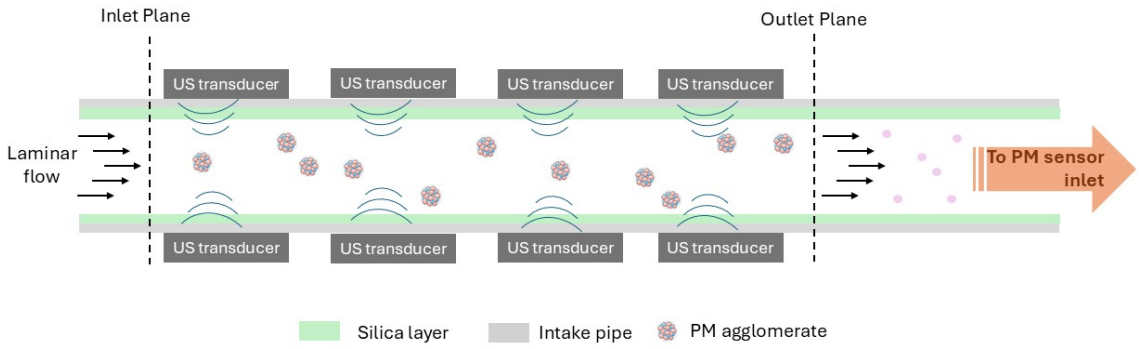

Fig. 1: Low-power air preconditioning module for particulate matter.

C. Hardware Optimization for Humidity Mitigation

A compact pretreatment module is being developed to minimize humidity-induced artifacts in LCS sensors. As shown in Figure1, ambient air enters through an intake pipe whose inner surface is coated with a thin silica aerogel layer acting as a passive desiccant. Along the pipe, ultrasonic (US) transducers are mounted transversely and driven in phase to generate localized oscillations and mild heating. This action promotes de-aggregation of PM agglomerates and accelerates moisture desorption from particles, while simultaneously regenerating the silica layer by enhancing vapor transport. The laminar flow then reaches the PM sensing chamber with reduced aggregation and humidity effects.

Finite-Element simulations guide the optimization of acoustic and thermal fields to achieve these effects with low power consumption, and a PWM-controlled heater can be added if ultrasonic energy alone is insufficient. Ongoing evaluation quantifies the reduction of humidity-related artifacts by comparing sensor responses with and without the module under controlled conditions.

IV. Results

A. Data Collection

Several key activities were carried out to enhance the accuracy and reliability of low-cost air quality sensors using artificial intelligence and high-performance computing resources.

We completed a comprehensive dataset collection [15] that includes:

- 4 Italian air quality datasets (e.g., ARPA regional agencies),
- 10 international datasets across various urban environments,
- Meteorological variables, including temperature, relative humidity, atmospheric pressure, and wind speed/direction, collected specifically for each city to support model robustness and correction accuracy.

All datasets include measurements from co-located low-cost sensors and regulatory reference stations, which is a critical requirement for developing accurate correction models. Co-location ensures that both LCS and RS measure the same environmental conditions at the same time and place, enabling a direct comparison between the two. This alignment is essential for calibrating LCS readings, as RS data provide a validated high-quality ground truth against which LCS measurements can be adjusted. The availability of synchronized data supports the development of reliable correction algorithms that significantly enhance the accuracy and trustworthiness of LCS output. Furthermore, all datasets feature at least an hourly measurement frequency, ensuring adequate temporal resolution for both real-time applications and time series analysis.

B. AI-Based Sensor Data Correction

In the preliminary phase of our study, we conducted evaluations of various anomaly detection and correction algorithms using some of the air quality datasets collected. The goal was to improve the quality of the sensor data and improve the performance of the model in subsequent prediction and correction tasks. These initial experiments provided insight into the effectiveness of both statistical and AI-based methods in identifying and correcting anomalies, as well as in accurately modeling time series data.

a) Anomaly Detection: To identify anomalous patterns in the AQ time series data, we applied a range of traditional outlier detection techniques. These included density-based spatial clustering of noise applications (DBSCAN), the inter-quartile range (IQR) method, and the three-sigma rule. Each method contributed to detecting noise and irregularities across different temporal contexts. For time series repair, we employed K-Nearest Neighbors (KNN) interpolation, which proved effective in reconstructing missing or corrupted values. Our preliminary results indicate that the inclusion of these anomaly detection and repair steps in the pre-processing pipeline leads to measurable improvements in model performance. In particular, we observed increases of up to 0.1 in the coefficient of determination (R^2) in some cases, highlighting the value of robust data preparation.

b) AI Algorithms for Correction: To correct and calibrate sensor readings, we tested a wide spectrum of traditional and advanced machine learning models. Among traditional

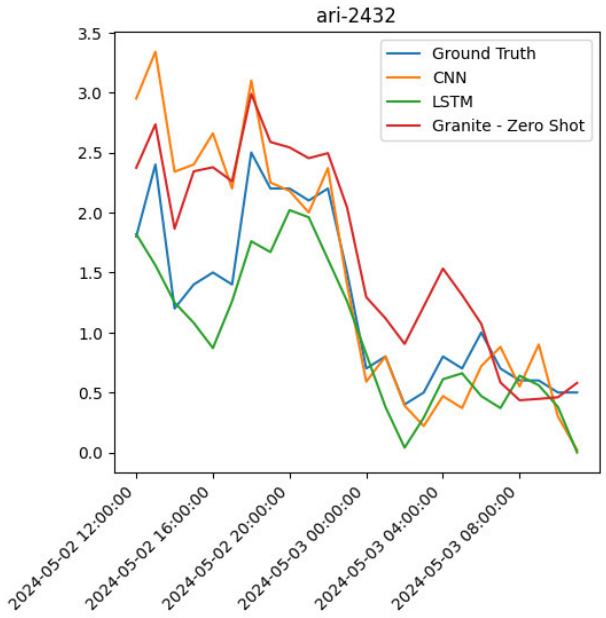

Fig. 2: A 24-hour forecast produced using different deep learning approaches on a randomly chosen AQ sensor.

regression techniques, we employed Linear Regression, Lasso, Ridge, and Elastic Net, all of which served as baseline models for evaluating correction accuracy.

We then explored supervised machine learning models, including Support Vector Regression (SVR), Decision Trees (DT), Random Forest (RF), XGBoost, and LightGBM. These models demonstrated varying degrees of effectiveness in correcting sensor data, with ensemble methods generally outperforming simpler approaches.

In addition to these methods, we investigated a fuzzy logic-based correction strategy using the Adaptive Neuro-Fuzzy Inference System (ANFIS) [16]. ANFIS achieved performance levels comparable to those of neural network models, obtaining a value R^2 of approximately 0.68 on the primary test dataset. Further experimentation with ANFIS on five additional datasets, focusing on model interpretability, yielded Pearson correlation coefficients exceeding 0.75 in all cases and reaching up to 0.97 in the best scenario.

Neural network models, particularly Multilayer Perceptrons (MLPs) [17], were also tested. These models achieved strong performance, with an R^2 value of 0.92 in one of the urban scenarios. Moreover, we implemented dynamic correction functions to account for the hygroscopic effect of humidity using both empirical and data-driven approaches. These corrections led to improvements of up to 0.3 in R^2 values during the autumn period, demonstrating the importance of incorporating environmental factors in correction models.

c) Deep Learning Architectures:: We also performed a series of preliminary tests using deep learning architectures, evaluating their potential in modeling AQ time series. These included Convolutional Neural Networks (CNNs), Long Short-Term Memory (LSTM) networks, Gated Recurrent Units (GRUs), Temporal Convolutional Networks (TCNs), and Transformer-based models. These architectures were trained and tested on domain-specific AQ datasets, with particular attention to their ability to reproduce both general trends and specific point values.

Among these, the CNN and LSTM models showed the most promise in accurately modeling the observed behaviors. Our early results suggest that, while these models are capable of capturing overall trends, fine-grained prediction of individual values remains challenging in cases of high temporal variability. Further optimization, particularly in terms of network architecture and hyperparameter tuning, is necessary to enhance performance and potentially surpass the results obtained from simpler models.

In addition, we evaluated the performance of foundation models designed for time-series analysis. Two such models, TimesFM [18] and Granite [19], were tested. TimesFM was evaluated in zero-shot mode, while Granite was tested both in zero-shot and fine-tuned settings. Initial findings suggest that these foundation models can achieve performance comparable to traditional deep learning models without requiring extensive training. Notably, fine-tuning Granite on specific AQ datasets further improved its accuracy, indicating the potential for transfer learning in environmental sensing applications. However, further investigation is needed to draw definitive conclusions, as specific metrics are still under analysis.

Figure 2 illustrates an example of 24-hour time series from one AQ sensor. In these examples, both the trained architectures and the foundation model successfully capture the ground truth trend. While sharp variations (left panel) present challenges in reproducing point values, smoother patterns (right panel) are more accurately modeled. Figure 3 provides a comparative overview of the R^2 values obtained from all tested deep learning models. It is worth emphasizing that preliminary tests highlight the critical importance of defining appropriate training, validation, and test sets, as their configuration significantly impacts model performance. Ongoing experiments aim to systematically address this issue and validate the robustness of the observed results.

