The complex exponential term in (9) represents the phase shift of the array phase center relative to the origin. If the position of the array is shifted so that the center of the array is located at the origin, this phase term goes away. The array factor after phase shift and normalization becomes:

$$AF = \frac{1}{N} \frac{\sin\left(\frac{N\psi}{2}\right)}{\sin\left(\frac{\psi}{2}\right)} \tag{10}$$

### *B. Planar Array*

Unlike linear arrays that can only scan the main beam in one polar plane ($\theta$ - the elevation plane or $\phi$ - the azimuth plane), planar arrays scan the main beam along both $\theta$ and $\phi$. Planar arrays offer more gain and lower sidelobes than linear arrays, at the expense of using more elements. The design principles for planar arrays are similar to those presented earlier for the linear arrays. Since the elements are placed in two dimensions (see Fig. 2), the array factor of a planar array can be expressed as the multiplication of the array factors of two linear arrays [5]: one along the x-axis and one along the y-axis:

$$AF_{planar} = AF_x * AF_y = \frac{\sin\left(\frac{N_1\psi_x}{2}\right)}{N_1 \sin\left(\frac{\psi_x}{2}\right)} \frac{\sin\left(\frac{N_2\psi_y}{2}\right)}{N_2 \sin\left(\frac{\psi_y}{2}\right)} \tag{11}$$

where:

$$\begin{aligned} \psi_x &= kd_x \,\mathbf{sin}\,\theta\,\mathbf{cos}\,\phi + \alpha_x \\ \psi_y &= kd_y \,\mathbf{sin}\,\theta\,\mathbf{sin}\,\phi + \alpha_y \end{aligned} \tag{12}$$

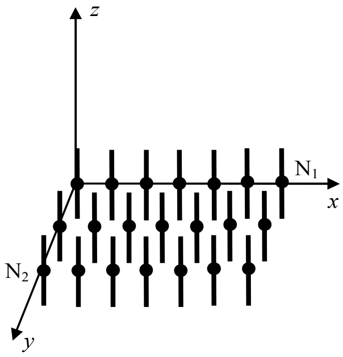

Fig. 2 The planar array antennas

### C. Three – dimensional Array (3 – D Array)

Starting from the planar array, where it is considered that the system has a rectangular configuration of elements, the three – dimensional array antenna (Fig. 3) is achieved by introducing a number of planar arrays on the *z* axis. In this case, the array factor is:

$$AF_{3D} = AF_x * AF_y * AF_z =$$
$$= \frac{\sin\left(\frac{N_1\psi_x}{2}\right)}{N_1\sin\left(\frac{\psi_x}{2}\right)} \frac{\sin\left(\frac{N_2\psi_y}{2}\right)}{N_2\sin\left(\frac{\psi_y}{2}\right)} \frac{\sin\left(\frac{N_3\psi_z}{2}\right)}{N_3\sin\left(\frac{\psi_z}{2}\right)} \quad (13)$$

where:

$$\begin{aligned}\psi_x &= kd_x \sin\theta\cos\phi + \alpha_x \\ \psi_y &= kd_y \sin\theta\sin\phi + \alpha_y \\ \psi_z &= kd_z \cos\theta + \alpha_z\end{aligned} \quad (14)$$

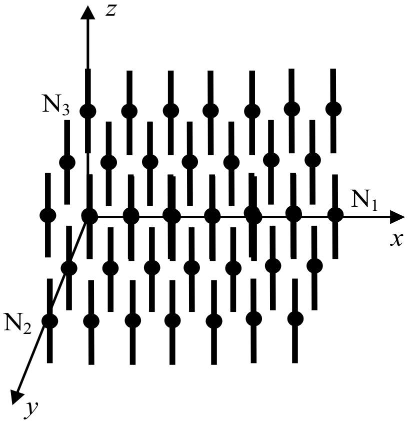

Fig. 3 Three – dimensional array antennas

In case of three – dimensional array antennas there are restrictions regarding the distance between elements on *z* axis which could not be less than elements dimensions.

## III. Simulation Results

Our simulations are made for linear, planar and three – dimensional array antennas. Starting from a linear array antennas with logarithmic directivity pattern, composed between 2 – 9 elements (dipole antenna) that are evenly spaced with the distance of *λ/2*, we built a planar array and, respectively three – dimensional array antennas.

The simulations are made in Matlab and all results are displayed normalized. The radiation patterns obtained in different situations are generated in two planes, *xOy* plane (*H* plane) and *xOz* plane (*E* plane). We use the opening angle of the main lobe to compare the results obtained in these situations [7].

Because for a linear array antenna the increases in a phase shift between currents injected in two consecutive elements leads to decreases in directivity, we are focused on planar and *3D* array antennas.

The radiation patterns obtained in *xOy* plane (*H* plane) for planar array antennas with different number of elements and phases are represented in Fig. 4. In Fig. 4.c a radiation pattern for 45° phase shift of currents injected in array elements is presented.

The radiation pattern obtained in *xOz* plane (*E* plane) is presented in Fig. 5.

For planar array antenna with 7 × 7 elements, and three – dimensional array antenna with 7 × 7 × 7 elements, and 0° phase shift, the radiation patterns are presented in Fig. 6.

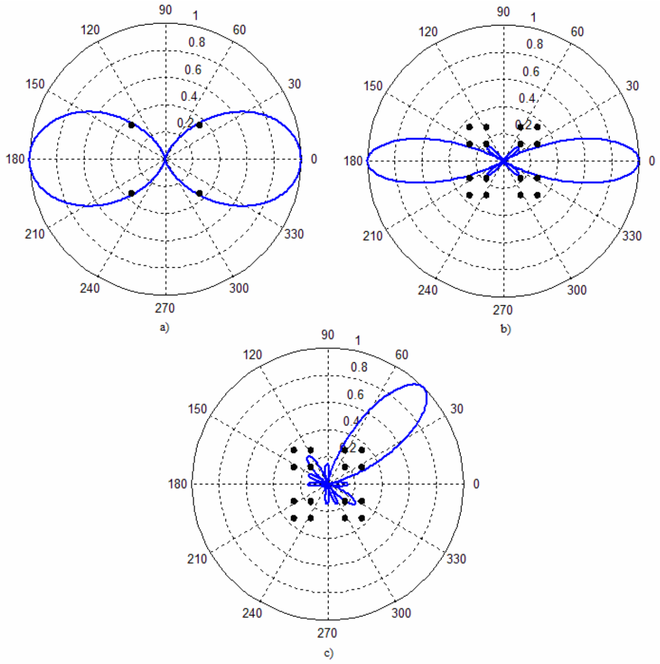

Fig. 4 Radiation patterns obtained in *H* plane for planar array antennas: a) with 2x2 elements and 0° phase shift; b) with 4x4 elements and 0° phase shift; c) with 4x4 elements and 45° phase shift

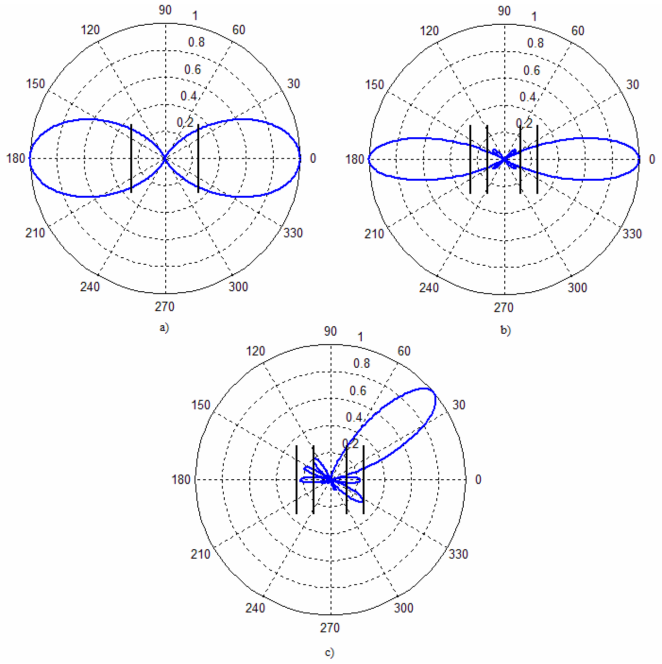

Fig. 5 Radiation patterns obtained in *E* plane for planar array antennas: a) with 2x2 elements and 0° phase shift; b) with 4x4 elements and 0° phase shift; c) with 4x4 elements and 45° phase shift

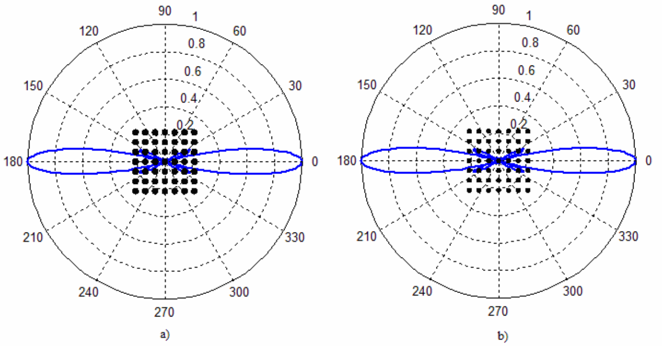

Fig. 6 Radiation patterns obtained in *H* plane for: a) planar array antennas with 7x7 elements and; b) 3D array antennas with 7x7x7 elements

As a comparison we used the opening angle of the main lobe. In case of identical currents injected in array elements the results are presented in Table I.

During the experiments we conclude that increasing the number of elements over 7 does not lead to significant increase of directivity, so we suggest that the maximum number of elements for an array should not be greater than 7. Using planar array antennas with 7 × 7 elements and introducing a phase shift of 30° and 165° between the currents injected in two consecutive elements, we obtain the radiation patterns represented in Fig. 7. For three – dimensional array antennas with 7 × 7 × 7 elements and with a phase shift equal to 105° and 165° respectively, the radiation patterns are represented in Fig. 8.

The 3D patterns for planar array and three – dimensional array are presented in Fig. 9. Because we used a distance between elements equal with *λ/2* for phase shift equal with 180° the obtained pattern is same as in case of no phase shift.

The values obtained for the opening angle of main lobe in case of array antennas formed by 7 elements with different phase shift between consecutive elements are presented in Table II.

We could observe that the opening angle for different structure array is same if the phase shift is complement to 180°, but for angles lower than 30° or higher than complement to 180° or for angles between 70° and 110° the pattern characteristic has two lobes, one in direction determined by phase shift and another to the direction complement to 180° attenuated with 20%.

## IV. WSN APPLICATIONS

One of the most interesting applications for directional antenna is Wireless Sensor Networks (WSN). WSN represent a spatially distributed of large number of autonomous sensors which collect data from environment and is able to send it to a main certain locations. WSN has many applications from different field. The main areas of applications of WSN are: military (monitoring forces, equipment and ammunitions; battlefield surveillance; targeting, etc.), environmental (forest fire detection; bio-complexity mapping of environment; flood detection; air and water pollution), health (telemonitoring of human physiological data, tracking and monitoring doctors and patients, drug administration), home and office (automation; smart environment), automotive (reduces wiring effects; measurements in chambers and rotating parts, remote technical inspections, conditions monitoring e.g. at a bearing) [8].

The architecture of the WSNs can take many forms starting from a star network to an advanced multi-hop wireless network. One possible solution for WSN communications architecture is presented in Fig. 10.

The components of the networks are called nodes; each of them is connected to one or, sometimes, several others. The main structure for sensor nodes is presented in Fig. 11.

In many cases in order to connect to send data it is necessary to obtain a maximum signal to noise ratio in transmission [9].

Because the transmission system has a consumption that depends on the signal to noise ratio, it is necessary to improve this parameter.

In a transmission system the signal to noise ratio could be improved without increasing energy if we are able to increase the gain of the antenna or if we are able to orient the antennas in a way in what the pattern characteristics are aligned. Using an array antenna we can control the orientation of the pattern characteristic without any energy consumption. This leads to the increased signal to noise ratio and to the reduced energy consumption because it is not necessary a mechanical orientation of the elements of the node in order to obtain maximum signal to noise ratio.

TABLE II.
OPENING ANGLE FOR ARRAY ANTENNAS FOR PHASE SHIFT

| Phase shift | Linear | | Planar | | Three – dimensional | |
|---|---|---|---|---|---|---|
| | ***H*** | ***E*** | ***H*** | ***E*** | ***H*** | ***E*** |
| $0^0$ | 13,7° | 40,1° | 13,7° | 13,7° | 13,7° | 13,7° |

## V. Conclusion

A brief overview of antenna array aspects has been given. We observe that in cases of planar array and three – dimensional array, the systems become more directly. Also, if a phase shift between current injected in the antenna elements is introduced the linear array become impracticable in terms of directivity pattern.

During the experiments we conclude that increasing the number of elements over 7 does not lead to significant increase of directivity, so we suggest that the maximum number of elements for an array should not be greater than 7.

In order to obtain an oriented pattern characteristic, only planar and 3D array could be used because a linear array has many secondary lobes, and in this case the gain decreases. Also in order to obtain a good directivity the phase shift should be between 30 and 150 degree.

Array antennas are increasingly used nowadays because using them can improve radio transmissions by:

- increasing signal coverage, by increasing capacity for data transfer,
- reducing interference due to multipath signal propagation, simultaneous multiple signals radiated to different users,
- better focus of the beam radiated to the direction of interest.

For a better orientation of the beam radiated to a user, the array antenna must be able to detect the direction from which the signal arrives from the user. Future work is oriented to investigate what is happened in case of changes the regularity of the array structure and also a new structure for planar array.

*Abstract* — **The presented paper is focused on analysis of two methods of marker localization. The markers are passive RFID transponders (without or with identification chip) consisting of tuned LC circuit and being used to mark and trace underground networks such as cables and pipes. Localization of the marker is based on evaluation of signal amplitude received from the excited marker, i. e. it is RSSI based localization method. The excitation of marker can be periodically repeated or continuous. In the first case the localization process consists of two stages – excitation and receiving of marker damped oscillations, in the second case the amplitude of continuously generated excitation signal is decreased by vicinity of the marker. Both localization methods are mathematically analyzed by modeling of their circuits using differential equations. The results of analysis are used to compare both methods and to evaluate their suitability for practical utilization.**

## I. Introduction

INDUCTIVELY coupled RFID (Radio Frequency Identification) systems [1] are now being widely used in many industrial applications. For example, the marking of goods by RFID technology enables the traceability of goods which is helpful to control the whole logistic chain from production to sale. In addition to these applications, the RFID transponders are being used for marking of underground facilities location. Such RFID transponders are called “markers”. The marker is a passive RFID transponder consisting of a tuned LC circuit without identification chip (1-bit) or with identification chip tuned on low frequency in 77 kHz – 170 kHz band.

For localization of some older underground facilities (cables, pipes etc.) a signal can be injected into their continual metal conductor and this signal can then be received on terrain surface and the cable or pipe can be traced. Today’s underground facilities are mostly constructed from plastic material so this simple localization and tracing method cannot be used, therefore in this case the marking of underground objects by RFID markers is the only useable method.

The unknown position of marker under the terrain surface can be estimated by a localization device (locator). Moreover, the depth of marker can be estimated by RSSI (Received Signal Strength Indication) similarly as described in [2], [3]. In [4] the authors describe marker localization methods based on marker damped oscillations and on continuous generating of electromagnetic waves. This work extends the analyses of RSSI based marker localization methods. The method based on damped oscillations of marker is extended by introduction of separate damping and sensing resistors and the analysis of method based on continuous marker excitation is done by applying differential equations instead of algebraic equations to analyze the transient phenomena in sensing circuit.

## II. Related Works

The localization of moving underground objects (for example animals) based on inductive coupling is described in [5]. This application assumes the use of sensor network consisting of transmitting coils fixed on terrain surface and the moving underground object equipped with receiver collects data transmitted from these coils.

Indoor localization based on triaxial coils applied in both transmitter and receiver with very low working frequency 2.5 kHz is published in [6]. Low frequency magnetic field is suitable for underground localization purposes, too, because it is not affected by ground properties.

Another approach is presented in [7]. This work assumes localization based on UHF RFID tags in mining industry, but it is performed in mining tunnels and localization from the terrain surface is not assumed so the UHF signals do not propagate through layer of ground.

## III. Mutual Inductance

An important quantity in the models presented in next chapters is the mutual inductance $M$ between marker and locator coils which depends on the geometrical arrangement of coils according to equation [1], [4], [8]:

$$M = \frac{\sqrt{L_R L_T}\, r_R^2 r_T^2 \cos\theta}{\sqrt{r_R r_T}\left(r_R^2 + x^2\right)^{\frac{3}{2}}} \tag{1}$$

978-83-60810-66-8/$25.00©2015, IEEE

where $r_R$ is radius of RFID locator antenna coil, $r_T$ is radius of marker coil, $x$ is distance between the locator antenna and the marker and $\theta$ is the angle between coil of locator antenna and marker coil (note that if $\theta$=0 ° then coils are parallel).

## IV. Mathematical Model Based On Damped Oscillation

This principle of localization assumes that the localization device periodically excites the marker LC circuit and in the pauses between excitation periods the response from marker in form of its damped oscillations is received. The simple model with one resistor was analyzed in [4]. In this chapter a more complex model with separate damping and sensing resistors will be analyzed. The first resistor $R_D$ is used for fast damping of locator $L_RC_R$ circuit damped oscillations and its value was calculated from equation (2). The second resistor $R_M$ is used for current sensing in the receiving stage of localization. The model is shown in Fig. 1.

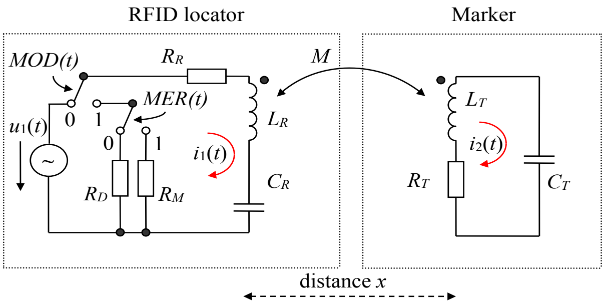

Fig. 1 Model of localization with separate damping and measuring resistors

$$R_D = 2\sqrt{\frac{L_R}{C_R}} - R_R \tag{2}$$

For this model the next system of equations (3) can be derived

$$L_R\frac{di_1(t)}{dt} + [(1-MER(t))MOD(t)R_D + MER(t)MOD(t)R_D + R_R]i_1(t) + \\ + \frac{1}{C_R}\int_0^t i_1(\tau)d\tau - M\frac{di_2(t)}{dt} = (1-MOD(t))u_1(t)$$

$$L_T\frac{di_2(t)}{dt} + R_Ti_2(t) + \frac{1}{C_T}\int_0^t i_2(\tau)d\tau - M\frac{di_1(t)}{dt} = 0 \tag{3}$$

The modulation function $MOD(t)$ is given by equation (4) and the sensing (measuring) resistor $R_M$ is switched by function $MER(t)$ given by the equation (5)

$$MOD(t) = \frac{\mathrm{Sign}\left(-\sin\frac{2\pi ft}{250}\right)+1}{2} \tag{4}$$

$$MER(t) = \frac{\mathrm{Sign}\left(-\sin\frac{2\pi f(t-\Delta T)}{250}\right)+1}{2} \tag{5}$$

i. e. it is binary square signal with a frequency 250 times lower than the frequency of excitation signal source and shifted (delayed) by $\Delta T$ in time against the modulation function $MOD(t)$. During the small delay $\Delta T$ the oscillations of locator tuned circuit has to be damped.

The excitation signal source is assumed harmonic, i. e.

$$u_1(t) = U_1\sin(2\pi ft) \tag{6}$$

The system of integrodifferential equations (3) was numerically solved after its conversion to the 1st order system of differential equations (7) by substitution $x_1(t)=i_1(t)$, $x_2(t)=\mathrm{d}i_1(t)/\mathrm{d}t$, $x_3(t)=i_2(t)$, $x_4(t)=\mathrm{d}i_2(t)/\mathrm{d}t$, $\omega=2\pi f$. Then we get:

$$\begin{aligned} \frac{dx_1(t)}{dt} &= x_2(t) \\ \frac{dx_2(t)}{dt} &= -a_1x_1(t) + a_2(1-MOD(t))\omega U_1\cos(\omega t) - a_3x_3(t) - a_4x_4(t) - \\ &\quad - a_2\left[R_R + [1-MER(t)]MOD(t)R_D + MER(t)MOD(t)R_M\right]x_2(t) \\ \frac{dx_3(t)}{dt} &= x_4(t) \\ \frac{dx_4(t)}{dt} &= -b_1x_1(t) + b_2(1-MOD(t))\omega U_1\cos(\omega t) - b_3x_3(t) - b_4x_4(t) - \\ &\quad - b_2\left[R_R + [1-MER(t)]MOD(t)R_D + MER(t)MOD(t)R_M\right]x_2(t) \end{aligned} \tag{7}$$

where the individual coefficients $a_1$, $a_2$, $a_3$, $a_4$ and $b_1$, $b_2$, $b_3$, $b_4$ are given by (8).

$$\begin{aligned} a_1 &= \frac{L_T}{C_R(L_RL_T-M^2)} & b_1 &= \frac{M}{C_R(L_RL_T-M^2)} \\ a_2 &= \frac{L_T}{L_RL_T-M^2} & b_2 &= \frac{M}{L_RL_T-M^2} \\ a_3 &= \frac{M}{C_T\left(L_RL_T-M^2\right)} & b_3 &= \frac{L_R}{C_T\left(L_RL_T-M^2\right)} \\ a_4 &= \frac{MR_T}{L_RL_T-M^2} & b_4 &= \frac{L_RR_T}{L_RL_T-M^2} \end{aligned} \tag{8}$$

The used values of $R_R$, $L_R$, $C_R$ and $R_T$, $L_T$, $C_T$ are listed in the next table:

Table I.
Values of Components Used in Numerical Calculations

| $R_R$ | $L_R$ | $C_R$ | $R_T$ | $L_T$ | $C_T$ |
|---|---|---|---|---|---|
| 15.7 Ω | 1 mH | 1.621 nF | 7.85 Ω | 1 mH | 1.621 nF |

Note that the values of $L_R$, $C_R$ and $L_T$, $C_T$ were selected so that the corresponding resonant frequencies are $f_R$=$f_T$=125 kHz.

The radiuses of both coils used in numerical calculations are $r_R$=$r_T$=0.1 m, distance between them is $x$=0.4 m and the angle $\theta$=0 °. Corresponding mutual inductance M is then calculated from (1). Amplitude of the excitation signal is $U_1$=10 V, its frequency $f$ is 125 kHz.

The damping resistor $R_D$=1533 Ω calculated from (2) in this case ensures the minimum time of $L_RC_R$ transient response. The used values of the measuring resistor are $R_M$=100 Ω for comparison with the results obtained in [4] and $R_M$=1 Ω to maximize the current response $i_1(t)$ from marker.

The time course of the current $i_1(t)$ for model of marker localization with two resistors is shown in Fig. 2 and Fig. 3 for $R_D$=1533 Ω, $R_M$=100 Ω and $R_M$=1 Ω, respectively.

Moreover, the dependence of maximum current amplitude $I_{1\_Max}$ on the distance $x$ was calculated for this model and it is shown in Fig. 4. Note that the current maximum was calculated in the time interval after the transients of the excitation current decay. For comparison of the presented analysis results and the results from simplified model calculated in [4] the case when $R_D$=$R_M$ was calculated, too. This case is identical with the simplified model and the comparison is shown in Fig. 4.

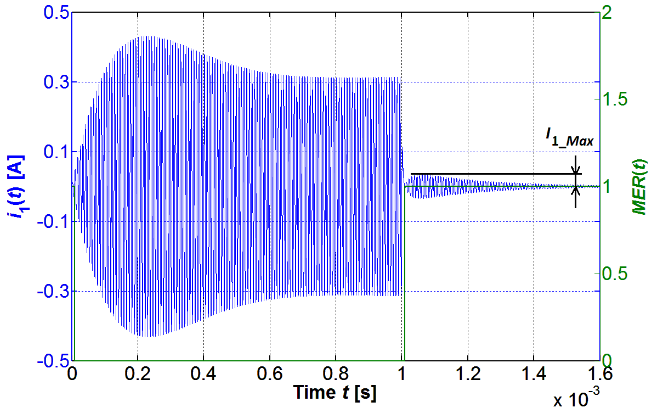

Fig. 2 Time course of the current $i_1(t)$ for $R_D$=1533 Ω and $R_M$=100 Ω

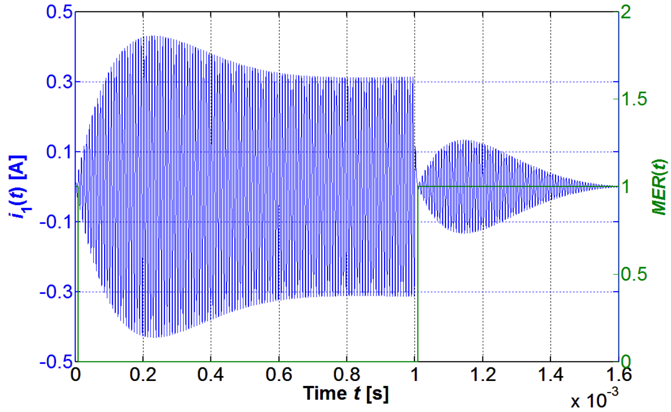

Fig. 3 Time course of the current $i_1(t)$ for $R_D$=1533 Ω and $R_M$=1 Ω

The measuring resistor $R_M$ influences the maximum current amplitude $I_{1\_Max}$ because this resistors acts as additional damping resistor for $L_RC_R$ circuit so that the ideal situation is when $R_M \rightarrow 0$.

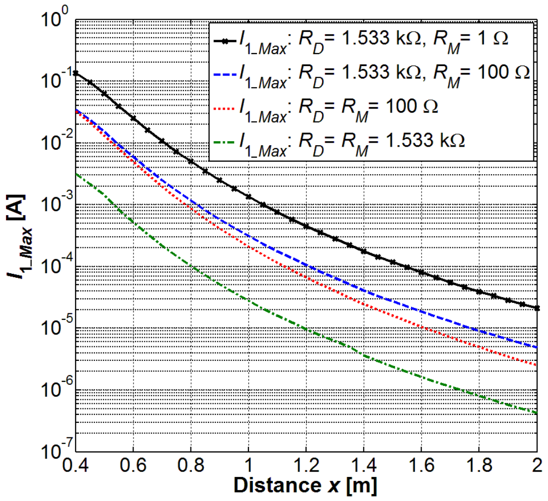

Fig. 5 Maximum amplitude of current response from marker for damped oscillation model

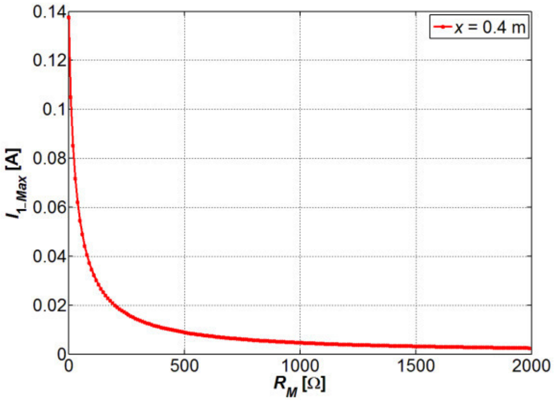

Fig. 6 Dependence of maximum current amplitude on the measuring resistor $R_M$ for distance $x$=0.4 m

## V. Mathematical Model Based On Continuous Excitation of Marker

This localization principle is used when the RFID locator continuously generates the magnetic field by its antenna coil $L_R$. The amplitude of current in locator circuit is then influenced by resonant circuit of marker so that the steady state current amplitude in locator circuit decreases if the marker is nearby.

The model is derived from the previous case by eliminating the switches. Schematic diagram of this model is shown in Fig. 7. In dependence on the distance *x* between coils the marker resonant circuit influences the amplitude of current $i_1(t)$ in locator antenna circuit.

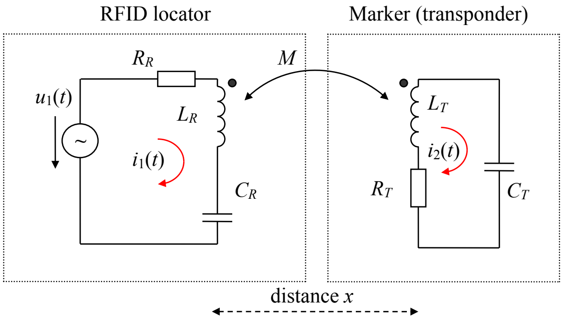

Fig. 7 Model of localization based on continuous excitation

This model can be analyzed by using of complex impedances of its components as it was performed in [4]. But such analysis did not show the transient phenomena in locator circuit and the results give only steady state solution. Therefore new model based on differential equations was created.

This model can be described by the following system of differential equations:

$$L_R\frac{di_1(t)}{dt}+R_Ri_1(t)+\frac{1}{C_R}\int_0^t i_1(\tau)d\tau-M\frac{di_2(t)}{dt}=u_1(\text{t})$$
$$L_T\frac{di_2(t)}{dt}+R_Ti_2(t)+\frac{1}{C_T}\int_0^t i_2(\tau)d\tau-M\frac{di_1(t)}{dt}=0 \qquad (9)$$

The signal source in Fig. 7 is harmonic as defined by (6). Similar as in previous chapter the system of integrodifferential equations (9) was transformed by substitution $x_1(t)=i_1(t)$, $x_2(t)=di_1(t)/dt$, $x_3(t)=i_2(t)$, $x_4(t)=di_2(t)/\mathrm{d}t$, $\omega=2\pi f$. Then we get the 1st order system of differential equations (10) which can be easily solved by standard mathematic software.

$$\begin{aligned}\frac{dx_1(t)}{dt}&=x_2(t)\\ \frac{dx_2(t)}{dt}&=a_1x_1(t)+a_2x_2(t)+a_3x_3(t)+a_4x_4(t)-a_5\omega U_1\cos(\omega t)\\ \frac{dx_3(t)}{dt}&=x_4(t)\\ \frac{dx_4(t)}{dt}&=b_1x_1(t)+b_2x_2(t)+b_3x_3(t)+b_4x_4(t)-b_5\omega U_1\cos(\omega t)\end{aligned} \qquad (10)$$

where individual coefficients are given by (11). Note that these coefficients are different from the coefficients given by (8).

$$\begin{aligned}a_1&=\frac{L_T}{C_R(M^2-L_RL_T)} & b_1&=\frac{M}{C_R(M^2-L_RL_T)}\\ a_2&=\frac{L_TR_R}{M^2-L_RL_T} & b_2&=\frac{R_RM}{M^2-L_RL_T}\\ a_3&=\frac{M}{C_T\left(M^2-L_RL_T\right)} & b_3&=\frac{L_R}{C_T\left(M^2-L_RL_T\right)}\\ a_4&=\frac{MR_T}{M^2-L_RL_T} & b_4&=\frac{L_RR_T}{M^2-L_RL_T}\\ a_5&=\frac{L_T}{M^2-L_RL_T} & b_5&=\frac{M}{M^2-L_RL_T}\end{aligned} \qquad (11)$$

In this case the detection of marker vicinity is more complicated as in the previous chapter because there is not the time stage in which only the response from excited marker can be received but the excitation signal in locator circuit is always present. The symptom of marker vicinity is decreasing of steady state current amplitude in locator circuit. When the distance between marker and locator is big ($x\rightarrow\infty$) then the mutual inductance calculated from (1) is very small ($M\rightarrow 0$). In this case the current $i_1(t)$ has maximum value $I_{1max}$, which is measured in steady state after the time $t$=2.5 ms. The marker vicinity then causes current drop $\Delta I_1$ (12) which can be calculated as difference between steady value of current $i_1(t)$ (see Fig. 8) and its maximum $I_{1max}$ measured in the same time point when no marker is nearby the locator.

$$\Delta I_1=I_{1max}-I_1 \qquad (12)$$

The time course of current $i_1(t)$ in the RFID locator circuit (Fig. 8) was numerically calculated from the system (10) for the same parameters as used in previous chapter. The dependence of current drop $\Delta I_1$ versus distance *x* is shown in Fig. 9.

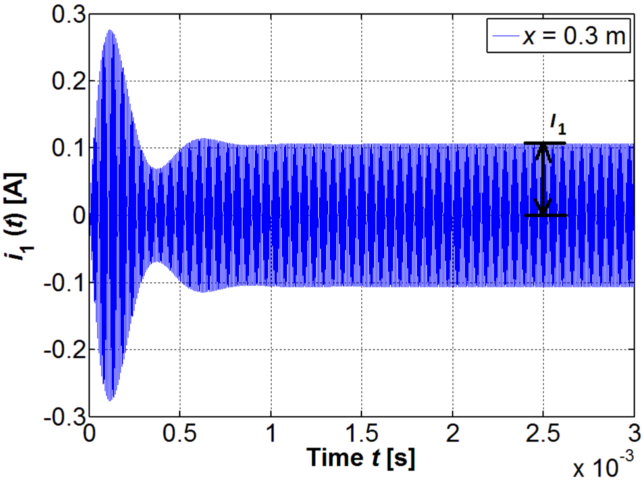

Fig. 8 The time course of current $i_1$(t), distance $x$=0.3 m

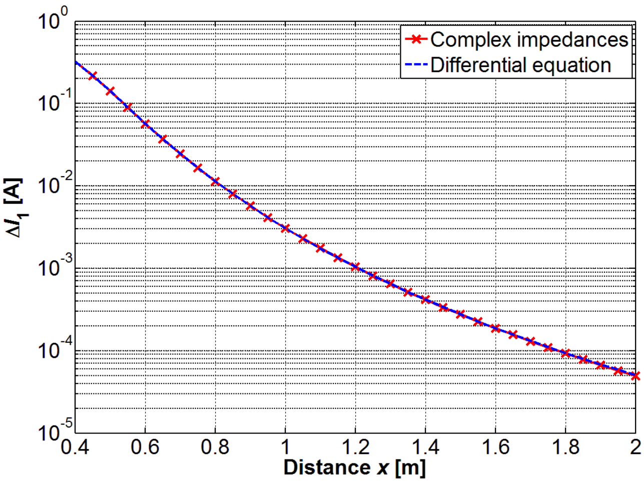

Fig. 9 Current drop $\Delta I_1$ versus distance $x$

The results calculated by analysis based on differential equations (10) were compared with the results obtained by analysis based on algebraic equations and complex impedances from [4]. This data is shown in the same graph in Fig. 9. As shown in this figure, both analyses give the same results.

## VI. Conclusion

Presented paper extends the mathematical analyses of marker localization principles. Two possible marker localization methods were analysed. For practical use the first method seems to be appropriate because the signal in receiving stage of localization can be directly processed.

The second method based on continuous marker excitation would require more complicated signal processing in locator. This complication is caused by "mixing" the excitation and response signals so that the marker vicinity cannot be simply detected by signal presence detection as in the first case but by detection of signal drop. Moreover the transient phenomena occur as documented in Fig. 8.

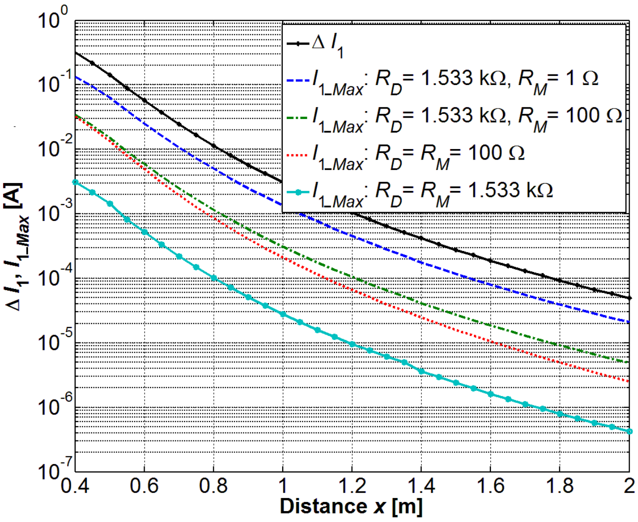

Fig. 10 Comparison of both localization models

Another criterion for evaluation of presented localization methods is based on their sensitivity to the marker vicinity. From comparison in Fig. 10 the second method seems to be more sensitive to the marker vicinity. Because the markers are typical near field application, the current amplitude in both cases decreases very rapidly when the distance between marker and locator increases.

The next research will be focused on the design of hardware needed to perform series of measurements so that the results of performed analyses will be compared with real measured data.

***Abstract*—Nowadays, adopting an optimized irrigation system has become a necessity due to the lack of the world water resource. Moreover, many researchers have treated this issue to improve the irrigation system by coupling the novel technologies from the information and communication field with the agricultural practices. The Wireless Sensor and Actuators Networks (WSANs) present a great example of this fusion. In this paper, we present a model architecture for a drip irrigation system using the WSANs. Our model includes the soil moisture, temperature and pressure sensors to monitor the irrigation operations. Specifically, we take into account the case where a system malfunction occurs, as when the pipes burst or the emitters block. Also, we differentiate two main traffic levels for the information transmitted by the WSAN, and we use an adequate priority-based routing protocol to achieve high QoS performance. Simulations conducted over the NS-2 simulator show promising results in terms of delay and Packet Delivery Ratio (PDR), mainly for the priority traffic.**

***Index Terms*—WSANs, Drip irrigation, Priority-based Routing.**

## I. Introduction

DURING the last decade, the Precision Agriculture (PA) has emerged as novel trend to enhance the agricultural practices. The principal aim of the PA is to monitor the spatio-temporal characteristics of the agricultural parcel [1]. By this way, the crops yield can be optimized while the natural, financial and energetic resources can be preserved. However, since the monitored agricultural regions are generally scattered and suffer from a variable environmental conditions, the need for accurate and real-time collected information is more pronounced. Also, the classical solution as the satellite imagery, aircraft or other systems based on the map cannot be supported by all farmers due to their heavy cost. To overcome this limitation, the Wireless sensor networks (WSNs) were introduced into the agricultural environment context [2].

Technically, the sensor nodes are deployed into the farmland. They start to collect environmental information and monitor soil characteristics. Then, they cooperate according to designed protocols to communicate the collected information to a central node. After that, this information is processed and treated to make an eventual decision.

The WSN have been explored in different ways for the agriculture field. As example, in [3] the authors have used four nodes types: soil, environmental, water and gateway to monitor the water content, temperature and soil salinity at farm located in Spain. Another work presented in [4] where authors have designed a node system for the collection of farmland information at different growth period of wheat, typically: seeding, jointing and heading. The study focuses in the optimal antenna height to use at the different growth period. Further examples presented in [5] and in [6] concern the greenhouse monitoring and the water saving irrigation using the WSN.

The security aspect is another example of how can the WSN improve the agricultural yield. In fact, crops are negatively affected by human or animal intruders. Also, the production process is still insufficiently controlled which lead to a potential product loss. To overcome this point, the video-surveillance nodes can be used to detect and identify intruders as well as to better take care of the production process [7]. In addition, the video-surveillance system allows the farmers to protect their sensors and equipment being installed in the crops from theft or potential damage.

One of the most important application of the WSNs in the PA is the irrigation system control. The interest comes naturally from saving water. For this aim, many researches were conducted to enhance the irrigation control system by coupling novel technologies with the agricultural practices. Among irrigation strategies, the drip irrigation system was considered as the most efficient policy to save water use. Moreover, combining this strategy with the WSNs leads us to have a great benefit from the farmlands. However, the irrigation system reliability need more attention, mainly in the case of general or partial dysfunction. For this aim, we present in this paper a model architecture for a drip irrigation system using the WSANs. Our model includes the soil moisture, temperature and pressure sensors to monitor the irrigation operations. Specially, we take into consideration the case when a system dysfunction occurs, as when the pipes are broken or the emitters are blocked. Also, we differentiate two main traffic levels for the information transmitted by the WSAN. Furthermore, based on our previous work [8], we can achieve a high QoS performance through an adequate priority-based routing protocol. The aim was to ensure an efficient and real-time communication between the different nodes type and the sink.

The remainder of this paper is organized as follows: in section II, we review some related works designed for an

978-83-60810-66-8/$25.00©2015, IEEE

efficient irrigation system. In section III, a description of our designed drip irrigation system is given. The priority-based protocol for DIS with simulation results are given in section IV. Finally, in section V, we draw the conclusion and give perspectives.

## II. Related work

To the best of our knowledge, monitoring the dysfunction of the drip irrigation system using the WSNs with an adequate priority-based routing protocol was never suggested before in the specialized literature. Therefore, in this section we summarize some related works for the irrigation system control.

In [9], authors propose an energy efficient method for the wireless sensor communication used in an automated irrigation system. This method is based on the Time Division Multiple Accesses (TDMA) scheduling that allows nodes to turn ON/OFF their radio according to scheduled slots. The main advantage of such scheme is saving the node's energy and reducing radio interference. Also, authors give a comparison between two methods to transmit the collected data to the sink node; namely the direct communication method and the data fusion method. For each method, the energy consumed and the data throughput are studied over the NS2 simulator.

To optimize water use in agricultural context, authors propose in [10] an automated irrigation system based in the WSNs technology. The developed system is composed of two kinds of sensors to collect soil-moisture and temperature information. The sensors are placed in the root zone of the plants. Also, a gateway was used to gather sensor information, triggers actuators, and transmits data to a web application. To control the water quantity, authors had programmed into a microcontroller an algorithm with threshold values of temperature and soil moisture. Concerning the energy, photo-voltaic panels are used to power the system. The entire system can be controlled through a web page which help to program an irrigation schedule and performs a data inspection.

In [11], authors present practical irrigation management system using a deployed WSN. This system includes a remote monitoring mechanism through a GPRS module to send SMS message containing land characteristic such as soil temperature and soil moisture, or the network performances such as packet delivery ratio, RSSI or the nodes energy level. The main contribution of this paper is to design and implement a low-cost efficient irrigation management system that combines sensors and actuators in a wireless sensor/actuator network. Authors conclude through this study that the deployment of the sensor nodes in the agricultural field is a critical issue. Furthermore, they suggest that the distance between sensor nodes has to be as short as possible in order to enhance the effectiveness of the system. However, the main weakness of this study is that authors employ only five sensors for the experiment.

We conclude for all referred works, that authors don't take into consideration the case of irrigation system dysfunction. Also they don't use the pressure sensor to monitor the irrigation flow rate. In addition, no priority-based protocol is designed to distinguish the importance of the communicated information. In the following section we present our proposed drip irrigation system that can overtake the dysfunction case.

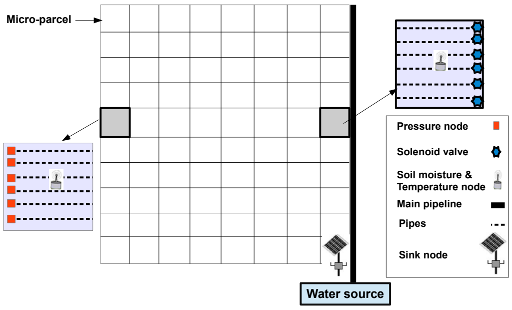

Fig. 1: Drip Irrigation System layout

## III. Proposed Drip Irrigation System Model

Recent practices in precision agriculture include two main micro irrigation methods which promote interesting water efficiency. The first method is the drip irrigation. It allows water to be dripped to the plants roots through pipes containing several emitters. This irrigation system is composed of the following components: water source (generally is a tank) which is connected with a main tube called main pipeline. To this line, several pipes are connected using manual or electrical valves that control the water flow. The pipes go through the field and distribute water for each plant.

The second method is the sprinkler irrigation which delivers water through a pressurized pipe network to the nozzles of sprinkler which spray the water into the air [12]. However, this method is less efficient than the drip one, since more water is losing due to evaporation and runoff. Therefore we choose the drip strategy for our design.

Our proposed model is a closed-loop model. As defined in [13], a system can be categorized as a closed-loop model if the response of the system is monitored and used to adjust the control. We note also that our proposed model is designed for a site-specific irrigation where the crops are characterized by a spatio-temporal variation of the irrigation requirements. The variability comes from the soil type, crop type, crop and meteorological conditions [13]. The main purpose of our design is to handle the dysfunctional situation of the drip installation. As discussed in [7], the crops are negatively affected by human or animals intruders. This is more critical in the case of drip irrigation installation. In fact, the pipes can be broken by rangers or by accident which can cause water waste and plants damage. Also the pipe emitters can be blocked due to environmental condition (sludge, sand) which can cause plant stress. To overtake these shortcoming the water flow rate into the drip installation must be monitored. For this aim, our proposed system include the following sensors and actuators:

- Soil moisture sensor: It is used to optimize irrigation and to warn of plant stress by controlling some parameters such as the electrical conductivity of soil or the underground volumetric water content (VWC). Measuring the soil moisture can help the farmers to manage their irrigation systems more efficiently by using less water to grow a crop and increasing quality and yields.

- Temperature sensor: It is used to monitor the ambient temperature. It can be analog or digital and help farmer to adjust their irrigation schedule according the temperature measured to avoid risk of evaporation.
- Pressure sensor: It is used to measure a pressure of gases or liquids and change it into a quantity that can be processed electronically. It generates a signal as a function of the pressure imposed. In irrigation application, this kind of sensor helps to monitor the abnormal pressure of pipe installation. In such case, by means of communication module (Zigbee/802.15.4), a message can be transmitted to the corresponding solenoid valve or the master valve (which control the main pipe) to shut down the system. A very low pressure value can be synonymous of a broken pipe or failure to open valves. Having a high pressure value can indicate that a valve is not closed correctly or some emitters are blocked.
- Solenoid valve: It is an electromechanical valve for use with liquid or gas controlled by running or stopping an electrical current through a solenoid, which is a coil of wire, thus changing the state of the valve [14]. Combined with a Zigbee module, the valve can be controlled trough wireless communication. Concerning the energy issue, the valve can have an external energy sources as solar panel.
- Sink node: It corresponds to the gateway of the system. All sensor nodes in the topology need to forward their gathered information to the sink node to be processed. Also, through this node, a request commands are generated to corresponding actuators or sensors.

An illustration of drip irrigation system with a deployment of the WSANs is shown in Fig .1

### A. Deployment strategy

Deploying the sensor nodes to monitor a farmland is crucial issue. In fact, many parameters must be considered to choose the most beneficial deployment, as the crops characteristics, the micro meteorological parameters, the sensors and nodes specification and obviously the farmer's budget. According to a generic guide proposed in [15] the coverage of the sensor nodes in agricultural WSN must be dense. By this way, all the required measurements can be gathered to have reliable knowledge of the monitored area. Authors in this guide argue that for a field with 100 $m^2$ size, at least 80-90 nodes are needed. They consider roughly 1 sensor node per 1 $m^2$. Of course, with such density we can reduce the sensors transmission power to the lowest level to save energy. In addition to have an adequate number of nodes, the topology formation must be determined. Among start, tree, or grid topology, the right choice depends to field's size and the plants formation. However, for middle or high surface, the grid topology remains the most suitable.

Based on the above discussion, we choose the grid topology for our drip irrigation design. We divide the field area into several equal micro parcel as suggested in [16]. The size of the parcel must be a trade-off between monitoring quality required, the communication coverage and the deployment cost. In the middle of each parcel we fix a soil moisture and temperature node. We make the assumption that the soil moisture and the temperature remain the same inside the parcel.

### B. Communication strategy

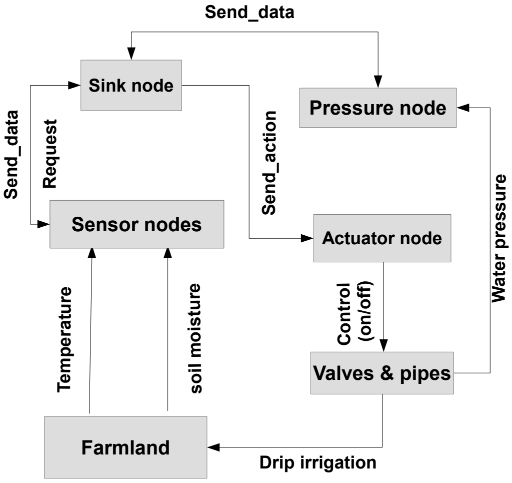

Fig. 2: Drip Irrigation System communication

In Fig. 2 we present a flowchart of the communication between all actors in the designed drip irrigation system. The sensor nodes gather the temperature and the soil moisture from the farmland periodically. According the value obtained, the sensor nodes decide to send the information to the sink or not. At the sink node, the abnormal information is processed and an eventual decision is taken to adjust the irrigation schedule according to the plant requirement. The same irrigation schedule is transmitted to the pressure nodes to be awakened at the same time of irrigation process. Once the actuators receive an action from the sink, they control their corresponding valves to be opened or closed. If the valves are opened, the water flow goes through the pipes and the pressure nodes start sensing. If any abnormal pressure value is gathered, an alert message is transmitted to the sink node to shut down the irrigation process and request an external human verification of the pipe installation.

We make the assumption that the sensor nodes communicate only with the sink node through a multi-hop protocol. Also, the actuators receive only actions from the sink. We assume also that the sink node can request some information from the sensor nodes at any time.

## IV. Priority-based DISM

### A. *Priority-based protocol*

As discussed in section III, we have two main traffic type gathered from sensors. The first one related to information gathered from temperature and the soil moisture sensors. We classify this traffic type as normal traffic since no need for an urgent intervention is required. The second traffic type is related to information gathered from pressure sensors. We classify this traffic type as priority traffic due to the need for an emergency resolution of the detected problem (shut off the main valve, require human intervention ... etc). Now, in the case when both traffics are active simultaneously, it is clear that the reliability and the timeliness of the priority traffic is more requested than those of the normal traffic.

However, in the wireless context, there are many troubles that can occur due to the sharing of the same communication medium. Among these problems we cite the interference problem, the exposed and the hidden problem [17]. Another problem that must be considered is the effect of the carrier sense range on communication performances. As discussed in our previous work [8], the carrier sense range is usually more larger than the transmission and the interference range. So carefully routing process must be applied to avoid any trouble between multiple sources and to satisfy the requested QoS for each traffic.

Let us take the example presented in Fig. 3. Two source nodes need to send their data to the sink. The first source node $A$ sends a priority traffic and the source node $B$ sends a normal traffic. We make the assumption that only one path is constructed from each source node. The circle presented around each node represents the transmission range. We avoid adding the carrier sense range in the figure to not overload it. As shown in Fig. 3, the black path refers to the path constructed from the node $A$ to the sink node. After that, the node $B$ needs to find out a valid path to reach the sink. If the red path is chosen, then all the nodes from the black path and the red one will be in concurrence to access to the communication medium which will degrade the final performance. The green lines represent relation between these nodes. To avoid such situation, the node $A$ must construct the blue path. Thus, even if the number of hops is higher the performances at the sink node are better. In what follow we will describe how the two paths can be constructed.

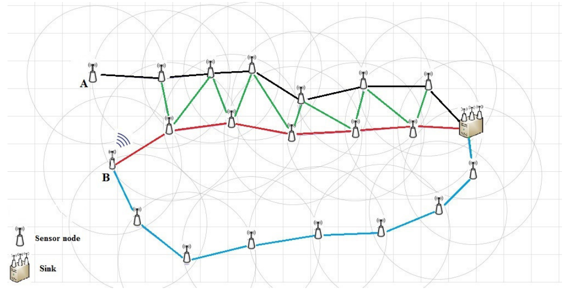

Fig. 3: Carrier sense effect in the case of multi-sources

### B. *Protocol description*

Based on our previous work [8], we design a routing protocol that can allow the priority source node (namely the pressure node) to construct an efficient routing path while avoiding the carrier sense range effect. In this work we make the assumption that nodes are aware of their positions and the position of the sink node. In the following, we give a short description of how the paths are constructed according to our approach.

When a priority source node seeks to communicate with the destination, it sets up a route discovery process by sending a priority forward agent (P-FAGT) to construct a short multi-hop path. The choice of the next hop node is based on the geographic information available at each node. For each selected node $i$, the node state is changed from free to busy, and a Hello message is broadcasted to all neighbors in the communication range to notify the new state of the node $i$. Every neighbor node $j$ of the node $i$ becomes a banish node, that means it cannot be selected for any communication. After that, each node $j$ broadcasts in its turn a hello message in their neighborhood. Now, if a normal source node needs to send some information, it constructs the routing path by sending a normal forward agent (N-FAGT) which must respect the following rules: the next hop must not be blocked, and must not be a banish node or having a banish node in its neighborhood. A node is in a blocked state when the destination is unreachable through this node. To avoid a blocking situation when a node cannot reach the destination, we use the same principle as in [18], called the step-back method. The same method is used by the agent when the selected next hop has a banish node in its neighborhood.

Once the destination is reached, the forward agent (either P-FAGT or N-FAGT) becomes a backward agent and an optimized reverse path is travelled. At each intermediate node, the agent records the valid next hop into the routing table, after that, it chooses from the reverse path the nearest neighbor to the current node. The same procedure is repeated until reaching the source node.

In the case where the P-FAGT finds an already constructed path (used by a normal source), it follows this path and changes the state information of all nodes involved in it. After that, the normal source is informed by a special agent to start another discovery phase to take into consideration the current priority source communication.

When the communication is ended, all the nodes altered by the communication process reset their state and become ready for further transmissions. In the remaining of this paper, we denote our approach by Carrier Sense Aware (CSA).

### C. *Simulation & result analysis*

#### *Working environment*

Our simulation scenario is based on the topology presented in Fig.1. The topology area is 200*200 $m^2$, and the total number of nodes is 280 (including pressure, temperature/soil moisture and valve nodes). We make the assumption that the micro parcel size is 20 $m^2$. Two random source nodes (pressure and temperature/soil moisture) are selected and start transmission at different instance but in the same interval time. To distinguish the two traffic in the simulation in the NS2 simulator [19], we choose for the temperature/soil moisture source node a constant bit rate (CBR) traffic with **X** packets per second, where:

$$X=\{8,16,24,32\}$$

For the pressure source node, we choose an exponential traffic (Exp) with a data rate equals to 20 Kbytes. The duration of communication is 30 s, and no mobility is supported in this scenario. For every value of **X**, 20 scenarios are generated and the average value of results is computed. We present the results with a confidence interval of 95%. According to the characteristic of the MicaZ node [20] and the two-ray-ground propagation model equation, we define the reception and the carrier sense threshold (RXThreshold and CSThreshold). Their respective value was $3.981{*}10^{-13}$ Watt and $3.981{*}10^{-14}$ Watt which represent nearly 20 m for the transmission range and 35 m for the carrier sense range. We compare our work with the Two Phase geographical Greedy Forwarding (TPGF) protocol [18] since it adopts also a geographical approach.

Table I summarizes the parameters used for simulation.

TABLE I: Main configuration parameters

| Parameters | value |
|---|---|
| link layer | LL |
| MAC layer | IEEE 802.15.4 |
| radio propagation | two ray ground |
| interface queue | PriQueue |
| ifqlen | 50 |
| antenna | omni-antenna |
| Antenna height (m) | 0.0864 |
| Frequency | 2.4 GHz |
| $CPThreshold$ (dB) | 10 |
| $CSThreshold$ (Watt) | $3.981 * 10^{-14}$ |
| $RXThreshold$ (Watt) | $3.981 * 10^{-13}$ |
| Pt (Watts) | 0.001 |
| Packet size | 100 Bytes |

*Result analysis*

We start our analysis by studying the PDR metrics for both normal and priority traffic. From Fig. 4, which represents the PDR for the normal traffic, we can see that, for both protocols, the PDR decreases as the number of Packet Per Second (PPS) increases. It is quite expected since more the traffic is higher more the collision likelihood is higher too. For the CSA protocol, it has the higher PDR between 8 and 24 PPS, after that, the PDR becomes slightly lower than that of the TPGF. We explain such behavior by the constructed paths of each protocol. In fact, the CSA protocol builds path for the normal traffic while avoiding any banish node as described in subsection IV-B. Concerning the TPGF path, it builds paths according to the greedy forwarding mechanism, so shorter paths are constructed. Therefore, the number of hops in the case of the CSA is higher than that of the TPGF. We can tolerate such performance, since the normal traffic is usually loss-tolerant.

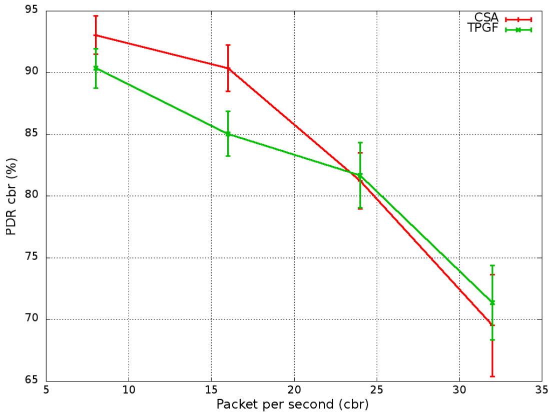

Fig. 4: Average PDR of normal traffic vs packet per second

For Fig. 5, which represents the PDR for the priority traffic, we can see also that, for both protocols, the PDR decreases as the number of PPS increases. However, it is clear that the CSA protocol achieves higher PDR than the TPGF. The PDR gain can reach 20%. For the TPGF, it provides a poor PDR value mainly when the traffic rate increases. Such performance cannot be acceptable for the priority traffic, which is almost loss-intolerant. In fact, as discussed in subsection IV-A, the carrier sense range effect occurs when a node cannot transmit when another node in its carrier sense range is already in transmitting phase. Therefore, when the number of PPS is higher, the nodes of all paths deprive mutually the channel access since there is a competition between them. Thus, the likelihood of loss packet is more pronounced.

In Fig. 6, the delay for both protocols in the case of priority traffic is depicted. As first observation, we can see that the delay increases as the number of PPS increases. We can see also that the CSA protocol provides a lower delay compared to the TPGF protocol. It is quite expected since the construction path process in the CSA protocol, ensures that the priority traffic will not be disturbed by any communication in the neighborhood. Such performance is suitable for the priority traffic which is usually delay sensitive.

## V. Conclusion and Future Work

In this paper, we have presented a model architecture for a drip irrigation system using the WSANs. Our model includes the soil moisture, temperature and pressure sensors to monitor the irrigation operations. Specially, we take into account the case where a system malfunction occurs, as when the pipes are broken or the emitters are blocked. Also, we differentiate two main traffic levels for the information transmitted by the WSAN, and based on our previous work, we achieve a high

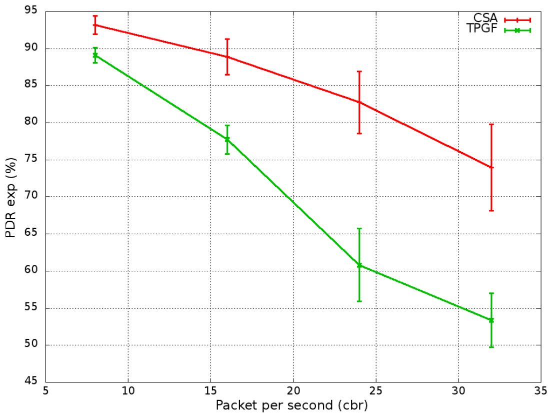

Fig. 5: Average PDR of priority traffic vs packet per second

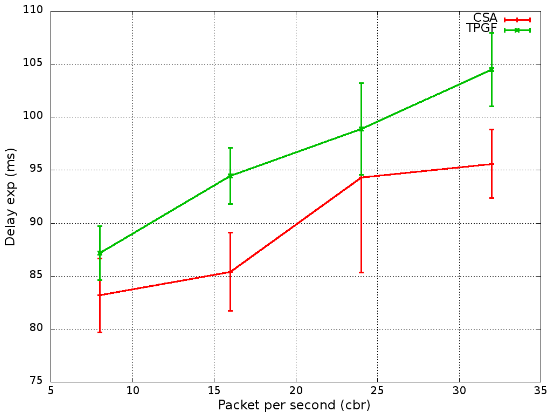

Fig. 6: Average delay of priority traffic vs packet per second

QoS performance through an adequate priority-based routing protocol.

We have performed extensive simulations. The results prove that our solution gives better performances in terms of delay, PDR for the priority traffic. As a future work, we intend to realize a real test-bed to investigate the effectiveness of our approach.

# Information Technology for Management, Business & Society

IT4MBS is a FedCSIS conference aiming at integrating and creating synergy between FedCSIS events that thematically subscribe to the disciplines of information technology and information systems. The IT4BMS area emphasizes the issues relevant to information technology and necessary for practical, everyday needs of business, other organizations and society at large. This area takes a sociotechnical view on information systems and relates also to ethical, social and political issues raised by information systems. Events that constitute IT4BMS are:

- **ABICT'15** - 6th International Workshop on Advances in Business ICT
- **AITM'15** - 13th Conference on Advanced Information Technologies for Management
- **ISM'15** - 10th Conference on Information Systems Management
- **IT4L'15** - 4th Workshop on Information Technologies for Logistics
- **KAM'15** - 21st Conference on Knowledge Acquisition and Management

# 6th International Workshop on Advances in Business ICT

ABICT focuses on Advances in Business ICT approached from a multidisciplinary perspective. It will provide an international forum for scientists/experts from academia and industry to discuss and exchange current results, applications, new ideas of ongoing research and experience on all aspects of Business Intelligence. ABICT will be also an opportunity to demonstrate different ideas and tools for developing and supporting organizational creativity, as well as advances in decision support systems.

We kindly invite contributions originating from any area of computer science, information technology and computational solutions for different applications areas, data integration and organizational implementation of ABICT, as well as practical ABICT solutions.

## Topics

Topics include (but are not limited to):

- Advanced technologies of data processing, content processing and information indexing
- Analytics as a service
- Big Data: benefits and challenges
- Business Analytics
- Business applications of social networks
- Business data mining and knowledge discovery
- Business Intelligence
- Business Rules
- Business-oriented time series data mining, analysis, and processing
- Cloud based Business Intelligence
- Creativity Support Tools
- Customer Relationship Management, social Customer Relationship Management
- Data driven marketing
- Data Warehousing
- Decision support
- Digital Business Strategy
- Enterprise Device Management
- ICT technologies in enterprise management
- Information forensics and security, information management, risk assessment and analysis
- Information Systems Design
- Internet of Things
- Knowledge Management (for better Decision Support, Collaboration and Competitiveness)
- Legal text processing
- Leveraging ICT for Transforming Organization
- M2M Device Management, M2M Solutions
- Semantic Web and Ontologies in Business ICT
- Virtual Enterprise
- Web 2.0 and Web 3.0 in fusing Business Intelligence systems and Decision Support Systems
- Web-Based Data Management Systems

# Opportunities for Business Process Semantization in Open-source Process Execution Environments

Krzysztof Kluza and Krzysztof Kaczor and Grzegorz J. Nalepa and Mateusz Ślażyński
AGH University of Science and Technology
al. A. Mickiewicza 30, 30-059 Krakow, Poland
E-mail: {kluza,kk,gjn,mslaz}@agh.edu.pl

***Abstract*—Business Process models help to visualize the processes of an organization. There are open-source process execution engines that provide the environments for enacting process models. However, they lack semantization capabilities. In this paper, an overview of Business Process semantization techniques is provided. Moreover, we discuss the common architecture of the selected open-source process execution environments (Activiti, jBPM and Camunda) and provide the insights how they can be improved using semantization methods. We also present the use of the introduced techniques in the Prosecco (Processes Semantics Collaboration for Companies) research project.**

***Index Terms*—Business Process Model and Notation (BPMN), Business Process Semantization, Business Process Management**

## I. Introduction

BUSINESS Process Management (BPM) [1] is a modern approach to improve organization's workflow, which focuses on reengineering of processes in order to optimize procedures, increase efficiency and effectiveness by constant process improvement. A Business Process (BP) model constitute a graphical representation of a process in an organization, which is composed of related tasks that produce a specific service or product for a particular customer [2].

The BP runtime environment manages and monitors processes as they perform. It orchestrates the activities and interactions of the process with web services or other third-party applications. Such software also supports user tasks, handles exceptions or escalations by tracing the workflow in the model. There are more than 70 BPMN implementers[1],

As process models can be ambiguous, the top leader vendors that develop proprietary software introduced semantization techniques to their solutions. This helps to support more intelligent functions, like web services discovery or element name suggestions. These techniques use semantic annotations, which can be based on a formally specified ontology.

For the purpose of this paper, we focused on the selected open-source process execution environments that are freely accessible, use the BPMN 2.0 notation [3] on the executable level and can be easily extended with new functions. We analyze the possible ways of enhancing them with semantization methods. Some of these methods have been introduced in the Prosecco (Processes Semantics Collaboration for Companies) research project[2], which takes advantage of the Activiti execution engine.

The paper is structured as follows. In Section II, we present selected open-source process execution environments and their general architecture. Section III gives an overview of business process semantization approaches, especially focusing on the solution developed in the SUPER project and the SAP AG company. Section IV analyzes the possibilities of process semantization in the open-source process execution environments. The paper is concluded in Section V.

## II. Open-source Process Execution Environments

All three environments, Activiti[3] [4], jBPM[4] [5], and Camunda[5] [6], are light-weight BPM suites with extensible BPMN 2.0 process engines. They can be run in any Java environment, embedded in an application or as a service. The engines allow a user to execute business processes using the BPMN 2.0 specification, and are open-source software distributed under the Apache license.

All the projects include such components as:

- Process Engine – an execution engine that provides Process Virtual Machine; the engine uses BPMN 2.0 as the underlying XML format for the process definitions.
- Web-based Process Modeler – a web-based process editor for modeling business processes (mainly for analysts).
- Eclipse-based Process Designer – more complex process editor for modeling and implementing detail aspects of process models, it allows graphical modeling, development and debugging of models.
- Process Management Interface – a web application providing access to the runtime engine for all users of the system, this includes task and job management, process instance inspection, viewing reports based on statistical history data, etc.
- Process Repository – a repository for storing and managing process definitions.
- History Log – a log for storing history information about the process instances that are being executed, which can be further used to generate reports, etc.

The overview of this common architecture is presented in Figure 1 and comparison of their components is provided in Table I. Such an architecture is further considered for semantization of the execution environment.

## III. OVERVIEW OF BUSINESS PROCESS SEMANTIZATION POSSIBILITIES

This section presents the overview of the semantization approaches for business processes and business process runtime environments, based on the analysis of the research results in this field. It focuses on Business Process semantization in: the SUPER project, the BPM product of the SAP AG company, as well as some substitute of semantization which can be observed in Signavio Process Editor.

### A. *Business Process Semantization in the SUPER project*

The goal of the SUPER project [6] was to create tools for business process semantization by describing process models using concepts from the ontology.

A BPM system that uses ontology as a common language of communication can facilitate clear expressing the statement by the people from the business and provide a method of unambiguous communication between the system, IT people and non-technical people associated with the business.

*The SUPER project architecture*

The elements of the architecture of the SUPER environment is presented in Figure 2. WSMO Studio is a stand-alone application (also available as a plugin for the Eclipse integrated development environment), which provides the following functions: enables customers to create ontologies, specify goals, web services and mediators, as well as provide appropriate interfaces for these elements. Additionally, the environment provides dedicated editors, including SAWSDL editor to annotate semantics to WSDL.

*Ontologies in the SUPER project*

In the SUPER project ontology the following elements can be distinguished (the relationship between them is presented in Figure 3):

- Web Service Modeling Ontology [7] specifies formally the terminology of the information used by all other components and provides the semantic description of web services (their functional and non-functional properties, and their interfaces).
- Business Domain Ontologies related to the business domain knowledge (Business Functions, Business Process Resources, Business Roles and Business Modeling Guidelines Ontologies).

[6] The website of the SUPER project http://www.ip-super.org/content/view/196/163/ is no longer maintained. However, some pieces of information about the results can be found at: http://www.sti-innsbruck.at/results/movies/sbp-execution-developed-in-super as well as in the project publications.

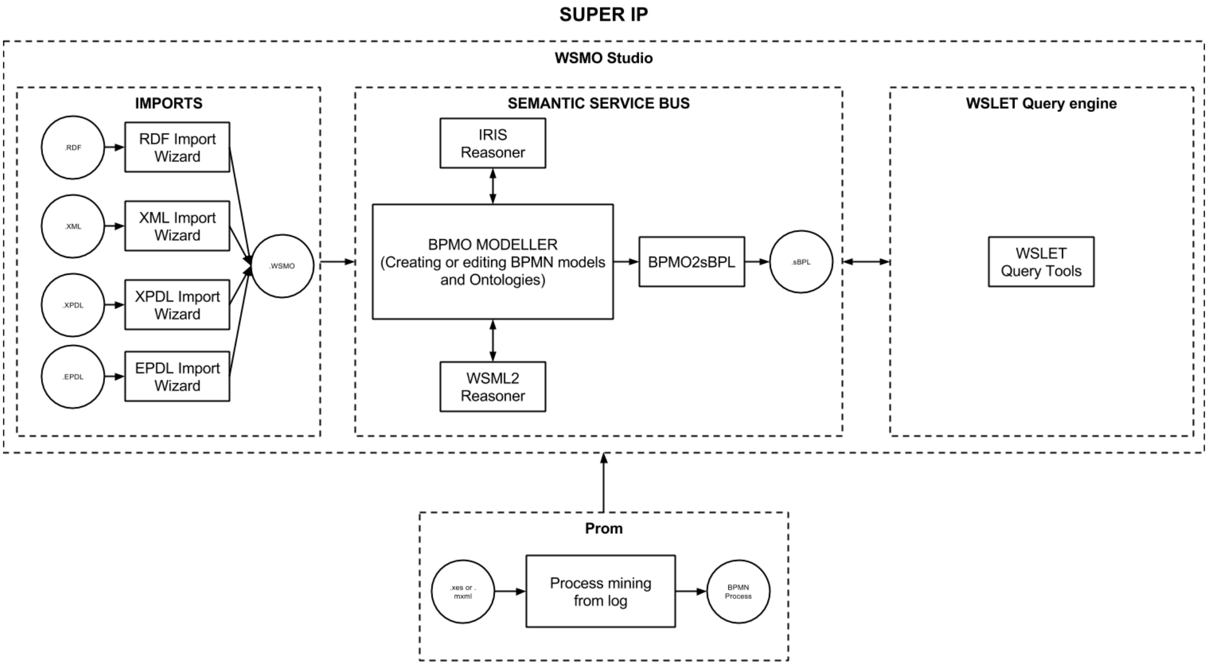

Figure 2. The elements of the basic architecture of the SUPER project (based on the description from the SUPER project website)

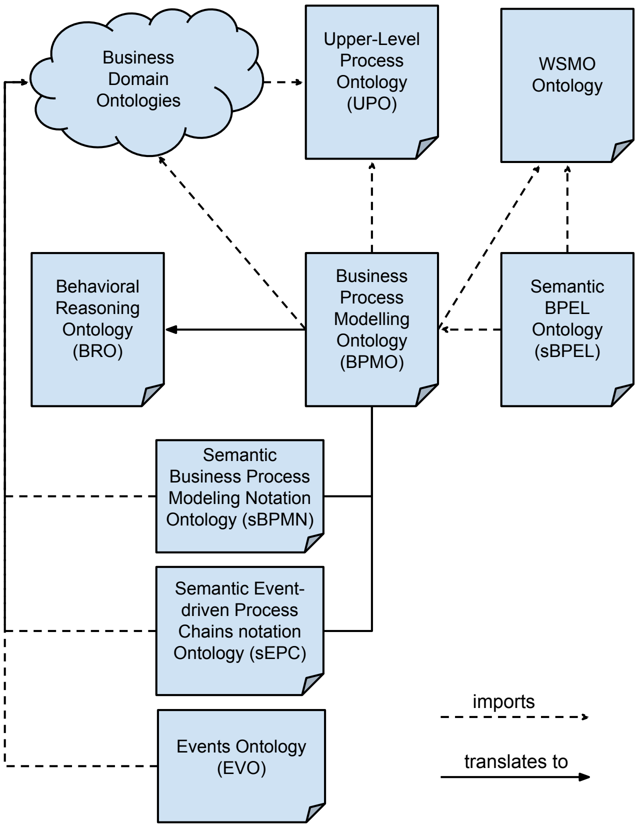
- SUPER Ontology Stack:
  - Upper-Level Process Ontology (UPO) is the top-level ontology that aims to represent high-level concepts for Business Process modelling.
  - Business Process Modelling Ontology (BPMO) acts as a bridge between the business level and the processes execution level and is used for representing high-level business process workflows.
  - Semantic Event-driven Process Chains notation Ontology (sEPC) supports the annotation of process models created with EPC tools.
  - Semantic Business Process Modeling Notation Ontology (sBPMN) for formalization of the core subset of the BPMN notation.
  - Semantic BPEL Ontology (sBPEL) extends the ontology of BPEL with a Semantic Web Services model.
  - Behavioral Reasoning Ontology (BRO) for reasoning over the business processes behaviours using WSML axioms.
  - Events Ontology (EVO) that constitutes a reference model for capturing logging information used by the execution engines and the analysis tools.

*The SUPER project process life cycle*

The methodology of the SUPER project defines four phases that form the business process life cycle [9]. For these phases the appropriate methods and techniques for business process semantization were developed. In the following paragraphs, these phases are elaborated.



Business Domain Ontologies
Upper-Level Process Ontology (UPO)
WSMO Ontology
Behavioral Reasoning Ontology (BRO)
Business Process Modelling Ontology (BPMO)
Semantic BPEL Ontology (sBPEL)
Semantic Business Process Modeling Notation Ontology (sBPMN)
Semantic Event-driven Process Chains notation Ontology (sEPC)
Events Ontology (EVO)

Strategic Semantic Business Process Management
Semantic Business Process Analysis
Semantic Business Process Modelling
Semantic Business Process Execution
Semantic Business Process Configuration
Ontological Foundation

Figure 4. Phases in the SUPER project methodology [9]

*Phase 1: Semantic Business Process Modelling*

The first phase of the life cycle in the SUPER methodology consists in developing business process models based on the BPMO ontology. It uses the environment for semantic modeling (WSMO Studio tools with the integrated BPMO editor). The business process model is based on the domain ontologies specified for the particular company as well as on Semantic Web Services and Goals. Its source can be implicit knowledge of business analysts or analysis of reports from the previous Semantic Business Process (SBP) Analysis phase.

*Phase 2: Semantic Business Process Configuration*

Semantic Business Process Configuration (SBPC) is a second phase in the SUPER methodology life cycle that uses the semantic business process models which are the output from the previous phase. During this phase, the semantic business process models are configured.

The configuration phase consists of deriving an sBPEL ontology from a BPMO instance, discovering the possible Semantic Web Services (SWS) [10], identifying the potential data mismatches, and based on them creating the interface mappings and data mediators. Lastly, the process is validated in terms of the correctness of the semantic process description before the execution and potentially refined.

*Phase 3: Semantic Business Process Execution*

In the third phase of SUPER methodology, modeled and configured processes are executed and processed. During the runtime, data, which will be used for analysis, are collected. As this phase is performed without user interactions, it minimizes the time required for its completion. In this pahse, process execution is supported by the semantic BPEL (BPEL4SWS) and detection and execution of Semantic Web Services (SWS).

In Figure 5, the scenario of semantic business process execution is presented. This scenario involves the following seven steps [9]:

1) *Request Service* – in order to initialize a semantic BPEL process, a user have to send request through the Semantic Service Bus to SBPELEE.
2) *Achieve Goal* – invocation of SWS is delegated to SEE by SBPELEE which passes the WSMO Goal to it.
3) *Discover Service* – SEE queries the Semantic Web Services repository to discover the desired SWS.
4) *Invoke Service* – SEE invokes the discovered SWS.
5) *Engine Return Result* – SEE returns the result received from SWS to SBPELEE.
6) *User Return Result* – After the process execution has been finished, the result is returned to the user.
7) *Process Tracking* – During the execution, execution events are published to Execution History for persistence and to the Monitoring Tool for tracking process executions.

The most important benefits of using such an approach are:

- flexible use of Web Services,
- supplier matching supported by Semantic Web Service discovery and invocation from within semantic business processes,
- more flexible traffic routing,
- automates supplier matching and traffic routing process taking into account all existing suppliers,
- minimizes time-to-offer.

*Phase 4: Semantic Business Process Analysis*

The last phase of the process life cycle concerns the analysis of the executed processes. In this phase, various analysis goals are supported, such as: overview over process usage, detecting business and technical exceptions, etc.

Thanks to this phase, it is possible to get an overall overview about system usage, finding out exceptions within process flow and bottlenecks, as well as get necessary information needed to apply 6 Sigma methodology.

*Data, Information, and Process Integration with SWS*

The SUPER project took advantage of the experience of the DIP[7] (Data, Information, and Process Integration with Semantic Web Services) [11] platform.

The aim of the DIP platform was extending the semantic web technologies and web services in order to create a new technical infrastructure – Semantic Web Services (SWS).

The DIP platform provides: Web Service Modelling Ontology (WSMO), Web Service Modeling Language (WSML) as the language for modeling web services, and Web Service Execution Environment (WSMX) as software framework for runtime binding of service requesters and service providers.

### B. *Business Process Semantization in SAP AG*

Another more extended solution related to business process semantization is an approach developed [12] and patented[8] by the SAP AG company.

Semantization of business processes in the SAP AG uses the semantic descriptions for business process artifacts. The integration consists in linking the identified semantic pieces of information described in the form of ontology with the elements of business process models.

The approach also supports semantic modeling by matching elements of a process model to concepts from ontologies and using fitting functions for choosing proper semantic annotations. This is achieved by comparing the given context and text description with instance domain ontology. In the approach, three goals are achieved: support for modeling, exploring relevant services, and searching the process model repository.

Figure 6 shows the main components of the process modeling tool semantic extension. The BPMN data objects are used for describing activities by defining the related objects and state transitions. For such activities, a user can graphically specify their preconditions and postconditions, as well as define the related objects with the specification of the object state changes before and after the execution of the activity.

An ontology in this approach contains the information about objects, states, state transitions, and actions related to the domain. For each object the possible states and state transitions are defined and they form the object life cycle. These kinds of domain ontologies support semantic process modeling by using their concepts in model elements specification, especially by suggesting relevant concepts or instances of objects. For suggesting the relevant components (data objects, activities, associations and states), a combination of different algorithms associated with the text matching was used. The algorithms take advantage of contextual information related to the process model as well as domain knowledge ontology.

Thanks to the domain knowledge, the names of tasks can be suggested based on the object life cycle. The object life cycle can also be used to exclude re-using the task names that have already been modeled.

The system also supports the semantic description of data flow. The object status can be visualized directly in the diagram. The “less than” sign (<) denotes the object status before and the “greater than” (>) denotes the object status after performing the associated tasks.

Such semantization supports consistency checking and extends the capabilities of semantic searching. Compared to the approach of the SUPER project, it supports more flexible and accurate semantic annotations by referring directly to the elements from the defined domain ontology.

[8] See: The patent “Semantic extensions of business process modeling tools” number US 8112257 B2: https://www.google.com/patents/US8112257.

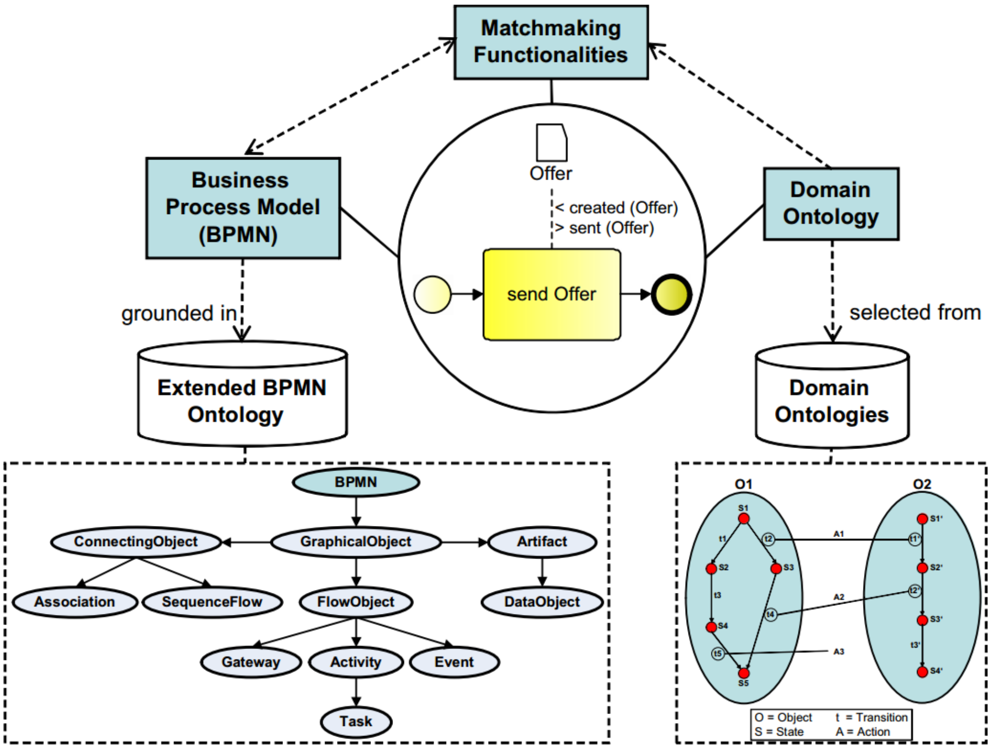

Figure 6. The main components of the semantic extension tools for modeling business processes in the SAP platform [12]

### C. Other possibilities of semantization

As the considered open-source process execution environments use REST interfaces, the possibility of semantization of the REST interface is presented in [13]. The authors compare the different semantic annotation languages for REST interfaces and show how to take advantage of them by creating a website which combines online applications from different sources (in particular internet services) - the so-called mashup. They also proposed a new language SAWADL, based on WADL (Web Application Description Language), for REST Web Services semantization.

In the Signavio Process Editor[9], some basic semantization in the form of a dictionary can be observed. In the dictionary one can define the concepts, assign them to one of the 6 categories (Organizational Unit, Documents, Activities, Events, IT System, Other), add the appropriate descriptions, as well as assign to them additional documents (links to them). Then, these concepts can be used to describe the elements of the BPMN model, e.g. during choosing a name for the particular task in the process (see Figure 7).

Although the tool does not support the formal semantic description in the form of the ontology, it supports multilingual description of the same concepts what allows users to work with the same model in different countries in their own languages.

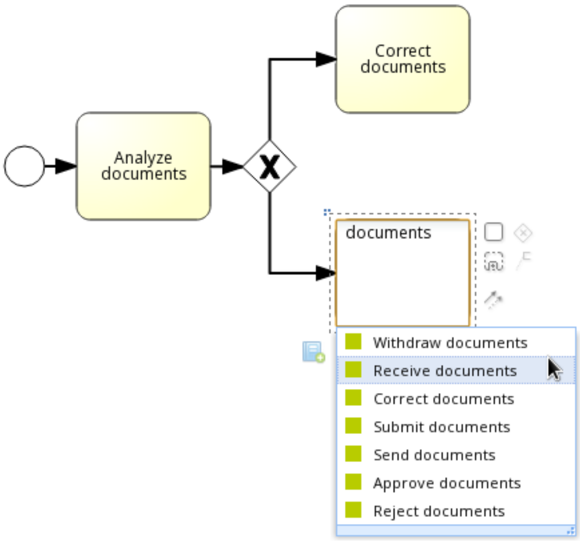

Figure 7. Using dictionary during modeling in the Signavio Process Editor

Other works related to semantic business process modeling can be found in the papers [14], [15], where the processes in the form of Petri nets are connected with the ontology describing the network. Their objective is to standardize the terminology, in particular with regard to the level of abstraction of the labels used in the model. This allows for validating models and detecting the incorrect names of the elements.

[9] See: http://academic.signavio.com.

# IV. Analysis of semantization of selected runtime environments

## A. Prosecco System

The Prosecco (Processes Semantics Collaboration for Companies) project aims at addressing the needs and constraints of Small and Medium Enterprises (SME) by designing methods that will significantly improve BPM systems by simplification of the system design and configuration, targeting the management quality and competitiveness improvement, fostering decisions making and strategic planning in the SME market sector. The Prosecco system involves three technologies for specification of business logic: business processes, rules and ontologies. Additionally, these technologies are supported by external services providing additional functionalities and integrating core of the system with external tools.

The architecture of the system is oriented towards services what significantly improves its portability and high versatility. Such architecture also enables integration with external tools that provide their functionality as a service. As each element of the architecture provides own data management, there is no centralized repository for all models. Therefore, Prosecco repository consists of several repositories for various models:

1) Repository for Business Processes is called *prosecco-business* and is managed by Activiti engine. It stores information concerning existing processes and their instances, variables and other data processed by the engine. Additionally, the repository contains components that can be used for creating new processes.
2) *Prosecco-knowledgebase* is a repository for rules. It is divided into two parts. The first part stores rules processed by Drools rule engine. The second contains rules learned according to decisions made by the users that are traced on the business process level.
3) Ontology is stored in the OWL format. The POJO model, which is suitable for process and rule engines, can be generated from the OWL representation.
4) *Prosecco-profilemanager* repository stores information related to users and ACL (Access Control List).
5) System History is managed by the Cassandra tool and stores information concerning operations performed within the system.