Among the traditional architectures, *LSTM*, *GRU*, and *CNN* demonstrate exceptionally high performance with R^2 values approaching 1.0, suggesting that these models are highly capable of capturing temporal dependencies and nonlinear patterns in the data. The *Transformer*, despite its theoretical strengths, shows comparatively lower performance ($R^2 \sim 0.87$), possibly due to the need for more extensive hyperparameter tuning or larger datasets to fully leverage its self-attention mechanisms.

The *TCN* model performs well with an R^2 of 0.95, slightly below the recurrent models but still in a strong range. This suggests TCNs can be a competitive alternative.

Regarding foundation models, *TimesFM - Zero Shot* achieves an R^2 of 0.93, which is notable given that it was used without any fine-tuning. Similarly, *Granite - Zero Shot* performs slightly better ($R^2 \sim 0.96$), indicating strong out-of-the-box generalization capabilities. However, the *Granite* -

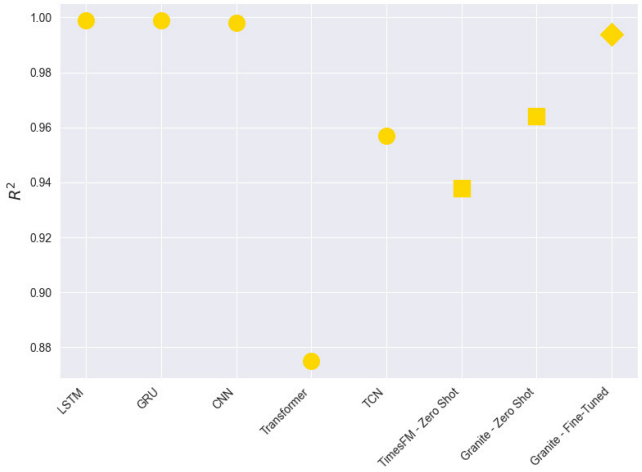

Fig. 3: Comparison of R^2 metrics computed over several deep learning architectures on a test set includes all the available AQ sensors.

Fine-Tuned model outperforms all other approaches with an R^2 of 0.99, highlighting the significant boost in performance that can be gained from domain-specific fine-tuning.

C. Pollution-Aware Routing System

We extracted and analyzed cycleway and footpath data from OpenStreetMap (OSM) and Open Data portals, focusing on the city of Modena. The data was modeled as a directed graph, where $Nodes$ represent OSM-defined junctions or road shape points, with properties such as the OSM identifier and the GPS coordinates, $Edges$ correspond to roads, with properties including: *geometry* representing the shape of the road, *distance*, i.e., the geometric length of the road, *green_area* indicating whether the segment traverses a green space (e.g., parks).

Only pedestrian-accessible roads (e.g., sidewalks, footpaths) and cycleways were included. The graph was implemented in Neo4j, using the spatial plugin.

To enable pollution-aware routing, we sourced open air quality data for Modena. Due to the absence of hyperlocal measurements (e.g., particulate matter sensors), we generated synthetic PM_{10} data by analyzing historical measurements from ARPAE's two regulatory stations in Modena, applying Inverse Distance Weighting (IDW) interpolation using the GDAL library[2] to estimate PM_{10} levels across the road network, assigning each edge an air_quality property, calculated as the average PM_{10} concentration within a configurable buffer around the road.

Using the enriched graph, we developed a routing algorithm to prioritize low-pollution pedestrian paths leveraging on the routing algorithms (Dijkstra and A*) of the APOC library[3].

Preliminary tests were performed using randomly selected locations within the urban area of Modena, computing optimal routes based on edge properties including *distance*, *green_area*, and *air_quality*. Figure 4 presents a comparison between two routes connecting the San Paolo kindergarten and the "Fontana dei due fiumi". The left route represents the distance-optimized solution (shortest path), while the right route maximizes green space exposure along the path.

V. Conclusion

This paper presented the AIQS project, an integrated approach to enhance the reliability of low-cost air quality sensors (LCS) using AI-driven correction and to enable pollution-minimizing "green routing" for pedestrians.

The AI-based sensor correction ca be performed using Multilayer Perceptrons (MLPs), Adaptive Neuro-Fuzzy Inference Systems (ANFIS), or foundation models (e.g., TimesFM, Granite), and achieves up to 0.92 R^2 accuracy against reference data across diverse urban environments. The configurable routing tool leveraging OpenStreetMap and Dijkstra/A* algorithms to compute paths minimizing cumulative pollution exposure while balancing user preferences has been validated in Modena and confirmed the opportunity to generate actionable green routes.

Upcoming efforts will focus on finalizing the integration of the AI models into the open source MitH framework. The framework will be validated on at least 6 real AQ datasets to ensure robustness across diverse conditions. On the hardware side, planned field trials will rigorously assess the effectiveness and durability of the proposed pre-treatment module in real environments. In parallel, the routing system will evolve into a deployable web application with multi-objective optimization, adaptable to different urban contexts. By addressing both data accuracy and usability, AIQS contributes to the development of healthier, cleaner, and more sustainable cities.

By addressing both data accuracy and application usability, AIQS aims to contribute to the development of healthier, cleaner, and more sustainable cities through AI-enhanced environmental monitoring and decision-making tools.

Acknowledgment

This work was carried out as part of the AIQS project (AI-enhanced Air Quality Sensor for Optimizing Green Routes), under the project code DIP_AIQS_PO_2025_PNRR_ECOS_SK4AF_E93C22001100001. AIQS was funded through a closed call within the initiative "Ecosystem for Sustainable Transition in Emilia-Romagna" (ECOSISTER), financed under the National Recovery and Resilience Plan (PNRR) – Mission 4 "Education and Research", Component 2 "From Research to Business", Investment 1.5 "Creation and strengthening of innovation ecosystems, building territorial R&D leaders" – funded by the European Union – *NextGenerationEU* (Grant Agreement No. 0001052, dated 23/06/2022 – Project ECS_00000033 – CUP E93C22001100001).

***Abstract*—In this paper, we analyse rolling stock cyclic job scheduling problems with maintenance to maximize the total availability of vehicles or to minimize the total maintenance cost. The considered issues can be formulated as cyclic job scheduling problems on parallel machines with time and usage based deteriorating effects and maintenance. Since these problems are strongly NP-hard, we propose a dedicated double crossover genetic algorithm and compare its efficiency with other metaheuristics: particle swarm optimization, simulated annealing, and genetic algorithm (using a single crossover). The computational experiments reveal that our approach is robust, optimizes various instances, and overwhelms the other evaluated algorithms for the analysed scenarios correlated with real-life cases. Thus, our new method is applicable for the industrial practice to maximized availability of vehicles as well as to minimize maintenance costs.**

***Index Terms*—Scheduling, Rolling stock, Deteriorating, Maintenance, Metaheuristic**

I. Introduction

SCHEDULING problems with deteriorating effects and/or maintenance activities have attracted particular attention in the research society (e.g., [1], [2], [3]). It follows from the practical meaning of the related research, since most of the industrial systems undergo degradation, and to avoid unexpected breakdowns preventive maintenance are performed. It is especially important in a railway domain, where the related rules concerning maintenance of vehicles are strictly defined. Usually, for locomotives five levels of activities are distinguished: inspections (Level 1), periodic inspections (Level 2), extended periodic inspections (Level 3), overhauls (Level 4), overhauls and upgrades (Level 5) [4]. However, they are not only time consuming and making vehicles unavailable [5], but they are also expensive (see [6]) especially for higher levels. On the other hand, the maintenance dates can be controlled within a certain range by scheduling taking into account required mileage of transport tasks and additional constraints following from maintenance policies defining time-based maintenance (TBM) and mileage based-maintenance (MBM) cycles. Such approach was for the first time analysed, developed and implemented by the author for a locomotive rental company, and his results including the dedicated mathematical (simulation) model and the optimization algorithms were described in details in the industrial report [7].

In this paper, we will follow that approach on rolling stock cyclic job scheduling problems with maintenance to maximize the total availability of vehicles or to minimize of the total maintenance cost. To solve them, we will propose a dedicated double crossover genetic algorithm and compare its efficiency with other metaheuristics known from the literature such as our previous implementations of particle swarm optimization [8], simulated annealing ([7], also presented in [5]) and a genetic algorithm with a single partially mapped crossover PMX [5] adjusted to solve the required criteria.

II. Problem formulation

In this section, we will describe the analysed rolling stock cyclic job scheduling problems to maximize the total availability of vehicles (TA) and to minimize the total maintenance cost (TC) as a cyclic job scheduling problems on identical parallel machines with deteriorating effects and maintenance. It is worth highlighting that these problems are covered by the mathematical (simulation) model, which was formulated solely by the author (R. Rudek) and precisely described in his industrial report [7]. Its fundamental part is the discrete event simulator (DES) including the model parameters and their relations describing vehicles, maintenance policies, jobs, schedules and rules allowing for determining dates and durations of maintenance activities and calculating various criteria. These main assumptions in a simplified form were presented to a broader audience *inter alia* in [9] and [5] to optimize the total availability criteria, the total maintenance cost [8] or the total income [10].

Let us recall that the discussed problems can be formulated as cyclic job scheduling problems on parallel machines with time and usage based deteriorating effects and maintenance under the these criteria. The scheduling problem (model) parameters and constraints are given as follows. There is a time horizon $\mathcal{T} = \{1, \ldots, t, \ldots, T\}$ is divided into T periods (in practice referring to succeeding months). A set $\mathcal{V} = \{1, \ldots, v, \ldots, n\}$ of n parallel machines (representing locomotives) that have to process a set $\mathcal{J} = \{1, \ldots, j, \ldots, n\}$ of n cyclic jobs (identified with transport tasks) during all periods T. A job can be assigned exactly to one and the same machine for a given period t, and a machine can process only one job at a time, but the reassignment in the next periods is allowed. Moreover each job $j \in \mathcal{J}$ is characterized by the average milage per day (workload) w_j that defines daily deteriorating of a machine (increasing its accumulative mileage) during all days in period t, when that machine is

operational (available) and processes job j. On the other hand machines, due to their deteriorating, must to undergo periodic preventive maintenance activities MAs, and each of them belongs to exactly one family (type) $f \in \mathcal{F} = \{1, \ldots, F\}$. Machines of a given type f share the same maintenance policy (MP), which defines time-based maintenance (TBM) and mileage (distance) based-maintenance (MBM) cycles divided into K^f levels of complexity. Each level $k = 1, \ldots, K^f$ of MP is described by the related parameters TBM_k^f and MBM_k^f, which are the predetermined threshold values triggering MA according to TBM or MBM, respectively. A maintenance activity of level k for a machine of type f is described by the expected duration MD_k^f and the cost MC_k^f. The maintenance activities of lower levels are covered by the higher levels and the following relations hold: $TBM_k^f < TBM_{k+1}^f$, $MBM_k^f < MBM_{k+1}^f$, $MD_k^f < MD_{k+1}^f$ and $MC_k^f < MC_{k+1}^f$ for all $k = 1, \ldots, K^f - 1$. Each machine $v \in \mathcal{V}$ is characterized by its deteriorating (condition) parameters $VT_{v,k}$ and $VM_{v,k}$ denoting the period and the accumulated mileage since the last maintenance of level k, respectively. The maintenance activity MA of level k for machine v of type f is started, when the first of the following deteriorating rules does not hold: $VT_{v,k} \leq TBM_k^f$ or $VM_{v,k} \leq MBM_k$ for all $k = 1, \ldots, K^f$ (referring to time and usage deteriorating). If a machine is out of order due to MA, then each job assigned to that machine during related unavailability periods is serviced by the third party. After MA of level k is completed (meaning also the completion of lower levers) the related deteriorating values (counters/conditions) are set to zero $VT_{v,i} = 0$ and $VM_{v,i} = 0$ for $i = 1, \ldots, k$ and a machine can process an assigned job (returned from the third party).

The considered problem is to find a schedule S that is an assignment of all jobs $j \in \mathcal{J}$ to all machines $v \in \mathcal{V}$ during all periods $t \in \mathcal{T}$, which optimizes the required criterion value Q, i.e., the total availability of machines (vehicles) TA or the total maintenance cost TC. In other words, the schedule $S = \langle S_1, \ldots, S_t, \ldots, S_T \rangle$ is the sequence of the assignments of jobs to machines (vehicles) $S_t = (S_t(1), \ldots, S_t(v), \ldots, S_t(n))$ in succeeding periods $t = 1, \ldots, T$, where $S_t(v) \in \mathcal{J}$ is the index of a job assigned to machine (vehicle) v at period t. Note that S can be represented unambiguously by the sequence of permutations S_t. Furthermore, a schedule determines the deteriorating of machines in particular periods (usually months) caused by processing of jobs, which together with model parameters and constraints (such as the maintenance policies) imply the maintenance plan (dates of maintenance activities) that is precisely described by our mathematical model RRR including the discrete event simulator [7]. Thus, the calculation of the criterion value $Q(S)$ for a given schedule S is based on the maintenance plan provided by our model, and it requires $O(MKn)$ steps, where M is the number of performed maintenance activities and $K = \max_{f \in \mathcal{F}}\{K^f\}$ is their maximum level for all machines. Therefore, the objective is to find a schedule S^* that optimizes the criterion value $Q(S)$, i.e., the maximization of the total availability of machines (vehicles) TA: $S^* = \arg\max_{S \in \mathbb{S}}\{Q(S)\} = \arg\max_{S \in \mathbb{S}}\{TA(S)\}$, the minimization of the total maintenance cost TC: $S^* = \arg\min_{S \in \mathbb{S}}\{Q(S)\} = \operatorname{argmin}_{S \in \mathbb{S}}\{TC(S)\}$, where $\mathbb{S}$ is the set of all feasible schedules.

III. Computational complexity

The rolling stock cyclic job scheduling problem to maximize the total availability of vehicles is strongly NP-hard [5]. Here, we will present a sketch of the strong NP-hardness proof of the analysed problem to minimize the total maintenance cost, since its full version is beyond the scope of this paper.

Theorem 1: The rolling stock cyclic job scheduling problem to minimize the total maintenance cost is strongly NP-hard.

Proof. The strong NP-hardness follows from the proof of the strong NP-hardness of the problem with the minimization of the total time on maintenance activities (see [5]). It can be done by extending the pseudopolynomial time transformation such that the parameter *maintenance cost* $MC = 1$ is added and the criterion $MA(S, T)$ is replaced by correlated the total cost of maintenance activities $CMA(S, T)$. Thus, it can be observed that $CMA(S, T)$ is equal to $y = 0$ only if $MA(S, T) = y = 0$ and $CMA(S, T) > y$ only if $MA(S, T) > y = 0$. □

Thus, it is highly unlikely (until $P = NP$) to construct an exact polynomial time algorithm for the considered problem. On the other hand, the solution space $\mathbb{S}$ is significantly greater than for typical scheduling problems, since it is spread by the sequence of permutations with the cardinality $|\mathbb{S}| = O((n!)^T)$. Therefore, we will proposed a dedicated double crossover genetic algorithm (GARDX) and compare its efficiency with other methods already published (e.g., [5], [8]).

IV. Genetic algorithm

In this section, we will present our genetic algorithm railway double crossover (GARDX), which is based on the general concept of the genetic algorithm metaheuristic [11]. In particular, it follows the construction for one permutation [12], later on extended to the sequence of permutations being our earlier basic implementation GA (see [5]) evaluated for the total availability criterion TA. Let us bring closer the idea behind GARDX, which is describe by Algorithm 1. It uses the mathematical model developed and implemented solely by the author (R. Rudek) [7] and included in his dll library `RudRobustRailway` (RRR). Since GARDX is designed to optimize arbitrary criteria Q that are based on the maintenance plan resulting from the schedule, the proper handler has to be chosen (e.g., TA or TC) and also the values of its meta parameters have to be given, i.e., $PopulationSize$, $OffspringSize$, $MixSize$, $StopConition$ (see step 1). Each individual in the population is expressed as the pair (S, Q), where $S = \langle S_1, \ldots, S_t, \ldots S_T \rangle$ is the schedule represented by the sequence of permutations S_t and Q is the corresponding criterion value (e.g., calculated according to TA or TC). Thus, we will refer to the schedule S and to the criterion value Q of the idxth element from a required set (e.g., $Population$) as follows: $Population[idx].S$ and $Population[idx].Q$ (step 2).

Algorithm 1 Genetic Algorithm Railway Double Crossover GARDX

```
 1: Input: parameters and criterion type Q(·);
 2: Refer to the schedule S and the criterion Q of
    the element idx from the set SetName by
    SetName[idx].S, SetName[idx].Q;
 3: Population[1] = provided by FA;
 4: Population[2] = provided by BH;
 5: Population[3] = provided by PSO (StopCondition=10s);
 6: Population[4] = provided by SA (StopCondition=10s);
 7: for p = 5,...,⌊PopulationSize/2⌋
 8:   S' = a sequence of random permutations;
 9:   Calculate the criterion Q' for S': Q' = Q(S');
10:   Population[p] = S' and Population[p].Q = Q';
11: end for
12: for p = ⌊PopulationSize/2⌋ + 1,...,PopulationSize
13:   S' = Population[1].S;
14:   for t = 1,...,T
15:     for r = 1,...,⌊n/2⌋
16:       u = random vehicle index from {1,...,n};
17:       v = random vehicle index from {1,...,n};
18:       Swap jobs between u and v in S'_t
19:     end for
20:   end for
21:   Calculate the criterion Q' for S': Q' = Q(S');
22:   Population[p] = S' and Population[p].Q = Q';
23: end for
24: while (StopCondition ≠ true)
25:   ParentPool = {choose 2*OffspringSize random
      elements from Population};
26:   for idx = 1,...,OffspringSize
27:     ParentXX = ParentPool[2*idx − 1];
28:     ParentXY = ParentPool[2*idx];
29:     t_a = random period index from {1,...,T};
30:     t_b = random period index from {1,...,T};
31:     (S^X, S^Y) = TPX(ParentXX.S, ParentXY.S, t_a, t_b);
32:     S^C = ROX(S^X, S^Y, MixSize);
33:     Calculate the criterion value Q^C
        for the child schedule S^C: Q^C=Q(S^C);
34:     Offspring[idx].S=S^C and Offspring[index].Q=Q^C;
35:   end for
36:   Population = Choose PopulationSize best elements
      from the set {Population ∪ Offspring}
      ordered from the best to the worst Q;
37:   if Population[1].Q is better than Q* then
38:     Q* = Population[1].Q and S* = Population[1].S;
39:   end if
40: end while
41: Return the schedule S* = (S*_1,...,S*_T)
    and its criterion value Q*;
```