In turn, due to the fact of usage of the ontology, the project assumes that all data types and their instances existing within the system are consistent with the ontology. Because of the separate data repositories, the object types and existing instances have to be continuously synchronized with the ontology. For example for rule engine the POJO (Plain Old Java Object) model is generated according to the ontology, and for external tools dedicated integration interfaces providing type alignment were developed.

The Prosecco system uses Activiti as the process engine. Apart from the system types generated according to ontology, the Activiti uses also other semantization techniques. The possible scenarios of semantization of the open-source process engines are considered in the following section.

## B. Analysis of semantization scenarios of Activiti, jBPM and Camunda runtime environments

In Section II, six components of the open-source Activiti, jBPM and Camunda environments are distinguished. Semantization of each of them allows for disambiguation of data description and controlling their integrity. Moreover, it may extend their functionality and possible use scenarios in the following way:

1) Process Engine – may allow for invoking semantically matched web services, rule-based components or subprocesses.
2) Repository of Processes – may enable semantic search of models in the repository.
3) Web-based editor of Processes – may provide semantic-based recommendation of the elements during the modeling process.
4) Eclipse-based editor of Processes – may suggest names of a process elements, artifacts, etc.
5) Process Management System – may support semantic search in the system e.g. running process instances.
6) Log – logging of system events described semantically.

Semantization of these components can bring advantages. Some of these semantization scenarios are considered in the Prosecco project.

Moreover, Prosecco also extends Activiti with a module supporting additional data types. Activiti provides poor data type system[10]; natively, it supports only five data types (`String`, `Long`, `Enum`, `Date`, `Boolean`) that are often insufficient[11]. Therefore, the developed module provides dedicated form-based user interface that allows for entering the values and provides validation mechanism for such new data types as:

- `Month` and `Season`, `Text`,
- `Double` (floating point number),
- `PIN` (Personal Identification Number),
- `PESEL` (Polish national identification number),
- `Country` (list of countries).

Semantization of this module may include additional descriptions of these types as well as their instances, e.g.:

- `Month` – number of days,
- `Season` – months or days in particular season,
- `Text` – minimal or maximal length of the text,
- `Double` – number of significant digits, unit, displaying format, etc.,
- `PIN` – number of digits, number of attempts to enter correct value, additional security information,
- `PESEL` – interpretation of digits in the number (e.g. birth date, gender),
- `Country` – geographical location, polity, etc.

According to the project assumptions, all the types as well as their semantic descriptions that are used within process must be consistent with the ontology.

[10] See: http://www.activiti.org/userguide/#formProperties.

[11] The Activiti environment provides also two additional advanced data types: `User` and `ProcessDefinition`, which are not listed in the user guide, but available in the environment [4].

## V. Summary and future works

The paper gives an overview of business process semantization approaches in the existing proprietary software. It also presents the selected open-source process execution environments (such as Activiti, jBPM and Camunda) and outlines their general architecture, as well as analyzes the possibilities of process semantization in these open-source environments.

Some of the proposed semantization methods have already been introduced in the Prosecco (Processes Semantics Collaboration for Companies) research project, which takes advantage of the Activiti execution engine. Activiti was chosen because it can be easily extended and provides a good documentation [4]. Activiti is the winner of a 2013 Best of Open Source Software Awards (BOSSIE)[12].

Our future works will focus on development of new semantization techniques that can improve business process management environments not only with simple semantic annotations [16]. This can be used for extending recommendation methods in Activiti [17] or semantization of rules in the Wiki environment integrated with processes [18]. Moreover, it is possible to take advantage of semantization in business process verification [19].

*Abstract*— **The paper is devoted to the problem of temporal knowledge validation and verification during the process of implementing a system supporting organizational creativity. The motivation for implementing a temporal knowledge base system is presented, the implementation methodology is outlined, and the V&V (validation&verification) process is described in detail, using an example of the Logos reasoning tool. The main achievements of the paper are: elaborating a new implementation methodology for a temporal knowledge base system, and elaborating detailed V&V steps**.

**Keywords: organizational creativity, temporal knowledge base system, validation, verification, implementation methodology, Logos tool..**

## I. Introduction

ORGANIZATIONAL creativity is a relatively new concept in the theory of management, which has partially arisen on the ground of knowledge management.

There are many definitions of organizational creativity, but it is commonly perceived as a team, dynamic activity, responding to changing features of organization's environment, a team process – see e.g.[15], [1].

The organizational creativity is therefore to be perceived in the context of organizational dynamics, because it depends on the situational changes and is composed of processes. Therefore while discussing the question of computer support for organizational creativity, the temporal aspects should not be omitted.

Such a way of formulating this problem – underlining its dynamic aspect – justifies a proposal of using an intelligent system with a temporal knowledge base, as a tool supporting creation and development of organizational creativity, which is understood as organizational asset (see e.g. [7], [14]).

By the system with a temporal knowledge base we will understand (slightly modifying the definition given in [8]) an artificial intelligence system, which explicitly performs temporal reasoning. Such a system contains not only fact base, rule base, and inference engine, but also directly addresses the question of time. For an intelligent system to be temporal, it should contain explicit time representations in its knowledge base – formalized by the means of temporal logics – and at least in the representation and reasoning layers. In the paper we use an example of the Logos tool – a reasoning system constructed by the authors within the frame of the research project under the same name. One of the assumptions of the Logos project is the possibility of using it for different scientific researches and experiments, among others using it for building temporal knowledge base research prototype.

The main aim of the paper is to present a new implementation methodology for a temporal knowledge base system supporting organizational creativity, and to present – in detail – the steps performed during validation and verification of the temporal knowledge embedded in the system.

## II. Motivation

While reading many authors' discussions on the essence of organizational creativity, one sees that this is primarily team activity. The effect of this activity may be referred to as "creative knowledge", which itself generates new ideas, concepts, and solutions. To do so, the creative knowledge must be first codified, and next disseminated. This justifies the use of a knowledge base system. But the creative knowledge changes in time, due to several reasons.

First, organizational creativity is a process, therefore its effects are subject to change. Moreover, the process encompasses solving problems that also change, because the organization's environment changes [8] p. 13-15, [3] p. 150 and next, 176 and next.

Second, each knowledge – including the creative one – changes simply with the passage of time, with the flow of new information about objects [2].

Third, organizational creativity is linked with dynamics, which can be seen e.g. in the assets approach to this creativity

This paper has been supported by a grant: „Methodology for Computer Supported Organizational Creativity" from National Science Centre in Poland, 2013/09B/HS4/00473.

978-83-60810-66-8/$25.00©2015, IEEE

or in the requirement of adapting creative knowledge to situational context.

All the above leads to conclusion that a knowledge base system is not enough to support organizational creativity, because classical knowledge bases do not support time. Therefore in this paper we propose the use of a temporal knowledge base system, as defined earlier. Such system is able to perform the tasks arising from the characteristics of organizational creativity and its artifacts.

An important element of the implementation methodology of the proposed system is the process of validation and verification of temporal knowledge embedded in the system. The system is a rule-based one (strictly speaking: a temporal rule-based one), thus in order to run properly, its knowledge base must be correct. And a "correct" temporal knowledge base means that it has been verified and validated to ensure that there are no anomalies such as: redundant rules, subsuming rules, contradictory rules, unused attributes, unused values, recursive rules (inference loop, circularity),

Thus, the procedures of validation and verification (V&V) are an important fragment of implementation methodology for the proposed system. In more detailed manner we describe this problem in section 5.

## III. Related Work

In the literature, there are many methodologies concerning expert systems, among others [9], p. 136:

- blackboard architecture,
- KADS and CommonKADS,
- HyM for hybrid systems,
- Protégé,
- CAKE.

It must be however noted, that the above mentioned methodologies have been created for expert system, while the proposed temporal knowledge base system is not a typical ES. In the context of its architecture, it is worthy of considering the blackboard architecture, which is by some authors understood as a knowledge engineering methodology [6]. It enables to explicitly represent knowledge and its structure in a rule-based system (and the proposed temporal knowledge base system is a rule-based one). It may be acknowledged that a postulated division of system's knowledge base into several sub-bases means implementing the blackboard architecture and achieving its assumptions.

The second interesting methodology is CAKE (Computer Aided Knowledge Engineering), elaborated by Michalik. The detailed description of CAKE may be found e.g. in [11], [9]. Its advantages are similar to those of the blackboard methodology:

- use of the blackboard systems methodology,
- easy management of heterogeneous knowledge sources,
- support of groupworking,
- automatic control of formalized creative knowledge code,
- knowledge base editor,
- a package of wizards facilitating the coding process of the acquired knowledge.

It has to be pointed out, however, that the knowledge coding formalism, embedded in the CAKE system, has no temporal references. A sample diagram of knowledge base anomalies can be found e.g. in [16] and more detailed discussion on verification and validation in [12]. Some introductory concepts concerning V&V in Logos system being subject of our presentation can be found in [10]. Very interesting remarks on V&V in the context of knowledge engineering in the CommonKADS Methodology can be found in [13]. Authors differentiate between internal validation for both internal and external meaning, e.g. saying that some people use the term verification for internal validation and apply validation concept against user requirements ("is it the model right?").

## IV. System Implementation Methodology

It is also important that the aforementioned methodologies relate mainly to building expert systems, while the methodology needed for a temporal knowledge base system has to take into account also the processes of implementing the system in a creative organization. Therefore it is not possible to directly use any of the aforementioned methodologies, and a new one has to be developed, suited to the task of supporting organizational creativity by a temporal knowledge base system. Two very important questions thus arise.

First, the proposed system is an intelligent one, containing at least one temporal knowledge base, therefore the implementation methodology has to make use of (but not copying directly) existing methodologies for implementing such systems, as e.g. expert ones.

Second, the main aim of the system is to support organizational creativity, therefore the most important system elements are user interface and knowledge base. The first enables both adding creative knowledge to the system, and querying this kind of knowledge, the second is needed in representation and reasoning layers. The proposed methodology should accommodate also these elements.

The implementation methodology for a temporal knowledge base system has to be conformable to temporal knowledge base system's lifecycle. We propose the following lifecycle for the system (adapted from [5]):

1. Problem identification, and definition of users' needs;
2. System's formal specification, encompassing dialogues with users;
3. Definition of knowledge sub-bases', and general knowledge base structure and scope, choice of knowledge representation technique(s), creation of reasoning algorithm;
4. Creative knowledge acquisition;
5. Prototype creation and verification;
6. System coding and testing;

7. System maintaining and development – principally the creative knowledge bases and user interface.

The implementation methodology for the temporal knowledge base system covers points 1,2, 4-6, and 7 of the proposed system's lifecycle.

The methodology should be focused primarily on the creative knowledge, and on user interface. Therefore its main elements are creative knowledge engineering, and system engineering, with emphasis put on interface design and prototyping. The general structure of the proposed methodology is presented in fig. 1.

The proposed methodology has been inspired by other knowledge engineering methodologies for the process of knowledge management – particularly by the work [18] – and by classical, fundamental methodologies for implementing expert systems: [17], p. 135-139, and [4], p. 139. Obviously, it was not possible to directly merge the existing models, the proposal concerning knowledge engineering had to be remodeled in the context of organizational creativity process, while methodologies for implementing expert systems had to be adapted to the temporal knowledge base system, and its main task.

The methodology for implementing a temporal knowledge base system starts with the group of activities concerning capturing, and modeling of creative knowledge. At this stage it is essential to discover creative processes running within the team of employees involved in organizational creativity. This will enable to identify needs concerning the creative knowledge, and its usage by an organization (or team). Having this information, the next step of the methodology is to choose and/or design tacit creative knowledge acquisition methods, as well as to acquire explicit creative knowledge. This is so because we assume that the creative knowledge, as any other kind of knowledge, may be divided into tacit and explicit one. Next, it is necessary to identify (with the aid of previously gathered information) tacit knowledge, and sources of explicit knowledge, and to acquire both types of creative knowledge. Only then it is possible to model and analyze the creative knowledge, which is to be incorporated in the temporal knowledge base system.

During each stage of the proposed methodology, especially during the creative knowledge engineering stage, it is indispensable to closely cooperate with system users, that is the employees involved in the process of organizational creativity. Without them it is impossible to identify, and to acquire tacit knowledge. Moreover, the system will be useful only if people want to use it.

Activities concerning creative knowledge modeling, implementation, and verification are absolutely crucial, therefore in the proposed methodology there is a possibility to return to previous stages, in order to refine knowledge representation and implementation, or even to completely change the design of the knowledge model.

It also has to be explained why activities concerning system's specification, design, and implementation are placed at the end of the methodology, which differs from classical implementation methodologies for intelligent systems. As it has been already said, the main task for the temporal knowledge base system is to support organizational creativity, so its most essential elements are temporal creative knowledge base(s) and GUI. Thus the methodology is focused on these elements. Activities concerning system's engineering are also important, but are of ancillary nature regarding temporal KB, creative knowledge management, and GUI design.

As it has been already said, an important element (step) in the proposed methodology concerns temporal knowledge validation and verification, to ensure that the knowledge base is correct. The V&V step is preceded by knowledge analysis&modeling, and knowledge implementation. These three steps may be followed several times, continuously refining the knowledge base. Due to the importance of the V&V procedure, it is described in detail in the next section.

## V. Validation and verification of temporal knowledge during the process of implementing a temporal knowledge base system – the Logos example

As mentioned, we build the Logos reasoning system, being software platform for our experiments with temporal knowledge bases as well as with temporal reasoning. Additionally, while developing this system, we take into account the very important factor of V&V. At present main procedures discovering some anomalies in knowledge bases are ready. What have to be done – according to our thesis concerning V&V in temporal knowledge bases – is creating algorithms to discover some specific temporal anomalies. The thesis is that in temporal knowledge bases some new, very specific anomalies and errors, may theoretically appear. On the other hand, most of V&V methods already built-in in Logos for conventional (not temporal) knowledge bases are also useful and even necessary. The reason is that temporal knowledge bases may include the same kind of anomalies as the conventional ones. Most of the temporal anomalies we plan to detect as a first step while building Logos relate to incorrect time dependencies as declared in knowledge base. As we mentioned in section 3, the correct temporal knowledge base means that it has been verified and validated to ensure that there are no anomalies such as the following [11], [9]:

**Redundancy**

Two rules we regard as redundant, if for two rules:
$R_i \leftarrow W_{i1} \wedge .. \wedge W_{in}$ and
$R_j \leftarrow W_{j1} \wedge .. \wedge W_{jn}$, where $i \neq j$,
holds: $\{ W_{i1}..W_{in}\} = \{ W_{j1}..W_{jn}\}$

**Subsuming rules**

If for two different rules:
$R_i \leftarrow W_{i1} \wedge .. \wedge W_{im}$ and
$R_j \leftarrow W_{i1} \wedge .. \wedge W_{in,}$ where $i \neq j$,
holds $\{ W_{i1},..,W_{im} \} \subseteq \{ W_{i1},..,W_{in} \}$, then we say, that rule $R_j$ subsumes $R_j$.

**Contradictory rules**

Two rules we regard as contradictory if
$R_i \leftarrow W_1 \wedge .. \wedge W_n$ and

$\neg R_j \leftarrow W_1 \wedge .. \wedge W_n$, where $i \neq j$.

**Inconsistent rules**

Two rules we regard as inconsistent if
$R_i \leftarrow W_1 \wedge .. \wedge W_n$ and
$R_j \leftarrow W_1 \wedge .. \wedge W_n$, where $i \neq j$ and $R_i \neq R_{j,.}$
In our opinion, in such case system should give warning for knowledge engineer about possibility of inconsistency as understood in logic (here we use terminology of our system). Such situation, may in fact potentially lead to a contradiction or can be result of any other mistake of knowledge engineers they should be aware.

**Incompleteness**

We assumed that temporal knowledge base is complete when contains all possible combinations of attributes and their allowable values in rules' antecedents and consequents. It should be noticed that in practice not all combinations are required, so this kind of verification is only warning for knowledge engineer that some rules could be missing.

**Missing rules**

The anomaly called here as missing rules can be treated as a special case of incompleteness. While creating V&V module of Logos system we consider missing rules as the case when some of decision-making attributes are not present in any of the rule antecedents. This situation can appear as side effect of rapid prototyping and incremental method of knowledge base development.

**Unused attributes and values**

Our system in order to be able to detect some anomalies and errors requires explicit declaration of attributes and values being used in the knowledge base. When given attribute or value is never used in any of rules then Logos gives warning addressed to knowledge engineer because it may be information about serious anomaly in knowledge base. On the other hand, similarly as in the case of missing rules it can be side effect of using methodology of rapid prototyping and incremental development of knowledge base.

**Recursive rules (inference loop, circularity)**

Recursion in most of rule-based systems is very important anomaly in knowledge base with serious consequences and sometimes very difficult to detect by knowledge engineer without software support, e.g. as implemented in our Logos system. Recursion in this context may take a variety of patterns. In the simplest case can be like this:

$$K_i \leftarrow W_1 \text{ and } K_i = W_{1.}$$

This type of recursion (loop) is very easy to detect for knowledge engineer, even without special algorithms. The sign '=' does not mean simple equality but may have more complex semantics of ability of two expressions to match. Other variants of the same direct recursive call of the conditions to the conclusions of the rule may take one of the following schemes:

$K_i \leftarrow W_1 \wedge .. \wedge W_n$ and $K_i = W_1$

$K_i \leftarrow W_1 \wedge .. \wedge W_n$ and $K_i = W_n$

$K_i \leftarrow W_1 \wedge ..W_j.. \wedge W_n$ and $K_i = W_j$

While recursion in rules of logic programs is very useful and correct situation (provided their correct semantics), the recursion in expert systems is generally treated (as mentioned) as serious knowledge base anomaly.

We rejected using recursions in Logos for many reason, the main is that logic programming is first of all programming formalism (e.g. Prolog) and not knowledge representation language for temporal knowledge bases.

Much more difficult situation to detect by the knowledge engineer is that of indirect recursion. Sometimes, in large knowledge bases with several levels of inference, it can be practically not possible to detect in reasonable time. Then software support as e.g. that we implemented in Logos is absolutely necessary. In such case of indirect recursive call it does not occur at the same level of a given rule to its conclusion, within a single rule. This can be illustrated by the following example:

$R_1$: $K_1 \leftarrow W_{11} \wedge .. W_{1j} .. \wedge W_{1x}$
$R_i$: $K_i \leftarrow W_{i1} \wedge .. W_{il} .. \wedge W_{iy}$
$R_n$: $K_n \leftarrow W_{n1} \wedge .. W_{nm} .. \wedge W_{nz}$
where: $W_{1j} = K_i$ i $W_{il} = K_{n.}$ i $W_{nm} = K_1$ and '=' means matching/unification

In this case, the recursive call is related to a lower level in the hierarchy of rules, making its location is difficult to detect for a knowledge engineer. NB: Incidentally, defined earlier contradiction of rules – as mentioned - can also be caused by indirect inference.
Direct contradiction:
$p \leftarrow q$
$\neg p \leftarrow q.$
Indirect contradiction appearing during inference process:
$\neg p \leftarrow r$
$p \leftarrow q$
$q \leftarrow r.$

## VI. Concluding Remarks

Our main goal at this stage of research was design and development of software platform to make experiments with temporal knowledge bases. In this paper we focused on the problem on V&V, which is always present while building knowledge bases, but sometimes underestimated. The consequences of badly evaluated knowledge bases in this respect can be very serious, and for example some anomalies can't be detected for long time giving bad decisions. The more so, as we showed some of the anomalies, as for example recursions (inference loops) can be sometimes very difficult to detect by knowledge engineer. So our objective since the beginning of the project Sphinx was to build computer aided knowledge engineering system automatically supporting knowledge engineer especially helpful in such difficult to analyze cases. The next step in our researches concerning temporal knowledge bases will be identification of the specialized anomalies typical only for temporal systems. We suspect that beside the simple related to time errors we may discover special kind of temporal anomalies. Even some of already identified and described in our paper some anomalies can take the new character in relation to time. We have also additional hypothesis that temporal knowledge bases have kind of anomalies which are completely specific and different from that described. Verification of theses hypothesis we take as our next goal of our researches.

# Unifying Business Concepts for SMEs with Prosecco Ontology

Grzegorz J. Nalepa*, Mateusz Ślażyński†, Krzysztof Kutt‡, Edyta Kucharska§, Adam Łuszpaj¶
AGH University of Science and Technology
Al. Mickiewicza 30, 30-059, Krakow, Poland
*gjn@agh.edu.pl, †mslaz@agh.edu.pl, ‡kkutt@agh.edu.pl, §edyta@agh.edu.pl, ¶adam@softhis.com

*Abstract*—**Knowledge management in business information systems often requires a unified dictionary of business concepts, that allows for a transparent integration of such systems. Thanks to it sharing the conceptualization between users becomes possible, and better decision support facilities can be provided. The Prosecco project is a research and development project aims to address the needs and constraints of small and medium enterprises by designing methods that will significantly improve BPM systems. In this paper we focus on the development of ontology-based mechanisms allowing for creating taxonomies of business logic concepts unifying system objects. Building a taxonomy of business concepts shared by number of SMEs targeted in the project and then turning it into a formalized ontology integrating the software components is a major challenge. The paper demonstrates how this ontology is used to unify vocabulary of business processes and rules. The original contribution of this research discussed in the paper is the design and implementation of the ontology, and the demonstration of its practical use in the system.**

## I. Introduction

Providing a unified dictionary of business concepts is often a critical aspect of knowledge management in business information systems. Such a dictionary allows for a transparent integration of these systems. Moreover, it allows for sharing the conceptualization between different users providing better decision support facilities. For over a decade, it has been a common approach to support this task with Semantic Web technologies, including ontologies. Specifically formalized ontologies e.g. in OWL are of great practical importance. They become not only a tool for capturing the conceptual description of a business system, but also provide a technical backbone for software modules it is composed of. From the technical point of view, building ontologies is a knowledge engineering task that is currently mostly well supported. However, number of challenges remain, including practical integration of dedicated ontologies in a business information systems, often including business process and business rules (BR) management modules. Possible unification of these through an ontology is a non trivial task of great importance.

The *Prosecco* (Processes Semantics Collaboration for Companies) project [1] is a 32 month research and development project funded by NCBR (2012-2015). Provisioning of Business Process Management (BPM) systems is an important activity of main IT vendors. However, such systems are dedicated mainly for large companies, organizations and agencies. The motivation of the project is to address the needs and constraints of small and medium enterprises (SME) by designing methods that will significantly improve Business Process Management (BPM) systems. The main goal is to provide technologies that improve and simplify the design and configuration of BPM systems integrated with Business Rules Systems, targeting the management quality and competitiveness improvement. Moreover the project aims at fostering decision making and strategic planning in the SME market sector (mainly in the selected services sector). Specific objectives of the project include: a) development of business process modelling methods taking into account semantic dependencies between business process models and rule models, b) providing recommendation methods for analysis of semantically described business process models, and even more importantly, c) the development of ontology-based mechanisms allowing for creating taxonomies of business logic concepts unifying system objects.

In this paper we focus on the above mentioned objective c). In fact, building a taxonomy of business concepts shared by number of SMEs targeted in the project and then turning it into a formalized ontology integrating the software components is a major challenge. The paper demonstrates how this ontology is used to unify vocabulary of business processes and rules. The original contribution of this research discussed here is the design and implementation of the ontology. Furthermore, we demonstrate its practical use in the Prosecco BPM system.

The rest of the paper is composed as follows: In Section II we briefly discuss the architecture of the Prosecco system. Then in Section III we describe the design process of the ontology. Section IV demonstrates the capturing the semantics of business logic components of the system. Related work is included in Section V. The paper ends with a brief evaluation and summary in Section VI.

## II. Prosecco System Architecture

From the technical point of view, some of the main objectives of the Prosecco system that meets the project goals include the development of the:

1) integrated business logic model composed of business processes and rules,
2) runtime environment suitable for execution of the model,
3) recommendation modules for the design and use of business artifacts,

[1] See http://prosecco.agh.edu.pl for the project website.

978-83-60810-66-8/$25.00©2015, IEEE

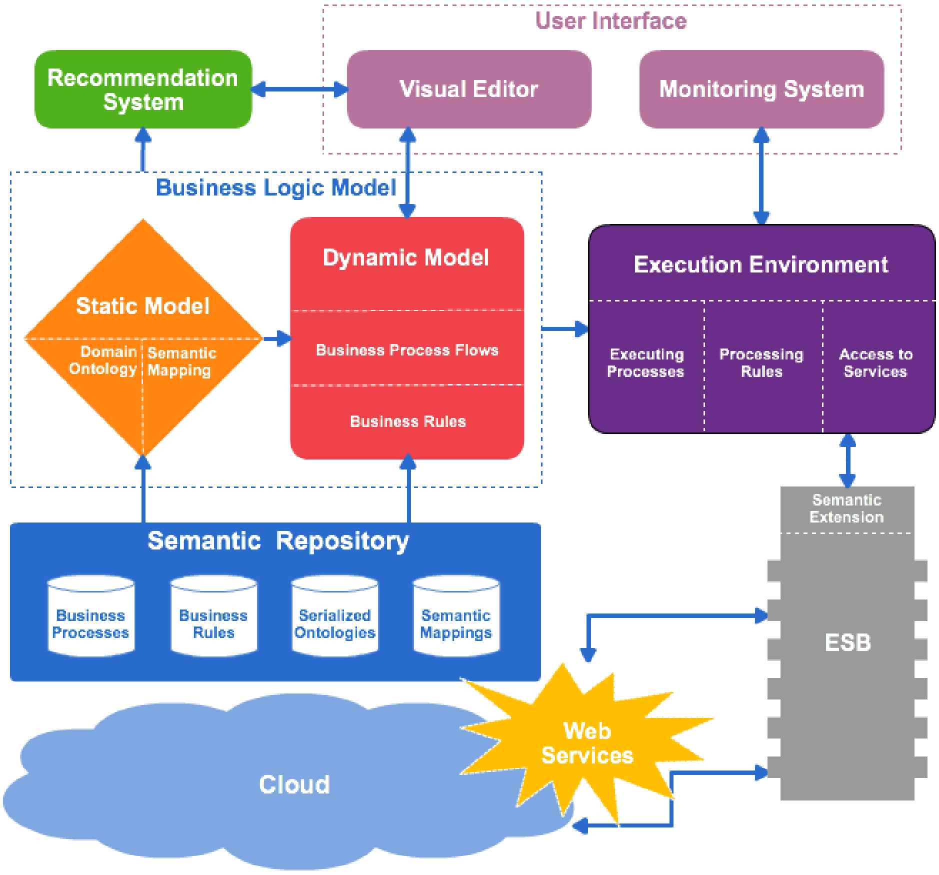

Figure 1. Outline of the Prosecco system architecture.

4) repository of business objects,
5) enterprise service bus (ESB) integrating the system components in a cloud environment, and
6) system ontology based on the taxonomy of shared business concepts.

The outline of the system can be observed in the Fig. 1.

The end users of the Prosecco system are SMEs, in fact selected employees as well as management of companies. The system aims at supporting carrying out of the main business processes of a company. Moreover, these processes are accompanied by business rules, capturing the details of the business logic, including lower level processing, as well as high-level constraints. Within the system these are modeled with the help of BPMN (Bussiness Process Model and Notation), and appropriate BR models identified with SBVR (Semantics of Business Vocabulary and Business Rules) and implemented with the help of the Drools BRMS as well as the HeaRT rule engine.

The process models and rule models are based on concepts captured during initial structured interviews with SMEs. The resulted taxonomy of concepts was used to design and implement the Prosecco ontology that works as the main unifying backbone of the system. It contains all the business terms needed for expressing and capturing the artifacts in business process models and rules. Moreover, it allows to monitor the execution of these models on a semantic level. The execution environment uses the ontology, so users can actually trace how these concepts are used in the executed processes and rules.

From the point of view on the integrators of the system, the ontology supports recommendation mechanism that allows for adaptation of business process and rule models to the needs of specific companies. Furthermore, the repository of business objects uses semantic annotation based on this ontology. It makes it possible for an easy retrieval of needed objects based on semantic queries. In the next section the design of the Prosecco ontology is described.

## III. Design of the Prosecco Ontology

### A. Requirements for the Ontology

The ontology that will be a part of a management system has to identify key concepts and relations describing static aspect of opertions of considered SMEs. Furthermore, it must be integrated with business processes and rules that describe the dynamic aspect of SME management.

Based on Prosecco system architecture described above, some assumptions for the Prosecco Ontology were established:

- Ontology should be modularized: each module should describe different domain (different topic).
- Ontology is designed to be used as dictionary of concept describing elements of business processes and rules.

- Ontology should be defined in a simple description logic language (OWL Lite$_A$, OWL 2 QL, or eventually OWL 2 RL).
- Each concept and role must be documented with short description (what exactly the term means) and possible connections with other ontology elements.
- Ontology is designed for Polish companies so all concepts should be written in Polish language and adjusted to Polish law.
- There should be a possibility to extend ontology by Prosecco system users.

### B. How the Ontology was built

There are some methods and tools that support ontology engineering, but there are no standard approaches how to develop ontologies in general [1]. Brief survey [2] indicates that:

- Existing methods are relatively old.
- The methods can be grouped into categories: incremental and iterative, or more comprehensive ones.
- Most methodologies consists of same main steps: assessment, deployment, testing and refinement.
- Most studies suffer from lack of information about tools.
- Only few recent studies suggests decrease in research activity in this field.

These conclusions encouraged Prosecco analysts to review the most significant and best-established methodologies for creating and managing ontologies [1], [2]. Three main approaches were considered: TOVE (*Toronto Virtual Enterprise*) [3], Enterprise Model Approach [4] and METHONTOLOGY [5]. Analysis of these methodologies resulted in specifying number of steps that are required to develop proper ontology. These steps designate the sequence of work in Prosecco project:

1) *motivating scenarios*: exemplary problems that ontology should resolve,
2) *competency questions*: which questions the ontology should answer,
3) *knowledge acquisition*: interviews with experts, domain texts analysis,
4) *conceptualisation*: extraction of concepts, objects and relations between them,
5) *integration*: consideration of existing ontology reuse,
6) *implementation*: expressing ontology in terms of a formal system,
7) *evaluation*: validation and verification, check for completeness, redundancy and contradictions,
8) *documentation*: comments and documents describing the concepts and relations in ontology.

In Prosecco project each step was performed incrementally in few iterations.

Besides comprehensive methodologies mentioned above, there are projects that provide "good practices" for selected steps in ontology engineering process, e.g. Ontolingua, CommonKADS, KACTUS, PLINIUS, ONIONS, Mikrokosmos, MENELASPHYSSYS, SENSUS (for overview see [1]).

Examined methodologies and "good practices" postulate separation of informal and formal part of ontology development. Some of them suggest introducing a middle representation, that will be a connector between unstructured text and a set of formal axioms. This layer can use structured language or simple graphical language (see IDEF5 methodology [6]). In Prosecco project three "formalization levels" were used:

1) *Unstructured notes*, gathered during interviews with experts (SME workers).
2) *Taxonomy in structured language*, prepared during conceptualisation step. Written down using Prolog language and visualised using custom scripts (see Fig. 2).
3) *Formal ontology*, written in OWL 2 language.

There are three main approaches to defining taxonomies [7]:

- *top-down*: the most general concepts are defined at the beginning and then more specific ones are gradually determined,
- *bottom-up*: low-level concepts and relations are defined at first and then they are generalized,
- *middle-out*: conceptualisation begins with identifying the most relevant concepts; more general and specified ones are determined as needed. It was selected as the best suitable approach for the Prosecco project.

### C. Description of the Ontology

Prosecco Ontology was partitioned into several parts. Each represents a different area in SME management:

1) Project artifacts (PL: *Artefakty*) – components connected with planning and implementation of the project.
2) Organizations (PL: *Organizacje*) – types of companies and their main properties (e.g. e-mail, VAT number).
3) Organization structure (PL: *StrukturyOrganizacji*) – elements that describe company structure, e.g. customer care department.
4) Documents (PL: *Dokumenty*) – concepts and relations associated with various kinds of documents.
5) People (PL: *Osoby*) – depiction of people: key properties (e.g. name, surname) and occupation.
6) Methodologies (PL: *Techniki*) – things connected with methods and tools used in company, e.g. code repository.
7) Resources (PL: *Zasoby*) – grouping into human resources, tangible and intangible resources.
8) Events (PL: *Zdarzenia*) – event types and their properties.
9) Prosecco (PL: *Prosecco*) – main module, the parent of other modules that integrates them and adds additional values common to all of them, e.g. uid or name.

Each part consists of at least one concept, object or dataproperty from another module. These nine parts constitute modules of the Prosecco Ontology that consists of: 86 classes, 70 object properties and 64 data properties. All of them are described by 1042 axioms. Classes are arranged in a hierarchy using `rdfs:subclassof` properties. Besides this simple generalization/specialization relations, each class can be inferred from object and data properties that this class has, e.g.

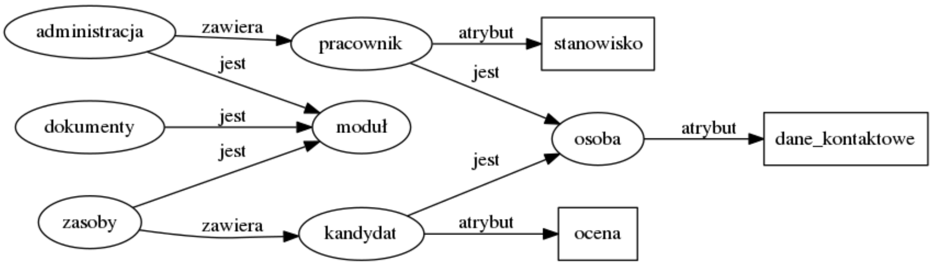

Figure 2. Visualisation of middle layer taxonomy.

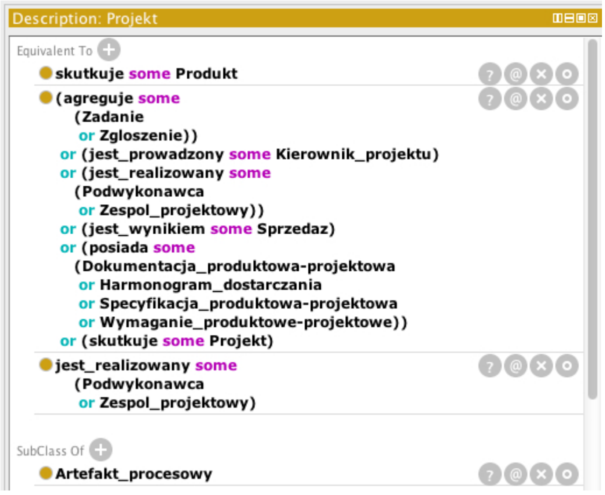
`Project` is something that aggregates some `Tasks` or something that is managed by the `Project leader`. Axioms allows inference only in one way: if something aggregates `Tasks`, it must be a `Project`. Fact that something is a `Project` does not infers conclusion that it must aggregates `Tasks`. Example (in Polish) is presented on Fig. 3. For axioms that connect classes with object and data properties, cardinality was also defined as it is presented in Table I.



Description: Projekt

Equivalent To

```
skutkuje some Produkt
(agreguje some
    (Zadanie
     or Zgloszenie))
  or (jest_prowadzony some Kierownik_projektu)
  or (jest_realizowany some
    (Podwykonawca
     or Zespol_projektowy))
  or (jest_wynikiem some Sprzedaz)
  or (posiada some
    (Dokumentacja_produktowa-projektowa
     or Harmonogram_dostarczania
     or Specyfikacja_produktowa-projektowa
     or Wymaganie_produktowe-projektowe))
  or (skutkuje some Projekt)
jest_realizowany some
    (Podwykonawca
     or Zespol_projektowy)
```

SubClass Of

```
Artefakt_procesowy
```

Figure 3. Exemplary concept definition in Prosecco Ontology.

| Cardinality | Protégé code | Example |
|---|---|---|
| $0, 1$ | `max 1` | `home_address max 1 string` |
| $1$ | `exactly 1` | `created exactly 1 dateTime` |
| $[0, \infty)$ | `only` | `description only string` |
| $[1, \infty)$ | `some` | *Not used yet. Defined for future use* |

Table I
CARDINALITY DEFINED IN AXIOMS THAT CONNECTS CLASSES WITH OBJECT AND DATA PROPERTIES.

### D. Tools and resources used

Different tools were used in different steps during the development process of the Prosecco Ontology.

*Taxonomy in structured language:*

- *SWI-Prolog*[2] for interpreting concepts and rules that were recorded with prepared templates for concepts `c(?Id, ?Name)`, relations `r(?Subject, ?Predicate, ?Object)` and attributes `a(?Class, ?AttributeName, ?ListOfPossibleValues)`
- *Custom scripts* for validation and visualisation using *Graphviz* tool[3] (see Fig. 2).

*Formal ontology:*

- *Protégé*[4] editor was used for preparing Ontology in OWL 2 language. It was selected because of its documentation, users support, official handbooks (e.g. [8]) and huge amount of design patterns [9].
- *Git repository* for collaborative work with following iterations of Ontology. *OntoCVS*[5] plugin was used for better tracking of Ontology changes.
- *Ontology modularization tool.* Ontology was implemented as a coherent model. In last step it was divided into modules. Different ontology modularization techniques were analysed. One of the most important is the Atomic Decomposition method [10]. It is based on atoms that consist of a set of axioms that occur together. Correlation between axioms inside atom is so strong, that this axioms have to be together. Single module is a single atom or a set of atoms. Using atomic decomposition alorithm [11] results in a set of modules. For Prosecco Ontology this algotihm generates 62 modules, where one of them consists of 574 axioms (of overall number 1042 axioms). These modules were not functional and decision about manual modularization was made.

The whole development process of the ontology lasted 12 months, including preliminary analytic meetings with SMEs. The development team included 4 business analytics and 4 developers; a 2 person evaluation team was also included.

## IV. Capturing the Semantics of Business Logic

In order to integrate the complete ontology model into the Prosecco architecture some additional works had to be performed. Different formal models, designed to capture dynamics of business processes, were created by separate teams, and they had to be matched with the ontology's concepts. This refinement process can be divided into three separate steps.

Firstly, both BPMN and rule models had very uneven granularity levels: abstract concepts were often mixed with detailed and concrete names of particular tools and documents. Due

[2] See: http://www.swi-prolog.org/.

[3] See: http://www.graphviz.org/.

[4] See: http://protege.stanford.edu/.

[5] See: https://code.google.com/p/ontovcs/.

to these inconsistencies integration of both dynamic models was nearly impossible. During the first step, all the concepts in business processes and rules were generalized or rejected where necessary to represent the same level of abstraction as ontology. The resulting models were smaller and more general than previous versions:

- Exemplary rule that was rejected due to the limitation only to selected SMEs: `It is necessary that each Employee has the available vacation days.`
- Exemplary rule before: `It is possible that a` *`programmer`* `can change a task status [...]` and after generalization: `It is possible that a` **`specialist`** `can change a task status [...].`

Secondly, due to the incoherences in concepts' naming, both models have been aligned with names provided in the ontology. Every noun and verb in BPMN and rule models was compared against the ontology: both name and the possible usage described by object and data properties. If equivalent concept exists, it replaced word used in dynamic model. Furthermore ontology had to be filled with lacking concepts. In particular there were added many data type attributes due to the low-level characteristics of rules – every attribute used in conditional or decisive part had to be formally specified inside the related class. It was a very important step to achieve an automatic execution of hybrid BPMN/rule models.

As a result, both dynamic models of business logic shared the same taxonomy, along with attributes' types and relations between the concepts. Unfortunately, neither Prosecco's external services nor environments used to execute and validate these models do not support semantic data directly and there had to be introduced a solution to integrate them with ontology in an indirect manner. The proposed solution is based on automatically generated Plain Old Java Objects (so-called POJO), which represent ontological concepts in serializable and executable manner. The ontology is used to infer: a) types of classes (corresponding to the ontological classes), b) types of the class attributes (corresponding to data type properties), and c) relations between the classes (corresponding to object properties).

Within the practical implementation of the architecture depicted in Fig.1 we integrated the Prosecco ontology as the core of the system. The Prosecco system uses Activiti as the business process engine [12]. Apart from the type system generated according to ontology, Activiti uses also other semantization techniques. The Prosecco repository consists of several sub-repositories, including business process models for Activiti, rule models for Drools, user information in ACL, and system history managed by the Cassandra tool. Data repositories are separate from the type system and existing instances are continuously synchronized with ontology. Thanks to the use of the ontology the project assumes that all data types and their instances existing within the system are consistent with the ontology.

## V. Related Work

During the development of the Prosecco Ontology, existing organization ontologies were analysed and compared with Ontology discussed in this paper. Four models were considered:

1) *An organization ontology* [13] – developed by W3C and Epimorphics Ltd. and implemented in simple description logics language ($\mathcal{SIF}$(D)). It is aimed at describing basic organizational information in a number of domains. Comparing to the Prosecco Ontology, this model is less acurate and more general.
2) *IntelLEO Organization Ontology* [14] – created during IntelLEO project and currently not further developed. It models organization structures using people responsibilities and relations between them. This ontology models access rights what is outside the scope of Prosecco Ontology. On the other hand, it is not suitable for describing business processes.
3) *Ontology for organizations* [15] – is a part of a larger one that is used to annotate The Gazette[6] contents. It is best suitable for characterize activities of the organization (e.g. if it is a government or charity organization). This ontology does not provide concepts for describing organization structure, what was one of main goals of Prosecco Ontology.
4) *PROTON (PROTo ONtology)* [16] – upper-level ontology that is simple and well-documented. This is the biggest one among analysed models (it consists of 250 classes). As Prosecco Ontology, it describes projects, documents and organization structure. It lacks the support for business processes modelling.

Three more models draw attention, but due to the fact they are not public, there was no possibility to analyse them insightful and compare them to the Prosecco Ontology:

1) *Unified Enterprise Modelling Ontology (UEMO)* [17] – is based on UEML (Unified Enterprise Modeling Language) and depicts companies and information systems. It is coupled with BPM (Business Process Management).
2) *O-CREAM-v2, a core reference ontology for the CRM domain* [18] – is a very detailed CRM (Customer Relationship Management) ontology. One of its drawbacks is the lack of emphasis on services.
3) *WeCoTin* [19] – ontology designed to modelling process of matching the offer to the customer's requirements.

## VI. Evaluation and Summary

Knowledge management in business information systems often requires a unified dictionary of business concepts, that allows for a transparent integration of such systems. Thanks to it sharing the conceptualization between users becomes possible, and a better decision support facilities can be provided. In this paper we focused on the development of ontology-based mechanisms allowing for creating taxonomies of business logic concepts unifying system objects considered

[6] See: https://www.thegazette.co.uk/.

in the Prosecco project. We demonstrated how this ontology is used to unify vocabulary of business processes and rules in the Prosecco BPM system. The practical contribution discussed in the paper is the design and implementation of the ontology, and the demonstration of its practical use in the system.

The Prosecco Ontology, whose development and structure were described in the earlier sections, fulfills all the requirements of the project. As a result of careful design and iterative refactoring it can be considered as a formal definition of data and concepts appearing in the other parts of the Prosecco system, especially BPMN models and business rules. In comparison to less formalized data models it has certain advantages like mature tools, unambiguous semantics and possibility to formally prove coherence thanks to the available reasoners. Moreover, the formal approach to design system around a semantic model has proven to be a valid option among the standard solutions – the Prosseco Ontology is already successfully used to generate model layer of the system's services and future plans include usage of semantic queries to enhance data retrieval and storage.

A certain limitation of the current version of the ontology is the fact that it is based on the Polish vocabulary. However, it was a conscious decision and the requirement of the project related to the Polish regulations. In general most of the modules of the ontology could be easily adapted to other SMEs so the ontology would be suitable for international use. However, from the practical point of view an adaptation to some specific regional regulation (e.g. EU) should be considered. Certain parts specific to the Polish law would have to be replaced.

The biggest disadvantage of the proposed solution is lack of a direct integration between different modeling techniques and technologies; due to this limitation there was proposed an intermediate translation of semantic classes in a form of the corresponding Java classes. Currently the works are focused on the creation of environments which could help to model business logic enhanced by use of the ontological background.

Our future work include the use of the ontology to improve the usability of the execution environment. We are considering how semantic annotations could enhance intelligibility of the business logic. Thanks to the already integrated domain ontology, it would be easy to enhance rules with semantic annotations, leading to more meaningful design of the system, and possibly porting it to mobile platforms [20], and simplyfying a formalized modeling [21]. We are also working on a tighter integration of the components of the BPM system, including semantic tracking of business objects and a BP editor [22]. Moreover, we consider possible extensions of the ontology towards the needs of other SMEs from different sectors.

□

*Abstract*—**The paper deals with the assessment of an experimental data modeling approach which is intended to support the agile oriented data modeling. The approach is based on the Anchor Data Modeling technique and is applied on a multidimensional data model. The assessed approach is expected to facilitate more effective execution of queries in the data mart environment. The emphasis is placed on the comparison of the query execution performance using database schemas, each built using traditional and the experimental approach. The tests are done in the environment of selected modern Business Intelligence tools, and using two test queries with varying output dataset sizes. The results show that the use of the database schema, created according to the experimental data modeling approach, had positive impact on the querying performance in several cases. The magnitude of impact on the querying performance, however, varied depending on each query's respective resulting dataset size.**

## I. Introduction

Multidimensional data modeling principles are one of the cornerstones of the Business Intelligence (BI) system's design and development process. These principles were introduced more than 3 decades ago by Ralph Kimball and then developed to today's well-known bus architecture and dimensional modeling methodology [1]. While the BI system is usually a critical decision-making and management support system, it is crucial to devote the best of care to its development and management. Although current trends strongly promote big data as the new Holy Grail for today's CIOs, the fact is that standard relational data marts will still be a thing in the coming future. Vast amounts of company's historical business data are stored predominantly in traditional relational database environments. Moreover, the business process management will always rely on the analysis of historical facts in relation to current real-time data. This is also supported in [2] where the authors state that the data and information integration are the most fundamental issues in the integration of decision support systems into processes, to enhance decision support performance.

The dynamics of event incidence and subsequent changes in the business world produce new business process management related requirements. Therefore, high impact on almost all aspects of the data mart architecture design, usage and its continuous adaptation and evolution is experienced almost on a regular basis. According to [3], one of the information system's success dimensions is the information timeliness and currency with respect to related business processes. The adaptation to the time aspect is therefore very important and it has an impact on the quality of data used in the decision-making process. This is supported also by [4] where the perception of data warehouse system's success dimensions by its users is studied. The authors determined that the quality of the underlying data is emphasized as an important antecedent of information quality and indirectly also of the system quality as important aspects of information system's success. Other aspects, like system performance (including query execution performance), service quality and usefulness of the BI system's toolset were also studied (the query execution performance is one of the main themes in this paper).

Changes usually encompass a set of data updates and schema changes, constraint modifications (keys, value containment) or metadata adjustments [5]. Kimball has already introduced and developed methods for the time-aware evidence of critical data in business dimensions represented in a multidimensional database schema. In terms of the data mart development, the standard Kimball's approach offers several non-destructive methods of capturing changes in values of dimensional attributes (i.e. horizontal changes) [6]. Although these methods are actively used in practice, some space is still left for further research in this part of the well-established data mart development paradigm [7]. Drawbacks of these methods usually reveal themselves sooner or later during most BI projects. These include mainly notable data volume increases and obvious limits in the length of change

capture time period. The assessment of an innovative approach addressing these issues in the data modeling practice are main research interests of the author of this paper.

Issues of business change adaptation dynamics are closely related to the agile development paradigm. Agile principles have already built a strong position in the software development area. In the data modeling practice, during the information system development life cycle, there is also an effort put into the adoption of such practices and principles. Generally, the agile approach emphasizes intense cooperation with customers as a vital asset. A core principle which is promoted by the "agile", and is especially relevant to the data modeling, is the modularity principle. The modularity facilitates easier adaptation of a software solution to changes in business requirements.

Also the multidimensional data model must reflect the most current business requirements and easy adaptation of the data model to these changes is an issue that needs to be solved most effectively. [8], [9] write about such agile oriented data modeling techniques applicable in the data warehouse development field. These techniques, although referenced as very effective in the practice, pose, however, rather agile oriented data modeling process management solutions than particular agile oriented data definition solutions. This issue is particularly relevant also to the development of the data mart architecture and is addressed by the experimental approach.

In recent works [10], [11], [12] an experimental (hybrid) data modeling approach was introduced. The proposed approach is focused on representing database schema of the multidimensional data model (designed using standard Kimball's dimensional modeling process) in an agile oriented fashion – i.e. as an implicitly modular data model. For this purpose, a data modeling technique, called the anchor data modeling (ADM), is leveraged and its principles and guidelines are adapted to the needs of the multidimensional data modeling field. The ADM technique was created by Olle Regardt, Lars Rönnbäck and their colleges, and fully described in [13].

In this paper, the emphasis is placed on the assessment of the usage of the experimental data modeling approach in the environment of selected client-side Business Intelligence tools. The goal of this paper is then to compare query execution performance in selected tools using the ADM based multidimensional database schema on one side, and a more traditional multidimensional database schema on the other side (both schemas are derived from a sample multidimensional data model described further in the text). The results will help to build more evidence of the possible applicability of the mentioned experimental data modeling approach. The mentioned approach, along with other methodological background, is described in the section II and the query performance assessment is presented in section III.

## II. Methodology

### A. Short overview of the Anchor Data Modeling technique

By definition, the ADM technique's application should lead to the creation of a highly decomposed database schema. The relations in such schema can change in time separately, both in terms of attribute values and structure in a more effective fashion. The implicit modularity feature brings the possibility of passing changes in the semantic background of the data model to changes in the final database schema without breaking the structure of source entities. This can make the data modeling more flexible and possibly promote non-destructive ways of managing changes even in multidimensional data models, according to most recent changes in the business environment.

The ADM technique is based on the usage of several distinctive conceptual constructors that are designed for easy and understandable representation of semantic terms and the evolution of the database schema. The resulting database schema is called the anchor database schema by default. The technique is intended to be a part of the relational data management paradigm, but the usage can easily span also in the object-oriented data modeling field [13]. Each entity is represented by one *Anchor* constructor and a set of *Attribute* constructors – both terms conceptually represent basic semantic features of an entity (name and properties). Each *Attribute* is dedicated to serve as a representation of each entity's property (i.e. attribute), containing usually only identifier (composite key) and an actual value of the entity's property. *Anchors* are connected using *Ties* which represent, by default, $M$ *to* $N$ relationships between entities (i.e. *Anchors*).

### B. Description of the experimental data modeling approach and differences from the traditional approach

Let a simple multidimensional data model be defined as a set of $i$ dimensions $DIM_i$ and a fact records subset. The fact records subset is matrix of records comprised of $n$ quantitative process performance measurements $M$ so that each fact record is represented as $facts = \{M_1, M_2, \dots, M_n\}$. Each dimension has $j$ dimensional properties $P$, i.e., each $DIM_i = \{P_{i,1}, P_{i,2}, \dots, P_{i,j}\}$. The description of the difference between traditional and the anchor data modeling (ADM) based database schemas follows.

Let the traditional multidimensional relational database schema, derived from the simple multidimensional data model ("trad."), be a set of $i$ relational tables, each for one dimension $DIM_i$, and one relational table for the fact records subset (the fact table). Each relational table $DIM_i$ consists of $j$+1 columns $C$, one column $C_K$ for the primary key and others for each property $P_j$. The whole tuple of the $i$-th dimension is then $DIM_i = \{C_{i,K}, C_{i,1}, C_{i,2}, \dots, C_{i,j}\}$. All dimensional properties are then included in one relational table. The fact table consists of $n$ respective metrics $M$ and a subset of composite key columns $K^*_{DIM}$, each referencing the $C_K$ column in one of the $DIM_i$. The whole tuple of the fact table of the "trad." schema is then $facts = \{K^*_{DIM_1}, K^*_{DIM_2}, \dots, K^*_{DIM_i}, M_1, M_2, \dots, M_n\}$.

Let the ADM based multidimensional relational database schema, derived from the simple multidimensional data model ("ADM"), be defined as a set of $i$ *Anchor* relational tables $A_i^{DIM}$ (one for each dimension $DIM_i$) and a set of $i \times j$ *Attribute* relational tables $Attr_{i,j}^{DIM}$ (one for each property $P_j$ of $i$-th dimension $DIM_i$). Each $A_i^{DIM}$ contains only identifying columns $C_{\mathrm{K}}$ of $i$-th dimension, i.e. $A_i^{DIM} = \{C_{i,\mathrm{K}}\}$. Inclusion of more attributes is, however, possible, e.g. to store ETL (ELT) process metadata (e.g. data quality related information). Each *Attribute* relation should contain only identifying composite key column and another column $C^*$ for $j$-th property of $i$-th dimension, i.e. $Attr_{i,j}^{DIM} = \{C^*_{i,\mathrm{K}}, C_{i,j}\}$. The primary key of the *Attribute* relation can then be extended with additional datetime columns if the historization is to be applied to the respective dimension's property. So one less *Attribute* relation must be created to represent the same dimension as it is in the traditional schema, but each *Attribute* should have identifying column, which is the obvious drawback of the approach, in this regard. The composite key column in the *Attribute* relation relates to the primary key column in the *Anchor* relation. Most modern database systems can perform elimination of tables in joins in query optimization procedures. This feature mitigates join demands of a hierarchically more extensive query by excluding tables from join from which no columns are selected to be used in the output of a query [13]. The fact table again consists of $n$ respective metrics $M$ and then a subset of composite key columns $K^*_{A^{DIM}}$, each referencing the $C_{\mathrm{K}}$ column in one of the $A_i^{DIM}$ relations. The whole tuple of the fact table is then, in fact, the same as for the "trad." schema, therefore $facts = \{K^*_{A_1^{DIM}}, K^*_{A_2^{DIM}}, \dots, K^*_{A_i^{DIM}}, M_1, M_2, \dots, M_n\}$.

The modular nature of the resulting anchor database schema implies normalization of relations into the 5th normal form. The schema can then be qualified as a highly decomposed[1]. Moreover, if the historization of *Attribute* values is applied, the *Attribute* relation is in the 6th normal form [14] and the primary key of the *Attribute* relation is complemented with a time validity aspect (i.e. column with a date and time data type).

The normalization of all relations in the anchor database schema into the 6th normal form is implied by original ADM technique's guidelines [13]. However, the results in previous related publication [15], concerning one of the first applications of the ADM in the multidimensional data modeling field, indicated that the normalization of the fact table leads to severe querying performance problems. Therefore, in the presented experimental approach, only Attribute relations in the schema should be normalized into the 6th normal form, if it is desired.

One of the expected benefits from using the ADM technique, when constructing a multidimensional database schema, relates to typical user behavior in the analysis and reporting – users typically select only few dimensional properties in their queries. Also, relevant values of these properties are usually filtered so that only a limited set of values is used to calculate the final results of the query. The high degree of normalization that is applied in the ADM based multidimensional database schema, then leads to the elimination of the need for scanning whole rows of a dimensional table (potentially large one). This aspect is then mirrored in expected query execution performance benefits. Also the straightforwardness and ease of applying implicit *Attribute* values' historization (each attribute can be historized separately) is a notable asset of the experimental approach. The high degree of dimensional properties' decomposition offers also a possibility of effective use of specific query processing optimization techniques, including compression and table data pre-ordering. This may bring some enhancements into already used relational data management environments, similar to those known to be present in columnar storage engines.

### C. Description of the sample multidimensional data model

The multidimensional data model that was used as a source for the creation of the sample database schemas is a typical banking model with 6 dimensions, as presented by Kimball and Ross [1]. Fact records represent monthly account data with cardinality of 50 million rows. Dimensions also come from the same publication and provide descriptive data to Accounts (220 000 rows), Households (i.e. Customers, 200 000 rows), Banking products (20 rows), Branches (1000 rows) and Account states (3 rows). The time dimension defining the monthly granularity of facts spans over 12 years (2000–2012; 156 rows). Fig. 1 provides a conceptual outlook on the structure of the sample multidimensional data model.

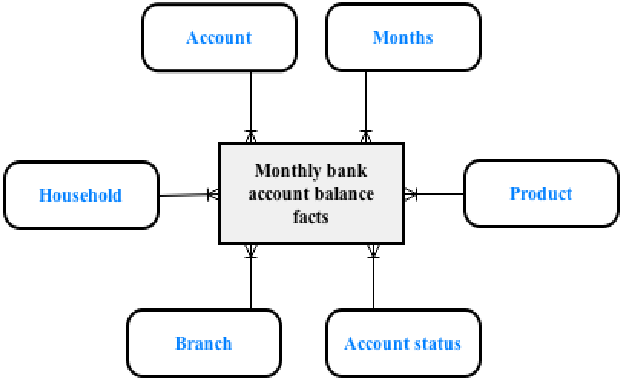

Fig. 1 Conceptual view on the sample multidimensional data model

### D. Description of the query testing process

None of the client-side tools used, however, support usage of an aggregated SQL query definition of data source for a

[1] From a conceptual point of view, the topology of the data model (and the database schema in the end) gets close to the snowflake topology, while the traditional data model stays with the classical star topology.

report. Both test queries therefore had to be stripped of aggregate functions and group by statements. This paper will, therefore, deal with query execution time (QET) results related to full dataset extraction because this mode is supported by all of the BI tools used in the test. The time dimension filtering condition was set to filter 5 specific calendar years (2008 to 2012) along with additional filtering options. In the appendix, there are both SQL queries listed, in both versions for both schema variants (with mentioned additional filtering options). Each query was then executed in each BI tool and query performance results were gathered using Microsoft SQL Profiler. This tool was used to get data on QET results, as well as actual CPU demands and the count of logical data reads performed during the execution of each query in each tool. Also the Apache jMeter 2.10 tool was used for the execution of specified test queries directly on the database server.

The testing process was done using a database server with Microsoft SQL Server 2012 64-bit bundle installed, with following server hardware configuration: Intel Xeon Quad-core 2.66 GHz CPU and 4 GB RAM. Although the server hardware is not the best-of-breed in the data warehousing field, I was able to get meaningful query execution performance results with it. Client-side tools were installed and run on a standard PC with 8 GB RAM and Intel Quad-Core processor.

### *E. Business Intelligence client-side tools for the assessment*

Gartner Research [16] published the 2015 version of their annual 'Magic Quadrant for Business Intelligence and Analytics Platforms' research report. The list of tools in this analytical report was a main source of tools that were assessed for the use in the process of query execution performance analysis. BI tool selection process respected following criteria:

1) the software is a client-side and stand-alone tool, without the need for installation of any application and/or OLAP server,
2) the software has a trial or free desktop version available for download,
3) the software is a BI reporting/dashboard management tool,
4) the software allows seamless connection to a relational database (SQL Server 2012 specifically).

The final list (Table I) includes 6 tools that passed the criteria and were successfully installed and run without stability and connectivity issues (both queries were executed without crashes and/or timeout problems). All tools are modern solutions, allowing for fast and intuitive data discovery and visualization. User interfaces offer self-service functionalities and also several data analysis features. Database connectivity features include connection to structured as well as unstructured data management solutions. The Tableau Desktop software also offers very fast on-the-fly in-memory computing capabilities. According to the Gartner Research report [16], all vendors of these tools, except for Tibco, are recognized as 'Leaders' in the magic quadrant chart (Tibco is viewed as a 'Visionary' and is located very close to the 'Leaders' quadrant). So the way how the data is handled and processed internally in each tool's software environment, and using respective connectivity interfaces, is the main differentiating factor for all 6 tools.

TABLE I.
SELECTED BI TOOLS AND DATABASE CONNECTIVITY PROPERTIES

| Short code | BI tool name | Database connectivity interfaces |
|---|---|---|
| Tibco | Tibco Spotfire Desktop 7.0 | .NET data provider |
| Tableau | Tableau Desktop 8.3 | ODBC |
| Lumira | SAP Lumira 1.23 | JDBC |
| MSTR | Microstrategy Analytics Desktop 9.4 | ODBC |
| Qlik | QlikSense Desktop 1.0 | ODBC, OLE DB |
| MSPP | Microsoft PowerPivot for Excel 2013 | OLE DB, .NET data provider, ODBC |

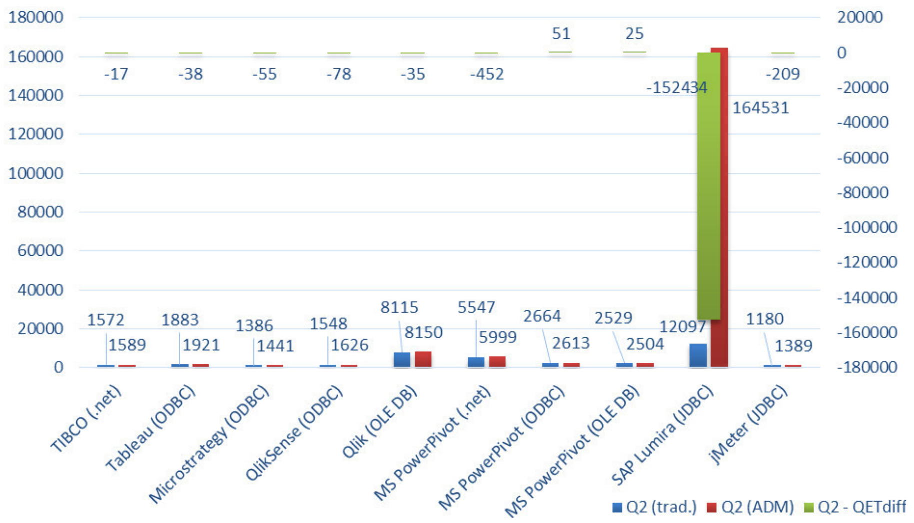

Fig. 3 QET results for the query Q2 in selected tools with QET differences between schema variants

## III. Results of Query Execution Performance Tests and Discussion

The results of the query performance testing process, which took into consideration both the highly decomposed ADM based database schema of the sample multidimensional data model and the traditionally structured counterpart provided interesting insights.

Fig. 2 (Q1) and Fig. 3 (Q2) show full dataset extraction QET results acquired for both queries after its execution in each tool as well as the on-server result obtained using the jMeter. Figures show also difference values $QET_{diff}$ that were calculated according to the formula: $QET_{diff} = QET_{trad.} - QET_{ADM}$.

The results for the query Q1 show that the usage of the ADM based database schema was beneficial in 4 cases as seen in the Fig. 2. The Tibco tool had bigger problems with the ADM based schema. The Qlik had slight problems too, but the $QET_{diff}$ was only -108 ms in this case. The usage of the OLE DB interface in the MSPP resulted in the $QET_{diff}$ = -295 ms which was also still relatively close to zero.

Since the query Q1 results in a large dataset to be extracted from the database (9 615 712 rows), the greatest difference may lie in the way of how each tool processes large datasets are being extracted. The Lumira is doing a bad job in this matter because resulting $QET_{diff}$ values were noticeably greater in comparison with other tools. The difference between QET value obtained for the ADM based schema and the traditional one came out largely in favor of the traditional schema. The client-side usage of the JDBC interface may have some part in the magnitude of QET value differences along with the connection to the database server through LAN. All in all, the Lumira, as a stand-alone client-side BI tools, is clearly not beneficial for usage with the ADM based schema. Table II shows a comparison of actual CPU demands and the amount of data reads performed during the usage of each tool.

Table II.
Physical characteristics of query Q1‘s execution

| BI tool | Interface | Q1 (trad.) | | Q1 (ADM) | |
|---|---|---|---|---|---|
| | | CPU | Reads | CPU | Reads |
| Tableau | ODBC | 13530 | 199556 | 14547 | 199586 |
| Tibco | .NET d. p. | 8827 | 199556 | 11391 | 199586 |
| MSTR | ODBC | 10109 | 199575 | 10938 | 199562 |
| Qlik | ODBC | 9141 | 199542 | 12812 | 200395 |
| | OLE DB | 12482 | 200081 | 12687 | 199626 |
| MSPP | .NET d. p. | 11857 | 199954 | 14033 | 200137 |
| | ODBC | 11936 | 199542 | 14124 | 199562 |
| | OLE DB | 12860 | 200107 | 14238 | 200375 |
| **mean** | | **11343** | **199739.1** | **13096** | **199853.6** |
| **std. dev.** | | **1761** | **259.1** | **1370.9** | **379.9** |
| jMeter | JDBC | 8360 | 199825 | 10000 | 199848 |
| Lumira | JDBC | 51641 | 38662071 | 429640 | 230975841 |

In the table II, it is visible that each tool’s internal algorithm of a large dataset processing plays an important role when using a more normalized data source (besides the perceived problem with Lumira).

Results for the query Q2 (Fig. 3) show that the usage of the ADM based database schema was beneficial in 2 cases (if we take into account only positive $QET_{diff}$ values). The lowest $QET_{diff}$ value is indicated only in the case of MSPP using .NET data provider interface ($QET_{diff}$ = -452 ms). In almost all cases, however, the $QET_{diff}$ was relatively low (in absolute terms and again excluding the Lumira case). The QET result obtained using the jMeter was very close to 4 tools which may, however, be mainly due to the nature of the query Q2 and resulting row count. Nevertheless, the $QET_{diff}$ = -209 ms which is relatively lower than most client-side tools (excluding cases of Lumira and MSPP using .NET interface). The size of the Q2’s resulting dataset (507 978 rows) points out on one possible effect that stems from the high normalization of the ADM based database scheme – if the size of the dataset gets lower the $QET_{diff}$ differences get closer to zero (except some cases).

Table III shows a comparison of actual CPU demands and the amount of data reads performed during the usage of each tool and query Q2.

TABLE III.
PHYSICAL CHARACTERISTICS OF QUERY Q2‘S EXECUTION

| BI tool | Interface | Q2 (trad.) | | Q2 (ADM) | |
|---|---|---|---|---|---|
| | | CPU | Reads | CPU | Reads |
| Tableau | ODBC | 1781 | 16033 | 1516 | 13959 |
| Tibco | .NET d. p. | 1281 | 15471 | 1595 | 13407 |
| MSTR | ODBC | 1514 | 15579 | 1418 | 13484 |
| Qlik | ODBC | 1655 | 16057 | 1671 | 13435 |
| | OLE DB | 1688 | 16145 | 2141 | 14456 |
| MSPP | .NET d. p. | 1968 | 16033 | 1874 | 13937 |
| | ODBC | 1640 | 15451 | 1891 | 13379 |
| | OLE DB | 1936 | 16033 | 1936 | 16042 |
| **mean** | | **1683** | **15850.3** | **1755.3** | **14012.4** |
| **std. dev.** | | **222.9** | **294.4** | **244.3** | **902.8** |
| jMeter | JDBC | 1595 | 15451 | 1717 | 13379 |
| Lumira | JDBC | 11625 | 12529763 | 94125 | 3824425 |

For this relatively smaller dataset (in comparison to the Q1's resulting dataset), it is evident that each tool's internal algorithm of the extracted dataset processing played relatively less important role, i.e. when using a more normalized data source (again besides the already perceived problem with Lumira's usage).

As for the related works, there are, regrettably, still no other works yet that deal specifically with the assessment of ADM technique's use. Besides the original paper [13] there are books [8], [9] that address agile oriented data modeling process guidelines in the traditional development of a data warehouse. However, there are works that deal with certain data modeling issues that are also addressed by the experimental approach (although mostly the conceptual part of the data modeling process is handled). Evolutionary aspects of the data in the data warehouse are dealt with in [17] and [18]. These works deal with the addition of temporal aspects into the UML based logical multidimensional data model (i.e. class model in which the conceptual model decomposition can be handled quite easily). In the paper [18], a rather general solution using only specific classes with temporal properties (a prototype based example of the application is presented) was proposed. In the paper [17], a more complex conceptual modeling approach was proposed. Along with modelling time-varying dimensional property objects, the authors propose also a solution for modelling time-varying hierarchies and hierarchy levels. Moreover, the way of mapping the resulting UML class schema to the entity relationship model of a data mart is proposed, although the paper lacks a practical example. In the paper [19], a graph theory based hybrid modeling method is introduced. The approach decomposes entity properties (attributes) and mutual relationships into graph nodes and edges. The schematic representation of data sources and requirements is then combined with the graph based representation and a conceptual multidimensional data model is derived. The changes in entities of the data model are induced by checking requirement-derived constraints, but time-validity aspects are not considered in the approach. The authors also present a short application example.

## IV. CONCLUSION

The query execution performance results were analyzed with the conclusion that the ADM based schema performed better in specific cases (BI tools). The performance differences were more in favor of the ADM based schema if the source dataset was larger rather than smaller. The larger dataset related results had, however, wider spread in maximum/minimum QET results. These facts will be studied in more detail in further research, also in contrast with the aggregated query execution performance results. Also, differences in the use and demands of particular physical query processing operators will provide important insights on how are the test queries internally processed.

The results indicate that the ADM based hybrid data modeling approach has certain future potential, although more evidence will be vital to justify its practical usefulness. The potential may be further increased if the application of more advanced query optimization techniques will have a positive effect on the query execution performance – both synthetic on-server and in-tool test results will be compared in this matter.

Also, further research effort will focus on using other BI tools, especially those that can or need to use separate OLAP/application server which may provide additional benefits. The expectation here is that the direct communication of the database server and the OLAP/application server may have additional benefits regarding query execution performance when using the ADM based multidimensional database schema.

***Abstract*—Taking an existing large-scale simulation model of the German toll system we identify possibilities for parallelization in order to enhance simulation performance. We transform parts of the model from its current serial implementation to a parallel implementation. Afterwards we evaluate the achieved performance enhancement and compare the results to a synthetic benchmark model.**

## I. Introduction

As technology advances in electronics, systems and processes with higher complexity, interconnectedness and heterogeneity can be developed. Simultaneously, user requirements are constantly increasing. Unfortunately “more is different” [1] as it is summarized in the definition of a “distributed system” as “one in which the failure of a computer you didn’t even know existed can render your own computer unusable” [2]. Modeling and simulation techniques are applied to design, analyze, evaluate, validate, and optimize such complex systems. Especially in specification and design stage executable models deliver tremendous value by lowering the system design uncertainty – even expert advice is known to be over-confident [3], a well-known cognitive bias that needs to be mitigated by the system design process. Yet in many parts of everyday life people depend [4] on software-intensive systems.

The use of simulation models is one way to increase the specification speed and quality [5]. Hence, current system design approaches like Simulation Driven Design [6] are characterized by applying executable models to a large extend. A prerequisite to apply executable models is a so called execution domain: In our context Discrete Event Simulation (DES) [7] has gained significance. DES is used in many industries, e.g. energy, telecommunications, production, logistics, avionics, automotive, business processes, and system design. Inter alia DES is applied for dimensioning of resources, to answer questions about topology (e.g. [8]), scalability and performance regarding operational scenarios, to predict system behavior, and to estimate risks. Increasingly the performance in defining and executing models becomes vital due to the increased complexity of systems and processes as well as the customer requirement to create holistic, integrated, high accuracy models up to real world scale. Several use cases of simulations are only possible once the simulation performance is ‘good enough’: simulating the long-term dynamic behavior, iterative optimization loops, automatic test batteries, real-time models (higher reactivity to market demands and changes), and automated specification and modeling processes (including model transformation/generation) [9]. In this context Parallel Discrete Event Simulation (PDES) [10] helps to provide the necessary simulation performance. In the article we identify possibilities for parallelization of a large-scale simulation model of the German toll system implemented in MSArchitect [11]. We transform parts of the model from the current serial, nonparallel implementation to a parallel implementation. Afterwards we evaluate the achieved performance enhancement.

The outline of the article is as follows: Section II gives an overview of the automatic German toll system and the corresponding simulation model. Typical use cases involve simulations at a scale of 1:1 spanning time periods of up to one year – necessitating a high-performance simulation model. The aim of this article is to investigate parallelized simulation models. To that end section III introduces the simulation framework architecture followed in section IV by a synthetic benchmark model for the use in PDES simulation. Section V describes the parallelized simulation model of the German automatic toll system and evaluates the simulation performance achieved. Section VI summarizes the results and describes future work and applications of our simulation model.

## II. Simulation model of the German toll system

The German automatic toll system is a typical example of a state-of-the-art tolling system [12, 13] based on global navigational satellite systems (GNSS). At present it is the largest system of its kind in operations – collecting more than 4.3 bn€ annually [14–16]. It was the first large-scale GNSS-based tolling system with more than 800 000 on-board-units (OBUs) deployed at present. More than 90% of the tolls are

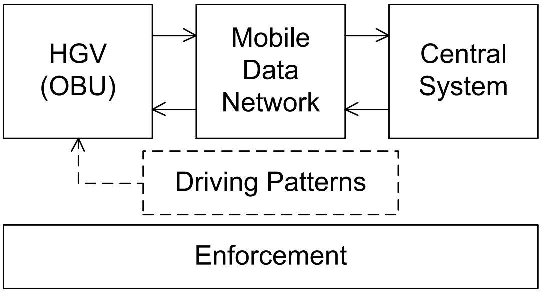

Fig. 1. High-level system design of a GNSS-based electronic tolling system and its dependency on the user interaction (driving patterns).

collected automatically the remainder using a manual process via internet or one of around 3 500 toll-station terminals.

The generic architecture of a GNSS-based tolling system is given in figure 1: The tolls are collected via OBUs installed in the heavy goods vehicles (HGVs) and transmitted via mobile data networks to the central system for processing. A separate part of the toll system is responsible for the enforcement and in the case of the German toll system an additional manual mode of tolling is implemented (not shown in the figure). The simulation model implements those technical systems and processes relevant for collecting tolls and for deploying updates to the OBUs: The vehicle fleet with its OBUs, the central systems required – i.e. a typical DMZ and the servers to receive toll data or provide updates – and the IP-based communication via mobile data networks.

Modeling the toll system we aimed to include all relevant processes at time scales of one second or longer, the technical systems in turn generate events with a higher temporal resolution in the model. However, the model of the tolling system needs to be accompanied by a model of the user behavior ("driving patterns" in figure 1) – the points in time when a given HGV is powered on or off, creates a toll event, looses or recovers its connection to the mobile data network.

The simulation model is applied in forecasting the dynamic behavior of the real-world tolling system – either the operations of the existing system (see section II-C) or for anticipated changes to the system (see sections II-A and II-B). Each application requires the simulation to predict the system behavior over several months – where the typical work-flow expects the simulation results to be available on the next business day. The existing simulation model is implemented to utilize a single CPU core and considerable effort has been expended to achieve an adequate performance [17–19]. However, over time the level of detail included in the simulation model and the number of OBUs in the real-world system increased. In addition simulation runs should deliver medium- and long-term predictions encompassing six months to one year.

### A. *Simulations in the Analyze and Design Phase*

In the analysis phase we use the simulation model to validate the system requirements. Addressing the large amount of requirements in typical software-intensive systems, requirements are defined at different levels of abstraction: The top level defines why the system is built and what the owning organization hopes to achieve. This type is termed as business or stakeholder requirements. Already at this level-of-abstraction the requirements need to be validated as soon as possible – is the requirement really necessary at the documented level? Seemingly inconsequential numerical targets can have profound effects on the technical solutions, e.g. by necessitating a high-availability architecture.

The translation of the requirements into an executable specification (or simulation model) allows exploring the effects of the requirements on the solution space early on and vice versa: The virtual prototype transports operational properties of the real-world system back to the solution space potentially modifying or restricting the requirements. An example of our approach is the comparison of a thin-client and a thick-client solution in the domain of electronic tolling [20].

Our focus in this phase is to avoid system operation faults based on wrong assumptions or conjectures of the new requirements. The most important aspects checked by us are:

- Excessing the capacity limits of the key subsystems
- Appearance of non-valid system states
- The worst case scenarios in case of eventual system failures.

The aspects we want to simulate are designed manually. The most frequent checks are based on the system behavior checking concerning various system parameter values.

In the design phase the system architecture becomes more detailed: The analysis model is linked with the used frameworks, libraries and other third party software components such as database or GUI. The executable specification helps in drafting accurate requirements and the simulation runs yield the resulting dynamic behavior prior to the implementation of the system. At the same time, the simulation model becomes in itself more specific by adding the necessary behavior and parameters to allow measuring its performance. Depending on the complexity and runtime the optimization can be delegated to an automatic optimization algorithm.

In the design phase we can validate the system behavior with improved functional granularity. During this phase the software development process invests in design documents – consistent, fine-grained and formal models start to show up in the documentation. In our approach we can take these models as a starting point and use model transformations to transform the architecture models into the appropriate simulation model.

### B. *Simulations in the Develop and Test Phase*

The implementation phases shift the focus to the system under construction. Here the requirements are supposed to remain fixed and only minor adjustments need to be returned to the requirements repository. The simulation model is an executable representation of the state-of-knowledge and is technically able to integrate a given component into the overall system – especially as long as the whole system is not yet available.

In that way simulations are part of the decision making process: Implementation variants can be explored and com-

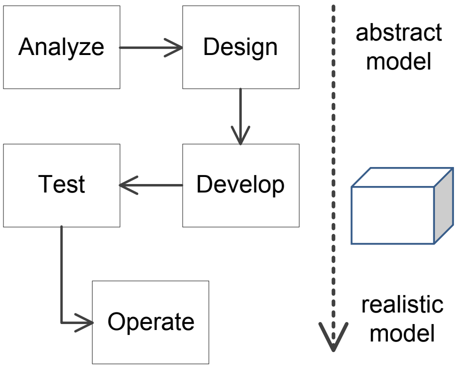

Fig. 2. The system development process (left) can be accompanied by a simulation model (right)

pared through simulations. The developed components are functionally integrated (transformed) and evaluated in the simulation environment. For an example one could look at the avionics industry [5, 8, 21].

In the test phase, the high-level requirements are used for acceptance tests of the whole system. Usually the development of the virtual prototype is considerably ahead of the real system. Therefore the soft- and hardware components are initially integrated into a whole working simulated system rather than the real world components: So called Software-in-the-Loop (SiL) and Hardware-in-the-Loop (HiL) tests. The simulation model provides the still missing components and allows to test dynamic coupling effects even when not all components of the real system are available. In other words we use the simulation environment as a stimulus for testing the individual software components – the simulation environment is a test driver for the developed software components. The test drivers are currently generated manually. Our goal is to generate them fully automatically via UML-enhancements to define the simulation test drivers during the software components design.

### C. Simulations supporting System Operations

In the case of the German toll system the main objective of the simulation model is to support and to safeguard the day-to-day operations of the automatic toll system. To that extent the simulation model includes the most important processes (receiving toll data from the OBUs and sending updates to the OBUs) in a realistic way at a scale of 1:1. The dynamic behavior – with a strong daily and weekly rhythm – the predictions of the simulation model can and must be verified against data from the real-world system [22, 23] and typically show a good correlation [24].

Simulation models of the kind discussed here address the operator of a software-intensive system-of-systems. Typically the operator faces two challenges simultaneously: The day-to-day operations and the necessary changes and updates within the technical systems. Of course, the handling of technical details can and typically will be outsourced to specialized providers. The one challenge that remains for the system operator to handle is the integration of all technical and organizational parts into a working whole [25].

As in the test-driven-development (TDD) case, testing is not the aim of simulation-driven-development (SDD) rather the "driven [...] focuses on how TDD leads analysis, design, and programming decisions" [26]. In that sense, SDD tries to put the design to the ultimate test-case – the real-world operational context. The simulation model – an executable specification of the existing real-world system – is the starting point to focus any software development on the operational consequences. These consequences might be of a purely technical nature, e.g. the system architecture and performance, or include non-functional requirements and business or financial aspects. In particular these challenges dominate environments that are rich in legacy systems. The on-going development of theses systems is largely faced with integration issues between systems [27]. SDD addresses integration of systems as a cross-cutting concern by providing the software developer (or requirements engineer) with an executable copy of the real-world system.

## III. Simulator architecture and benchmark model

To transition from a sequential DES simulation model to a parallel one we first look at the possibilities offered by the simulation and modeling tool in use (see section III-A) and different ways of parallelizing existing models as discussed in literature (section III-B). The section ends with brief remarks on the PDES performance in general – the next section introduces and discusses a particular benchmark model.

### A. Simulation and modeling tool, DES and PDES performance considerations

To model and simulate the structural and behavioral properties of the German toll system we selected and applied a system design tool for modeling and executing DES models [11]. The tool is specialized in integrated design of complex distributed systems and processes across different design levels. It offers a unique blend of performance [28] and customizability to manage extremely complex models within diverse usage environments. The simulation tool consists of several separated, mostly platform independent components, as a graphical user interface including a multi model editor, a simulation kernel, a library of standard model components, and a mission controller to run multiple simulations in parallel.

The simulation kernel used supports the execution of sequential DES and parallel DES (PDES) models. With DES and PDES the operation of a system is expressed as a discrete sequence of events in time. Each event occurs at a particular instant in time and marks a change of state in the system. Between consecutive events, no change in the system is assumed to occur. Thus the simulation can directly jump in time from one event to the next. All events are managed by a so called future event list (FEL).

### B. How to approach parallelizing DES models

PDES can substantially improve the performance and capacity of simulation, allowing the study of larger, more detailed

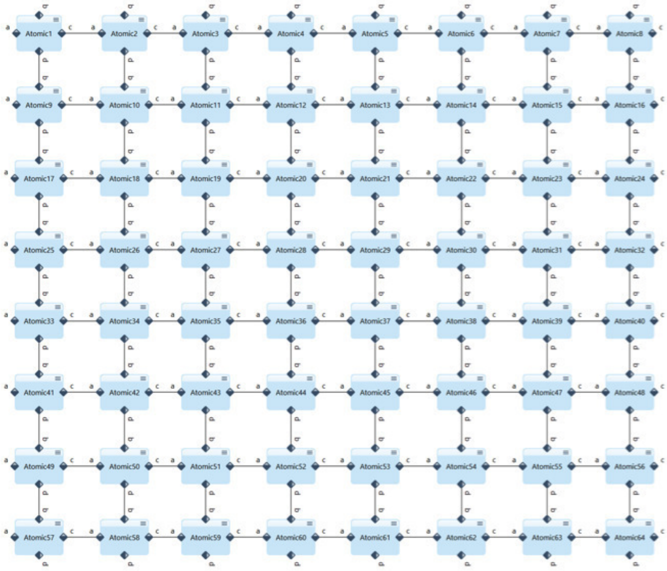

Fig. 3. Block diagram with a synthetic benchmark model using 8x8 network nodes.

models, in less time, and to be able to scale a problem if necessary. Thereby the performance and scalability is limited by communication latencies between the participating cores and nodes. Unfortunately, a prerequisite of parallelization is the decomposition of the model for processing on multiple processors or processor cores – it might become necessary to refactor existing serial mode models. This can be done in several ways [29]:

- Through the use of parallelizing compilers,
- In the form of replicated trials (run multiple serial simulations in parallel) or
- Distributed functions or
- Distributed events (with centralized FEL).
- Especially for optimizations a simple approach is the time-parallel domain decomposition (run multiple serial simulation in sequence) whereas
- the space-parallel domain decomposition (run multiple model parts in parallel) is used to accelerate a single simulation run.

The last enumerated decomposition approach, the space-parallel decomposition, is used by our simulation tool. Here, the simulation model is decomposed into sub-models or components. Each component is assigned to a process, where several processes may run on the same processor. This approach is applicable to any model and shows the greatest potential in offering scalable performance for complex models [30, 31]. Since the FEL is also decomposed into individual local FELs, it would never become the bottleneck. A higher degree of parallelism is expected because concurrent processing is encouraged.

In general, PDES approaches can be divided into two categories — conservative and optimistic — according to the way they handle the causality constraint of local FELs. Violating the causality constraint means that the future can affect the past leading to incorrect simulation results. In our case the simulation tool supports an optimistic synchronization mechanism, also known as time warp [32]. Causality errors are detected and fixed using rollback algorithms at the additional cost of necessitating rollback functions within the model.

### C. *PDES performance*

Optimistic synchronization mechanisms have inherently more overhead than conservative synchronization mechanisms. The overhead includes e.g. state saving, global virtual time calculation and rollback steps. The degree to which they may affect the simulation performance depends among other things on the granularity of the model to be simulated and the support from the hardware. Both approaches – conservative and optimistic – have their advantages depending on the specific application case. In terms of general purpose simulation the optimistic approach appears to be slightly in advantage [33].

## IV. PDES Benchmark model

In this section we introduce a synthetic network model consisting of a grid of simple networking units (section IV-A) and give the sequential and parallel simulation performance for different model sizes in section IV-B.