Algorithm 2 Two Point Crossover (TPX): $(S^X, S^Y) = TPX(S^{XX}, S^{XY}, t_a, t_b)$

```
 1: Input: parent schedules S^XX, S^XY and
    crossover parameters t_a, t_b;
 2: if t_a > t_b then exchange values t_a and t_b;
 3: for t = 1 to t_a − 1
 4:   S^X_t = S^XX_t;
 5:   S^Y_t = S^XY_t;
 6: end for
 7: for t = t_a to t_b
 8:   S^X_t = S^XY_t;
 9:   S^Y_t = S^XX_t;
10: end for
11: for t = t_b + 1 to T
12:   S^X_t = S^XX_t;
13:   S^Y_t = S^XY_t;
14: end for
15: Return resulting schedules S^X and S^Y;
```

Algorithm 3 Random Order Crossover (ROX): $S^C = ROX(S^X, S^Y, MixSize)$

```
 1: Input: parent schedules S^X, S^Y and
    parameter MixSize;
 2: Initialize the child schedule:
    S^C = ⟨S^C_1,...,S^C_t,...S^C_T⟩ = S^X;
 3: for q = 1,...,MixSize
 4:   t = random period index from {1,...,T};
 5:   for v = 1 to n
 6:     Get job index j assigned to vehicle v
        at period t for parent X: j = S^X_t(v);
 7:     Mark vehicle v in child schedule S^C_t as
        not assigned: S^C_t(v) = −1;
 8:     Mark job j as not assigned to the child:
        isJobAssigned[j] = false;
 9:     rv = random value from {0.0,...,0.9};
10:     if rv < 0.5 then
11:       Assign job j to vehicle v in S^C_t: S^C_t(i) = j;
12:       Mark j as assigned: isJobAssigned[j] = true;
13:     end if
14:   end for
15:   u = 1;
16:   for v = 1 to n
17:     Get job index j assigned to vehicle v
        at period t for parent Y: j = S^Y_t(v);
18:     if isJobAllocated[j] == false then
19:       while (S^C_t(u) > 0)
20:         u = u + 1;
21:       end while
22:       Assign job j to vehicle u in S^C_t: S^C_t(u) = j;
23:     end if
24:   end for
25: end for
26: Return the child schedule S^C = (S^C_1,...,S^C_T);
```

The first four individuals in the initial population (steps 3–6) are constructed by the following methods FA, BH, PSO and SA. Namely, Fixed Assignment (FA) is the constant assignment of jobs to vehicles during all months (no job reassignment between vehicles), i.e., a sequence of natural permutations (introduced as a default reference in [7], later on used in [5]). Balance Heuristic (BH) was developed and introduced in [7], later on used and shown to a broader audience in [9], whereas Particle Swarm Optimization (PSO) was presented in [8], and Simulated Annealing (SA) was introduced in [7], later on used in [5]. The applied PSO and SA optimize the criterion type chosen for GARDX and their meta parameter values are given in Section V, whereas their stop condition in GARDX is 10 seconds. Next $p = 5,\ldots,\lfloor PopulationSize/2 \rfloor$ individuals are the sequences of random permutations (steps 7-11). The rest of elements of the population $p=\lfloor PopulationSize/2 \rfloor+1,\ldots, PopulationSize$ are constructed on the basis of FA, where for each S_t jobs are swapped between two random vehicles u and v that are drawn $\lfloor n/2 \rfloor$ times (steps 12-23) for every $t=1,\ldots,T$.

In the each iteration of the main loop (steps 24-40), the algorithm chooses $OffspringSize$ random pairs from the population (step 25) that are the intermediate parents $ParentXX$ and $ParentXY$ (steps 27-28). Following them and for two random periods t_a and t_b (steps 29-30) the target parents are constructed represented by schedules S^X and S^Y (step 31). It is done by using the two point crossover TPX (Algorithm 2), which exchanges permutations of schedules

$ParentXX.S \equiv S^{XX}$ and $ParentXY.S \equiv S^{XY}$ in ranges $t \in \{t_a, \ldots, t_b\}$ (where $t_a < t_b$) returning the new schedules S^X and S^Y. On their basis, a new child schedule S^C is created following the random order crossover ROX and parameter $MixSize$ (step 32). The related procedure ROX described by Algorithm 3 initially clones the first parent schedule S^X to the child schedule S^C. Next, it draws $MixSize$ times random period indices $t \in \mathcal{T}$. For each t, the particular assignments of jobs to the vehicles from the permutation of the first parent S^X_t are copied with probability 0.5 to the related permutation of the child schedule S^C_t, whereas not chosen jobs are marked as unassigned. Subsequently, these missing jobs are assigned to unoccupied vehicles in S^C_t according to the order determined by the permutation of the second parent S^Y_t.

After the complete set $Offspring$ of $OffspringSize$ new schedules is generated, the new population is constructed. It is done by choosing $PopulationSize$ best solutions from the temporary set consisting the previous population and the new offspring, i.e., $\{Population \cup Offspring\}$ (step 36). If the new population contains a solution that is better than the best already found Q^*, then it is updated (steps 37-39). Note that *better* (step 37) for TA means that the new criterion value is greater than Q^*, whereas for TC means that it has to be smaller to be updated. Nevertheless, if the algorithm is implemented such that the availability TA is represented by positive and the cost TC by negative numbers, then we can unify the notation and focus only on the maximization, thereby the best found solution is updated only for greater values.

The computational complexity of a single iteration of GARDX (steps 24–40) is equal to $O(OffspringSize(MK+T)n)$ that is determined by TPX (step 31), ROX (step 32) and the calculation of $Q(\cdot)$ based on the maintenance plan (step 33), which are equal to $O(Tn)$, $O(Tn)$, $O(MKn)$, respectively.

V. Experiments

Let us now verify the accuracy of the proposed algorithm GARDX in reference to other methods implemented for similar problems. To provide reliable analysis of our algorithm, especially referring to the methods already described in the literature (particle swarm optimization PSO, simulated annealing SA, genetic algorithm GA), we will compare the scheduling algorithms for the instances constructed similarly as in the related works [5].[1] The set of all evaluated algorithms and their configurations are given as follows: Particle Swarm Optimization (PSO): $\omega = 0.6$, $c_1 = 0.5$, $c_2 = 0.5$, swarm size $m = 10$, bounds $X_{\min} = 0.0$, $X_{\max} = 4.0$, $\nu_{\min} = -4.0$, $\nu_{\max} = 4.0$ (following [8]); Simulated Annealing (SA): $Temp = 1000000$, $\alpha = 0.01$ (introduced in [7], later on used in [5]); Genetic Algorithm (GA): $PopulationSize = 200$, $OffspringSize = 50$, $MixSize = \lfloor 0.2T \rfloor$, (following [5]); Genetic Algorithm Railway Double Crossover (GARDX): $PopulationSize = 160$, $OffspringSize = 40$, $MixSize = \lfloor 0.2T \rfloor$. The initial solution (schedule) for each metaheuristic is determined by FA. To provide a fair comparison, due to nondeterministic nature of these methods, we run each of them 10 times and choose the best result (similarly as in [5]) as well as the stop condition for all metaheuristics is the same and set to 90s. Thus, we slightly extended the running times of PSO, SA and GA set in [8] and [5], giving them more time to traverse the search space.

[1]The algorithms were coded in C# (Microsoft Visual Studio 2022) and simulations were run under Windows 10 on PC, CPU Intel® Core™ i9-10885H 2.40GHz and 32GB RAM. All the corresponding software and algorithms, their previous as well as the current versions were coded solely by R. Rudek

TABLE I: Example preventive maintenance cycles, durations and costs of maintenance activities for Škoda 31E ($f = $ Š) and for E6ACTa Dragon 2 ($f = $ D) (see [10])

Type f	Level k	TBM^f_k	MBM^f_k [km]	MD^f_k [days]	MC^f_k [PLN*]
Š			Škoda 31E		
	1	14 days	2,500	0.125	1,000
	2	110 days	22,000	2	7,000
	3	32 months	220,000	21	50,000
	4	8 years	620,000	74	800,000
	5	16 years	1,200,000	84	1,000,000
D			E6ACTa Dragon 2		
	1	3 months	30,000	0.125	2,000
	2	1 year	150,000	2	12,000
	3	4 years	660,000	21	80,000
	4	8 years	1,220,000	74	1,000,000
	5	32 years	4,800,000	84	1,400,000

It is worth noticing that all the considered metaheuristics (PSO, SA, GA, GARDX) were developed and implemented solely by the author such that they can be applied for an arbitrary criterion based on his model developed in [7] and included in his dll library `RudRobustRailway` (RRR). Thereby, the only necessary action to optimize the required criterion by these algorithms is to choose and to apply a proper handler Q calculating the criterion value, e.g., referring to TA or TC; for Algorithm 1 see its step 33. Though our previous implementations SA, GA (e.g., [5]) and PSO [8] were originally used for different objective functions, they can be applied in the exactly same form to optimize also TA or TC (only by choosing a proper objective function handler).