### A. *Description of the synthetic model*

To evaluate the potential of parallelization we developed a synthetic benchmark model using our modeling and simulation tool. The model consists of several communication network nodes. When a network node receives an event, it consumes this event, handles some synthetic workload and sends a new event to a randomly selected neighbor network node with random delay. The synthetic workload on every event is approximately 10 000 floating point operations and the random delay is exponentially distributed with a mean of 5. Initially

TABLE I
Computation time in msec

| | 8 | 4,11 | 4,77 | 5,46 |

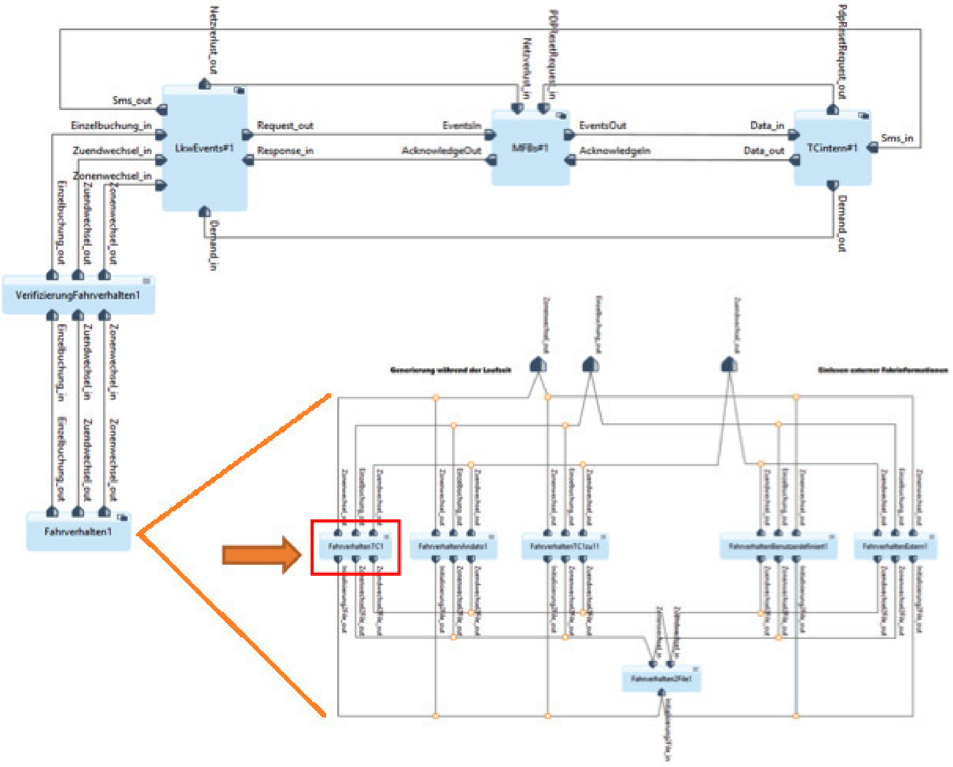

Fig. 4. Component responsible for generation of driving patterns

every second network node sends an event, which results in an event density of 50 percent. During a simulation run the total number of events in the system remains constant, due to the similar parametrization and behavior of all network nodes. Figure 3 shows the block diagram of the model with 8x8 network nodes.

### B. *Parallel and serial performance of synthetic model*

In order to evaluate the simulation performance we simulated three sizes of the network model (8x8, 8x16 and 16x16 network nodes) using 1 to 8 threads. The clustering of the model and the assignment of these clusters to threads was done automatically by the simulation kernel. All simulations were executed on a PC using a i7-3635QM CPU with 2.40GHz, 4 cores and 8 threads and the simulation kernel of MSArchitect® Enterprise in version 2.3 with 64Bit.

The results are summarized in tables I and II. The first table gives the computation time needed for the simulation runs and the second table lists the relative speedup factor for each parallel simulation compared to the serial simulation. In theory the optimal speedup factor could be equal to the number of threads resp. cores used. Practically this is not possible due to the communication and synchronization overhead between the threads and the fact that the CPU does not offer 8 threads of equal computational power. All in all a substantial performance increase of up to 5.46 with 8 threads can be observed – higher than the 4 CPU cores offered and lower than the 8 parallel threads offered by the CPU.

## V. Parallelization of the simulation model

The synthetic benchmark model presented in the previous section allowed a sizable speed-up through the use of a PDES simulation kernel. In this section we look at the challenges when an existing simulation model is the starting point of the parallelization effort (section V-A). In particular, some parts of the model are intrinsically serial – as required from the particular application domain. Section V-B discusses the process of selecting appropriate parts of the simulation model for parallelization.

### A. *Partial transformation as proof of concept*

After successfully evaluating the parallel simulation approach using a synthetic model and the promising performance potential we decided to shift from serial to parallel simulation for the model of the toll system. Since the parallelization is a time-consuming process, we pursue an incremental model transformation, starting with the performance critical parts. In a first step we looked to the application-level performance of our model of the German toll system to locate appropriate model components for parallelization. This was done using both the kernel logging capabilities of our simulation tool and an external profiling application [17, 18]. Kernel logging allows to count the number of calls of atomic models as well as the total number of samples (corresponding to a processor cycle). The external profiler allows measuring the space complexity (memory), the time complexity (duration,

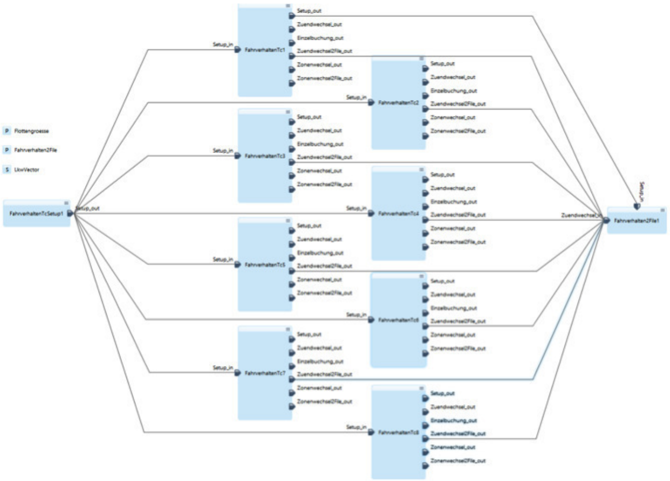

Fig. 5. Partial parallelization of the simulation model: Using 8 threads in generating the driving patterns.

CPU time), and the usage of particular instructions of a target program by collecting information on their execution.

To implement a partial parallelization we choose a setup using a similar hardware and software constellation as the synthetic model. The fleet size used in the simulation runs was set to 800 000 OBUs and a time frame of 20 weeks was considered. In the simulation runs the component responsible for generation of driving patterns was identified as performance critical (figure 4). This component consumes about 9.7% of the overall computation time in serial mode.

### B. Selecting parts of the model for parallelization

To allow the execution of a given simulation model in parallel simulation mode the underlying PDES kernel calls a different set of atomic interface functions than in the serial mode: Instead of the function `run()`, which is called every time an event is received, the functions `runForward()`, `runReverse()` and `runCommit()` need to be implemented. This is necessary in the case of optimistic synchronization since this mechanism allows the speculative execution of events that might require a rollback to ensure causality. In addition the model architecture needs to be adapted following three rules:

- Reduce the dependencies between model components to simplify clustering,
- Transfer external states to internal states or to port based communication,
- Restructure the internal architecture of model components to enable functional parallelization, while leaving the interfaces stable.

In our case the selected model component is responsible for the generation of driving patterns for the whole vehicle fleet. We refactored this component so that the internal structures were multiplied according the number of parallel simulation threads (in our case 8) – the driving patterns of different heavy-goods-vehicles are inherently independent in our model. In that way each internal structure is responsible for one-eighth of the vehicle fleet, each executed as a separate thread (see figure 5). Executing the driving patterns component separately from the overall model in parallel mode let to a computation time of 3 min 30 sec compared to 8 min 28 sec in serial mode. This means a speedup of factor 2.4, which is quite good compared to the theoretical speedup factor of the synthetic model of factor 5.46.

### C. Complete parallelization and backward compatibility

To parallelize the model of the German toll system completely the architecture of about 60% of the model components (composite blocks) need to be reworked according to the three architectural rules mentioned above. The remainder (mostly atomic blocks) need at least to be transferred to the set of parallel atomic interface functions. Both interfaces – for serial and parallel execution – can coexist in the simulation tool chosen for this work. This allows for an incremental porting of complex simulation models towards a fully parallelized model.

## VI. Summary

Simulation models offer the ability to transform the software development process by placing each step into the realistic operational context. One important pre-condition is that the simulation model is sufficiently fast to generate realistic behavior at a scale of 1:1. Staying with a realistic level-of-abstraction the application of some models is limited by the execution time. In our example the large number of objects at run-time – models of on-board-units – and the necessity to predict the dynamic behavior of the system for a considerable length of time limit the use of simulation runs in the day-to-day decision making process.

In this paper we looked into increasing the simulation performance through parallelization either automatically or at the level of the simulation model. To further the discussion we implemented a synthetic network model with a configurable grid of identical components as a benchmark for the automatic parallelization achieved by the simulation kernel. In this case the speed-up compared favorably with the performance offered by the CPU chosen to run the benchmark.

In the real-world example the speed-up is more difficult to achieve – large parts of the model are either difficult to parallelize or contribute negligibly to the overall computation time. Profiling the simulation model we identified one part – the model of the user behavior – as both particularly time consuming and compact (as expressed by the size of this particular part of the model). Parallelizing only a part of the model limits the speed-up: The remaining model parts run in serial mode and we achieve only a speed-up of 2.4 using 8 threads. However, this speed-up is the result of re-factoring only 5% of the simulation model.

Future work is needed to automate the parallelization of existing models and to steer the modeling engineer to the most promising parts of a given simulation model.

***Abstract*—The concept of Internet of Things appeared several years ago and in that time has evolved into one of pillars of the new technologies sector. The next step is to add the artificial intelligence to Internet of Things systems. Artificial intelligence is increasingly used in everyday life. It is a concept of a wide range and applies in practice in many fields of science. The aim of presented paper was to investigate the usefulness of selected artificial intelligence methods in the concept of Internet of Things. To investigate this purpose, exemplary system was built and it uses the artificial neural networks.**

## I. Introduction

THE Internet is a powerful tool used in all kinds of the information systems. The network is available almost anywhere, at home, at work, also on mobile devices (phones, watches). People start to think to connect the Internet to almost all devices of everyday use, so they can communicate with each other by taking simple decisions for people and helping them in their life. Such idea is called the *Internet of Things (IoT)*. It is estimated that currently about 15 billion devices are connected to the Internet, but this number is still less than 1% of things that in fact could be connected to the network [10].

The next step is to add the artificial intelligence to Internet of Things systems. Artificial intelligence is increasingly used in everyday life. It is a concept of a wide range and applies in practice to many fields of science. It is used in applications such as prompting videos to watch, having regard to the history of the watch (service *netflix*) or recognize people on the recordings of the monitoring. Its great advantage is the elements related to machine learning, through which different methods of artificial intelligence are able to interpret a lot of data and present some of their summary. This is definitely a big amenity for a man who no longer has to statically analyse all the data coming from the specified system, for example view a recording of the monitoring in the context of searching for a particular person.

The presented paper examines whether the chosen methods of artificial intelligence are suitable for use in the concept of *Internet of Things*. The main assumption is to use the mobile device (mobile phone) as a smart object in the Internet of Things. The system based on the concept of *Internet of Things* was designed and built to examine this issue and this system was then implemented with different methods of artificial intelligence.

The presented paper is structured as follows: section 2 presents the issues of Internet of Things concept with its definitions, section 3 gives the outline of the architecture of IoT, presenting the three-layer and five-layer architectures, while section 4 deals with the aspect of communication in IoT concept. Section 5 describes the use of selected methods of artificial intelligence in the conception of IoT and section 6 presents the created exemplary IoT system using such methods.

## II. Concept of Internet of Things

The concept of the Internet of Things appeared several years ago and in that time has evolved into one of the pillars of new technologies sector. There is no clear definition of this concept in the literature. In many cases, the definitions are complementary, creating a more accurate description of the problem.

The Internet of Things is a vision, in which objects become part of the Internet, where every object is uniquely identifiable and accessible on the Web. These objects may directly or indirectly collect, process or exchange data via data communications network. This concept can be described by a simplified equation [1]:

$$\textit{physical objects} + \textit{sensors and microprocessors} = \textit{IoT}$$

One of the first attempts to define this concept was pretty simple concept. The Internet of Things is all objects in everyday life, which are equipped with wireless identifiers and so that they can communicate with each other and be managed by a computer [3].

The shortest definition, which may describe the concept of the Internet of Things shows that it is clearly identification of objects and their representation in the structure of the Internet. This is the most general definition that may expresses the most important elements concerning the issue of IoT [4].

By analysing this information, it can be concluded that the IoT systems have a lot of common issues with multi-agent systems. However, it is worth saying that these two concepts are not identical and have some subtle differences. One of the important difference is a fact that all objects in the concept of the Internet of Things should be able to communicate with the environment, be aware of what they are and be clearly identifiable in their environment [5].

978-83-60810-66-8/$25.00©2015, IEEE

On the basis of all above definitions of the issues of IoT and taking into account its important aspects, the concise and yet comprehensive definition of this concept was created. Thus,

*Internet of Things is a concept, where clearly identifiable and smart objects can communicate with each other in a defined environment to make autonomous decisions by analysing and processing the data collected from the environment.*

The environment can be the Internet or only a portion (e.g. local area network and the devices used only at home). Additionally, there may be mentioned also that the interconnected devices provide the user with various number of applications and services which enable it to communicate with them. To take the autonomous decisions, except to analyse the collected information, objects may use generally understood knowledge, that is, for example, elements related to the habit of the user in some aspect, so that the object will be able to make the better decisions.

## III. Architecture of Internet of Thing

Architecture and technology for smart objects, included into Internet in accordance with the concept of Internet of Things must be extremely flexible. They have to provide the infrastructure, taking into account the heterogeneity of devices and the need for ubiquitous communication, which must be continuous. Just as in the definition of the concept of IoT, specifying its architecture can not clearly define how it should look like. There are many general proposals for IoT infrastructure, but not all of them are sufficiently flexible.

To start talking about specific aspects concerning system architecture based on the IoT, we need first to mention the main pillars of this concept, which will be the basis for the design of adequate infrastructure, namely (Fig. 1):

- anytime,
- anyplace,
- anything.

Taking into account the main pillars and intelligent objects features posted on the Internet, the main aspects that the IoT architecture must meet can be presented. This means for example, that every item included in the Internet of Things (considering its first feature) has a unique identifier in the particular environment in which it occurs and it is available anytime, anywhere and with anything (for all other devices in the structure). Similarly, we can develop two more features of intelligent objects in conjunction with the main pillars of the IoT. This analysis makes us aware that the provision of adequate infrastructure in accordance with the concept of the Internet of Things is not a trivial issue [1], [2], [6].

Implementation of systems based on the concept of Internet of Things requires a comprehensive look at the infrastructure, from the lowest layers of collecting data from the sensors to the highest layers presenting the user different statements of analysed data.

### A. 3-layer architecture

The basic architecture which can be successfully used in such systems is called 3-layer architecture of IoT. It consists of the following layers, starting from the lowest [7], [8]:

- perception layer,
- transport layer (network layer),
- application layer.

*Perception layer* is the first layer in a three-tier architecture of IoT. It is responsible for collecting the data from the real world. Its role is to combine the real world with the virtual world in the context of collection and pre-processing of information. It includes various types of sensors or electronic tags. Most of the modern smartphones are equipped with various sensors, such as ambient light sensor, accelerometer, gyroscope and proximity sensor. This means that the mobile phone can be successfully used in the smart object of IoT, which additionally can pre-process the collected data so that they will be readable for the rest of the system [9], [7].

The second layer, *transport layer (network)*, of this architecture provides the processing of data from sensors, some local storage and forwarding them to the application layer. This layer can be compared to a neural network located in the brain. Since it depends which way and where (to which device) the information will be provided. One of its main tasks is to ensure the effective reach of information and taking care of continuous operations. The network layer is based on modern communication technologies, wired and wireless.

The last layer of this architecture, *application layer*, is the most extensive. It ensures the delivery of services and applications for the end users. It may seem that the important element in this layer is to ensure a user-friendly interaction with the interface. However, this is a small part of the responsibility of the layer. Its fundamental role is to provide a platform for data collection and subsequent analysis. It is understood as its appropriate interpretation, processing and establishing the relationships.

### B. 5-layer architecture

The 3-layer architecture is the fundamental architecture of the Internet of Things. It describes all the necessary infrastructure elements used in the IoT, however, by the fact that there are relatively few layers, each of which is responsible for many aspects. In consequence, it should be more extract components attributable to the particular layer. Such elements include a 5-layer architecture. Its use increases the flexibility of the entire infrastructure.

The 5-layer architecture of IoT introduces two additional layers between the existing layers of 3-layer architecture. Starting from the lowest layer, this architecture has the following (Fig. 2) [9]:

- perception layer,
- access to gateway layer,
- network layer,
- middleware layer,
- application layer.

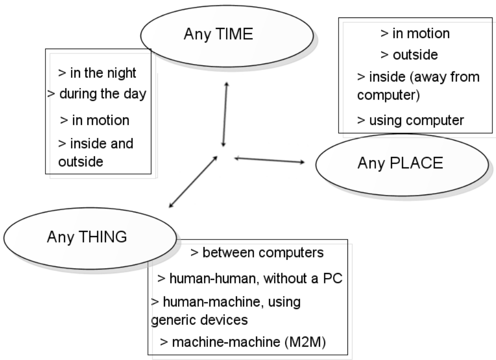

Fig. 1. Schema presenting the main pillars of IoT concept for its communication

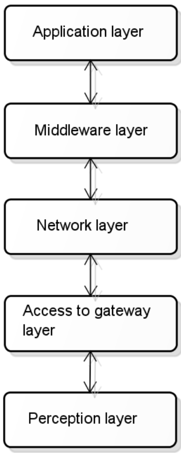

Fig. 2. Schema presenting the 5-layer architecture of IoT

The first layer, *perception layer*, just is primarily responsible for the collection of data from the environment. Another, a new *access to gateway layer* supports the *communication network layer*. Both these two layers are responsible for management of data in exchange infrastructure. The main idea of adding a new layer is to transfer the data directly between the intelligent objects.

With this approach, we can definitely increase the flexibility of the system due to the ability to isolate the communication between devices and services. This second layer is a communication bus between objects and network gateway.

Another newly-added layer is called *middleware layer*. The main purpose of this layer is to increase the flexibility of the interface between the hardware and the software. Information coming from network layer is transmitted to the middleware layer, which is a certain abstraction from both the upper and lower layers. It can be compared to API in the context of the issue of appropriate interfaces for application layer in data management. This approach makes it easier to make the modifications in the whole computer system [9].

The presented architectures form a whole and their mutual application (including joining) may successfully allow to build the complex systems based on the IoT.

## IV. Communication between Internet of Things elements

Today, the concept of the Internet of Things is a component of many different technologies. From a logical point of view, the systems based on the issue of IoT can be seen as a set of smart devices that work together to achieve a set goal. From a technical point of view, such system may consist of several modules, each of which can be implemented in different technologies, uses different architecture and thus uses different items related to the processing of data and even the internal communication [1], [11].

The concept of Internet of Things can be divided into three main elements, relating to the data that is transmitted in the system:

- data capture,
- aggregation of data,
- analysis and data processing.

The first element in the general concept of topology of IoT is *data capturing*. Sensors can be treated as separate components or as part of IoT devices. One device can have more than one sensor. Data obtained from the environment and pre-processed by the device can be exchanged between them in order to achieve a common goal. At this stage, the first communication occurs within the same IoT devices. It can be achieved by wireless or wired technologies.

Once all the required elements at the device level are achieved (data collection and preliminary processing), the *aggregation of data* starts in the IoT and the data is sent to the gateway, where later via the Internet it is delivered to different data centres. Then data is properly *analyzed, processed and presented* to the user with the use of appropriate applications. This processing may take place in specialized servers. It should be added that the prepared data is usually sent to the device again, so it can respond accordingly. Of course, the user can influence the IoT devices in the context of their actions (configurations).

The concept of the Internet of Things has great potential and can make life easier in many aspects. However, the creation of very large IoT systems may encounter many problems, which may be called the challenges which need to be addressed. The main challenge is the heterogeneity of devices. Since IoT vision involves connecting almost all devices to the Web, it has to do with the large variation mainly due to the computational and communication capabilities. In addition, this involves a huge amount of data collected from the sensors. We can talk here about the big data, that is for large and diverse data sets, where processing and analysis are difficult, but valuable, because they can lead to acquiring the new knowledge. The main element that can provide support for this challenge is well-chosen architecture and protocols [9].

Equally important challenges are still the elements associated with *location*, *self-configuration* and *data management*. As each device in IoT is uniquely identifiable, it is possible to locate it and its location will be used as a additional functionality. However, there is a problem with the confidentiality. Due to the number and complexity of systems, an important issue is the self-configuration, to relieve a man. It is also a challenge, since a multitude of configurations can lead to the fact that people will not understand how some elements of the system have to behaviour in the context of the property, which may prove to be as dangerous as the lack of data security. The exchange and analysis of data are important in IoT. Therefore, in addition to their safety, it is important to ensure the proper data models and description of their contents, to use them as a sure knowledge.

## V. Internet of Things systems using artificial intelligence

Systems built using the concept of Internet of Things are based not only on the simple sensors that transmit information to the systems, that operate primarily on the basis of statistics and simple mathematical calculations. Such systems are increasingly complex and can make the decisions in bigger number of aspects. It is easy to imagine a system that switches the heating only based on the ambient temperature. However, it could also regulate the temperature in terms of the number of people present in the room, the habits of certain users (individuality), the specific rooms and time of a day. Therefore, to give some intelligence to these systems is an important issue, but rather complex.

Previously mentioned example with temperature and habits of users shows that IoT systems should learn the habits and adapt to them (teaching) in this case. Such elements are not achieved by ordinary statistics or simple equations. In this case the system needs more sophisticated tools, such as artificial intelligence methods.

The idea of the use of artificial intelligence in the Internet of Things is associated with another issue. It is the fact of independence of the machines in the context of their supervision. Application of AI methods can affect in a positive way to save the time. It is important not to lose a control over the device completely, but equally important is the lack of monotonous supervision of these applications from the point of use. It is better to be able to communicate with the system in a way natural for humans than for machines – based on the example with temperature – while overheating of the room, it's better to make the interaction with the device using command "is too hot" than reduce the temperature of 0.432 Celsius degree.

The main element associated with the operation of IoT system with the artificial intelligence is its location in the architecture. An important aspect is the performance and the appropriate amount of place for data, which is a knowledge of the system, so the AI methods can not be placed at each level. Figure 3 shows the general idea of placing the artificial intelligence methods in the context of major IoT architectures.

The most natural places for AI methods are all kinds of servers because of their computing power. Such location has a positive effect on another aspect too. It is about the fact of reuse. The place of operation of different artificial intelligence methods can be compared to the human brain. The fact that all the knowledge and the associated inference and learning are placed in the server rooms, it is possible to use it in a larger perspective.

Figure 4 presents our idea of general scheme of information flow in the IoT systems, using artificial intelligence. There are three main elements in the flow of information:

- Preliminary communication – data sent from the real world for a variety of systems.
- Context communication – data processed by systems that already have the appropriate context and make the IoT systems and devices can respond accordingly (take appropriate decisions).
- Internal communication – understood as an additional channel of communication between intelligent objects.

The first stage can be called a *preliminary communication*. At the beginning, in accordance with the concept of Internet of Things, the data from the environment (real world) is collected by the IoT devices. They can be the external sensors, as well as those built into the device. Then, data is preprocessed to be clear for the rest of the system. Depending on the particular case, the data is further transmitted over the Internet to the main IoT systems or between other devices to gather all relevant information from the real world (internal communication elements). In the context of mobile devices, it is important to assure the temporary storage of information in things during the lack of access to the Web. When all the data in the context of a particular cycle, is already in the main IoT systems, respectively, it is prepared for external artificial intelligence systems. This process may involve selecting an appropriate specific information to get to a particular method of artificial intelligence (for example the ambient temperature and the number of people as inputs to the neural network in the system controlling the temperature).

The next communication step is a *context communication*. Its main purpose is to provide the concrete system answers to the IoT devices and to the subsystems that are designed to take concrete actions in the context of the relevant decisions. When the artificial intelligence methods have exited and give a reply, it should be properly interpreted. This task should address the

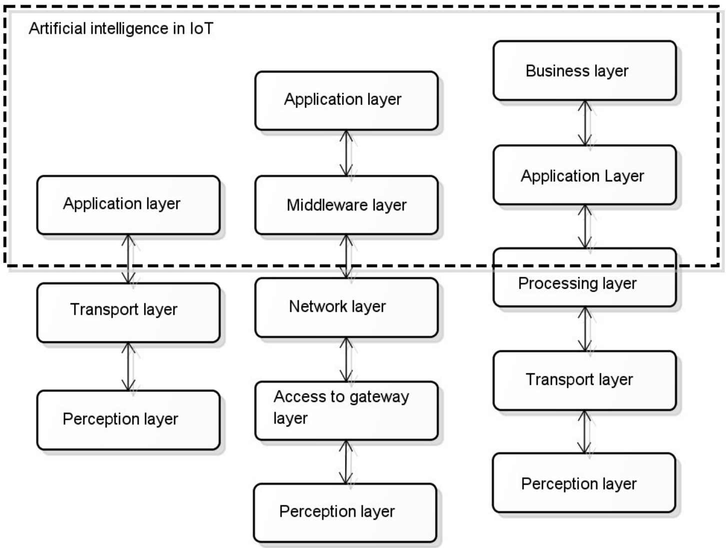

Fig. 3. Placing the artificial intelligence in the background of IoT architectures

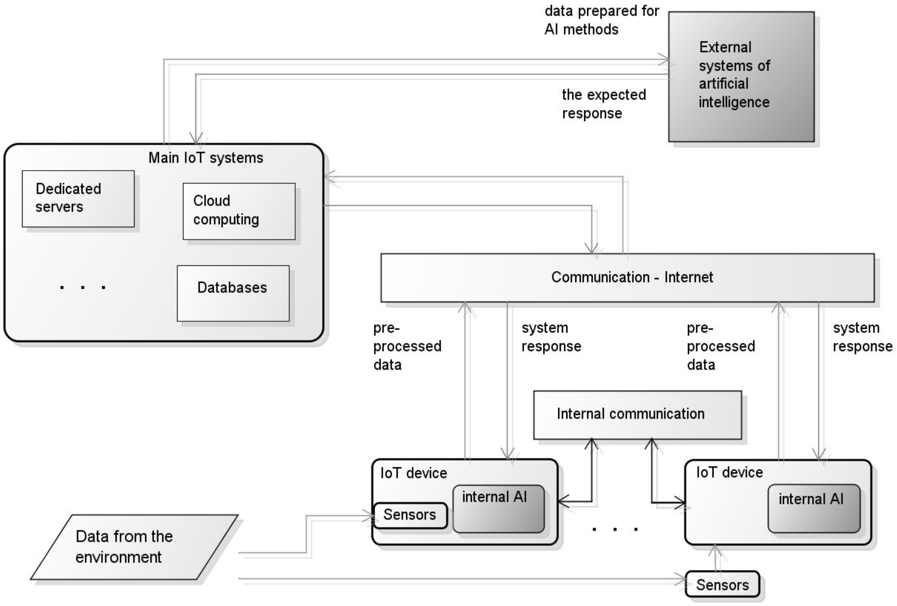

Fig. 4. General scheme of information flow in IoT systems with the use of artificial intelligence methods

main IoT systems. Very often the AI answer include digits that do not make much sense without the proper context. Therefore, an important step is to link them with the knowledge located in the system to be able to conclude the overall response of the system to a particular problem. In this way the system can properly react, so take the decision. This idea can be seen as smart making of autonomous decision.

Properly processed data, which are located in the main IoT systems should usually be further sent to certain IoT devices so that they can properly respond. A situation where the processed data must be sent to other IoT devices than those which are derived from the original data can be imagined. The monitoring system can be an example. Devices with cameras may send data to the main IoT systems, that after detecting of a specific threat (AI systems use object recognition) can send data to the other Internet of Things devices which may in some way respond to such a threat.

The last extra communication is called *internal communication*. It can be placed both at the initial communication, as well as at the contextual one in the proposed model. In the first case it can be used to gather enough data from multiple devices and simultaneously to send them to the upper layers of the system. In the second case, having a concrete answer from the system, it can be used the multiple devices work simultaneously together. This approach is combined with additional AI elements contained in the devices – it can enter into intelligent objects more aspects of their autonomy.

## VI. IoT system with the use of artificial intelligence

To investigate the actual usefulness of selected methods of artificial intelligence in the concept of the Internet of Things, the information system *smart-IoT* was created. Its main task is to test the time to return home and set the alarms at the right time to put the event. The proposed system consists of three main elements:

- mobile devices – smart objects,
- central server – acts as an IoT management system,
- micro-services – include elements of AI.

The system is based on the 4-layer architecture:

- Perception layer – covers only mobile devices. Its main task is to collect the data from the environment using sensors embedded in mobile phones (GPS, accelerometer, gyroscope) and pre-treatment of this data.
- Network layer – is responsible for transferring data between all the elements of the system using LAN and Wi-Fi communications channels.
- Processing layer – an essential element of the whole system. This layer is responsible for the processing of information in a central server with the appropriate use of micro-services, so the methods of artificial intelligence. Its primary aim is to convert the input data and generate a specific answer for that data in the context of the service.
- Application layer – is responsible for providing data to the end user. Its fundamental role is to ensure the validity of data (to be updated with information from the decision-making module).

Intelligent objects in the proposed system are mobile devices (specifically mobile phones). Their main task is to collect the relevant data from the real world by using the built-in sensors. The next stage is the initial processing of the data. All of these tasks are performed by using the dedicated mobile application.

In accordance with the concept of Internet of Things, all devices must be uniquely identifiable throughout the system. For this reason, the *smart-IoT* system proposed the use of unambiguous numeric identifiers. Each mobile device has a given unique identifier, which is recorded in the central management server. Such an approach also allows to limit the access of unauthorized devices, because the system will support only those for which the information is stored in the database.

The main components of IoT, understood as the main systems of the Internet of Things, are represented by a central server, acting as a manager. It consists of 4 major components:

- module of services identification,
- module of artificial intelligence management,
- decision-making module,
- database module.

## VII. Conclusions

The Internet of Things is a technological revolution that represents the future of computing and communication. This concept is characterized by heterogeneous technologies and devices and assumes that all devices will be connected to the Internet. The next step is to add the artificial intelligence to IoT systems. Thanks to this, devices become intelligent and can make autonomous decisions. These smart devices have the ability to interact with humans and other smart devices.

These devices should have a certain autonomy in the context of decision-making process. In building of IoT systems an important element is its architecture and its scalability and flexibility. Their key action aspect is the exchange and analysis of data. Joining of this type of systems with artificial intelligence is not a trivial task. AI methods typically use a lot of processing power, therefore, using them directly in devices often becomes impossible. They are usually placed on external servers, so a user can use them in the context of multiple devices at the same time.

The presented paper investigated the usefulness of artificial intelligence in the concept of Internet of Things. To do this the exemplary system was built and it uses the artificial neural networks. This system uses mobile devices as the smart objects. Neural networks have been taught by back-propagation algorithm. Experiments with neural networks were carried out by using the main services of the system (such as auto set alarms for a specific event and estimating the time to return home). These experiments show that artificial intelligence methods are suitable for use in concept of Internet of Things.

# Sentiment Analysis of Twitter Data within Big Data Distributed Environment for Stock Prediction

Michał Skuza

Email: michalskuza@hotmail.com

Andrzej Romanowski

androm@kis.p.lodz.pl

Lodz University of Technology, Institute of Applied Computer Science, Poland.

*Abstract*— **This paper covers design, implementation and evaluation of a system that may be used to predict future stock prices basing on analysis of data from social media services. The authors took advantage of large datasets available from Twitter micro blogging platform and widely available stock market records. Data was collected during three months and processed for further analysis. Machine learning was employed to conduct sentiment classification of data coming from social networks in order to estimate future stock prices. Calculations were performed in distributed environment according to Map Reduce programming model. Evaluation and discussion of results of predictions for different time intervals and input datasets proved efficiency of chosen approach is discussed here.**

***Keywords***: Sentiment Analysis, Big Data Processing, Social Networks Analysis, Stock Market Prediction.

## I. Introduction & Rationale

It is believed that information is the source of power. Recent years have shown not only an explosion of data, but also widespread attempts to analyse it for practical reasons. Computer systems operate on data measured in terabytes or even petabytes and both users and computer systems at rapid pace constantly generate the data. Scientists and computer engineers have created special term "big data" to name this trend. Main features of big data are volume, variety and velocity. Volume stands for large sizes, which cannot be easily processed with traditional database systems and single machines. Velocity means that data is constantly created at a fast rate and variety corresponds to different forms such as text, images and videos.

There are several reasons of a rise of big data. One of them is the increasing number of mobile devices such as smartphones, tablets and computer laptops all connected to the Internet. It allows millions of people to use web applications and services that create massive amounts of logs of activity, which in turn are gathered and processed by companies. Another reason is that computer systems started to be used in many sectors of the economy from governments and local authorities to health care to financial sector. The analyses of information that is a by-product of different business activities by companies can lead to better understanding the needs of their customers and prediction future trends. It was previously reported in several research papers that precise analysis of trends could be used to predict financial markets [1]

Big size of data and the fact it is generally not well structured result in situation that conventional database systems and analysis tools are not efficient enough to handle it. In order to tackle this problem several new techniques ranging from in-memory databases to new computing paradigms were created.

Besides big size, the analysis and interpretation are of main concern and application for big data perspective stakeholders. Analysis of data, also known as data mining, can be performed with different techniques such as machine learning, artificial intelligence and statistics. And again it is important to take into consideration the size of data to be processed that in turn determines if a given existing algorithm or approach is applicable.

### A. Big data

There are several definitions what Big data is, one of them is following: "Big data refers to datasets whose size is beyond the ability of typical database software tools to capture, store, manage, and analyse." [2] This definition emphasizes key aspects of big data that are volume, velocity and variety [3]. According to IBM reports [4] everyday "2.5 quintillion bytes of data" is created. These figures are increasing each year. This is due to previously described ubiquitous access to the Internet and growing number of devices. Data is created and delivered from various systems operating in real-time. For example social media platforms aggregate constantly information about user activities and interactions e.g. one of most popular social sites Facebook has over 618 million daily active users [5]. Output rate of the system can be also important when nearly real-time analyses are needed. Such an on-the-fly analysis is required in recommendations systems when the user's input affects content provided by web site; a good examples are online retail platforms such as Amazon.com. This aspect requires various ways of storing the data to maximize speed and sometimes using column-

978-83-60810-66-8/$25.00©2015, IEEE

oriented database or one of schema-less systems (NoSQL) can do the job, since big data is rarely well structured

But big data is not only challenging but primarily creates opportunities. They are, among the others: creating transparency, optimization and improving performance, generation of additional profits and nothing else than discovering new ideas, services and products.

### *B. Social media*

One of the trends leading to rise of big data is Web 2.0. It is a major shift from static websites to interactive ones with user-generated content (UGC). Popularization of Web 2.0 resulted in many services such as blogging, podcasting, social networking and bookmarking. Users can create and share information within open or closed communities and by that contributes to volumes of big data.

Web 2.0 led to creation of social media that now are means of creating, contributing and exchanging information with others within communities by electronic media. Social media can be also summarized as "built on three key elements: content, communities and Web 2.0" [6]. Each of those elements is a key factor and is necessary for social media. One of the most important factors boosting social media is increasing number of always Internet-connected mobile devices such as smartphones and tablets.

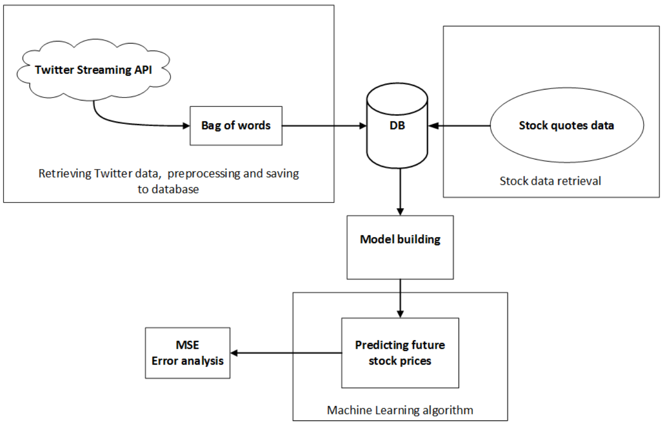
Twitter is a micro blogging platform, which combines features of blogs and social networks services. Twitter was established in 2006 and experienced rapid growth of users in the first years of operations. Currently it has over 500 million registered users and over 200 million active monthly users [7]. Registered users can post and read messages called "tweets"; each up to 140 Unicode characters long – originated from SMS carrier limit. Unregistered users can only view tweets. Users can establish only follow or be-followed relationships. A person who subscribes to other user is referred as "follower" and receives real-time updates from that person. However users do not have to add people who are their followers. Twitter can be accessed from various services such as official Twitter web page, mobile applications from third parties and SMS service. As Twitter is an extremely widespread service, especially in US and as the data structure is compact so it forces users to post short comments authors of this paper believe this is a good source of information in the sense of snapshots of moods and feelings as well as for up-to-date events and current situation commenting. Moreover, Twitter is a common PR communication tool for politicians and other VIPs shaping, or having impact on the culture and society of large communities of people. Therefore Twitter was chosen for experimental data source for this work on predicting stock market.

## II. Predicting Future Stock Prices

### *A. Experimental System Design and Implementation*

Main goal of this section is to describe implementation of a system predicting future stock prices basing on opinion detection of messages from Twitter micro blogging platform. Unlike the authors of [12] we chose Apple Inc. – a well known consumer electronics company – a producer of Mac computers, iPod, iPad, iPhone products and provider of related software platforms and online services just to name a few.

System design is presented on Figure 1 and it consists of four components: Retrieving Twitter data, pre-processing and saving to database (1), stock data retrieval (2), model building (3) and predicting future stock prices (4). Each component is described later in this text.



Twitter Streaming API
Bag of words
DB
Stock quotes data
Retrieving Twitter data, preprocessing and saving to database
Stock data retrieval
Model building
MSE Error analysis
Predicting future stock prices
Machine Learning algorithm

Figure 1: Design of the system

1. Retrieving Twitter data, pre-processing and saving to database.

This component is responsible for retrieving, pre-processing data and preparing training set. There are two labelling methods used for building training set: manual and automatic.

2. Stock data retrieval

Stock data is gathered on a per minute basis. Afterwards it is used for estimating future prices. Estimation is based on classification of tweets (using sentiment analysis) and comparing with actual value by using Mean Squared Error (MSE) measure.

3. Model building.

This component is responsible for training a binary classifiers used for sentiment detection.

4. Predicting future stock prices

This component combines results of sentiment detection of tweets with past intraday stock data to estimate future stock values.

### *B. Twitter data acquisition and pre-processing*

Twitter messages are retrieved in real time using Twitter Streaming API. Streaming API allows retrieving tweets in quasi-real time (server delays have to be taken into consideration). There are no strict rate limit restrictions, however only a portion of requested tweets is delivered. Streaming API requires a persistent HTTP connection and authentication. While the connection is kept alive, messages are posted to the client. Streaming API offers possibility of filtering tweets according to several categories such as location, language, hashtags or words in tweets. One disadvantage of using Streaming API is that it is impossible to retrieve tweets from the past this way.

Tweets were collected over 3 months period from 2nd January 2013 to 31st March 2013. It was specified in the query that tweets have to contain name of the company or hashtag of that name. For example in case of tweets about Facebook Inc. following words were used in query ’Apple’, ’#Apple’, ’AAPL’ (stock symbol of the company) and ’#AAPL’. Tweets were retrieved mostly for Apple Inc. (traded as ’AAPL’) in order to ensure that datasets would be sufficiently large for classifications. Retrieved data contains large amounts of noise and it is not directly suitable for building classification model and then for sentiment detection. In order to clean twitter messages a program in Python programming language was written. During processing data procedure following steps were taken. Language detection information about language of the tweet is not always correct. Only tweets in English are used in this research work. Duplicate removal - Twitter allows to repost messages. Reposted messages are called retweets. From 15% to 35% of posts in datasets were retweets. Reposted messages are redundant for classification and were deleted. After pre-processing each message was saved as bag of words model – a standard technique of simplified information representation used in information retrieval.

### *C. Sentiment Analysis*

Unlike classical methods for forecasting macroeconomic quantities [13,15,16] prediction of future stock prices is performed here by combining results of sentiment classification of tweets and stock prices from a past interval. Sentiment analysis [8,14] - also known as opinion mining refers to a process of extracting information about subjectivity from a textual input. In order to achieve this it combines techniques from natural language processing and textual analysis. Capabilities of sentiment mining allow determining whether given textual input is objective or subjective. Polarity mining is a part of sentiment in which input is classified either as positive or negative.

In order to perform a sentiment analysis classification a model has to be constructed by providing training and test datasets. One way of preparing these datasets is to perform automatic sentiment detection of messages. This approach was used in several works such as [9]. Another possibility of creating training and test data is to manually determine sentiment of messages, which means it is a standard, supervised learning approach. Taking into consideration large volumes of data to be classified and the fact they are textual, Naïve Bayes method was chosen due to its fast training process even with large volumes of training data and the fact that is it is incremental. Considered large volumes of data resulted also in decision to apply a map reduce version of Naïve Bayes algorithm. In order to perform sentiment analysis on prepared bags of words a model has to be constructed by providing training and test datasets for classification. These datasets were created using two different methods. One was applying an automatic sentiment detection of messages. It was achieved by employing SentiWordNet [10] which is a publicly available resource aimed to support performing sentiment and opinion classifications. The other method was a manual labelling of sentiment of tweets. Each message was marked as positive, negative or neutral. There were two training datasets. First one consisted of containing of 800 hundred tweets. The other dataset consisted of 2.5 million messages. Only 90% of each dataset was used directly as a training set the other 10% was used for testing.

As a result of two classifiers were obtained using manually labelled dataset. First classifier determines subjectivity of tweets. Then polarity classifier classifies subjective tweets, i.e. using only positive and negative and omitting neutral ones. In order to use classification result for stock prediction term: ’sentiment value’ (denoted as a **ε**) was introduced - it is a logarithm at base 10 of a ratio of positive to negative tweets (Eq. 1).

$$\varepsilon = \log_{10} \frac{number\_of\_positive\_tweets}{number\_of\_negative\_tweets} \quad (1)$$

If **ε** is positive then it is expected that a stock price is going to rise. In case of negative **ε** it indicates probable price drop. In order to estimate price of stock, classification results are combined with a linear regression of past prices where one weight is a sentiment value. Predictions for a specific time point are based on analysis of tweets and stock prices from a past interval - Eq. 2 shows the formula for the relationships of past value of stock taken into analysis.

$$y_i = \alpha + (\beta + \varepsilon_i)x_i \quad (2)$$

where: $y_i$ is a past value of a stock at a given time of $x_i$, $x_i$ is time variable, $\varepsilon_i$ is a sentiment value calculated for a given time of $x_i$, $i = 1, \ldots, n$ , $\beta$ is a linear regression coefficient defined as (Eq. 3)

$$\beta = \frac{\Sigma x_i y_i - \frac{1}{n}\Sigma x_i \Sigma y_i}{\Sigma x_i^2 - \left(\frac{1}{n}\Sigma x_i\right)^2} \quad (3)$$

and $\alpha$ coefficient is given by (Eq. 4):

$$\alpha = \overline{p} - \beta\overline{t} \quad (4)$$

where $\overline{p}$ and $\overline{t}$ are mean values of price of stock over a period of $t$.

## III. Results and Analysis

Predictions were prepared using two datasets for several different time intervals, i.e. time differences between the moment of preparing the prediction and the time point for which the forecast was prepared. Predictions were conducted for one hour, half an hour, 15 minutes and 5 minutes ahead of the moment being forecasted. Two tweet datasets were used: one with messages containing company stock symbol 'AAPL', and the other dataset included only tweets containing name of the company, i.e. 'Apple'. Training datasets consisted of 3 million tweets with stock symbols and 15 million tweets with company name accordingly. Tweets used for predictions were retrieved from 2nd to 12th of April 2013. Approximately 300 000 tweets were downloaded during New York Stock Exchange trading hours each day via Twitter Streaming API.

Experiments were conducted using two models of classifiers, first was built using manually labelled, dataset-based trained classifier and the other was trained with automatically labelled tweet training datasets. Experiments were conducted in the following manner. For each of the following prediction time intervals: 1 hour, 30 min and 15 min all four models (permutations of manual or auto-classifiers coupled with AAPL or Apple keywords) were used. For 5 minutes prediction small number of tweets with stock symbol (AAPL) per time interval resulted in limiting predictions only to models trained with messages with company name (Apple).

Time axis shown on Fig 2 and following figures shows NASDAQ trading hours converted to CEST 1 time zone. Results of predictions are also compared to actual stock prices using Mean Square Error (MSE) measure that are presented in table 1. Sample predictions are presented for 1 hour, 30 minutes, 15 minutes and 5 minutes, while following figures are presented only for 1 hour, 30 min and 5 min.

TABLE 1: MEAN SQUARE ERROR VALUES OF PREDICTED AND ACTUAL STOCK PRICES.

| MSE | 1 Hour | 30 Min | 15 Min | 5 Min |
|---|---|---|---|---|
| Manual & 'AAPL' | 1.5373 | 0.6325 | 0.3425 | - |
| Auto & 'AAPL' | 0.947 | 0.3698 | 0.2814 | - |
| Manual & 'Apple' | 1.9287 | 1.5152 | 0.9052 | 0.5764 |
| Auto & 'Apple' | 1.8475 | 1.4549 | 0.8325 | 0.3784 |

### One-hour predictions

A first objective was to test a performance of predictions for 1-hour intervals. Example results of 1-hour interval predictions are presented on Fig. 2.

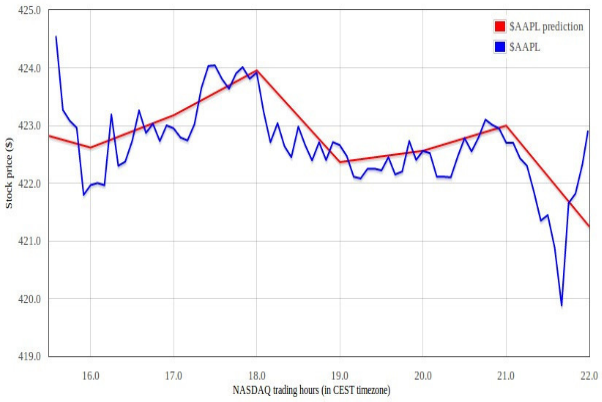


Figure 2: One-hour prediction. Manually labelled 'AAPL' training dataset.

Blue line (fluctuated) corresponds to actual stock prices and red line (steadily changing) shows predicted values. Predictions in this time intervals would not provide accurate result but they can be used to evaluate if the method correctly estimates trends. Predictions for the same day are presented below using 4 different models of classifier.

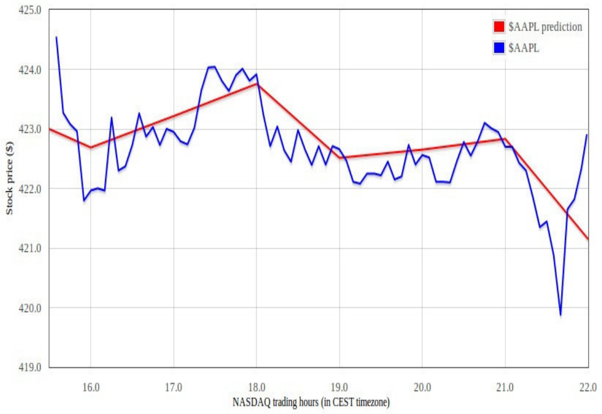

Figure 3: One-hour prediction. Automatically labelled 'AAPL' training dataset.

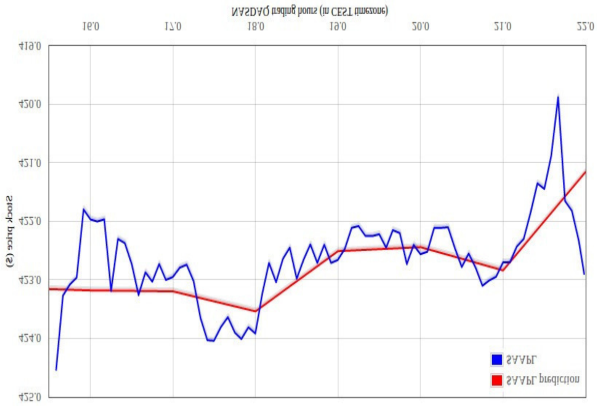

Figure 4: One-hour prediction. Manually labelled 'Apple' training dataset.

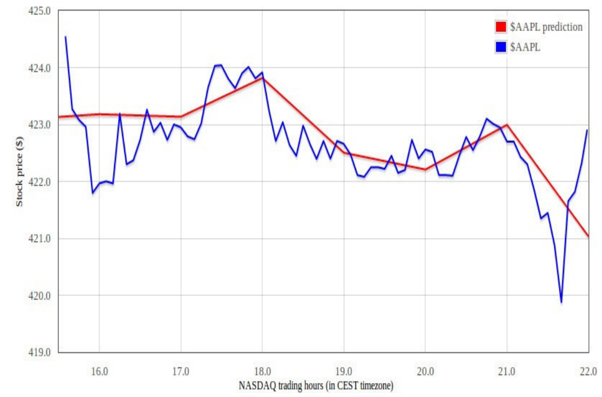

Figure 5: One-hour prediction. Automatically labelled 'Apple' training dataset.

As it can be observed on Fig. 2-5 predictions of each model are similar. They correctly forecast trends however due to big time interval, i.e. 1 hour it is not possible to determine whether models can predict sudden price movements. Furthermore when comparing results for two datasets, predictions using models trained with tweets with stock symbol perform better that those trained with tweets containing company name.

### 30 minutes predictions

This subsection describes 30 minutes predictions. It is expected for these predictions not only to forecast trends but sudden price movements as well; this expectation is due to the fact of smaller time interval between time of prediction and forecasted moment. Results are shown on Fig. 6-7 graphs. First model (‘manual’ for AAPL keyword) predictions are less accurate in comparison with second model (auto/AAPL). Yet, significant difference between predicted and actual prices from 17 to 21 in both first models is still there (for further analysis no figures for AAPL is shown from this point on since APPLE gives better performance). Models using dataset with actual company name (plots at Fig. 6 and Fig. 7) perform much better than two first ones. Predictions of prices follow actual ones. However in all cases price forecasting is less accurate when there are several dynamic changes of price movement trend. It is especially visible in all figures for periods from 18 to 20 hours that predictions do not show correlations with actual prices. It may result, among the others, from too long time intervals in comparison to rapid price movements.

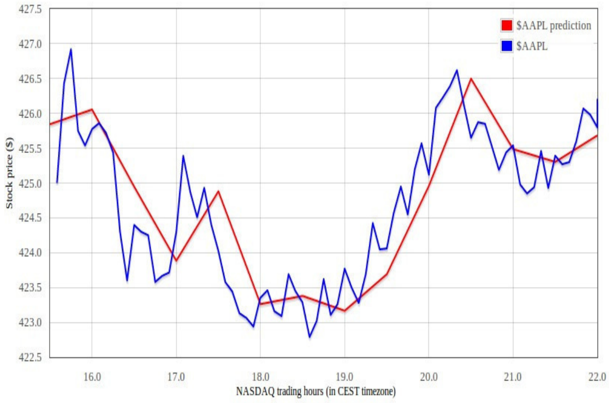

Figure 6: 30 minutes prediction. Manually labelled ’Apple’ training dataset.

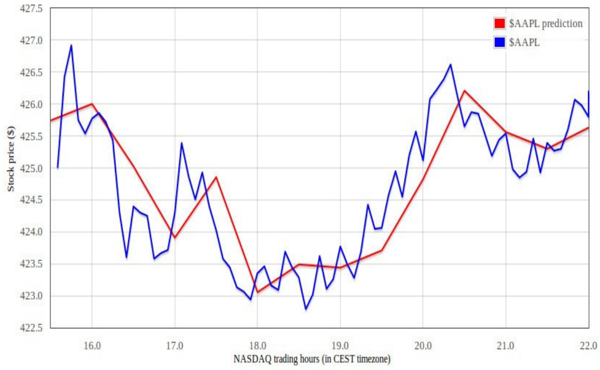

Figure 7: 30 minutes prediction. Automatically labelled ’Apple’ training dataset.

For 15 minutes dynamic price movements are somehow reflected in prediction, although it is not any significant indication in a sense of preserving real nature and amplitude of those fluctuations. Rapid price movements are not easily indicated due to chosen time interval; still too long for better accuracy. Only for this 15 min interval classification based on tweets with stock symbol yield better results. Furthermore it is important to note that using automatically trained training with bigger number of records strongly affects result of prediction.

### 5 minutes predictions

Last experiment was to perform 5 minutes predictions. Due to short time interval it was expected that prediction would the most accurate. In this part only dataset build with messages with actual company name was used. This is because the number of messages from datasets with stock symbol per time interval was very small and the results of predictions were not reliable.  Results are shown on fig. 8-9.

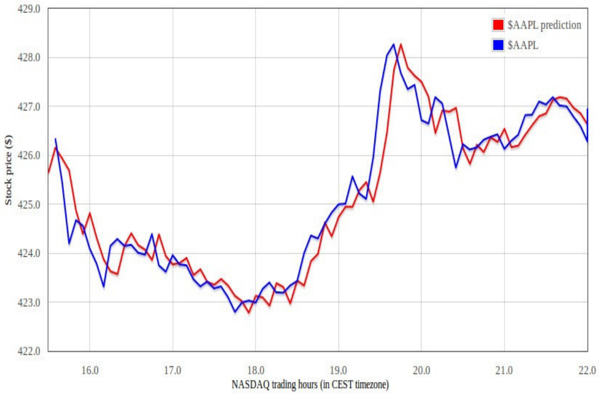

Figure 8: 5 minutes prediction. Manually labelled ’Apple’ training dataset.

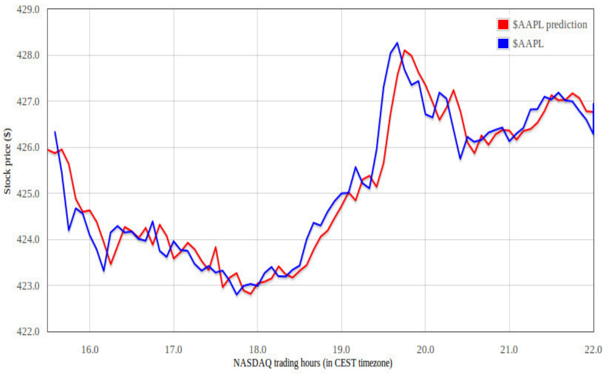

Figure 9: 5 minutes prediction. Automatically labelled ’Apple’ training dataset.

## IV. DISCUSSION OF RESULTS

As it can be observed from presented results, predictions of stock prices depend strongly on choice of training dataset, their preparation methods and number of appearing messages per time interval. Predictions conducted with models trained with datasets with messages containing company stock symbol performs better. It can be explained by the fact that these messages refer to stock market. Tweets with company name may just transfer information, which does not affect financial results. Another important factor is a choice of preparation of training set. Two methods were used. One of the methods was a manual labeling sentiment value of messages. This method allows to more accurately label training data but is not effective for creating large training sets. The other method was applying SentiWordNet, which is a lexical resource for sentiment opinion mining. It enabled to create bigger training datasets, which resulted in building more accurate models. Last factor that is important for prediction is number of appearing messages per time interval. Although model trained with datasets with company name were not accurate in comparison to the other datasets, there is bigger number of tweets per time interval. It allowed performing prediction for shorter time intervals, which were not possible for dataset with messages containing company stock symbol. Described methods can be also used with other stock predictions procedures in order to maintain higher accuracy. It is also important to note that stock prediction methods are not able to predict sudden events called 'black swans' [11].

## V. Conclusions

This paper discusses a possibility of making prediction of stock market basing on classification of data coming Twitter micro blogging platform. Results of prediction, which were presented in previous section show that there is correlations between information in social services and stock market. There are several factors that affect accuracy of stock predictions. First of all choice of datasets is very important. In the paper two types of datasets were used one with name of the company and the other with stock symbol. Predictions were made for Apple Inc. in order to ensure that sufficiently large datasets would be retrieved. There were large differences in size between these two sets. This lead to situation that it was not possible to perform 5 minutes predictions basing on tweets with stock symbol due to too few messages. Additionally although dataset with company name was bigger it may not be accurate for predictions. This due to the fact that company name can be used as a household name and the messages do not refer to stock market. In case of tweets with stock symbol there is bigger probability that people who posted are relating to stock prices. Predictions can be improved by Adding analysis of metadata such as exact location of a person while posting message, number of retweets, number of followers etc. This information may be used to determine which users are more influential and creating a model of interactions between users. Number of messages posted by a user and its frequency may be used to discard spammers and automated Twitter accounts. It is also possible to employ different sources of information. Although Twitter is very popular and offers nearly time communications there exist other sources information such different social networks, blogs, articles in online newspapers. Adding analysis of other may contribute to more accurate predictions.

***Abstract*—A growing number of users, seeking to influence their friends, are adopting social network sites, like Facebook to increase their social presence. In the relatively few scholarly studies that consider how writing comments on social network sites influences their friends, the focus has been on marketing or promotion. Little is known about the impact of user writing versus reading on social media. In our paper, we address this gap by studying how the writing comments influences the reactive behavior (likes, comments) of their friends. Our research sheds more light on what motivates users on social networks sites to write and publish on their page. Specifically, we study the user-to-user interactions on Facebook. We found that the number of messages the user broadcasts is dependent on the feedback he or she received from friends.**

## I. Introduction

LARGE volumes of status update messages are posted by Facebook (FB) users on their pages to inform their friends and followers about their current activity like eating in restaurant, watching movie or others [1]. They are an increasingly popular form of communication that allow users to interact with their followers who can react with a comment or a ‘‘like’’. Status updates enable quick and effortless one-to-many communication [2]. On average, there are 60 million status updates per day FB making it by far most popular social network site (SNS) and a logical place to study user influence behaviors and consequences of the social processes associated with SNS usage [3]. The popularity and novelty of status updates makes it a very interesting topic for a variety of empirical studies [4].

This paper focuses on understanding users’ write or posting activity, which is crucial for the social network site’s existence. *What reactions are influencing users to publish?* Our research finding shows that feedback given by friends and followers has a critical influence on the writing activity. Data obtained from social networks sites are undoubtedly an important source of knowledge about user behaviors and constitute an important source of information for developing a new business models. Facebook thanks to Graph API protocol, provides access to information on the behaviors through consistent view of the social graph with a representation of objects in the graph (e.g., people, photos, events, and pages) and the connections between them (e.g., friend relationships, shared content, and photo tags). Certainly, every user must provide permission to allow access to their data. Social network sites reflect how people act in their social environment. An interesting aspect of living in a society is how an individual’s behavior changes under the influence of other people. Social network sites seem to be a natural environment for influencing behaviors captured by SNSs like FB, become a good source for empirical research [3]. This reactive behavior is a powerful organizing standard that governs the social structures and weaves interpersonal webs of connection [5]. Several other studies on social network behavior have found presence of influence in groups with similar age or ethnicity [6].

Status updates are short messages that are posted to the personalized welcome page (News Feed) of all FB friends of the user as well as on the user’s own profile page. Most social networking sites, like FB, Google+, and MySpace utilize some form of status updates, and in some cases, like on Twitter, they serve as the main function. These posts are restricted in length (e.g., 420 characters on FB) and recipients can comment on them or indicate that they ‘‘like’’ them. Status updates enable effortless and fast one-to-many communication

This research could be utilized for understanding user behaviors that are useful for market analysis. However, user information must be analyzed with compliance of privacy laws to avoid any individual privacy infringements. Adequate care to anonymize data before publishing the results would be helpful.

In the next section, we provide a brief overview on the related works in the scope of the behavioral research on social networks, with the examples from FB-related studies. Additionally, we have reviewed select studies on user behaviors in social media. In the third section, we discuss our methods of empirical data gathering and provide background information on the research group and variables included in our pilot study. The fourth section presented results yielded from our analysis of empirical data. The final section discusses our conclusions and elaborates on future research opportunities from this work.

## II. Related Work

Companies today have their social media departments gain insights into the behaviors of their customers through social networks sites like FB, Twitter and others for understanding user behavior on social networks. In addition, social networks sites are ideal grounds for observing influential behaviors that encourage more interactions and affect their followers’ opinion [7]. In fact, [8] suggest SNS can be used for rating the relevance of information by using SNS conventions such as

# 13th Conference on Advanced Information Technologies for Management

WE ARE pleased to invite you to participate in the 11th edition of Conference on "Advanced Information Technologies for Management AITM'15". The main purpose of the conference is to provide a forum for researchers and practitioners to present and discuss the current issues of IT in business applications. There will be also the opportunity to demonstrate by the software houses and firms their solutions as well as achievements in management information systems.

## Topics

The topics of interest include but are not limited to:

- Concepts and methods of business informatics
- Business Process Management and Management Systems (BPM and BPMS)
- Management Information Systems (MIS)
- Enterprise information systems (ERP, CRM, SCM, etc.)
- Business Intelligence methods and tools
- Strategies and methodologies of IT implementation
- IT projects & IT projects management
- IT governance, efficiency and effectiveness
- Decision Support Systems and data mining
- Intelligence and mobile IT
- Cloud computing, SOA, Web services
- Agent-based systems
- Business-oriented ontologies, topic maps
- Knowledge-based and intelligent systems in management

**This paper focuses on one of the most popular issues in the Polish finance – is the 'buying stock market winners' profitable on the Warsaw Stock Exchange? This study tested whether Ichimoku trend following strategy performed better than simple buy & hold benchmark. For automated backtests WIG30 index components in the period 2012-12-28 to 2015-05-06 were used. The empirical results suggest that buying recent "winners" is very ineffective. These preliminary findings may imply contrarian nature of the short-term Polish financial market.**

## I. Introduction

TRADERS take many investing approaches. One of these tactics is to buy well-performing companies with expectations the performance will continue. The decision can be made using either, among others: momentum, or trend following strategies. These strategies may appear similar, but in reality they use different assumptions.

Trend following is an investment or trading strategy that tries to take advantage of long, medium or short-term price movements that seem to play out in various markets. Traders who employ a trend following strategy do not aim to predict specific price levels; they simply jump on the trend (when they perceive that a trend has established with their own peculiar reasons or rules) and ride it. A market "trend" is a tendency of a financial market price to move in a particular direction over time. If there is a turn contrary to the trend, they exit and wait until the turn establishes itself as a trend in the opposite direction. In cases their rules signal an exit, the trader closes long positions and re-enters when the trend is re-established [1, 2].

Momentum strategies rely on the assumption that prices respond (at least in part) to the strength of their supply and demand inputs. Momentum takes many forms: the earnings reports for publicly traded companies, the relationship between buyers and sellers in the market, the typical rate of historical price rises and falls, etc. In a sense, momentum trading can be paradoxically concerned with the fundamentals of technical analysis [3].

There are many trend following strategies [4]. For instance "Cross Exponential Moving Average (EMA)" enters the market when candle closes above 5-period EMA and exits when candle closes below 20-period EMA. "Simple Moving Average (SMA) and Moving Average Convergence Divergence (MACD)" on the other hand, enter the market when price crosses 20-period (this value can be adjusted) EMA and MACD oscillator is positive. Most strategies are based on fairly simple indicators operating on short-term historical prices. Due to that feature of trend-following strategies, authors have chosen Ichimoku method. This method sometimes is called trading system due to its complexity comparing to standard trend following techniques. Ichimoku is also a moving average-based trend identification system, but it contains more data points than standard candlestick charts and provides a clearer picture of potential price action. Authors have chosen this technique not because it is better than the others, not because it performs better or worse but because it takes into consideration much more aspects of price than other strategies. This feature of this technique is crucial for quantitative backtests performed in this paper.

This paper re-examines the profitability of a short-term trend following strategy, which aims to buy stocks that have performed well in the past. These backtests do not include short-sale trades. It is not the author's intention to prove or disprove efficiency of Ichimoku technique. The main question to be answered is: does buying recent winners from the WIG30 index pay off.

The question of profitability of the trend following strategy on the Warsaw Stock Exchange (WSE) is important because existing evidence provides mixed results. Numerous scientists documented abnormal profits of the momentum or trend following strategies. Rouwenhorst [5] finds it on twelve European markets, and [6] for some stock emerging markets. Hameed and Yuanto [7] positively identify six Asian markets. Schiereck, DeBondt and Weber [8] find momentum profitable for intermediate-term German market. In contrast to these findings there are numerous examples of contrarian markets. For example Jagadeesh [9] and Lehmann [10] find reversals in short-term horizons. DeBondt and Thaler [11, 12] report long-term price reversals. Chang, McLeavey and Rhee [13] document short-term contrarian nature of Japan. Hameed and Ting [14] have similar findings about Malaysia. Finally Kang, Liu, and Ni [15] report the overreaction to firm-specific information as the single most important source of the short-term contrarian profit in China stock market. The state of short-term trend following on Polish WSE lacks similar conclusions.

## II. METHOD

For the purpose of the backtests an automated trading-agent was implemented. Basically the agent buys and sells stocks according to hard-coded Ichimoku rules. The testing framework is a part of the A-Trader system [16]. Presented work is an extension and follow-up of previous experiments conducted using A-Trader. Technically, the presented system is a multi-agent solution that supports the analysis of the time series of high frequency, such as trading instruments. The main features are its openness for integration, development of new system functionality and ensuring adequate communication between the various agents. The agents can act as data providers, indicators or final decision makers. The service orientated architecture and cloud computing solves the problem of computing power. This could be an issue for higher than daily trading frequencies.

The Ichimoku trading-agent consists of 6 elements (as in Ichimoku trading system [17]).

Tenkan-sen calculation: (highest high + lowest low)/2 for the last 9 periods. It is primarily used as a signal line and a minor support/resistance line. The Tenkan Sen is an indicator of the market trend. If the red line is moving up or down, it indicates that the market is trending. If it moves horizontally, it signals that the market is ranging. The Tenkan-sen Line is computed below.

$$TS = \frac{max(s_9) - min(s_9)}{2}$$

$s_9$ - time series created from last 9 periods.

Kijun-sen calculation: (highest high + lowest low)/2 for the past 26 periods. This is a confirmation line, a support/resistance line, and can also be used as a trailing stop line. The Kijun Sen acts as an indicator of future price movement. If the price is higher than the blue line, it could continue to climb higher. If the price is below the blue line, it could keep dropping. The Kijun-sen Line is computed below.

$$KS = \frac{max(s_{26}) + min(s_{26})}{2}$$

$s_{26}$ - time series created from last 26 periods.

Senkou span A calculation: (Tenkan-sen + kijun-sen)/2 plotted 26 periods ahead. Also called leading span 1, this line forms one edge of the kumo, or cloud if the price is above the Senkou span, the top line serves as the first support level while the bottom line serves as the second support level. If the price is below the Senkou span, the bottom line forms the first resistance level while the top line is the second resistance level. Span is computed below.

$$SSA = \frac{TS + KS}{2}$$

TS - tenkan-sen line,
KS - tenkan-sen line.

Senkou span B calculation: (highest high + lowest low)/2 calculated over the past 52 time periods and plotted 26

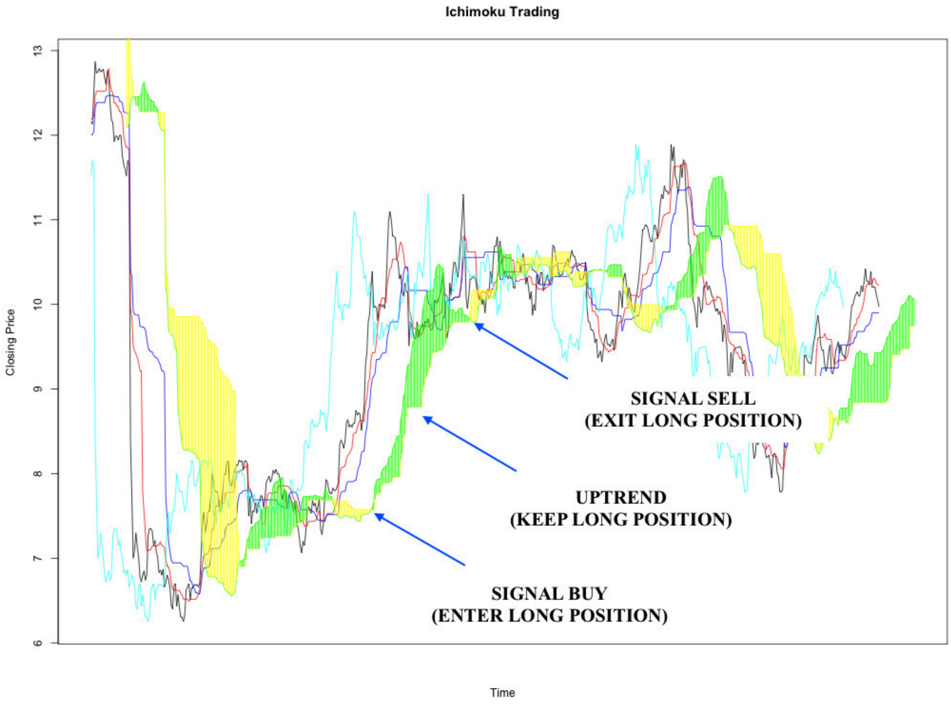

Fig. 1 Ichimoku Trading - entering and exiting long positions (symbol ORANGEPL).

periods ahead. Also called leading span 2, this line forms the other edge of the kumo. Span is computed below.

$$SSB = \frac{max(s_{52}) + min(s_{52})}{2}$$

$s_{52}$ - time series created from last 26 periods.

Kumo cloud is the space between senkou span A and B. The cloud edges identify current and potential future support and resistance points. The Kumo cloud changes in shape and height based on price changes. The Kumo height represents volatility as larger price movements form thicker clouds, which creates a stronger support and resistance. As thinner clouds offer only weak support and resistance, prices can and tend to break through. Generally, markets are bullish when Senkou Span A is above Senkou Span B and vice versa. Traders often look for Kumo Twists in future clouds, where Senkou Span A and B exchange positions, a signal of potential trend reversals. In addition to thickness, the strength of the cloud can also be ascertained by its angle; upwards for bullish and downwards for bearish. Any clouds behind price are also known as Kumo Shadows.

Chikou line calculation: today's closing price projected back 26 days on the chart. Also called the lagging span it is used as a support/resistance aid. If the Chikou Span or the green line crosses the price in the bottom-up direction, that is a buy signal. If the green line crosses the price from the top-down, that is a sell signal. Visually the rules implemented in automated-strategy are presented on the figure 1.

Figure 1 shows all Ichimoku elements with entry and exit positions. The colors on the figure corresponds to listed below Ichimoku elements:

- red Tenka-sen line,
- blue Kijun-sen line,
- green Senkou span A,
- yellow Senkou span B,
- cyan Chikou line.

It is important to avoid biases related to backtesting buy-only strategies on uptrend markets only. Therefore the backtests were conducted during diversified market periods. Fig. 2 shows corresponding WIG30 period (daily observations).

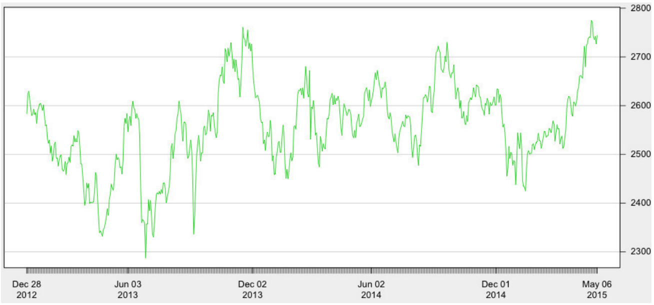

Fig. 2 WIG30, in backtested period, presenting non-monotonous trend.

During the backtested period the daily WIG30 returns had moderate skewness, with mean centered almost around zero. The weekly and monthly WIG30 returns were also slightly positive, with no significant variance. The summary of basic statistics is presented in table 1.

The backtests were performed in A-Trader with extensions written in R programming language. The reason of choosing R is because it is well tested statistical programming framework with wide variety of libraries and large community. This approach makes the backtests less vulnerable to errors. The backtesting architecture, presented in detail in [16], is shown at the fig. 3.

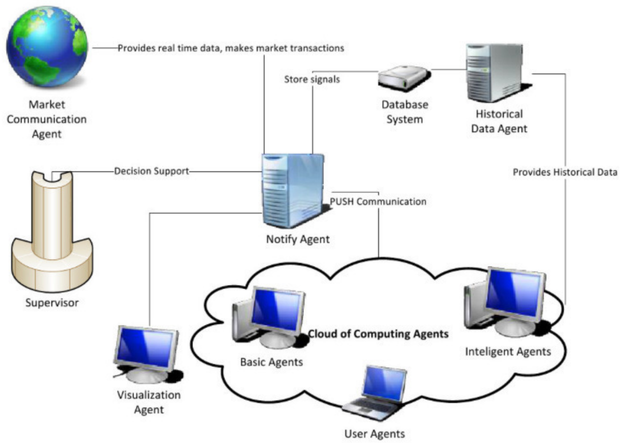

Fig. 3 A-Trader architecture.

TABLE I.
STATISTICS OF WIG30 RETURNS - VARIOUS TIME RESOLUTIONS

| Returns | # Obs | Minimum | Quartile 1 | Median | Mean | Quartile 3 | Maximum | Stdev |
|---|---|---|---|---|---|---|---|---|
| Daily | 581 | -0.0527 | -0.0054 | 0.0030 | 0.002 | 0.0057 | 0.0311 | 0.0097 |
| Weekly | 123 | -0.0865 | -0.0122 | 0.0019 | 0.007 | 0.0126 | 0.0578 | 0.0217 |
| Monthly | 29 | -0.0877 | -0.0189 | 0.0031 | 0.0028 | 0.0328 | 0.0818 | 0.0386 |

The following agents and components are distinguished in the A-Trader architecture:

- Notify Agent (NA),
- Historical Data Agent (HDA),
- Cloud of Computing Agents (CCA),
- Market Communication Agent (MCA),
- User Communication Agent (UCA),
- Supervisor (S),
- Database System (DS).

The data was acquired from the brokerage department of BOS Bank (the Polish Bank Ochrony Środowiska). Data was aggregated to 1-day periods. As a middle storage layer, a HDFS distributed file system was used. Such approach enables huge improvements in computation time and allows the data to perform millions of simulation in real time. These extensions of the A-Trader built framework are easily customizable and can be used in a variety of tests with minimum programming work.

## III. RESULTS

For the purpose of backtesting we took components of WIG 30 index (as of 2015.05.07). The list of backtested companies included: ALIOR, ASSECOPOL, BOGDANKA, BORYSZEW, BZWBK, CCC, CYFRPLSAT, ENEA, ENERGA, EUROCASH, GRUPAAZOTY, GTC, HANDLOWY, INGBSK, JSW, KERNEL, KGHM, LOTOS, LPP, MBANK, ORANGEPL, PEKAO, PGE, PGNIG, PKNORLEN, PKOBP, PZU, SYNTHOS, TAURONPE, TVN. Next, the data was trimmed to the earliest possible point where the WIG30 index provides first observation (2012-12-28). Additionally the company quotes were shifted by 52 trading days to prepare signals for trading since the first day of WIG30 (2012-10-12).

Each of the benchmarks produced a visual output of Ichimoku components with price. Additionally, cumulative returns of the tested trend-following strategy were plotted along the classical "Buy & Hold" benchmark.

Visual examination of two different results of strategies helps understand the mechanics of gains and losses. The first example shows a situation where the cumulative return of trend following-strategy outperformed the Buy & Hold benchmark. Figure 4 presents the company with symbol GRUPAAZOTY and its Ichimoku components. Figure 5 presents cumulative returns.

Opposite to the previous example where Buy & Hold outperformed, the trend following Ichimoku strategy is presented on figures 6 (flags, lines) and 7 (cumulative returns).

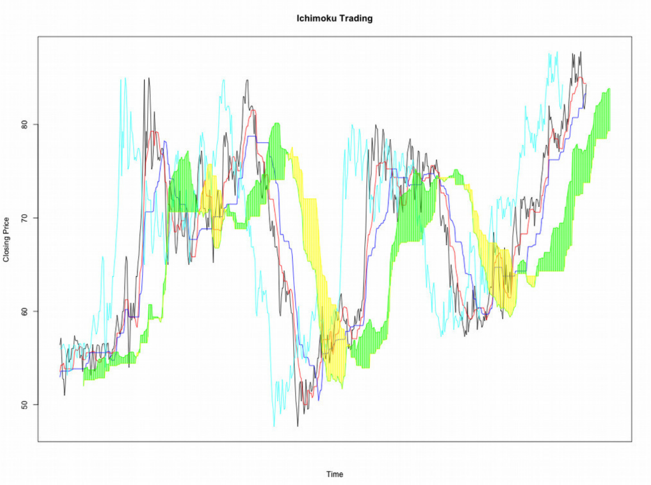

Fig. 4 Ichimoku flags and lines for GRUPAAZOTY.

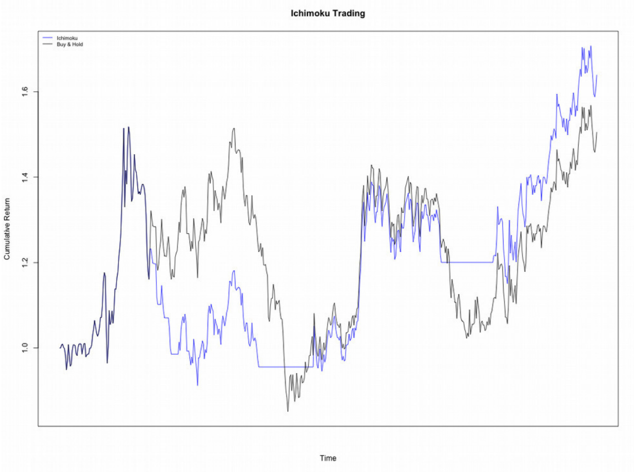

Fig. 5 Cumulative returns - comparison of Ichimoku and Buy & Hold strategies (GRUPAAZOTY).

Final summary of the results leave no doubts. The trend following strategy performed worse than Buy & Hold in 26 out of 30 cases. In most cases, the winning situations were merely protecting losing positions. The table 2 presents summary of the results for all the companies in the backtests. The numbers in column I and II show cumulative returns. Values below "1" are losses of initial capital.

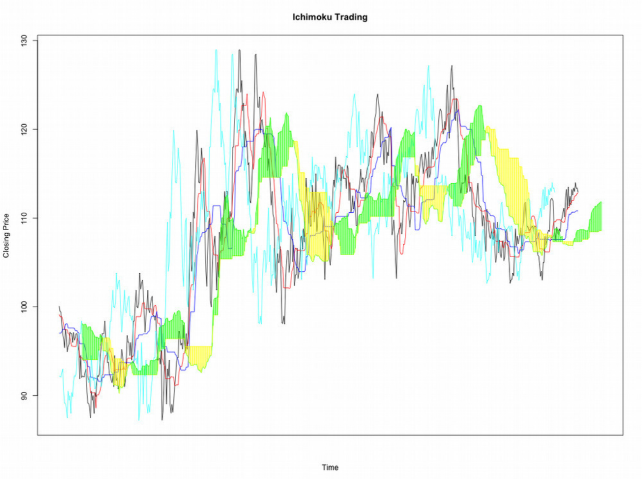

Fig. 6 Ichimoku flags and lines for HANDLOWY.

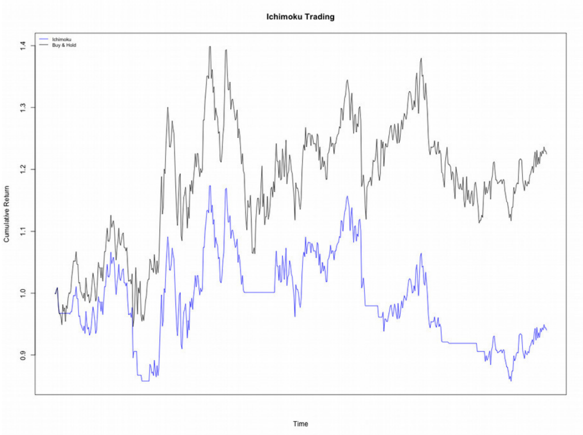

Fig. 7 Cumulative returns - comparison of Ichimoku and Buy & Hold strategies (HANDLOWY).

The statistics of cumulative returns across backtests is presented in table III.

## IV. Discussion

As shown in backtests buying winners on Warsaw Stock Exchange with Ichimoku short trend following strategy did not perform well. There might be a few reasons for such results.

First is past-winners do not have enough strength to beat the market in the future. Buy and hold benchmark seems to confirm this thesis. This is not a typical situation on well-developed capital markets where buying winners usually outperform the market [18]. The assets for the backtests were taken from the WIG30 index component list. Perhaps those assets were considered overpriced, due to the short term overreaction to the news, and therefore there was no steady potential to outperform the market. Investigation into other segments of the market might be helpful to verify this statement.

Second reason of the losses is the potential inefficiency of Ichimoku technique as the trend following strategy. There is a possibility that Ichimoku with used parameters does not follow trend as intended. In such cases, further backtests with different strategies might deny or confirm this thesis. However looking at the Buy & Hold strategy, it seems that the buying "winners" approach is the problem, not the chosen strategy itself. Nevertheless other strategies might shed some additional light on this matter.

In general, trend following scored worse in almost every case, except one: investment protection. The minimum Buy & Hold cumulative return is 0.1562, while, for trend following, the protection shut the trading down at 0.4646. Although this additional protection limits losses, it also trims gains.

Table II.
Statistics of WIG30 returns - various time resolutions

| Trend Following | Buy & Hold | Symbol | Result |
|---|---|---|---|
| 0,95 | 1,32 | ALIOR | LOSS |
| 1,38 | 1,39 | ASSECOPOL | LOSS |
| 0,60 | 0,65 | BOGDANKA | LOSS |
| 1,16 | 1,21 | BORYSZEW | LOSS |
| 1,05 | 1,39 | BZWBK | LOSS |
| 2,15 | 2,72 | CCC | LOSS |
| 1,34 | 1,56 | CYFRPLSAT | LOSS |
| 0,69 | 1,09 | ENEA | LOSS |
| 1,18 | 1,31 | ENERGA | LOSS |
| 0,68 | 0,78 | EUROCASH | LOSS |
| 1,64 | 1,51 | GRUPAAZOTY | WIN |
| 0,89 | 0,74 | GTC | WIN |
| 0,94 | 1,22 | HANDLOWY | LOSS |
| 1,52 | 1,62 | INGBSK | LOSS |
| 0,61 | 0,16 | JSW | WIN |
| 0,46 | 0,54 | KERNEL | LOSS |
| 0,59 | 0,69 | KGHM | LOSS |
| 0,73 | 0,84 | LOTOS | LOSS |
| 1,32 | 1,42 | LPP | LOSS |
| 1,19 | 1,48 | MBANK | LOSS |
| 1,16 | 0,87 | ORANGEPL | WIN |
| 0,78 | 1,21 | PEKAO | LOSS |
| 1,00 | 1,22 | PGE | LOSS |
| 1,13 | 1,20 | PGNIG | LOSS |
| 1,00 | 1,38 | PKNORLEN | LOSS |
| 0,84 | 1,06 | PKOBP | LOSS |
| 0,80 | 1,18 | PZU | LOSS |
| 0,75 | 0,94 | SYNTHOS | LOSS |
| 0,85 | 1,11 | TAURONPE | LOSS |
| 1,86 | 1,89 | TVN | LOSS |

Final conclusions are that joining recently established uptrends, in the case of WIG30 components in period 2012-12-28 to 2015-05-06, did not lead to excessive returns and did not provide any other kind of improvements. Of course, the presented backtesting approach is very general: the algorithms can be adjusted, additional variables can be specified, and more sophisticated models can be used. However, the broad backtests performed in this research

TABLE III.
STATISTICS BETWEEN RETURNS ACROSS ASSETS

| | **Trend Following (Ichimoku)** | **Buy & Hold** |
|---|---:|---:|
| **Min.** | 0.4646 | 0.1562 |
| **1st qu** | 0.7579 | 0.8830 |
| **Median** | 0.9768 | 1.2070 |

# Fuzzy logic in the multi-agent financial decision support system

Jerzy Korczak, Marcin Hernes, Maciej Bac
Wrocław University of Economics ul. Komandorska 118/120, 53-345 Wrocław, Poland

e-mail:{jerzy.korczak, marcin.hernes, maciej.bac}ue.wroc.pl

***Abstract*—The article presents the application of a fuzzy logic in building the trading agents of the a-Trader system. The system supports investment decisions on the FOREX market. The first part of the article contains a discussion related to the use of fuzzy logic as an agents' knowledge representation. Next, the algorithms of the selected fuzzy logic buy-sell decision agents are presented. In the last part of the article the agent performance is evaluated on real FOREX data.**

## I. Introduction

FINANCIAL decisions are made under conditions of risk and uncertainty that influence their level of performance. These decisions are usually supported by decision support systems and various computational models. Among them, there are multi-agent systems [2] which use various methods based on mathematics, statistics, finance or artificial intelligence [3, 4, 6, 10, 13, 14, 18, 20, 21,25, 28, 48]. A-Trader [22] supporting investment decisions on the FOREX market (Foreign Exchange Market) may serve as the example of such a system. FOREX is one of the biggest financial foreign exchange markets in the world. Currencies are traded against one another in pairs, for instance EUR/USD, USD/PLN. Trading on FOREX relies on opening/closing long/short positions. A long position is a situation in which one purchases a currency pair at a certain price and hopes to sell it later at a higher price. This is also referred to as the notion of "buy low, sell high" in other trading markets. On FOREX, when one currency in a pair is rising in value, the other currency is declining, and vice versa. If a trader thinks a currency pair will fall, he will sell it and hope to buy it back later at a lower price. This is considered a short position, which is the opposite of a long position. The A-Trader receives tick data which are grouped to minute aggregates (M1, M5, M15, M30), hourly aggregates (H1, H4), daily aggregates (D1), weekly aggregates (W1) and monthly aggregates (MN1). The A-Trader supports a High Frequency Trading (HFT) and puts strong emphasis on price formation processes, short-term positions, fast computing, and efficient and robust indicators.

High frequency traders are constantly taking advantage of very small quote changes with a high rate of recurrence to generate important profit rates. As many HFT experts underline, the traders seek profits from the market's liquidity imbalances and short-term pricing inefficiencies. Hence, the minimization of time from the access to quote information, through the entry of an order until its execution, is vital. Generally speaking, to support traders, the systems must provide as soon as possible advice as to which position should be taken: buy, sell or do nothing. Time series forecasting is more difficult while online trading has to be served.

The architecture of a-Trader and the description of the different groups of agents have already been detailed [23, 24]. In general, the agents possess their own knowledge, they can continuously learn and change their knowledge in order to improve their performance.

Different methods of agents' knowledge representation can be applied in a-Trader. In our previous work [23, 24] we were focused on three-valued knowledge representation of this group of agents. Value "1" denoted „buy" decision, value "-1" denoted „sell" decision, value "0" denoted „ leave unchanged". Agents are implemented using the C# environment and MQL4 language.

The key part of the system is the Supervisor agent. Its task is, among others, to coordinate the work of agents on trading strategy and it presents the final strategy (suggestions of open/close positions) to the trader. The Supervisor uses various strategies and evaluates their performance.

The a-Trader allows also for making arbitrarily independent decisions by traders (experts)on the basis of their knowledge and experience. The traders' decisions can be stored in a database, evaluated and compared with strategies provided automatically by agents.

The purpose of this paper is to present a manner of applying a fuzzy logic as the agents' knowledge representation and evaluating the performance of selected agents in the a-Trader system.

In the first part of the article, the fuzzy logic as agents' knowledge representation is briefly discussed. The algorithms of three selected agents are then described. The final part discusses the results of the performance evaluation of these agents.

## II. Fuzzy logic as agents' knowledge representation

The literature on the subject presents many different methods for agents' knowledge representation. The main ones include first-order predicate logic, production systems, artificial neural networks, frame representation, ontologies such as semantic web and semantic networks, multi-attributes and multi-values structures, and multi valued logic [12, 17, 32, 33, 39, 40, 42, 43, 44, 46]. Some of these methods are closely related to fuzzy logic.

The first-order predicate logic that is one common knowledge representation is founded on the following general assumptions [11]:

- the knowledge representation is independent of physical media,
- agents' internal states are related to the objects of external environment,
- the knowledge representation consists of symbols forming the structure,
- reasoning is based on the manipulation of these structures to derive other structures.

Often agents' knowledge is represented as multi-attribute and multi-value structures which allow representation the real world environment in wide scope of objects features.

Multi-valued logic and fuzzy logic are more suitable methods for HFT. Three-valued logic is a very simple language consisting of proposition symbols and logical connectives. It can handle propositions that are known true, known false, or completely unknown. The set of possible models, given a fixed propositional vocabulary, is finite, so entailment can be checked by enumerative models. Inference algorithms for three-valued logic include backtracking and local–search methods and can often solve large problems very quickly [35]. Three-valued logic is reasonably effective for certain tasks, but does not scale to environments of unbounded size because it lacks the expressive power to describe the real world objects.

To reduce this weakness, a fuzzy logic can be applied in HFT. Fuzzy logic is an approach founded on "degrees of truth" rather than the usual "true or false" values (1 or 0). The idea of fuzzy logic was first proposed by Zadeh in the 1960s when he was working on the problem of computer understanding of natural language [47]. Fuzzy logic is a form of multi-valued logic derived from fuzzy set theory [3] to deal with approximate reasoning. In contrast to "crisp logic", where binary sets are processed by binary logic, fuzzy logic variables may have a truth value that ranges between 0 and 1 that allows the user to express imprecision and flexibility in a decision-making system [41], [45], [30]. Fuzzy logic is used, for example, in multi-agent systems for information extraction [34], energy management [26] or robotics [18]. Fuzzy logic was also used for trading on FOREX, for example, in Expert Advisor [31] or technical analysis system [9] or fuzzy time series forecasting [1], [8], [36]. However, in these systems, the probability of decisions is ranged to [0..1]. In trading systems it is unfavorable, because the trader can buy, sell or leave a currency unchanged. Therefore, in the a-Trader system, the confidence of decisions range is [-1..1], where "-1" level denotes "strong sell" decision, "0" level denotes "strong leave unchanged" decision and "1" level denotes "strong buy" decision. The positions can be open/close with different levels of confidence of decision. For example, the long position can be open, when a level of confidence is 0.6 or short position can be open, when a level of probability is 0.7. Therefore the timeframe for the opening/closing position is wider than in the case of three valued-logic. An example of this difference is presented in Fig 1 and Fig 2 ($A_i$ – denotes the ith agent). In the case of three-valued logic (Fig 1), the green color points denote a "buy" decision, the red color ones denote a "sell" decision, and the black color points denote a "do nothing" decision. There are often agents that generate buy/sell decisions too fast or too late. In the case of fuzzy logic, the ranges of decisions probability often cover the best point for trading. In Fig. 2, the green triangle denotes transition from "do nothing" decision to "buy" decision, and the red inverted triangle denotes transition from "do nothing" decision to "sell" decision, and the black color denotes a "do nothing" decision). Therefore it is possible to place open/close positions closer to the optimal decision than in the case of a three-valued logic. Of course, the level of probability of decision for open/close position plays a vital role. This level can be determined on the basis of trader experience, or by the Supervisor on the basis of, for example, a genetic algorithm.

Using the fuzzy logic as agents' knowledge representation allows the trading decision to be closer to real experts' decisions (made under conditions of risk and uncertainty) that are also taken with a certain level of probability.

Fuzzy logic can be also used by trading advisors for the following tasks:

- forecasting, i.e. the possibility to calculate the output value for input data lies outside the scope initially predicted,
- expressing the agent's knowledge in a flexible, intuitive way.,
- computation of decisions' probability level,
- implementation of different automated learning algorithms,
- validation and consistency measuring that can speed up automated learning and improve user interpretability,
- taking into consideration ambiguity – the "natural" way for expressing uncertain knowledge.

The next part of the article describes selected fuzzy logic buy-sell decision agents implemented in a-Trader.

## III. Description of the fuzzy logic buy-sell decision agents

A-Trader contains approximately 1400 agents, including about 800 processing data agents (they calculate different indicators on the FOREX market, for instance trend indicators, oscillators) and 300 agents (running in all time periods) setting the buy-sell decision, including: 200 three valued logic agents and 100 fuzzy logic agents, also 200 agents providing the strategies. In order to illustrate the performance analysis, four agents were chosen: *BollingerFuzzy, WilliamsFuzzy, TrendLinear-RegFuzzy* and *ConsensusFuzzy*.

### *A. . The BollingerFuzzy agent*

The *BollingerFuzzy* agent is created on the basis of the Bollinger Bands indicator [5]. These bands are volatility constraints placed above and below a moving average. Volatility is expressed by the standard deviation, which changes as volatility increases and decreases.

The bands automatically widen when volatility increases and narrow when volatility decreases. The buy decision's probability level is calculated when the price is close to the upper Bollinger Band or breaks above it, and the sell decision is calculated when the price is close to the lower Bollinger Band or falls below it. The algorithm of this agent is the following:

**Algorithm 1**

```
Input:   q  //a value of quotation,
         bbandup // value determination by processing data agent
           named BBANDUP, which calculates the upper band,
         bbandlo //  value determination by processing data agent
           named BBANDLO, which calculates the lower band.
         sma // value determination by processing data agent named
           SMA, which calculates the simple moving average of
           quotation.
Output:  The fuzzy logic decision D (value range [-1..1]).
BEGIN
Let D:=0, calcBands:=0; //counter for fuzzification.
      maxcount:=0.  //maximum counter limit for fuzzification.
      Δ =Abs((sma-((bbandlo+bbandup)/2))/10).
If q<(bbandlo (+Δ)) then
      If (calcBands>0) then calcBands=0, calcBands:=calcBands-1.
      If (calcBands<-maxcount) then calcBands=-maxcount,
         D=calcBands/maxcount;
If q>(bbandup (-Δ)) then
      If (calcBands<0) then calcBands=0, calcBands:=calcBands+1.
      If (calcBands>maxcount) then calcBands=maxcount;
         D=calcBands/maxcount;
END
```

In a trading system the fuzzification is understood as a process of conversion of an input variable (i.e. signals determined by processing agents) to fuzzy set.

### *B. . The WilliamsFuzzy agent*

The *WilliamsFuzzy* agent is created on the basis of Williams %R indicator [19]. Williams %R is a momentum indicator that is the inverse of the Fast Stochastic Oscillator. Also referred to as %R, the indicator reflects the level of the close relative to the highest high for the look-back period. In contrast, the Stochastic Oscillator reflects the level of the close relative to the lowest low. %R corrects for the inversion by multiplying the raw value by -100. As a result, the Fast Stochastic Oscillator and Williams %R produce exactly the same lines, only the scaling is different. Williams %R oscillates from 0 to -100. The buy decision's probability level is calculated when Williams %R value falls below -80 and the sell decision is calculated when Williams %R value rises above -20. The algorithm of this agent is as follows:

**Algorithm 2**

```
Input:   q  //a value of quotation,
         williams  // value determining by processing data agent
           named WILLIAMS,   which calculates the Williams %R
           indicator.
         Δ – an external parameter denotes range of williams %R less
           than -80 or above -20 (it is assumed that the maximum
           value of williams %R does not have to be 0 and the
           minimum value of williams %R does not have to be -100.
           This parameter range is [1..20] and it is calculated by the
           genetic algorithm or determined by user.
Output:  The fuzzy logic decision D (value range [-1..1]).
BEGIN
Let D:=0.
If williams<=-80 then  D=(williams-(-80- Δ))/ Δ.
If williams>=-20 then D=-(williams-(-20)/Δ.
END
```

### *C. . The TrendLinearRegFuzzy agent*

The agent operates on the basis of the assumption that the trend of a certain number of *M* quotations is approximated with the straight line by the equation: $y = ax + b$. The straight line inclination depends on the value of the "*a*" parameter or the tangent value of the inclination angle with the use of linear regression [20], [27], [38]. The agent computes the probability level of a buy decision when the coefficient value changes from positive to negative and the probability level of a buy decision is calculated when the coefficient changes value from negative to positive. The change in the agent's decision is made with the use of hysteresis, the level of which is defined by means of the coefficient Δ, the value of which should be higher than the transaction costs.

The algorithm can be described as follows:

**Algorithm 3**

```
Input:   $w=<w_1, w_2, .... w_M>$ //The vector of quotation value of the
         quotations consisting of  M quotations (current quotation and
         M-1 previous quotations – the M is calculated by  the genetic
         algorithm or determined by the user),
         preva  // the previous value the a coefficient.
Output:  The fuzzy logic decision D (value range [-1..1]) with respect
           to w and preva value.
BEGIN
Let  sumy:=0; sumx:=0.0; sumxy:=0; sumx2=0.
      // where: sumy means the sum of the value of M quotations,
      sumx means the sum of the particular quotations' number in
      vector (suma numerów poszczególnych notowań np. jeśli M=5 to
      sumx = 1+2+3+4+5 czyli 15) in the vector, sumxy means the
      sum of the products of the quotation value and particular
```

```
        quotation number in the vector, and sumx2 means the sum of
        the squares of quotation numbers in the vector.
       D:=0, countTRL:=0; //counter for fuzzification,
       maxcount:=0.  //maximum counter limit for fuzzification.
For (i=1;i<=M;i++)
     sumy:= sumy+$w_i$; sumxy:= sumxy+$w_i$*i; sumx=: sumx +i;
     sumx2:= sumx2+i*i; i:=i+1;
c:= sumx2*M-sumx*sumx.
If c=0 then c:=0,1.
a:=(sumxy*M-sumx*sumy)/c.
If (a=preva=0) or (a<0 and preva<0) or (a>0 and preva>0) then D:=0.
If (a>0 and preva<0) then
   If (countTRL>0) then countTRL=0.
   countTRL:=countRL-1.
   If (countTRL<-maxcount) then countTRL=-maxcount.
   D=countTRL/maxcount;
If (a<0 and preva>0) then
   If (countTRL<0) then countTRL=0.
   countTRL:=countTRL+1.
   If (countRL>maxcount) then countTRL=maxcount.
    D=countTRL/maxcount;
preva:=a.
END
```

### *D. The ConsensusFuzzy agent*

The *ConsensusFuzzy* agent (detailed in [22, 23]) is founded on the consensus theory [15, 16, 29] and determines the decisions on the basis of the set of decisions generated by other fuzzy logic agents in the system.

The algorithm is as follows:

**Algorithm 4**

```
Input:  A= {$D^{(1)}$, $D^{(2)}$, .... $D^{(M)}$ } //The profile consists of M fuzzy logic
          agents' decisions, where M – number of fuzzy logic agents in
          the system, $D^{(1)}$, $D^{(2)}$, .... $D^{(M)}$ – decisions of particular agents
Output: The Fuzzy logic consensus CON  (value range [-1..1])
according to A.
BEGIN
Let  CON:=0.
Determine a sequence B by sorting elements of A profile in an
increasing order.
$k_1$=(M+1)/2 the element of B.
$k_2$=(M+2)/2 the element of B.
Set CON as any value from interval [$k_1$, $k_2$].
END.
```

It should be noted that currently in the system there are 100 agents using fuzzy logic representation. This set of trading agents may be easily extended if required. The evaluation of the performance of presented fuzzy logic agents will be shown further in the article.

## IV. Experiments

The agents performance analysis is performed for data within the M1 period of quotations from the FOREX market. For the purpose of this analysis, a test was performed in which the following assumptions were made:

1. EUR/USD quotes were selected from randomly chosen periods, notably:
   - 17-04-2015, 9:40 am to 17-04-2015, 9:50 pm, (710 quotations)
   - 20-04-2015, 0:00 am to 20-04-2015, 7:00 pm (1140 quotations),
   - 22-04-2015, 0:00 am to 22-04-2015, 7:00 pm (1140 quotations),
2. At the verification, the strategies (signals for open long/close short position-equals to 1, close long/open short position-equals to -1) of the Supervisor are based on different decisions' probability levels calculated by fuzzy logic agents described in section III (the example of strategy is presented in Figure 3, where the green line means the "long position" and the red one the "short position").
3. It was assumed that decisions' probability levels for open/close position are determined by the genetic algorithm (on the basis of earlier periods).
4. It was assumed that the unit of performance analysis ratios (absolute ratios) is pips (a change in price of one "point" in Forex trading is referred to as a pip, and it is equivalent to the final number in a currency pair's price).
5. The transaction costs are directly proportional to the number of transactions.
6. The capital management - it was assumed that in each transaction the investor engages 100% of the capital held at the leverage 1:1. It should be pointed out that the investor may define another capital management strategy.
7. The performance analysis was performed with the use of the following measures (ratios):
   - rate of return (ratio $x_1$),
   - the number of the transaction,
   - gross profit (ratio $x_2$),
   - gross loss (ratio $x_3$),
   - the number of profitable transactions (ratio $x_4$),
   - the number of profitable transactions in a row (ratio $x_5$),
   - the number of unprofitable transactions in a row (ratio $x_6$),
   - Sharpe ratio (ratio $x_7$)

$$S = \frac{E(r) - E(f)}{|O(r)|} \cdot 100\% \qquad (1)$$

where:

$E(r)$ – arithmetic average of the rate of return,

$E(f)$ – arithmetic average of the risk-free rate of return,

$O(r)$ – standard deviation of rates of return.

- the average coefficient of volatility (ratio $x_8$) is the ratio of the average deviation of the arithmetic average multiplied by 100% and is expressed:

$$V = \frac{s}{\left|E(r)\right|} \cdot 100\% \,. \qquad (2)$$

where:

$V$ – average coefficient of variation,

$s$ – average deviation of the rates of return,

$E$(r) – arithmetic average of the rates of return.

- Value at Risk (ratio $x_9$) – the measure known as value exposed to the risk - that is the maximum loss of the market value of the financial instrument possible to bear in a specific timeframe and at a given confidence level [7].

$$VaR{=}P{*}O{*}k \qquad (3)$$

where:

$P$ – the initial capital,

$O$ – volatility - standard deviation of rates of return during the period,

$k$ – the inverse of the standard normal cumulative distribution (assumed confidence level 95%, the value of k is 1,65),

- the average rate of return per transaction (ratio $x_{10}$), counted as the quotient of the rate of return and the number of transactions.

8. For the purpose of the comparison of the agents' performance, the following evaluation function was elaborated:

$$y = (a_1 x_1 + a_2 x_2 + a_3(1 - x_3) + a_4 x_4 + a_5 x_5 + \ldots$$

$$+a_6(1 - x_6) + a_7 x_7 + a_8(1 - x_8) + a_9(1 - x_{19}) + a_{10} x_{10}) \qquad (4)$$

where $x_i$ denotes the normalized values of ratios mentioned in item 6 from $x_1$ to $x_{10}$. It was adopted in the test that coefficients $a_1$ to $a_{10}$=1/10. It should be mentioned that these coefficients may be modified with the use of, for instance, an evolution/genetic method or determined by the user (investor) in accordance with his/her preference (for instance the user may determine whether he/she is interested in the higher rate of return with a simultaneous higher risk level or lower risk level, but simultaneously agrees to a lower rate of return).

The function is given the values from the range [0..1], and the agent's efficiency is directly proportional to the function value.

9. The results obtained by the tested agents were compared with the results of the Buy-and-Hold benchmark (a trader buys a currency at the beginning and sell a currency at the end of an investment period) and the EMA benchmark (Exponential Moving Average -- a type of moving average that is similar to a simple moving average, except that more weight is given to the latest data).

Table 1 presents the results obtained in the particular periods.

Source: Experiment results

In general, it may be noticed that the fuzzy logic agents generated not only profitable decisions. In the performance analysis not only the rate of return was taken into consideration but also other ratios, including the level of risk involved in the investment. It may be noticed that the values of efficiency ratios of particular agents differ in each period: for instance the estimated values of such ratios as *Gross Profit* and the *Number of Profitable Consecutive Transactions*. The values of *Rate of Return, Sharpe Ratio* and *Average Rate of Return per Transaction* show significant dispersal among particular agents. It may also be noticed that in the case of the agents *WilliamsFuzzy, TrendLinearRegFuzzy* and *EMA*, the values of these ratios have shown variability in particular periods. The evaluation function provides the immediate choice of the best agent. It may be noticed that the values of the evaluation function oscillate in the range from 0.01 to 0.61.Thus, the use of this function reduces the deviation of the values of the ratios. The results of the experiment allow us to state that the ranking of agents' evaluation differs in particular periods. In the first period, the *ConsensusFuzzy* was the best agent, the *BollingerFuzzy* agent was ranked higher than *WilliamsFuzzy,* and *TrendLinearRegFuzzy* agents were ranked lower than the *EMA*. In the second period, the *BollingerFuzzy* was the best agent, and the *ConsensusFuzzy* and *TrendLinearReg* agents were ranked higher and *WilliamsFuzzy* was ranked lower than the *EMA*. Considering the third period, it may be noticed that the *WilliamsFuzzy* was the best agent and *BollingerFuzzy* and *ConsensusFuzzy* agents were ranked higher and the *TrendLinearRegFuzzy* was ranked lower than *EMA*. The *B&H* benchmark was ranked lowest in all the periods, and in second and third periods it generated the losses. It should be noticed that in the first period, the upward trend was observed, therefore *B&H*'s *Rate of Return* was positive. The second and the third periods shown a downward trend, and therefore the *B&H*'s *Rate of Return* is negative.

Taking into consideration all the periods, it may be stated that there is no agent ranked highest most often. Also, agents achieving the highest Rate of Return were not always ranked in the highest positions. The low level of risk was influenced by the ranks of the *ConsensusFuzzy* and *WilliamsFuzzy* agents. And, on the other hand, the *EMA* was often ranked low because of a high risk level (low value of *Sharpe Ratio*). Moreover, it generated a high number of transactions, so transactions costs are very high.

In the case of fuzzy logic agents, the value of buy-sell decision agents' evaluation is most often higher than the value of *EMA* and *B&H* benchmarks (see last row of Table 1). In the case of three-valued logic agents, instead, there are many cases where the value of buy-sell decision agents' evaluation is lower than the value of *EMA* and *B&H* (see [Korczak et al. 2013, 2014]). Also, the values of such ratios as *Rate of Return* and *Number of profitable transactions* were about several percent higher in the case of fuzzy logic. The risk measuring ratios (*Sharpe ratio, the average coefficient of volatility*) values were similar using fuzzy and three-valued logic.

The fuzzy logic has also demonstrated the better performance of the Supervisor strategies, because the opening/closing positions were generated closer to the optimal point determined by the genetic algorithm. In order to analyse the fuzzy logic agents' decisions efficiency it is also necessary to take into consideration the thresholds for open/close positions determined by the genetic algorithm (Table 2).

The optimal thresholds for opening/closing long/short positions differ in the case of particular agents. However, these levels often do not equal 1, 0 or -1(as in the case of three-valued logic). In addition, the levels for the open long position are different to levels for the close short position, and levels for the open short position are different to levels for the close long position.

TABLE II.
THRESHOLDS FOR OPEN/CLOSE POSITION

| Agent | Open Long | Close Long | Open Short | Close Short |
|---|---|---|---|---|
| BollingerFuzzy | 0.38 | -0.72 | -0.98 | 0.37 |
| WilliamsFuzzy | 1.00 | -1.00 | -0.73 | 1.00 |
| TrendLinearRegFuzzy | 1.00 | -0,88 | -0.89 | 0.88 |
| ConsensusFuzzy | 0.18 | -1.00 | -0.94 | 0.27 |

Source: Experiment results.

Therefore, the fuzzy logic agents may suggest the "out of market" status - in a period of uncertainty on the market - in a broader scope than three-valued logic agents.

## V. CONCLUSION

The fuzzy logic agents in the a-Trader system take independent buy-sell decisions with a certain level of probability. The analysis results presented in this article allow us to draw the conclusion that the application of fuzzy logic as an agents' knowledge representation allows for opening/closing long/short positions closer to the optimal level than the agents based on the three-valued logic.

In consequence the prediction performed by a-Trader were more precise, in periods with both upward and downward trends.

The implementation of fuzzy logic entailed the development of new agents and new trading strategies. The computational complexity of fuzzy logic algorithms is not higher than in the case of three-valued logic, so the computing time of trading positions was almost the same.

It can be also concluded that depending on the current situation on the FOREX market, the level of performance of a particular agent changes. There is no one agent which definitely dominates over the others. The automatic setting of the best agent in time close to real time is performed by the use of the performance evaluation function. It has, in turn, a positive influence on investment effectiveness.

Currently tests are being performed on the implementation of the fuzzy logic agents using fundamental analysis and the analysis of experts' sentiments. It is also planned to evaluate the a-Trader system on more periods and other quotations pairs.

***Abstract*—The emergence of a closer relationship between cloud service providers in the cloud computing market is the inevitable consequence of the computing as utility concept. The closer cooperation creates competitive advantages for providers and users of cloud services as well. Capacities and services can be used in a collaborative and flexible way. Despite the numerous potentials of composite cloud services, trust, policy and privacy are the major challenges resulting from the distributed and flexible data handling. The paper derives requirements and solutions in the field of inter-cloud service communication with a special focus on security. The proposed architecture is evaluated with a sample collaborative business process of inter-cloud service interaction.**

## I. Introduction

IN 2008 vice president of Gartner Research Thomas J. Bittman published his thoughts on future development of Cloud Computing (CC). In the early monolitic phase, cloud services were built on proprietary architectures of dominant Cloud Service Provider (CSP), such as Google, Salesforce or Microsoft. The second phase vertical supply chain distinguishes itself by the development of first ecosystems of smaller companies within the CC market. New CSPs use proprietary Cloud platforms of dominant providers, i.e. Google App Engine or Microsoft Azure, in order to provide their own services. In the last phase, smaller providers unite to a horizontal federation. That way, the union increases earnings by expanding their capacity and reducing costs through more efficient resource allocation. In parallel, open interoperability standards of service communication in intercloud-environment are developed [1].

The creation of a closer relationship between CSPs on the CC market is a inevitable extension of the computing-as-utility concept, which is about providing computing resources as a service over the Internet. Users of cloud based services may benefit in terms of cost reduction by renting their own distributed, virtualalized IT-infrastructure, improving service robustness and preventing provider dependence by means of interoperability standards [2], [3], [4].

A close cooperation creates certain advantages in competition for providers of cloud services. By using other CSPs' capacities, providers may deliver their products and services even faster and more effective to their clients. Further, making use of virtualization technology reduces costs for a flexible and customizable IT-infrastructure. Its dynamic and smooth scaling has a positive effect on service deployment time. Due to dynamic outsourcing of computational services, power consumption costs for computer centres can be significally reduced [3], [5].

Beside several advantages of collaborative cloud services, cloud specific issues concerning the security of service communication in an intercloud environment still exist. Trust is an essential precondition in order to create an intercloud federation. Without trust, security of cloud-interactions can't be guaranteed. Policy is another issue concerning intercloud interactions. It is essential to have effective control mechanisms so potential policy clashes, which would affect the safety of the whole system, are detected and removed. Identity and data privacy are other challenges to intercloud communication since users of cloud services transfer their personal data to the CSPs. Appropriate tools for access and identity management are essential for data protection [2], [6], [5], [7].

The paper focuses on the creation of an intercloud architecture, which enables secure service communication in collaborative business processes. The second chapter consists of an overview of relevant theoretical concepts while the next chapter introduces and explains a collobarative process of payment transaction. Communication models of services in the Intercloud environment are analyzed in chapter four. Further, chapter five introduces a draft architecture and suggestions for its implementation. Finally, the conclusion completes the paper.

## II. Theoretical background

The following chapter deals with the theoretical basis of service communication in the intercloud environment. Special attention is paid to security aspects of service interactions in collaborative business processes. Table I gives a resume of criteria for safe service communication that will be elaborated in this chapter.

The work presented in this paper was funded by the German Federal Ministry of Education and Research under the projects PREsTiGE (BMBF 16KIS0082K) and LSEM (BMBF 03IPT504X).

TABLE I
CRITERIA FOR SECURE COMMUNICATION IN THE INTERCLOUD

| **Criterion** | **Challenge** | **Solution** |
|---|---|---|
| Interoperability | Diverse, partly proprietary communication protocols | Broker; standardized interfaces; hybrid approach |
| Robustness | Single point of failure; workload balancing | Distributed implementation of the IT infrastructure |
| Optimal service provisioning, service selection, and service allocation | Orchestration of services and dependency resolution in real-time; automated selection of QoS-Criteria | Central platform that fulfills the orchestration in the intercloud; mechanisms for conflict resolution in case of conflicting QoS policies |
| Access & identity management | Management of multiple accounts of service users and CSPs; Establishment of a secure trust context for service interaction | Outsourcing of credential management to third parties; digital identities; Identity federation with the use of protocols such as Security Assertion Markup Language (SAML), eXtensible Access Control Markup Language (XACML), OpenID, OAuth, WebID, and SSO; secure authentication methods; multi factor authentification |
| Trust | Establishment of a secure trust context; dynamic determination of trust; de-perimeterization | PKI, XACML and SAML based communication protocols; reputation based, dynamic trust index |
| Policy | Inconsistency; inefficiency; semantic interoperability; static, predetermined SLAs, that hinder the ad-hoc service interaction | Mechanisms for the combination of policies on cloud federation level; monitoring and conflict resolution; dynamically, automatically, and instantaneously created federation-level agreements |
| Privacy | data privacy; identity privacy | Encryption; anonymization; pseudonymization |

### A. *Intercloud environment*

The term *intercloud* is not standardized in scientific literature. Though terms like *cross-cloud* [5], *multicloud* [7] or *cloud-federation* [2] can be found, but summarizing author-specific definitions do not differ basically.

Our work is based on the definition of the Global Inter-Cloud Technology Forum: "A cloud model that, for the purpose of guaranteeing service quality, such as the performance and availability of each service, allows on-demand reassignment of resources and transfer of workload through an interworking of cloud systems of different cloud providers based on coordination of each consumer's requirements for service quality with each providers SLA and use of standard interfaces." [8]

If not explicitly stated different, our work uses the term *intercloud*. In the authors' opinion intercloud is a better definition for a multicloud environment since it deals with a highly integrated environment where service communication is structured by the use of coordinating instances. Fig. 1 describes a typical intercloud environment with different types of Clouds. Closer cooperation of CSPs enables the usage of different strategies for resource consumption like outsourcing and cloud bursting. Service users are either the end consumers or other CSPs as well.

By combining different CSPs' services, the problem of being dependent on one provider, so called lock in effect, is solved in the intercloud environment. Moreover, flexibility as well as scalability and robustness of the whole system can be improved, because all intercloud CSPs are able to provide identical services. Further, energy can be used more effectively [3], [4].

The heterogeneity of this environment is a special challenge for technical implementation on all levels of intercloud architectures. The cloud-spanning integration of services emphasizes the importance of availability and access speed of services. Interoperability of interclouds is reduced by proprietary interfaces that are needed for service interaction.

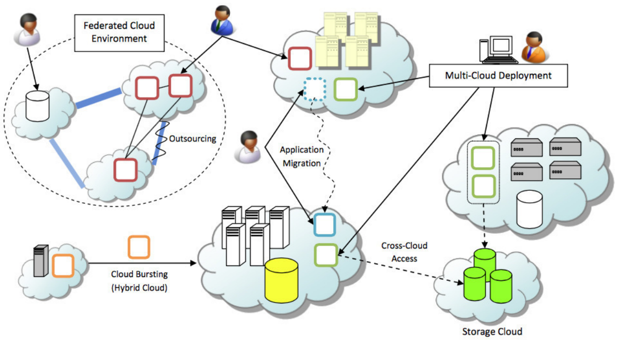

Fig. 1. Cloud interoperability [7]

In addition, the current service delivery model is incompatible with an open and dynamic collaboration, so using customer-specific tools leads the cloud interoperability to a vendor lock-in.

Due to limited access rights of unauthorized users and the bundling of provided services with other resources of the same provider, personalized service customization and cloud-spanning service composition are affected [6], [5], [4].

A secure collaboration of a multitude of CSPs in a heterogeneous environment is only enabled by complex intercloud architectures that meet several requirements. Fig. 2 provides an overview of intercloud architecture challenges. Several ideas of Toosi haven been applied [7]. This paper focuses mainly on the highlighted security relevant aspects.

From a technical point of view, interoperability can only be accomplished through a broker, which is in control of all communication between the CSPs, or via standardized interfaces. It's possible to use a hybrid of both ideas, depending on whether it is economically and technically useful. The

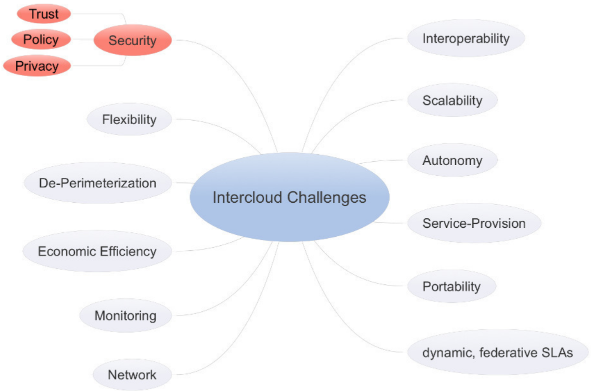

Fig. 2. Challenges of intercloud architectures

last option consists of an adaption of the architecture by all participants, such as the CSPs and the service users. A better option could be the introduction of a central platform, which would reduce the need for adaptation when joining the intercloud federation and which would provide a uniform interoperable vision of service communication.

### B. Cloud based collaborative business process

A collaborative business process is a dynamic process, run by several involved instances. All steps are conducted locally by interacting work-flow engines, following a common service definition. The engines of the interacting process partners are staying in control of all of their subprocesses [9].

### C. Trust

Due to de-perimeterization, trust is a very important factor in the intercloud environment. Since resources are outsourced to the CSPs, service users lose control over their personal data and that's why CSPs need to be trustworthy and service consumers need to be equipped with effective control mechanisms [6].

The transitive trust is essential when giving authorization to a third party. First, mechanisms of delegation have to allow a dynamic creation of service level agreements (SLA) in order to deny access to unauthorized user. Second, third parties must not modify service requests arbitrarily. Third, delegation has a time limit so service user representatives may only act in a certain time period legitimately. Another intercloud communication problem is the creation of a trust context between the interacting CSPs. Current intercloud trust models are based on a public-key-infrastructure-system (PKI), which judges the trustworthiness of entities in an absolute way and is therefore not suitable for a dynamic certification. The reputation-based trust complements the trust-context creation with dynamic aspects. When using parameters of reputation, utilizing relatively trustworthy computing resources in the intercloud is given, if they match with practical experience values of participating CSPs. Hence, it is possible to create a real trust federation along with third parties [10], [7].

Federated identity management is very important in the intercloud environment. It is possible to create an identity federation, which will support the Single-Sign-On (SSO) approaches and the management of digital identities by using formalized internet protocols like SAML and XACML specifications as well as open-source ones like OpenID, Oauth and WebID. This results in taking charge from interacting CSPs by outsourcing the credential management [5].

Literature addresses other dynamic and scalable approaches of confidentiality. The friend of a friend approach is interesting, since it provides machine-readable ontologies for object description. Despite of security concerns, the approach is flexible and executable without a centralized database [7].

### D. Policy

Policies are guidelines for the execution and monitoring of the interactions between the CSPs. Because of its inconsistency and incompatibility, policy-heterogenity causes the main security risk in an intercloud environment. Conflicts arise from a collision of local CSPs' policies and federated policies.

Policy-inconsistencies especially arise from a collision of access guidelines in distributed environments with a multitude of interacting entities. Different policies may be contradictory to each other if they have different effects on entities and their attributes. An exception occurs when two policies affect the same instance differently while being hierarchically linked. A policy-correlation leads to a partial conflict, where two overlapping policies treat one certain object differently, but only one of the two policies allows overlapping.

In an intercloud environment, policies can be collected in a list of guidelines, which could lead to significant reduction of the communication performance of access authorization. Firstly, policy-redundancies may occur in a way that one request is mapped to various policies with identical effects on one and the same object. Secondly, when combining policies, attention has to be paid to semantical and syntactical correctness of the new federated policy [6].

The SLAs complete the IT policies with legal aspects and are essential for policy-compatible intercloud interaction. At the moment, SLAs are limiting the dynamic intercloud communication because they reduce the flexibility of CC business models. More complex SLAs, which possess powerful management and monitoring tools, are essential for proper legal data processing [6], [7].

Another important policy aspect is quality of service (QoS). It helps clients to choose an appropriate service. The mechanisms of service selection have to be able to harmonize various rivaling and maybe excluding QoS objectives [2], [11]. The incorporation of QoS factors makes an intercloud system more flexible, customer-oriented and eventually more attractive to potential user.

### E. Privacy

Privacy is a strongly by legal restrictions influenced concept, which assures control over information and information flows and restricts access for illegitimate entities. Different laws (i.e. European and American) apply to the term Privacy in different ways, especially in terms of sensibility of personal data and legal precautions. Countries of the EU apply the data minimization concept: no access to personal data unless absolutely necessary. Service users may explicitly prohibit the usage of their personal data for advertising purposes. The USA do not have an equivalent to those legal restrictions [12], [13]. Therefore, it is extremely important to compare and adjust definitions, especially in terms of trans-regional interclouds.

The technical realization of these privacy requirements is a complex issue. It is necessary to distinguish between two basic privacy-strategies: data privacy and identity privacy. Data-privacy strategies consist of altering the content beyond recognition so data cannot be used by third parties easily. Data-perturbation completes original with *noise data* which subsequently becomes unreadable for non-legitimate instances. Unfortunately, the resulting redundancies may cause scalability problems in the intercloud. By using compression methods, cost for communication and request-handling can be cut. Perturbation approaches have to be flexible in order to find a compromise between the user and the privacy guarantee [13], [6].

Encryption by data transformation is one common privacy method. Besides several advantages, this method causes restrictions in the intercloud environment, from a service-communication point of view. First, data-utility aspect plays a more important role than the safety aspect. Second, *data at rest encryption* blocks data indexing and data search. Finally, no efficient methods for operation of data at transit are developed yet [13].

Identity privacy strategies aim at hiding the real identity of interacting instances from unauthorized user. By using anonymity, one CSP can authenticate a user without revealing his true identity. Unlinkability hinders CSPs from identifying users by using a transaction portfolio [14].

## III. Collaborative sample process

After providing basic information about intercloud environment in chapter II, an example is introduced in the following section. Building up on the example, chapter V will deal with the implementation of an architecture.

### A. Scenario

In the last few years providers like Google and Apple have contributed their solution of mobile payment to the market with Google Wallet and Apple Pay. Despite being two of the most successful companies, support by commerce for these providers is still missing. A better solution consists of retailer and customer are working with a neutral and flexible intermediary, i.e. payment provider.

This example deals with the scenario of electronic payment via smartphone. Mobile payment comprises customer authorization and realization of payment via smartphone. Instead of paying via credit card, the smartphone has to be put on a terminal to initiate the payment. Through near field communication (NFC) two electrical devices, in direct physical proximity, are able to exchange data. In this case, the payment amount is authorized via smartphone. After having put the smartphone on the terminal, the central CSP is contacted and requested for user identification of the smartphone. Afterwards, the user has to authorize the payment via finger print or PIN. When successfully matched, the transaction will be initiated by the central CSP. In order to explain which accounts are involved and which internal processes are initiated in the Central CSP, the process shown in fig. 3 will now be explained in more detail.

### B. Coupling of customer's account and payment provider

In this scenario, the CSP acts as an intermediary. The CSP does not have an account and cannot transfer any payments, it only delivers the payment order to the payment provider. Payment providers do not necessarily have to be one and the same nor even similar. Examples of payment providers may be PayPal, Visa or the German website sofortueberweisung.de. Payment provider have to be added to the central CSP in advance. This process is called linking and should ideally only be executed once. While linking, the user is authenticated at the provider and receives two tokens (access and refresh token). The client, in this case the central CSP, uses these tokens to authenticate future orders at the payment provider. After the linking, all payment providers are available via the CSP service and account. If a customer wants to use the payment service of the central CSP, only the authentication to the CSP is needed.

### C. Service discovery and execution of the transaction

Fig. 3 provides a detailed overview of the introduced process so all internal steps of the central CSP are visible. After placing the smartphone on the terminal and after the successful authorization, an automatic selection of a payment provider follows, according to rules and settings the customer has set before. Useful rules involve e.g. minimal transaction costs. Afterwards, the payment is initiated at the provider's side.

If the transaction failed, another provider will be chosen according to the rules set by the customer until the transaction is finally successful. This confirmation will be forwarded to the retailer in order to print the receipt. It is important to mention that the BPMN model is only constructed for a positive result. The exception of not finding an appropriate payment provider, due to strict selection criteria or only negative responses, has to be considered in future work.

### D. Evaluation

A big advantage in the introduced scenario is that the central CSP is provider neutral. If the CSP integrates new providers, customers and retailers will benefit. Further, the CSP is able to provide its orchestrated service as a SaaS in the intercloud federation.

## IV. Service Communication Models in heterogeneous Intercloud Ecosystems

The selected communication models of services provide a comprehensive conceptual view on the intercloud communica-

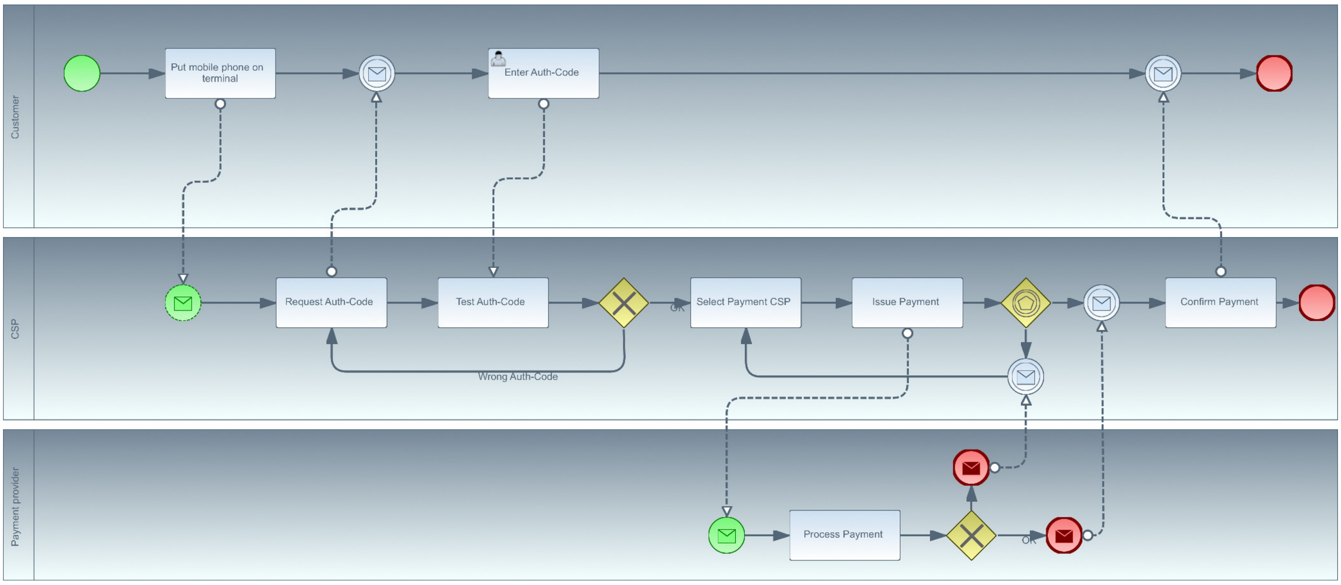

Fig. 3. Collaborative sample process

tion and provide a basis for our proposed architecture. Since some intercloud models, e.g. Demchenko and Makkes [15], [16], [17] and Lloret [4], are well known but focus on special areas of CC, e.g. Demchenko and Makkes focus on IaaS, we present only those models that are relevant for our work.

### A. Intercloud Domain-based Trust Model by Bernstein

The intercloud roots (IR), intercloud exchanges (IE), intercloud gateways (IG), and cloud computing resource Catalogs (CCRC) provide the basis of the domain-based trust model proposed by Bernstein [10]. Fig. 4 provides a comprehensive view of all components as well as the corresponding technologies and protocols.

The IR handle the broker functions to operate the service communication. They are structured hierarchical and self reproducing like nodes in peer-to-peer networks. IRs act as security trust service providers, handle the namespace, dynamic naming of the intercloud, and host the distributed CCRCs [19], [18].

The communication and collaboration of the heterogeneous intercloud environment is supported by the IEs, which utilize the information of the CCRC to provide an optimal computation resource matching. IEs act as the trust agents of one domain by collecting information of the confidentiality of other domains and providing the trust level of a domain while initiating the interaction between the domains [10].

The IGs provide authentication mechanisms and standards and protocols for interoperability. Another responsibility of the IGs is to check for availability of resources, the state of interactions and to transform the parameters of the communication from one cloud to another [10].

The CCRC provides a holistic and abstract view on computing resources in the intercloud federation. It enables the resource adjustment between individual CSPs on the basis of selected preferences and constraints. The catalog stores information on available resources, interoperability standards and guidelines, and SLAs [18], [10].

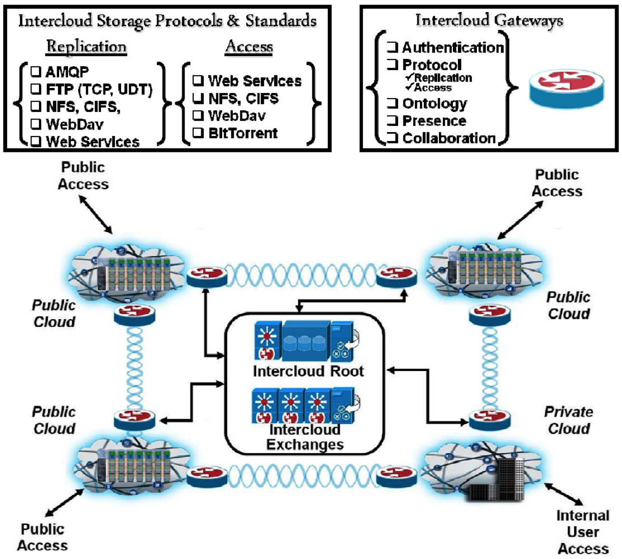

Fig. 4. Intercloud domain-based trust model by Bernstein [18]

The trust management of the intercloud consists of two components, the PKI provides services for the use of trust certificates and trust chains. The fixed-term certificates for short-term transaction are issued by IEs, the long-term transactions are certified by IRs. The PKI is of limited suitability for the certification of processes in the intercloud, since it classifies entities either as trustworthy or not [10].

CSPs are differentiated into confidentiality domains based on the dynamic, time-dependent trust index. The trust index

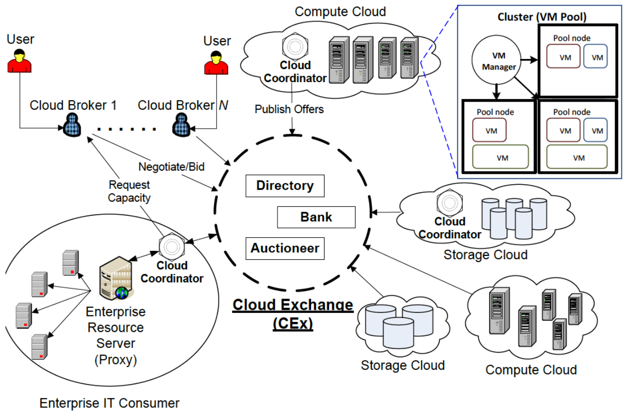

Fig. 5. Utility-oriented federation of clouds by Buyya [2]

comprises information on the CSP and its reputation. The application of the trust index enables the consumption of relatively trustworthy resources that may be located in another domain with a lower trust index [10].

### B. Utility-oriented Federation of Clouds by Buyya

Buyya proposed an intercloud architecture that focuses with economically efficient resource matching in the cloud market. The major components of the model are cloud coordinator (CCr), cloud broker (CB), and cloud exchange (CEx) as shown in fig. 5. The CCr, which is integrated into the CSPs' infrastructure, manages domain-specific clouds. It provides a programming, management, and installation environment for applications in the federation of clouds. The CCr acts as a proxy for communication between the participating CSPs and manages all corresponding processes for information exchange [2].

The CCr's service matching process is deeply influenced by economic aspects, e.g. energy consumption, heat output, and node utilization of virtualized cloud environments. It is also influenced by the QoS optimization problem that the service consumer may have selected multiple conflicting QoS objectives. The CCr resolves such conflicts by applying heterogeneous optimization algorithms [2].

The CEx manages all service requests and offers of the cloud federation and supports a SLA based matching process. Further it supports the exchange of information on the current state of allocated resources between the individual CSPs. Given that all participants provide standardized interfaces a directory service enables the CE to lookup desired service offers or requests. The trading process is managed by a dynamic bidding based service, which provides a trustful auctioneer and takes care of offer updates in the cloud federation. The payment management is implemented by an autonomous banking entity, which enforces the agreements on financial transactions of the global CExs. To ease the handling of financial transactions the integration of cloud based accounting systems with existing online payment systems, e.g. PayPal, is taken into consideration [2].

Finally, CB identifies appropriate cloud services on behalf of the users and agrees on the QoS based resource reservation with the CCrs. If a cloud is not able to process an incoming request locally, CB creates a new query comprising QoS information and forwards this query to the CE. Essential conditions for the successful completion of the matching process are: feasibility of QoS targets specified by the user and the equal resource distribution to the individual nodes [2].

### C. Cross-Cloud Federation by Celesti

Celesti proposes a process oriented ad-hoc cross-cloud federation, which comprises three phases: in the discovery phase a cloud looks for available resources of other clouds. Afterwards the most appropriate CSP is selected during the matching phase. Finally the authentication phase comprises establishment of a trust context for secure communication of the interacting clouds. The model distinguishes two types of clouds: the home cloud requests compute resources that are offered by the foreign cloud [5].

Fig. 7 provides an overview of the entities and components involved in creating the intercloud federation. In order to form a cross-cloud the internal architecture of the participating cloud must be converted to the following 3 layer structure, first: virtual machine manager (VMM), virtual infrastructure manager (VIM), and cross-cloud federation manager (CCFM) [5].

VIM is a dynamic orchestrator for virtual environments and enables the creation, installation, and management of virtual environments regardless of the underlaying technology. If the home cloud is not able to instantiate another virtual machine due to a lack of additional resources, it forwards the request to the cloud federation. Subsequently the VIM selects a suitable foreign cloud. To securely share and transfer resources with each other the VIMs of the individual clouds create a trust context with each other [5].

The CCFM orchestrates the three phases of the cross-cloud federation. The discovery agent supports the discovery process of the dynamic intercloud environment by publishing and updating the information on offered cloud services on behalf of the individual cloud [5].

The match-making agent makes authorization decisions based on policies and performs compatibility testing of communication policies of interacting clouds. In case of incompatible policy languages the match-making agent applies some transformation algorithms [5].

The authentication agent provides credential management to the cross-cloud federation and coordinates the creation of a security context for the cross-cloud communication using identity providers. By applying SSO after authenticating once with the system the services can be consumed without additional security checks. Using digital identities, which are provided by external identity providers, home clouds can connect to any foreign cloud [5].

The security context in cross-cloud federation is created in two layers: on authentication agent layer and on VIM layer.

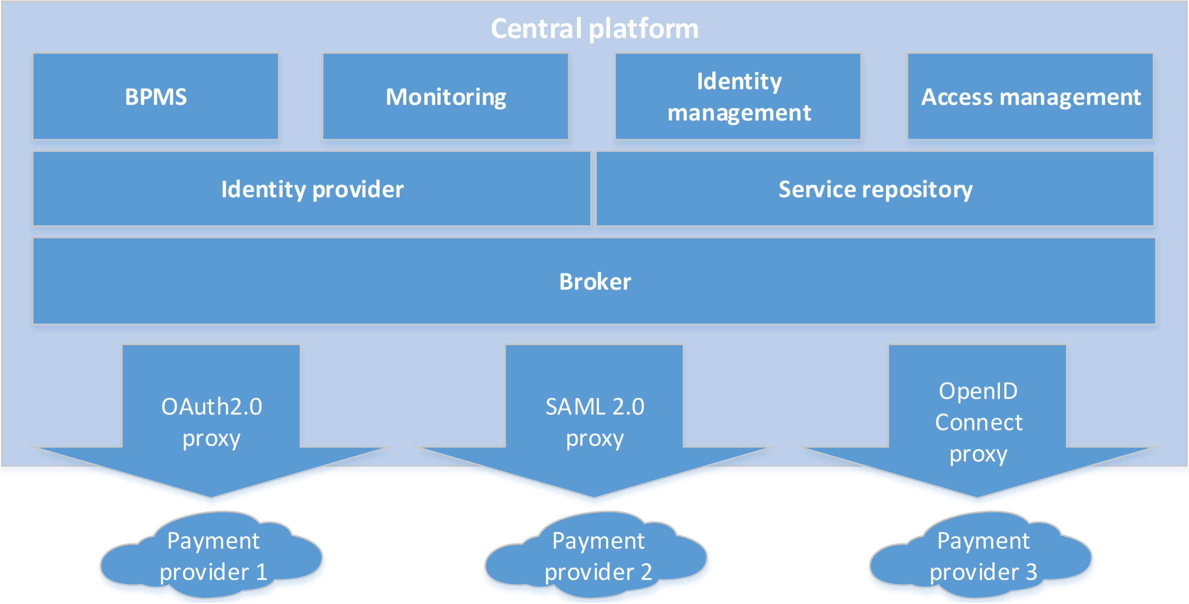

Fig. 6. Intercloud architecture for collaborative business processes

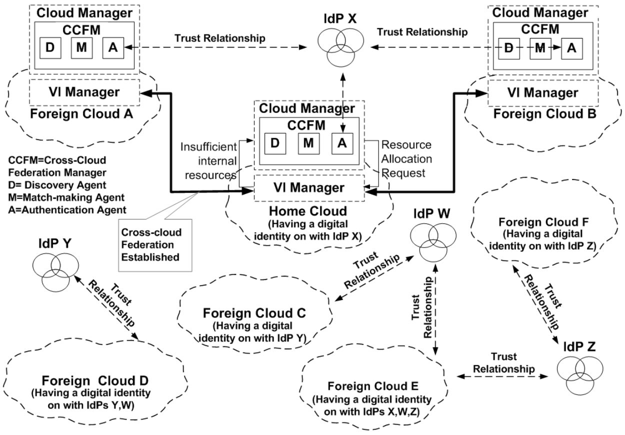

Fig. 7. Cross-Cloud federation by Celesti [5]

The latter act on a lower level compared to the CCFM and facilitate cross-cloud resource provisioning [5].

### D. Proxy-based Computing Cloud Framework by Singhal

Singhal proposes another way of tackling the secure communication problem in intercloud environments. In this model the proxy is the central component, which establishes secure communication without predetermined agreements or standardized interfaces and specification [6].

A proxy is an intermediary for traffic between interacting clouds and provides a confidential and trustworthy computing platform, which protects the user data and cloud applications from malicious attacks. The strategic proxy deployment is crucial for efficiency. Thus, in the proxy selection criteria such as latency and forecasted load are taken into account [6].

Since the proxies act on behalf of the users or CSPs, a mechanism for secure delegation is necessary. This mechanism includes dynamic SLA creation, prohibit the proxy access on the processed data, as well as protection against malicious proxy interaction, e.g. modification of transactions. Further a proxy is only allowed to act on behalf of an entity as long as its task is not completed. Such secure delegation can be realized by warrant-based-proxy signatures, PKI or OAuth protocol. Proxies monitor and eliminate conflicts based on policy heterogeneity while processing the service request to avoid potential security risks [6].

A cloud service can be accessed by multiple proxies, these proxies can be assigned different, specific roles. They operate automatically and need no further interaction with the commissioned instance. This interaction is realized by allowing proxies to communicate with other proxies and to initiate necessary service request by themselves. Hence, secure collaboration of multiple CSPs without predetermined agreements is possible [6].

The proxy based model features five types of intercloud architectures: cloud-hosted proxy, proxy as a service, peer-to-peer proxy, on-premise proxy, and hybrid proxy infrastructure. The individual scenarios differ in the implementation strategy of proxy instances.

In the cloud-hosted proxy scenario proxies are integrated into the infrastructure of the individual CSPs. This approach is advantageous from the CSPs point of view, because the CSPs maintain control over the proxies and can adjust the proxies to specific needs [6].

The proxy-as-a-service scenario proposes an autonomous proxy cloud, which provides proxies to the CSPs. Users can create an account either on the proxy cloud or the CSP's cloud. In both cases resource requests are handled by the proxy [6].

The peer-to-peer-proxy scenario organizes the proxies in a P2P-manner. The proxies are managed collectively by the CSPs or proxy providers or autonomously by the proxy nodes [6].

In the on-premise scenario proxies are part of the client's infrastructure. Users can submit their request either via a proxy or directly to the CSP. If the provider is not able to provide the requested resource this will be forwarded to the proxy that will continue the service discovery process with other CSPs [6].

If some or all of the previous variants are combined this is called hybrid-proxy infrastructure. The proxy selection may depend on the type of the requested service and infrastructural peculiarities of the CSP. This approach provides the greatest flexibility in term of intercloud creation [6].

## V. Architecture for secure intercloud communication

In this section we propose an architecture for secure intercloud communication in terms of trust, policy, and privacy and evaluate a prototype of this architecture with the sample process of chapter III.

### A. *Intercloud architecture for the sample process*

Basically the collaborative communication of the services is organized by a central platform, which applies concepts of the work shown in the previous section. To enable the communication with the payment providers of the sample process, we propose to use proxies to bind the payment services to the platform. Such a modular handling is necessary as there is no common standard for authentication in CC. Fig. 6 shows the main components of the architecture for secure collaborative business processes. OAuth 2.0, SAML 2.0, and OpenID Connect are the selected proxies that we have implemented as a proof of concept because these are the most widely used authentication standards in CC.

The components and a short description of their tasks is shown in table II. The connection of services through proxies enables flexible scaling of the platform. Another advantage is that the maintenance of the communication infrastructure remains in the CSPs' responsibility. In addition to the integration of the payment process into existing service ecosystems the payment process can be provided as a separate service that can be used by multiple CSPs. The evaluation environment assumes the integration of a payment terminal at the merchants, but there are far more scenarios possible. Since the service is part of payments it requires very high security standards. Hence, sophisticated security components need to be incorporated into the platform. The identity and access management system ensures it is clearly decidable and accountable who is authorized for performing certain actions with the resources, e.g. who is allowed to issue a payment. Such a system needs to authenticate with other system. Hence, protocols for authentication and authorization need to be supported. The most widely used protocols for authentication and authorization are shown in table III.

TABLE II
Core components of the architecture

| Kernkomponente | Funktion |
|---|---|
| BPMS | Business process management system to model, instanciate, and collaborative business process on the platform |
| Monitoring | Monitoring of the whole system |
| Identity Management | Secure and connect third party identities to the local identities; management of local identities |
| Access Management | Access policy enforcement and policy conflict handling |
| Service Repository | List of available services and their descriptions |
| Broker | Service selection and QoS |
| Proxy | Invocation of services |

The prototype we have implemented and evaluated for our research implements OpenID Connect. There are two reasons. On the one hand OpenID Connect is a protocol for authentication and authorization that is very new but already adopted or will be adopted in the very near future by plenty of the big CSPs, e.g. Google, Microsoft, and PayPal. On the other hand there are two kinds of protocols: centralized and federated ones. Since federated ones are more complex in terms of communication flow and the prototype should be recognized as a proof of concept we chose the federated OpenID Connect protocol.

When a business process is instantiated by the BPMS and the BPMS needs to perform a task of the business process, the broker selects an appropriate service of the service repository. The broker looks up the type of the service's invocation pattern and instantiates the right type of proxy. Then the proxy performs the actual service call and sends the data back to the broker. Prior to sending the user data to the proxy the broker applies privacy rules. This behavior is discussed in [20].

The proxies are composed of four internal components: communicator, privacy guard, data adapter, and service adapter. A service request first passes the communicator that ensures that all communication to the outside of the proxy is encrypted and secured in compliance with the policies. The privacy guard is applies the privacy policies to the payload of the service request by hiding, anonymization, and pseudonymization of data. The privacy compliant payload is then forwarded to the data adapter, which transforms the data from the internal data scheme to the payment provider's data scheme. This is necessary since every payment provider uses another set of parameters to issue the payment. Finally, the transformed payload is sent to the payment provider's service by the service adapter. After the procession of the service request the data goes the same way back threw all components of the proxy. While the data flows threw service adapter, data adapter, privacy guard, and communicator all changes applied to the payload are reverted. This approach ensures a maximal security and privacy level while consuming the service.

### B. Evaluation of the architecture

The proposed architecture ensures secure service interaction in collaborative intercloud scenarios with a maximal flexibility in terms of the participating cloud authorization protocols. Table IV shows the implementation of the requirements that have been put on the system.

## VI. Summary and outlook

This paper addressed the question how security challenges for service communication that arise due to the adoption of Intercloud environments can be addressed. To illustrate the identified challenges a sample business process has been introduced. This collaborative process that is operated by a central CSP is able to handle payment requests of merchants with a maximum flexibility in terms of the selected payment provider. To identify the optimal architecture multiple approaches of Intercloud service interaction have been reviewed. Based on the outcome of the reviews an architecture for secure service invocation in collaborative business processes has been developed. The architecture is based on proxies that are managed by a central broker engine.

During evaluation phase it turned out that this architecture is able to cope with the most challenges, e.g. interoperability, flexibility, scalability, and auditing. We also identified some limitations of the proposed architecture. First, due to the central management of the proxies it is necessary that the CSP provides enough resources to create and operate enough proxies, even when there are big peaks of requests. The centralized infrastructure also exposes the platform to the risk of outages if a component of the platform has a failure. To reduce this risk we implemented fault tolerance mechanisms into central parts of the platform on virtual machine level.

To ensure a maximal security of all components additional research is necessary. A first step has been made in [20], in this paper the communication flow and structure of the broker and proxy layer is described in detail. Another important field for additional research is the handling of access control to ensure data privacy throughout the whole business process.

TABLE III
EVALUATION OF AUTHORIZATION AND AUTHENTICATION PROTOCOLS

| **Criterion** | **SAML 2.0** | **OAuth 2.0** | **OpenID Connect** | **CAS** |
|---|---|---|---|---|
| Exchange format | XML | URL parameter / JSON | URL-Parameter / JSON | URL-Parameter |
| Transfer protocol | HTTP, SOAP | HTTP | HTTP | HTTP |
| Token size | $5.7kB$ | $77B$ | $121B$ | $35B$ |
| IdP discovery | x | | x | |
| SSO | x | x | x | x |
| Strengths | Encryption | Wide spread | Authentication & authorization | |

TABLE IV
EVALUATION OF THE ARCHITECTURE

| **Requirement** | **Description** | **Implementation** |
|---|---|---|
| Interoperability | Communication has to be independent of the used authentication and authorization protocol | By the use of proxies the actual authentication and authorization protocol is been hidden from the other components. The broker instantiates the right proxy for the service provider. |
| Scalability | Flexible expandability | By adding new proxies the system can easily be expanded for new service providers. |
| Reliability | High availability of the payment service | In case on payment provider is not available the broker select the next suitable service provider. Hence, only if all suitable payment providers are unavailable the whole service is not working any more. |
| Optimal service provisioning | Service discovery, separation of combined services | The platform is divided into the components central platform, broker, service repository, and proxies |
| Access & identity management | Secure management of multiple identities; secure trust context | The identity management is done by the identity management system that is part of the central platform. This ensures no information is transferred to third parties unnecessarily. Additional firewall policies to protect the central platform are applied. Necessary communication on identities is realized by proxies, which implement secure authentication and authorization protocols. |
| Trust | Trust context | Externally by the use of proxies. Our sample process uses OpenID Connect and its PKI |
| Policy | Policy resolution | Monitoring |
| Privacy | Data & identity privacy | All communication, internal and external, is encrypted. The broker applies privacy control on the data. |

***Abstract*—This paper presents issues related to a process of the automatic summarization of the text documents connected with economic knowledge performed by the cognitive agents in an integrated management information system. In contemporary companies, the unstructured knowledge is essential, mainly due to the possibility of obtaining better flexibility and competitiveness of the organization. Therefore more often the decision are taken in the enterprises on the basis of the summaries. The first part of the paper shortly presents the state-of-the-art in the considered field; next, the summarization process in the Cognitive Integrated Management Information System is characterized; the case study related with the summaries generating agent is presented in the last part of this paper.**

## I. Introduction

IN contemporary companies the unstructured knowledge is essential, mainly due to the possibility of obtaining better flexibility and competitiveness of the organization. The unstructured knowledge supports structuralized knowledge to a high degree. It is mainly stored in natural language, so it is processed with symbols (not numbers). One example of unstructured knowledge is experts' opinion about a predicted currency trading. Some experts may argue that the exchange rate of the currency will rise, others that it will decrease, and still others that it will remain unchanged. In addition, expert opinions include the reasons for these predictions. The number of such opinions in the Internet is usually very large (hundreds, thousands of the opinions). An investor who makes a decision, for example, on the financial markets, needs to analyze and summarize these opinions to formulate the correct decision. However, the manual realization of these processes is extremely difficult, and often impossible, due to time constraints [14]. Thus, often the processes of the analysis and summarization of the text documents are made automatically by computer systems, including the integrated management information systems. They may be constructed, for example, on the basis of the number of the cognitive agents [16]. Generally speaking, the cognitive agent is a smart program that not only concludes on the basis of the data received, takes specific actions to achieve the desired objective (this can be, for example, decision support), but also learns at the same time gaining experience. An example of a cognitive agent's architecture is The Learning Intelligent Distribution Agent (LIDA) [35]. This is a hybrid architecture that allows for symbolic and emergent knowledge processing and uses the semantic net with node and links activation level (the "slipnet") [19] to represent a knowledge.

Broadly understood, the analysis of the text documents is mainly based on document retrieval, information extraction, text mining and natural language processing. Summarization, instead, can include the contents of a document or set of documents. The basic idea of summarization is to get a summary that contains the most important information from the source document. One of the parameters of this process is the text volume. A good document summary frees the system user (investor, manager) from the need to read and analyze all of the text documents, and give the opportunity to focus his attention on aspects of the rapid and effective decision.

So far, the methods of summarization of the electronic text documents, containing economic knowledge and represented by the "slipnet" (semantic net with node and links activation level), has not been developed. It should be noted, however, that this type of representation allows the processing of both

978-83-60810-66-8/$25.00©2015, IEEE

knowledge represented in a symbolic way and knowledge represented in a numerical way.

The aim of this paper is to develop a method for automatic summarization of the electronic text documents, containing economic knowledge. This method will be implemented in the architecture of the cognitive agents running in the Cognitive Integrated Management Information System (CIMIS). The agent-based approach is used mainly because it enables taking automatic decisions and performing actions on the basis of summarization results.

This paper is organized as follows: the first part shortly presents the state-of-the-art in the considered field; next, the summarization process in CIMIS is characterized; the case study related with summaries generating agent is presented in the last part of paper.

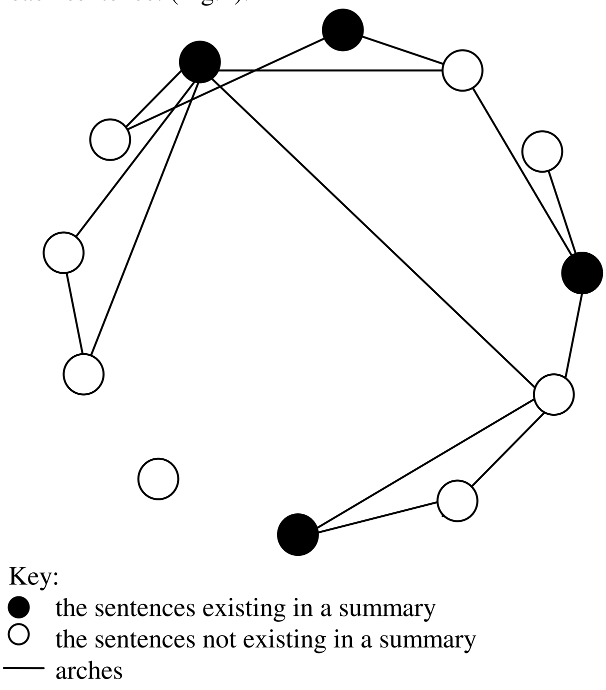
## II. RELATED WORKS

The problems of automatic summarization have been widely considered in many papers and practical solutions. The simplest method for creating summaries is based on the assumption that the weight of the sentence depends on the weight of its words, calculated on the basis of their frequency in the text. In addition to the counted weight of words, other factors are also taken into account, such as the position of sentences in the text and the occurrence of words in the title or header [30]. An important work on the problem, was the project Parseval/GEIG, where the phrase structure grammars have been compared [4]. In this project using an anaphoric relations to create appropriate groups (consisting of paragraphs) has been proposed. The authors propose is that either all members of the group belong to the summary, or no element of the group appears in the summary. The solution proposed by [24] was based on several standard heuristics (e.g. sentence length, sentence position, keywords). However, the poor quality of the summaries generated using these tools has led to the search for alternatives. Another solution was tf-ifd system, used in ANES (Automatic News Extraction System), which determined the weight of words based on the number of their instances in the analyzed document [5]. R.Barzilay and M.Elhadad [3], instead, used an algorithm based on lexical chain for automatic creation of summaries. In the Tipster project a series of activities focusing on tasks such as summarization, translation and searching, were realized [18]. The paper [20] presents an overview of the different methods of summarization. Description of the elements of natural language processing and information retrieval methods have been widely presented in the works [2] and [7]. D.Weiss [43] presents algorithms of lemmatization and stemming, and a hybrid solution combining both approaches. P.Sołdacki [38] devoted his doctoral dissertation to an automatic processing of documents in natural language, in particular the use of text analysis methods for the shallow processing of documents in Polish. The problems with the automatic creation of summaries of texts document in Polish were well represented in the work of A.Dudczak [10]. Also E. Branny, M. Gajecki [46] present an algorithm for text summarization in Polish. Most of the mentioned works have been related to the creation of a single document summaries. Issues related to the creation the summaries of a set of documents can be found, for example, in the works [9], [30]. The papers [14], [27, 28] present two main streams of research related to the analysis of natural language texts:

- the formal description of the language and the real world's right,
- the statistical methods that bypass the problem of understanding of the text for the analysis of the prevalence of selected dependences.

J. Gramacki and A. Gramacki [15] used selected algebraic methods of analysis of textual data for automatic creation of summaries. Their paper presents the data structures and data modeling, which showed the essence of the reduced vectors' space of the mapped texts.

The paper [40] however, concerns the use of semantic roles in the process of summarization. The work [25] proposes a system of summarization of text documents by using a semantic net (semantic graph) for knowledge representation and mechanisms of the support vectors in the learning process. The methods rely on creating a new node for each sentence. (Fig.1).



Key:
● the sentences existing in a summary
○ the sentences not existing in a summary
—— arches

Fig 1. The example of semantic graph.

If two sentences have common word then these sentences' nodes are connected by an arc (if the sentences have more than one common word - for each pair a separate arc is created). Sub-graphs whose nodes are connected by arches with other sub-graphs contain statements that define a good topic, while the nodes of sentences that have the highest cardinality (most arches) are the most significant sentences in the considered text, and should be included in the summary. However the applied semantic net does not include the activation levels of nodes and arcs.

Taking into consideration issues related to a text documents analysis process, nowadays the hybrid methods for processing unstructured knowledge are used; the methods involve structuralization of knowledge, followed by symbolic processing (e.g. with the use of expert systems or genetic algorithms) or converting knowledge into numerical representation followed by numerical processing (e.g. with the use of neural networks or fuzzy logic systems). In both cases, for knowledge processing, the following methods are used [32]:

- Information Retrieval,
- Information Extraction,
- Text Mining,
- Natural Language Processing.

There are two categories of analysis of text documents in the literature of the subject (for example [38]):

1. Deep Text Processing, that is a linguistic analysis of all possible interpretations and grammatical relationships occurring in natural text. The full analysis can be very complex. Moreover in many cases, the information obtained in this way may not be necessary. For this reason, more and more often there is a tendency to carry out only a partial analysis of the text, which may be much less time-consuming and is a compromise between precision and performance.
2. Shallow Text Processing, is defined as the analysis of the text to which the effect is incomplete in relation to the deep analysis of the text. The usual limitation lies in the identification of non-recursive structures or of limited recursion level, which can be diagnosed with a large degree of certainty. The structures requiring a complex analysis of the many possible solutions are overlooked or analyzed in part. The analysis is addressed mainly at recognizing proper names, noun phrases, verb groups without resolving their internal structure and function in a sentence. In addition, recognized are some main parts of sentences, for example the judgment or the judgment group.

There are several different methods within these categories.

For information retrieval the Boolean Logic Model (BML) or ranked-output systems are used [39]. A BML query consists of words or phrases concatenated with logical operators, such as AND, OR, and NOT. As a result, the set of documents is divided into two sub-sets: the first sub-set consists of documents matched with the query and the second sub-set consists of documents mismatched with the query. A ranking system, using vector algebra, assesses the probability of the content of documents matching the content of the query, and on this basis the ranking of the found documents is created. In this approach, for example, the Vector Space Model, Probabilistic Model or Interface Network Model are used [34].

One of the methods used in the shallow analysis of text documents is machine learning [33]. Under this method there are used, among other things, the naive Bayesian classifiers [12] and support vector machines [21]. In these approaches an analysis is made of the prevalence of individual words (terms) in the documents concerned. For example, in work [42] with the use of support vector machines it was determined, that the product attribute is considered part of the text, whereas in work [43] polarity of the opinion was expressed during the passage of the text.

Another method of both deep and shallow analysis of text documents is the use of rules, on the basis of which identification (annotation) of pieces of text for a specific topic is performed. Such rules are based on templates, taking into account the relationship between words and semantic classes of words [37]. The basis for the generation of rules can be automatic or manual analysis of the annotated corpus [31]. An analysis of documents by using rules rely on identifying the importance of text fragments in accordance with the principles enshrined in the rule. In certain cases it can be thought of as assigning the document to the category. The analysis of text documents with the use of the rules has been used, among others, to the extraction of spatial relationship [45], identification of the requirements for the IT projects~~,~~ expressed on Internet forums [41] or extraction of information from real estate ads [33]. In turn, the article [1 shows the characteristics of the project Semantic Monitoring of Cyberspace, that uses rules analysis in order to search cyberspace offers regarding illicit trafficking in drugs.

The text files are often represented in databases with key words contained in the document (symbolical representation of knowledge). However, such representation makes it difficult to compare documents, especially when it comes to measuring distance between documents - distance meaning similarity between the documents. Increasingly semantics nets are used to represent text documents, for example the topic maps. In work [11] it was found that the topic map allows to record information ontology and data taxonomy, structured semantically and at the same time it allows for knowledge mapping (both structured and unstructured) on a wide variety of hierarchical dependencies that exist between economic concepts and semantics (the concept of this type include, among others, ~~to~~ text documents in the field of management and economics).

However to match fully the needs of decision makers, a decision structure must consist of the level of certainty because the economic decision most are taken in terms of risk or uncertainty. Nowadays such structures [36] and consensus algorithms as regards these decisions~~,~~ are elaborated [23, 47, 50].

Thus it is possible to determine a certainty level of semantic relations between nodes (topics). In case of the economic knowledge it is very important issue, because the decisions making on the basis of this knowledge is performed usually takes place under risk and uncertainty conditions.

## III. Automatic summarization in the CIMIS

The CIMIS is dedicated mainly for the middle and large manufacturing enterprises operating on the Polish market (because the user language, at the moment, is Polish language). This does not preclude the implementation of other language text documents processing in the CIMIS. The process of analysis of text documents highly depends on the language. In addition, it is more difficult in case Polish language than, for example, in case English or German due to the greater complexity of Polish grammar [32].

The Learning Intelligent Distribution Agent (LIDA) architecture is used in CIMIS construction [8], [13]. In the construction of a LIDA agent mixed-used symbolically-connexionistic organization of memory is used in an attempt to ground the meaning of all symbols. It is necessary to properly process the unstructured knowledge, recorded mostly using natural language, such as customer's opinion about products. Grounding is meant as these cognitive processes, which are responsible for establishing and maintaining a connection between the language and the corresponding objects in the world [22]. The LIDA consists of the following modules [13]:

- Sensory Memory
- Perceptual-Associative Memory,
- Workspace,
- Transient Episodic Memory,
- Declarative Memory,
- Attentional Codelets,
- Global Workspace,
- Procedural Memory,
- Action Selection,
- Sensory-Motor Memory.

In the LIDA architecture it was adopted that the majority of basic operations are performed by the so-called codelets, namely specialized, mobile programs processing information in the model of global workspace.

In 2011, the CCRG group released the Framework LIDA, which allowed the use of this architecture by a wider circle of users. Framework LIDA is a software underlying the implementation of the cognitive agents. The Framework contains the object class (implemented in JAVA), performing operation in the field of agent architecture (definition and methods of handling all types of memory, communication protocols, methods for making reservation by the agent operations on real-world objects, such as searching for and identifying the objects, specify characteristics of objects, specifying associations between objects). The programmer's task is to fill in tools provided by the framework LIDA (write a program code) about aspects related to the specific domain of the problem - for example related to economics, management.

The CIMIS consist of following sub-systems: fixed assets, logistics, manufacturing management, human resources management, financial and accounting, controlling, CRM, business intelligence. These sub-systems are described in detail in [16]. In this paper we focus on summarization module, which is a part of CRM sub-system (Fig 2.). The module consist of following groups of agents:

- document retrieval,
- information extraction,
- text analysis,
- summaries generating.

Document retrieval agents search and retrieve~~,~~ from the internet sources the documents according to users' needs (consistent with the query retrieval ) and save full content of these documents in a database. Retrieving the documents is carried out by codelets operating in an agent environment. In order to achieve a higher level of retrieval effectiveness each agent running on the basis of different document searching engines, for example:

- Java Searching Engine,
- Microsoft BING API,
- Custom Search API,

The documents from the top of its list are stored in database. The number of stored documents is given in the form of a parameter in the agent configuration file (e.g. 10, 20, 50 documents). The format of retrieved documents is not limited (e.g. Pdf, PS, doc, html, xml), while in the database, each document is stored as text, except that html document is saved along with markers.

The role of information extraction agents is to identify essential information in text documents. For example, if opinions of mobile telephone users are to be analyzed, only those pieces of texts which contain opinions (advertisements are to be omitted) need to be extracted from text documents (saved in a database by documents searching agents). Each agent uses a different method of extracting information, for example:

- determining tags of beginnings and ends of essential fragments of texts in a document - the method is mainly used in case of files saved in html/xml format (for example, the series of characters ""/><p>" is treated as the beginning of an opinion whereas the series of characters "</p>" is treated as an end of an opinion (the characters are determined on the basis of a learning set of text documents);
- identifying essential fragments of texts on the basis of sets of key words or rules - the method is used in case of any document formats (for example an opinion about a phone may be identified on the basis of such

key words as "make", "model", "recommended/not recommended"),

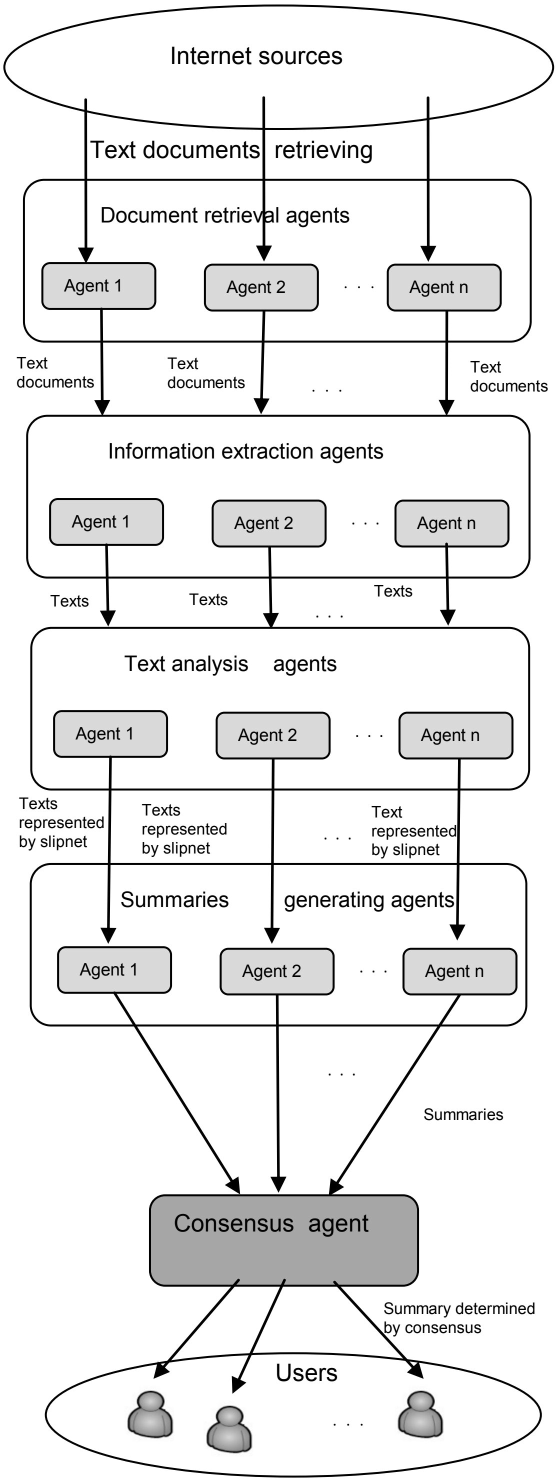


Fig 2. The functional architecture of automatic summarization module.

- identification of essential fragments of texts using documents representations in the form of a semantic network - semantic networks are created on the basis of a learning set, the networks serve as patterns representing particular classes of information (for example a semantic network representing a client's opinion on a given mobile phone), whereas in the process of IE a text document is saved also in the form of a semantic network, and then a cognitive agent searches for a given pattern in a semantic network representing a text document (the degree of similarity is defines as a parameter). This method allows for including a context of extracted information.

The results of the agents' running are stored in the text database.

The environment in which text analysis agents operate constitutes a set of text documents containing information which is the result of operation of agents extracting information (for example opinions of customers about mobile phones) located in a database of a system. Text analysis is performed in the following way:

1. A semantic network containing terms and connections between them is created in the perceptive memory on the basis of a learning set (for example a set of opinions about mobile phones). The perceptive memory stores also synonyms and different variations of words (thesaurus). In the perceptive memory of LIDA agents terms are represented by means of nodes, whereas connections are represented by means of links.

2. Individual text documents are added one by one into the sensory memory.

3. Opinions are analyzed by codelets, i.e. programs which search through texts according to certain criteria specified by means of configuration parameters. Values of the parameters may be indicated by users (parameters are saved in xml file structure and used in the program code of codelets). Codelets have been divided into two groups:

1) Codelets performing shallow analysis of texts. In the frame of this group the following codelets are running:

- tokenization,
- morphological analysis,
- removing the ambiguity,
- recognition of proper names, replacing pronouns,
- the distribution of complex sentences to the simple sentences,

2) Codelets performing in-depth analysis of texts. These codelets, by using thesaurus and results of shallow analysis codelets' operation, search for all possible interpretations and grammatical relations present in an analyzed document, represented in the form of a semantic network ("slipnet") in the perceptive memory of an agent. Results of documents' analysis, represented also in the form of a semantic network, are saved in a database.

4. The next step consists of passing the situation model to the global working memory, and from the procedural memory the following patterns of action are automatically selected: “saving results of opinions analysis into a database” (noSQL database – analysis of results – semantic network – are saved in XML format) and “entering another document into the sensory memory”.

The environment in which summary generating agents operate, on the other hand, consists of a set of text documents represented in the form of a semantic network constituting the result of operations of agents analyzing documents. Summary generating agents function in a way similar to documents analysis agents, however, codelets perform tasks connected with summarizing and they are divided into the following groups:

1. Codelets of text level units – responsible for analyzing relations between fragments of a semantic network, e.g.: probability, proximity in a text, common references, language ties (taken from a thesaurus for example), syntactic and semantic relations. Results of analyses are saved in the form of a semantic network with levels of nodes and links activation reflecting the degree of similarity and relations.

2. Discourse level codelets – responsible for performing analysis in the course of which the format of a whole document is taken into account, its rhetoric structure and issues touched upon in the document. The codelets use the method of creating semantic graphs and their subgraphs (graphs and subgraphs are also created in the form of a semantic network “slipnet”) using mechanisms of vectors facilitating the learning process. Levels of activating links in a graph depend on the level of the meaning of a given sentence (or phrase) in an analyzed text.

Next, the situation model is transferred to the global workspace, and from the procedural memory, the following patterns of action are automatically selected: “saving results of opinions analysis in a database”, “generating summaries in a natural language” (a summary in the form of a text in a natural language, which can be presented to a user, is created on the basis of a summary in the form of a semantic network) and “entering another document into the sensory memory”.

The integration of summaries is performing by consensus agent. This agent determines a summary presented to user (users). The use of consensus methods [17], [26], [29], instead, allows for the integration of summaries. The general meaning of the term consensus refers to an agreement. A consensus of a certain set (profile) of text documents may constitute a new document (hypothetical one) created on the basis of documents contained in the profile [48, 49].