Similarly as in [5] and [10], the computational experiments are provided for the instances constructed on the basis of two extreme types of vehicles representing one of the oldest (Škoda 31E series 181 produced till 1965) and one of the most modern locomotive (E6ACTa Dragon 2 produced since 2018) offered by rail vehicle rental companies in Europe. The maintenance cycles of these vehicles describing the time based TBM and the mileage based MBM maintenance policies, maintenance durations DM and costs MC are given in Table I. In the industrial practice, the maintenance activities of levels $k \geq 3$ start one day earlier than following from TBM^f_k [7]. Although the financial values are correlated with the market, they do not refer to any particular company. Moreover, if it is needed to analyse these values in US Dollars, the exchange rate to Polish Złoty (PLN) on 30 April 2025 was \$1 $\approx$ 3.77 PLN. The instances are based on $n \in \{10, 20\}$ vehicles of the same type

chosen from the considered locomotives. It is assumed that the simulations start at 01.01.2024 and at that day all vehicles are just after maintenance of the highest level K_f (overhaul) or they are just delivered from their producer, thereby $VT_{v,k}=0$ and $VD_{v,k}=0$ for $v=1,\ldots,n$ and $k=1,\ldots,K_f$ (identical parallel machines). The number of jobs is equal to the number of vehicles divided into $G=\lceil n/2 \rceil$ groups that share the same average mileage per day from range $w_j \in \{400,\ldots,700\}$ (see [5]). We consider periods referring to popular strategic planning time frame (from shorter to longer) $T^{(y)} \in \{5,10,15\}$ in years, i.e., $T \in \{60,120,180\}$ in months. The analysed algorithms $A \in \{$FA, PSO, SA, GA, GARDX$\}$ are evaluated for each instance I according to the following measures depending on the criterion $Q \in \{TA, TC\}$: the total availability of vehicles TA with $\delta_{TA}(A) \equiv \delta_{TA}(A,I) = TA(S^A) - TA(S^{FA})$ is the improvement (additional days) in reference to FA (higher values are better); $\Delta_{TA}(A) \equiv \Delta_{TA}(A,I) = TA^* - TA(S^A)$ is the total loss in days in reference to the best solution $TA^* = \max\{TA(S^A)\}$ for instance I (lower values are better); where $TA(S^A)$ is the total availability of vehicles (in days) for the schedule S^A provided by algorithm A; the total maintenance cost TC with $\delta_{TC}(A) \equiv \delta_{TC}(A,I) = TC(S^{FA}) - TC(S^A)$ is the improvement (financial savings) in reference to FA (higher values are better); $\Delta_{TC}(A) \equiv \Delta_{TC}(A,I) = TC(S^A) - TC^*$ is the total loss in savings in reference to the best solution $TC^* = \min\{TA(S^A)\}$ for instance I (lower values are better); where $TC(S^A)$ is the total maintenance cost for the schedule S^A provided by algorithm A. Note that Δ_{TA} and Δ_{TC} are redundant to δ_{TA} and δ_{TC}, respectively. Nevertheless, they are introduced for a more comprehensive comparison of the algorithms to clearly show differences between them and to easily recognize leading approaches (lower values are better).

The results of the computational experiments for instances based on the considered locomotive types, including criterion values TA (the total availability of vehicles in days) and TC (the total maintenance cost in thousand PLN), the improve-

ments to FA (δ_{TA}, δ_{TC}) and the losses to the best solutions (Δ_{TA}, Δ_{TC}) are shown in Tables II and III, respectively. It can be seen that all metaheuristics improved the results obtained by FA for both criteria. Our newly proposed GARDX overwhelms all other previous algorithms PSO, SA and GA for all considered instances under each of the separately optimized criteria: the total availability of vehicles TA and the total maintenance cost TC. It found schedules that offer additional measurable profits in reference to FA, e.g., from 128 additional days in 5 years and 10 locomotives to 586 days for 10 years and 20 locomotives (see Table II) and significant savings in the maintenance cost that exceed 2M PLN (c.a. \$0.5M) for $T^{(y)} = 5$ years and $n = 10$ locomotives or it can even reach 6M PLN (c.a. \$1.5M) for $T^{(y)} = 10$ and $n = 20$. The experiments revealed that GARDX is a robust method that well optimizes various instances, whereas other algorithms are instable. Therefore, GARDX can successfully replace each of the previous metaheuristics PSO, SA and GA for the optimization of TA or TA. Although the maximization of the total availability of vehicles TA is correlated with the minimization of the total maintenance cost TC, they are not equivalent. The optimization of TA does not need to lead to the identical improvement of TC, due to specifications and nonlinearity of these criteria. We have managed for Škoda instances to choose the costs of maintenance activities MC_k^f on particular levels (within the range of real values correlated with the market, see Table I) that allows us for the following analysis. Namely, for $T^{(y)} = 5$ and $n = 10$, FA obtained the maintenance plan that was characterized by TA equals to 15,718 days (Table II) and at the same time TC is equal to 15,718 thousand PLN (kPLN) (see Table III). Thus, we can see that the best result for TA is 15,846 days provided by GARDX and the ranking of algorithms is GARDX, SA, GA, PSO (see Table II), whereas the best value for TC is 15,385 kPLN obtained also by GARDX, but the ranking is different, i.e., GARDX, GA, SA, PSO (see Table III). GARDX optimizing TA for that instance was able to find the schedule S^{TA} resulting with a maintenance plan characterized by the best availability $TA(S^{TA}) = 15,846$ days (Table II) and the related total maintenance cost was $TC(S^{TA}) = 15,414$ kPLN. However, if GARDX optimized the criterion TC, then a different schedule S^{TC} was found corresponding to a maintenance plan characterized by the best total maintenance cost $TC(S^{TC}) = 15,385$ kPLN (Table III) and the related total availability in days was $TA(S^{TC}) = 15,826$. It can be seen that the total availability $TA(S^{TA}$ is better (greater) than $TA(S^{TC})$ if TA is optimized, and the total maintenance cost $TC(S^{TC})$ is better (smaller) than $TC(S^{TA})$ if the optimization objective is TC. Thereby, optimization of TA is not equivalent to optimization of TC.

VI. Conclusions

We analysed rolling stock cyclic job scheduling problems with maintenance to optimize the following objectives: the maximization of the total availability of vehicles TA and the minimization of the total maintenance cost TC. They were formulated as cyclic job scheduling problems on parallel machines with time and usage based deteriorating effects and maintenance. We constructed dedicated efficient genetic algorithm GARDX and we adjusted other metaheuristics PSO, SA, and GA known from the literature. The computational experiments revealed that GARDX overwhelms all compared methods and it proved its usefulness to the industrial practice to maximized TA and to minimize TC translating into convincing financial profits. For instance, it was able to significantly improve TA in reference to FA, e.g., from 128 additional days in 5 years and 10 locomotives to 586 days for 10 years and 20 locomotives. If it was applied to optimized TC, it found savings in reference to FA that exceeded 2M PLN (c.a. \$0.5M) for 5 years and 10 locomotives and 6M PLN (c.a. \$1.5M) for 10 years and 20 vehicles.

***Abstract*—Black-box explainability tools like LIME and SHAP are widely used to interpret machine learning models. However, their post-hoc, local nature often results in inconsistent and semantically opaque explanations. This paper presents a model-driven explainability approach using grammatical evolution (GE), enabling the discovery of symbolic, human-readable models. We compare black-box explanations to symbolic GE-generated models on two benchmark tasks: a quadratic equation classification problem and the Iris dataset. GE produces interpretable, consistent, and semantically meaningful expressions consistent with domain knowledge, offering a more trustworthy foundation for explainable AI. The use of Meaningful Intermediate Variables (MIVs) further improves the clarity and expressiveness of the symbolic models.**

***Keywords*—Explainable Artificial Intelligence (XAI); Grammatical Evolution; Symbolic Regression; Model-Driven XAI; Black-Box Explanations; Post-Hoc Explainability; Transparent AI Models**

I. Introduction

THE INCREASING deployment of machine learning (ML) systems in critical domains has renewed attention to the need for transparency, interpretability, and trust in artificial intelligence (AI) models. In practical applications, such as biomedical diagnostics and regulatory environments, it is not sufficient for a model to produce a correct prediction; it must also be able to explain *how and why* it provided a decision in a way understandable to human users [1], [2].

Explainable Artificial Intelligence (XAI) aims to make AI systems more interpretable and trustworthy [1], [3]. XAI methods include inherently transparent models (e.g. decision trees) and post hoc techniques such as LIME [4] and SHAP [5], which approximate black-box models locally. However, post-hoc explanations are often inconsistent, sensitive to sampling, and lack semantic grounding in the domain [6], [7].

These challenges have led to a growing interest in *Model-Driven* approaches to XAI, which construct interpretable models directly from data using symbolic techniques [8], [9]. Among them, Grammatical Evolution (GE) is a promising evolutionary algorithm that evolves human-readable expressions guided by context-free grammars [10]. GE has shown effectiveness in symbolic regression, functional modeling, and equation discovery - especially when domain knowledge is embedded through grammar design or Meaningful Intermediate Variables[1] (MIV) [11], [13].

This paper presents a comparative exploration of symbolic model-driven explanations using GE and black-box post-hoc tools. We argue that symbolic models offer greater semantic clarity, stability, and alignment with human reasoning. Using two benchmarks, a synthetic quadratic classification task and the Iris dataset, we show how GE produces simple, meaningful models that either recover known functional relationships (e.g. $d = b^2 - 4ac$) or leverage interpretable MIVs (e.g. petal area) to achieve high accuracy with full transparency.

Our main contributions are as follows:

- We contrast symbolic and black-box explanations on two classification tasks, highlighting the strengths and weaknesses of each approach.
- We show that GE provides clear, interpretable models aligned with domain knowledge, unlike the often unstable outputs of LIME and SHAP.
- We demonstrate the use of MIVs to enhance interpretability and simplify the model structure.
- We propose a methodology for integrating GE into a transparent MD-XAI pipeline.