Deriving consensus consists of three basic stages. In the first stage, one needs to determine a method of text documents representation. In this paper it has been assumed that the documents are represented in the semantic net. The next step requires defining the function of calculating distance between individual variants. The third stage involves developing consensus deriving algorithms, i.e. determining a representation of a set of documents (profile) where the distance between the representation (consensus) and individual documents of the profile is minimal (according to various criteria). If, for example, the different summaries of the documents describing the given phenomenon have been generated by cognitive agents, then using the consensus methods, on the basis of this summaries, the one variant of summary can be generated and presented to the user. This variant does not need to be one of the summaries generated by the cognitive agents. It can be a new variant determined on the basis of these summaries. Thus, all the summaries on a given phenomenon can be taken into account. Such a solution allows, among other, for shortening the time of determining the target summary (the user does not need to analyze the individual summaries and reflect on their choice - multi-agent system performs these steps automatically for user) and for decreasing the risk related to the choice of the worst summary (because all the summaries are taken into account in the consensus). As a result, the business processes within an organization can be implemented more quickly and efficiently.

## IV. Functionality of Summaries Generating Agent – the Case Study

In the frame of this case study the Polish language text documents will be taken into consideration.

The functioning of the module generating summaries of text documents will be presented on the example of experts’ opinions present in the Internet. A document-searching agent has received a task to find in the Internet documents whose content matches the following question: “In what stocks to invest during the uncertainty on the market?” For further investigation, one of the opinions obtained by an information-extracting agent was selected (the method of information extraction by determining beginning and end characters or marks of essential pieces of text in a document was used – see section III). The text of the opinion looks as follows: (sentences/phrases) of the opinion have been numbered by authors in order to simplify further analysis):

*“(1) The market is in the period of uncertainty (2) therefore investments are to be made into companies representing the defensive branches. (3) Among them, we can first of all mention telecommunication companies stocks, (4) as well as those which are related to public utility. (5) We are talking here about for example energy, (6) or all other companies which make investments using public money. (7) They are the least affected by changes in the economic situation (8). Many companies conduct different types of promotion actions aimed at making people invest in them. (9) However, one should not fall for that. (10) One should not invest in retail sector companies as their prices change greatly during a fluctuation on the financial market”.*

On the basis of a learning set, a semantic network containing terms and connections between them related to the investment topic, as well as a thesaurus for the terms were saved in the perceptive memory of a text analysis agent[1]. Next, a sample opinion was entered into the sensory memory of the agent, and a shallow analysis of the text was performed. As a result of the analysis, for example words “invest”, “investments” were changed into “investment”, and the phrase “changes in the economic situation” were changed into “fluctuation” (tokenization). Complex sentences were also broken into simple sentences (for example the sentence: “The market is in the period of uncertainty therefore investments are to be made into companies representing the defensive branches.” was broken into two sentences: “The market is in the period of uncertainty” and “therefore investments are to be made into companies representing the defensive branches). In the next step, codelets performing in-depth analysis of the text (see item 3) saved an opinion in the semantic form. Figure 4 on the other hand shows representation of the following sentence: “especially during of uncertainty on the market”.

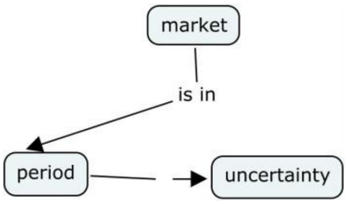

Fig. 3. A section of the network which relates to the following sentence: “especially during of uncertainty on the market”

Figure 4 presents a section of the network which relates to the following sentence: “Investments are to be made into companies representing defensive branches”.

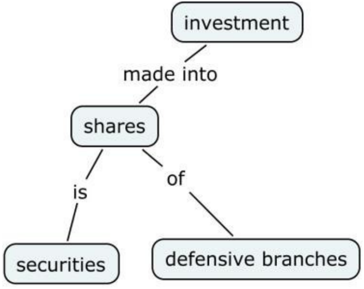

Fig 4. A section of the network which relates to the following sentence: “Investments are to be made into companies representing defensive branches”

It can be observed that the network has been enriched with the meaning of words “shares” and “companies”. It has been stated that they refer to “securities”.

The sentence: “Many companies conduct different types of promotion campaigns aimed at making people invest in them” (it is a dependent sentence so it has not been divided into two sentences) is represented in a way shown in figure 5. One may notice that the network has been enriched with the meaning of the phrase “promotion actions” – it has been specified that these are “actions”/”campaigns”. The remaining sentences or sentences of the opinions are represented in a similar way.

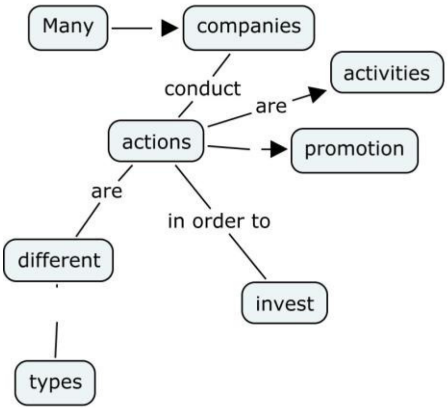

Fig. 5. A section of the network which relates to the following sentence: Many companies conduct different types of promotion actions aimed at making people invest in them”.

Next, the opinion, in the form of a semantic network, is sent to the sensory memory of a summary-generating agent. Discourse level codelets generate a semantic graph (figure 6) whose nodes refer to individual sentences of an opinion (the number of sentences is specified after breaking dependent sentences into simple sentences – in case of the particular opinion, there are 10 sentences). This graph corresponds to the opinion in Polish (see an Appendix). The nodes of the graph have been joined using links whose activation levels are directly proportional to the number of words common for the investigated sentences (activation level is defined in the following way: the longest sentence in a particular opinion consists of 10 words (excluding linkers) and the activation level is defined within the range [0..1], so in case of each common word the level of activation increases by 0,1.) [2].

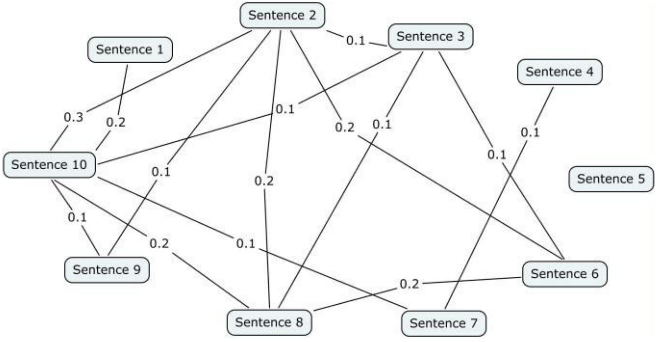

Fig 6. The semantic graph representing the considered opinion.

The most meaningful sentences are marked by nodes which have the highest total number of activation links which come out of them. The sentences should be included in a summary. Taking into account the presented semantic graph, these are the following sentences: “Sentence 2” (total

[1] The way for text analysis by cognitive agent is broader described in the paper [6].

[2] The longest sentence in the present opinion is 10 words (not including conjunctions) and the level of activation is defined in the interval [0..1], therefore, corresponds to one common expression on the activation level rise of 0.1.

of links activation levels: 0.9), “Sentence 6” (total of links activation levels: 0,5), and one of the sentence: “Sentence 10” (the sentences have the total of links activation levels: 1.0).

Apart from discourse level codelets (analyzing semantic graph) there are also text units level codelets. They enable finding sentences of different semantics despite comprising similar vocabulary. “Sentence 2” and “Sentence 8” serve as examples. The semantic graph suggests that it is enough to use just one of the sentences, however, after analysis performed by text units level codelets, it appears that “Sentence 2” (“Investments are to be made into companies representing the defensive branches”) refers to investing into shares, whereas “Sentence 8” (“Many companies conduct different types of promotion actions aimed at making people invest in them”) refers to taking action by companies (in Polish the words “shares” and “actions” are the same, i.e. “akcje” – see the Appendix) . Discourse level codelets mark sentences which shall be used in a summary by setting the level of activation of nodes for these sentences at the value 1 (value 0 for nodes representing sentences which shall not be placed in a summary).

Consequently, as a result of summary generating agent’s operation the following text of a summary of considered opinion has been defined:

*“During fluctuation on the financial market, investments are to be made into companies, representing the defensive branches, or all other companies which make investments using public money. One should not invest in retail sector companies”.*

It needs to be stressed that using representations of knowledge of a cognitive agent in the form of a semantic network “slipnet” enables taking into account a greater number of criteria which determine which sentences (or phrases) are to be included in a summary. For example, one can specify if more important are sentences whose nodes have a smaller number of links but whose levels of links activation are high (the sentence is “strongly” connected with other sentences, however the sentences refer to a small fragment of a summarized text), or whether more important are sentences whose nodes have a very high number of links of low activation level (the sentence is poorly connected with other sentences, however the sentences refer to a large fragment of a summarized text). Additionally, a cognitive agent, on the basis of an obtained summary, is capable of taking automatic decisions (on behalf of a user – investor) concerning abandoning investments in equities or starting investments in, for example gold. An agent will automatically sell equities (if an investor has been investing on a given market) and buy a gold.

On the basis of results of the preliminary research experiment performed by using 30 text documents, it has been state, that in about 70% cases the automatic generated summaries were very similar to summaries generating by users.

However, the main limitations of presented proposal are as follows:

- the results of text document analysis are not always properly, therefore a summaries generated on the basis of these results are also not always correct,
- in many cases, complex sentences weren’t broken into simple sentences,
- there are also summaries which consist of not correct generated text (linguistic error).

## V. Conclusion

The paper has demonstrated the development of a model of generating summaries of text documents containing mainly economic knowledge, represented by means of the semantic network “slipnet” (containing, apart from arch nodes, also levels of their activation). This sort of representation enables processing symbolically represented knowledge as well as numerically represented knowledge. It is possible then to define the level of probability or strength of semantic connections between terms, sentences, or phrases. Thanks to that, the cognitive agent takes into consideration user’s criteria which generated summaries should satisfy. Using cognitive agents in the devised model also enables taking automatic decisions and performing actions (on the basis of knowledge acquired in the process of summarizing documents).

Proper summarization of text documents is of great significance, particularly in integrated management information system design to support decision-making processes. Their functionality has a direct effect on user decisions and – ultimately – affects the organization as a whole.

Further research works will concern, inter alia, the developing, by using a fuzzy logic, a method for determining the activation level of nodes depending on the context of the sentence (or expressions).

## Appendix

The considered opinion in Polish is as follows:

„(1) Rynek znajduje się w okresie niepewności, (2) więc należy inwestować w spółki reprezentujące tzw. branże defensywne. (3) Wśród nich można wymienić przede wszystkim akcje spółek telekomunikacyjnych, (4) a także tych, które mają związek z użytecznością publiczną. (5) Chodzi tu np. o energetykę. (6) lub wszystkie inne spółki, które wykonują inwestycje z pieniędzy publicznych (7) W małym stopniu są one narażone na zmiany koniunktury (8) Wiele spółek przeprowadza różnego rodzaju akcje promocyjne aby w nie inwestować. (9) Nie należy im jednak ulegać (10) Nie należy inwestować w spółki działające w handlu detalicznym gdyż ich cena ulega dużym zmianom w okresie fluktuacji na rynku papierów wartościowych”.

***Abstract*—A term of transaction which has its origin in database processing, representing a set of operations that must be performed all or none of them. The notion of transaction is also used in some business process modeling approaches such as the DEMO (Design & Engineering Methodology for Organizations) and the REA (resource-event-agent) value modeling approach. The DEMO's transaction forms a basic building block from which a business process is composed. The REA value modeling approach utilizes transactions in an REA model representing a business process. In general, both methodologies utilize the notion of transaction, which has, however, a different meaning in these approaches. The aim of the paper is to describe the basic models of both approaches and to show, with the 'rent-a-car' example, the principal differences between the notions of transaction between them. The paper also reflects on possible mutual collaboration between both approaches.**

## I. Introduction

BUSINESS process modeling unquestionably belongs to software development process. It usually directly influences the database solution of the problem domain. Most of the business process modeling methodologies simply originated form 'best practice' without a vigorous theory from which the methodology is derived, see [9]. They mostly focus on production actions, which are usually described as an event that happens instantaneously or over a period of time. Generally, the most recommended notation of business processes is an UML activity diagram with swim lines, see [8]. Each swim line represents a human being, more precisely an actor role. Human beings are an inseparable part of business process modeling. However, the absence of a vigorous theory means that business process modeling approaches suffer from various incompleteness.

DEMO methodology stems from Enterprise Ontology [3] which represents a generic approach to business process modeling. The benefit of this methodology is that it perfectly identifies principal transactions that create the business process including human beings. It also provides necessary abstractions that enable us to obtain the essence of the modeling reality. On the other hand, this methodology is designed to be generic, which means that it registers production activities and is aware of them but without affecting them.

The other ontology which is at the core of our interest is REA ontology, see [1]. Its name is derived from three fundamental concepts, namely: *Resources*, *Events* and *Agents*. This modeling approach originated from accountancy systems but was developed into a fully-fledged tool for business process modeling. Economic resources are things of economic value that have utility for economic agents and for that reason they are planned, monitored, and controlled. Examples of economic resources are money, raw materials, labor, tools, products, and services. Economic events are activities within an enterprise that represent either an increment or a decrement in the value of economic resources. Some economic events occur instantaneously, some occur over time. Examples of economic events are sales of goods, rentals, and provision and use of services. Economic agents are individuals or organizations that participate in the control and execution of economic events. Examples of economic agents are customers, vendors, employees and enterprises. The structure of the paper is as follows: Section Two describes the main features of the DEMO methodology that are further utilized. The REA value modeling approach is clarified in Section Three. After a narrative description of the example, Section Four states the DEMO and REA solution to the example. Section Five discusses both approaches and Section Six summarizes the results achieved.

## II. DEMO Methodology

According to DEMO methodology [3], [4] an organization is composed of people (social individuals) that perform two kinds of acts, *production* acts and *coordination* acts. By performing production acts, people fulfill the aims of the organization. A production act can be either material or immaterial. By a material production act we mean a tangible act such as a manufacturing or transportation act. By an immaterial act we mean an intangible act such as the approval of an insurance claim or delivery of a judgment. By performing coordination acts human beings enter into and comply with commitments. They initiate and coordinate production acts. Abstracting from the particular subject that performs the action, the notion of the *actor role* is introduced. A subject in his/her fulfillment of an actor role is called an actor.

The result of successfully performing a production act is a *production fact*. An example of a production fact may be that the payment has been paid or an offered service was accepted. All realization issues are fully abstracted. Only the facts as such are relevant, not how they are achieved. The result of successfully performing a *coordination act* is a *coordination fact*. Examples of coordination acts are *requesting* and *promising* a production fact.

The diagram in Fig. 1 shows the standard transaction pattern (transaction). It contains two actor roles, the initiator and the executor and coordination and production acts between them. Each transaction starts with a *request* coordination act made by the initiator. In response to the *request*, the executor performs either a *promise* or *decline* coordination act. In short, a *decline* means the

978-83-60810-66-8/$25.00©2015, IEEE

end of a transaction. The *promise* goes on in a *production act* which results in a *production fact*. The production fact is *stated* to the initiator who can either *accept* it or *reject* it. The standard transaction pattern can be extended to the complete transaction pattern. In this case, the transaction pattern also contains four cancellation patterns that enable revoking of an act and completely model real conditions. For the purpose of the paper, only the transaction pattern will be used. The transaction itself can be expressed in a more condensed way, see Fig. 2.

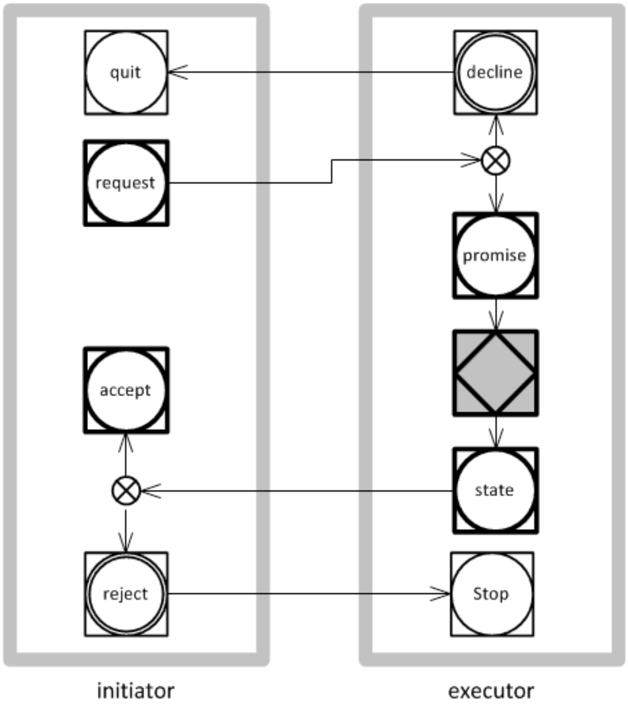

Fig. 1 DEMO transaction – standard pattern Source: [3]

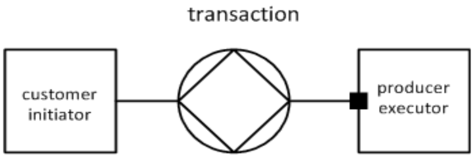

Fig. 2 Transaction in the Construction Model Source: [3]

The diagram in Fig. 2 shows the relation between the initiator (the relation is indicated by the plain line) and the executor (the relation is indicated by the dot at the executor). The DEMO methodology provides four mutually integrated aspect models. In this paper, only the Construction Model is used. The commission of the Construction Model is to identify actor roles and transactions. The task of the Process Model is to show how transactions are causally and conditionally related. The Construction Model has a crucial position in comparison with the REA model. The basic unit for declaring business processes is the notion of transaction. Transaction represents the basic building block between two social subjects. Apart from the basic states of *request*, *promise*, *production*, *state* and *accept* it also contains the other states that address erroneous states such as *decline* and *refuse* and the states which come from cancellation. Business process in DEMO methodology is defined as a set of enclosing transactions with a definite result (fact).

## III. REA Value Modeling Approach

The main benefits of the REA approach are being able to keep track of primary and raw data about economic resources. This explains why the REA approach offers a wider, more precise, and more up-to-date range of reports. All accounting artifacts such as debit, credit, journals, ledgers, receivables, and account balances are derived from data describing exchange and conversion REA processes. All reports based on accounting artifacts are always consistent, because they are derived from the same data by [6]. For example, data describing a sale event is used in warehouse management, payroll, distribution, finance and other application areas, without transformations or adjustments. REA ontology also benefits from the presence of a semantic and application independent data model, an object oriented perspective, and abstraction from technical and implementation details. These features enable the possibility of calculating the value of the enterprise's resources on demand, as opposed to calculation at pre-determined intervals.

Apart from keeping track of the past and current economic events, an REA model has the capability of modeling economic events that will occur in the future. However, the principal feature of REA ontology that originates from accountancy systems is that it explicitly distinguishes between past and current events and events performed in the future. And thus for events that occur in the future, REA introduces a new entity called a commitment entity. For this reason, the utilization of a commitment entity is not obligatory but depends only on the specific modeling context. That is, if the model does not address 'future events' there is no need for modeling a commitment entity. In addition, in many cases, only the data concerning real production, which means data about economic events and directly related entities (economic resources, economic agents), are utilized for further processing. The operational level is the part of the REA model which deals with the past and current events. The policy level is the upper part of the REA model which addresses the future events for which the commitment entity and contract entity are necessary. Although the operational level of the REA model can exist independently, the policy level of the REA model can exist only when mutually bound with the operational level. An REA model is illustrated in Fig. 3.

The commitment entity addresses the issue of modeling promises of the future economic events and the issue of the resources reservation, see [5]. Commitment entities and their relationships with other entities are shown in Fig. 3. This figure shows that the commitment entity copies the structure of the event entity to a considerable extent, by which we mean the existence of an increment and decrement commitment and exchange reciprocity relationship.The relationship of *committed provide* and *committed receive* means that some level of agreement about the future exchange must be achieved between economic agents. The *exchange reciprocity* relationship between the increment and decrement commitments identifies which resources are *promised* to be exchanged for which others. The reciprocity relationship is a relation of many-to-many (1..*, 1..*), see [6].

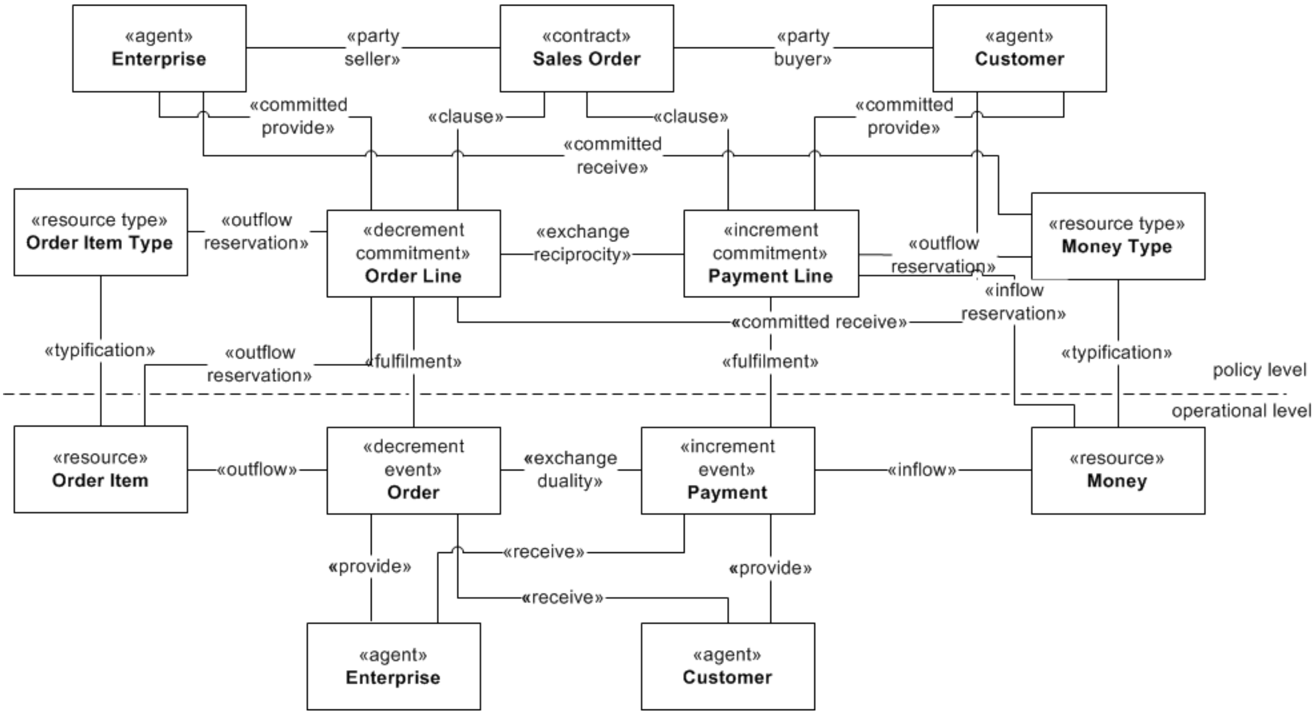

Fig. 3 REA model of an exchange process Source: adapted from [6]

Each commitment is related to an economic resource by a *reservation* relationship, which specifies which resources will be needed or expected by future economic events. The reservation relationship between the resource and commitment entities represents the obligation of economic agents to provide or receive rights to economic resources in exchange processes and represents scheduled usage, consumption or production of economic resources in conversion processes.

In its basic form, an REA transaction is represented by an economic event, an economic resource and a pair of economic agents. The economic event represents an event that happens or has happened in the past. REA transactions are related to each other by a duality relationship which is located at the operational level. In order to model future economic events, an REA model has to be extended with the policy level. This level contains commitment entities, contract entities and resource type entities. In short, a resource type entity represents a category item whereas a resource entity represents a physical item.

## IV. Rent-a-Car Example

This practical and probably familiar example can elucidate the differences and common issues of both methodologies. The Rent-a-car example covers both current and future events and it is not too complex to comprehend. To introduce the problem a short narrative description follows. Rent-a-car is a service which is provided either to walk-in customers or customers who make a rental reservation by telephone, fax or email. A car may be rented on the same day or may be reserved for a specific term in the future after a contract between an employee of the rental company and a customer has been signed. The company which rents out cars has many branches around the country. So the rented car may be picked up and dropped of at different branches. The rental payment depends directly on the number of days of rental and kind of car rented. The signed contrast states, among other things, the period of the rental and the name of the branch where the car will be dropped off. If the period of rental or/and the drop off branch do not coincide with the conditions in the signed contract, the customer is liable for a penalty payment. The contracted payment must be made by the starting day of the rental at the latest. Additional penalty payments must be made at the drop off point.

### *DEMO Solution*

This solution comprises the Construction model as it is fully in compliance with the necessity of both approaches comparison. The Construction model requires identification of the actor roles, transaction kinds and product kinds. In terms of actor roles there is an actor role CA0 who represents an employee of the rental company. The Construction model is illustrated in Fig. 4.

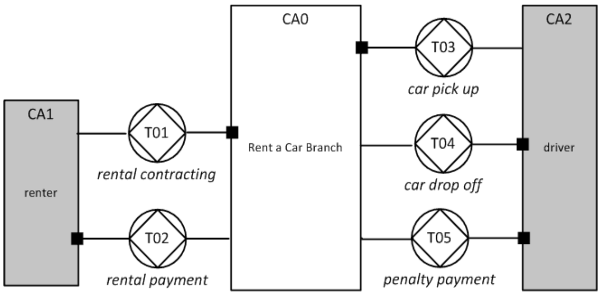

Fig. 4 Demo Construction model Source: [4]

The other actor roles represent a renter and a driver respectively. Utilizing the actor role principle provides a more accurate modeling perspective because a human being can have more than one actor role and one actor role can be represented by different human beings.As it is not a complex example, it is not difficult to identify essential transactions. The first transaction T01 - rental contracting covers signing a contract to rent a car. The next transaction T02 – rental payment must be promised before the contract is signed and this must be done by the first day of the rental at the latest. The car pick-up transaction (T03) includes the promise of the rental company employee regarding the starting conditions of the rental. The other part of this transaction covers the pick up of the car. The car drop-off transaction (T04) is composed of two parts. In the first part the customer promises to observe the conditions specified in the contract. The second part of the transaction represents the actual drop-off the car at a branch of the rental company. The penalty payment transaction (T05) is an optional transaction which is executed if the driver exceeds conditions agreed in the contract.

Going more carefully through the transactions it can observe that coordination steps (act & fact) enable mutual interconnecting (enclosing) of the transactions. The rental contracting transaction (T01) includes entering into and complying with a mutual commitment regarding the transaction T03, the car pick-up and transaction T04, the car drop-off. Both transactions involve detailed specifications about the beginning and end of the rental in the form of commitments. From the narrative description it is clear that the T02 rental payment transaction must be committed before the signing of the rental contract. This is due to the fact that in the text description the renter has to complete the payment by the first day of the committed car rental at the latest. The renter and the employee of the branch must also enter into and comply with any penalty payment to be paid if the period of rental is exceeded or the car is not returned to the branch where it should be dropped off. From this analysis it follows that at the rental contracting stage only the T01, rental contracting transaction, is accepted. The rental payment transaction (T02) must be paid by the starting day of the rental at the latest. The other transactions are usually promised but not yet accepted. The T03 car pick-up transaction is accepted only on the day that the rental starts.

As can be seen from the example, DEMO strictly follows actual conditions and provides great flexibility for a true description of a modelled reality. For example, in some cases the rental payment can be paid at the end of the rental or an advance payment must be made before the rental. This ability of DEMO is enabled by the distinction between the coordination and production acts and fact in a transaction. DEMO methodology is also beneficial when an immaterial product such as a judgement or a schedule is created within the transaction.

*REA Solution*

An REA solution can be modelled in two variations. The first variation represents the operational level of the REA model, whereas the second variation stands for both the operational and policy levels. The first variation enables the modeling of current and past economic events, whereas the second variation also enables the modeling of past, current and future events, described in [2]. Economic events, as a basic part of the REA transactions, must be identified first. Next, the corresponding economic resource and economic agents must be found. Once this has been done, a duality relationship between economic events must be established. The REA value modeling approach usually works with at least one pair of transactions which must be complementary to each other (give and take).

The first REA transaction is created by the rent-a-car economic event, the rent-a-car service economic resource and the renter and rental car company economic agents. The renter agent receives the rental service for a given period of time and the rental car company provides the car. The second transaction is formed by the rental payment economic event, the money economic resource and the pair of economic agents, the same as in the first transaction. What differs is the relationships between the agents and the events. In this case, the rental agent provides the money resource and the rental car company receives the money resource. The third transaction is similar to the second transaction apart from an additional event, which is the penalty payment economic event. These three transactions are related to each other by a duality relationship. This relationship allows us to keep track of which resources have been exchanged for which others.

The REA model illustrated in Fig. 6 represents the second variation of an REA model which includes future events. These events are in the REA approach represented by the commitment entities. The contract entity is composed of the commitment entities and terms. Under the conditions specified by the terms, a contract can create additional commitments. Thus, the contract can specify what should happen if the commitments are not fulfilled. Economic agents are related to the contract entity by the party relationship.

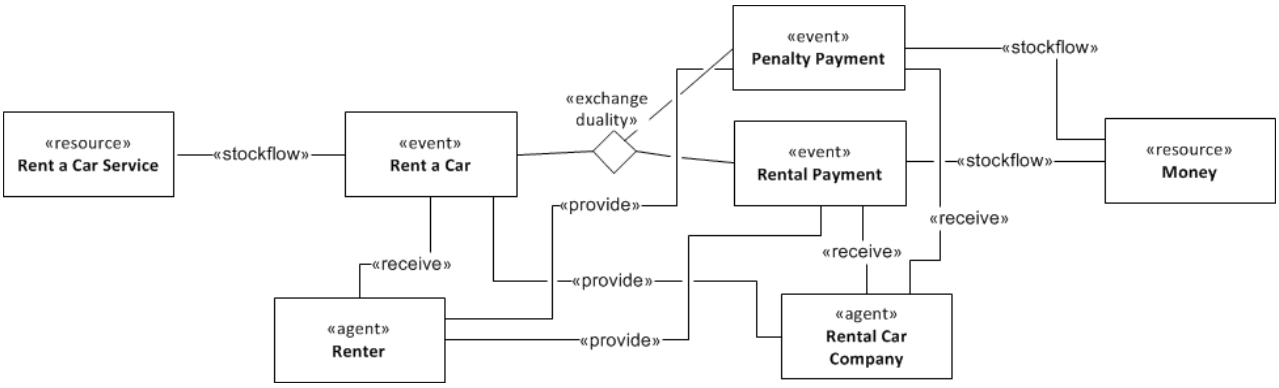

Fig. 5 REA model – operational level (first variation) Source: authors

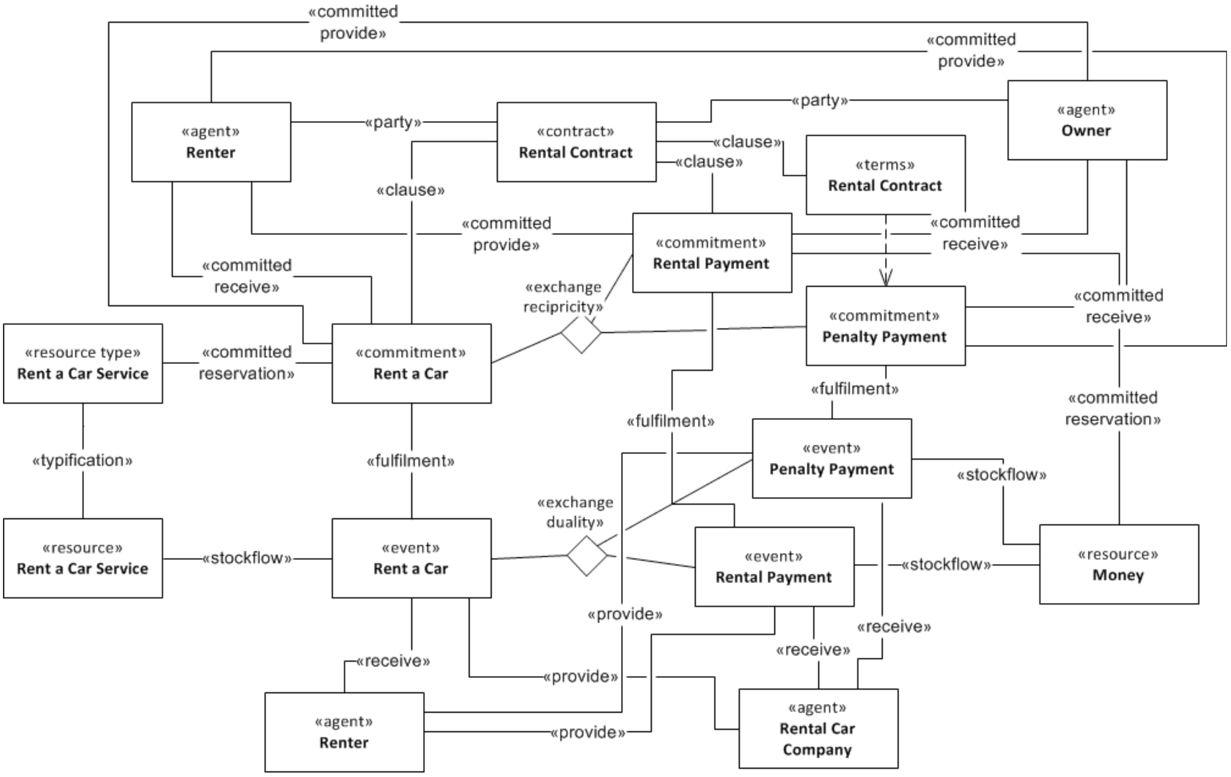

Fig. 6 REA model (second variation) Source: authors

The structure of the commitment entities corresponds with the structure of the event entities. The commitment entities are related to each other by a reciprocal relationship. The practical meaning of the reciprocal relationship is that the future events have been promised and that the resources have been reserved for the future events. The REA solution copies the domain rules.

## V. Discussion

Although, the DEMO transaction and the REA transaction have similar formal meaning their semantic representations are significantly different. This is caused by the fact that the DEMO methodology represents a generic ontology, whereas the REA modeling approach stands for a domain-specific ontology. DEMO methodology utilizes a 'single' transaction as a basic building block from which a business process is composed. The operation axiom divides actions into coordination and production actions and each action is concluded by the result (fact). The DEMO transaction model contains cancellation and revoking operations and is far the most suitable for modeling real world. The DEMO transaction integrates past, current, and future events into one consistent unit. Transactions in a business process are organized in a tree structure, which is far closer to a domain model than a flat sequential structure used by other business process methodologies, including the REA modeling approach.

Among others, it is the operation axiom that has brought DEMO far closer to the world of human beings. Coordination actions enable human beings to enter into and comply with commitments. A production fact comes into existence after it is accepted by the corresponding coordination fact. Being a generic ontology, DEMO knows about real world events with good empirical evidence but it has limited means to deal with production acts and facts.

Contrary to DEMO methodology, the REA value modeling approach does not distinguish between coordination and production activities. Above all, this modeling approach keeps track of the value of economic resources. These resources can either be exchanged for other economic resources or be converted to different economic resources. The REA model, which represents a business process, is composed of at least two mutually binding transactions representing 'give' and 'take' operations in an exchange process, or 'use', 'consume' or 'produce' operations in a conversion process. In an analogy with the DEMO building block, the REA building block is a structure that connects at least two semantically bound transactions. By semantically it is meant that the binding transactions are in compliance with economic laws for the exchange or conversion of economic resources. Despite the benefits of the REA approach which were summarized in the introductory section, there are several drawbacks which prevent this ontology from becoming more widespread. Among REA drawbacks is the explicit separation of past and current events and future events [7]. In the REA model, two separate very similar structures exist. One belongs to the commitment entities and the other to the event entities. It is said that there is mirroring between event and commitment structures [2]. Both structures relate to agent and resource entities. Despite the fact that the REA approach explicitly defines a specific contract entity there is still the open issue of how to create this type of entity which is immaterial in character. Another REA weak point is the absence of a clear state machine declaration. Currently, states are derived from the states of resources during exchange or conversion processes.

There is an idea of how both ontologies can be utilized in mutual accordance. DEMO is fully aware of everything that happens in the real world with high empirical evidence. Utilizing DEMO on the most generic level would mean having a modeling approach that covers broad modeling abilities and is closer to human beings. The REA modeling approach could be exploited to a higher degree and closely cooperate with the generic level. REA approach would be utilized due to domain specific knowledge and the ability to solve its specific production actions. However, this idea would require simulating the REA model (its coordination part) by the DEMO methodology. The problematic issue relating to this idea is the relatively large variety of the 'give' and 'take' transactions which are interrelated. In addition, these transactions may be delayed in time.

## VI. Conclusion

The aim of the paper was to show and with a simple example demonstrate the similarities and differences between the DEMO and REA concepts of transaction. The stated example illustrates the DEMO approach, which, with simple transactions, can model future commitments and in this way contracted actions. The REA value modeling approach that distinguishes between past, current and future events, and uses an explicitly defined contract entity for this reason. A contract entity contains related commitments and commitments that would be instantiated in exceptional circumstances. The paper also considered the idea of mutual collaboration of these different approaches of business process modeling.

***Abstract* — *The aim of our study was to provide a contribution to the research field of critical success factors (CSFs) with a focus on SCM system implementations. Therefore, we conducted a systematic literature review in order to identify CSFs for those projects. On the basis of that review, we conducted interviews within German large-scale enterprises and with consultants experienced with SCM system implementations. As a result, we showed that all the factors found in the literature also affected the success of SCM projects in the studied companies. Additionally, we were able to identify six further CSFs with the interview study. However, within those SCM projects, technological factors gained more importance compared to those factors which influence the success of ERP projects the most. For SCM projects, factors like Data migration, as well as SCM system tests, are even more important than Top management support or Project management, which are the most important factors for ERP projects.***

## I. Introduction

Today's enterprises are faced with the globalization of markets and rapid changes in the economy. In order to cope with these conditions, the use of technology, as well as information and communication systems, is almost mandatory. Specifically, the adoption of enterprise resource planning (ERP) systems as standardized systems that encompass the activities of an entire enterprise has become an important factor for today's businesses. The demand for ERP applications has increased for several reasons, including competitive pressure to become low-cost producers, expectations of revenue growth, and the desire to re-engineer businesses to respond to market challenges. A properly selected and implemented ERP system offers several benefits, such as considerable reductions in inventory costs, raw material costs, lead time for customers, production time, and production costs [1]-[4]. Therefore, the majority of enterprises around the world use ERP systems.

However, using ERP systems to optimize "the inside conditions" of an enterprise still may not be sufficient to be competitive in today's business environment. In the last decade and continuing through today, the logistics of an enterprise are strongly influenced by changing business conditions. These conditions have changed dramatically in recent years — e.g., customers expect that companies will respond quickly to their needs and wishes and that these companies will also be very flexible. In addition, the customers more frequently are requiring widely different product variants. In addition to this required variety, there is also a trend towards increasing collaboration with a variety of suppliers and the inclusion of a wide variety of distribution channels, mostly on an international level, caused by increasing globalization. To cope with these requirements, the optimization of enterprises and their processes has to extend beyond the companies' borders; therefore, information systems have to be able to cross these borders, too. Here, the focus lies on optimal planning, management and control of the material, and information flow across the entire value chain [5]. Confronted with these issues, ERP systems are often reaching their functional limits.

One approach to dealing with the needs for joint planning of production and logistics activities across enterprise borders is the supply chain management (SCM) concept. To provide the needed relevant information for adequate planning and calculations and to support the exchange of information between supply chain partners, information systems are essential components within the SCM concept [6]-[8]. As supply chain-wide information systems, SCM systems are becoming increasingly important for enterprises. The increasing importance of SCM systems is also emphasized by the fact that many companies have already implemented such systems, or at least plan to implement these systems in the near future. Therefore, the use of and the need for adequate SCM systems has increased in recent years [9].

However, the implementation of an information system (e.g., an ERP system or an SCM system) is a complex and time-consuming project during which companies face great opportunities, but at the same time also face enormous risks. To take advantage of the potential opportunities rather than get caught by the risks of these implementation projects, it is essential to focus on those factors that support the successful implementation of an information system [10], [11]. By

978-83-60810-66-8/$25.00©2015, IEEE

being aware of these factors, a company can positively influence the success of their implementation project and effectively minimize the project's risks [10]. Recalling these so-called critical success factors (CSFs) is of high importance whenever a new information system is to be adopted and implemented or a running system needs to be upgraded or replaced. Errors during the selection, implementation, or maintenance of information systems, wrong implementation approaches, or systems that do not fit the requirements of the enterprise can all cause financial disadvantages or disasters, perhaps even leading to insolvency. E.g., when considering ERP implementation projects, several examples of negative scenarios can be found in the literature (e.g., [12], [13]). Here, SCM implementation projects can result in an even more complex project structure since the companies face not only enormous internal challenges but many external challenges as well.

However, literature dealing with SCM projects and their critical success factors can only rarely be found, whereas CSFs of ERP projects have already been considered in numerous scientific publications. Several case studies, surveys, and literature reviews on CSFs of ERP projects have been conducted by different researchers (e.g., [4], [14]-[17]).

Hence, considering the increasing importance of the use of SCM systems, the aim of our study was to focus on the implementation of SCM systems, focusing in particular on the differences in CSFs of ERP projects and SCM system implementations. Therefore, we conducted a systematic literature review in order to identify CSFs for SCM projects and to update the existing reviews of CSFs. On the basis of the CSFs we identified, we conducted multiple interviews within German enterprises which have already implemented an SCM system, as well as with consultants from SCM manufacturers with specific experience in SCM projects, in order to obtain insights into the similarities and differences among CSFs for SCM system implementations. Overall, our study was driven by the following research questions:

Q1: What are the critical success factors of SCM system implementations?

Q2: What similarities and differences exist between critical success factors for ERP implementation projects and SCM implementation projects?

Therefore, the paper is structured as follows. The next section deals with the results of our literature review. We will point out which factors are most important and which factors seem to have little influence on the success of an SCM implementation project. Next, our data collection methodology is described before the results of the interviews are presented and discussed and the research questions are answered. Finally, the paper concludes with a summary of the results and discusses the limitations of our study.

## II. Literature Review of Critical Success Factors for SCM projects

A critical success factor is defined according to [15] as any condition or element that is seen as necessary in order for the system implementation to be successful. As mentioned in the introduction, in order to identify factors that affect the success or failure of ERP projects, several case studies, surveys, and literature reviews have already been conducted by a number of researchers (e.g., [15], [16], [18]). However, most of the literature reviews cannot be reproduced, because descriptions of the review methods and procedures are lacking. Some researchers have pointed out the limitations of the currently available literature review articles, specifically noting that they lack methodological rigor [19]. Therefore, in order to gain insight into the field of CSFs for SCM projects, we conducted a literature review by systematically reviewing articles in five different databases, as well as papers drawn from several international conference proceedings. The literature review to identify the CSFs was performed in several steps, similar to the approach suggested by [20]. Here, we adapted an approach which we have previously used to update the existing CSF frameworks for ERP projects (see [17], [21]).

The steps of our review procedure are presented below. An overview is given in Figure 1 with regard to the numbers of papers identified or remaining during/after each step. With each step, the number of papers was reduced according to the assembly of different criteria.

**Step 1 & Step 2:** The first two steps were to define the sources for the literature review and the search terms for the database-driven review. Therefore, several databases and conference proceedings were first identified. Keywords selected for this search were mostly derived and adapted from the keywords we used for our systematic review of the ERP CSF literature [17], [21]. To make our review reproducible, we have listed the databases and search terms in Table 1.

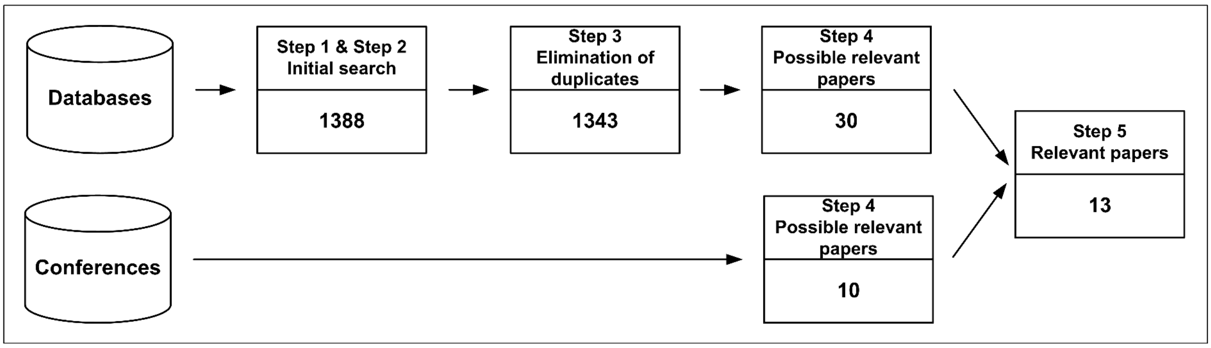

Figure 1. Progress of the literature review

TABLE 1. SEARCH FIELDS AND SEARCH TERMS FOR THE DATABASE-DRIVEN REVIEW

<table>
<tr><th>Database + Search fields</th><th colspan="2">Search terms / Keywords</th></tr>
<tr><td><b>Academics Search Complete:</b><br>“TI Title” OR “AB Abstract or Author supplied abstract”</td><td rowspan="5">SCM + system + success*<br>SCM + system + fail*<br>SCM + system + crit*<br>SCM+ system + fact*<br>SCM + system + csf<br>SCM + system + cff<br><br>APS + system + success*<br>APS + system + fail*<br>APS + system + crit*<br>APS + system + fact*<br>APS + system + csf<br>APS + system + cff</td><td rowspan="5">supply chain management + system + success*<br>supply chain management + system + fail*<br>supply chain management + system + crit*<br>supply chain management + system + fact*<br>supply chain management + system + csf<br>supply chain management + system + cff<br><br>advanced planning and scheduling + system + success*<br>advanced planning and scheduling + system + fail*<br>advanced planning and scheduling + system + crit*<br>advanced planning and scheduling + system + fact*<br>advanced planning and scheduling + system + csf<br>advanced planning and scheduling + system + cff</td></tr>
<tr><td><b>Business Source Complete:</b><br>“TI Title” OR “AB Abstract or Author supplied abstract”</td></tr>
<tr><td><b>Science Direct:</b><br>“Abstract, Title, Keywords”</td></tr>
<tr><td><b>SpringerLink:</b><br>“Title” OR “Abstract”</td></tr>
<tr><td><b>WISO:</b><br>“General search field”</td></tr>
</table>

Since the WISO database also provides German papers, we used the German translation of most of the search terms as well. For the conferences, only inappropriate search fields and search functionality were provided.

Hence, we decided to review the abstracts and titles of the conference papers in this step manually. We used the proceedings of four conferences:

- International Conference on Information Systems (ICIS)
- Americas Conference on Information Systems (AMCIS)
- European Conference on Information Systems (ECIS)
- Wirtschaftsinformatik (WI)

**Step 3:** During step 3 we performed the initial search according to step 1 and step 2, and afterwards eliminated duplicate results. The initial search provided 1,388 papers from the databases. After eliminating the duplicates, 1,343 articles remained. From the conference search, 10 papers remained. Altogether, 1,353 papers were identified during the initial search step.

**Step 4:** Step 4 included the identification of irrelevant papers. During the initial search, we did not apply any restrictions. The search was not limited to the research field of IS; therefore, papers from other research fields were also included in the results. Thus, these irrelevant papers had to be excluded. Additionally, the majority of SCM papers focused on the implementation of the supply chain management concepts itself without dealing with information systems. Therefore, these papers had to be excluded as well. The identification of these irrelevant papers was done by reviewing the abstracts of the papers and, if necessary, by looking into the paper’s content. Of the 1,353 papers, only 30 stemming from the database search remained, along with all 10 conference papers. Together, this yielded a total of 40 papers that were potentially relevant to the field of CSFs for SCM system implementations (see Figure 1).

**Step 5:** The fifth and final step consisted of a detailed analysis of the remaining 40 papers and the identification of the CSFs. Therefore, the content of all papers was reviewed in depth for the purpose of categorizing the identified success factors. Emphasis was placed not only on the wording of these factors, but also on their meaning. After this step, only 13 relevant papers that suggested, discussed or mentioned CSFs of SCM projects remained. In five of these 13 papers, CSFs of SCM projects were directly focused on within the conducted investigation, whereas in the other eight papers CSFs were discussed but these factors were not explicitly investigated with empirical studies. For each paper, the CSFs were captured along with the publication year, the type of data collection used, and the companies (e.g., the number and size) from which the CSFs were derived.

All 13 papers were published between 2000 and 2012. Table 2 shows the distribution of the papers by publication year. As is shown, there are not many papers published per year that deal with CSFs of SCM system implementation projects.

TABLE 2. PAPER DISTRIBUTION BY YEAR

| Year | Papers | Year | Papers |
|---|---|---|---|
| 2012 | 1 | 2005 | 1 |
| 2011 | | 2004 | 2 |
| 2010 | | 2003 | |
| 2009 | 3 | 2002 | |
| 2008 | 1 | 2001 | |
| 2007 | | 2000 | 2 |
| 2006 | 3 | | |

Overall, 22 factors influencing the success of SCM system implementations could be identified within the literature review. Table 3 shows the results of our review, i.e., the CSFs identified, ordered by each factor's total number of occurrences in the reviewed papers.

The factors *Top management support and involvement*, *Compatibility of the SCM system*, and *Data migration / data accuracy* are the three most-named factors, with each being mentioned in seven articles.

However, the differences in the CSF frequencies are only minimal and are related to the small number of identified papers. Therefore, to derive CSFs that are important for SCM implementation projects and to realize their different levels of importance is difficult due to the small number of studies focusing solely on these CSFs. Here, the minimal focus paid to SCM system implementations can be clearly seen as a research gap in the SCM system research field. To gain a deeper insight into this research field and to identify further factors not mentioned in the small number of articles, we set up an empirical study focusing on CSFs of SCM system implementations. We investigated these CSFs in depth by interviewing experienced SCM consultants as well as enterprises that have already implemented SCM systems. The results of this interview study will be part of the following sections.

Due to space constraints, detailed descriptions and definitions for each identified factor cannot be given within this article, but will be provided by the first author upon request.

TABLE 3. SCM PROJECT CSFS IN RANK ORDER BASED ON FREQUENCY OF APPEARANCE IN ANALYZED LITERATURE

| Critical Success Factor | Number of papers | Critical Success Factor | Number of papers |
|---|---|---|---|
| Top management support and involvement | 7 | Available resources | 3 |
| Compatibility of the SCM system (with other information systems and the IT infrastructure) | 7 | (Organizational) Fit of the SCM system | 3 |
| Data migration / data accuracy | 7 | Involvement of end-users and stakeholders | 3 |
| User training | 6 | External consultants | 3 |
| Balanced project team | 5 | SCM system tests | 3 |
| Project management | 4 | SCM system acceptance / resistance | 2 |
| Change management | 4 | Environment and organizational culture | 2 |
| Clear goals and objectives | 4 | Project team leadership | 2 |
| Company's strategy / strategy fit | 3 | Use of a steering committee | 1 |
| Cooperation with supply chain partners | 3 | Skills, knowledge, and expertise | 1 |

## III. Interview Study – Critical Success Factors for SCM implementation projects

### I. *Study Design – Data Collection Methodology*

To gain an empirical insight into SCM implementation projects and to gain an understanding of the CSFs for those projects, we used a qualitative exploratory approach within German large-scale enterprises and within German SCM system manufacturers. We chose to focus on German companies due to our cultural background.

The units of analysis in our study are the implementation projects carried out within the enterprises, as well as the SCM projects that the consultants have performed thus far in their careers. For the data collection, we conducted several interviews with members of the SCM implementation project teams and with consultants from German SCM system manufacturers in order to identify the factors that they determined to be relevant for the success of the projects.

During this process, we interviewed employees from nine large-scale enterprises located in Germany. The companies operate in different industry sectors and have implemented different SCM systems. Table 4 gives an overview of the companies and the interviewees. Within these enterprises, different SCM systems have been implemented (which cannot be named directly within this paper for data protection reasons).

Table 4. Overview of the Large-scale Enterprises and Interviewees (Number of Employees are Categorized due to Data Protection)

| Company | Industry sector | Number of employees | Interviewee |
|---|---|---|---|
| C 1 | Automotive industry | 1,000 – 5,000 | Head of the IT department |
| C 2 | Manufacturing of metal goods / Machine-building industry | 100 – 500 | Head of the *materials management* department |
| C 3 | Automotive industry | 1,000 – 5,000 | Head of the *company organization* department |
| C 4 | Consumer goods industry | > 15,000 | Project leader of the SCM project |
| C 5 | Automotive industry | 1,000 – 5,000 | Head of the *accounting and IT* department |
| C 6 | Building services engineering | > 15,000 | Business unit manager for *SCM* |
| C 7 | Construction industry | > 20,000 | Head of the *materials management* and *IT* departments |
| C 8 | Construction industry | 1,000 – 5,000 | Project manager for *logistics* |
| C 9 | Electronics industry | > 20,000 | Business unit manager for *supply chain innovations* |

Four companies have implemented the same SCM system; all the other companies have implemented different systems — some quite small and industry-specific systems and some more widespread systems on the SCM market. Most of the implementation projects took place in the mid-2000s. All of the interviewees were somehow directly involved in their respective companies' SCM system implementation projects.

In order to gather and include the SCM system manufacturers' perspectives in our study, we focused on information system manufacturers, with a specific emphasis on SCM implementations. Here, we interviewed three consultants from three different SCM manufacturers. Among the SCM consultants, we were able to interview consultants with longtime experience in several implementation projects.

To gain a deep and detailed view of the enterprises and their structures as well as of the consultants' experiences, we chose semi-structured interviews as our method of data collection. The interviews were conducted in retrospect regarding the SCM projects between July and October 2013. The interviews were designed as partially standardized interviews using open to semi-open questions as initial starting points for the conversation. Both personal (face-to-face) interviews and telephone interviews were conducted by the authors. An interview guideline was developed, based on the questions of [22], who conducted a similar study within the field of ERP implementation projects, and also on the basis of one of our previous CSF studies (in the field of ERP projects), which focused on smaller companies and their experiences in ERP implementations [21]. We changed the questions to align with our identified CSFs (see Table 3) to ensure that all of the factors were discussed in the interviews. The interview guideline consisted of more than 30 main questions with further sub-questions that referred to the identified CSFs. These questions were formulated in an open way, so that it would be possible to identify "new" CSFs from the interviews that were not identified in the literature review. This questionnaire was sent to interviewees prior to the interviews to allow them to prepare for their interviews. The complete listing of the formulated questions and their assignment to the success factors is not included in this paper, but will be provided by the first author upon request.

For a better analysis of the results, we recorded all of the interviews (the interviews typically took between 60 and 90 minutes) and transcribed them afterwards. As a first step, non-verbal and para-linguistic elements and other elements that were not relevant to the study were excluded. Next, in order to evaluate the CSFs, the interviews were analyzed with reference to each CSF question block. We matched the answers and statements of the interviewees to the respective factors. Therefore, we had to formulate respective coding rules. Afterwards, each CSF was ranked according to a three-tier scale (2–very important factor; 1–medium important factor; 0–less/non-important factor) and, for a finer classification, according to a five-tier scale (4–very important factor; 3–important factor; 2–factor was seen as relevant; 1–factor was mentioned but not seen as being very relevant; 0–factor was not seen as relevant or important/factor was not mentioned at all). This rating was done regarding the respective statements of the interviewees. We used these two scales to gain a preliminary understanding of whether differences would occur by using a finer/more detailed scale. Here, the five-tier-scale could be seen as more appropriate for determining the different levels of importance for the factors. After setting up this ranking of CSFs, we discussed the factor rating with other researchers in this field to reduce the subjectivity of the rating. Finally, this procedure resulted in a ranking of the CSFs according to the interviewees' statements and answers.

## *II. Results of the Interviews*

For each interview, a ranking of the critical success factors was set up by the authors. A final ranking was created including all interviews and all individual rankings (see Table 5). As shown, the top three most important factors for SCM system implementation projects according to our study are *Change management*, *Data migration / data accuracy*, *SCM system tests* and *Available resources* with around or above 35 out of possible 48 points. Each of the 22 factors stemming from the literature review was mentioned by at least one interviewee.

Additionally, six further factors (*Organizational structure*, *Business process reengineering*, *Troubleshooting*, *Knowledge management*, *Project champion* and *Vendor's tools and implementation methods*) could also be identified during the interviews. These factors are printed in bold in Table 5.

However, four of these additional factors seem to have less influence on the success of SCM implementation projects, since they are ranked as 20 or lower. Only *Organizational structure* and *Business process reengineering*—with nearly or above 30 out of 48 possible points—seem to have at least a medium influence on the SCM project success.

To categorize critical success factors, [18] suggest a matrix scheme. Here, they consider the tactical or strategic direction of the CSFs and divide them into organizational and technological factors [18]. Thus, tactical CSFs relate instead to short-term aspects and goals of the system implementation project itself, whereas strategic factors aim at the long-term impacts of activities with strong connections to the development of the organization in relation to the mission, vision and core competencies of the business activity. Considering the technological and organizational character of the CSFs, the specificity and significance of technological factors are strongly dependent on the SCM systems themselves, whereas organizational factors focus on corporate culture and its environment with its specific processes and structures [18], [23], [24]. Table 6 gives an overview of the categorization of the top twelve of the identified CSFs in our study with a focus on their ranking.

TABLE 5. CSFS ACCORDING TO THE FIVE-TIER-SCALE RATING

| **Rank** | **Factor** | **Factor rating (five-tier-scale)** | **Rank** | **Factor** | **Factor rating (five-tier-scale)** |
|---|---|---|---|---|---|
| **1** | Change management | 38 | **15** | Project team leadership | 27 |
| **2** | Data migration / data accuracy | 36 | | Vendor relationship and support | 27 |
| **3** | SCM system tests | 35 | | Communication | 27 |
| | Available resources | 35 | | Compatibility of the SCM system (with other information systems and the IT infrastructure) | 27 |
| **5** | Top management support and involvement | 32 | **19** | Company's strategy / strategy fit | 26 |
| | SCM system acceptance / resistance | 32 | **20** | **Troubleshooting** | 25 |
| **7** | User training | 31 | **21** | **Knowledge management** | 24 |
| | Project management | 31 | | Environment and organizational culture | 24 |
| | Skills, knowledge, and expertise | 31 | **23** | Involvement of end-users and stakeholders | 19 |
| | Clear goals and objectives | 31 | **24** | Cooperation with supply chain partners | 18 |
| | **Organizational structure** | **31** | **25** | External consultants | 17 |
| **12** | Balanced project team | 30 | **26** | Use of a steering committee | 14 |
| **13** | (Organizational) Fit of the SCM system | 28 | | **Project champion** | 14 |
| | **Business process reengineering** | 28 | **28** | **Vendor's tools and implementation methods** | 7 |
| 4–very important factor; 3–important factor; 2–factor was seen as relevant; 1–factor was mentioned but not seen as being very relevant; 0–factor was not seen as relevant or important/factor was not mentioned at all) / maximum possible rating on the basis of 12 interviews = 48 | | | | | |

We oriented around the classification and categorization of the factors according to [23], [24]. The factors of the top three are highlighted. It is shown that only a few CSFs (2 out of the top 12) are technological factors, whereas more than 50% of the factors (7 out of the top 12) are organizational factors with a strategic characteristic. However, the top 12 factors are spread out among all four categories, although most of them are part of the organizational category. Remarkably, two of the most important factors are part of the technological view.

TABLE 6. CATEGORIZATION OF CSFS (MODEL ADAPTED FROM [18], [23], [24])

| | Strategic | | Tactical | |
|---|---|---|---|---|
| | Critical Success Factors | Rank | Critical Success Factors | Rank |
| Organizational | **Change management** | **1** | User training | 7 |
| | **Available resources** | **3** | Skills, knowledge and expertise | 7 |
| | Top management support and involvement | 5 | Project management | 7 |
| | SCM system acceptance / resistance | 5 | | |
| | Clear goals and objectives | 7 | | |
| | Organizational structure | 7 | | |
| | Balanced project team | 12 | | |
| Techno-logical | | | **Data migration / data accuracy** | **2** |
| | | | **SCM system tests** | **3** |

## IV. DISCUSSION

Regarding these factors, the interviewees mostly acknowledge the descriptions of how the factors are summarized in the literature.

By looking at the rankings of the literature review, both at the ranking of the interview study and as a comparison at the ranking of an ERP CSF literature review from a former investigation (see [21]), the differences become obvious. Table 7 shows the respective top five factors.

As it is shown, the factor *Top management support and involvement* is always part of the top 5 factors. In both literature reviews this factor is the most important factor for the projects' success. Also, *Change management* is seen as a very important factor both for ERP projects and for SCM projects (as it is mentioned as the most important factor within the interview study). However, for SCM projects, technological factors (e.g., *Data migration / data accuracy* and *SCM system tests*) also seem to have a larger influence on the projects than they have on ERP projects. At least these factors are not ranked very high in the literature review for ERP implementations (see [21]).

An additional comparison of the results from the literature analysis and the interview study shows that the interviewees named and described twelve out of the 28 CSFs as they are described and defined in the literature, whether for SCM implementations or for ERP implementations. These factors are:

- Business process reengineering
- Knowledge management
- Change management
- Organizational structure
- Company's strategy / strategy fit
- Project management
- Compatibility of the SCM system
- Project team leadership
- Data migration / data accuracy
- SCM system tests
- Environment and organizational culture
- User training

Regarding the 16 other factors that are discussed by the interviewees in the way other than how they are described and defined in the literature, we cannot discuss the differences of all 16 factors at this point. However, we will point out these differences for some example factors:

- *Top management support and involvement:* The support of the top management was not seen as helpful by all interviewees. Some of them even mentioned that this had a negative influence on the project. For these interviewees, a lower level of top management support and less involvement from the managers were seen as beneficial since this would avoid long decision-making processes and other complications.

TABLE 7. COMPARISON OF THE TOP FIVE FACTORS

| Rank | Results of the SCM projects' literature review (13 papers) | Results of the ERP projects' literature review (320 papers) | Results of our interview study |
|---|---|---|---|
| 1 | Top management support and involvement | Top management support and involvement | Change management |
| | Compatibility of the SCM system | | |
| | Data migration / data accuracy | | |
| 2 | | Project management | Data migration / data accuracy |
| 3 | | User training | Available resources |
| | | | SCM system tests |
| 4 | User Training | Change management | |
| 5 | Balanced project team | Balanced project team | Top management support and involvement |
| | | | SCM system acceptance / resistance |

- *Balanced project team:* According to the literature for this CSF, project teams should consist of fixed and variable project members. However, such project team compositions were only used in two of the interviewed companies. The majority of the enterprises tended to use fixed project teams without variable members. Furthermore, in considering the literature, a high level of experience for the project team members in the field of software implementations is also an important aspect for the project team. However, this was not confirmed by interviewees. Mostly, the project members were not very experienced in this field.

- *Skills, knowledge, and expertise:* In the literature, experience, training and personal capabilities, skills and knowledge are all seen as positive impact factors on the project's success and can help to avoid errors and mistakes during the various project phases, or at least can lead to fast reactions. In the studied enterprises, the users' skills and knowledge (especially with regard to SCM systems or other software implementation projects) were described as really low. But this lack of experience and knowledge did not have any apparent negative impact on the projects' success.

- *Use of a steering committee / Troubleshooting:* Clear differences are also shown with respect to the use of a steering committee. According to the literature, it is almost essential to use a steering committee to manage and to supervise the implementation projects. However, only a few companies in our study had at least established some kind of a steering committee. Most of them did not see the necessity for a steering committee. In addition, the project plans of the companies contained no predefined troubleshooting plans or actions, which are seen as a mandatory aspect for software implementations according to the literature.

- *Communication:* As stated in the literature, in order to have adequate communication within the project teams, within the company itself and among SCM cooperation partners during the entire SCM system implementation, the development of a specific and detailed communication strategy is important. Yet, in the interviewed enterprises communication was done, for example, on a regular basis via meetings or telephone conferences. However, an explicit and specific communication strategy was developed only for one implementation project. Considering the communication, some interviewees also mentioned that it is sometimes easier just to inform the management rather than getting the managers too heavily involved. This again supports the discussion of the factor *Top management support and involvement*.

## V. Conclusion and Limitations

The aim of our study was to gain insight into the research field of CSFs for SCM implementation projects. Research in the field of software implementation projects and their CSFs provides valuable information that can enhance the degree to which an organization's implementation project succeeds [15]. As a first step, we carried out a systematic literature review to identify CSFs for SCM projects. Our review turned up only a small number of papers focusing on SCM system implementations—we could only identify 13 relevant papers in this research field. From these papers, we derived 22 different CSFs. However, compared to the CSF literature for ERP system projects (a separate literature review yielded 320 papers dealing with 31 different CSFs for ERP projects), this can be seen as a clear lack of research.

Here, to gain a deeper insight into this field, we set up an empirical study with a specific focus on SCM system implementations. We conducted several interviews within large-scale enterprises which have implemented SCM systems and with consultants who have several years of SCM project experience. Using a guideline consisting of more than 30 initial questions about CSFs, we conducted twelve interviews. We found that all 22 factors identified in the literature review were mentioned by at least one interviewee. Additionally, we were able to identify six additional factors during the interviews. Therefore, there are 28 factors which somehow affect the success of SCM system projects. However, contrary to the rankings resulting from an earlier literature review for ERP projects (see [17] and [21]), we identified factors with a more technological focus as being important for SCM projects. Here, the factors *Data migration / data accuracy* and *SCM system tests* are two out of the top three CSFs for SCM implementations. Hence, factors with an organizational characteristic could also be identified as part of the top 5 factors in our interview study (*Change management*, *Available resources*, *Top management support and involvement*, and *SCM system acceptance / resistance*).

Regarding research question 1 (Q1), we were able to clearly identify 28 factors that have an influence on SCM system implementations. However, we could also show that the importance of the factors for SCM projects differs from the CSFs' ranking for ERP projects (Q2). The implementing companies as well as the SCM system manufacturers have to be aware of these differences in the factors' characteristics, also focusing on technological aspects of the SCM system implementations rather than focusing mainly/only on the organizational factors.

A few limitations of our study must be mentioned as well. For our literature review, we are aware that we cannot be certain that we have identified all relevant papers published in journals and conferences since we made a specific selection of only five databases and four international conferences. Therefore, journals that are not included in our selected databases and the proceedings from other conferences might also provide relevant articles. Another limitation is the coding and ranking of the CSFs. We tried to reduce any subjectivity by formulating coding rules and ranking rules and by discussing the coding of the CSFs with several independent researchers. However, other researchers may code and assess the CSFs in different ways. For the interview study, the interviews conducted and data evaluated represent only an investigation of sample SCM projects in German enterprises. These results are limited to the specifics of these companies and the particular experiences of the consultants. In light of this, we will conduct further case studies and some larger surveys to broaden the results of this investigation.

# Approach to Analysis and Assessment of ERP System. A Software Vendor's Perspective

Ilona Pawełoszek
Częstochowa Univeristy of
Technology, Management Faculty
Poland
Email: ipaweloszek@zim.pcz.pl

***Abstract*—The paper presents an approach to analysis and assessment of benefits brought by an implementation of an Enterprise Resource Planning system. The research has been conducted on a sample of 10 Polish companies using the Xpertis software, which is one of the popular applications for supporting the business activities of small and medium companies. The approach presented hereby aims at elaboration of the assessment method which can be easily applied by the software vendor, moreover it is acceptable by the customers because it does not disclose the confidential business information and still gives the results informative enough to be valuable as well for the software company as for its customers. Cluster analysis conducted through the Orange Data Mining tool was proposed as a technique of data analysis. The comparative study of the Xpertis ERP features and the customers' characteristics has been briefly presented and the directions of the future development of the considered software have been proposed.**

## I. Introduction

THE Assessment of benefits brought by an implementation of an ERP system is important from the point of view of two groups of stakeholders. The first group are companies which choose to use the system, incur costs of its implementation and maintenance. The other group's members are the system creators and vendors for which the system is a commodity for sale and a product covered by information and promotion campaigns. The aims of both groups of stakeholders – vendors and buyers – are somehow similar. In both cases there is a need for a forecast how the implementation of integrated information system will influence the functioning of the user-company in different areas. That information is crucial for a customer who buys the ERP system and wants to know how successful the investment will be and whether it will bring him operational effectiveness and competitive advantage. On the other hand the ERP vendors are strongly interested in effectiveness and usability of their system to use that knowledge in further development of their product and improvement of the level of their services (customer support, training, helpdesk applications etc.).

The domain of information systems analysis and assessment is a broad field related to many aspects of the company's functioning. The ERP assessment issues are well grounded in the literature, however most of the approaches represent the customer's perspective.

The critical success factors (CSFs) for an ERP implementation, with the number of over 80 [17]  have been well documented in the literature [13]. The factors such as: top management support, project team competence, interdepartmental cooperation, clear goals and objectives, project management, are considered to be monitored during the implementation of the system. [21]. But the question arises how to assess the system that has already been implemented and in the same time to check whether the successful implementation directly translates into the overall performance of the system during the consecutive years of its exploitation [11].

The main problem that confronts the current measurement frameworks is the fact that much of the benefits are strategic, therefore they are hard to quantify and may only appear several years after the implementation of the solution [4].

The aim of this paper is to present an approach that can be taken by software companies to create a method for evaluation of their products in terms of customer needs and identification of areas for the product's improvement.

The presented approach aims at bringing relevant and informative results that can also be presented to future customers to show them the usefulness of the system and reduce the information asymmetry which is cited as an important factor of ERP implementation failure [23]. The approach used in this study is based on the example of Xpertis ERP system offered by Macrologic Inc.

The structure of the paper is as follows. Section 2 introduces context for the study which is rooted in Polish market of ERP systems. The main focus has been on small and medium software companies and the issues they face in competing on highly demanding Polish market. Section 3 briefly describes the problems of ERP evaluation from the vendors perspective with special focus on software usability

978-83-60810-66-8/$25.00©2015, IEEE

and sustainability. Section 4 provides the description of research approach and design. Section 5 presents the data analysis approach based on clustering methods. Sections 6 and 7 present the research results, respectively the system features and the customers' characteristics. The conclusion section summarizes the outcome of the work, and suggests future research directions.

## II. The Polish market of ERP

ERP systems today grow in popularity and importance among enterprises of all sizes. For today's companies the support from well-tuned IT solution seems absolutely necessary although according to Central Statistical Office of Poland the share of Polish companies using ERP was only 18% in the year 2013 and grew to 22% in 2014, which is around 9% points less than average for 28 EU countries. [2]

Most of the small and medium Polish companies built their own systems (almost 40% of manufacturers with 100 to 1000 employees) or do not have the integrated IT system at all. The lack of integrated enterprise system hinders and delays information flow within an organization because the data is kept in many loosely coupled applications. Such a situation negatively impacts the company's competitiveness [14].

An analysis of the numerous reports from ERP market brings the reader to the conclusion that the market capacity is high. The potential target group are small and medium companies that do not have the ERP, but also large companies that need to replace or modernize their legacy system.

However the survey among managers of the Polish SME companies reveals little awareness of the need to implement the ERP and its impact on the company's profitability (only 33% of respondents declared to see the need to implement the ERP system) [24].

Many companies complain that after their huge investments in ERP systems, they find the systems do not bring the expected results in terms of new orders, new profits, or competitive advantage. [8]

For the majority of small and medium enterprises the decision of adoption as well as the selection of the appropriate ERP system is a difficult task. The main issues are shortage of financial resources, limited qualified IT personnel, lack of resources and time have been cited as the main factors that make this task difficult and risky [22]

The Polish ERP market is a very competitive one. There was 31 ERP vendors in Poland in 2014. The unquestionable market leader is SAP (39.6% share), which is followed by Comarch, Oracle, IFS and BPSC. The remaining market share of around 26% is divided among other small companies one of which is Macrologic Inc..

Large companies own enough financial and managerial resources to develop and bring to market new software products and to gain dominant share of the market. Contrarily, small software companies often meet difficulties in finances and staffing while running their businesses. Therefore they often choose to concentrate on a market niche, which is disregarded by large companies. Small companies also opt to build their competitive advantage mainly on the basis of their excellent responsibility and flexibility.

Actually, due to the limitation of resources faced by small and medium companies best practices which have proven in large firms might be too expensive or time consuming to perform. Accordingly, the recent researches start to find specific solutions to improve small companies' software processes in several aspects. [19]

## III. The Problems of ERP Evaluation From the Vendors' Perspective

The software systems today are more than just a commodity, they are strategic asset custom tailored to the issues each company is facing. They provide the ability to precisely adapt the software components to the needs of the organization. They are characterized by the requirement to provide maximum flexibility, understood primarily as a possible use by a variety of organizations [26].

Due to the complexity of enterprise systems, bringing a new product to the market is both expensive and risky for the vendor. Initial investment requires both highly skilled human effort, time and specialized IT tools. A software packages ERP life cycle has two linked segments: vendor's and customer's. The vendor's segment includes phases: analysis, design, developing and maintenance [27]. While planning and developing a new software product it is necessary to anticipate its complete lifecycle which is of even 10 to 20 years of exploitation. During its lifetime the ERP system needs to be securely operated, patched, upgraded, extended and integrated with other systems, and still preserve the functional requirements of the end-users.

From the marketing point of view, one of the most important factors is usability of the ERP system, which, according to ISO Standards can be viewed as a set of three factors: effectiveness, efficiency and satisfaction [10]. While users' satisfaction is quite easy to asses by asking the users for their opinion, there is more confusion when it comes to actually measure the system's efficiency or effectiveness especially in economic terms. It is hard to say to what degree the system impacts the overall performance of a company. Moreover the values to be measured are dynamic and change with the time that has elapsed since the completion of implementation.

Usability can be also described in narrower sense as a set of three following criteria [20]: navigation, presentation and learnability. Navigation is about accessing the information easy and finding system's functions by using the elements of the user interface. Presentation is the feature describing visual layout of the screen and the layout of printed documents. The layout of the interface elements such as menus, dialog boxes and controls should be logically structured and legible. Learnability is the most tricky to asses because it highly depends on other non-system issues such as users' skills, technical background, previous experiences with similar systems etc. Learnability can be measured as time needed to get basic knowledge to work with the system. Learnability is associated with accessible online or offline help files and additional training offered by the vendor. Learnability can be also measured as the degree of ease to learn how to use the system effectively, however this measure is very subjective. It often happens that the first implementation of the ERP system in a given company requires changes in business processes in such case the users can report difficulties in understanding the system as it does not correspond with the processes they are used to.

Security and reliability are also important issues that the vendor should be able to assess. This can be done by collecting data from system logs, especially those associated with error events. The events recorded by an ERP system should be semantically interpreted to find out the direct or indirect causes of failures.

In recent years, increasing environmental and social concerns posed a new challenge to the software vendors to improve sustainability of their products. Sustainability in broader perspective (in contrast with the narrow focus on reducing emissions of carbon dioxide) covers all aspects that potentially impact the use of any limited resource. Many resources in software development and operation can be considered as limited ones, for example: the number and expertise of administrators, the time of end users getting used to software or fulfilling a certain task, the available hardware etc., Sustainable software takes these constraints into account and balances them with the value added by the software [6].

The factors of sustainability are hard to predict and it is only during the exploitation phase that they can be determined. The evaluation of the system always requires cooperation of the stakeholders in determining where the highest probabilities of weak points exist. These observations are valuable as well for the vendor to gain knowledge about the products as for customers to help them improve their businesses.

## IV. Research Approach and Design

The aim of the study was to evaluate the impact of the ERP system on different areas of the company where the system is supposed to bring improvements in comparison to the situation before the system implementation. The studied product was the ERP system Xpertis developed by Macrologic Inc.. The system has been chosen as the object of the study due to the fact that it is exploited for educational purposes at Czestochowa University of Technology and so the author, working as an educator, had a chance to get familiar with its functions and business logic. The other important aspect is the pro-innovative attitude of the Macrologic's Executives who are substantially interested in continuous improvement of their product and competitiveness on the demanding Polish enterprise software market. The company is searching for new approaches to get valuable product and customer knowledge. These two kinds of knowledge are closely related to each other.

Product knowledge is an essential sales skill. The software manufacturer and vendor have their own subjective view of the product. To get the whole picture of the complex software product it is necessary to consider the customer's perspective. Moreover by acquiring the customers' knowledge the vendor gains deep understanding of the product features that allows the vendors to present the benefits accurately and persuasively. Customer knowledge is an essential asset since it represents a source of customer value improvement [5].

The market of ERP systems is overloaded with a lot of competitors offering very similar products. Therefore it can be hard to recognize the differences between them as well for the customer as for the vendor. In this situation the competitive advantage can be found in the way of communicating with the future and existing customers. The key element of communication seems to be the way of presenting them a value proposition. In marketing, a customer value proposition consists of the total sum of benefits which a vendor promises a customer will receive in return for the customer's associated payment [9].

Customers are a brilliant source of knowledge for the companies, because they gain expertise while using products or services [7]. However gaining customer knowledge is a difficult task. Survey practitioners often experience difficulties in collecting reliable data due to various privacy concerns. The exposed problem is mentioned in many publications. Some of the companies refuse to take part in the survey as their company policy do not allow sharing internal information with outsiders even for academic purposes [18]. Companies are afraid to conduct the research because it could reveal weaknesses in the management process, which are known but ignored by the executives of these companies [12]. Some of the companies' excuse for not taking part in the surveys is that the studies do not seem to bring any value for the respondents. To avoid such situation the goal of the study should be clearly defined and the utility value for the respondents should be the communicated at first.

The presented approach to analysis and assessment of ERP systems addresses the problem of commercially-sensitive information. This could be achieved through an adequate design of the survey questionnaire.

The approach, although it is tailored to fit the needs of the Macrologic Inc. and the Xpertis ERP, can be used by other software companies offering similar systems after some necessary modifications of the survey questionnaire according to the specificity of their product.

The survey has been conducted on the sample of 10 Polish companies, who have recently (during the past three years) completed the implementation of the Xpertis system. The participants for the survey were selected using a non-random decision rule intended to select the set of companies who satisfy the following conditions:

- The surveyed companies localized in different cities representing at least 50% of Polish voivodeships (administrative districts).
- The Company's management board's permission for the employees to undergo the survey.
- The Companies differentiated throughout the branches of industry (furniture, metallurgic, chemical, foundry, services and other).
- There were usually 7-10 persons who were surveyed in each of the companies. The persons are employees who are directly involved in operating the selected system's modules.

The survey questions were brainstormed by the team of three IT and management experts, all of them having experience in using the considered ERP.

The responders were employees operating the system in their daily work. They were asked to evaluate the impact of the system using the Likert-type scale from -2 to 2 (presented in Table I). The lack of evaluation were also allowed in cases when particular question was not relevant to the scope of the company's activities.

The reasons for the choice of the Likert scale instead of concrete values were twofold:

- the chosen scale is easy to interpret and compare because the values are normalized,
- the Likert-type scale was acceptable to the surveyed companies as a form of the survey that does not disclose their detailed financial and operating information.

TABLE I.
RATING SCALE AND ITS INTERPRETATION

| Very bad/ significant deterioration | bad/ deterioration | neutral/ no changes | good /improvement | Very good /significant improvement | Not applicable* |
|---|---|---|---|---|---|
| -2 | -1 | 0 | 1 | 2 | NA |

* The answer in case the given ERP module was not implemented or the company does not operate in the given area.

Source: Own elaboration

The survey questions covered 11 areas of the organization's activity:

1. Production - execution of orders
2. Sales
3. After-sales services
4. Recycling
5. Marketing
6. Procurement
7. Warehouse management
8. Economic analyses
9. Organization
10. Human resources and payroll,
11. Accounting and finance

The questions for all the aforementioned areas are organized into 3 categories and subsequent factors:

1. General factors:

- Compliance with the business requirements (Pre-implementation analysis)
- Compliance with business strategy
- functional adjustment to the business process specificity

2. User interface factors and usability factors:

- Overall satisfaction of the user
- Ease of use
- Functional adjustment to the user's tasks
- User friendliness of the interface
- User assistance in problem solving
- User's autonomy (necessity of the system's administrator assistance)
- Visual attractiveness of the printed documents

3. Specific factors – different for each area of company, associated with specific business operations.

The dataset yields a matrix containing 10 units of observation, each one is described by 205 factors..

The first aim of analysis was to extract the factors which are important and influence the functioning of the Xpertis ERP system, usability and effectiveness of the users' work and at the same time eliminating those factors which appear to be irrelevant (mainly assessed as 0 and ND)

The second aim was to find similarities between evaluations made by 10 surveyed companies. These similarities and differences can be useful to create the profiles of features and needs of different groups of customers. This research will allow to get knowledge about the needed future adjustments of the ERP system to the customers' needs.

## V. DATA ANALYSIS METHOD

The analysis could be performed on an intuitive way by a simple method of screening the data and selecting those factors which received the highest and the lowest scores in the customers' opinions. However establishing a more detailed approach to the classification of important features of ERP can be performed through the means of data-mining as it offers statistically based methods for identification of patterns in data sets.

For the considered dataset cluster analysis seems to be the appropriate choice because it allows to identify groups of similar records and moreover it is a well described and investigated method that is still being developed and ameliorated up till today [15].

Cluster Analysis or clustering is a common technique of statistical data analysis – specifically unsupervised machine learning. The objective of clustering is to assign observations to the groups (called clusters) in a way that the observations in the same cluster are similar to one another in some sense.

There are many clustering methods based on various algorithms that can be applied depending the nature of the dataset under consideration. Different clustering algorithms may render different results on the same data. Moreover the same clustering algorithm may bring different results on the same data, if it involves arbitrary initial parameters.

However interpreting the results of cluster analysis is not a trivial task, because it requires knowledge of semantic relations between investigated attributes of the ERP system and the domain it supports.

There are three important steps in the preparation of cluster analysis:

1. Selecting a distance measure – The similarity between various objects is defined by a distance measure. The distance measure plays an important role in obtaining semantically meaningful clusters. For simple datasets where the data is multidimensional, Euclidean distance measure can be employed. [25]. Moreover the Euclidean distance is appropriate for data measured on the same scale, as in this case.

TABLE II.
THE STATISTICS OF THE CLUSTERS

| Cluster | Number of features | Evaluation | | | | | |
|---|---|---|---|---|---|---|---|
| | | -2 | -1 | 0 | 1 | 2 | ND |
| cluster 0 | 87 | 0,0% | 0,0% | 11,1% | 31,7% | 55,1% | 2,1% |
| cluster 1 | 13 | 0,0% | 0,0% | 7,7% | 12,3% | 78,5% | 1,5% |
| cluster 2 | 36 | 0,3% | 0,3% | 32,1% | 37,6% | 18,7% | 2,0% |
| cluster 3 | 36 | 3,3% | 0,3% | 0,6% | 75,6% | 19,4% | 0,8% |
| cluster 4 | 11 | 2,7% | 4,5% | 50,9% | 34,5% | 0,9% | 6,4% |
| cluster 5 | 22 | 0,0% | 0,0% | 19,1% | 3,6% | 0,0% | 77,3% |
| sum | 205 | | | | | | |

* The answer in case the given ERP module was not implemented or the company does not operate in the given area.

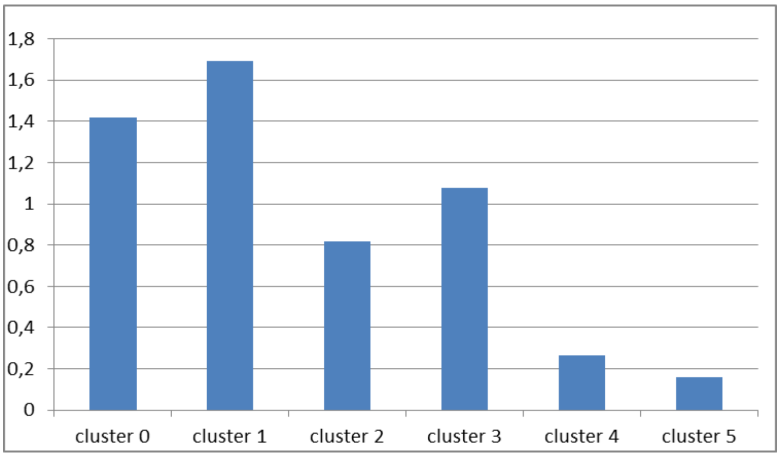

Fig. 2 Average evaluation for each cluster; Source: Own elaboration

2. Choosing clustering method and tool. A Hierarchical clustering method has been applied to classify the data set. The clustering algorithm were used and analyses were performed with Orange 2.7.1 software (developed by developed by Bioinformatics Lab at University of Ljubljana, Slovenia, in collaboration with open source community [3].

3. Determining the number of clusters in a data set. It is still an open problem in the machine-learning research community. There is no generally recognized state of the art statistical method to set the right number of clusters. The heuristics, rule of thumb can be recommended instead. The most important rule is to preserve an informative value of the clusters. Each of the clusters should have its own general characteristics differing from the others.