The remainder of the paper is organized as follows. Section 2 outlines the background and methods. Section 3 presents experiments. Section 4 discusses the results and implications, and Section 5 concludes with insights and future work.

II. Related Work and Methods

This section outlines the two primary paradigms of explainability considered in this study: post-hoc explanation methods for black-box models, and model-driven symbolic approaches based on Grammatical Evolution. We discuss their principles, strengths, and known limitations, focusing on their impact on semantic clarity, model transparency, and alignment with domain knowledge.

[1] A Meaningful Intermediate Variable (MIV) has clear semantics, is derived from simple functions, and depends on data or other MIVs.

Topical area: Advanced Artificial Intelligence in Applications

A. Black-Box Explanation Techniques

Post-hoc explainability interprets black-box models (e.g. ensembles, neural networks) by analyzing the output without accessing internal structure. Two widely used methods are LIME [4] and SHAP [5]:

- **LIME** fits a local linear surrogate model by perturbing input data to explain predictions.
- **SHAP** uses game theory to calculate feature contributions by calculating Shapley values.

Although popular for their visual intuitiveness, LIME and SHAP face intrinsic key limitations [7], [3], [6]:

- *Instability:* Results vary with random seeds or sampling.
- *Locality:* Explanations are instance-specific and are not generalizable.
- *Poor semantics:* Attributions lack domain or causal grounding.
- *Explainer opacity:* The logic behind them is often difficult to validate.

These weaknesses have motivated the development of model-driven alternatives that prioritize transparency and interpretability by discovering and designing structures [15], [7], [8].

B. Symbolic Regression with Grammatical Evolution

Symbolic regression seeks interpretable mathematical expressions that fit the data accurately. Unlike classical regression with fixed structures (e.g. linear, polynomial), it explores a broad space of formulas composed of variables, constants, and operators, producing models that are directly interpretable and verifiable by humans.

Model-driven explainability seeks to construct models that are inherently interpretable. Among symbolic machine learning techniques, GE provides a flexible and powerful approach to discovering human-readable models [10].

GE is a genetic programming technique that uses context-free grammars to define valid symbolic expressions. Solutions are encoded as genomes that are decoded into mathematical formulas or rules based on the grammar.

- **Expressive Power:** GE supports arithmetic, logic, and domain-specific operations via customizable grammars.
- **Interpretability:** The output models are human-readable symbolic expressions.
- **Incorporation of Domain Knowledge:** Grammar rules or MIVs embed prior knowledge into the search space.

This approach has been successfully applied in various domains, including bioinformatics [9], symbolic regression [10], [12], and model-driven XAI [11], [8], [13]. GE discovers interpretable functions that reflect the data structure while allowing integration of constraints and semantic guidance.

Using user-defined grammars, GE can enforce domain-specific constraints or promote particular structural patterns. For instance, intermediate variables or known transformations can be explicitly included in the grammar, guiding the search process toward semantically valid and explainable models. This makes GE especially suitable for applications that require compliance with expert knowledge or regulatory compliance.

Our prior work [13] showed that GE can rediscover symbolic relationships (e.g. the quadratic discriminant) and generate compact and transparent classifiers. For example, using the hand-made variable $PLmPW = \text{petal.length} \cdot \text{petal.width}$, GE accurately classified the Iris species with high accuracy and full transparency.

Recent research explores hybrid methods that combine GE with neural networks or extract symbolic rules from black-box models [14].

C. Comparison Criteria

In this work, we evaluate post-hoc and symbolic explanation methods based on the following key dimensions:

- **Fidelity:** Accuracy of the explanation relative to the model or the true function.
- **Simplicity:** Complexity of the resulting explanation (e.g. expression length, tree depth).
- **Semantic Alignment:** Degree to which the explanation uses meaningful or domain-relevant variables.
- **Stability:** Consistency of the explanation across multiple runs or perturbed inputs.

D. Incorporating GE into XAI Pipelines

To formalize the use of GE as an alternative to post-hoc explainers, we propose a transparent pipeline for integrating it into explainability workflows. This replaces black-box interpretation with directly evolved, interpretable models:

1) **Feature Preprocessing:** Prepare input data; optionally derive MIVs.
2) **Grammar Specification:** Define a context-free grammar with domain semantics.
3) **GE Model Training:** Apply GE to evolve models mapping features/MIVs to outputs.
4) **Symbolic Rule Extraction:** Select models according to fitness, simplicity, and semantic alignment.
5) **Validation and Interpretation:** Assess accuracy and interpret model structure.

Figure 1 illustrates the structure of this methodology.

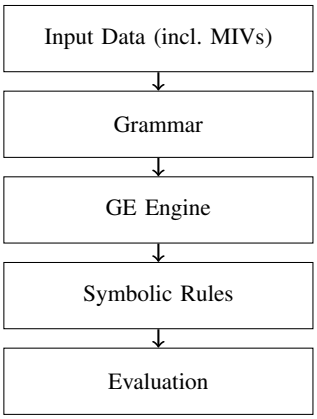

Fig. 1. Pipeline for symbolic model construction using GE

III. Experimental Comparison

To compare black-box explanation methods with symbolic GE models, we performed experiments on two tasks: a synthetic quadratic discriminant classification and the Iris dataset, a standard benchmark for interpretability studies.

A. Quadratic Classification Task

This task involves a simple symbolic function: the discriminant of a quadratic equation $d = b^2 - 4ac$ to classify input into two ($d > 0$), one ($d = 0$) or no real solutions ($d < 0$).

The dataset contains synthetic (a, b, c) tuples labeled with the corresponding value of d.

In the initial phase of the experiment, we trained models to classify the number of real roots using only (a, b, c), without providing $d = b^2 - 4ac$. This tested whether standard methods, linear regression, decision trees, and random forest (RF), could learn the decision boundary from data alone. The performance of the model was assessed using two metrics: RMSE (Root Mean Squared Error), defined as $\text{RMSE}(y, \hat{y}) = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}$, and its normalized form, NRMSE, $NRMSE = \frac{RMSE}{\bar{y}}$.

The prediction accuracy is presented in Table I. Although random forest had the lowest test error, none of the models produced interpretable rules or captured the underlying structure. Their generalization, especially near $d = 0$, was unstable.

TABLE I
RMSE and NRMSE of selected machine learning models trained on (a, b, c) without access to the discriminant

Model	RMSE (train)	NRMSE (train)	RMSE (test)	NRMSE (test)
Linear Regression	0.8267	0.8026	0.8239	0.8368
Decision Tree	0.5431	0.5273	0.8142	0.8224
Random Forest	0.2284	0.2218	0.5883	0.5942

This motivated the introduction of a domain-informed variable representing the discriminant to evaluate the benefits of symbolic modeling and explainability.

a) LIME and SHAP Results: We applied both explanation tools to the RF classifier and observed notable inconsistencies in predictions:

- LIME frequently attributed great importance to the variable b, with fewer or inconsistent roles for a and c.
- SHAP produced attributions in which c often appeared dominant, sometimes contradicting LIME.

Neither method revealed the discriminant formula or suggested that a quadratic combination of a, b, and c was relevant.

As shown in Fig. 2, LIME and SHAP sometimes disagreed on both the importance and direction of the feature. Similar instability was observed in [13], where shallow explanations lacked semantic consistency.

b) GE Results: In contrast, the GE model directly rediscovered the symbolic form of the discriminant: $d = b^2 - 4ac$ GE then generated an interpretable rule-based classifier:

$$\texttt{ifelse}(d > 0, \text{"two"}, \texttt{ifelse}(d == 0, \text{"one"}, \text{"zero"}))$$

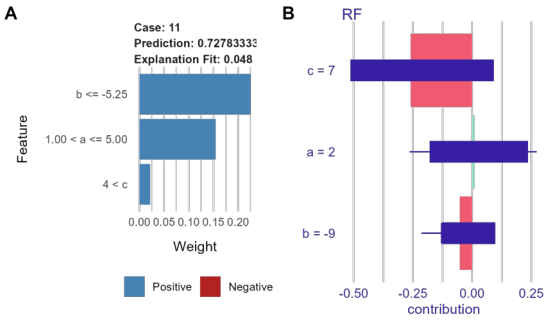

Fig. 2. (**A**) LIME and (**B**) SHAP explanations for a given prediction

This compact and interpretable structure is exactly consistent with the known semantics of the problem. Figure 3 illustrates the classification process: calculate the discriminant d, then assign the class based on its value.

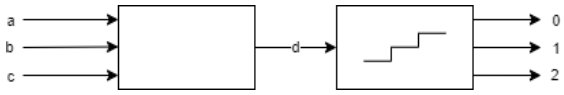

Fig. 3. GE-evolved symbolic rule with intermediate variable d representing the discriminant. The rule exactly matches the theoretical solution structure.