In the present case the cluster analysis can be applied to two purposes:

- to distinguish groups of the features which received similar ratings from the customers using the Xpertis ERP system. For this analysis data matrix should be prepared with the column names indicating the specific customers and the rows corresponding with the 205 studied features,
- to identify similarities between customers. In this case of analysis the matrix should be transposed (customers described by rows, features in columns).

## VI. Feature clustering results

In the case of feature clustering the dataset was divided on 6 clusters numbered from 0 to 5. Each of the clusters contains observation with similar values assigned by the users of the Xpertis ERP. Table II presents brief statistic characteristics of each cluster. As it can be easily seen from the Figure 1 (which is graphical representation of the data from the Table 2) the clusters differ markedly from each other. Also discrepancy in the average evaluation for each cluster can be seen.

Cluster 5 (Table III) contains attributes which are mostly irrelevant for the evaluation of the system or describe the areas that are not influenced by the system. The attributes in the cluster 5 describe the following areas:

- recycling (all the attributes from this group),
- human Resources and Payroll, – 3 attributes,
- accounting and finance (2 attributes).

The aforementioned attributes from the cluster 5 indicate that the companies do not involve in the recycling activities and do not see the need to support this area by ICT tools.

The other area in this cluster is human resources management. This one is probably seen as a diverse collection of “soft” skills that can be hardly supported by IT tools. The system could be extended by the functions of replacement workforce management in the area of registering the profiles of employees and job seekers. Additionally the decision support tools could be implemented to the recruitment process to make it more effective at getting the best person for a job or a project.

TABLE III.
THE ATTRIBUTES IN CLUSTER 5 – MOSTLY IRRELEVANT

| Area | Attributes |
|---|---|
| Recycling | Compliance with business requirements<br>Compliance with strategy<br>Matching to business processes and functions<br>Overall user satisfaction<br>Ease of use<br>Matching functional requirements (does the system support all the user’s tasks)<br>Interface - user-friendliness<br>User support in problem solving<br>User’s autonomy (the need for intervention of the system administrator)<br>Visual appeal of the printed documents<br>Evidence of post-consumer waste<br>Evidence of revenue resulting from the post-consumer waste.<br>Cooperation with recycling companies<br>Recycling rates<br>Recycling costs<br>Cost and time planning<br>Compliance with legal regulations |
| Human resources and payroll | Human resources management |
| | Creation of replacement workforce |
| | Employment of replacement workers in projects |
| Accounting and finance | Budgeting |
| | Daily expenditure plans |

Source: Own elaboration

Cluster 4 represents the areas on which the ERP system does not have the clear impact or the impact is slightly positive. The system attributes in this cluster are presented in the table IV.

TABLE IV.
THE ATTRIBUTES IN CLUSTER 4 – NO CLEAR IMPACT OR SLIGHTLY POSITIVE EVALUATION

| Area | Attributes |
|---|---|
| Production | User’s autonomy (the need for intervention of the system administrator) |
| | Integration of technical and administration areas (toolroom) |
| Sales | Easiness and speed of planning (ie. visits to customers) |
| | Speed of handling the users' complaints |
| After-sales services: | User’s autonomy |
| Marketing | Increased number of non-electronic customer orders |
| Procurement | Reduction of prices of supplies (by increased competition between suppliers)<br>Identification of delays and their causes |
| Warehouse management: | Loss of value of commodities under storage<br>use of storage space |
| Organization | Creation of the e-communities of employees |

Source: Own elaboration

Analyzing the results of the evaluation we can draft some recommendations and suggestions for changes and further development of the system. In the areas of production and after-sales services there is a need for more user autonomy. However the need for the administrator's intervention was mostly indicated by two of the surveyed companies.

Creation of e-communities seems to be interesting future development direction of the ERP system. E-communities may focus on different aspects of the company's functioning and also support the knowledge flow and retention. There is a movement taking place in the IT industry that is really driven by major consumer technology vendors like Apple, Google, and Facebook. In fact, employees and managers of most any business are already communicating with each other through various Web 2.0 technologies. However all of this communication is taking place outside the bounds of formal and secure IT systems [1]. Adding collaborative Web 2.0 technologies to ERP applications could be a way to address these challenges both for business users and IT.

TABLE V.

THE ATTRIBUTES IN CLUSTER 3 – MODERATELY GOOD AND VERY GOOD EVALUATION

| **Area** | **Attributes** |
|---|---|
| All the areas apart from recycling | User-friendliness of the interface |
| | Visual appeal of the printed documents |
| Production - execution of orders | Work planning |
| Sales | The User's autonomy |
| | Document automation |
| Marketing | User's autonomy |
| | Increasing number of contractors |
| | Increasing the number of customers |
| | Quick response for the customers' needs (new products offerings) |
| Procurement | The User's autonomy |
| | Increasing number of contractors (wider choice of raw materials and manufacturing tools) |
| | Differentiation of suppliers |
| Warehouse management | The User's autonomy |
| Economic analyses | The User's autonomy |
| Organization | The User's autonomy |
| | Corporate dictionaries |
| Human Resources and payroll | The User's autonomy |
| Accounting and finance | The User's autonomy |

Source: Own elaboration

The cluster 3 is characterized by moderately good (75,6%) and very good (19,4%).evaluation of the Xpertis ERP features. There are 36 elements in the cluster 3 - mainly the features associated with the user's interface and visual aspects (Table V).

Although the overall assessment is positive there are also signals pointing to the problems regarding the users' autonomy in different modules of the system. This may indicate the poor practical skills and theoretical background of some of the users. The lowest ratings (-2) were given by

TABLE VI .

THE ATTRIBUTES IN CLUSTER 2 – GOOD AND VERY GOOD EVALUATION

| **Area** | **Attributes** |
|---|---|
| All the areas apart from recycling | Compliance with the business strategy |
| Production - execution of orders | Lower production costs |
| | Decreased number of production downtimes |
| Sales | Acceleration of the sales process |
| | Automation of notifications |
| | Number of orders |
| | Number of completed orders |
| | Acceleration of orders completion |
| | The time of answering for the customer's questions |
| After-sales services | Compliance with business requirements (pre implementation analysis) |
| | Functional adjustment to the processes |
| | Ease of use |
| | Information on the customer's complaints |
| | Identification of problems |
| | Decreased cost of after-sales services |
| | Loyalty systems and analysis of their effectiveness |
| | Revenues from after-sales service |
| Warehouse management | Virtual warehouses |
| | Decrease in stocks |
| | Costs savings on warehousing |
| | Decrease in the storage period |
| | Reduced time of warehousing operations |
| | Reduced costs of non-moving articles |
| | Using data collectors |
| Organization | Project management support |
| Accounting and finance | Information on effectiveness of resources |
| | Increase in the financial revenue and decrease of loan service costs |

Source: Own elaboration

the customers who have been using the system for the shortest time (3 and 6 months).

This may indicate the need for additional training during the implementation and post-implementation phase.

The Cluster 2 contains attributes associated with all the areas of the companies' activities (apart from recycling). The relevant areas and attributes are presented in the Table VI.

As it can be seen from the survey results the users evaluation is good or very good for most of the attributes in this cluster. However there are also 5 attributes that received mainly 0, these are the following: "decreased cost of after sales services", "loyalty systems and analysis of their effectiveness", "revenues from after-sales service", "project management support", "increase in the financial revenue and decrease of loan service costs". The 0 marks mean that the system does not influence the aforementioned areas. However interpretation of the users' assessment indicates interesting possible ways of enhancing the functionality of the system modules. The CRM module could be extended with the possibility to create targeted loyalty programs with relevant and personalized rewards for the customers. Also project management is not directly supported by any module of the system. The project management support should be offered as an optional module integrated with Human Resources and financial modules. Although for now not all the customers practice project management, this discipline is becoming more widely recognized and used throughout the world [16]. Therefore it can be expected that the enterprise project management support could be one of the important features distinguishing the ERP product.

Cluster 1 (Table VII) contains features that are considered very positively influencing the business (mainly marks 2 and 1). This cluster mainly describes the areas associated with enterprise-wide communication and information management. The Users reported significant improvement in marketing effectiveness and efficiency relative to the performance before the implementation of Xpertis system.

The considered ERP system allows a company to manage its business with potential benefits of improved process flow, reduced inventories, more comprehensive data analysis and better customer service.

The Xpertis system has significant impact on acceleration of information flow, document circulation, reporting and analyses. The four companies of the 10 surveyed, claimed that the system does not influence the number of offers sent to their customers and the number of received responses. This fact can be caused by the business specificity and long-term contracts with their customers.

Cluster 0 is the largest one with 87 factors of the system evaluation. The data in this cluster reflect the very positive or moderately positive impact of the system on the surveyed areas of the business. The cluster contains data associated with 10 modules (apart from the recycling module). The most often appearing features are:

- ease of use,
- overall satisfaction or the users,
- support in problem solving,
- automation and acceleration of the specific operations.

Regarding the large number of factors in this cluster and the limited size of the hereby publication the factors are not listed.

TABLE VII.

THE ATTRIBUTES IN CLUSTER 1 – VERY POSITIVE EVALUATION

| Area | Attributes |
|---|---|
| Marketing | New medium of communication |
| | Number of offerings sent |
| | Number of responses received |
| | Number of electronic orders |
| Procurement | Acceleration of order completion |
| Warehouse management | Acceleration of stocktaking |
| | Raw materials assigned to specific orders/processes |
| | Materials management according to orders |
| Economic analyses | Greater scope of reporting |
| | Analysis of effectiveness of accessible fixed assets |
| Organization | Additional communication medium |
| | Communication regardless of location of the employees |
| Accounting and finance | Monthly balance sheet and reporting online |

Source: Own elaboration

The above analysis of the effects of the Xpertis ERP system on the business in 10 surveyed companies, shows that the considered software in most of the cases contributes to an improvement of the users' work in various aspects (communication, reporting, acceleration of operational tasks).

So far the potential areas of weakness seem to be factors from the cluster 5, and 4. Particularly the need for administrator's intervention reported by two of the 10 surveyed companies. To facilitate such analyses in the future some of the factors should be reconsidered in the questionnaire:

- human resources management (probably the problem was framed too broadly),
- creation of replacement workforce and employing the replacement workers in the projects (probably the surveyed companies do not practice project management)

The question about the system's compliance with business strategy is recognized by the surveyed employees as correlated with the support for operational tasks.

## VII. The customers' characteristics

In practice of marketing management segmenting is the popular technique of putting customers into groups based on similarities. Segmenting technique assumes the groups are pre-defined. Here we propose clustering method to find similarities in customers so that they can be grouped, and therefore segmented. Then the groups generated by the clustering algorithm undergo semantic interpretation. Semantic interpretation requires some additional insight to find out the reasons of the similarities between the cluster member.

This part of the research approach is aimed at identification and analyses of regularities and similarities between companies exploiting the ERP system.

Although the sample was only 10 companies, the large number of factors taken into consideration makes the problem appropriate for the use of statistical methods. This time the clustering based on k-means algorithm was the choice. The dataset is partitioned into 4 clusters and the data points are randomly assigned to the clusters resulting in clusters that have roughly the same number of data points.

The aforementioned Orange Data Mining tool was used to perform clustering. The Figure 3 presents the visualization of the clusters. The index on the vertical axis refers to the particular customer and the horizontal axis represents the cluster number.

By comparing the data on the time that has elapsed since the completion of the implementation with the clusters created by k-means algorithm it is easy to see some regularities in the evaluations made by customers assigned to the same cluster. It should be noted that the clustering was performed only on the basis of the customers evaluations of the system. Such an approach was taken intentionally to check how far the evaluation depends on the customers' characteristics. The table VIII presents the features of the surveyed Macrologic's customers along with the division on clusters.

A it was mentioned before the customer 5 and 8 reported problems with the users' autonomy, that were caused by little experience because the time after the completion of the system's implementation was relatively short (3 and 6 months). It can be reasonably expected that the evaluation will get better with time. The both observations were located in the cluster 4.

Regarding the data in Table VIII it can be assumed that the period of 1 year is the threshold time after which the users get enough experience to easily operate the system. Also the one year of exploitation gives the comprehensible view of achievements of targets assumed in pre-implementation phase.

The survey results also show the low evaluation cases in spite of the long post-implementation period (customer 2). In case of this customer the interview and observation showed the classical example of information asymmetry between the buyer and the vendor of ERP system.

In each of the considered cases the process of implementation had been preceded by pre-implementation analyses and the Xperits system had been customized to fit the customer's needs and business specificity. The information asymmetry could be eliminated or at least mitigated by devoting more time to discussions, consulting and collaboration between the vendor and the buyer. On the other hand it would significantly extend the time and increase the costs of the ERP implementation. The time-cost tradeoff problem is an important issue in the scheduling the large information system implementations.

By considering available data regarding the specificity of the surveyed companies along with the evaluations of the ERP system it can be found that there is no clear dependence between branch of industry and the customer perception of the system. For example the customer 1 and 8 both represent the metallurgic industry, however their production is different. Their evaluations of the system are very divergent so they were assigned to the different clusters and represented by the two points on figure 2 that are far apart from each other.

The closer look at the company 1 shows that the customer is very demanding in terms of the IT system and at the same time has very carefully elaborated procedures and is highly aware of the IT capabilities and own expectations. The implementation of the Xpertis system for this customer was difficult and many issues occurred that made it necessary to modify the system or change some process as well as the employees' habits. However the cumbersome and costly implementation resulted in achieving of the expected results and now after the 36 months of exploitation the system is considered as very valuable for the company.

Another example that proves the hypothesis of interdependence of time factor and the user's evaluation of the system is cluster 2 which contains two customers (9 and 4). Both customers evaluations were similar and the time after the completion of implementation is 18 months in both cases. The clear correlation between the number of IT staff, the form of employment and the customers' evaluations could not be identified.

TABLE VIII.

THE ATTRIBUTES OF THE CUSTOMERS

| Customer | Time since ERP implementation (months) | Cluster | Number of IT staff | Branch |
|---|---|---|---|---|
| **Customer 1** | 36 | 1 | 1 | Metallurgy |
| **Customer 2** | 36 | 3 | 1 | Furniture |
| **Customer 3** | 12 | 1 | Casual employee | Metallurgy |
| **Customer 4** | 18 | 2 | Additionally acting | Chemical |
| **Customer 5** | 3 | 4 | 1 | Services, projects |
| **Customer 6** | 30 | 2 | 9 | Services |
| **Customer 7** | 20 | 1 | 1 | Plastics and paper processing |
| **Customer 8** | 6 | 4 | 1 | Metallurgy |
| **Customer 9** | 18 | 2 | 2 | Metallurgy, molding |
| **Customer 10** | 12 | 3 | 1 | Production, plastics |

Source: Own elaboration

## VIII. CONCLUSION

The problem of post-implementation analysis of the ERP systems deserves further exploration. The study presented in the hereby paper is an attempt to elaborate the easy to use methodology for the software vendors to get more insight about their customers' needs and the possibilities of improvement of their products. The main issues in the ERP implementations seem to be precise description of the customer expectations and confronting it with the system capabilities. The approach presented hereby let the vendor create an insight on the overall system features in a way that does not reveal private information of the investigated companies. Therefore the research results can be presented to potential customers to better illustrate the areas of the impact of the ERP system on business processes.

The cluster analysis is an easy to use and flexible method to discover structures in a data set however it does not provide any explanation itself. The semantic interpretation of clustering effects can be performed by combining the data of each cluster with the knowledge of experienced members of the implementation team. The exploited tool – Orange Data Mining is free and easy to use because it is based on visual data modeling.

The analysis presented in this paper could be extended further to identify more similarities between the customers and the specific modules of the ERP system. For example clustering can be performed to analyze the features of each separate module. Such analysis only requires to prepare the data set limited to the selected features. The new dataset can be then easily loaded to the model built in Orange Data Mining tool.

The approach presented in this paper could be an inspiration for small and medium software companies to elaborate their own methods for products evaluation and comparison of their customers. The sophisticated research approaches based on data mining are often considered as reserved for large businesses with expansive budgets and creative departments. However, with open source data visualization and analysis tools available it is easier than ever for small and medium companies to gain knowledge on their products and customers to let them more effectively compete with larger companies on software market.

## ACKNOWLEDGMENT

The survey prepared is a collaborative effort. Therefore the author thanks Cezary Stępniak for the idea of the research and cooperation on preparation of the survey questionnaire. The author would like to thank Janusz Jakóbczak consultant to the Management Board of Macrologic Inc. for consulting the survey questionnaire, gathering data and his comments to the draft of the paper.

# Efficiency of formal verification of ArchiMate business processes with NuSMV model checker

Piotr Szwed
AGH University of Science and Technology
E-mail: pszwed@agh.edu.pl

***Abstract*—We investigate an application of model checking techniques to automated verification of business processes expressed in ArchiMate language. As a verification tool the state of the art symbolic model checker NuSMV is used. The proposed approach consists in fully automated translation of behavioral elements embedded in ArchiMate models into a corresponding representation in NuSMV language and then verifying its properties specified in CTL. Since our goal is to build an interactive verification tool, we focus on time efficiency of the verification process. We report results of tests performed on artificial process models of various complexity, as well as on a real business process example. The results show, that the described approach can be applied successfully, however, verification of complex business process specifications may face the problem of state space explosion. In such a case, to make the verification feasible, various reductions and simplifications can be applied.**

***Index Terms*—ArchiMate, business process verification, model checking, NuSMV**

## I. Introduction

THE GOAL of business process verification is to check if processes intended to be used or already implemented within an organization exhibit desired behavioral properties. The analyzed models may represent combinations of manual tasks performed by employees with operations supported by IT tools, as well as fully automated specifications run by process execution engines. In both cases process verification is appreciated by business organizations, as it can detect potential errors, design flaws and ambiguities.

Although graphical process modeling tools offer support for local syntax checking, e.g. correct use of links between elements of the diagram, some structural errors remain undetected, especially those resulting from incorrect use of synchronization mechanisms [1]. Partial analysis of model behavior can be performed by simulation techniques, however, only application of formal methods can give unequivocal answer that the verified system meets formally specified requirements.

Obviously, the landscape of business process modeling notations is dominated by such languages, as BPMN [2] or EPC [3], [4]. In this work, however, we decided to focus on verification of process models defined in ArchiMate, a contemporary, open and independent language intended for description of enterprise architectures [5]. Although ArchiMate comprises a variety of elements intended to model important aspects of enterprise architectures, constructs allowing to model behavior can be found only in the *Business* layer. They include events, processes (also understood as activities), interactions, collaborations and several types of junctions.

Formal system verification can by done either by deductive reasoning or model checking [6]. Deductive reasoning consists in formulating theorems specifying desired system properties and proving or falsifying them using manual or automated techniques. However, deductive reasoning methods gives very little information on causes, if the verified property does not hold.

Model checking allows to verify a concurrent system modeled as a finite state transition graph against a set of specifications expressed in a propositional temporal logic. It employs efficient internal representations and quick search procedures to determine automatically, whether the specifications are satisfied along the computational paths. Moreover, if a specification is not met, the verification procedure delivers a counterexample that can be used to analyze the source of the error. The main problem faced by model checking is state space explosion [7]. At the very beginning only small examples could have been processed. A significant progress in this technique was achieved with application of ordered binary decision diagrams (OBBD) [8] allowing to model systems consisting of millions of states and transitions.

Although formal tools reached the state of the art, they are not commonly used in the engineering practice. According to Huuck [9] three factors decide on successful application of formal tools: they should be simple to use, the time spent on model preparation and verification should be comparable with other user activities, and, finally, a tool should provide a real value, i.e. deliver information that was previously not available.

We were motivated by an idea of developing a software tool that fully automatically translates behavioral elements of a business model expressed in ArchiMate language to a corresponding finite-state graph required by the model checker. Then, after running the verification and detecting errors, valuable information about specifications not met and counterexamples can be returned to the process designer.

The concept of verification system is presented in Fig. 1. The business model is defined within Archi [10], a well known ArchiMate modeling tool.

As a verification platform the state of the art symbolic model checker NuSMV [11] is used. NuSMV allows to enter a model comprising a number of communicating finite state machines (FSM) and automatically checks its properties specified as Computational Tree Logic (CTL) or Linear Temporal Logic (LTL) formulas. We have developed an Archi plugin that

978-83-60810-66-8/$25.00©2015, IEEE

extracts a subgraph of ArchiMate behavioral elements and transforms it into NuSMV model descriptions. Specifications of desired properties are defined by a process designer, however, a part of them is generated automatically by an analysis of the process structure.

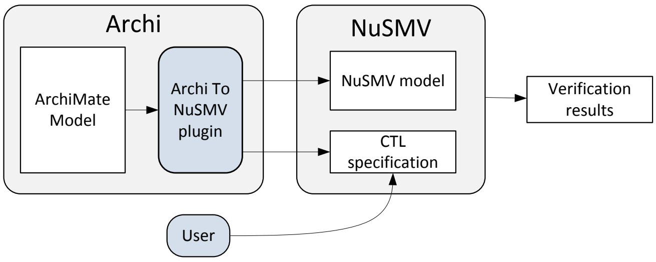

Fig. 1. The concept of the verification system

This paper is a continuation of our previous work [12], where an initial concept of a model checking verification system dedicated to ArchiMate models was described. Since our goal is to build an interactive verification tool, the main concern in this work is the *time efficiency* of the verification process. In order to assess it, we performed tests a for set of artificial process models of various complexity, as well as we verified a real business process example. In all cases we collected information related to the size of state space and processing time.

The paper is organized as follows: next Section II discusses various approaches to the verification of business models. Section III presents basic concepts of ArchiMate language. It is followed by Section IV, which describes details of the NuSMV model generation procedure. Section V reports results of time efficiency tests. Section VI provides concluding remarks.

## II. Related works

Application of formal methods to verification of business processes was surveyed by Morimoto [1]. Author distinguished three prevalent approaches: based on automata, Petri nets and process algebras. The first approach consists in translating the process description into a set of communicating automata (state machines) and performing model checking with such tools, as SPIN [13] or UPPAAL [14]. In analysis of Petri net models, basically simulation techniques are used, especially in the case of more expressive colored Petri nets.

Model checking has an established position in verification of business processes. It was applied in [15] to BPMN models extended with temporal and resource constraints. In [16] verification of of e-business processes was achieved by translation to CSP language and checking refinement between two specifications. In [17] authors implemented a system that translated BPEL specification into NuSMV language, what allowed them to check properties defined as CTL formulas. Three types of correctness properties were analyzed: invariants, properties of final states and temporal relations between activities. The first two can be classified as *safeness*, the last as the *liveness* property. Similarly, in work by Fu et al. [18] CTL was applied to the verification of e-services and workflows with both bounded and unbounded numbers of process instances. The work [19] discusses verification of data-centric business processes. The correctness problem was expressed in the LTL-FO, an extension to the Linear Temporal Logic, in which propositions were replaced by First Order statements about data objects.

Wynn et al. [20] discuss verification tools developed for models in YAWL language [21], with a special focus on OR-joins and cancellation constructs. The verified process properties are predefined. e.g. a soundness property is a combination of three conditions: a process should always complete, after the completion all its subprocesses should be inactive and every its part should be executable. Verification algorithms for YAWL are closely related to those of Petri nets, i.e. analyzing reachability graphs and in hard cases applying Petri nets reduction techniques.

In our previous works [22], [23] we proposed a method for verification of ArchiMate behavioral specifications based on deductive reasoning. The described approach consisted in transforming ArchiMate model into a set of LTL formulas, then extending it with formulas defining desired system properties and formally proving them using semantic tableaux method.

Although verification of business processes have been investigated for at least 15 years, surprisingly, there is very little information provided about efficiency of applied techniques. This in particular concerns the formal verification with the model checking approach. However, quantified results for a quite complex process specified in YAWL are given in the work [20] entitled remarkably “Business Process Verification - Finally a Reality!”. Without reductions the soundness verification of the process stages took about a few dozen seconds; applying reductions decreased the verification time of the whole process below ten seconds.

NuSMV [11] is a state of the art model checker that has been succesfully used for various verification tasks including formal protocol analysis [24], verification of requirements specification [25] or planning tasks [26]. The package uses a special language (named also NuSMV) to define the verified model as a set of linked finite state machines, as well as its specification in form of temporal logic formulas. The model submitted to the verification tool must be manually coded in NuSMV language or generated from another language amenable to state transition system, e.g a state charts [27] or reachability graphs of Petri nets [28].

## III. ArchiMate

ArchiMate [5] is a contemporary, open and independent language intended for description of enterprise architectures. The definition of ArchiMate has been accompanied by an assumption, that in order to build an expressive business model, it is necessary to use the relationships between completely different areas, starting from business motivation to business processes, services and infrastructure.

The language comprises five main modeling layers shortly characterized below.

- *Business* layer includes business processes and objects, functions, events, roles and services.
- *Application* layer contains components, interfaces, application services and data objects.
- *Technology* layer gathers such elements as artifacts, nodes, software, devices, communication channels and networks.
- *Motivation* layer allow to express business drivers, goals, requirements and principles.
- *Implementation&Migration* layer contains such elements, as work package, deliverable and gap.

ArchiMate allows to present the architecture in the form of views, which, depending on the needs, can include only items from one layer or can show vertical relations between elements belonging to different layers, e.g.: a relationship between a business process and a function of the component software.

ArchiMate provides a small set of constructs that can be used to model behavior. It includes *Business Processes*, *Functions*, *Interactions*, *Events* and various connectors (*Junctions*), which can be attributed with a logical operator specifying, how inputs should be combined or output produced. According to language specification casual or temporal relationships between behavioral elements are expressed with use of *triggering* relation. On the other hand, ArchiMate models frequently use *composition* and *aggregation* relations, e.g. to show that a process is built from smaller behavioral elements (subprocesses or functions).

In should be also noted that *Business Activity* present in ArchiMate 1.0 specification was removed in version 2.0. Instead, an atomic process should be used.

Although the set of behavioral elements seems to be very limited when compared with BPMN [2], after adopting a certain modeling convention its expressiveness can be similar [29]. An advantage of the language is that in allows to comprise in a single model a broad context of business processes including roles, services, processed business objects and elements of lower layers responsible for implementation and deployment.

Another process modeling notation that can be almost directly mapped on ArchiMate constructs is *Event-driven Process Chain* (EPC) [3], [4]. All behavioral elements of both languages are exactly the same: events, functions (or processes in ArchiMate) and various joins and splits (XOR, OR and AND).

## IV. Model generation

This section discusses language patterns that can be used to model ArchiMate elements in NuSMV, as well as details of the translation procedure.

### A. ArchiMate model

The internal structure of an ArchiMate model constitutes a graph of nodes linked by directed edges. Both nodes and edges are attributed with information indicating the type of element or relation. While generating NuSMV code describing behavioral aspects of ArchiMate model, we focus on components of the *Business layer*: processes (interactions, functions), events and various junctions.

It should be noted that ArchiMate behavioral constructs have no precisely defined semantics. In fact, translation from ArchiMate specification to NuSMV assigns a semantics, which, although arbitrarily selected, follows a certain intuition, e.g. how to interpret an activity or an event.

**Definition 1** (ArchiMate model)**.** ArchiMate model $AM$ is a tuple $\langle V, E, C, R, v, e\rangle$, where

- $V$ is a set of vertices,
- $E \subset V \times V$ is a set of edges,
- $C$ is a set of ArchiMate element types,
- $R$ is a set of relations,
- $vt\colon V \to C$ is a function that assigns element types to graph vertices
- $et\colon E \to R$ assigns relation types to edges.

As we focus on business layer elements that are used to specify behavior, it is assumed that $C = \{$*Process*, *Function*, *Interaction*, *Event,Junction*, *AndJunction*, *OrJunction*, *Other*$\}$ and $R = \{$*triggering*, *association*, *composition*, *other*$\}$.

We will discuss the procedure of NuSMV model generation on a small process example presented in Fig. 2. The whole process is activated upon occurrence of the event *Start*. Then the subprocess *P1* is launched, which is followed by *P2*. If *P2* terminates correctly, a decision is made whether additional subproces *P3* should be executed or the control flow leads to event *End* directly. However, execution of *P2* can be interrupted by the event *Interrupt*, which redirects back to the process *P1*.

### B. NuSMV model

The basic structural unit in NuSMV language is a *module* understood as a set of variables and statements that assign initial values to variables and define a transition relation. Depending on the module definition, we may distinguish input variables corresponding to stimuli, internal state variables and output variables (actions).

Definition of a module introduces a new type that can be instantiated. Hence, it is possible to declare a variable of a module type and bind it during declaration resembling a constructor call to a number of input variables. Subsequent variables definitions may reference outputs of other modules instances as their inputs. This allows to define a system of communicating state machines of desired complexity, which propagates input stimuli to its components causing subsequent state changes and generation of output signals. Typically, the model integration is achieved within the special *main* module, however, it can be distributed among lower level modules, which are referenced from *main*.

Fig. 3 shows the structure of NuSMV model corresponding to the process in Fig. 2. Although the structure of the presented process is clearly sequential, it is realized by a number of concurrent state machines (modules) linked by their output

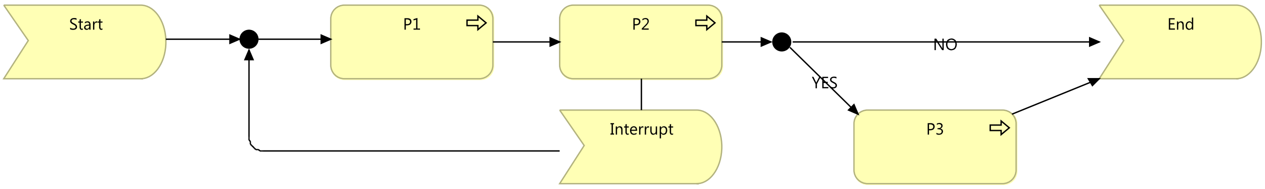

Fig. 2. Sample ArchiMate process specification

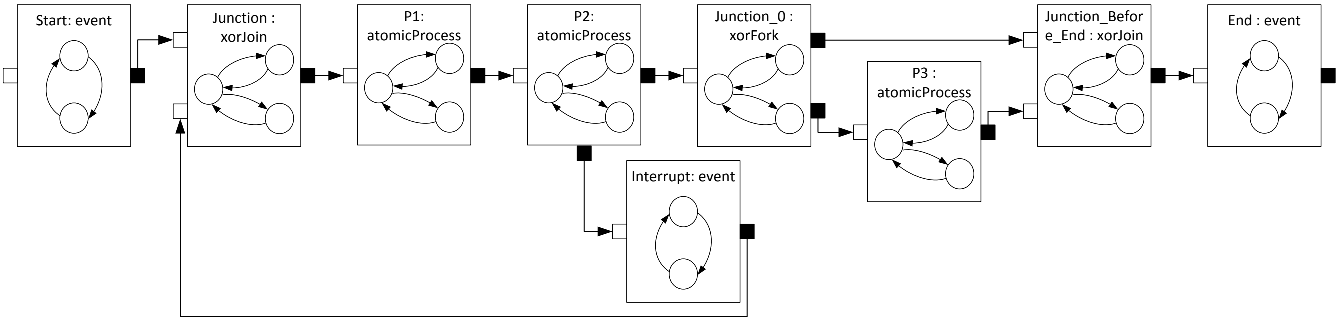

Fig. 3. Linked NuSMV modules used to model the process in Fig. 2

and input variables. The reusable modules correspond to the language constructs: processes, events, forks, joins, etc.

After conducting an analysis of components used to describe ArchiMate processes the following basic modules were identified and implemented:

- $atomicProcess_n$: $n$-ary atomic process has exactly one input, one primary output and $n$ additional outputs, which can be activated if one of $n$ exceptions occurs. The exception should be modeled in ArchiMate as an event linked with the process by the association relation.
- $event$: has only one input and one output (a boolean flag). Multiple recipients may use this flag as trigger.
- $andFork$: used to model AndJunction in Archmate. The module construction is analogous to event.
- $andJoin_n$: $n$-ary andJoin produces output signal, if all $n$ inputs are set to TRUE.
- $xorFork_n$: $n$-ary xorFork have one input and $n$ outputs. Upon module activation, only one among possible outputs will be triggered.
- $xorJoin_n$: $n$-ary xorJoin has $n$ inputs and sets the output flag if any of them is set. Moreover it tracks the number of inputs, e.g. if two from $n$ inputs are activated, the output flag will be set twice.

Fig. 4 shows the state diagram of the module `atomicProcess1`. The number "1" appearing in the module name indicates the number of additional outputs, which can be set as a result of exception occurrence. The process is activated by the input signal *trigger*. Upon the signal arrival it changes the state from *idle* to *started*. Then a choice can be made between the states *finished* and *interrruptedl*. Synchronously, the corresponding output variable is set: either *outflag* or *exccptflag1* to *TRUE*. The output variable, whichever is set, will be cleared during the transition to *idle* state.

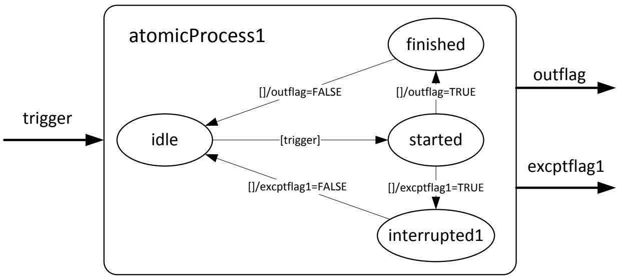

Fig. 4. State machine modeling an atomic process

The NuSMV code for the module is given in Fig. 5. It should be mentioned, that in the case of a process having $n$ exceptional outputs, we generate module `atomicProcess_n` with states *interrupted1*,. . . , *interrruptedn* and $n$ output flags *exceptflag1*,. . . , *exceptflagn*.

Basically, all modules corresponding to ArhiMate language elements were implemented as state machines, which receive input(s), change their internal states and produce outputs. However, due to performance issues we provided also alternative synchronous implementations, which immediately compute output values based on inputs. An example of synchronous process implementation is given in Fig. 6. Its definition uses an invariant that restricts acceptable combinations of variables instead of a transition relation. Basically, synchronous implementations allow to reduce interleaving, what makes the internal model representation in NuSMV smaller and speeds up the verification process. However, synchronous implementations are rather intended to be used

```
MODULE atomicProcess1(trigger)
VAR
  state : {idle,started,finished,interrupted1};
  outflag : boolean;
  excptflag1 : boolean;
ASSIGN
  init(state) := idle;
  next(state) :=
    case
      state = idle & trigger: {started};
      state = started : {finished,interrupted1};
      state = finished & !outflag : idle;
      state = interrupted1 & !excptflag1 : idle;
      TRUE : state;
    esac;
  init(outflag) := FALSE;
  next(outflag) :=
    case
      state = finished : TRUE;
      state = idle : FALSE;
      TRUE : outflag;
    esac;
  init(excptflag1) := FALSE;
  next(excptflag1) :=
    case
      state = interrupted1 : TRUE;
      state = idle : FALSE;
      TRUE : excptflag1;
    esac;
SPEC
  AG (trigger = TRUE -> AF (outflag = TRUE | excptflag1 = TRUE))
```

Fig. 5. NuSMV code of the module `atomicProcess1` (the number 1 indicates number of exceptional outputs)

for such elements as business events, forks or joins, than processes, for which activation and termination should be modeled as two distinguishable events separated by time.

```
MODULE atomicProcessSynchro1(trigger)
VAR
  outflag : boolean;
  excptflag1 : boolean;
INVAR
  (!trigger & !outflag & !excptflag1) |
  (trigger & outflag & !excptflag1) |
  (trigger & !outflag & excptflag1)
```

Fig. 6. Synchronous process implementation, a simplification of the state machine in Fig. 4

It should be mentioned that in the generated code is compatible with with the input language of nuXmv [30], the NuSMV succesor released at the end of 2014. In particular, the `process` keyword is not used and the choice between synchronous and asynchronous execution of model elements is entirely done within the generated model.

### C. Generation procedure

The generation procedure consists of the following stages:

1) *Refactoring.* With relation to the numbers of inputs and outputs, it is expected that elements fall into one of two classes: $1 : m$ (one input and $m$ outputs) or $n : 1$ ($m$ inputs and one output). Hence elements with the arity $n : m$ are replaced by two two elements: the first is an appropriate xorJoin or andJoin of arity $n : 1$. The second is an atomic process, event or fork of arity $1 : n$.
2) *Assigning representation.* For each ArchiMate element an appropriate NuSMV module type is selected and configured based on element type and numbers of inputs/outputs. Only required modules are generated, e.g. if the specification uses only processes with one and three exceptional outputs, only modules defining `atomicProcess1()` and `atomicProcess3()` will be generated.
3) *Main module generation.* This step comprises declaration of variables and linking them. For roots (modules without inputs) appropriate initial variables and transitions are added as well.
4) *Generation of specification.* The implemented procedure analyses the graph of elements and generates CTL specifications. See Section IV-D.

The generated NuSMV code for the *main* module is presented in Fig. 7. It can be noticed that variables definition are unordered and the code contains forward references, e.g. the output variable `Junction.output` is referenced before `P1` definition. The event *Stop* has two inputs. As the result of model refactoring an *OrJunction* (variable `Junction_Before_End`) was introduced into the model. For the event *Start* constituting a root element, the boolean variable `Start_trigger` with corresponding transition was added. The initial value of `Start_trigger` is FALSE, and the next value is chosen from {FALSE,TRUE}.

```
MODULE main
VAR
  P1 : atomicProcess(Junction.output);
  P2 : atomicProcess1(P1.outflag);
  P3 : atomicProcess(Junction_0.outflag2);
  Start : event(Start_trigger);
  End : event(Junction_Before_End.output);
  Junction : xorJoin(Interrupt.outflag,Start.outflag);
  Junction_0 : xorFork(P2.outflag);
  Interrupt : event(P2.excptflag1);
  Junction_Before_End : xorJoin(P3.outflag,Junction_0.outflag1);
  Start_trigger : boolean;
ASSIGN
  init(Start_trigger) := FALSE;
  next(Start_trigger) := {FALSE,TRUE};
```

Fig. 7. Generated NuSMV main module code for the process in Fig. 2

### D. Generation of specification

As a specification language we use CTL, which allows to formulate properties applying to a tree of computations (paths) starting from a given state. As the tree defines a set of imaginable futures, CTL is called the branching time logic. CTL formulas are combinations of two types of operators *path quantifiers* and *linear-time operators*.

The path quantifiers are:

- $A\,p$ – $p$ holds for every path in a tree and
- $E\,p$ – there exists a path in a tree, for which $p$ holds

Temporal operators include:

- $F\,p$ – $p$ holds true sometime in the future,

- $G\,p$ – $p$ holds true globally in the future,
- $X\,p$ – $p$ holds true next time and
- $p\,U\,q$ - $p$ holds true until $q$ holds true.

Usually a specification formally describing requirements is entered by a user. However, we tried to derive some *liveness* requirements based on control flows within ArchiMate model (see Definition 1).

The implemented procedure generating a set of specifications comprises four steps:

1) Build a set of paths $\Pi = \{\pi_i\}$ within the ArchiMate model,
2) Restrict elements in $\pi_i$ to events only (elements from the set $Evt$)
3) Build a partial mapping $R\colon Evt \to 2^{Evt}$
4) Generate the specification for each pair $(e_i, R(e_i))$ in $R$

In the first step (1) a depth-first search starting from *roots* (ArchiMate elements having no predecessors) is performed. It returns a set of paths $\Pi = \{\pi_i\}$ comprising ArchiMate elements linked by control flow relation. For a path $\pi_i = (e_{ib}, \ldots, e_{ie})$, its last element $e_{ie}$ is either a final element in the model (without successors) or a branching element (already present in $\pi_i$). The set of obtained paths reflects only topological relations within the process model. The procedure does not attempt to interpret the model according to any behavioral semantics. This is left to the verification tool.

For the example presented in Fig. 2 the set of paths $\Pi$ comprises three elements:
$\pi_1$ = (Start, Junction, P1, P2, Junction_0, Junction_Before_End, End)
$\pi_2$ = (Start, Junction, P1, P2, Junction_0, P3, Junction_Before_End, End)
$\pi_3$ = (Start, Junction, P1, P2, Interrupt, Junction)

Any requirements specification must reference terms, in which the model is expressed. We decided to focus on elements of *Event* type, which in business process definitions are typically used to mark important process states (e.g. initial, final and intermediate events).

In the step (2) the paths from $\Pi$ are restricted to ArchiMate elements being events. For the discussed example the restricted set of paths $\Pi^r$={(Start, End), (Start, Interrupt)}.

In the next step (3) a partial mapping $R\colon Evt \to 2^{Evt}$ is built. The mapping $R$ assigns all (potentially) reachable events to first events appearing in paths from $\Pi$. Continuing the example from Fig. 2, the mapping $R$ contains only one pair: (Start, {End,Interrupt}).

Finally, in the step (4) for each event $e \in \operatorname{dom} R$, a pair $(e, R(e))$ is converted into a set of specifications taking the form of (1), where $\mathcal{G} = \{AG, EG\}$, $\mathcal{F} = \{AF, EF\}$ and $\mathcal{O} = \{\bigvee, \bigwedge\}$.

$$\mathcal{G}((f \to \mathcal{F}(\mathop{\mathcal{O}}_{l_i \in R(f)} l_i))) \tag{1}$$

Fig. 8. Generated CTL specifications for the process in Fig. 2

Fig. 8 gives specifications generated for the process from Fig. 2. The specification AG (Start.outflag -> EF (Interrupt.outflag | End.outflag)). is equivalent to the statement: *for every path, starting with Start event, it is possible to reach a state, where End or Interrrupt events occur.* This requirement is obviously true for the discussed example. On the other hand specifications, where conjunction of reachable events occurs are false. An example false specification is AG( Start.outflag -> AF(Interrupt.outflag & End.outflag)), what was justified by a counterexample trace comprising 20 elements produced by NuSMV. The types of generated specification are controlled by program parameters. In particular, generation of specifications using conjunctions of reachable events can be switched off.

## V. Experiments

The goal of the conducted experiments was to assess the efficiency of the workflow shown in Fig. 1, in which:

1) An ArchiMate specification is prepared with Archi tool.
2) With "one-click" a corresponding NuSMV model is generated.
3) A set of specifications for the obtained model is checked by calling NuSMV.

In particular we were focused on the time efficiency of the third step, as it seemed to be crucial for the presented approach. During the experiments NuSMV was launched as an external process in the interactive mode, then commands to load models, report numbers of variables and check automatically generated specifications were submitted. The NuSMV output was grabbed and information on models processed, as well as the execution times were collected.

### A. Artificial test cases

Tests reported in this section aimed at assessing the relationship between a process complexity and the time required to check CTL specifications with NuSMV. Obviously, process specifications can form very diverse structures, however, we assumed that the key feature characterizing the process complexity is the numbers of branches and loops in the control flow. Hence, the basic process pattern, which was analyzed, comprised several branches and loops placed between two events *Start* and *Stop*. Fig. 9 shows an example, in which four subprocesses are arranged to form two branches and two loops. We have prepared a number of test cases being variations of this pattern and the results were summarized in Table I.

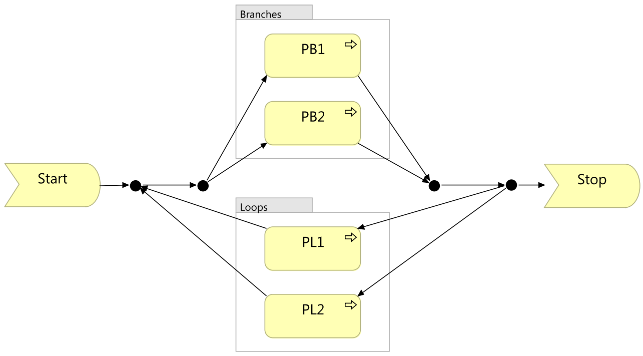

Fig. 9. Test case 4p2b2l: a process consisting of four subprocesses forming two branches and two loops

Each case name in Table I is encoded as a string: $n\,\mathrm{p}\,m\{\mathrm{b}|\mathrm{ab}\}\,k\,\mathrm{l}$, where $n$–number of processes, $m$–number of branches and $k$–number of loops. Symbol 'b' appearing in the case name means that the XOR branches (*xorJoins*) were used, wheras 'ab' corresponds to parallel branches placed between two *AndJoins*.

The column marked as $CC$ gives the value of cyclomatic complexity, a commonly used measure that can be interpreted as the number of independent paths in the specification [31]. It is calculated according to following formula: cc = e-n+2p, where where $e$ is the number of edges, $n$ is the number of nodes and $p$ is the number of connected components. The formula is applicable to sequential processes. For processes containing parallel activities the number of independent paths can be smaller, as activities starting and finishing synchronously actually build up a single control flow paths. Corrected values of cyclomatic complexity are added in parentheses.

Subsequent columns give numbers of state variables, total numbers of states and numbers of reachable states. *Dia* is a system diameter, i.e. the longest path from the initial state.

Columns *T* and *TPS* give total execution times and the execution time divided by the number of specifications (For each case 8 specifications were automatically generated and tested.)

NuSMV uses internally OBDD as a representation of a state transition system. It is well known, that the size of OBDD depends heavily on the variable ordering [8], [32], [33]. Selecting an optimal ordering is a NP-hard task, however several heuristics can be used to improve the ordering and in consequence reduce the model size, as well as the processing time. The corresponding option offered by NuSMV is called: *dynamic variable ordering*. The column *TD* gives the total processing time for dynamic variable ordering (the sift algorithm described in [34] was applied), whereas *TDPS* shows *TD* divided by the number of specifications.

The test cases are arranged into three groups. The first comprises process specifications with various numbers of branches, however without any loops. As it can be observed, in spite of growth of problem size, the numbers of reachable states and processing times remain relatively small.

The second group contains hard cases, i.e. those with several OR branches and loops. This makes both the numbers of reachable states very high and for the most complex case 24p12b12 (24 processes, 12 branches and 12 loops) the time spent to check one specification ranges to 80 seconds.

The third group includes cases with parallel branches that are synchronized at an *AndJoin*. This makes the space of reachable states much smaller, as well as keeps execution times relatively small (up to 560ms for the case 24p12ab12l). It can be noticed that for the cases 7p2ab5l, 8p3ab5l, 9p4ab5l and 10p5ab5l the numbers of reachable states are equal. This is a natural consequence of the model structure. Regardless of the number of parallel subprocesses, they all start and finish in the same states synchronized by the *AndJoin*.

Table I shows that applying dynamic variable ordering can be beneficial for complex models, e.g. for 16p8b8l, 20p10b10l and 24p12b12l it allowed to reduce the processing time up to 90%. For smaller models it was inefficient.

### B. Business process example

In this section we present results of performance tests for a medium size business process from the banking domain. The process evaluates a credit order sent over Internet and issues an approval or a rejection decision. Its description was prepared with Archi based on the EPC model published in [35] (on the page 44).

The process definition comprises five views presented in Fig. 10, Fig. 11 and Fig. 12. Following the modeling approach typical for the EPC, multiple events defining process states or conditions are used. Moreover, the events mark boundaries of subprocesses represented by the views. They bind them into a coherent model comprising branches or loops, whose endpoints are indicated by the referenced events. Due to limited space the presented models are restricted to behavioral elements, i.e. they do not comprise information on engaged roles, involved systems and processed data, which can be specified in ArchiMate.

The process is divided into three stages. The first, presented in Fig. 10, aims at collecting customer data for the received credit order. The subprocess handles two cases: when a customer is new or already present in the database of the banking system, what may influence the credit decision.

The next stage shown in Fig. 11 ends with three conditions: the credit order is accepted (green credit decision), rejected (red credit decision) or inconclusive (gray credit decision).

The final stage (Fig. 12) comprises activities, whose goals are to prepare the credit offer (in the case of green credit

TABLE I
RESULTS OF PERFORMANCE TESTS.

| Name | CC | Vars | Total states | Total states | Reachable | Dia | $T$ [ms] | $TPS$ [ms] | $TD$ [ms] | $TDPS$ [ms] |

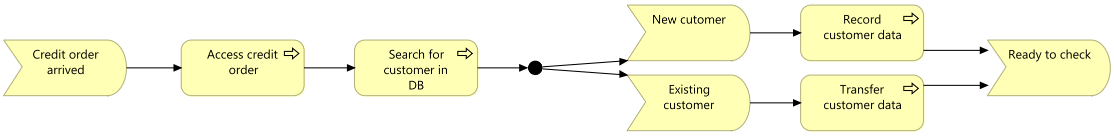

Fig. 10. Collect data

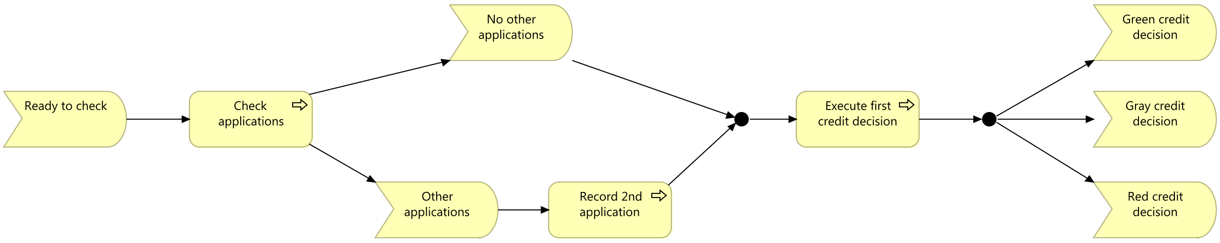

Fig. 11. First stage of the credit decision

decision), process credit order rejection for the red credit decision or reevaluate the submitted documents, if the decision was inconclusive (gray). The third case loops back the control flow to the results of the second stage.

Based on this specification the NuSMV model was generated. During the refactoring phase several joins were added before events: *Ready to check*, *Green credit decision*, *Gray credit decision* and *Red credit decision* events. An automatically generated specification checked during the experiment was the following:

```
AG( Credit_order_arrived.outflag ->
AF( Credit_offer_sent.outflag |
Contentual_problems.outflag |
Credit_order_rejected.outflag )).
```

It expresses the requirement that each credit order ends with a conclusive decision (an offer is sent or the order is rejected) or there are some problems related to the collected documents (conentual problems) that need further processing.

The cyclomatic complexity of the whole model was equal $cc = 55{-}42{+}2{\cdot}1 = 15(14)$. The value in the parentheses takes into account parallel tasks: *Create and send correspondence* and *Archive documents*.

Performing model checking for interleaving semantics of events, forks and joins failed. Without dynamic variable or-

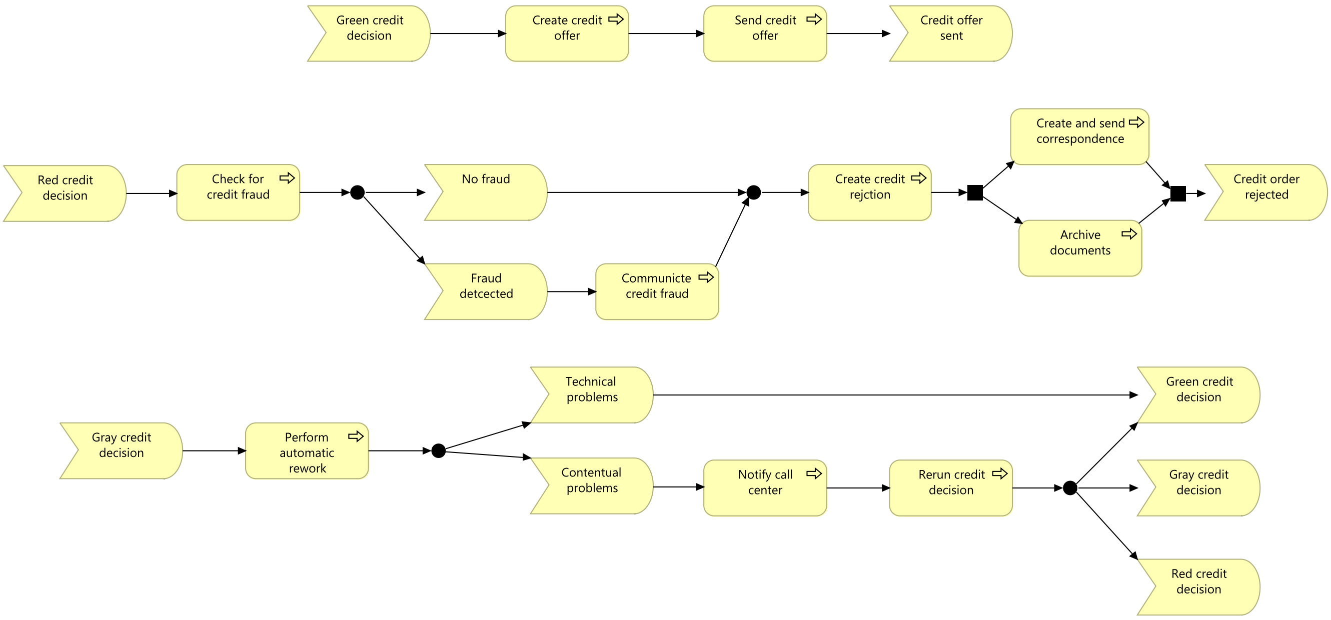

Fig. 12. Final stages of the credit decision

dering NuSMV consumed about 6GB memory. After applying dynamic ordering, the memory footprint was smaller (less then 500kB). However, in both cases the verification processes did not terminate in an acceptable time. This result was somehow disappointing, because based on the cyclomating complexity value, we were expecting that the verification is feasible.

For the synchronous semantics of events, binary forks and joins the model verification succeeded. The total number of states was equal $2^{53} \cdot 3^{17} \cdot 5^{2} \approx 2.90798 \cdot 10^{25}$. The number of reachable states was equal $3.05508 \cdot 10^{9}$ (i.e. greater by 2 orders of magnitude than the most complex processes in Table I). Without dynamic variable ordering the procesisng time was really long: 768522.57 ms = 12.5 min. However, applying dynamic variable reordering (sift method) reduced it to 41706.78 ms. We consider this result acceptable.

## VI. Conclusions

This paper investigates the problem of automatic verification of behavioral specification embedded within ArchiMate models. We propose an approach consisting in fully automatic translation of ArchiMate specification into a model in NuSMV language and then verifying it with the NuSMV model checker. Requirements specification in form of CTL formulas can be entered by user, but the implemented tool is capable of generating specifications based on analysis of control flows.

The main concern of our work was the time efficiency of the verification process. We tested it on a set of of artificial business process specifications, as well as on a real business process example.

The results show, that the described approach can be applied in an interactive verification tool, however, due to state space explosion problem, verification of complex business process specifications can still be a challenge for symbolic model checkers. Hence, dedicated model generation techniques focusing on keeping models compact, e.g. simplifying the models, avoiding interleaving and generating partial models, should be employed.

Although the presented considerations are related to processes defined ArchiMate language, the results of tests are applicable to process models defined in other languages including BPMN and EPC.

***Abstract*—Language barriers in day to day communication are common in all countries. In Sri Lanka we have a rising need for translation for Sinhala and Tamil to reduce language barriers and the statistical machine translation approach is more suitable for the concerned languages. Statistical machine translation method is one of the most promising and efficient method to perform machine translation for Sri Lankan languages likes Sinhala and Tamil. Statistical approach is more suitable for structurally dissimilar pairs of languages and efficient solution for large text translation. Sinhala and Tamil have a similarity in grammar and statistical approach will help to obtain more accurate results. We have developed a Real-time bi-directional translation system for both Tamil to Sinhala and Sinhala to Tamil for this research. We have used the Sri Lankan parliament corpus to train the language model. We have critically evaluated the both systems with parameter optimizations and have obtained the most accurate and efficient system. We have also utilized the scoring techniques like BLEU [2, 8] & NIST [2] for the system evaluation and we have integrated the MERT technique to tune the decoder.**

***Index terms*—Statistical machine translation, Natural language processing, Sinhala, Tamil, Machine Translation**

## I. Introduction

### A. Background

A*UTOMATIC machine translation* is one of the main concepts in simulating *Human Intelligence* which has several researches going on. The functionality of machine translation is to perform translation activities on natural languages which are complex and ambiguous. Machine translation comes under the learning area of Natural Language processing which depends on the subject areas like statistics, linguistics and computer science. Machine translation can be defined as *"Automatic translation from one language to another using computing devices and algorithms"*. A translation approach is about combining many techniques into one to get the translation right. Machine Translation can be divided into approaches such as transfer approach, Interlingua approach, direct approach and corpus based approaches which has two types like Example based and Statistical based)

### B. The Statistical Approach

According to proven results statistical machine translation is one of the most efficient and effective translation approaches which is well matched with western and Indic languages. Statistical MT approach helps to finish up with mathematically easily decomposable model. It is not very complicated when compared to other rule based approaches and has been proven as the most promising approach to all-purpose text translation. SMT approach has the standard algorithms and models available which can be applied to any language pair, with large corpora with few linguistic assumptions. This help to minimize the development duration.

### C. Goal, Objective, Scope & Motivation

The main goal of this research is to develop a real-time communication system which can perform statistical machine translation for Tamil and Sinhala.

Our objective is to research on the machine translation domain and create an efficient and accurate system than existing ones. The real-time system we have developed for this research performs machine translation in a very efficient way and can be used as a core for many types of software. Other than the development part of this system we also have some sections like MERT tuning, system evaluation using BLEU and NIST metrics.

The scope of this project is to develop a real-time instant text communication tool which can translate Sinhala and Tamil bi-directionally. The translation output is based on the type of the language corpora we use to implement the system. And the training data is updated continuous data from users through the reporting system which will increase the quality of the output with many users using it. First few months has been spent on research and learning of Natural language processing concepts. Few months period has been spent for the design and Implementation of the system. Software tools namely GIZA++, Moses, IRSTLM, MERT Module, NIST & BLEU module are the components that are built-in in the system.

The motivation to try out this project is to reduce the unavailability of translation systems which can be used for instant messages especially for Tamil and Sinhala. And previous researches in this domain are discontinued or not visibly used. Languages concerned in our researches are Tamil and Sinhala. When analyzing about the two languages the sentence structure on both languages seems to be identical in many occurrences. Disregard to some insignificant variations, the two languages has the same grammatical structure which is adequate to maintain the meaning understandable in both languages.

We are using Statistical Machine translation because it gives good results for even dissimilar language pairs and using rule based approaches for languages like Tamil & Sinhala will consume a lot time, effort and the result will be error full and inaccurate.

### *D. Statistical Machine Translation*

Statistical translation systems work by learning how the grammar of source and target languages are defined. They begin to work with less number of dictionary entries and language resources. Developers can train the system by increasing the entries to handle complex and extensive translation scenarios. Google is one big player in SMT related NLP applications.

*Diagram 01 : Statistical Machine Traslation*

Statistical MT systems usually work or get trained by breaking sentences into n-grams. Analyzing n-grams will improve accuracy and performance. A word may have many types of meanings but it will only have fewer meaning in a phrase form. Most of the SMT systems work on bi-gram and commonly tri-gram. Tri-gram simply means as three –word groups. Three-word groups are more than enough to process efficiently on the data set. Larger n-gram will require more power and time to analyze and translate. In a statistical machine translation system the common n-grams are tracked and more frequent translations are learned and used in the future translation activities. Statistical analysis of n-grams are happened which will analyze the position of the n-Gram with regard to the sentence. Mathematical translation models are updated after each and every translation which will result in accurate results. Faster processer will improve performance of training and tuning and reduce the time taken to it. Technologies such as C++, Java and Perl are used to develop NLP algorithms. As the languages are platform independent. They will enable their functionality on many Operating Systems. Training the SMT system extensively will lead to a highly accurate translation system. Compared to Rule based systems Statistical systems saves more time, money and effort. Rule-based systems for a language pair like Tamil & Sinhala will require many years and considerable amount of funding. Statistical systems can be trained to a good accuracy level in few months. This makes statistical approach less work intensive and that is the main reason we choose this approach for our short-term research purpose.

The SMT approach is more useful for corporate and government applications. One of the limitations in a Statistical machine translation approach is that it will require powerful computers for large training and accurate translation. The main concept in SMT systems is to select the target language phrase which has the maximum probability of being the translation on the source language phrase. A probabilistic model is a base for all the computations in the SMT system. Assumptions on Bayes Rules and Noisy channel model make the system less complex when generating the probabilistic model. When an input sentence is given into the system the target phrase with more probability will be selected as the output. This statistical translation approach can be briefly described in mathematical terms

$$\mathbf{t = argmax_t\ P\ (t/s)\ \ldots\ldots\ldots\ldots\ldots\ (1)}$$

Using Bayes' theorem, the value of P (t/s) can be given as

$$\mathbf{P\ (t/s) = (P\ (t)\ P(s/t))/\ (P(s))\ldots\ldots\ (2)}$$

Referring to equation (2), t can be written as,

$$\mathbf{t = argmax_t\ (P\ (t)\ P(s/t))/\ (P(s))\ldots\ (3)}$$

In equation (3), s is fixed in source language. As a result of this, P(s) can be removed from the equation when finding the sentence t. That has maximum probability. Then equation (3) becomes as equation (4)

$$\mathbf{t = argmax_t\ (P\ (t)\ P(s/t))\ldots\ldots\ldots\ldots\ (4)}$$

Element P (t) in equation 4 denotes the kind of sentences in Target language (T). P (t) is called Language Model of target language (T). The other element in equation 4, P (s/t) specifies how each sentence in target language (T) can be translated into source language sentences (s). This is called as the Translation Model. Equation (4) lays the foundation of statistical machine translation with the specification of two key components namely language model (P (t)) and translation model (P(s/t)).

Improving the language model in the SMT system is a manual job but we can use MERT techniques to train the system in minimum error rate which will result in accurate systems. MERT recommends a substitute training strategy for log-linear statistical translation models. MERT training is a straight forward method which will optimize translation quality using some automatic metric score. During the weight optimization of decoder parameters such as phrase translation table, language model, distortion, word penalty etc. MERT searches weight values that reduce translation errors. Metric scores supported by MERT are BLEU, NIST and TER. As the manual evaluation is hard and time consuming job, to make the evaluation more flexible metrics like BLEU and NIST were introduced. BLEU metric is a de facto standard which is used for Machine translation system evaluation. BLEU score gets the geometrical mean of modified precision score of the test corpora and multiply with some exponential brevity penalty factors. BLEU score increases to a higher value when the number of reference translations is increased. NIST [2] is a metric built on top of BLEU [2, 8] which enhances it with few modifications. One of the major modifications done by NIST is it assigns higher weights to rare or less occurring n-grams than regular ones. It simply applies the smoothing technique on rarely used n-grams.

## II. Related Work

There are numerous researches and projects developed on Statistical machine translation in the recent past. Sri Lankan developers have worked on many Sinhala, Tamil related NLP systems in the past few years. In the reference [3], the developers had developed statistical machine translation systems for 4 European based languages such as English, German, Spanish and French. The data they used was from a general domain and large in size. German to English SMT systems has an average BLEU score of 0.236. Spanish to English SMT systems has an average BLEU score of 0.340. French to English SMT systems has an average BLEU score of 0.316. The research [1] is a SMT implementation for English and Sinhala Languages. This research includes several refinements. This research talks about MERT inclusion, Translation Model tuning, Language Model Tuning and various word alignment and reordering techniques. The BLEU score obtain at the end of the research was around 0.1500 which is a very low value.

The research [2], which was developed by UCSC, is one of the best references for SMT implementations. This SMT system was implemented for Sinhala and Tamil Languages. This research also uses the data of specific domain which is from various public websites. The best BLEU score obtained from this research for Sinhala to Tamil system was 0.185. Even though it's not a very successful research this paper talks about some viable techniques and approaches for SMT based applications. This research uses some old tools and this research was just the beginning of a successful SMT system. The further researches by this team have given great result on evaluation. This research is one main reference for our current research. After reading all the related work we learned every strength and weaknesses of the systems and have embedded that knowledge into our research to obtain higher scores. We have used newer and updated techniques to our current research and we have also contacted the previous researchers on this domain and brainstormed ideas with them to come up with a good final output. The innovative thing we are proposing through our research is using this traditional SMT concept and implementing them into a real time communication application. This application will be less complex and will support all kind of users facing language barriers during communication.

## III. Data Preparation

In Sri Lanka when developing applications on Machine translation the only resource for datasets on Tamil and Sinhala is the parliament order papers on budget proceedings. We have used an electronic version of the parliament order papers which has parallel data on both Sinhala and Tamil. We used over 5000 phrases from each language which is totally more than 10000 sentences and more than 100000 words to train the system. One of the main reasons for the lack of development in translation systems in Sri Lanka is the unavailability of the corpus and the restrictions to obtain them. We obtained the Sinhala and Tamil Electronic version in a dirty manner where it is not aligned properly with the languages. The initial stages of the research was planned to develop a SMT systems in the chat domain for Sinhala & Tamil. After the research we found that parallel data Sinhala and Tamil in the chat domain is not available and building or creating one would require a lot of funding in the current situation. We limited ourselves to the parliament domain. The reason for using the parliament order papers is that the parliament members speak more formal languages which are not commonly used in the society. The languages are translated into more exact order in the parliament because in parliament discussion every word and phrase is important. We can 100% ensure that the meaning is not altered due to the variation in the language style. This process applies to both Sinhala and Tamil. One of the drawbacks of the system is that when we use a parliament corpus for the research the system is tuned to domain of parliament style translation so that we cannot use this system to translate non formal type of sentences or phrases. The obtained electronic versions of the parliament order papers were pre-processed before using them as inputs. Reasons for pre-processing are unwanted gaps between words, disordered words, disordering of Tamil Sentences aligned to Sinhala Sentences and some complex character are broken which makes it a garbage character. After cleaning the Sinhala and Tamil parallel data we can ensure that most of the sentences are in proper order in allowed manner, but still some issues will remain. We have to assume the pre-processed data as a perfect one. Redundant contents are removed randomly in some selected files and the final data set for the system is prepared. In a Statistical machine translation system implementation data preparation is essential and plays a major role in the final results. After the preparation of the datasets we did the selection process of the Data sets. We divided the data set into three such as

Training set, Tuning Set and Testing set. The table is given below. This table shows the number of word and phrases in the data sets.

TABLE 1: DATA SETS

| Data Sets (Words and Phrases) | | | | | | | |
|---|---|---|---|---|---|---|---|
| Language Model | | Training Set | | Tuning Set | | Testing Set | |
| Si | Ta | Si | Ta | Si | Ta | Sin | Ta |
| 165k | 77k | 99k | 78k | 3425 | 3078 | 3110 | 3204 |
| 6550 | 6104 | 5887 | 5887 | 200 | 200 | 200 | 200 |

Addition to the above mentioned datasets, as a team we have prepared our own dataset which includes parallel sentences of normally used phrases in Sinhala and Tamil. We prepared more than 2500 parallel sentences and in our system we have added a feature where the user can report the admin with the translations. These translation sentences will be added to the system's training data and the SMT core will tuned frequently in a periodical manner. This will improve the output quality. One of the reasons we started to develop a real time SMT chat application is that we can create new and improved trained data using users' contributions. This is will lead to an improved data set creation which can be used for future projects related to SMT as well.

## IV. OUR APPROACH

The system design is the heart of all system implementation. The design section consists of three main parts such as Architecture Design, Implementation Design and Evaluation Design. Architecture design is all about explaining how the modules and components are connected and working together. The implementation design illustrates about the implementation of folder structures and file paths which are used in the SMT system. The third one, evaluation design explains about how evaluation and experiments are carried out on the system to arrive at conclusions and results.

### *A. Architecture Design*

The main Architecture of this Real-time Statistical Machine Translation system is basically not an innovative one or a new thing to be researched. It has a long standing research history in its hands. The main component of this project is the SMT module and we don't need to alter the entire design of the SMT but have to follow the best practices. SMT approach is language independent. Many of the SMT implementations follow the common architecture. In our research, the both systems use this uncomplicated architecture as its backbone. Rather than mixing all the modules together, we are defining the components explicitly and linking them according to the need. The SMT system we are developing for this research is a layered architecture. This architecture helps us to make the system uncomplicated and easy to understand. The layered architectures help to add and remove components.

In the design when considering about the data preparation component, the functionality of it is to obtain the whole data set and divide into subsets. These separate data sets are used for training, tuning and testing purposes, which will lead to efficient system evaluation. Addition to this we can do language modeling if a monolingual corpus is available. The whole data set is divided into two subsets. One is for language modeling and other one is for model evaluation. Model evaluation will not require huge data set. Before these steps the whole data set is tokenized. Formed outputs are the inputs to language modeling component. In case of Sinhala to Tamil system, Tamil language model should be produced. The un-tokenized whole data set is divided into three parts for training, testing and tuning. Training data set is the input of translation modeling component. Tuning data set is the input for the automatic tuning & decoding component and testing data set is the input for evaluation component.

The Language modeling module consists of all executable files created by IRSTLM. N-gram and n-gram count are two modules needed for LM modeling and evaluation respectively. Outputs of the language modeling component is the Language model and the perplexity scores. To obtain an optimal language model from evaluation, it is required execute the LM with various smoothing and discounting parameters and obtain the scores. Manual evaluation scores after each language modeling would help decide the optimal one. The next component is the translation model which is created using the training set. We have referred GIZA++ tool to implement this module which creates the word alignment and translation model. We can adjust the word alignment and reordering strategies to create or obtain the best Translation Model. Decoder configuration file is created at the end of this procedure so that the decoder script will start running by referring this script. The tuning component is responsible for changing decoder parameters & weights modifications which will result in change in evaluation metric scores like BLEU & NIST. The next component is the decoder executable. The inputs for this module are the test data set and the TM components such as phrase table and word alignment table and the decoder configuration file. The actual translation function happens inside this module. Source language file is translated and the translation process stops at the formation of translated output file. Prior to the automatic evaluation via three metrics, a little formatting is essential on the input data sets of metric-modules. Inputs of metric modules are translated output, reference text and source text. In Sinhala to Tamil system, reference file needs to be in Tamil which is the genuine translation of the Sinhala test data set. Scoring is restricted for only one reference file. Other than these above modules we have another two separate modules which are called as back up module and reload module. Back up module backups all system inputs, configurations and the outputs. Reload module reloads the backup data and configurations into the system. With all these components we have also having a simple client to client chat or communication application to fulfill the scope. This application uses the SMT module as the core and serves the users who want communicate in their native languages without any barriers.

### *B. Implementation Design*

For a successful research a good Design is essential. As developers we have to also focus on implementation design to achieve what we wanted. Having good design architecture isn‘t lonely enough. Implementation design consist the details of folder and directory structure of the implementation which is very important for the performance and the efficiency of the system. A proper folder structure will also help for easy maintenance which will reduce errors and unwanted exceptions.

In our SMT system we have bi-directional implementation which includes Sinhala to Tamil and Tamil to Sinhala. Both the systems share some common files in the system. Some tools are configured and made common to both systems. Interaction with each system is feasible through bash scripts. In our system we will have two clients who does the communication part. The input string is received from one client end and then the SMT core translates it into a target language. The target string is sent to the client in the other side.

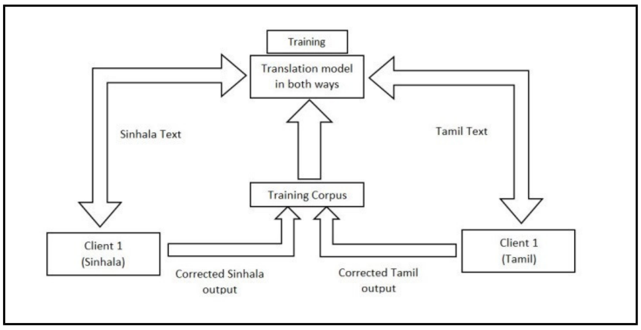

*Diagram 02 : Workflow of our Final Translation Application*

### *C. Evaluation strategy*

Evaluation of systems is an essential part of this research. A plan or strategy is developed during the development phase about how we are going to evaluate the system. The evaluation strategies we have followed here are change parameters and algorithms in different combinations and obtain BLEU and NIST score from each system. From those results we can obtain an accurate and efficient system for the languages like Tamil and Sinhala. The evaluations results are presented in a statistical form. These combinations of evaluation end in many number of system backups and as we are dealing with many evaluation techniques we can call this as a good evaluation strategy.

## V. Implementation

Major parts of our implementation are Sinhala to Tamil MT System and the Tamil to Sinhala MT System. For a successful research, excellent design architecture in hands endorses effective maintenance and help reducing mistakes. Having good design architecture isn't only enough. Implementation or the directory structure holds a place to handle executions and maintenance comprehensively. Good directory structures are formed bearing maintenance/ backup/restore simplicities in mind.

The **LM input files** directory will hold the Data sets (both Sinhala and Tamil) for language models creation and LM test files (both Sinhala and Tamil) are located here. Calculated perplexity values are written to files residing in "lm evaluation" directory. The **Input** directory will contain the inputs for both SIN-TAM and TAM-SIN system. In case of SIN-TAM, reference file (Tamil) should be the corresponding parallel corpus of test file (Sinhala). The **Output** directory will have the final de-tokenized translated output of the system. NIST, BLEU and TER scores are saved in the **Results** directory. The **Scripts** directory will contain some Bash scripts to control operations such as cleaning, backup, restore, and load backup, run components like Data model, language model, Decoder, Automatic tuning component and evaluation component of entire SMT. There is also a directory in our system called **Word** and this will store tool's output/input files.

Corpus has tokenized parallel corpora. Evaluation directory is with raw system output and formatted output files (for automatic metric evaluation). Language model is located inside "lm" directory. MERT files and tuned decoder configuration files are found in tuning directory. The same structure as that of SIN to TAM applies to TAM to SIN system also but instead of all Tamil files, Sinhala files should be there and vice versa. In backing up process, "input, output, work, lm evaluation, results and importantly all Configurations files and used commands" will be copied to a new location. This process is essential as lots of experiments need to be done and as outputs are required to be loaded again for further tests or for re-evaluation purposes.

The directories "IRSTLM, GIZA++, Moses, TER modules" have all installed files but when porting the system to another location these may be ignored as all executable are located in "executable". During our development we have used some modules from some tools such as IRSTLM, GIZA++ and Moses. The IRST Language Modeling Toolkit features algorithms and data structures suitable to estimate, store, and access very large n-gram language models. It can be used in Linux platform. IRSTLM offers the most advanced n-gram smoothing methods to estimate large LMs and approximated smoothing methods to estimate gigantic LMs. It includes methods for pruning and quantization of LMs, efficiently storing LMs on disk and in memory and it offers several language adaptation methods: linear interpolation, minimum discrimination information, and probabilistic latent semantic analysis.

Moses is one of the open source toolkits for statistical machine translation. Moses toolkit uses some tools for some of the tasks to avoid duplication such as GIZA++ for word alignments and IRSTLM for language modeling. The information about Moses was obtained from Moses documentation. The Moses toolkit has achieved some objectives such as Accessibility, Easy maintenance Flexibility, user-friendly, distributed team development and Portability. The Real-time chat application is developed using Java programming language. It is very light weight and we have developed that software in which it can be applied as a layer on top of the SMT core system and operate in good efficiency.

## VI. Evaluation

### A. Basic System Evaluation

Our evaluated system's entire language model is domain specific. And Number of 2-gram hit is relatively high in both language models. All n-gram hits in Sinhala are not as much as Tamil Language.

TABLE 2:
N-GRAM COUNTS FOR SINHALA & TAMIL

| Language Model | Sinhala | Tamil |
|---|---|---|
| 1-Gram | 4703 | 5946 |
| 2-Gram | 15337 | 16283 |
| 3-Gram | 8474 | 13280 |

TABLE 3:
AUTOMATIC METRIC SCORES FOR BOTH SYSTEMS WITHOUT MERT TUNING

| *Systems* | Sinhala - Tamil | Tamil – Sinhala |
|---|---|---|
| BLEU | 0.4277 | 0.5599 |
| NIST | 4.4090 | 4.1244 |

After the evaluation we obtained highly excellent BLEU & NIST scores in both systems and Tamil to Sinhala System gives the highest from the two systems. The BLEU score results in high values which is a proof that the system has high accuracy. In the Sinhala to Tamil system, the value of BLEU is not that best as NIST. However all these metrics favors the output of Tamil to Sinhala system in a positive manner. The both systems gives high positive values on scoring other than the existing systems developed by the past researches and experiments.

### B. Tuned system Evaluation

The good thing of the research was that we had very good score with normal settings, but more quality output can be expected after fine tuning the system. We used the Minimum Error Rate Tuning (MERT) technique to achieve more scores. After MERT [2] technique we received new scores. Below table shows the new values obtained for the both systems in a table format. The score values are in four decimal places. These scores show some great improvements.

TABLE 4:
AUTOMATIC METRIC SCORES FOR BOTH SYSTEMS WITH MERT TUNING

| *Systems* | Sinhala - Tamil | Tamil - Sinhala |
|---|---|---|
| BLEU | 0.5957 | 0.6693 |
| NIST | 4.4182 | 4.8563 |

It is very much acceptable that MERT has enhanced the scores of the both systems in a good rate. BLEU score has been improved in both systems by a good number. NIST score has been improved in the Tamil to Sinhala translation system but not much in the Sinhala to Tamil System. BLEU has been improved in the highest percentage and NIST get the least improvements. When talking about decision making of the system we have developed is that the scores are well improved values than previous research on SMT with local languages like Tamil and Sinhala. And we can mark this as a successful research. Addition to scores we have also calculated the time taken for the translations for both systems.

TABLE 5:
AVERAGE TIME TAKEN FOR TRANSLATIONS IN BOTH SYSTEMS

| *System* | *1 - sentence* | *3-sentences* | *5- sentences* |
|---|---|---|---|
| Sin - Tam | 0.778s | 1.94s | 2.052s |
| Tam - Sin | 0.035s | 0.249s | 0.299s |

## VII. Conclusion

In a summary, both translation systems have given positive results and scores. One of the beneficial things from good BLEU scores is that we can extend the research to new heights with a positive system. Word alignment algorithm we used was *grow-diag-final* and reordering algorithm was *msd-bidirectional-fe*. According to the tables mentioned in the evaluation section the BLEU & NIST scores were better than existing system and it improved even more after MERT technique. The final BLEU scores of the achieved systems are 0.595668 & 0.669333 and also achieved NIST scores are 4.4182 & 4.8563. Both systems also have very less and efficient translation times. These systems can be improved into a highly accurate system by using large dataset of training data and changing the architecture.

## VIII. Further Work

There are many future plans to improve the research and improve the system further more usable. One of the main further plans for this project is that to use a large dataset of Tamil & Sinhala phrase set to train the system. The data we used for this research for now is very minimal and with the real-time system we have developed with the reporting feature, we can hopefully prepare more amounts of translation pairs to create a translation with high quality. The limitation we faced while starting the project was the unavailability of chat data on Sinhala & Tamil. The human effort required to prepare the data is too high and costly, but we have started preparing the data using some volunteers and planning to take to the next level in the future. One step on that is the implementation of the automatic reporting system in the chat application. We will be working on the negative outcomes from this research. In the future we can differentiate the build architecture and make the translation module usable for application like Facebook and related technologies. One of our visions on this research is to make this translation functionality as a service and make it available for the developers to use it.

## Acknowledgement

The authors of this research paper wish to acknowledge the supervisors and members of Faculty of Information Technology, University of Moratuwa who helped in many ways for the research. Special thanks to UCSC, Sri Lanka for the data and the past research papers related to machine translation. The authors have adapted few technologies and research procedures for this research from their past researches.

***Abstract*—Multi-criteria decision analysis (MCDA) methods have become increasingly popular in decision-making. Numerous methods in this field were developed to solve real-world decision problems including various engineering and scientific areas. Unfortunately, the proper use of each method is difficult due to the dispersion of the domain knowledge and lack of knowledge databases in this area.**

**The paper presents research focused on knowledge management aspects in MCDA domain. In order to achieve a high level of practicality on different levels of decision making, the ontology as a form of conceptualization is implemented.**

## I. Introduction

Together with the development of operational research, as an alternative approach evolution of MCDA methods has been observed. This applies both in theoretical studies that result in the continuous development of existing methodologies and techniques, and in the emergence of new methods as well as the application layer covering new areas of application methods in business practice.

In each case of individual specification of environmental decision-making situations, the selection of a multi-criteria method should be carried out with great care [1], and the recommendations of selection techniques for modeling and aggregation of preference should be carried out with the following considerations:

- taking into account a detailed specification of the discussed problems and pending issues, including their complex and multi-level character,
- an intuitive dialogue with the decision-maker and the user at the stage of formulating and implementing the assessment process with the subjective linguistic approach implemented,
- possible use of imprecise preference information by the evaluators, including variability of the assessment,
- the possibility of missing a situation assessment and incomparability of decision variants for multiple forms of preferential information with the deterministic, not deterministic, ordinal or fuzzy character.

The natural consequence of various areas of application of multi-criteria methods is the need for the development of dedicated approaches adjusted to the specifics of the problem. This is confirmed by a detailed analysis of the literature, where research in various scientific disciplines is effectively carried out using a number of multi-criteria methods [13] [11]. Combined with a variety of specific decision problems discussed by the authors of studies in this field, the natural direction of research can be an attempt to systematize the knowledge in this area. An additional prerequisite for undertaking research in this area is a large heterogeneity of domain knowledge including available scientific publications and the existing decision support systems.

In the literature, attempts to develop models of knowledge representation of MCDA problems and methods areas can be observed. For example, the article [6] presents an ontology designed to describe the structure of decision-making problems. It is a component of the support for the group decision-making processes. On the other hand, in [8] an ontological representation of the multi-criteria method of AHP and a set of inference rules were developed. In this way, clearly defined and formalized concepts related to the method of AHP and knowledge reusing allowed implementation in the form of ontologies. Earlier studies of systematized knowledge about various aspects of decision-making are presented [9][10]. One of the approaches is based on using ontology knowledge model integrating knowledge about decision-making process [9]. It includes such elements as the decision-making situation, the decision problem, a set of alternatives and evaluation criteria, rules, preferences and decision-makers. Then the developed model was verified within the problem of decision-making for the ERP system selection. The proposed approach was later extended by ontology components based on a generalized approach to formalization of methods of decision support [10]. The proposed ontologies focused on knowledge that makes it possible to structure knowledge about the decision problem. However, they take the problem of systematization of knowledge about the various methods of multi-criteria

978-83-60810-66-8/$25.00©2015, IEEE

decision support only to a small extent. Characterized ontologies do not include knowledge about the characteristics of the different MCDA methods and their environmental context and use cases [7].

The purpose of this article is to develop a ontology based knowledge model of MCDA methods. Taking into account the contemporary standards of knowledge engineering, it is justified to implement a repository of knowledge in the form of ontologies. In order to build the first stage of such a solution, literature related to MCDA methods was reviewed and analyzed. This formed the basis of the development of a taxonomy and ontology. Ontology as a proposed form of the conceptualization can be used as a source of knowledge that can be used repeatedly. The study was divided into two parts: a discussion of the literature and the development of a taxonomy of MCDA methods together with the ontology of MCDA methods. The article ends with the author's practical ontology verification using competency questions.

## II. Methods of multi-criteria decision support

Research on MCDA area led to the development of two main groups of methods and directions. They differ significantly from each other both in the approach to the decision situation and in the way of choosing the best alternative . These are approaches based on utility theory and outranking relations [4]. An approach based on utility theory is derived from the American MCDA school . Two kinds of relationships between alternatives are identified: indifference ($a_i$ $I$ $a_j$) and preference ($a_i$ $P$ $a_j$) of one alternative over another. The methods in this group exclude non-comparability of the decision variants and assume transitivity of preference [4]. Among the methods based on utility theory main approaches include: MAUT (Multi-Attribute Utility Theory), AHP (Analytic Hierarchy Process), and UTA (Additive Utility Theory). These methods usually do not take into account the uncertainty, vagueness and ambiguity that can occur in the data [4]. Methods based on outranking relations are derived from the European MCDA school and the outranking relationship is characterized by the lack of transitivity between pairs of decision variants.. These methods mainly include methods from ELECTRE family (ELimination Et Choin Traduisant la REalite) and PROMETHEE (Preference Ranking Organization Method for Enrichment Evaluations). Methods from this group frequently extend a set of basic preferential situations with the result that includes indifference of decision variants ($a_i$ $I$ $a_j$), weak preference one variant over another ($a_i$ $Q$ $a_j$), the strict preference of a variant of the decision-making relative to the other ($a_i$ $P$ $a_j$), and incomparability between data variations ($a_i$ $R$ $a_j$) [18]. Furthermore, couples of variants can be grouped to determine the relationship connecting the two or three basic situations. With the occurrence of the grouped relationship, it is impossible to distinguish, without additional parameters, the basic relationship of the grouped situations. Such situations are: “nonpreference” which are groups of indifference and incomparability situations ($a_i$ $N$ $a_j$), “preference” which are situations of weak and strict preference ($a_i$ $L$ $a_j$), “guess preference” which combines situations of indifference and weak preference ($a_i$ $J$ $a_j$), “K-preference” which are groups of strict preferences and situations of incomparability ($a_i$ $K$ $a_j$), and “outranking” which contains the situations of indifference strong and weak preference ($a_i$ $S$ $a_j$) [12]. Due to variations of the relationship between the decision-making, two basic approaches can be distinguished to aggregate operational performance variants : (1) aggregate to a single criterion (2) aggregation by using the outranking relationship [12]. The first operational approach excludes the incomparability situation and contains only the most indifference relationships and strict preference. It is strongly associated with the American school of decision support. The second approach takes into account incomparability and outranking and is generally used in the methods derived from the European MCDA school. Based on an analysis of the literature, a complex set of available MCDA methods was identified and the general characteristics of which are shown in Table 1. The exact classification of methods along with the characteristics is presented in the rest of the article followed by a description of the process of building a taxonomy of MCDA methods.