The symbolic rule for d was discovered by evolutionary search on a grammar encoding arithmetic operations and constants relevant to the discriminant:

```
<expr> ::= <var> | <op>(<n>, <var>)
    | <op>(<var>, <n>) | <op>(<expr>, <expr>)
<op>   ::= "-" | "*" | "^"
<var>  ::= a | b | c
<n>    ::= 1 | 2 | 3 | 4
```

The grammar for the final classification, which assigns the number of solutions of a quadratic equation, is listed below:

```
<result>     ::= ifelse(<expr>, "one", "other")
<expr>       ::= (<expr> & <sub_expr>)
        | (<expr> | <sub_expr>) | <sub_expr>
<sub_expr>   ::= <comparison>(<var>, <func_var>)
<comparison> ::= > | < | ==
<func_var>   ::= <num> | <var> | <func>(<var>)
<func>       ::= mean | max | min | sd
<var>        ::= a | b | c | d
<num>        ::= 0 | 1
```

The GE model achieved 100% accuracy on the training and test sets due to perfect alignment with the true decision boundary. In contrast, the random forest misclassified 4–5% near $d = 0$ and failed to generalize. This case demonstrates that GE provides strong performance and formal transparency, providing stable, reproducible, and verifiable expressions, unlike post-hoc black-box explainers. This experiment highlights the value of MIVs, like d, which capture complex feature relationships. MIVs reflect domain knowledge and decompose learning into interpretable parts. As shown in [13], they help GE efficiently discover accurate and human-readable rules, which post-hoc tools such as LIME or SHAP cannot achieve due to their lack of structural abstraction.

B. Iris Dataset

The Iris dataset includes 150 samples labeled: Setosa, Versicolor, or Virginica, each with four features: sepal length/width and petal length/width. It is commonly used to assess the interpretability of the model.

a) LIME and SHAP Results: RF trained on the Iris dataset was explained with LIME and SHAP. Compared to the quadratic task, the results were more consistent. Both tools often highlighted *Petal.Length* and *Petal.Width*, though discrepancies remained. As shown in Fig. 4, LIME negatively emphasized all features, while SHAP prioritized petal features over sepal ones.

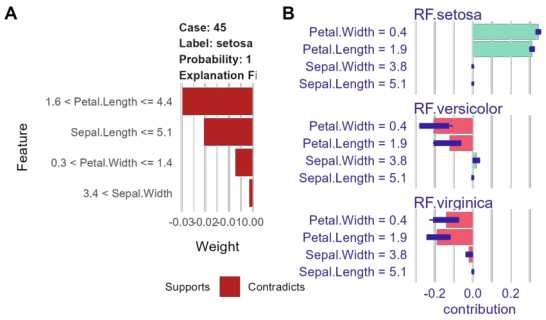

Fig. 4. (**A**) LIME and (**B**) SHAP explanations for the same Iris sample

Despite improved consistency compared to the delta experiment, neither method offered a compact or semantically meaningful rule that could generalize throughout the dataset.

b) GE Results: GE was applied to the full feature set to minimize misclassifications, running for 1000 iterations with default settings and the grammar shown below:

```
<expr>       ::= (<expr> & <sub_expr>)
       | <expr> | <sub_expr>) | <sub_expr>
<sub_expr>  ::= <comparison>(<var>, <func_var>)
<comparison> ::= > | < | == | >= | <=
<func_var>   ::= <num> | <var> | <func>(<var>)
<func>       ::= mean | max | min | sd
<var>        ::= Sepal.Length | Sepal.Width
               | Petal.Length | Petal.Width
<num>        ::= 1 | 1.5 | 2 | 2.5 | 3 | 4 | 5
```

Representative symbolic models and their corresponding plots are shown below, highlighting the effective separation of the *setosa* and *versicolor* classes.

```
ifelse(Petal.Length <= Sepal.Width, "setosa",
"other")

ifelse((Petal.Width <= 1.5)&(Petal.Length >= 2.5),
"versicolor", "other")
```

Although the model identified all *setosa* samples, its classification of *versicolor* at 94.66% accuracy indicates potential for further improvement.

To improve the classification, we extended the feature set by introducing a Meaningful Intermediate Variable that approximates the petal area:

$$PLmPW = petal.length * petal.width \quad (1)$$

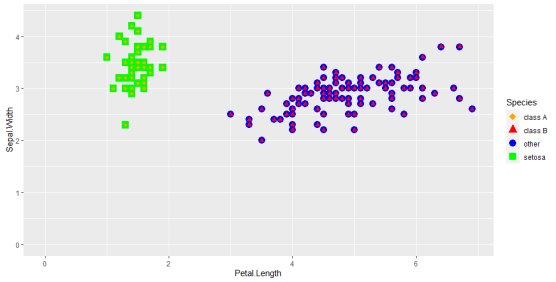

Fig. 5. *Setosa* classification with sepal width and petal length

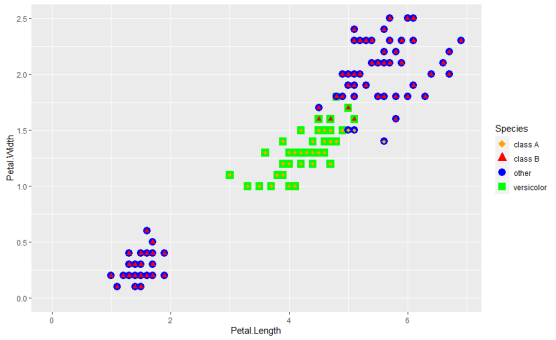

Fig. 6. *Versicolor* classification with petal width and petal length

Using this MIV, GE developed a simple and accurate rule-based model:

- If $PLmPW \leq 2$: Setosa.
- If $2 < PLmPW \leq 8$: Versicolor.
- If $PLmPW > 8$: Virginica.

This rule achieved approximately 95% precision, with a decision structure that is semantically meaningful and easy to understand.

Figure 7 presents the functional model obtained by combining the individual rules.

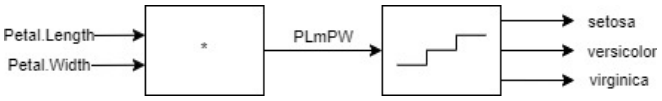

Fig. 7. Functional model for Iris species classification with MIV

The results of the classification process performed with the functional model provided are depicted in Figure 8.

We also introduced additional MIVs including the sepal area:

$$SLmSW = sepal.length * sepal.width, \quad (2)$$

petal and sepal perimeters, and various length-to-width ratios to improve model accuracy.

MIVs used in the model may be derived not only from the original input features but also from other previously defined MIVs. One such example is the petal-to-sepal area ratio, proposed using the MIVs defined in Equations 1 and 2:

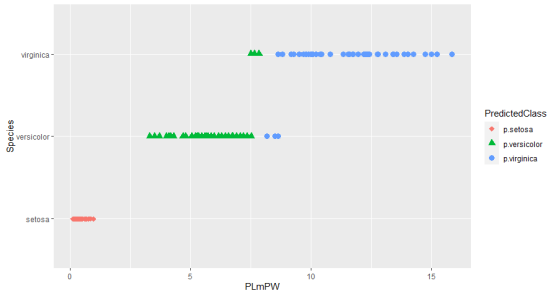

Fig. 8. Iris species classification with $MIV = petal.length * petal.width$

$$PdS = \frac{PLmPW}{SLmSW} \tag{3}$$

Using the GE approach, the following classification rules were generated on the basis of the derived PdS value:

```
ifelse(PdS <= 0.2, "setosa", "other")
ifelse((PdS <= 0.43) & (PdS >= 0.22),
"versicolor", "other")
ifelse(PdS >= 0.43, "virginica", "other")
```

These rules define a functional model, presented in Figure 9.

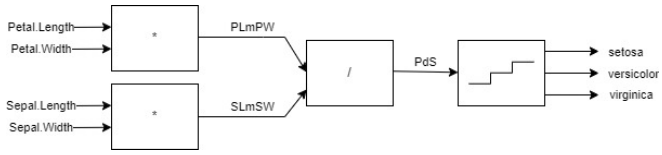

Fig. 9. Functional model for Iris classification with multiple MIVs

The classification results obtained using the functional model based on multiple MIVs are presented in Figure 10.

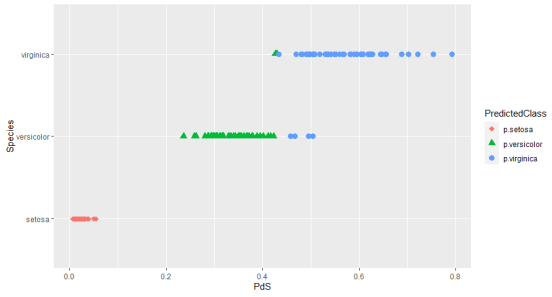

Fig. 10. Iris species classification with multiple MIVs

The model demonstrates an improvement over the previous one, achieving an accuracy of 96%.

IV. Analysis and Discussion

The experimental results highlight differences between post-hoc explainability techniques and model-driven symbolic methods. Our comparative analysis focuses on four critical dimensions: stability, interpretability, semantic alignment, and predictive performance.

A. Stability and Reproducibility

An intrinsic limitation of post-hoc methods is the *instability*. Attribution values vary across runs or small input changes, especially in the quadratic task. For example, LIME overemphasized b, while SHAP inconsistently prioritized c, reducing reliability in high-stake settings.

In contrast, GE consistently produced models with stable structure and clear semantics across runs, offering strong support for reproducibility, system auditing, and model understanding.

B. Interpretability and Semantic Coherence

GE produces symbolic models based on mathematical or logical rules that are directly interpretable. In the quadratic task, it rediscovered $d = b^2 - 4ac$. In the Iris dataset, MIV-based rules (e.g. petal area, petal-sepal ratios) reflect domain structure and improved transparency.