## III. Building taxonomy and ontology of multi-criteria decision support

Ontology is treated in the literature as a set of definitions of the terms of the area and the relationship between them [3]. It is also referred to as the specification conceptualization providing a description of the concepts and relationships that occur between them [2]. The use of ontologies as a solution supporting the choice of an MCDA method is designed to assist the user in selecting the right solution for a given decision situation described using specific criteria and parameters. The ontology should also provide detailed information about the various methods for multi-criteria decision support.

The first step in the construction of an ontology is to develop a taxonomy of criteria describing the MCDA methods. Identification and analysis were based on the analysis of 25 MCDA methods for creation of a set of criteria and sub-criteria characterizing the different solutions. A total set was formed comprising four main criteria (available binary relations, linear compensation effect, the type of aggregation and the type of preferential information) and 16 sub-criteria. This collection was also

TABLE I. CHARACTERISTICS OF SELECTED METHODS OF MCDA

| Method name | Essence of the method | Reference |
|---|---|---|
| AHP | The problem is formulated in a hierarchical form. Overall rank is based on the collective aggregation of partial marks obtained in a paired comparisons in matrix. | [19] |
| Additive weight method | Aggregation based on the inadditive function. Choosing the best alternative with the highest value of the global index obtained as the sum of the partial marks for all criteria. | [20] |
| EVAMIX | Ranking of alternatives on the basis of global dominance index (ordinal indices and cardinal dominance). | [21] |
| Electre I | The aim of the method is to determine the subset of variants containing the best alternative. The procedure is based on the construction of compliance and non-compliance tests, following the structure of the outranking graph. Preferences modeling is done using the true criteria. | [22] |
| Electre II | Extension of ELECTRE I method. The essential part is the use of two outranking relations :weak and strong. | [23] |
| Electre III | Ranking of variants based on outranking relationship. Modeling preferences with pseudo criteria and weights. | [24] |
| Electre IS | The method constitutes a development of ELECTRE I with additional modeling preferences based on pseudo criteria. | [25] |
| Electre IV | Ranking of variants based on the relationship with outranking pseudo criteria. It does not apply weights to the criteria. | [26] |
| Electre TRI | Sorting variants into categories based on outranking relationship. Modeling preferences with pseudo criteria. | [1] |
| MAUT | Ranking of variants based on the aggregation of sub-additive utility function form. | [27] |
| MAVT | Ranking of variants based on the aggregation of multiplicative utility function. | [27] |
| MELCHIOR | The extension of the ELECTRE IV method. Ordinal relationship validity of the criteria is added. | [28] |
| Maximin method | The aim of the method is to choose the strongest variant of the weakest. | [20] |
| Maximin fuzzy method | The aim of the method is to choose the strongest variant of the weakest. Evaluation of alternatives has the fuzzy form. | [29] |
| Methods of extracting the minimum and maximum values of the attribute | Methods reject criterion values successively above and below the predetermined value. | [20] |
| NAIADE | Application of fuzzy measures distances and of paired comparison. Calculation of preferences as in PROMETHEE. | [30] |
| ORESTE | Uses alternatives assessment and weighting of the criteria described only on an ordinal scale. | [31] |
| PROMETHEE I | The method constitutes a development of ELECTRE methods, but expanded the number of binary relations describing preferences to six. | [32] |
| PROMETHEE II | Extension of PROMETHEE I by the global results for all variants. | [32] |
| REGIME | The method is based on a pairwise comparisons matrix. Scale {1,0,1} is used. The values of the scale correspond to the domination, equivalence and dominance. | [33] |
| Additive fuzzy weight method | The method is based on a fuzzy version of the additive weight method where weight and evaluation are modeled as fuzzy numbers. | [34] |
| Fuzzy methods of extracting the minimum and maximum values of the attribute | Methods reject variants' criterion values successively above and below the predetermined value. Take the form of fuzzy evaluation. | [35] |
| SMART | Ranking of variants based on the aggregation of partial form of additive utility function. Global evaluations are calculated as a weighted average of partial evaluations. | [36] |
| TOPSIS | Choice of the best option is based on the multidimensional evaluation of the distance from the ideal and opposite solutions. | [20] |
| UTA | The model is additive utility function. Partial utilities are determined by using principles of ordinal regression. | [37] |

the basis for the construction of taxonomies of analyzed solutions. Table 2 presents a summary of the criteria and information about them by the various methods of multi-criteria decision support.

Based on a defined set of criteria, sub-criteria, and information about fulfilling them by selected solutions, the taxonomy created solutions for specific MCDA methods. This taxonomy is presented in the ontological form. This task requires distinguishing the concept on the basis of criteria and sub-criteria and establishing their hierarchy.

Figure 1 presents a graphical diagram of a set of criteria and sub-criteria of the main built taxonomy. The taxonomy provides a set of MCDA methods shown in Table 2, with a set of differentiating criteria and a network of taxonomic relationships between concepts (relations between the different classes of instances). Using this taxonomy, there is a possibility to select methods based on selected criteria.

A detailed analysis of taxonomic relationships reveals the full features of the different MCDA methods. This is the basis for a simple reusable but structured domain

TABLE II. TAXONOMY OF SELECTED METHODS OF MCDA

knowledge area. Based on preset criteria a user can receive detailed information about the satisfying method (methods) with its specific taxonomic characteristics. An example set of graphical results is shown in Figure 2, illustrating a method (here ELECTRE Tri) which met the criteria for the query: binary relations R and S, the partial effect of linear

compensation, aggregation using outranking relations, the type of preferential information – order.

## IV. Conclusion

This article discusses the problem of the construction of a taxonomy of MCDA methods and reference examples. The paper presents characteristics of identified MCDA methods. Based on the following analysis an identified set of criteria and sub-criteria characterizing the different solutions was presented. The results formed the basis for the construction of taxonomic relationships between the different MCDA methods and a complete taxonomy of MCDA methods and their use cases.

The results confirmed the possibility of the conceptualization of knowledge in the area of MCDA methods. The use of the proposed taxonomy supports the decision-maker's correct choice of multi-criteria method and allows for full domain knowledge about each one. It should be noted that the standard used for the construction of the ontology (OWL) ensures full compliance with current international semantic standards. This allows further use of the developed solution as well as its connection to other ontologies in various fields within the rapidly growing trend of knowledge engineering.

Further research should be supplemented by ontology of reference cases of the application of each method in various areas (management, logistics, environment, medicine, etc.) and reference publications characterizing the different MCDA methods. For ontology, additional multi-criteria methods can be attached, as well as criteria characterizing the various methods and the environmental context of their use. It makes possible the greater use of the adequacy of the reasoner and requests the use of various methods in decision problems using SWRL language rules.

*Abstract*—**The aim of this article is to present the methodological framework for Decision Support System for the process of selecting the location of renewable energy sources. For this purpose, the paper presents the methodology and MCDA methods sequentially structuralizing and modeling the decision space and exploiting the developed model. The detailed area of research and verification of proposed approach are related to the problem of offshore wind farm localization. Proposed framework defines input information together with methodological background required for decision support processes.**

## I. Introduction

In recent years, there has been increasing interest in renewable energy sources (RES). The conditions for such a situation are related to the development of new technologies that look for ways of making the national economies of many countries more independent from conventional energy sources. Additionally, the continuing decline of natural energy resources, while their prices increase in the global market, has forced changes in macro and micro strategies to find new sources of energy. Renewable energy sources can be used almost anywhere in the world. The main problem is establishing the correct economical, technological, environmental and social justifications for the location and infrastructure construction using new technologies and resources. In terms of this study, the above issues were narrowed by focusing on the use of offshore wind farms. Decision related to selection of renewable energy sources should be taken carefully due to high impact on environment and community. Big number of factors and preferences create area for the use of Decision Support Systems [13]. Due to the complex set of factors, determining the multi-criteria profitability of this class of investments in wind energy for further study the MCDA methods were used as a methodological basement. This approach is also justified by the analysis of previous studies related to selecting and evaluating renewable energy installations.

## II. Renewable energy sources

According to the classification of the World Energy Council, wind energy is one of the various types of renewable energy sources [1]. This type of energy is used to produce electricity, utilizing wind farms composed of devices using wind turbines to convert wind energy into mechanical energy, which is then converted into electrical energy [3]. The effective operation of a wind farm is crucially influenced by the choice of location. This choice determines the efficiency of its operation and also has an impact on the costs, the benefits, and the environment. For obvious reasons, potential areas for the implementation of this type of investment must be assessed in terms of numerous factors: wind, water depth, and possible conflicts or formal legal exclusions (for example, if the potential area is located in a protected area [4]). In addition, there is a complex set of factors determining the success of this type of investment. Detailed analyses include determining the impact on the marine environment of the investment area and existing users of those areas. The fact that offshore wind farms generate some noise and have an impact on the landscape, which in turn affects the level of acceptance from local communities, must also be considered. That is why it is important to maintain an adequate distance from areas where there are marine mammals, fish species particularly sensitive to noise, birds, marine space, and fishing areas. Improperly located farms can be a source of negative environmental and social impacts. Another extremely important consideration is therefore the appropriate selection of criteria, which determines the accuracy of the entire decision-making process. The multitude of often conflicting criteria makes it methodologically formulated as a multi-criteria decision problem. Among the many available methods of research, the AHP method and Promethee II were chosen for this study; therefore, the article presents the concept of multicriteria model for a decision support system for choosing an investment location.

Review of the existing literature indicates the possibility of using multi-criteria decision methods for problems of selection for different types of economic activities. For

978-83-60810-66-8/$25.00©2015, IEEE

example, Forte [16], in the assessment of land management options, used the method of REGIME, NAIADE, AHP and FLAG. In [20], the region in the context of the use of various installations of renewable energy sources using the AHP method was assessed. Similar problems were also solved by Burton and Hubacek [14], who used the method of MACBETH and assessed the potential locations of such facilities. Eleftheriadou and others [19] used the PROMETHEE II method to evaluate the different variants in the foundation of wind turbines. Such a problem is presented also in the work of Cavallaro and Ciraolo [15], where the authors used the NAIADE method. This method was also proposed in the work of Gamboa and Munda [17] to assess the potential for wind farms in Spain. In contrast, the work in [19] was devoted to the evaluation of alternatives that consider different possibilities for the deployment of wind farms in one of the provinces in China, with the help of the AHP method. The work of Georgopoulou [18] is also relevant, as that research integrated different types of RES in Greece using the ELECTRE III method. The synthesis of research relating to the use of MCDA methods in problems of RES locations are given in Table 1.

## III. The use of multi-criteria decision support methods in chosing the location of an offshore wind farm

The procedure presented in this paper is in accordance with the guidelines contained in [8] and includes five successive stages:

- defining a set of decision variants,
- structuring the decision problem,
- setting priority vectors using the AHP method,
- exploitation of model and ranking of the decision variants using the Promethee II method,
- interpretation of the model with Plane Gaia and a sensitivity analysis of the set of decisions.

The first step in obtaining solutions is to define a set of decision variants for the problem of choosing the location of offshore wind farms in the Baltic Sea. Based on the map developed by the Maritime Institute in Gdansk [5] [6], including a list of potential sites for the location of offshore wind farms, 6 areas were selected. On this basis, a 6-piece set of variants for decision-making was established: W = {W1, W2, W3, W4, W5, W6}, where Wn is one of the locations on the Baltic Sea. The locations are shown in Figure 1.

Table I. Research relating to the use of MCDA methods in problems of RES locations

| No. | Assessment | Category | Main criteria | | | Method | Number of criteria | Type of data | Ref. |

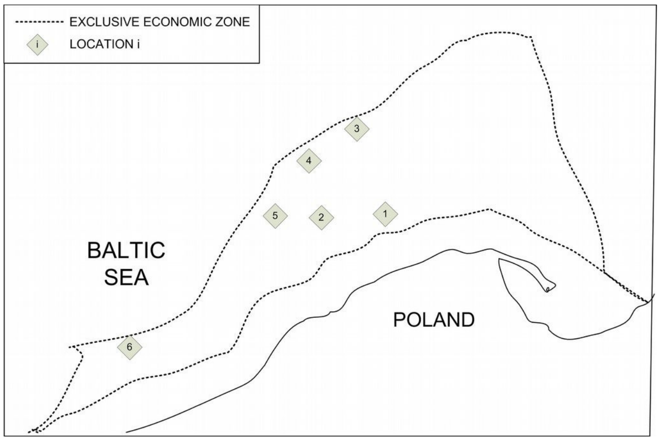

Fig 1. Map of potential locations

Selected locations have similar wind conditions, but vary in size, which determines the number of possible wind turbines that can be installed.

In the next step, the structure of the decision problem was identified. Analysis of work related to wind energy, including [2] [17] [3] [19] was used as a foundation to build a set of criteria: K = {K1, K2, K3}, where: K1 - spatial factors, K2 - economic factors, K3 - the social and environmental risks. As part of a set of criteria, three subsets were extracted: K1 = {K11, K12, K13, K14}, K2 = {K21, K22, K23}, K3 = {K31, K32, K33}, where: K11 - the average depth of the basin [m] , K12 - the distance from the shoreline [km], K13 - distance to connection NEN (National Energy Network) [km], K14 - the type of seabed; K21 - the cost of the investment, K22 - payback time, K23 - annual energy production; K31 - conflict with fisheries, K32 - the risk of navigation safety, and K33 - the impact on protected areas. The detailed specifications are shown in Table 2. The values of the criteria for each decision variant were determined using the reference literature contained in Table 2, and their resultant values are shown in Table 3.

Given the above results from individual investigations, the criteria were defined. Due to the fact that the different sets of criteria are related to different perspectives of looking at the same decision-making problem, it is difficult to clearly and objectively determine their weight. Consequently, it was assumed that the weight of each of the sets are mutually equal: K1 = K2 = K3. On the other hand, to determine the weights of the more specific criteria within each set, the AHP method was used [21]. This method was used because it is difficult to determine the absolute values of the weights of the individual criteria. However, the AHP method allows for the determination of the relative weights of criteria by

TABLE II. DETAILED SPECIFICATIONS OF EVALUATION CRITERIA

| Criteria | | | Type of criterion | Description of criterion | Reference literature |
|---|---|---|---|---|---|
| K1 | | Spatial factors | | | |
| | K11 | Average depth of the basin [m] | cost | Was determined in each location on the basis of the available bathymetry data. | [5] |
| | K12 | Distance from the shoreline [km] | cost | Distance from the coast is measured in a straight line. The increase in the distance from the edge causes a significant increase in the cost of building the farm (transport equipment, longer build time). | [5] |
| | K13 | Distance from the NEN connection [km] | cost | Distance of each farm to the nearest NEN port. | [7] |
| | K14 | Type of seabed | profit | Quality rating of the seabed for marine construction: rocky bottom - the best, grainy - very good, silty-sandy bottom - good, muddy - moderately good. | [6], [12] |
| K2 | | Economic factors | | | |
| | K21 | The investment cost [million PLN] | cost | Investment costs were estimated assuming a 7 MW turbine power. | [7], [9] |
| | K22 | Payback time [years] | cost | The calculation of payback periods makes possible to obtain annual profit. This value is determined using the unit price of electricity, the unit price of certificates of origin, and operating costs. Based on the calculated profit for the year, as well as taking into account the specified operating baskets payback time. | [9], [3] |
| | K23 | Annual energy production [GWh] | profit | Annual energy production is based on information concerning the annual average wind speed and wind turbine performance. | [7], [9], [1] |
| K3 | | Environmental and social risk | | | |
| | K31 | Conflict with fisheries | cost | Conflict of interest with the marine fisheries sector was estimated at a 9 points scale with 9 as the biggest conflict). | [6] |
| | K32 | Threat to navigation safety | cost | Based on the traffic map of water, determining how much influence it can have on a location for sailing in terms of possible dangers of ship collisions with wind farms. | [10] |
| | K33 | Influence on the protected areas | cost | The proximity of Natura 2000 protected areas of the potential offshore location. Determines the possible impact of investment on the protected areas on a nine-element scale, assuming that 1 means the least impact on protected areas, while 9 is the biggest. | [11] |

TABLE III. VALUES OF CRITERIA FOR DECISION VARIANTS

| **Criteria** | | | **Variants** | | | | | |
|---|---|---|---|---|---|---|---|---|
| K1 | Spatial factors | | **W1** | **W2** | **W3** | **W4** | **W5** | **W6** |
| | K11 | Average depth of the basin [m] | 40 | 31 | 29 | 62 | 51 | 35 |
| | K12 | Distance from the shoreline [km] | 34,7 | 45,6 | 86,3 | 77,1 | 63,1 | 44,9 |
| | K13 | Distance from the NEN connection [km] | 31 | 45 | 82 | 79 | 61 | 41 |
| | K14 | Type of seabed | very good | good | very good/good | moderately good | very good | good |
| K2 | Economic factors | | | | | | | |
| | K21 | The investment cost [million PLN] | 9040 | 9023 | 11231 | 10602 | 7870 | 7324 |
| | K22 | Payback time [years] | 9 | 10 | 11 | 15 | 14 | 12 |
| | K23 | Annual energy production [GWh] | 2803 | 2432 | 3132 | 3415 | 2132 | 1897 |
| K3 | Environmental and social risk | | | | | | | |
| | K31 | Conflict with fisheries | 8 | 5 | 9 | 4 | 5 | 6 |
| | K32 | Threat to navigation safety | 2 | 1 | 5 | 1 | 5 | 2 |
| | K33 | Influence on the protected areas | 2 | 8 | 1 | 1 | 4 | 1 |

mutually comparing their validity in a pairwise comparisons matrix, and then aggregating the results of these comparisons in the vector of preference. This is more effective for the decision-maker than determining the absolute weights [22], as one of the criteria for significance here is the point of reference in determining the validity of the other. The arrays of paired comparisons within the validity criteria sets of criteria K1 = {K11, K12, K13, K14}, {K2 = K21, K22, K23}, {K3 = K31, K32, K33} are contained in Tables 4, 5 and 6.

TABLE IV. PAIRWISE COMPARISONS OF VALIDITY OF THE "SPATIAL FACTORS" CRITERIA

| **CR=0,004** | **K11** | **K12** | **K13** | **K14** | **Weights (K1)** |
|---|---|---|---|---|---|
| **K11** | 1 | 1/2 | 1/2 | 2 | 0,189 |
| **K12** | 2 | 1 | 1 | 3 | 0,351 |
| **K13** | 2 | 1 | 1 | 3 | 0,351 |
| **K14** | 1/2 | 1/3 | 1/3 | 1 | 0,109 |

TABLE V. PAIRWISE COMPARISONS OF VALIDITY OF THE "ECONOMIC FACTORS" CRITERIA

| **CR=0,024** | **K21** | **K22** | **K23** | **Weights (K2)** |
|---|---|---|---|---|
| **K21** | 1 | 3 | 1/2 | 0,32 |
| **K22** | 1/3 | 1 | 1/4 | 0,122 |
| **K23** | 2 | 4 | 1 | 0,558 |

TABLE VI. PAIRWISE COMPARISONS OF VALIDITY OF THE "SOCIO-ENVIRONMENTAL HAZARDS" CRITERIA

| **CR=0,009** | **K31** | **K32** | **K33** | **Weights (K3)** |
|---|---|---|---|---|
| **K31** | 1 | 1/2 | 2 | 0,297 |
| **K32** | 2 | 1 | 3 | 0,54 |
| **K33** | 1/2 | 1/3 | 1 | 0,163 |

Tables 4, 5, 6 also show a right-hand value in each eigenvector matrix. This vector contains the aggregate weight of each criterion.

Assuming different weights of the individual sets of criteria (K1 = K2 = K3), the global weights of the criteria were determined. They are presented in Table 7.

TABLE VII. GLOBAL WEIGHTS OF CRITERIA

| **Set of criteria** | **Criterion** | **Global weight** |
|---|---|---|
| K1 | K11 | 0,063 |
| | K12 | 0,117 |
| | K13 | 0,117 |
| | K14 | 0,036 |
| K2 | K21 | 0,107 |
| | K22 | 0,041 |
| | K23 | 0,186 |
| K3 | K31 | 0,099 |
| | K32 | 0,180 |
| | K33 | 0,054 |

For ranking decision variants, the multi-criteria decision support Promethee II method was selected. It uses the outranking relation to the decision to choose the best alternative. This method uses the positive and negative flows of preferences specifying how much one alternative is greater than the other, and how much it is surpassed by other variants. Promethee II solves the sorting problem, and delivers the ranking of variants and indicate the best of them (in terms of Pareto evaluation). Using the Promethee II method, a decision maker can choose between six preference functions: simple criterion, the quasi criterion, the criterion with linear preference and preference level to the level of equivalence and preferences, the criterion with linear preference and indifference area, Gaussian criterion [23].

Preference functions based on the Promethee II method are shown in Figure 2.

Fig 2. Preference functions used in the Promethee II method

Rankings of alternatives were determined using ordinary criterion as a function of preferences. The results of evaluating the options and their positions in the ranking are presented in Table 8 and Figure 3. In line with the weights of criteria as the best option, the location of W1 was selected. When analyzing Fig. 3, the various variants of the specific form of solutions due to the applied criteria and their weights should be noted. Two solutions are ranked as the best (W1 and W2), two as good (W4 and W6) and two as bad (W5 and W3).

The presented ranking of decision variants is not final. The subjective nature of the vector of introduced priorities and the need to examine the strength of fixation in the ranking of the different alternatives provide a basis for decision-making executed in the next stage sequentially involving the analysis of sensitivity of this decision-making model.

TABLE VIII. PREFERENCE FLOWS IN ALTERNATIVES AND THEIR POSITION IN THE FINAL RANKING

| **Decision variant** | **Preference flow Φ+** | **Preference flow Φ-** | ***Preference flow Φ netto*** | ***Ranking*** |
|---|---|---|---|---|
| W1 | 0,5967 | 0,36 | *0,2367* | *1* |
| W2 | 0,5724 | 0,3645 | *0,2079* | *2* |
| W3 | 0,2906 | 0,6517 | *-0,3611* | *6* |
| W4 | 0,5297 | 0,4125 | *0,1172* | *3* |
| W5 | 0,3362 | 0,6007 | *-0,2645* | *5* |
| W6 | 0,4994 | 0,4356 | *0,0638* | *4* |

## IV. SENSITIVITY ANALYSIS OF THE RESULTING SOLUTION TO THE PROBLEM OF CHOOSING A WIND FARM LOCATION

The Promethee II method also enables a broad analysis of theresults , including a sensitivity analysis, and also provides an analytical tool, GAIA (ang. Geometrical Analysis for Interactive Assistance). GAIA aims to provide a complete graphical representation of the decision problem, so it allows the analysis of "goodness"-obtained solutions and provides directions for its possible improvement. The GAIA methodology information concerning the k-criteria of the decision problem in the k-dimensional space that is projected onto a sphere, so that a part of the information is lost, is presented, among others, including the Л vector, indicating the weights assigned to each criterion [24]. Alternatives are represented by points and criteria preferences are symbolized by vectors. If these vectors are oriented in the same direction, this means that they are not represented by the criteria in a similar way and it affects the global assessment of variants. The length of the vector indicates the strength of a given criterion to assess the global options. The closer a vector is to the end of a particular alternative, the more the vector supports this alternative, resulting in its ranking [23]. Examination of the results was conducted through a GAIA analysis representing individual criteria, which is shown in Figure 4.

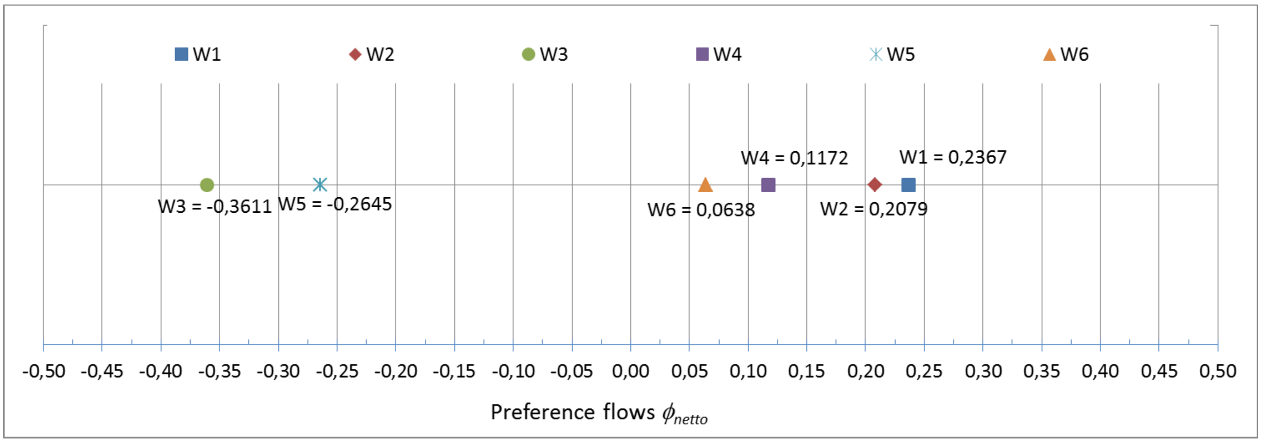

Fig 3. Netto preference flows in variants

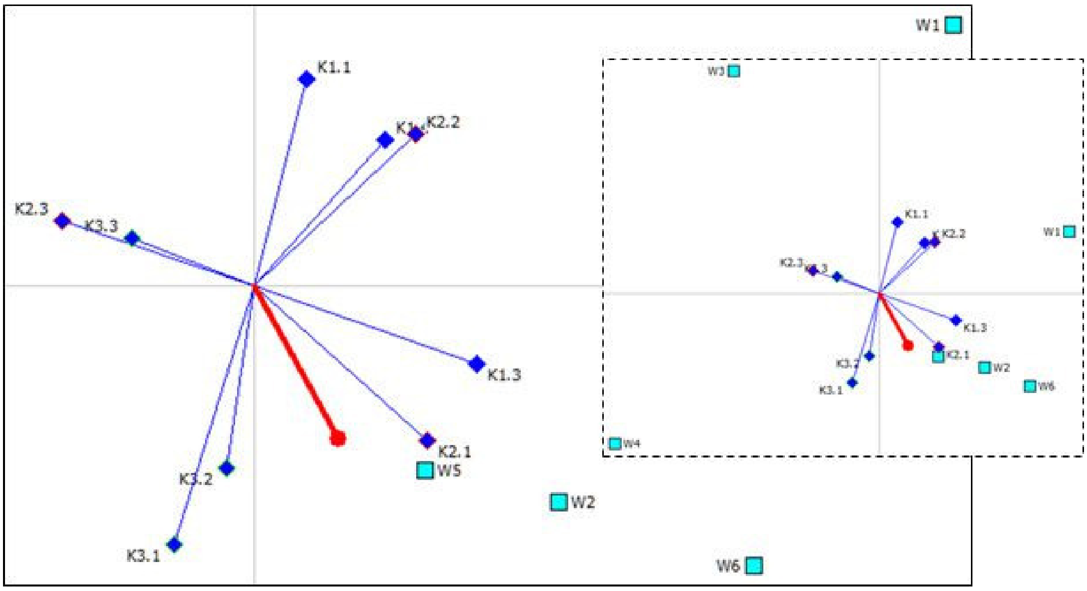

Fig 4. GAIA sphere representing individual criteria

When analyzing Fig. 4, it can be concluded that all the criteria have a similar effect on the acquired global assessment of variations, since the lengths of their vectors are all similar. However, there is a slight difference between the lengths of the K31 and K32 vectors, resulting from the difference of the weights given to these criteria. Shown here are the criteria coalitions and conflicts. For example, the criteria for K31 and K32 are compatible in the sense that, for most embodiments, a high value of K31 is associated with a high value of K32. However, these criteria are in conflict with K11; for variants with a high level of K31 and K32, the value of K11 is usually low. K14 and K22 support variant W1 because they are turned in his direction, and K13 and K21 criteria support the variants W1, W2, W5, W6, undermining the global assessment of the W3 and W4 variants. Due to the fact that the analysis of a multi-criteria decision problem using the GAIA strategy is projected onto a sphere, some information is lost. An example could be a vector compromise that seems to aim towards W5, while the highest rating is given to variants W1 and W2. The study also obtained solutions through the analysis of the GAIA sphere, which represented the sets of criteria. This sphere is shown in Figure 5.

Seeing The GAIA sphere from the perspective of criteria sets, it can be seen that the criteria related to spatial factors support the W1, W2 and W6 variants the most, since the end of the vector representing this collection lies closest to the specified options. The socio-environmental criteria strengthen the position of variants W2 and W4. The strength of the impact of these two sets of criteria for the solution of the decision problem is similar and is much larger than the impact of economic factors. Compromise vector reveals that variants of W1, W2, W4 and W6 are a much better choice than W3 and W5 variants. It should also be noted that the various sets criteria are not opposed to each other, and to some extent, the economic criteria are consistent with the environmental and social criteria.

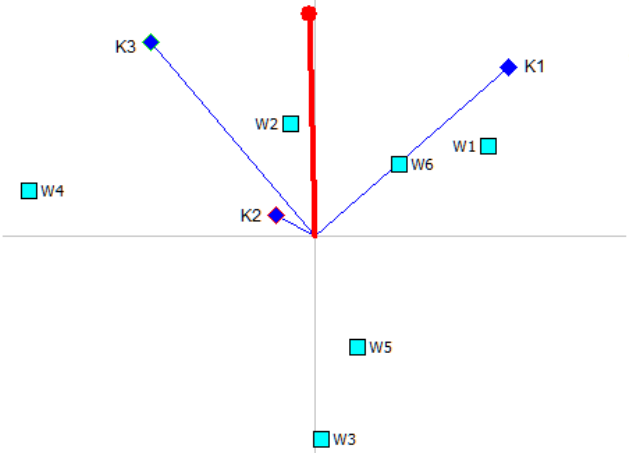

Fig 5. The GAIA sphere sets of criteria

The next step in the study was the analysis of the results to determine the stability of the sensitivity of the solution obtained, in terms of changing the weights of criteria. Due to the fact that, when looking at the problem from different perspectives (economic, localization, social and environmental), the relevance of the different sets of criteria may be seen as different, the weight of the sets of criteria was considered in this analysis. The results of the sensitivity analysis were included in Figure 6.

A sensitivity analysis shows that the solution is resistant to changes in sets of criteria weights in the range of 3%. If the environmental and social risks were much more important than other factors (weight K2> 45%), or if the weight of the economic factors was more than 75%, then the best option would be the W4 variant of the decision problem. The

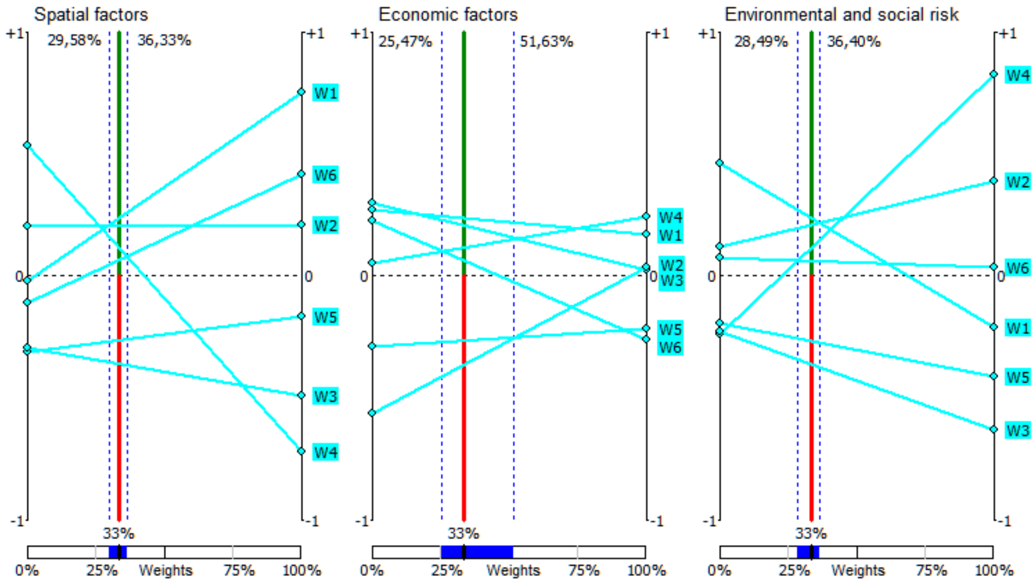

Fig 6. Sensitivity analysis of obtained solutions and weights

weight of a small range of socio-economic risks (36.4% - 45%), means that the best solution is also becoming a variant W2.

As part of the verification of the results the problem of ranking variants was determined by using a linear preference function instead of the true criterion. In this case, as a preference threshold for each of the criteria the standard deviation of variants with respect to a given criterion was computed. The netto preference flows and the rankings obtained in this study are included in Table 9.

Using the linear preference, there only one change of position of the resulting ranking; an exchange of the positions of the W4 and W6 variants was observed. As for the Pareto optimal solution, variant W1, using the linear preference, still received a higher than previously aggregated overall rank. The results of the sensitivity analysis for the solution obtained by using a linear preference function is shown in Figure 7. It shows the ranking of higher stability generated by applying the criterion with linear preference, as compared to the ranking obtained using the true criterion. Option W1 is the best at any weight and increase collections of spatial and economic criteria. For a group of socio-environmental criteria it remains in the first position in the ranking and increasing the importance of this group of up to nearly 12%. It can be concluded that the variant of the wind farm location W1 is a rational solution to the decision problem.

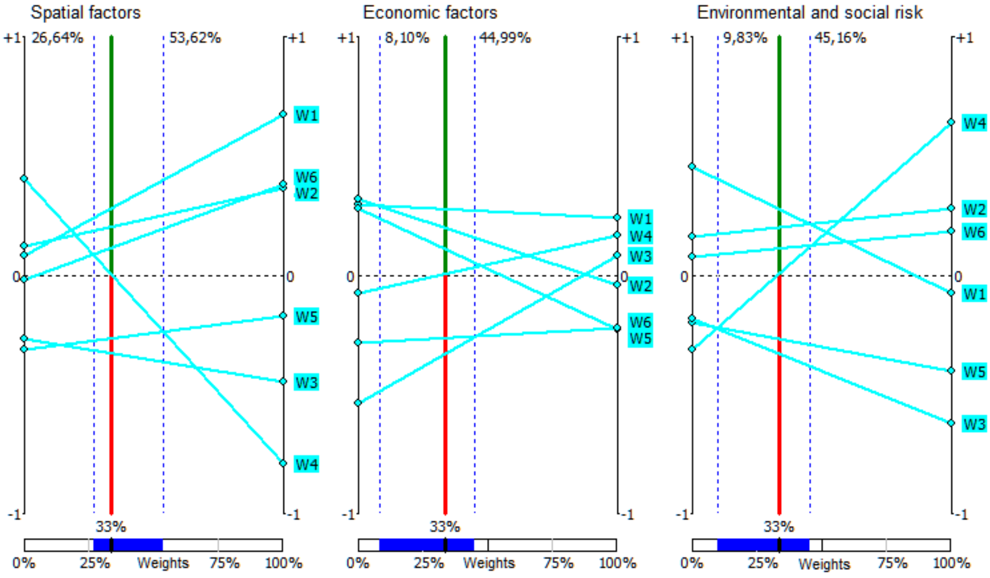

Fig 7. Sensitivity analysis of solutions obtained using the linear preference function

TABLE IX. PREFERENCE FLOWS IN ALTERNATIVES AND THEIR POSITION IN THE RANKINGS

| Preference criterion | Simple criterion | | Criterion with linear preference | |
|---|---|---|---|---|
| **Decision variant** | **Preference flow Φ netto** | **Ranking** | **Preference flow Φ netto** | **Ranking** |
| W1 | 0,2367 | 1 | 0,2773 | 1 |
| W2 | 0,2079 | 2 | 0,2001 | 2 |
| W3 | -0,3611 | 6 | -0,33 | 6 |
| W4 | 0,1172 | 3 | 0,0056 | 4 |
| W5 | -0,2645 | 5 | -0,2649 | 5 |
| W6 | 0,0638 | 4 | 0,1121 | 3 |

## V. SUMMARY

Design of Support system for selection of the location of renewable energy sources requires proper analytical methods. A practical application of multi-criteria decision support methods, as a maethodological basement for this system such as AHP and Promethee II was presented in this paper. It was verified for assessment of the potential location for offshore wind farm in Polish maritime areas. The possibility of linking these methods was presented and an advantage of the proposed approach was demonstrated. The pairwise comparisons, associated mainly with AHP, were used for the priorities to determine the vector which was used during the usage of Promethee II calculation method. The Promethee II method allowed for a comprehensive analysis of the resulting solution of the decision problem by using the GAIA sphere and sensitivity analysis. In addition, the solution obtained using the real criteria was confirmed by using a linear preference function. It should be noted that there were some limitations of the analysis conducted. Data representation is restricted to the field of crisp numbers, but each of the presented methods allows the use of fuzzy logic rules. In the future work it is assumed to extend the discussion about the use of an assessment methods based on, for example, the impact matrix implemented within the NAIADE method.

# Integration of B2B system that supports the management of construction processes with ERP systems

Monika Łobaziewicz
OPTeam SA, Tajęcina 113,
36-002 Jasionka
Email: mlobaziewicz@opteam.pl

***Abstract*— B2B is not only a model of cooperation between enterprises. It may also be implemented in companies with a dispersed organizational structure to which construction companies belong. It turns out that B2B systems contribute to an effective implementation of the investments located even in distant geographical locations. The use of Internet technology contributes greatly to the successful exchange of information between the ERP system and other IT systems or applications. Thus, the management of complex processes is facilitated by automating the flow of information and data integration. In construction companies, each investment may be treated as a large and complex project. Therefore, the ERP systems are very useful there. Combined with Web Services with advanced B2B supporting construction processes, they are a powerful tool for managing a construction business.**

**The purpose of this article is to present the results of an analysis of the idea to integrate ERP systems with OPTIbud system based on research conducted under the second stage of the project *"The prototype of an innovative and technologically advanced OPTIbud B2B platform that supports the management of construction processes through the integration of data and information from multiple sources."***

## I. INTRODUCTION

IT TOOLS are used in construction companies all the time, before the beginning of the investment process, during its implementation, and after its completion. In the construction industry, the IT solutions support not only the management of business, financial, and human resources processes, but also the processes typical for the industry, such as tendering, cost estimating, designing, monitoring, standardization, project management, construction works, etc. In the construction industry, the most frequently used systems or applications facilitate design, such as Computer Aided Design (CAD) that helps the architects and designers to quickly and efficiently create a project that requires to make advanced calculations, taking into account investor requirements, different quality standards presented in technical and engineering norms, wide range of building materials and works.

From the effective construction projects management point of view, the system that support the investment process is equally important, in terms of the management and the flow of materials, goods, finances, and human resources. For this purpose, ERP systems integrated with sophisticated IT applications are often used.

Then, the key for the enterprise is whether the data on the progress of implementation of the investment are available in real time. This is important from the decision making point of view. In ERP systems there are mechanisms capable of simulating potential actions and analysing their effects, including analysing financial outcome. This allows, among other things, forecasting, planning, testing, and comparison of possible decision-making activities [1].

ERP systems have a beneficial effect on the functioning of companies. They allow to collect and process data, to make analyses necessary for the development of the whole company as well as for a specific construction project. The author's experience suggests that such a solution proves to be efficient in practice in any company with a complex organizational structure and, in particular, with dispersed structures or organizations that use the model of a remote work, characteristic for construction companies.

ERP systems with dedicated modules or trade applications operating on the basis of a central database connected by mechanisms integrating with other systems, simplify the communication between the construction company and its subcontractors and other business partners or between the headquarter of a construction company and the building site, contribute to cost reduction and the integration of construction processes and the improvement of the quality of services rendered to investors.

For the construction industry, the key aspect is the best combination of the company activities with the implementation of investment projects, often in geographically remote locations, with an intensive rotation and exchange of employees working on construction sites. The right project implementation also requires coordination with many subcontractors and the use of building equipment. Therefore, it turns out that the specific applications or systems supporting construction processes should be integrated with ERP systems. One of the possibilities is B2B system making the use of data stored in ERP system database, processes them, and exports the information back to the base of the system.

In the following section of this article, first the research methodology, then the most popular ERP systems together with the results of the market research are presented. The next sections present the outcome of an integration of ERP systems with other IT systems and applications, methods, architectures, and tools related to ERP systems.

978-83-60810-66-8/$25.00©2015, IEEE

Each section has some relevant literature and includes conclusions. Finally, the most important recommendations as a result of the study are presented.

## II. Research Methodology

The purpose of this article is to present the results of an analysis of the idea to connect B2B OPTIbud with ERP systems based on research conducted under the second stage of the project entitled "*The prototype of an innovative and technologically advanced OPTIbud B2B platform that supports the management of construction processes through the integration of data and information from multiple sources.*"[2][1]

To complete this purpose, the following methodology has been adopted. As part of the first stage of the project, the existing computer systems that are being used in the construction industry have been analysed together with indicating the directions of their development in terms of managing the construction processes and technology in which they were created. Then, at this stage, there was conducted in-depth research that covered 10 construction companies. The tool used in the research was a questionnaire consisting of 60 questions regarding the detail lements of a construction process, such as: budgeting, construction manager panel, equipment and transport base, tenders and quoting.

As a result of the research, the designed B2B OPTIbud system should handle the following internal and external processes:

- organization of tenders, including their recording and documents flow,
- budgeting of projects in relation to the most popular programs for cost estimation, such as: Winbud, Rodos, Zuzia, Norma,
- scheduling of construction works,
- supporting of the work of a construction manager with the application of data exchange with the ERP system in on-line way,
- settlement of work time of equipment, people as well as fuel usage and building materials,
- handling of the equipment and transport base.

The outcome of the research led to assumptions that are now the basis for the development of the functional architecture of the designed B2B OPTIbud system.

Comparative analysis between the functional expectations of construction companies regarding a dedicated system and the functionalities of computer systems available on the market allowed developing a list of functionality gaps that should be complimented and implemented in the B2B OPTIbud system so that it would create the competitive advantage compared to other solutions.

Based on the results of the first part, the second stage involved an analysis of ERP systems that are most frequently used by enterprises from the construction industry, paying special attention to their architecture, functionalities, mechanisms, tools, and capabilities, bearing in mind the aforementioned possibility to integrate the computer solutions with the developed B2B OPTIbud system.

## III. ERP Systems

### *A. The market of ERP systems in Poland and in the world*

According to Gartner, on the global market of ERP systems the leaders are [3]:SAP, Oracle, Sage ERP X3, Microsoft Dynamics AX, Microsoft Dynamics NAV, Infor ERP. In Poland, the market leaders of ERP systems are SAP, Oracle, Comarch, IFS, and BPSC.

According to IDC, in 2012 more than 40% of market share belonged to SAP [4]. The Comarch was at the second place (12.5%), followed by Oracle with 11.7% of the share. The next two places were occupied by IFS (4.8%) and BPSC (4.0%). Analysis of data from previous periods shows that the percentage share of the aforementioned companies has oscillated around these values for several years. Similarly, the position of leading suppliers of ERP systems on the Polish market has not been changed for several years.

Apart from the above mentioned leaders, on the domestic market, there are ERP products of such companies as Asseco Business Solutions, Unit4 Poland, and SIMPLE.

### *B. The types of implemented ERP systems and methods of their use*

Research conducted by Panorama Consulting Solutions [5] showed that the vast majority of enterprises in 2014 used traditional ERP systems (85%), and the remaining (15%) used ERP in a cloud or in SaaS formula. In comparison to 2013, there was a significant decrease in choosing cloud ERP software. In 2013, 26% of companies have chosen ERP software in the cloud or SaaS compared to 15% in 2014. Two most important reasons why companies did not implement cloud systems is a lack of knowledge about the technology (45%) and the risk and fear of breaches of data security (30%). The research also shows that the ERP cloud providers usually offer secure and reliable solutions that should be very important for managers in the process of choosing the software.

The research shows that smaller companies want ERP systems to used them in the most important areas of activity, while medium-sized companies expect integration of software with specialized applications in an integrated structure [6].

The important role in ERP systems is played by platforms and technologies for conducting electronic business, and mechanisms that optimize processes within the logistics supply chain [7]. One of the directions of the development of modern ERP systems is taking into account solutions important from the point of view of systems reserved for industries that were previously handled by independent, specialized software. This is primarily about construction

[1] The project, implemented by OPTeam SA is financed from INNOTECH program, HI-TECH path, carried out by The National Centre for Research and Development. The author is the chief scientific officer of the project.

companies, banks, insurance companies, or companies related to food processing on a small scale [8].

The designers of IT systems are facing new challenges involving the creation and implementation of solutions that support the integration of business processes, including processes specific to a given branch or industry, which would serve as an extension to the functionality of standard ERP management systems [9], [10]. For such solutions to be effective in practice, there must be a suitable mechanism designed for an access to multi-faceted data and information.

## IV. INTEGRATION OF SYSTEMS AND APPLICATIONS WITH ERP SYSTEMS

### *A. System integration*

Practice shows that the right combination of IT systems in an enterprise is, in many cases, necessary [11].

The system integration has helped to create standards that currently are tools that facilitate the programming works in this scope. High-level programming languages allow to launch created processes with their use programs without modifying various hardware and system platforms. The key role, thanks to its "portability," is played by XML, which is applicable in the domain of data structure description.

Correctly implemented system integration automatizes and improves the processes of the introduction and transfer of data. It is based on making it possible to enable an efficient cooperation of two completely different systems based on different technologies. The answer to these requirements is *Electronic Data Interchange (*EDI) and B2B solutions.

### *B. Integration of applications*

In turn, the integration of applications may be analysed in two ways. The first is based on an interaction between applications on the level of understanding the transmitted data bits. Over time, standards were developed which specified higher levels of communication model known as *Open System Interconnection Reference Model* (OSI RM). These included, respectively, the data-link layer (Ethernet) network (IP), transport (TCP, UDP), and higher layers. This enabled companies that created IT applications to gradually become independent of the elements of communication between the systems, so that they could focus on the semantics of data exchange between integrated elements. At the same time, standards for describing aspects of cooperation between applications were developed. An example of efforts to integrate applications and data within an enterprise that make the sharing of data possible between many heterogeneous computer systems and the integration of a distributed within the enterprise business processes into one coherent set is *Enterprise Application Integration* (EAI) [12]. On its basis, the *Service Oriented Architecture* (SOA) pattern was defined that describes integrated systems as independent services cooperating with each other [13],[14].

The attempts to use architectures based on SOA led to the creation of, among other things, the Distributed Component Object Model (DCOM) and Common Object Request Broker Architecture (CORBA). These technologies had a widespread applicability. However, the implementation of them with the use of SOA with technology proved to be impractical because of the dependence on a particular platform (DCOM) and high complexity (CORBA).

### *C. SOA model as an integration tool*

The dynamic development of the Internet has led to the need for integration both between applications inside organizations and between different companies by means of widely used communication protocols. In the construction industry, both types of integration exist. The author's experience leads to the conclusion that the diversity of computer system implementation environments and the pursuit of the reduction of costs associated with the implementation of solutions make the integration an expensive process.

SOA is a widely accepted programming, publishing, searching, and services launching standard. Its basic components include the following [15]:

- Service Provider - responsible for installing the service on the server, publishing its description in the registry and access control;
- Service requester - an application used by the user that discovers services in the registry and orders a demand for their start-up; and,
- Service Registry / Service Broker makes the provision of services possible.

SOA is the architecture for business applications created as a set of stand-alone components, arranged so as to provide services, operating according to certain criteria, and supporting the implementation of business processes [16]. From the end user's perspective, it is a set of services that support the implementation of business processes, and from the technological point of view, it is an infrastructure necessary to provide services.

SOA categorizes relationships between service providers and their customers represented by software components that implement complex business processes. It provides the reuse of software components, the encapsulation of functionality, the precise definition of interfaces, and the flexibility of applications created in a form of composing.

Commonly used element in the implementation of business services based on SOA are Web Services, which are understood as applications that make the business logic available outside the closed area of the network of organizations and which communicate through interfaces used in the Internet and communications protocols.

Web Services [17]:

- are autonomous applications available on the network through their URL (web address),
- have described interfaces and the way of using them by means of structures expressed in XML (Extensible Markup Language),
- are launched by other applications,

- perform heterogeneous operations ranging from simple responses to user requests to complex business processes,
- use standard communication protocols used on the Internet, and
- provide the possibility to launch and connect with other services providing new functionalities.

Web Services architecture refers to SOA. Therefore, it is based on the following principles:

- Message-oriented;
- Modularity of protocols - the use of the blocks that make up infrastructure protocols, which can then be used in almost any combination;
- The autonomy of services - allowing for independent construction, development, management, progress of versions, and securing endpoints;
- Transparency - control which aspects of endpoint are (or are not) seen by external services;
- Integration based on protocols.

To sum up, the process of integration is based on the interaction of individual systems and applications on the physical or functional level. SOA introduces a model of building computer systems based on communication between separated services. By creating dispersed applications, the individual functions of the program are distinct and separated into separate modules. Subsequently, these segments are merged to form a coherent and dispersed application.

Internet services based on Web Services enabled the effective implementation of the SOA concept in practice. Properly defined and simultaneously unambiguous specification of Web Services that includes, among other things, a description of the communication protocol SOAP and the language of interface description WSDL based on XML, mechanisms of semantic cataloguing and searching for providers caused that this standard quickly gained popularity and is now widely used in dispersed applications. At the same time, thanks to the support of Web Services by coding, language application services have been made available that are inconsistent with SOA through the establishment of appropriate adapters.

Web Services have caused people to move away from the paradigm of the classic integration of applications to the benefit of existing services in processes and their modelling, depending on changing needs.

## V. METHODS, ARCHITECTURE AND INTEGRATION TOOLS OF ERP SYSTEMS

### *A. SAP and MS Dynamics*

In the case of SAP, B2B system integration may be realized through the following: SAP .NET Connector, Microsoft BizTalk and Duet Enterprise.

The most beneficial tool is SAP.NET, because it may communicate with SAP system in two ways as:

- Client which queries SAP system (server) - client calls functions of SAP system and as a reply it receives results,
- Client playing the role of a server, receives calls from SAP while NET program adopts the role of RFC. (The SAP system treats the .NET application code as if it handled a different SAP system. Then, SAP sends a function call to .NET applications and receives results.)

Microsoft Dynamics operates in two versions, as Microsoft Dynamics AX and Microsoft Dynamics NAV. Regardless of which version we are dealing with, the system is delivered to the purchaser, together with its full source code and a set of tools for its development fully integrated with Visual Studio. Integrated Development Environment in MS Dynamics is MorphX that helps to create new modules, windows forms, reports, menus, queries, etc. The application is fully adapted to work with .NET platform. MS Dynamics allows for flexible development and software configuration according to the needs of an enterprise. This gives unlimited possibilities for adapting the system to any organization as well as integration with B2B systems.

The main advantages of the integration of MS Dynamics with other environments are the following:

- Using other technologies to develop the whole enterprise system is possible. Instead of code written in an internal X ++ language, it is possible to program functionalities in C # and have integration of Microsoft .NET with Microsoft Dynamics;
- MS Dynamics can be coordinated with external applications;
- There is the interaction functionalities and data exchange.

There are a few possibilities to integrate Microsoft Dynamics with other systems:

• The services and application integration platform - Application Integration Framework (AIF) and its services make business logic available to external business systems. MS Dynamics platform supports the integration of the AIF platform, using a services programming model. It exposes functionalities by means of services based on Windows Communication Foundation (WCF) from which code may use both MS Dynamics and external programs. WCF services in conjunction with the AIF provide a programming model, tools, and a complete infrastructure to integrate and exchange data using XML.

• .NET Business Connector allows external applications to access Microsoft Dynamics data and using its business logic.

• .NET Interop. allows to cooperate with .NET platform in both directions. It allows X ++ code to use the methods managed by the runtime environment of the .NET platform (Common Language Runtime) (CRL). It also provides solutions of proxy classes (C #, Visual Basic) for Class X ++ MS Dynamics generated in Visual Studio environment, from which C # code may directly benefit.

Business logic of MS Dynamics is made available through websites that use the latest Windows

Communication Foundation (WCF) rendered by the Application Object Server (AOS).

The configured pre-processor of requests (Request), AIF, captures all requests. MS Dynamics service runs the necessary business logic to process a request. A similarly configured postprocessor of response (Response) takes over the message of the post-processing response. Then it returns the response to the user.

The best way to integrate the ERP system with external applications is to use services that provide the business logic written in an internal X ++ language. In the Microsoft Dynamics environment, the programmer may build, modify, and publish services. Creating a service is based on defining, according to certain rules of X ++ class and website interface, and then their linking [18].

Making the services available through the Internet is made through Internet Information Services (IIS), which are equivalent to Web Services, and which redirect requests to the AOS regardless of whether they come from the Internet or intranet. AOS returns responses for the recipient of the service through IIS. The exchange configured to the use of Web Services is not queued, since it is supported synchronously.

AIF provides an extensible platform for the exchange of documents with external systems using XML technology. Both the synchronous and asynchronous transmission is possible. In the case of the synchronous exchange, the requests are paired with the answers, which means that the same connection it is used and that the demanding party does not continue work but just waits for a response. AIF immediately processes requests and sends responses. In asynchronous mode, the requests are queued, and the answers are sent with a time delay. The advantage is a more efficient processing of a large number of messages.

AIF supports the exchange in both directions: incoming and outgoing. Incoming exchange means that the external system, for example, B2B may send commands. On the other hand, outgoing is receiving data coming from the MS Dynamics system and sending them to the requesting user.

### *B. CDN XL*

The Comarch ERP XL system allows an interactive work with the user and also acts as an application server that provides external applications' built-in functionalities. This is provided by using a function mechanism, called the Application Programming Interface (API).

The external application may connect to CDN XL application server by means of API and use mechanisms available to the ERP system. This provides the openness of the system, making the integration possible with standard Microsoft Visual Studio programming tools and any external system. The CDN XL system provides an access to a dozen of API functions stored in the CDN_API.dll library supplied with the system.

The XL-API mechanism is used by IT companies who form their own solutions that cooperate with the Comarch ERP XL system. It allows for simplicity and security through the use of direct record in database and independence from the system and database platform, on which Comarch ERP XL runs.

The CDN XL system, while implementing the security policy, logs the changes to the database via the API functions. If an error occurs causing the termination of the application that calls out API functioning, there is a re-enactment of a database to the state before running the API function.

Approval of the transaction occurs upon the termination of entering the object or log- ut function (XL Logout).

XL API functionality with the development of CDN XL system is constantly being expanded. In order to ensure compatibility with previous API versions, there was introduced a versioning mechanism. It serves as a translator between API calls from external applications and structures used inside CDN XL system. For each version of the system, there is a corresponding version of the API libraries that allows the integration with it.

The programmer using the API functions defines its version based on which its structure is recognized and the transfer of the value to the internal CDN XL structure is made. In the case of non-compliance of structures, unused fields are filled with default values. The versioning mechanism is bi-directional. Data structures used by API also allow the return of data from CDN XL using the translation procedures.

## VI. RECOMMENDATIONS CONCERNING INTEGRATION

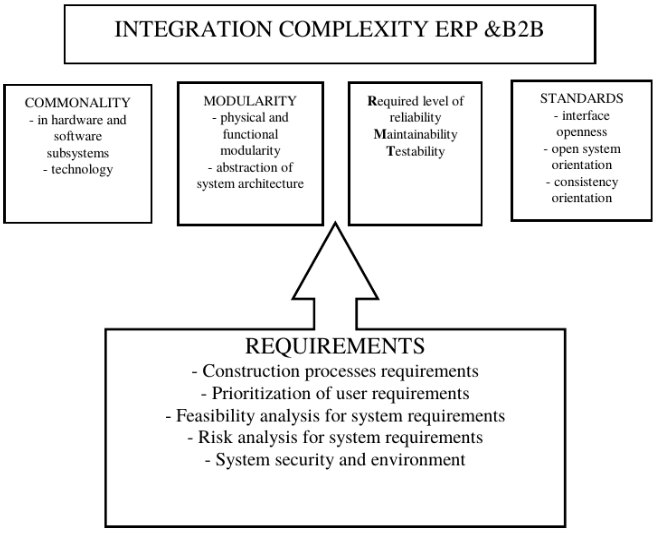
Based on the research of ERP systems and standards, integration tools, the following actions are recommended for the B2B OPTIbud platform:

- Implementation of mechanisms enabling a direct connection to the database of the ERP system,
- The use of Web Services available for ERP systems,
- Direct use of different ERP systems with a business logic characteristic in construction processes,
- Using an interface that is made available by the ERP system,
- The transfer of files with data using XML formats.

Moreover, there were identified the following activities characterising the impact of integration complexity requirements and architecture (Fig. 1).

The scale of the flow of various data and information is so large that it is difficult for companies to function on autonomous systems or computer applications. Integration complexity positively influences the optimization of business processes, enables a seamless cooperation of organizational units, and gives a possibility to operate on a one database to all participants of the processes work on the same actual data.

In many construction companies, heterogeneous applications coexist. The technological progress and market demands caused that construction companies carry out their operational activities through the Internet, and that is why the ERP software must cooperate with many applications. Considering the above, one of the key conditions for the



INTEGRATION COMPLEXITY ERP &B2B
COMMONALITY
- in hardware and software subsystems
- technology
MODULARITY
- physical and functional modularity
- abstraction of system architecture
Required level of reliability
Maintainability
Testability
STANDARDS
- interface openness

- Risk analysis for system requirements
- System security and environment

Fig. 1. Attributes having the impact on ERP system with B2B OPTIbud integration complexity

effectiveness of B2B OPTIbud is its integration with ERP systems end points. In this case, the interaction in the scope of data, information, and construction processes takes place on many levels.

The OPTIbud B2B system will be based on the philosophy of integrated systems that guarantees the flow of information between the individual modules in the ERP system, so the user would not have to repeatedly enter the same data in different functional areas of the system, but he will use the data already entered, transforming them into information necessary to make decisions and execution of construction processes. Thus, the B2B OPTIbud system, because of its autonomy may be able to be integrated with various ERP systems operating on the market. Thanks to built-in mechanisms, it would be able to communicate automatically with the database of the ERP computer system of a construction company.

# 10th Conference on Information Systems Management

THIS event constitutes a forum for the exchange of ideas for practitioners and theorists working in the broad area of information systems management in organizations. The conference invites papers coming from two complimentary directions: management of information systems in an organization, and uses of information systems to empower managers. The conference is interested in all aspects of planning, organizing, resourcing, coordinating, controlling and leading the management function to ensure a smooth operation of information systems in an organization. Moreover, the papers that discuss the uses of information systems and information technology to automate or otherwise facilitate the management function are specifically welcome.

## Topics

The areas and topics of interest include, but are not limited to two groups:

- Management of Information Systems in an Organization:
  - Modern IT project management methods
  - User-oriented project management methods
  - Business Process Management in project management
  - Managing global systems
  - Influence of Enterprise Architecture on management
  - Effectiveness of information systems
  - Efficiency of information systems
  - Security of information systems
  - Privacy consideration of information systems
  - Mobile digital platforms for information systems management
  - Cloud computing for information systems management
- Uses of Information Systems to Empower Managers
  - Achieving alignment of business and information technology
  - Assessing business value of information systems
  - Risk factors in information systems projects
  - IT governance
  - Sourcing, selecting and delivering information systems
  - Planning and organizing information systems
  - Staffing information systems
  - Coordinating information systems
  - Controlling and monitoring information systems
  - Formation of business policies for information systems
  - Portfolio management,
  - CIO and information systems management roles

***Abstract*—Providing e-Government services to business sector is a fundamental mission of governmental agencies in Saudi Arabia. The adoption of e-Government systems is less than satisfactory in many countries, particularly in developing countries.One pertinent, unanswered question is what are the key factors that influence the adoption and utilisation level of users from business sector. This paper utilised e-Government Adoption and Utilisation Model (EGAUM) proposed in our previous work in order to analyse determinants of higher level of e-Government adoption and usage. The study involved 48 participating business entities from two major cities in Saudi Arabia, Riyadh and Jeddah. The descriptive analysis is presented in this paper and the results indicated that all the proposed factors have degree of influence on the adoption and utilisation level. *Perceived Benefits, Functional Quality of Service, Previous Experience, Perceived Simplicity, Accessibility and Regulations & Policies* factors were found to be the significant factors that are most likely to influence the adoption and usage level of users from business sector.**

## I. Introduction

E-GOVERNMENT refers to the utilisation of various Information and Communication Technologies (ICTs) for facilitating communication between the government and the stakeholders; citizens, businesses and governmental agencies, providing effective, efficient and integrated e-Services that enhance the interaction between the government and the stakeholders through multiple and flexible channels that lead to an increased engagement. Adoption and utilization level is fundamental in terms of measuring the successfulness of the implemented e-Government systems. As governments develop e-Government systems to provide e-Services to stakeholders, the adoption and usage level is still low especially in developing countries [1][2][3]. Successful implementation of ICTs in government units and satisfactory usage level by all government stakeholders are the main goals of e-Government. Thus, analysing the significant factors that influence the adoption and utilisation of e-Government is becoming a necessity.

One of the main targeted stakeholders when providing e-Government services is business sector. The business sector, or what so called private sector in Saudi Arabia, is growing considerably in the recent years. The growth rate of the private sector is the highest between the three main sectors in Saudi Arabia, namely, governmental sector, private sector and oil sector [4]. Therefore, facilitating the communication and interaction between government agencies and business sector (business firms) is very important especially in the current advanced IT era. Many online e-Services have been provided to the private sector in the recent years in Saudi Arabia and there are more e-Services under development. Besides the need to increase the adoption and utilization level of the implemented e-Government systems, it is also crucial to understand the factors that can influence the adoption and usage of the new e-Services. The analysis of such factors will bring e-Government service provided to business sector to a more successful level and also will draw the path for developing new e-Government services.

In order to explore the determinant factors of high adoption and usage level of e-Government, we need to utilize a comprehensive framework. Thus, this paper used E-Government Adoption and Utilisation Model (EGAUM) see [5]. This model was developed based on critical evaluation of several common models and theories related to technology acceptance and usage including TAM and UTAUT, in conjunction with analysis of technology acceptance literature [5]. The rest of this paper will be divided as follows; the second section will explain the research methodology and the third section will present and discuss the research findings. The final section will provide a conclusion and our planned future work as this study is a part of our on-going research.

## II. Research Methodology

The study surveyed 53 business entities from different cities in Saudi Arabia, namely, Riyadh and Jeddah. Most of them were leader and large companies. Several medium and small business entities have also been involved in this study sample. The data has been collected in the period between August and October 2014. The business activities

978-83-60810-66-8/$25.00©2015, IEEE

of the participating companies were different in order to provide more comprehensive results. The sample included both business owners and employees who work in business firms and deal with government agencies with regard to their companies' transactions.

A 99-item questionnaire was distributed to the participants to respond to. The questionnaire comprised different forms of questions. Although the questionnaire was relatively long, it collected fundamental data that led to efficient and sufficient analysis. Moreover, a semi-structure short interview has been conducted with number of participants and it was optional. The questionnaire was distributed in person for several reasons including 1) ensuring high response rate, 2) clarifying questions when participant need, 3) conducting the short interview after completing the questionnaire. Users from business sector are usually busy. Therefore, meeting them in person at appropriate time to collect data is a useful method. The data has been collected from different cities in Saudi Arabia. Although this way consumed effort, cost and time, it enabled us to obtain more comprehensive and useful data.

Since the factors in the research model (EGAUM) are abstract [5], number of items was developed for each factor to measure its influence on the adoption of e-Government. Raubenheimer stated that number of items per factor is crucial specifically for scales with one factor which requires at least four items to be identified. However, most of the scales measure more than one factor. Scales that measure more than one factor, like this research scale, can be identified with as little as two items [6]. Table 1 shows the number of items for each factor in the scale developed for this study. The table exclude the personal factors since they are not measurable factors.

This research aims to study the influential factors of adopting and utilizing e-Government in the context of Saudi Arabia. Therefore, Saudi nationality was the targeted sample since the study involved some factors that aimed to be studied in the Saudi context such as socio-cultural, perceived trust and previous experience. The exclusion of non-Saudi nationalities is associated with the research goals of conducting a cross-sectional study of Saudi society. Moreover, the research instrument was designed to collect data relate to the Saudi context such as opinions about the available payment methods in Saudi Arabia, the Saudi post mail services and the influence of WASTA, which refers to the use of interpersonal relationships in transactions processing, on the adoption of e-Government. Moreover, incomplete questionnaires were also excluded since all the questionnaires' items need to be answered as they represent the research model constructs. Therefore, the total valid responses were from 48 business entities.

### *A. Reliability and validity*

Blunch stated that a research instrument is evaluated by its reliability. The reliability of a measuring instrument means its ability to provide identical results if it is repeated under identical conditions [7]. It concerns with a question "can we get the same results if we repeat the measurement test?". There are many different methods to determine the reliability of an instrument including Test-retest method, Split-Half method and Internal Consistency method. There were difficulties of using some of these methods in this research context. For example, repeating the test in different times with the same participants as in Test-retest method was difficult since the data collection phase in this study aimed to be conducted in different country, Saudi Arabia, whereas the researchers are in the United Kingdom. Moreover, Split-half method is appropriate for the long questionnaires that measure or test one construct and it is not suitable for instruments that measure several constructs as the current study [8]. Thus, this study used the internal consistency method to test the reliability with the use of Cronbach's Alpha. , see Table 1.

Internal consistency method determines how the items in a test relate to the other items. It is basically used to assess a survey items with a single construct to discover the consistency degree of the items that measure that construct. Cronbach's Alpha is the most common coefficient that can be calculated to evaluate the internal consistency of a test. It is applied to responses that have more than two options [9]. Therefore, it is applicable to this research instrument. Cronbach's Alpha reliability coefficient could range between 0 and 1 with value closer to 1 is considered to be high level of reliability. Acceptable level of reliability depends on the research purpose. The reliability of an instrument developed for research purposes is acceptable at 0.6 where in diagnostic research that the instrument is developed to make decision on individuals, such as psychological tests, need to be much higher [10].

In terms of validity, Bhattacharyya defined it as "the degree to which a test measures what it intends to measure" [11]. Validity of an instrument does not mean that the instrument is either valid or not but it is a matter of degree. The greater

TABLE 1: Internal consistency of the study instrument

| Measured variable | # of items | Cronbach's $\alpha$ |
|---|---|---|
| Perceived Benefits (PB) | 7 items | .825 |
| Socio-Cultural (SC) | 5 items | .686 |
| Awareness (AW) | 9 items | .822 |
| Functional Quality of Services (FQS) | 10 items | .800 |
| Previous Experience (PE) | 3 items | .601 |
| Perceived Simplicity (PS) | 6 items | .638 |
| Technical Quality of Service (TQS) | 5 items | .624 |
| Accessibility (ACC) | 4 items | .619 |
| Perceived Trust (PT) | 9 items | .792 |
| Regulations and Policies (RP) | 4 items | .899 |
| Intention to use e-Government (ITU) | 2 items | .659 |
| Perceived e-Readiness of e-Government (PER) | 2 items | .667 |

the evidence that an instrument produces valid results the greater the likelihood that we will get information that we need [12]. Validity cannot be calculated or measured directly, it is judged by the existing evidence [13]. There are several methods to determine or assess the validity of a research instrument and the most dominant ones include face validity, content validity, criterion validity and construct validity. This study utilised face validity and content validity methods to evaluate its validity degree.

Face Validity method provides useful information about the measure instrument and determines to what extent the instrument meets the intended purpose [12]. Test in which its purpose is clear, even for simple persons who have elementary knowledge, is judged to have high face validity. Where on the other hand, test in which its purpose is unclear would be judged to have low face validity [14]. Most of the items developed in this study were accurately face validated during the pilot study phase by the participants in accordance to the model factors' purposes, whereas some of them were not validated due to lack of understanding them clearly. Invalid items were either reworded if they were reported as unclear or deleted if they were reported as irrelevant. Furthermore, 5 academic members who are experts in interactive systems field have also reviewed the research instrument to have high content validity. Thus, it has been reviewed, tested and revised several times in order to have high validity.

## III. Research findings and discussion

This section provides an overview of the demographic characteristics of the respondents including age groups, education level, income, the use of the Internet and the use of e-Government systems. This is followed by a descriptive analysis for each factor proposed in EGAUM in order to explain their influence on the participants' adoption and utilisation of e-Government services provided to business sector.

### A. Respondents' demographic data

This section analyses demographic data obtained from the respondents (see Table 2). As per the questionnaire results, the average age group was ranging between 31 and 45 with males accounting for 89.5% of the participants and 10.4% were female. It is clear that the percentage of male participants was more than female participants. These percentages were expected for several reasons. Most of the employees who work in business sector (private sector) and use e-Government services in their jobs' activities are male employees. This is mainly because the jobs that involve dealing with government agencies to perform governmental transactions were almost exclusive to men before implementing e-Government in Saudi Arabia, therefore, they dominate these kinds of jobs due to their experience of dealing with the government services. Furthermore, it is difficult to collect data personally from female in Saudi Arabia, either business owners or employees, due to religious and cultural reasons.

TABLE 2: Demographic data

| Variables | % |
|---|---|
| **Participants gender** | |
| Male | 89.6 |
| Female | 10.4 |
| **Participants age in years** | |
| 18 - 30 | 20.8 |
| 31 - 45 | 64.6 |
| 46 - 60 | 12.5 |
| Over 60 | 2.1 |
| **Participants education level** | |
| Secondary school or less | 29.2 |
| Diploma | 20.8 |
| Bachelor degree | 41.7 |
| Master | 8.3 |
| **Proficiency of using computer** | |
| Average | 8.3 |
| Good | 41.7 |
| Excellent | 50 |
| **Internet usage rate** | |
| Several days a week | 6.3 |
| Several days a month | 2.1 |
| Everyday | 91.6 |
| **Participants relationship to the business** | |
| Owner | 27.1 |
| Representative | 18.8 |
| Employee | 54.2 |
| **Business age in years** | |
| 0 - 5 | 16.7 |
| 6 - 10 | 16.7 |
| 11 - 20 | 10.4 |
| Over 20 | 56.3 |
| **Number of employees in business** | |
| 0 - 10 | 18.8 |
| 11 - 50 | 8.3 |
| 51 - 250 | 4.2 |
| More than 250 | 68.8 |
| **Annual net profit in SAR (1 GBP $\approx$ 5.7 )SAR** | |
| 0 - 60000 | 10.4 |
| 61000 - 12000 | 4.2 |
| 121000 - 180000 | 2.1 |
| 181000 - 240000 | 4.2 |
| More than 240000 | 35.4 |
| Unknown | 43.8 |
| **Business field** | |
| Constructing and building | 14.6 |
| Restaurants | 2.1 |
| Food supply and grocery | 4.2 |
| Cars trade (sale and lease) | 12.5 |
| Communication | 6.3 |
| Health and medical supply | 14.6 |
| Other | 45.8 |

### B. Measures of central tendency

A measure of central tendency is a single value that attempts to describe a set of data. We define measures of central tendency to find some central values around which the data tend cluster or concentrate [15]. The mean is the most popular measure of central tendency and it can be computed by the following formula where $\bar{x}$ denotes to the mean, *n* is the number of values and *Xn* represents the values [16]:

$$\bar{x} = \frac{(X1 + X2 + .... + Xn)}{n}$$

The median is the middle score of the data set values that have been arranged in order of magnitude. Since

Likert response measures were used in this research, clarifications of the instrument scales will be presented in the following section. These clarifications helped us to choose the appropriate central tendency measures in the descriptive statistics and analysis.

### C. Likert-Type vs Likert Scale

Clason and Dormody identified the Likert-Type items as single questions that use some aspect of Likert responses. Whereas, Likert Scale is composed of multiple Likert-Type items that are combined into one single composite score/variable during the data analysis process. The composite score that combined multiple items represents a quantitative measure for the intended aspect that needs to be measured [17]. Likert-Type item categorized as an ordinal measurement scale and therefore, the recommended descriptive statistics are mode or median for central tendency and Inter-Quartile range (IQR) for variability. On the other hand, Likert Scale is categorized as interval measurement scale since it is represented as a composite score that is combined multiple items (either the sum or the mean of the combined items). Therefore, the recommended descriptive statistics are mean for central tendency and standard deviation (S.D.) for variability [18].

### D. Descriptive analysis of data

In this section, the collected data will be analysed in relation to EGAUM constructs [5]. The participants from business sector were asked to describe several characteristics including their attitude, behaviour and opinion towards adopting and utilizing the e-Government systems. Such characteristics were examined through number of statements using different Likert Scales. Likert Scale scores were also calculated in order to interpret the participants' responses.

***Perceived Benefits (PB)*** was measured with 7 items in order to indicate its influence on the respondents' adoption and utilization of e-Government systems. The participants were asked questions to determine their perception degree on several main benefits that they can gain from using e-Government services for their businesses. The perceived benefits that were measured included the speed of processing e-Transactions over the traditional ways, ensuring the equality of processing business entities' transactions and providing investment opportunities for the business sector. They also measured the respondents' perception of the ability of e-Government to save time, cost and effort. All the items in this factor were measured using 5-points Likert scale ranging from 'Strongly agree' to 'Strongly disagree'.

TABLE 3: The result of PB factor

| Factor | # of item | Mean | S.D. | result interpretation |
|---|---|---|---|---|
| PB | 7 | 1.37 | 0.49 | Very influential |

In respect to the perceived benefits influence, the results showed that the vast majority of the participants 97% believed that e-Government would enable them to perform their business transactions quicker than traditional ways. Moreover, around 95% of them believed that using e-Government services would save time, cost and effort. With regard to the benefits that they can gain for their businesses' entities, 89% of the respondents thought that using e-Government systems would minimize legal and regulatory violations that might occur from their businesses and 89% of them believed that using e-Government would help their businesses to comply with the governmental requirements.

The results also showed that the overwhelming majority (91%) of the respondents believed that using e-Government services would ensure equality in the dealing between governmental agencies and business entities. Furthermore, over 80% of the respondents thought that e-Government would increase the investment opportunities in business sector. It is clear from the results that the perception of the possible gained benefits from using e-Government was relatively high amongst users in the business sector. Table 3 presents the total score of this factor' items.

Perceived Benefits was found as a very influential factor with a total score of 1.37 i.e. PB has a strong impact on the adoption and utilization of users from business sector when using e-Government systems. The results suggest that the intention to use e-Government services is very likely to increase if users from business sector perceive the e-Services to be beneficial for their businesses. This indicates that to get business owners and business representatives to adopt and use e-Government services, these services must be genuinely useful for their business. They should be implemented efficiently and effectively in order to meet the needs of this category of stakeholders. These findings are in accordance with results reported in the literature, for example, [19] and [20] that have been conducted in the US. The findings also in accordance with a study conducted in Kuwait which is a close neighbour country to Saudi Arabia that have similar nature and culture. [21].

***Socio-Cultural (SC)*** was measured with 5 items using 5-points Likert scale. SC factor was concern with the influence of others, including colleagues and other business entities, on the intention to use e-Government. It also concerned with the influence of cultural norms, believes and behaviour patterns in Saudi Arabia on the adoption and use of e-Government services. For example, the respondents were asked to determine whether they feel that dealing with government agencies regarding their businesses' transactions should be real and tangible i.e. using papers not electronic means. The results showed that 70% of them disagreed with this item. Moreover, about three quarters of the respondents (75%) believed that e-Government would reduce the use of the interpersonal relationships (wasta) when processing business entities' transactions. This indicates a high perception about

TABLE 4: The result of SC factor

| Factor | # of item | Mean | S.D. | result interpretation |
|---|---|---|---|---|
| SC | 5 | 2.44 | 0.79 | Influential |

the ability of e-Government systems to eliminate or reduce this behaviour pattern. Furthermore, the results also showed that 81% of the respondents would be encouraged to use e-Government services for their businesses transactions if they know that other business entities use them. This indicates that the social influence is relatively high in terms of using e-Government services (see Table 4 for total score of SC).

The influence of some social aspects involved in this study, such as the influence of other, was not supported in other research such as a study conducted by AlAwadi and Morris [22]. However, the findings related to the influence of cultural aspects were in consistent with those reported in AlAwadi and Morris's study.

In respect to the ***Awareness (AW)*** factor, the respondents were asked two groups of questions with two different 5-points Likert scales. The first group (AW p1) was to evaluate the participants' awareness and measure the influence of the Awareness factor on their adoption and utilisation of e-Government systems. The 5-points Likert scale in this group was ranging from 'Strongly agree' to 'Strongly disagree'. The second group of questions was to measure the influence of several awareness methods that can affect the participants' awareness which in turn affect their willingness to accept and use e-Government services for their businesses' transactions. The 5-points scale used in this group was ranging from 'Very influential' to 'Very uninfluential'.

The results of the first group revealed that around 64% of the participants felt that they had good knowledge about e-Government potentials and services while 6% did not feel that. Moreover, 29% gave neutral or do not know responses. The reason of having slightly high percentage of 'Neutral or do not know' responses is likely because some participants did not know much about e-Government potentials and services due to lack of advertisements and awareness campaigns, so they did not feel that they had good knowledge about such benefits and services. Moreover, the results of the first group also showed that the majority of the respondents (89%) agreed with the item "Offering workshops and visual presentation about potentials and services provided for business sector would encourage me to attend to know more about e-Government". This indicates that such awareness campaigns would increase the adoption and usage level of the users from business sector. Table 5 presents the total score of AW p1. In the second part (AW p2), the most dominant advertising methods were introduced to the participants to determine the influence degree of such methods on their willingness to use e-Government services for their businesses' transactions. Fig 1 shows the introduced advertising methods and their influence on the participants' willingness to use e-Government services.

TABLE 5: The result of AW factor

| Factor | # of item | Mean | S.D. | result interpretation |
|---|---|---|---|---|
| AW p1 | 3 | 2.14 | 0.78 | Influential |
| AW p2 | 6 | 1.97 | 0.97 | Influential |

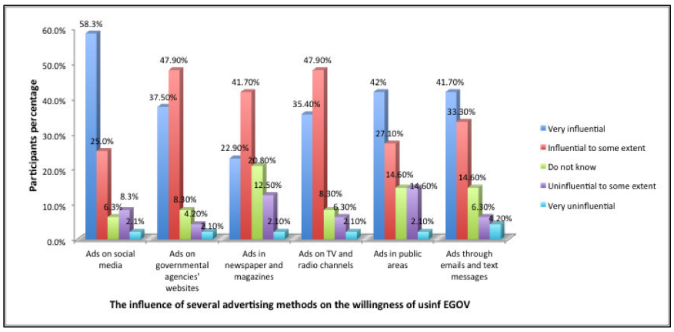

Fig. 1: The result of AW p2

It can be seen that 58% of the respondents reported that ads on social media significantly influence their willingness to use e-Government for their businesses' transactions. Albayari stated that social media revolutionized the business sector in Saudi Arabia since it creates sufficient ways to communicate with customers [23]. This means that most of business entities have accounts in social media networks and also new businesses are expected to follow the same trend of using social media. The result of this study and the status of social media spread in business sector in Saudi provide government with an excellent way of marketing e-Government services and increase the awareness about their benefits and potentials. Furthermore, 42% of the respondents reported that ads on public areas, such as billboards and banners, are very influential way that would increase their willingness to use e-Government services for their business. Advertising through emails and text messages comes third in terms of a very influential method with a percentage of 41%.

The higher three percentages of advertising methods that were reported as influential to some extent were ads on governmental agencies' websites (47.9%), ads on TV and radio channels (47.9%) and ads in newspaper and magazines (41.7%). It is likely that most of the participants are not usually exposed to such advertising; hence, they were reported as 'Influential to some extent' methods. Since the majority of the participating businesses were large companies, they usually linked to some governmental agencies electronically and thus, respondents did not see many ads on the agencies' websites. Being linked electronically means being viewed with the system directly not through website interfaces. Moreover, most of the respondents were employees in the participating businesses (70%) and it is likely that they do not usually have time to watch TV, listen to radio, read newspaper and magazines. Thus, they reported these methods as influential methods that affect their willingness to some extent. Participants who reported uninfluetial responses (either 'Very uninfluetial' or 'Uniflueti al to some extent') were relatively low in general.

The overall score for Awareness p2 was 1.97 indicating that the proposed advertising methods, which is part of the *Awareness* factor, influence to some extent the willingness to use e-Government systems for business entities' transactions. Furthermore, the overall findings of part 1 and 2 indicate the need for sufficient and efficient awareness and also indicate its influence on the adoption and usage level. These findings are similar to those revealed by AlAwadi [22], Alshihi [24] and Davies [25].

***Functional Quality of Service (FQS)*** has also been divided into two parts. The first part (FQS p1) comprised 4 items that measure the influence of the quality of service on the adoption and utilisation of e-Government systems but from functional aspect that concern with the e-Service itself. This part measures how the respondents feel about the general quality of provided e-Services through e-Government, how using e-Government would enhance the quality of their businesses' activities, what is the influence of important external factors (such as post and payment services) on the quality of services provided by e-Government. The items in this part were measured with 5-point Likert scale ranging from 'Strongly agree' to 'Strongly disagree'.

The results of the first part revealed that 48% of the respondents felt that e-Government services provided to business sector are high quality services. A slightly high proportion of respondents was neutral or did not know whether such e-Services are high quality and they represented 35%. When investigating neutral responses percentage, it was found that over 70% of them were employees. Employees who are responsible for performing e-Services in companies in Saudi Arabia usually are divided into different groups. Each group is responsible to deal with one governmental agency in terms of performing e-Transactions. Therefore, it is very likely that they cannot judge the e-Government services in general as they might be dealing with certain amount of e-Transactions. Moreover, The vast majority of the respondents (85%) agreed on that using e-Government systems would enhance the quality of their business activities.

The influence of significant external factors that are related to the functional quality of service such as the Saudi post mail services and payment options were also measured. Around 43% of the respondents agreed with that the Saudi post mail services are fast and reliable whereas 27% disagreed and 29% responded with 'Neutral or do not know' answers. Although the majority showed an agreement, the other proportions (disagree and neutral proportions) were relatively high. Those two percentages can be interpreted as that the Saudi post mail provides insufficient services for correspondence between business members and government agencies. Furthermore, it is likely that many business entities do not benefit from the Saudi post mail due to its limited services. With regards to the payment options, over three quarters (79%) of the respondents agreed with the sufficiency of SADAD system, which is the only payment method for governmental transactions in Saudi Arabia, whereas only 10% disagreed. SADAD is an intermediary system between banks and billers where it allows customers to pay for services. Although there are not many options for online payments methods in Saudi Arabia, the results showed high satisfaction level of the current payment system. Table 6 shows the total score of FQS p1.

TABLE 6: The result of FQS factor

| Factor | # of item | Mean | S.D. | result interpretation |
|---|---|---|---|---|
| FQS p1 | 4 | 2.21 | 0.66 | Influential |
| FQS p2 | 6 | 1.74 | 0.95 | Very influential |

The second part of *Functional Quality of Service* factor (FQS p2) comprised 6 items. They measured to what extent certain features, that are related to the functional quality aspect, are important to the respondents when using e-Government services for their businesses' e-Transactions. The measured features include the ability to track transactions online, the ability to view the history of the performed e-Transactions, the ability to appeal electronically, providing effective customers services and the ability to rate the quality of the provided e-Services.

The results of FQS p2 revealed that the ability to track governmental transactions online was very important to three quarters of the respondents (75%). The same percentage also reported that the ability to appeal online in case of transaction rejection was highly important to them. The vast majority of the respondents (80%) agreed on that the ability to view the history of all performed transactions online is of high importance degree. Over 70% of the respondents considered the feature of communicating with them regarding to the status of their businesses' transactions as of high importance. One of the functional features that is related to the quality of the provided services is providing customer care services. The participants were asked to determine the importance degree of providing such services that are dedicated only to serve customers from business sector with using e-Government services. The majority of participants (72%) reported high importance degree of the existence of such services.

The high importance degrees that were reported to most of the proposed functional features revealed the positive influence of providing these features when implementing e-Government services for business sector. Such functional features reflect high quality of the implemented e-Services and it is very likely that they would increase the adoption

TABLE 7: The result of PE factor

| Item | Median | IQR | result interpretation |
|---|---|---|---|
| PE1 | 2 | 1, 2 | Influential |
| PE2 | 1 | 1, 1 | Very influential |
| PE3 | 1 | 1, 3 | Very influential |

TABLE 8: The result of PS factor

| Factor | # of item | Mean | S.D. | result interpretation |
|---|---|---|---|---|
| PS p1 | 3 | 1.96 | 0.63 | Influential |
| PS p2 | 3 | 1.78 | 0.89 | Very influential |

and usage level (see Table 6 for total score of FQS).