LIME and SHAP offer intuitive local insights but lack structural integration. Their explanations are not reusable and generalizable, limiting their value for model critique and design.

C. Role and Value of Intermediate Variables

MIVs significantly enhanced interpretability and performance. In the Iris task, handcrafted variables like `PLmPW` and `PdS` helped GE derive simple domain-aligned rules by embedding biological knowledge into the search process. We also showed that MIVs can be composed hierarchically—for example, `PdS` combines two others, supporting scalable symbolic modeling in complex domains with important but implicit constructs.

D. Prediction Accuracy

Although symbolic modeling prioritizes interpretability, GE models also achieved high precision. In the quadratic task, GE accurately captured the decision boundary. For the Iris dataset, MIV-based models reached 96% accuracy—matching black-box classifiers, but with much greater transparency. In particular, some gains came from structured variables, emphasizing the value of hybrid approaches that combine domain knowledge with symbolic learning.

E. Limitations and Practical Considerations

Despite its advantages, GE has practical constraints. Grammar design requires domain expertise, and poor design either limits the search space excessively or fails to guide the model toward meaningful solutions. As a stochastic method, GE may require multiple runs or tuning. However, in domains with expert input or bounded problems, GE offers a controllable and verifiable alternative to opaque black-box explanations.

The comparative evaluation described in Section II-C established four key criteria: reproducibility, interpretability, semantic consistency, and structural clarity. These dimensions provided a principled framework for analyzing the strengths and limitations of each method. The experimental findings validate the relevance of this framework: post-hoc methods

like LIME and SHAP showed weaknesses in reproducibility and semantic alignment, often generating inconsistent or context-insensitive attributions. In contrast, the symbolic models developed through GE satisfied all four criteria. They were reproducible across runs, structurally coherent, interpretable by domain experts, and semantically aligned with known functional relationships. The use of this criteria-driven perspective was essential in highlighting that precision alone is insufficient when evaluating explainable models, and structural and semantic properties must also be considered.

To consolidate the results and observations discussed in the experimental sections, Table II provides a qualitative comparison of the three approaches evaluated. LIME, SHAP, and Grammatical Evolution. The comparison is organized around the four criteria defined in Section II-C: fidelity, simplicity, semantic alignment, and stability.

TABLE II
QUALITATIVE COMPARISON OF EXPLANATION METHODS

Criterion	LIME	SHAP	GE
Fidelity	Low–Medium	Low-Medium	High (in known domains)
Simplicity	Medium	Medium	High (compact rules)
Semantic Alignment	Low	Low	High (uses MIVs)
Stability	Medium	Medium	High

As shown in the table, LIME and SHAP provide partial fidelity and limited semantic coherence, particularly in tasks where the decision boundary depends on specific functional structures. Their attributions are also sensitive to sampling variability and lack cross-instance consistency. GE, by contrast, produces symbolic models that offer high fidelity when the target rule is recoverable, and do so using semantically meaningful constructs such as intermediate variables. These symbolic rules are compact and structurally transparent, providing an interpretable basis for classification decisions. This distinction is particularly evident in the quadratic task, where GE recovered the exact mathematical discriminant, while LIME and SHAP failed to detect the underlying structure.

V. CONCLUSION

This study presents a comparative evaluation of black-box post-hoc explanation methods (LIME and SHAP) and symbolic, model-driven approaches using Grammatical Evolution. In two classification tasks, GE consistently demonstrated superior semantic clarity, interpretability, and reproducibility.

The core findings are as follows:

- **Interpretability and Semantic Alignment:** GE-generated symbolic models are inherently interpretable, expressed as explicit formulas aligned with domain semantics (e.g., discriminants or feature ratios). In contrast, LIME and SHAP offer fragmented, instance-specific attributions that are often semantically opaque and inconsistent across similar inputs.
- **Structured Abstraction through MIVs:** GE incorporates structured domain knowledge via Meaningful Intermediate Variables, such as petal area or petal-to-sepal ratios. These enhance model clarity, simplify decision boundaries, and support composability by enabling hierarchical MIVs built from previously defined variables.
- **Accuracy and Trustworthiness:** While GE emphasizes interpretability, it also achieves competitive accuracy—up to 96% on the Iris dataset, generating compact and transparent rules. This combination improves trust and auditability in high-stakes or regulated applications.

These results suggest that symbolic regression techniques, and particularly GE, provide a viable alternative to post-hoc explainers in contexts where explanation fidelity and transparency are critical.

Future work will focus on intelligent and automated grammar generation, discovering intermediate variables, and improving convergence strategies for grammar-guided evolution.

***Abstract*—This study conducts a comparative analysis of Artificial Intelligence (AI) software and traditional GitHub repositories, focusing on workflow efficiency and sentiment dynamics. Using process mining and sentiment analysis techniques, we examine repositories from eight prominent projects, encompassing diverse datasets of issues and pull requests filtered for relevance and consistency. Our findings reveal that AI software repositories exhibit different workflow patterns and sentiment dynamics compared to traditional repositories. Sentiment analysis uncovers that contributors to AI software repositories experience more positive sentiment dynamics, likely reflecting structured workflows and collaborative tools. Conversely, traditional repositories exhibit longer resolution times and more fluctuating sentiment patterns, which may indicate higher complexity or less automation. These insights provide valuable recommendations for optimizing repository management, fostering contributor satisfaction, and improving collaborative software development environments.**

I. Introduction

MANAGING software development processes that are multi-disciplinary, human-intensive, and prone to change requires effective tools. Git, a free and open-source distributed version control system, is widely used to manage projects of all sizes with speed and efficiency. GitHub, an open-source hosting platform, extends Git's capabilities by offering cloud-based version control and collaboration features. As one of the leading data sources for software development research [1], GitHub enables developers to manage and store their code while providing a wealth of information for analyzing software development processes, particularly in collaborative software projects.

As artificial intelligence (AI) has become integral to modern software systems, understanding the development processes of AI software systems has emerged as a significant area of research in software engineering [2]. GitHub provides rich data, including information on issues, commits, projects, users, comments, and the defined GitHub development flow.

Process mining is a data science technique that extracts process insights from event logs stored in information systems [3]. GitHub data, generated during the software development can be converted to event logs to enable process discovery and analysis. By identifying elements of the actual software development process, such as issues, pull requests (PR), and commits, along with their descriptive attributes, process deviations and inefficiencies can be systematically investigated.

Mining Software Repositories (MSR) techniques focus on extracting and analyzing data from software repositories to uncover interesting, useful, and actionable insights about software systems. MSR is considered one of the fastest-growing and most compelling areas in the field of software engineering [4]. The literature contains numerous studies focused on mining GitHub repositories to analyze software development processes for specific purposes. These include detecting anomalies in PR processes [5], understanding and improving students' project workflows [6], [7], [8], managing issues in AI software repositories [9], and analyzing the effects of continuous integration and continuous deployment (CI/CD) practices on repositories [10]. Several tools such as GitHubDataViz [11], GitLab Analyser [6], and Git Truck [12] have been introduced to support the analysis of software development data by visualizing Git issue and commit data.

In this study, we present a GitHub-based data collection framework for process mining and an empirical analysis comparing actual software development processes using process mining techniques and sentiment dynamics in AI software and traditional software repositories. Specifically, this research explores whether AI software projects exhibit distinct patterns in issue resolution, PR management, and contributor sentiment compared to traditional repositories.

II. Related Work and Background

Poncin et al. [13] demonstrated the application of process mining in software repositories, facilitating the analysis of developer roles and bug report handling. Expanding on this, Macak et al. [7] used process mining techniques for the Git log of students' projects to understand their development processes.

Sentiment analysis has become an important tool in understanding the emotional undertones in software development processes. Comments of repository artifacts, such as issues, PRs, and code, contain unstructured and valuable data to understand the sentiment dynamics that impact workflow efficiency and collaboration.

Jurado and Rodriguez [14] conducted a study that explored the use of sentiment analysis to monitor distributed teams, highlighting how emotional analysis of developer-written issues and tickets can provide a richer understanding of the development environment. Yang et al. [15] carried out an empirical study specifically focused on sentiment analysis in the GitHub repositories, revealing that the emotional tone of comments significantly affects the speed of bug fixing. Guzman et al. [16] identified patterns indicating higher negative sentiment in Java-based projects and more positive sentiment in geographically distributed teams. Research into developer behavior in open-source projects indicates a strong correlation between developer activities and sentiment shifts, which can serve as predictors of project success [17]. Robinson et al. [17] provided insights into how these factors influence repository health and productivity. Sinha et al. [18] also analyzed the sentiment in commit logs, exploring the emotional undertones in commits and their impact on project outcomes. While these studies offer valuable perspectives on developer sentiment, our research differentiates itself by investigating how the development processes of AI software products might influence these sentiments.

Zhou Yang et al. [9]'s empirical study on issue management in AI software repositories highlighted challenges such as runtime errors and unclear instructions.

Our study extends previous studies to a broader range of repository artifacts, including issues, code comments, and commit messages, to provide a more holistic view of sentiment dynamics in software development processes, which are discovered through process mining techniques.

III. Methodology

A. Repository Selection and Data Collection

Data was collected from publicly available GitHub repositories using the GitHub REST API. AI software repositories (TensorFlow, PyTorch, scikit-learn, Keras) focus on machine learning algorithms and frameworks. Traditional repositories (Angular, React, Bootstrap, Node.js) emphasize conventional software technologies. The selected repositories are listed in Table I.