***Previous Experience (PE)*** factor comprised three items,namely, PE1, PE2 and PE3 that measured the influence of Previous Experience on the intention to adopt and use e-Government services provided to business sector. Each of which had different measurement scale with three possible answers. The answer options of this factor's items were narrowed to three because we would like to gain more accurate results for exploring the impact of previous experience.

The respondents were asked to rate their previous experience of using e-Government services for their businesses' transactions. The results showed that 43% were fully satisfied, 54% were satisfied to some extent and only 2% were not satisfied. Although the percentages of fully satisfied and unsatisfied respondents were good indication of efficiency of the current e-Government services, the high percentage of respondents who were satisfied to some extent was, on the other hand, questionable. Therefore, information about the reasons that made the previous experience of some respondents not fully satisfied has also been collected. The reported reasons included difficulty of using e-Government service, lack of clarity of the requirements and failure to obtain the expected results of using such e-Services.

The participants were also asked to indicate how the previous experience of using e-Government for their business would affect their future use in item PE2. Three quarters of them (76%) stated that it will encourage them to use such systems for all their businesses' transactions whereas 8% stated that it made them hesitant to use such systems again. The high percentage of the encouraged respondents was not necessary an indication of high satisfactory level. It is likely that the need for online governmental service was the main reason of this high percentage of encouraged respondents. The slightly high proportion of respondents who reported that there will be no effect of the previous experience (15%) support this assumption.

Another item that measure the influence of the previous experiences of using online services was item PE3. It asked the participants who have used non-governmental online transactions for their businesses whether such experience would affect their willingness to use online governmental services. The results showed that over half of the respondents (57%) answered 'Yes, positively', only 3% answered 'Yes, negatively' and around 39% answered 'No effect'. This indicates that using online transactions and services (not governmental ones such as online banking and online purchasing) is very likely to influence the willingness of using e-Government services and transactions. All the total scores of PE items are presented in table 7.

***Perceived Simplicity (PS)*** factor comprised two groups of items and each group had different measure scale. The first group (PS p1) involved three items and they measure to what extent the perceived simplicity would influence the participants' adoption and utilisation of e-Government systems. The results of this part revealed that the overwhelming majority of the respondents (85%) believed that e-Government services provided to business sector are easy to use. However, over half of them (68%) were feeling that using such e-Services requires high level of concentration. This is likely because the lack of instant communication between customers and e-Services providers. In traditional ways, customers can instantly interact with the governmental employees who serve or conduct governmental transactions and thus, governmental employees can inform the customers if there is any mistakes or incomplete information and documents that make the performed transaction unaccepted or rejected. Where in online environment, such communication is limited especially when there is no sufficient online communication method such as online chat with representatives. In this case, customers need more concentration when performing e-Services to avoid rejecting them due to lack of or mistakes in the provided information and documents. Furthermore, the results also showed that if using e-Government services were difficult and complex, 79% of the respondents would hesitate to use them again. The overall score of 1.96 (see Table 8) indicated that PS factor is likely influence the adoption and utilisation level. In other word, the difficulty and complexity of using e-Government services would negatively influence the willingness of users from business sector to use such e-Services.

In PS p2, the respondents were asked to determine the importance degree of proposed important information related to the simplicity of use. The proposed information involved detailed steps on how to perform e-Services online (item PS4), texts or pictures that clarify the required information and documents (item PS5) and explanation of processing steps of the intended e-Service (item PS6). The proposed information is strongly related to the ease of use and thus, the participants were asked to specify to what extent such information is important to them. Measuring the importance

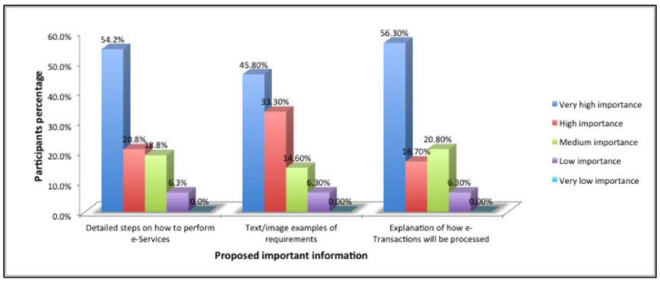

Fig. 2: The result of PS p2

of such information will give an indication on whether the simplicity would influence the adoption and utilisation of e-Services. The results of PS p2 are presented in Fig 2.

It is clear from the figure that almost half of the respondents believed that providing such information is very important to them and they represented 54% for item PS4, 45% for item PS5 and 56% for item PS6. Approximately 33% reported ’High importance’ for providing text\image examples of the requirements whereas 16% reported the same degree of importance to providing explanation of the processing steps and 20% also reported the same degree of importance to providing detailed steps on how to perform e-Services. Generally, clarifying the required information and documents with texts and pictures examples was the most important information as 79% of the respondents indicated ’Very high’ to ’High’ importance level. Remarkably, none of the participants believed that such information has very low importance degree. This indicated that all the proposed information had relatively high importance degree to the respondents (see Table 8 for the total score of PS p2) and therefore, it is very likely that providing such information would positively influence their adoption and utilisation of e-Government services.

E-Government services need to be straightforward and simple to use in order to enable all potential users to benefit from such e-Services. This simplicity is emphasised when it comes to providing e-Services to business sector where large number of e-Services and e-Transactions are needed. Other studies such as Carter and Belanger [26] and Phang et al. [27] also found that simplicity and ease of use is a significant factor that influence the intention to use e-Government.

***Technical Quality of Service*** factor was measured with five items and they were divided into two parts measured with 5-poits Likert scale (agreement scale and importance degree scale). The results of the first part revealed that 68% agreed with that the technical errors such as links not working and server errors would affect negatively their willingness to use such e-Services. This high agreement is expected since the technical aspects in e-Government systems are crucial in terms of quality of service especially when they are visible to the users. Moreover, the majority of the respondents (70%) agreed with that the interface design and layout of e-Government websites would influence their willingness to use e-Government for their business. It has been found from the results of this part (see Table 9) that the technical aspects are very important in terms of quality of service perception and thus, providing e-Services with high technical quality is fundamental. A high quality of the technical side including the design, structure and layout of e-Government portals is needed for the successful adoption and utilization [28].

TABLE 9: The result of TQS factor

| Factor | # of item | Mean | S.D. | result interpretation |
|---|---|---|---|---|
| TQS p1 | 2 | 2.40 | 0.96 | Influential |
| TQS p2 | 3 | 1.84 | 0.87 | Influential |

TQS part 2 was concern with measuring the importance degree of providing important information that is related to the technical side of e-Services (see Fig 3). Such information is important in terms of quality of service perception but from the technical side. The majority of the respondents reported that providing the proposed information is very important to them when using e-Services for their businesses. Half of the participants (50%) reported ’Very high importance’ for providing information about the expected time to complete their businesses’ e-Transactions, 45% reported the same importance degree for providing the last update time of e-Services websites and 47% also reported the same level of importance for providing the last update time of procedures and requirements that their businesses have to comply with. The overall score of 1.84 that is presented in Table 9 indicates that the proposed information had high importance degree for the users from business sector and thus, providing such information would likely increase their usage.

Furthermore, the results of TQS (part 1 and 2) indicates that this factor would influence the adoption and utilisation of users from business sector. They showed that reducing technical errors, enhancing interfaces design and providing information that reflect high technical quality of service would definitely increase the adoption and usage level of

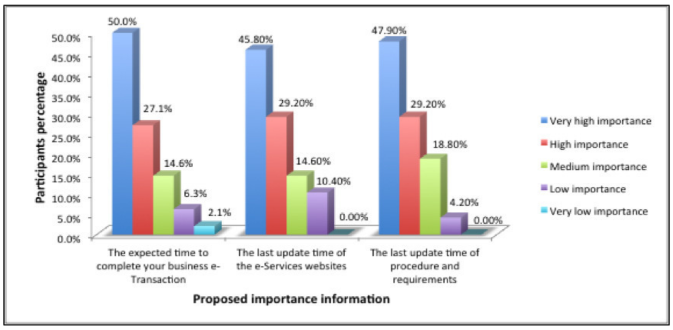

Fig. 3: The result of TQS p2

TABLE 10: The result of ACC1 factor

| Item | Median | IQR | result interpretation |
|---|---|---|---|
| ACC1 | 2 | 1, 2.5 | Influential |

| Factor | # of item | Mean | S.D. | result interpretation |
|---|---|---|---|---|
| ACC p2 | 3 | 1.71 | 0.85 | Very influential |

e-Government services provided to business sector. Therefore, paying more attention on technical aspects that appear directly to the users is important.

In terms of ***Accessibility (ACC)*** factor, three quarters of the respondents (75%) thought that the existence of authorised offices to help them to access and use e-Government services is a good idea. The authorised offices meant to be official agencies that are associated with governmental organisations to provide help to users with accessing e-Government systems, performing e-Transactions and corresponding with governmental organisations on behalf of users. This high percentage is likely because e-Government is still in early stages in Saudi Arabia and also the infrastructure of communications and post mails is in developing phases. Such help method is also useful for users in rural areas where there are no governmental agencies. This method can be introduced at lease in the developing phase of e-Services where many users are likely need help to access and use such e-Services. This result is supported by a study that has been conducted by Alsobhi et al. in Al-Madinah city, which is a large city in Saudi Arabia, to investigate the influence of intermediary agencies on the adoption and usage level. Those agencies were authorised to facilitate communication and coordination between public services providers and customers. The findings of Alsobhi's study showed that intermediaries are an extremely useful channel for improving the adoption and utilisation of e-Government [29]. Table 10 shows the overall score of this item (ACC1).

In the second part of Accessibility factor measurement, the participants were asked to indicate the importance degree of the existence of several features that are related to accessibility. These features are shown in Fig 4. It has been found that having full control of data presence in e-Government systems was highly important to three quarters (75%) of the participants. This indicate that users from business sector prefer to have a full access to their businesses data stored in e-Government systems and also to have full control over it where they can delete it or keep it stored. Moreover, accessing e-Government services provided to business sector at any time (24 hour and 7 days) was of high importance to approximately 77% of the respondents. Since most of the participating business entities (around 70%) were large companies, it is likely that they have large number of governmental transactions that they need to perform and the participants (just over 80% were employees) prefer to have flexibility to perform them at any time even out of working hours.

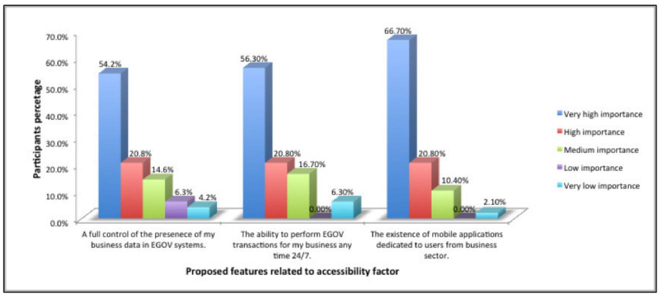

Fig. 4: The result of ACC p2

As another accessibility method that can influence the adoption and utilisation of e-Government services, providing e-Services through mobile applications was highly important to the vast majority of the participants with a percentage of 87%. This indicates that the flexibility to access e-Government systems from anywhere is very important to users from business sector and it is very likely that providing mobile application for this purpose will increase the adoption and utilisation level. Table 11 presents the overall score of ACC part 2 (1.71) which indicates the strong impact of *Accessibility* on the adoption and usage.

***Perceived Trust (PT)*** factor was measured with nine items using 5-points Likert scale ranging from 'Strongly agree' to 'Strongly disagree'. PT factor concerned with three crucial aspects, namely, trust, security and privacy. Thus, all these aspects were measured with different items. The analysis of this factor revealed that 58% of the participants agreed with that the Internet is safe to be used to perform governmental e-Transactions for their businesses whereas 27% disagreed. This indicates high security perception from the respondents towards using the online means for performing e-Government transactions although the proportion of disagreed responses was slightly high. Thus, the result was investigated further and it was found that the education level of 54% of the respondents who reported an agreement on that the Internet is not safe were secondary school or less. It is likely that the education level had an impact on the security perception when using online governmental services.

The results also indicated a relatively high privacy perception since over half of the respondents (56%) would not hesitate to provide sensitive information through e-Government systems. The same percentage of 56% also disagreed with a statement stated "Dealing with government agencies electronically online could cause invasion of my business privacy". Furthermore, 64% of the respondents

TABLE 12: The result of PT factor

| Factor | # of item | Mean | S.D. | result interpretation |
|---|---|---|---|---|
| PT | 9 | 2.34 | 0.71 | Influential |

TABLE 13: The result of RP factor

| Factor | # of item | Mean | S.D. | result interpretation |
|---|---|---|---|---|
| RP | 4 | 1.71 | 0.79 | Very influential |

believed that their business entities' data that are stored in e-Government systems cannot be used by other parties without their permission. Other parties meant to be other governmental organizations or other companies. Moreover, approximately 54% of the respondents believed that their company's data stored in e-Government systems cannot be misused. These results showed a relatively high trust, security and privacy perception.

The overall score of this factor was 2.34 (see Table 12) and this gives us an indication that Perceived Trust factor is likely influence the adoption and utilisation of e-Government from the perspective of users from business sector. Moreover, the high trust, security and privacy perceptions that have been shown in all items reflect the importance and the impact of trust for both the business owners and employees in business sector.

***Regulation and Policies (RP)*** factor is another factor that was proposed in the utilised model (EGAUM) and it was measured with four items. In these items, the participants were asked to determine the importance degree of providing important information related to the regulations and policies of using e-Government. The proposed information can be seen in Fig 5. It is clear from the figure that all the proposed information was of high importance degree for the majority of the respondents. The graph shows that around 83% reported that providing e-Version of the regulatory procedures and requirements that their business entities need to comply with was highly important to them. Such procedures and requirements are different according to the business field and activities and they are normally updated regularly by government.

Moreover, providing information security policies was also highly important to over 79% of the participants. Such policies involve security procedures applied in implementing e-Services, security procedures applied in storing users' data and security guidelines that the agencies follow when providing e-Services. Even if the agencies implement high standard policies of information security, users need to see and feel about such security matter. Furthermore, approximately 83% of the respondents reported high importance degree to the existence of information privacy policies with the highest percentage of 'Very high importance' answer.

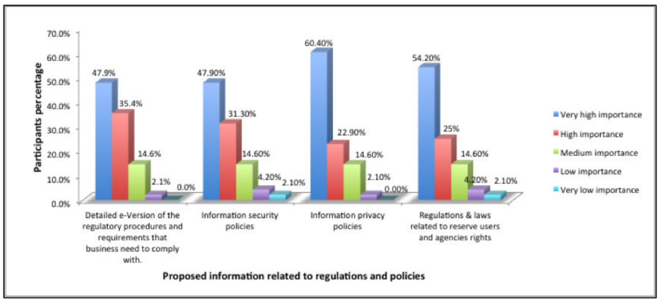

Fig. 5: The result of RP

Regulations and laws that are related to reserve users' and agencies' rights when using e-Government services were reported as of high important by more than three quarters of the respondents (79%). Such regulations and laws will protect users' rights when performing and using online e-Services for their business entities. For example, users need to know what they should do when conflict happen with e-Services provider regarding their e-Transactions. Also these regulations and laws will reserve governmental agencies rights when providing e-Services to customers and this include the cases and reasons that give the agency the right to refuse processing an e-Transaction. Remarkably, very low percentages of participants who responded low importance degree to each item.

The results revealed that applying strict, clear and detailed regulations and policies when implementing e-Government systems is very important to the users from business sector. This is likely because users from business sector are cautious and careful about their businesses' transactions. They do not want their business activities to be negatively affected due to lack of knowledge or understanding of regulations and policies especially for large business entities (around 70% of the participating business entities were large). The total score of 1.71 (see Table 13) indicates that RP is a significant factor that has a strong impact on the adoption and usage of e-Government services provided to business sector.

## IV. Conclusion

The adoption and utilisation of e-Government considered to be a challenge, and therefore, an interesting research area is introduced. This paper aimed to identify determinant of potential users' adoption and utilisation of e-Government services from the business sector perspective in Saudi Arabia. This study was based on a comprehensive framework (EGAUM) that proposed fundamental factors related to the adoption and interaction with e-Government services. The utilised model covered substantially all the aspects that have direct and indirect impact on such interaction. The results of the descriptive analysis in this study indicated that all the proposed factors have degree of influence. PB, FQS, PE, PS, ACC and RP were found to be significant factors that are very likely influence the adoption and usage level of the users from business sector.

This study is part of an on-going research and thus, the collected data will be analysed with further analysis procedures to explore the correlations between the model's variables. Although there are some limitations in this study such as the majority of male participants and the majority of large participating business firms, this study provides useful insights into the motivations underlying the intentions to adopt and use e-Government services from the business sector perspective in developing countries like Saudi Arabia.

□

*Abstract*— **We propose a novel software platform based on the notion of context-awareness which allows rapid and easy development of context aware applications. One of the fundamental goals of the proposed platform is extensibility, allowing the platform to react to new requirements without making fundamental and substantial changes. The Context Aware Application Development Platform- PCAD- has inspired from an operating system and modeled as a layered architecture. It exhibits a plug-and-play behavior very similar to devices and device drivers found on an operating system/kernel. The platform offers functions such as data management, notification, security and privacy as services. The platform provides a public interface to application developers in their development of context-aware applications. It covers a wide range of disparate application domains such as smart city and livestock monitoring applications.**

## I. Introduction

APPLICATIONS using information and communication technologies collect and process a diverse range of data using machines connected through communication networks. This phenomenon is captured in the term the *Internet of Things*. The Internet of Things is a complex interconnection of heterogeneous devices that include sensors, cameras, micro chips and RFID based products, and which generate large amount of data obtained from various domains. For this reason platforms or architectures must be designed in anticipation of the increase in the number of devices, and the varying demands of users and applications in different contexts. In order for a platform to be successful, it is imperative that it recognizes the context in which users and applications are operating, and enable service customization for a particular user. The creation of smart applications and environments then becomes a possibility by using context-aware computing, which acquires, analyzes, and interprets relevant context information, and responds to contextual changes.

Temperature, humidity, traffic congestion, road conditions, sea pollution, and river level are some examples of context information. Such context information can be used alone or in combination within context-aware applications to provide custom services in various domains, such as transportation, health and medical systems, tracking and control of environment, energy, agriculture, industry, sport events, and tourism. However, the effective use of this context information requires its efficient and effective acquisition, storage, processing and reasoning. In this way, productivity, economic output and quality of life can be increased.

This paper describes a novel, service-based software platform proposal based on the notion of context-awareness. The platform basically follows a middleware approach, which draws on the techniques taken from operating system design. The primary goal of the proposal is to offer a platform to simplify the development of context-aware applications by relieving the applications from complex context data management issues. In an open, dynamic and continuously changing environment, context data must be acquired, managed and ultimately offered to applications which will interpret the data according to the situation. The platform separates context acquisition from the application code and handles many context data management issues on behalf of the applications. The fundamental design force of the proposal is that the platform is agile, robust, and capable of reacting to new requirements without the need for fundamental and substantial changes.

The rest of the paper is organized as follows. The motivation section explains the rationale and design issues that motivated this work. Related works section includes an overview of the existing systems based on context-aware features. Section 4 presents the technical architecture of the platform. Section 5 gives a practical scenario from a smart city parking application, and finally, Section 6 draws conclusions about the proposed system.

## II. Motivation

Dey et al. has listed three characteristics of a context aware system as (i) information and services are presented to a user, (ii) a service is executed, and (iii) context is linked to information for later retrieval [1], [2]. Therefore, a service

□ This work is supported by the Scientific and Technological Research Council of Turkey – TUBITAK under Grant 114E938.

978-83-60810-66-8/$25.00©2015, IEEE

based software infrastructure support facilitates building context aware systems as it simplifies system creation by placing common context aware computing features in the infrastructure as services. A fundamental advantage of a service-based infrastructure approach is that the resources (i.e. data, sensors, devices, services) are shared, making maintenance and evolution of the infrastructure much easier [3]. Such an infrastructure is best realized in the form of a middleware, in which the infrastructure acts as a foundation on which other systems can be built. It takes responsibility for acquisition, storage, processing and interoperability of the context data, and provides services such as alarm, notification and security to the applications.

An architecture used in building the service-based infrastructure must possess certain attributes in order to be a viable option in creating context aware systems. Notable among those attributes are extensibility, robustness, scalability, and ease of use. Extensible architectures allow the addition or removal of components without breaking or taking down the system, and facilitate the seamless deployment of new sensors, devices and services. The entire system can evolve in a step-wise fashion. Robustness requires that the infrastructure operates in the case of a malfunction and terminates peacefully when breakage is unavoidable, while scalability ensures that infrastructure is able to serve many users and collect data from a diverse range and number of sensors. The amount of administrative effort must also be minimized to maintain the efficiency of services, devices and sensors. Finally, no matter how well the architecture is designed, it must be efficient and simple to use. Efficiency is measured in terms of time and space, which are influenced by the data storage, response and real time requirements of the system.

An Operating Systems inspired approach is the most suitable proposition in designing context aware infrastructure architectures. The primary aspect of Operating System architectures is the abstraction of inner details through layering and providing a high-level interface to allow uniform access to the functions of the system contained in its layers. Two typical examples from the UNIX world are the POSIX and device driver interfaces. POSIX interface allows the applications interact with OS services such as file system, network stack and devices, and device driver interface allows the seamless integration of new devices and drivers to OS kernel.

For the reasons mentioned above, a service based middleware architecture inspired by an OS is used in the design of PCAD system. The sensors, devices, services and more importantly, the applications are separated from each other, yet interact with one another. The loose coupling of components permits plugability and reduces fragility, the two essential characteristics of an extensible and robust system.

A prototype of the platform is currently under implementation together with two sample applications that utilize the platform. One of these is a livestock monitoring application that monitors livestock physiological data and notifies the farmer and the veterinary physician of potential livestock health problems. The second application is an implementation of a smart city parking scenario described in Section 5. Both applications will allow the evaluation of the effectiveness, robustness and performance of the platform applied to diverse domains. It will also demonstrate that the platform facilitates rapid context-aware application development.

Despite being an important issue in context aware systems, we have chosen not to address context modeling. Context is defined by [2] as: “any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves”. A piece of information is considered context data only if it is interpreted, otherwise, it is simply information belonging to an environment [4]. For applications and services to adapt their behavior based on the particular context, they need to be able to do reasoning. The method chosen for modeling the context has direct influence on the kind of reasoning performed [5], [6]. Therefore it is very important to choose a modeling technique that will facilitate not only easy reasoning, but also sharing of context with others. Since our primary focus is to define the platform itself and the interactions among the components, we defer the discussion of context modeling for our future work.

## III. Related Work

Many context aware architectures proposed in the past have borrowed ideas and features from operating system designs. Gaia project [7] describes one such architecture which is heavily influenced by operating system design. It extends the OS concepts by incorporating context-awareness. It has a context file system that organizes data by context and a Unix-like signal event mechanism to create channels to connect context data suppliers to consumers through a handle called *ContextType*. Another architecture influenced by operating system design is Context Toolkit in which a widget model is adapted resembling the device driver model of an OS. In the widget model, widgets are software components that provide an interface to a hardware sensor. In other words a widget acts like a device driver to a sensor. Context Broker Architecture (CoBrA) [8] employs an intelligent context broker to provide a centralized context model shared by devices, agents and services. One of the responsibilities of the context broker is to ensure that user privacy is protected through policies by allowing the user to control how contextual information is shared. The issue of how to control access to shared information is of key importance in operating systems.

There are other architectures based on layered architecture model which have the goal of abstracting sensor data management from users. SOCAM, Service Oriented Context

Aware Middleware [9], project is a middleware architecture that supports the building of context aware services in pervasive environments. Context aware services, which may also be applications, can obtain context using the context middleware layer from context providers. As expected from a middleware-based architecture, in SOCAM, context aware application code is separated from context acquisition and reasoning. Another example of a centralized middleware approach is found in CASS project [10], where the middleware itself is a server responding to context management requests of mobile context aware applications. Context acquisition is done by the sensor nodes and context data is sent to the server. Storage, modeling and reasoning tasks are performed by the middleware server. Consequently CASS applications neither need to communicate with the context source directly, nor are they affected by context-based inferences and behaviors. Another layered architecture tailored towards mobile devices that addresses the shortcomings and special needs of mobile devices is the Hydrogen [11] project. One of its three layers, the Management layer is responsible for storing context information and sharing it using XML protocol. A second layer, the Adapter layer, delivers information obtained from context sources, i.e. sensors, to the Management layer. The Application layer, where the application code resides, can access context data synchronously or asynchronously.

A common benefit of these architectures is their capability to prevent coalescing of application code with the context management functions by decoupling context sensing and acquisition from the application code.

In addition to architectures and frameworks several context aware systems for different domains have been built or proposed in the literature. Context aware systems for pervasive environments are surveyed in [12] and web services based systems are studied in [13] and a classification of context aware systems is given in [14].

## IV. PCAD Architecture

Context-Aware Application Development Platform-PCAD- has been inspired by operating systems design and modeled as a layered architecture. PCAD's primary goal is to offer extensible, scalable, robust, secure and general purpose software architecture for use by developers in several industrial processes and sectors. The platform particularly addresses the following design issues:

1) Extensibility
2) Security and Privacy
3) Simplicity (be applicable and pragmatic)
4) Generic (not domain specific)
5) Service Based

The platform itself adapts a middleware and blackboard [4] model, providing common services to the applications. This is similar to the conceptual separation of user and kernel services in an OS. Among the services provided by PCAD are data storage, alarm, notification, a simple rule engine and reporting facilities. One can view the platform as a layer providing kernel-like services, while the applications provide user level services and the physical sensors and their software act like devices and device drivers providing data to applications. The applications subscribe themselves to the sensors through the platform, after which they are notified by the context providers when a context data becomes available. The applications and the sensor software are bound to the platform using standard protocols (e.g., REST, web sockets, and raw socket). The architecture exhibits a plug-and-play behavior similar to the devices and their associated drivers found in operating system/kernel. The sensors can be added and removed, and applications can be registered to the newly added sensor without needing to modify the platform. The platform provides a public interface to enable the rapid and easy development of applications from various domains by application developers. It relieves the applications from implementing common services and functions, thus fulfilling one of the fundamental principles of software engineering – reusability.

### A. PCAD Services

PCAD's functionality is made available to applications through services. The services of PCAD and its architectural resemblance to Operating System architecture is shown in Figure 1. The list of services available in PCAD is given in Table I and explained in detail below.

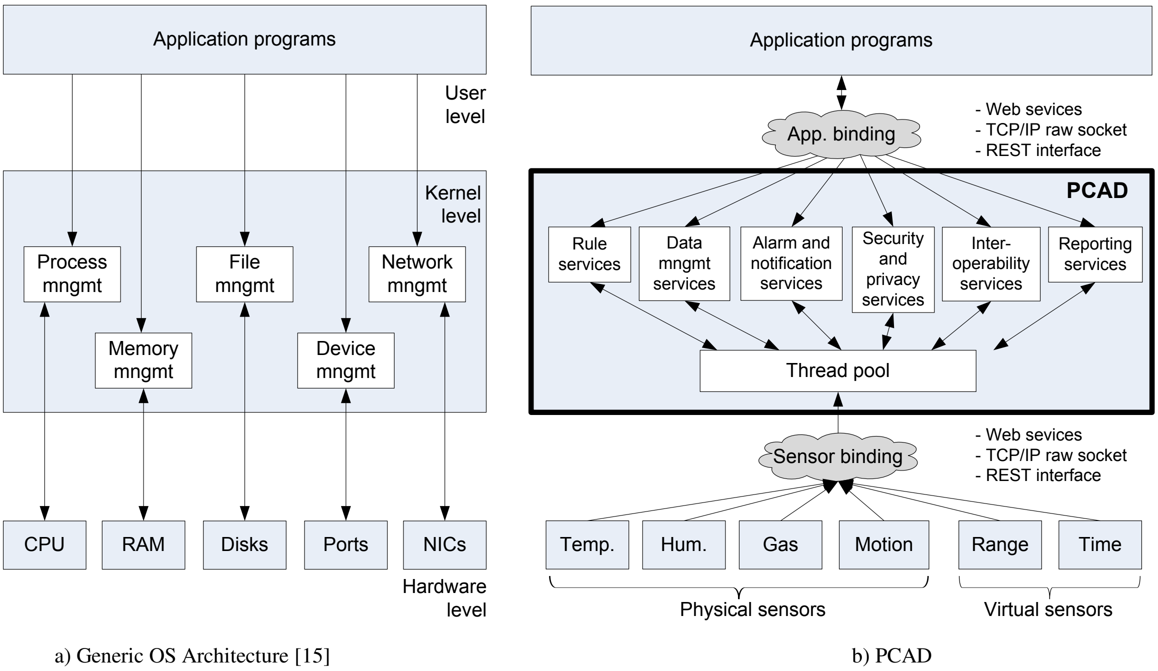
Table I.
PCAD Services

| Service name | Service description |
|---|---|
| Rule Service (RS) | Context processing |
| Data Management Service (DMS) | Stores context data and provides data upon request through a uniform interface. Underlying storage mechanism is transparent to the users. |
| Alarm and Notification Service (ANS) | Notifies the registered parties about context data. Filters data if necessary. |
| Reporting Services (RPS) | Generates detailed reports about context sources including data and status of the context source. |
| Security and Privacy Service (SPS) | Ensures only authorized parties can access to context data based on policies. |
| Interoperability and Communication Service (ICS) | Data exchange among similar platforms using standard communication protocols and message formats. |

*Rule Services*

A very simple and generic syntax will be designed in the form of if-then rules. The rules will be specified in an XML file, and will be verified against the Rule XML Schema using XSD. A generic rule will be of the following format:

```
if <cond> then action
```



a) Generic OS Architecture [15]

b) PCAD

Fig. 1 A Comparison of PCAD architecture and OS architecture

The condition in the rule can be a combination of conjuncts and disjuncts. When the condition evaluates to true, then the action is performed. This action could be further used to trigger other rules. Below, one such example is given:

```
if (raining and
    location=″main street″)
then congestion
```

When this rule is executed, firstly rain sensor data is retrieved, followed by location information. If the condition evaluates to true, which means that it is raining and the location name is *main street*, then the `congestion` rule is executed. Congestion rule simply retrieves the congestion data for the main street using the congestion sensor and returns it to the application.

The applications create a rule file in XML and hand over to PCAD for context processing. Alternatively, applications may perform their own context processing, thus opting out using the Rule service of PCAD.

*Data Management Services*

Data Management Services is responsible for storing of data received from multiple sources and making the data available to those requesting it. It provides a uniform interface for the transparent access of data by the applications. This interface let users of this service insert, update, delete and filter information. It is essential that the sensor data, whether collected synchronously or asynchronously, is stored without any loss. DMS could store data simply in a relational database, or it can use a cloud service. The underlying storage mechanism is transparent to the applications.

*Alarm and Notifications Services*

The Alarm and Notification Services (ANS) follow the paradigm of observer design pattern [16]. The applications attach themselves to a sensor of interest to acquire context information. There are two modes to query the presence of sensor data. In the asynchronous mode, ANS periodically queries the sensor and then reads and stores that data. It then immediately makes the data available to the applications that showed interest. In synchronous mode, the sensor software interrupts the ANS for a reading. Asynchronous mode requires support from the sensor software, which must notify ANS for data availability. This is generally not the conventional method of interacting with a sensor, and therefore is not available in most cases. The ANS provide sensor data to applications using either pull or push method. In the pull model, the applications receive only a minimal notification, and applications or users ask for specific details thereafter. In the push model, ANS sends applications detailed information about the sensor data.

A filtering mechanism will be employed to allow applications to register themselves to specific conditions so that they will be notified when such condition occurs. An example filter is shown in Figure 2. An application named *myApp* is only interested in data from the temperature sensor *temp001* between 9:00 AM and 12:00 PM, and only for values 39 and above.

*Reporting Services*

Detailed reports presenting sensor data and sensor availability shall be provided by the Reporting Services (RPS). Visualization of the sensor status and data provides a useful overview of the system, which is important because it is not easy to understand and interpret raw data. The data is presented to the user in different formats, such as tables, charts and text. It was decided to select open source reporting tools with an application programming interface. BIRT [17] is one such tool with several APIs to design, generate and render reports and charts.

```
<?xml version="1.0" encoding="UTF-8"?>
<Configuration name="MyApp">
<Sensor name="TME3m" id="temp001" >
<TimeFilter start="09:00:00"end="12:00:00"
      onMatch="ACCEPT" onMismatch="DENY"/>
<ThresholdFilter value="39"
      onMatch="ACCEPT" onMismatch="DENY"/>
</Configuration>
```

Fig. 2 Example filter

*Thread Pool*

The platform will ensure that the context data received from the sensors are properly stored and sent to the applications in a timely manner. A pool of threads, as shown in Figure 3, are to be created and tasks are assigned to threads whenever needed. Each thread will have two sub threads; one is responsible for real time delivery of raw data to applications, and the other responsible for the storage and processing of the context data.

*Real-time support*

A certain class of applications imposes constraints on the sensor data delivery time. Context aware systems using direct sensor access approach are better suited for meeting the hard real time requirements. Such systems collect information directly from the sensor without any intervening components, thus, time lapse in reacting to the events conforms to the real-time requirements. However, a disadvantage of these systems is their inability to re-use components due to the tight coupling of sensor device drivers with the application [11]. In contrast, systems that are built using layered architectures are considered superior because they are extensible and allow modifications to the architecture without modifying the applications. However, meeting the hard real-time requirements is difficult in layered architectures, as data flows through several layers before it reaches the application. Therefore, layered architectures are much more suited to soft real-time requirements. Soft real-time systems can tolerate larger time latencies and they still operate even when time constraints are violated, albeit with degraded performance.

PCAD addresses the soft real-time requirement by establishing a direct pipe or channel between the sensor software and the applications, as depicted in Figure 4. A dedicated thread is allocated to the channel, allowing raw sensor data to be transmitted through this channel, while a copy of the data is processed and stored by the platform concurrently.

*Security and Privacy Services*

Privacy is an important issue in PCAD as sensors will acquire information about the environment, and share it with different applications. As the sensor data is owned by the platform rather than the applications, it is the platform's responsibility to protect the privacy of the data.

A very basic Role Based Access Control (RBAC) [18] scheme mediates which sensor data is accessible to which application. An RBAC-like access control mechanism is preferred because it allows more complex policies to be accommodated in the future. The idea is to assign applications particular roles and assign access rights to roles, and then control which application can access sensor data based on those roles. Our use of RBAC will be much more closely aligned with Mandatory Access Control mechanism, where the sensor data is assigned privacy levels, and the applications are given clearance levels. The set of roles will be defined by the platform based on policy configurations. For instance, a weather application does not need to access to the transportation data.

The three basic elements of access control, Subject, Object and Access Right have the following mappings in PCAD: the subject is the software processes in which the applications run. Object is our context resources. These context resources may be physical or virtual sensors. Access Right would be the read right of the context data, or querying the status of the sensor providing the data.

Tables II-A, II-B and II-C show an example of role based access control. In this example, the subject is the application and the object is the sensor. *Application1* has been assigned roles *role1* and *role2*, which gives application the right to read *sensor2* and *sensor3*, and to query the status of *sensor1*. On the other hand *application2* can only query the status of the three sensors. RBAC makes it easy to put constraints, for instance, we could limit the number of applications collecting data from a sensor by limiting the number of applications assigned to a role.

TABLE II.
A. AUTHORIZATION EXAMPLE

| **Authorization** | **Description** |
|---|---|
| **read** | Allowed to acquire context data |
| **query** | Allowed to query the status of the context source |

B. APPLICATION ROLE MAPPING

| **Subject** | **Roles** | | |
|---|---|---|---|
| | role 1 | role 2 | role 3 |
| **application 1** | * | * | |
| **application 2** | | | * |

C. ACCESS CONTROL IN PCAD

| **Roles** | **Sensors** | | |
|---|---|---|---|
| | **sensor 1** | **sensor 2** | **sensor 3** |
| **role 1** | query | read | read |
| **role 2** | | read | |
| **role 3** | query | query | query |

Two aspects of equal importance are the authenticity of the sensor, and protection of the confidentiality and integrity of the information it provides. The field of network and information security has sufficiently matured in the provision of security features to allow combination of symmetric and asymmetric cryptography (digital certificates) to fulfill the authentication, confidentiality and integrity requirements of the platform.

### *Interoperability and Communication Services*

According to a recent survey, interoperability is listed as the number one quality driver for smart city applications [19]. Interoperability is a necessity since data is owned by other parties and managed by different platforms, similar to PCAD and also for making PCAD data available to other requestors. This creates a need for interoperability for exchanging context information among different applications. Interoperability and Communication Services are responsible for context data exchange using standard messaging format. As shown in Figure 5, PCAD uses XML as the data exchange format.

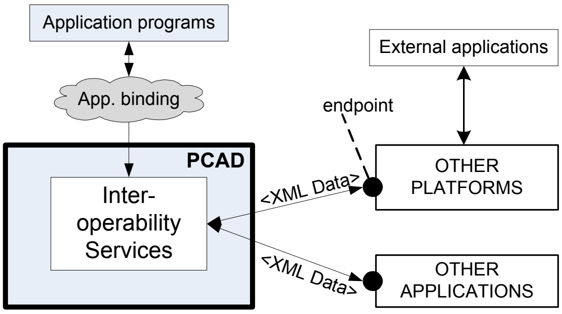

Fig. 5 Context data exchange

Applications built on top of the PCAD platform use this service to send context data to other applications. The applications can also ask the platform to receive context data from other platforms, including from another instance of the PCAD platform. In such a case, the applications must let the service know the endpoint information that has the data.

### *B. Sensor Layer*

The sensor layer consists of physical and virtual sensors. Examples of physical sensors are pH, humidity and temperature. Unlike physical sensors, virtual sensors use either Application Programming Interfaces or web services to obtain data, such as GPS position or real-time camera stream [20]. In many situations, data can be made meaningful by aggregating individual context data obtained from multiple physical and virtual sensors. This process, called context aggregation, generates combined data that is more accurate and relevant than information obtained from a single source. Context aggregation function is implemented also as a virtual sensor.

The sensor software will interact with the platform by registering to the platform and sending raw data to the platform, which is further formatted and processed by the platform. Sensor layer interacts with the platform through sensor binding layer.

### *C. Binding Layers*

For the purpose of allowing applications and sensor software to communicate with the platform, the platform contains two binding layers. The first is between the application software, and the platform and the second is between the sensor software and the platform. These binding layers are facades that simplify the application and the sensor software's interaction with the platform. The application binding layer is used by the applications when they require the services of the platform, such as receiving context data, registering and deregistering for sensor data, creating reports and receiving alarms and notifications. The sensor binding layer is used by the platform to gather data from a sensor and deliver it to the registered applications, possibly multiple times. Therefore, it is possible for many applications to access the same context data simultaneously, which may not be possible with the direct access to sensor alternative.

The implementation of the binding layer employs widely used protocols. Among the protocols supported are web services, web sockets and REST.

## V. A Scenario: Smart Parking

In this section, we present a scenario to demonstrate the interactions between an application PCAD and sensors. The scenario involves a context aware smart city application running on a mobile device developed for the purpose of finding a parking space based on certain constraints.

*One day Mr. Jones went out of the house and boarded his car. Just he was about to approach to his workplace in downtown, he remembered that he wasted time searching for a parking place the previous week. He started the application on his mobile phone and received the coordinates and the route information about the nearest parking location within a 500 meter radius on a map. He thought, "I did a good job of using this context-aware [sic] application to access to the information provided by the smart [sic] city, otherwise I would have been late for my appointment again."*

Following is the sequence of actions that take place in the application and PCAD platform:

1) User invokes the smart city context aware application on the mobile phone.
2) Smart city application starts a session with the PCAD platform.
   *A communication session is opened using WebSockets. The application and PCAD now begin to communicate via the application binding layer for fulfilling user's specific request about an available parking place.*
3) User requests route information about a parking place within the 500 meter radius of his workplace.
   *The user's operational parameters, such as the 500 meter constraint, are translated into rules and registered with the Rule Services (RS) of CAS, using the session established before. These rules get executed by PCAD later on.*
4) Smart city application sends user requests to PCAD via application binding layer.
5) PCAD periodically requests ground parking data from installed sensors, which includes sensor fingerprint (id, location, time) and parking availability.
   *Since the actual parking status changes often due to usage conditions, ground sensors are asked to send parking availability information in real-time. The frequency of sensor query is a configurable parameter. The scenario is an example of soft real time application because the latency of getting availability information is not critical to the operation of the application. PCAD collect these data via the sensor binding layer and notifies the application via application binding layer using alarm and notification services (ANS). The real time channel is used to send the data to the application. PCAD enforces data privacy by only providing parking data to the application.*
6) Smart city application determines the user's location.
7) Smart city application finds optimal parking space for the user.
   *Smart city application acquires user's location information from mobile device, and parking availability and parking location information from PCAD. The application then offers an optimal path using this information together with other constraints, such as shortest path, traffic signs or number of traffic lights etc. The application either gets some of this constraint information from PCAD or PCAD can aggregate this information from other sources, including other platforms using the interoperability and communicating services (ICS). This part directly points all other smart city applications working together.*
8) Smart city application presents the information including, coordinates and map to user.

This scenario shows how PCAD services are utilized by the application, and how the actions are performed by the actors of the system. Figure 6 shows the steps of interaction described above. The figure illustrates how sensor acquisition is decoupled from the application code.

This scenario can easily be adapted to other problems, such as finding a charging station for an electric car. A context-aware charge management system for electric vehicles is described in [21]. A more elaborate problem on parking lot management for charging stations is described in [22], while a parking reservation system based on telecommunication APIs is given in [23].

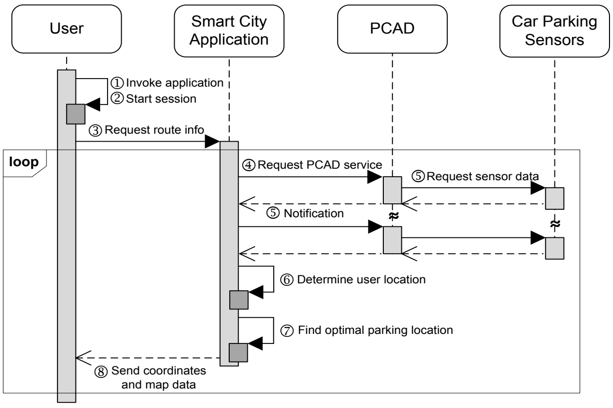

Fig. 6 Interaction diagram of the scenario

## VI. Conclusions

In this paper we propose a Platform for Context-Aware Application Development -PCAD based on operating system principles for rapid development and deployment of context aware applications. The platform has been inspired by Operating System design, and is based on a layered architecture that is modular, extensible, and follows the design pattern guidelines. The major premise of the platform was to provide a robust environment influenced by the theories of the architectural design of an operating system, and enable application developers to create context aware applications with minimum effort. The platform provides several services to both applications and sensor software. The platform has a number of benefits: it supports a diverse range of context sources, allows applications to access context sources synchronously or asynchronously using filters, decouples application code form context acquisition, and provides a simple rule engine for context processing. The platform supports soft-real time requirements by opening a direct channel between the context source and applications.

A prototype of the platform is currently under implementation along with two very distinct applications: livestock monitoring and smart city parking. These context-aware applications will verify that applications from a wide range of disparate domains can be built rapidly using the platform.

We purposefully omitted the treatment of context modeling, as our focus was to lay out the critical components of the infrastructure. Context modeling work is deferred to our future iterations of the platform. For this reason, our rule service currently provides very rudimentary services.

***Abstract*—Nowadays, more and more people are using Information and Communication Technologies (ICTs) in order to accommodate their daily needs. E-Government (e-Gov) adopts these technologies in an effort to provide prompt and secure services to citizens. However, the intention to use e-Government services has not yet been fully examined by the international literature. The present research attempts to bridge this gap, by examining the factors affecting citizens' intention to use e-Government services. In that direction, a conceptual framework (research model), based on an extensive review of the relevant literature, has been developed. The proposed conceptual framework has been empirically tested using a newly-developed structured questionnaire. Data were collected from a sample of 547 Greek citizens. The reliability and the validity of the questionnaire have been thoroughly examined, while the Structural Equation Modeling (SEM) technique has been used to analyze the data. Results indicate that perceived usefulness is the most important determinant of the intention to use e-Government services. Other important factors are perceived trust, internet experience, peer influence, computer self-efficacy and perceived risk.**

## I. Introduction

DURING the last 15 years, information and communication technologies (ICTs) play a central role in the global digital economy and are considered key tools of worldwide administrative reforms [1]. e-Government (e-Governance and / or e-Gov) is defined as "*an initiative aimed at reinventing how the government works and improving the quality of interactions with citizens and businesses through improved connectivity, better access, furnishes high quality services and better processes and systems*" [2]. Moreover, according to Ziemba, Papaj and Jadamus-Hacura [3], e-Government "*suggests the use of information and communication technology (ICT) to provide efficient and quality government services to employees, government units at the state and local levels, and to citizens and businesses*".

At the same time, official states (governments) are using e-Government in order to improve public services and strengthen political processes.

The intention of citizens to use e-Government services has been investigated by several previous studies [1] [2] [3]. Despite that, these studies have not reached consensus, while most of their empirical results are quite obvious (investigating already established concepts and validating ideas that have already been proven valid). Simultaneously, in the practical level, there have been many failed and costly attempts in developing citizen acceptance concerning e-Government services [1] [2].

The main objective of the present paper is to investigate the factors that have an impact on citizens' intention to use e-Government services. The proposed conceptual framework takes under consideration a bundle of factors that have never been collectively examined before. Its significance lies in the depth of its results, conclusions and empirical implications.

The following section attempts a brief literature review, while sections three and four include the presentation of the proposed conceptual framework and the research hypothesis. In the fifth section, the research methodology is being presented, while the paper is concluded with its main results and conclusions (sections six and seven respectively).

## II. Literature review

Many different definitions of e-Government can be found in the relevant literature. According to Sang, Lee and Lee [4], e-Government is based on ICTs and aims to achieve better governance. Carter and Bélanger [5] and Bekkers [6] argued that e-Government includes initiatives transforming government services and increasing their quality. Moreover, Doong, Wang and Foxall [7] underline the importance of technology in altering citizen behavior, while arguing that e-Government is a competitive tool for achieving higher efficiency of state affairs. However, these advantages can only be achieved if the technology is widely accepted [7]. Therefore, it is important to examine the determinants of acceptance and, hence, present the relevant theoretical models.

978-83-60810-66-8/$25.00©2015, IEEE

### A. Theoretical background

Diffusion of Innovation (DOI): According to DOI theory, the use of technology is a decision based on compatibility, relative advantage, social pressure and communication [8]. Phang, Li, Sutanto and Kankanhalliet [9] observed that the elderly are willing to learn and use new technologies that are accompanied by changes in the structure of the society. This is because the adoption of the technology can enhance the social status of the individual and play a positive role in assisting others to adopt the innovation themselves [2] [8].

Theory of Reasoned Action (TRA): The TRA is one of the first theories explaining the behavior, use and acceptance of computer technology. Three constructs are the main components of TRA: behavioral intention (BI), attitude (A), and subjective norm (SN). According to TRA, a person's behavioral intention depends on his attitude about the behavior, and his subjective norms (BI = A + SN) [11] [12].

Theory of planned behavior (TPB): The TPB has been proposed as an extension of TRA [13]. The elements of behavior and subjective norm are the same in TPB, as in TRA. The difference is that the TPB includes additional determinants of intention (more specifically, perceived behavioral control and self-efficacy). These modifications have increased the explanatory power of TPB.

Technology Acceptance Model (TAM) and TAM2: TAM builds upon the causal relationships of TRA in order to explain the technology acceptance behavior [10]. It suggests that perceived usefulness (PU) and perceived ease of use (PEOU) are the main determinants of technology adoption. TAM2, an extension of the initial model, incorporated additional constructs, such as social influence, subjective norms, voluntarism, social status, as well as cognitive processes, such as labor relevance, quality production and perceived ease of use [2].

Motivational model: Deci [13] focused on intrinsic motivation and argued that external motives do not have a significant persuasive power, in case the individual does not receive pleasure by the use of said technology [14].

Model of PC utilization: Thompson, Higgins and Howellet [16] argued that complexity, long-term benefits, social factors and facilitating conditions are determinants of computer use [15].

Social cognitive theory: Social cognitive theory argues that acquiring individual knowledge is directly related to observing others within the context of social interactions and experiences [4] [17] [18].

Unified Theory of Acceptance and Use of Technology (UTAUT): The UTAUT model was based on all previous theories. In comparison with previous models, UTAUT explains 70% of the variance in technology acceptance, a significant improvement from previous models (that only explained 40% of the same variance) [2]. Hence, UTAUT is considered as an enhanced model with robust features.

### B. Diffusion of innovation and e-Government adoption

The innovation diffusion theory was first systematically tested in the 1940s and has evolved exponentially since then [20]. According to Rogers [8], "*innovation is an idea, practice, or object that is considered new by an individual or another unit of acceptance*". Based on this definition, the use of e-Government services is a new practice and can be considered as an innovation for each individual user.

The diffusion of innovation theory suggests a general model including five groups of recipients, based on how early they start to use a specific innovation [21]. The five categories of recipients are: innovators, early recipients, early majority, slow majority, and laggards [21]. Each group has different characteristics.

Following the categories proposed by the diffusion of innovation theory, people who already use e-Government services can be perceived as early recipients. The diffusion of innovation theory presumes that early recipients share certain characteristics (young age, higher education and income) [21]. Previous studies conducted in the field of public administration have shown that people who use electronic public services fit this description [20] [22].

Atkin, Jeffres and Neuendorfet [23] compared internet adopters and non-adopters, using the following criteria: social status, communication needs, media use, and relation with technology. It was hypothesized that internet adopters will differ from non-adopters in specific demographics (age, education, income). Furthermore, internet adopters would be more cosmopolitan, would have increasing communication needs, and would be more interested in experimenting with new technologies. Indeed, the profile of early adopters showed that they followed the theory of diffusion of innovation, confirming all differences on demographic levels and use of technology [23].

### C. Previous studies

Lean, Zailani, Ramayah and Fernando [2] investigated the factors that influence the intention of Malaysian citizens to use e-government services. They developed a model incorporating factors from both DOI and TAM, while also taking under consideration various cultural factors, as well as trust. Their study included 150 participants. Empirical results revealed that trust, perceived usefulness, perceived relative advantage and perceived image have a direct positive effect on the intention to use e-Government services. On the other hand, perceived complexity was found to have a negative effect on intention. Lean, Zailani, Ramayah and Fernando [2] finally argued that, while online privacy has a positive impact on e-government usage, no significant effect exists between innovation factors (complexity, comparative advantage and image) and intention. Finally, they underlined that DOI has a better explanatory power than all the other employed models [2].

In another similar study, Wangpipatwong, Chutimaskuland and Papasrator [1] explored the factors affecting the intention of citizens to use e-Government websites. They used TAM as the basis of their research model, while the ability to use computers was incorporated as an additional factor affecting intention. A web-based survey was used to empirically test the proposed research model. The participants of the survey were 614, while each of them had (at least) a university degree and experience in visiting e-Government websites. Results revealed that perceived usefulness, perceived ease of use, privacy and the ability to use computers, directly enhance the intention to use e-Government websites [1]. However, it was concluded that different factors have different effect on intention. More specifically, perceived usefulness and ease of use seemed to be more important than the ability to use computers [1].

The effect of perceived risk and perceived trust on the willingness to use e-Government services was examined by Bélanger and Carter [24]. They proposed a model consisting of trust propensity, trust on the internet (TOI), trust on the government (TOG) and perceived risk. Empirical results revealed that trust propensity has a positive impact on both TOI and TOG, which in turn have a positive effect on intention to use e-Government services. Moreover, TOG negatively affects perceived risk, which in turn has a negative impact on intention. The proposed model of Bélanger and Carter [24] is a step towards identifying the unique elements of trust and risk in the e-Government literature [24].

Colesca [25] tried to identify the factors affecting public confidence towards e-government services. The study was conducted in Romania and the sample was 793 citizens. Empirical findings revealed that technical and organizational reliability, perceived quality, perceived usefulness, internet experience and trust propensity directly enhance e-Government usage. On the other hand, age and privacy concerns had a negative impact [25].

In another similar empirical study, Hung, Chang and Yu [26] examined the factors that determined the acceptance of the online submission system of tax declarations and payments (OTFPS) in Taiwan. The authors [26] developed a research model based on the theory of planned behavior. The study was conducted using a survey of 1099 citizens. Results showed that the proposed model explained 72% of the variance in usage behavior. More specifically, user acceptance of OTFPS was influenced by perceived usefulness, perceived ease of use, risk perception, trust, compatibility and peer pressure [26].

Sang, Lee and Lee [4] found that perceived usefulness, relative advantage and trust are significant predictors of e-Government adoption in Cambodia. Moreover, it was discovered that the determinants of perceived usefulness include image and output quality.

Finally, the empirical results provided by Dashti, Benbasat and Burton-Jones [27] demonstrate the significant role of trust on e-Government usage. More specifically, their study provided evidence supporting the relationships between 'felt trust' by e-Government, trust in e-Government, and intention to use e-Government websites [27].

## III. Conceptual framework

The proposed conceptual framework was developed after an extensive review of the existing relevant literature. Previous studies have been thoroughly examined and the most significant factors have been utilized in the proposed framework. Therefore, the present study offers a critical synthesis of existing empirical work on e-Government adoption. It adopts a holistic approach, unifying previous findings into an extensive conceptual framework.

The factors that have been used in the present study are briefly described in the following paragraphs.

### A. Perceived risk

For the past five decades, the theory of perceived risk is an important research agenda of consumer behavior. Perceived risk is defined as a concept of expected subjective injury [30] as well as desirable effect [31]. The literature [32] suggests that six types of perceived risk really exist. These types may vary, depending on the service or product. In the present study five types of risks are being incorporated in the proposed framework:

Performance risk: It concerns the risk of e-Government services not performing as they should be. For example, an electronic failure may result in unexpected losses [33].

Financial risk: According to Kuisma, Laukkanen and Hiltunenet [33] a transaction error or a misuse of the user's private information may bring economic consequences, thus, resulting in fear of conducting any transactions.

Social risk: It is regarded as the possibility of the purchase or use to provoke negative judgment by other members of the society (external psychological risk) [30].

Time risk: It is the risk relating to the user's loss of time during a transaction. The delay in loading the website and a disorganized site may be considered time delay causes [34].

Security risk: It is the risk of losing sensitive personal data during a transaction [35]. A breach of confidentiality is a usual fear during on-line transactions [36].

### B. Trust in e-Government

Trust is a factor that has been extensively investigated and defined in various differently ways. According to Rotter [42], trust is considered as "*the expectancy that the promise of a person or group can be relied upon*". Trust in the context of e-Government is measured through two dimensions: trust in the particular entity (which, in this case, is the government), and trust in the reliability of the enabling technology (which, in this case, is the internet) [24].

### *C. Perceived usefulness*

Perceived usefulness is the degree in which someone believes that using a particular system would enhance his or her job performance [11].

### *D. Perceived ease of use*

According to Davis [11], perceived ease of use can be defined as the degree in which someone believes that using a particular system would be free from effort [40].

### *E. Perceived quality*

Aaker [46] defined perceived quality as the consumer perception of the overall quality or superiority of a product (or a service) in relation to other alternatives. Perceived quality is different from tangible (real) quality, which is embedded in the manufacturing process [46]. No matter how high the level of every product's manufacturing quality, consumers are the ones that will determine its (perceived) quality in the marketplace.

### *F. Quality of internet connection*

Sathye [41] considered quality of the internet connection as one of the significant factors affecting the adoption of various electronic transactions.

### *G. Internet experience*

According to Eastlick and Lotz [37], the history of a user's behavior can positively affect the likelihood of adopting the same behavior in the future. Internet use is positively affected by internet experience [38].

### *H. Computer self - efficacy*

Computer self-efficacy is defined as the perception of an individual concerning his ability to use computers in order to conduct a certain task [45]. People with a high level of computer self-efficacy are able to efficiently use different software packages and computer systems, while those with a low level of computer self-efficacy perceive their potential as quite limited [45].

### *I. Self-image*

Venkatesh and Davis [10] defined 'image' as the degree to which the use of an innovation enhances the social status of an individual. A person is more likely to engage in an activity, if the activity is approved by others [5].

### *J.Peer influence*

Peer influence is the effect of the immediate environment on the behavior of the individual [14]. Peer influence (or peer pressure) encourages others to change their attitudes in order to conform to group norms.

### *K. Intention to use*

'Intention to use' is the main dependent factor of the present study, measuring the intention of citizens to use e-Government services [10].

## IV. Research hypotheses

The present study includes ten independent and one dependent factor. The relationships between these factors are analytically presented in the following paragraphs.

### *A. Perceived risk and intention to use*

Lee [49] has found that security risk (privacy risk) and financial risk have a negative effect on the intention to use online banking. In the same direction, Pires, Stanton and Eckford [50] argued that there is a negative correlation between perceived risk and intention to use web applications. Hence, it is hypothesized:

H1: Perceived risk has a negative effect on the intention to use e-Government services.

### *B. Trust in e-Government and intention to use*

According to the empirical results of a study conducted by Carter and Bélanger [5], trust is a significant predictor of the intention to use e-government services. In another similar study, the same authors [24] found out that disposition to trust positively affects trust towards the internet and trust towards the government, which in turn affect the intentions to use e-Government services. Dashti, Benbasat and Burton-Jones [27] also showed that trust for e-Government is an important factor that increases its use.

H2: Trust in e-Government has a positive effect on the intention to use e-Government services.

### *C. Perceived usefulness and intention to use*

The relationship between perceived usefulness and intention to use has been widely acknowledged by the empirical literature [20, 23, 47]. Davis [11] revealed that perceived usefulness is a key factor in the intention to use web system applications. It is only logical to assume that:

H3: Perceived usefulness has a positive effect on the intention to use e-Government services.

### *D. Perceived ease of use and intention to use*

As in the case of perceived usefulness, perceived ease of use has been found to have a positive effect on intention to use [2, 4, 10]. For example, Gefen and Straub [40] and Davis [11] argued that perceived ease of use is positively related to the use of present and future technology. Based on the above, it is hypothesized that:

H4: Perceived ease of use has a positive effect on the intention to use e-Government services.

### *E. Perceived quality and intention to use*

Colesca [25] suggests that the higher the perception of quality of an electronic service, the higher the level of trust towards that service and, consequently, the intention to use it. Moreover, Gronier and Lambert [48] argue that e-Government quality enables citizens to directly locate the services they need, thus, achieving higher levels of satisfaction and effectiveness. Therefore, it is hypothesized:

H5: Perceived quality has a positive effect on the intention to use e-Government services.

### *F. Quality of internet connection and intention to use*

Sathye [41] argued that internet access is one of the most important factors for the acceptance of electronic banking. Without a proper internet connection it is impossible to use electronic services [41]. Moreover, Pikkarainen, Pikkarainen, Karjaluoto and Pahnilaet [51] found out that a decent internet connection has significant influence on the intention to use e-Government services.

H6: Quality of the internet connection has a positive effect on the intention to use e-Government services.

### *G. Internet experience and intention to use*

Based on their empirical results, Corbitt, Thanasankit and Yi [52] argued that prior internet experience has a positive influence on the intention to shop online. Cho [53] reached the same conclusion, stating that experienced internet users are more likely to conduct an online transaction when they feel the urge to do so. It would be interesting to examine whether that is also the case with e-Government services.

H7: Internet experience has a positive effect on the intention to use e-Government services.

### *H. Computer self-efficacy and intention to use*

Wangpipatwong, Chutimaskul and Papasrator [1] empirically confirmed that the adoption of e-government depends upon the ability to use a computer.

H8: Computer self-efficacy has a positive effect on the intention to use e-Government services.

### *I. Self-image and intention to use*

Sang, Lee and Lee [4] have found out that individuals adopt an innovation in order to impress others that have not adopted it. On the other hand, Carter and Bélanger [5] failed to establish such a relationship, reporting that high levels of self-image do not directly affect the intention to use e-Government services. Therefore, it would be interesting to examine which is the case, adopting the hypothesis that:

H9: Self-image has a positive effect on the intention to use e-Government services.

### *J.Peer influence and intention to use*

According to Hung, Chang and Yu [26], peer influence is a key factor in using online tax applications. Moreover, Taylor and Todd [54] support that peer influence is an important determinant of Information System (IS) adoption. Since e-Government has the characteristics of these systems, it is only logical to hypothesize that:

H10: Peer Influence has a positive effect on the intention to use e-Government services.

Fig. 1 summarizes the above hypotheses, thus, presenting the proposed Conceptual Framework of the study.

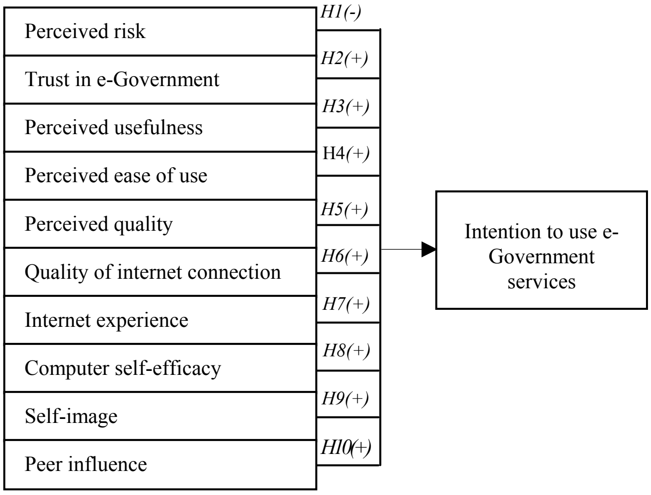

Fig. 1 The proposed conceptual framework of the study

## V. Research Methodology

### *A. The population of the study*

The proposed conceptual framework was tested with the use of a newly-developed structured questionnaire on a sample of Greek internet users. Hence, internet users living in Greece are the population of the present study. According to reliable data [58], internet users in Greece have reached 6.451.326 in December of 2013 (55,9% of the population).

Since the main dependent factor of the study is "intention to use e-Government services", respondents could be: (a) inexperienced e-Government users (non-users), (b) one-time e-Government users (not continual users), or (c) continual users. The sample of the study included individuals from the last two categories.

### *B. Measurement*

The measurement of each of the eleven factors of the proposed conceptual framework was conducted with the use of multiple questions (items) that were adopted from the international literature. The five point Likert scale was used for the measurement of all factors. Table I demonstrates the eleven factors of the study, the number of items used in each case and the studies from which they where adopted.

### *C. Data collection*

Primary data were collected from a random sample of internet users. The only criterion for citizens to participate in the survey was the use of internet. Personal interviews were conducted in order to collect the appropriate data. Citizens were selected in random (using the systematic sampling approach). The research period lasted two months (May to July 2013). Totally, 566 questionnaires were returned and 547 were used for data analysis.

TABLE I. FACTOR MEASUREMENT

| Factors | Items | Source |
|---|---|---|
| Perceived risk | 11 | 48, 49 |
| Trust in e-Government | 15 | 4, 23, 26 |
| Perceived usefulness | 4 | 10, 46, 55 |
| Perceived ease of use | 4 | 10, 39, 46 |
| Perceived quality | 4 | 24 |
| Quality of internet connection | 4 | 40, 50 |
| Internet experience | 3 | 51, 52 |
| Computer self-efficacy | 3 | 1 |
| Self-image | 4 | 3, 4 |
| Peer influence | 4 | 25 |
| Intention to use | 4 | 46, 54 |
| Total | 60 | |

### D. Reliability and validity

The instrument (questionnaire) that was used in the present study was tested for both its content and construct validity. The test for the content validity was conducted using a pilot study approach. Twenty (20) citizens were asked to fill in the final draft of the questionnaire and make comments concerning their level of understanding. Citizens' comments improved various aspects of the questionnaire (e.g. use of language).

For the control of the construct validity, each of the eleven research factors was evaluated: (a) for its unidimensionality and reliability (Table II), (b) for its goodness of fit to the proposed research framework (Table III).

The examination of the unidimensionality of each of the research factors was conducted using Explanatory Factor Analysis (EFA). Moreover, for the estimation of the reliability of these factors, Cronbach Alpha was used. All tests concluded that the scales used are valid and reliable (see Table II above for the main results).

The evaluation of the goodness of fit of each research factor to the proposed model was conducted using Confirmatory Factor Analysis (CFA). All tests produced satisfactory results (see Table III above for the main results).

It should be noted that Second Order CFA was conducted for the five dimensions of risk (performance risk, financial risk, social risk, time risk, security risk). All statistical measures extracted from this analysis where within satisfactory levels.

TABLE II. ESTIMATION OF UNIDIMENSIONALITY AND RELIABILITY

| Factors | KMO | Bartlett's Test | Eigen-value | TVE | Cronbach Alpha |
|---|---|---|---|---|---|
| Perceived risk | 0,82 | 1843,2[a] | 1,201 | 59,1% | 0,785 |
| Trust in e-Government | 0,70 | 595,9[a] | 2,195 | 73,1% | 0,817 |
| Perceived usefulness | 0,81 | 1624,9[a] | 3,174 | 79,3% | 0,913 |
| Perceived ease of use | 0,81 | 1680,9[a] | 3,181 | 79,5% | 0,914 |
| Perceived quality | 0,79 | 935,6[a] | 2,701 | 67,5% | 0,839 |
| Quality of internet connection | 0,80 | 1102,9[a] | 2,884 | 72,0% | 0,871 |
| Internet experience | 0,69 | 466,5[a] | 2,076 | 69,2% | 0,773 |
| Computer self-efficacy | 0,71 | 751,6[a] | 2,309 | 76,9% | 0,850 |
| Self-image | 0,73 | 1191,6[a] | 2,548 | 84,9% | 0,911 |
| Peer influence | 0,70 | 511,7[a] | 2,128 | 70,9% | 0,791 |
| Intention to use | 0,72 | 674,1[a] | 2,265 | 75,4% | 0,837 |

[a] p<0,01

TABLE III. ESTIMATION OF THE GOODNESS OF FIT

| Factors | Normed $X^2$ | C.R. | V.E. | RMSEA | CFI / GFI |
|---|---|---|---|---|---|
| Perceived risk | 2,49 | 0,84 | 78,8% | 0,091 | 0,99 / 0,97 |
| Trust in e-Government | 3,67 | 0,73 | 67,3% | 0,093 | 0,93 / 0,95 |
| Perceived usefulness | 3,34 | 0,61 | 55,6% | 0,089 | 0,94 / 0,96 |
| Perceived ease of use | 2,32 | 0,77 | 71,7% | 0,077 | 0,97 / 0,97 |
| Perceived quality | 2,53 | 0,64 | 75,1% | 0,094 | 0,99 / 0,99 |
| Quality of internet connection | 4,11 | 0,82 | 69,4% | 0,091 | 0,91 / 0,93 |
| Internet experience | 2,43 | 0,83 | 78,7% | 0,079 | 0,93 / 0,99 |
| Computer self-efficacy | 3,43 | 0,77 | 69,5% | 0,082 | 0,99 / 0,99 |
| Self-image | 2,93 | 0,68 | 73,7% | 0,099 | 0,91 / 0,94 |
| Peer influence | 1,97 | 0,84 | 69,3% | 0,095 | 0,97 / 0,99 |
| Intention to use | 3,43 | 0,88 | 89,2% | 0,084 | 0,93 / 0,97 |

## VI. RESULTS

### A. Basic measures

The examination of the proposed conceptual framework was conducted with the use of the "Structural Equation Modeling" (SEM) technique [59] [60].

To evaluate the fit of the (modified) overall model the chi-square value ($X^2$ = 99,9 with 26 degrees of freedom) and the p-value (p = 0,0356) were estimated. These values indicate a satisfactory fit of the data to the overall model. However, the sensitivity of the $X^2$ statistic to the sample size requires the use of other supplementary measures of evaluating the overall model, such as the “Normed-$X^{2}$” index (3,84), the RSMEA index (0,071) the CFI (0,94) and the GFI (0,96), that all indicate a very good fit. Additionally, the Construct Reliability (C.R.) and the Variance Extracted (V.E.) for all factors (constructs) are satisfactory.

### *B. Hypothesis testing*

As it can be seen on Table IV, six of the originally hypothesised paths were found significant (H1, H2, H3, H7, H8, H10), while thirteen new paths (presented on Figure II with dashed lines) were added to the model, based on the modification indexes function of AMOS. Moreover, two factors (quality of internet connection and self-image) were completely discarded from the model, while for four hypotheses (H4, H5, H6, H9) no statistical support was provided (although H4 is supported when indirect effects are considered).

The above modifications resulted in a modified structural model with improved fit (as already explained above). In more detail, the factors that are included in the final model can explain 52% of the variance in the dependent variable, i.e. intention to use e-Government services.

The modified conceptual framework presents an interesting view of the subject under consideration, arguing that every factor is significant in enhancing e-Government usage, either directly or indirectly. For example, perceived ease of use does not have a direct impact on intention, but it has an indirect effect, through perceived risk and perceived usefulness. On the other hand, perceived usefulness has both a direct and indirect effect on intention. Moreover, perceived quality does not seem to have any effect on intention whatsoever.

### *C. Further analysis*

The following observations can be made after reviewing the empirical results of the study (see Table IV and Fig. 2):

- Perceived usefulness directly affects intention. This is also confirmed by the Technology Acceptance Model (TAM) of Davis [11]. Moreover, this impact is not only statistical significant, but is also quite strong (r=0,51).

- Additionally, trust in e-Government has a significant direct effect on intention. The same conclusion has been drawn by Bélanger and Carter [24] and Colesca [25]. According to these authors [24] [25], when the user actually believes that the transaction and his personal data are secure, it is more likely to experience a higher level of intention to use the online services.

TABLE IV. RESULTS OF THE MODIFIED STRUCTURAL MODEL

| Causal Paths (hypotheses) | | Estimate | p | Result |
|---|---|---|---|---|
| H1 | Perceived risk → Intention to use | -0,10 | 0,000 | Accepted |
| H2 | Trust in e-Government → Intention to use | 0,25 | 0,000 | Accepted |
| H3 | Perceived usefulness → Intention to use | 0,51 | 0,000 | Accepted |
| H7 | Internet experience → Intention to use | 0,13 | 0,000 | Accepted |
| H8 | Computer self-efficacy → Intention to use | 0,10 | 0,000 | Accepted |
| H10 | Peer influence → Intention to use | 0,12 | 0,000 | Accepted |
| **New causal paths** | | | | |
| | Perceived ease of use → Perceived risk | -0,22 | 0,000 | New paths |
| | Perceived ease of use → Perceived usefulness | 0,42 | 0,000 | |
| | Perceived ease of use → Perceived quality | 0,13 | 0,000 | |
| | Computer self-efficacy → Perceived ease of use | 0,26 | 0,000 | |
| | Trust in e-Government → Perceived risk | -0,20 | 0,000 | |
| | Trust in e-Government → Perceived quality | 0,42 | 0,000 | |
| | Perceived usefulness → Trust in e-Government | 0,25 | 0,000 | |
| | Perceived usefulness → Perceived quality | 0,22 | 0,000 | |
| | Internet experience → Perceived ease of use | 0,61 | 0,000 | |
| | Internet experience → Computer self-efficacy | 0,76 | 0,000 | |
| | Internet experience → Perceived risk | -0,10 | 0,000 | |
| | Peer influence → Perceived usefulness | 0,16 | 0,000 | |

- Internet experience directly affects intention to use e-Government services. Cho [53] reached the same conclusion, arguing that repeated internet use for extended periods of time positively affects user behavior and system usage.
- Perceived risk has a negative effect on intention. This conclusion is in line with the studies of Lee [49] and Featherman and Pavlou [31]. For example, a loss of communication between user and server may have a negative impact on user trust and, therefore, in the intention to further use the online services.
- Peer influence positively affects intention. The same conclusion was reached by Hung, Chang and Yu [26]. A possible ‘reward’ from the immediate social environment predisposes the user towards using e-Government services.
- Moreover, computer self-efficacy has a direct positive effect on intention. Wangpipatwong, Chutimaskul and Papasrator [1] argue that people with increased computer

self-efficacy easily understand the functions of online services, thus increasing their confidence and their general intention to use such systems.

- In the same line as above, internet experience was found to have a quite strong impact on computer self-efficacy (r=0,76). It seems that experienced internet users believe that they are more capable of using their computer. Hence, internet experience affects intention both directly (r=0,13) and indirectly (through computer self-efficacy and perceived risk).
- Additionally, internet experience has both a direct and indirect effect on perceived ease of use. The same conclusion was reached by Cheong and Park [55]: the more time a user spends on the internet, the better his perception about the usability of the online platform.
- Perceived ease of use was found to have a direct positive effect on perceived usefulness, something that has been supported by, almost, every TAM study [9] [11] [49].
- The present study found that perceived usefulness has a positive impact on trust. In the same direction, Suh and Han [56] argued that when the user fully understands the usefulness of the online service, his confidence is being significantly increased.
- Furthermore, perceived ease of use was found to have a direct negative effect on perceived risk. This relationship was also identified by Hung, Chang and Yu [26], who concluded that users finding an online system easy to operate, believe that the overall risk of the transaction is quite small.
- On the same vein, perceived usefulness was found to have a negative effect on perceived risk. According to Bélanger and Carter [24], when a system is considered to be useful, it is also usually considered to be free of various risks.

## VII. Conclusions

### *A. General conclusions*

The present study developed a novel research framework in order to identify the main factors affecting the intention to use e-Government services. This framework (research model) was tested on a sample of 547 internet users.

The main conclusion of the present study does not concern a certain research factor. On the contrary, the empirical results support that both research and empirical focus should be drawn towards managing a bundle of factors (dimensions), which seem to be highly interrelated. The statistical analysis that was conducted highlighted various new causal relationships between the independent factors of the study. Therefore, one should not only pay attention to enhancing a limited number of factors, since the existence of various indirect effects underlined the need for a more integrated approach.

### *B. e-Government user profile*

The average user has the following characteristics: (a) is under the age of 40, (b) is quite educated, (c) his monthly income is satisfactory, (d) uses e-Government services for more than a year, (e) uses e-Government services in order to gather information and conduct transactions, (f) makes about five transactions each month.

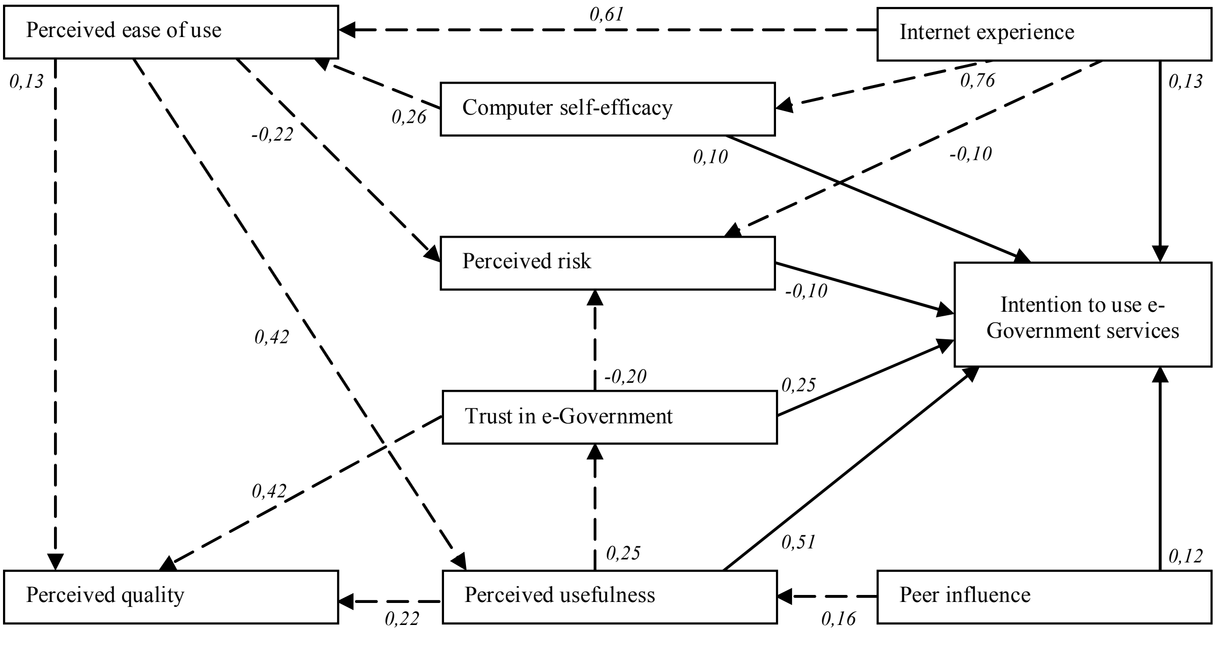

Fig 1. The modified conceptual framework of the study.

### C. *Managerial implications*

The empirical results showed that computer self-efficacy is positively related with the intention to use e-Government services. That finding is in line with Compeau and Higgins [45] and Wangpipatwong, Chutimaskul and Papasrator [1]. State officials should make efforts to fight computer illiteracy (seminars, incentives, etc), since only self efficient citizens will adopt e-Government.

Moreover, since trust is an essential element for the adoption of e-government, citizens should be convinced that state mechanisms are in place in order to protect their privacy and transactions in an impersonal medium, such as the internet. According to Dashti, Benbasat and Burton-Joneset [27] those responsible for public electronic services, should implement mechanisms for increasing public trust (receiving and answering to questions / comments, offer support via the phone, implement safety protocols, etc).

Additionally, according to Hung, Chang and Yu [26], external resources, such as television / news, significantly influence early-adopters and non-adopters of e-Government. By providing proper information to citizens (through the internet or in the form of leaflets), the state can bend the bias that exists towards online services [61] [62].

Finally, special focus should be given in enhancing the level of perceived usefulness [57]. Citizens are more interested in usefulness, as the effect of perceived ease of use is often reduced after a short period of time. In that direction, e-Government services should add value to citizens, offering access to useful information. There is no meaning in developing services that offer very little information and utility, while at the same time discourage citizens from future use. A useful application will attract the attention of the public and create more users in the near future.

### D. *Limitations and future research*

The present research used self-reported scales in order to measure the constructs of the proposed framework. This is a limitation inherent to all explanatory studies. Moreover, the sample of the study is national (Greece), while, on the other hand, an international sample would provide results that could be generalized to the international context. Finally, future studies could take the empirical results of the present study into consideration and further enhance its proposed conceptual framework.

***Abstract*—The main objective of this article is to identify the best e-banking websites in Poland from the point of view of an individual customer. Using modern IT tools for communications with customers of banking services, banks create competitive advantages, as well as, opportunities for providing banking services in a convenient way for consumers. After a short introduction the authors defines the assumptions for the study. The methodological approach—based on theoretical and empirical study in the field of e-banking, allows them to build the evaluation model for the construction of high quality e-banking website. Subsequently, the authors carried out multilateral analyses and presented the conclusions of the study. The identified categories are classified into three groups: economic, technological and anti-crisis. The originality of the work comes down to knowledge of the determinants of customer's quality perception of websites and a starting point for an effective quality management of their e-services system.**

## I. Introduction

IT APPEARS that the consequences of the worldwide crisis in electronic banking in Poland strengthen the tendencies which show that the crisis, which started in the second half of 2008, does not concern this area. Compared to 2013, the number of individual clients with potential access to account increased almost by 15% (9% more than in 2012) reaching over 25 million users; the number of active individual clients went up by over 5% reaching 13.060 million [12]. Undoubtedly it is the fastest growing banking sector and—as indicated in earlier articles—nothing points to the fact that something may undermine these positive trends. The increase in absolute numbers of clients is shown in Fig. 1. The increase in the number of clients with potential access to account via the Internet is accompanied by a continuous increase of active customers (at least one transaction a month). Since the end of 2008 till the end of 2014 the number increased by over 13 million users, which is an increase by 123%. Every year the population of new customers using the possibilities offered by the Internet to handle banking transactions is growing. In 2008 more than 890,000 people started to use e-banking services, and in 2014 the number was more than 3 million. There are nearly 53% of active users, out of all clients having electronic access to account.

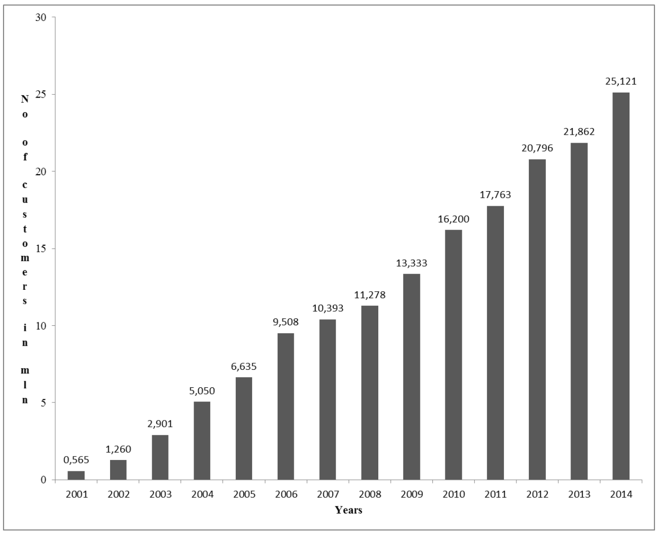

Fig. 1. The evolution of the number of clients with electronic access to account in 2001-2014 in millions [12]

Poland in the European statistics—with regard to penetration—compares quite well—according to ComScore [7] report—it takes the sixth place (52.3%), while the European average is 40%. The largest e-banking penetration is in the Netherlands—66%, the lowest in Switzerland (18.8%). France (60%), Finland (56.4%), Sweden (54.2%) are ahead of us, behind are among others: Germany, Spain, Denmark and Norway. The dynamics of the increase of the number of e-banking clients in Poland is still one of the highest on our continent—in recent years we note the increase of over one million every year. So, this is very important area of e-services, worth to conduct research.

There are many publications concerning the issue of evaluation of websites [3], [9], [13], [14], [15] and access to e-banking services [1], [10], [11] but there is no easy solution to the problems encountered [12], [6], [16]. The review of the literature shows that e-banking websites (as well as e-commerce websites) may be analysed from the point of view of:

- usability (site map, directory),
- interactivity (availability and responsiveness),
- functionality (search, navigation, relevance of content),
- visualisation (colour scheme, background, graphics, text),
- efficiency (cost of purchase, transport, the difference in prices offered by traditional and online shops),

978-83-60810-66-8/$25.00©2015, IEEE

- reliability and availability.

Most of evaluation methods are traditional scoring methods based on specific criteria sets, evaluated by means of an applied scale. Technical and functional criteria are the most commonly applied. Most of them contain factors which may be evaluated in a very subjective way: text clarity, attractive colours, images and pictures, the speed and intuitiveness of navigation, etc. Moreover, some users do not treat particular criteria sets in an equivalent way. However, on the other hand, there occur frequent problems with determining preferences for particular criteria and the evaluation of relations between them. This part of the work concerns the application of the authors own, though based on the literature, set of criteria for a scoring evaluation and a selection of electronic services of selected banks.

We are making an comparative analysis mainly in three cases, enabling:

- specification and accurate research into the area in which the software works,
- creating a ranking of IT solutions existing on the market,
- identification of the features which make particular solutions better than others.

Here we are concentrating on the third case.

## II. Assumptions of the Study

At the first half of 2014 (March-June), the authors carried out research on the quality of websites offering electronic access to services of the most popular banks among Polish individual clients on a sample of 361 people, where 311 respondents completed surveys correctly. The participants of the survey were students, aged 19-45, Faculty of Management University of Warsaw and Vistula University in Warsaw. Among the respondents, 69% were women and 31% men, mainly from Warsaw and surrounding areas. Each of the respondents declared to have at least one electronic access account with one of the banks operating in Poland (fifteen—used e-banking services provided by two banks, two people—of three banks), thus, in total, the authors examined access to 339 active electronic accounts (see Fig. 2).

In the surveyed population majority of people held accounts in the banks which are considered to be internet banks (mBank, Inteligo PKO BP), or regarded as modern (AliorBank, Millenium), or the largest ones (PKO BP, BZ WBK, CityBank). This does not correspond to the numbers of electronic access accounts declared by particular banks, however, considering the facts that only the active accounts were described and the fact that the surveyed population is relatively young and specific, the structure of the use of accounts is probably closer to reality than the one presented on the basis of official statistics.

This study belongs to a series of cyclical, yearly analyses concerning the factors influencing the usability of websites with online access to individual accounts in the banks [4], [5]. The same set of criteria has been applied in the evaluation of e-banking condition at 2013, 2011 and earlier, before the crisis began in 2008. They were created on the base of internet discussion among leading researchers in this field from some universities in Poland (Wrocław University of Economics, University of Economics in Katowice, Poznań University of Economics, University of Szczecin, Faculty of Economic Sciences and Faculty of Management University of Warsaw).

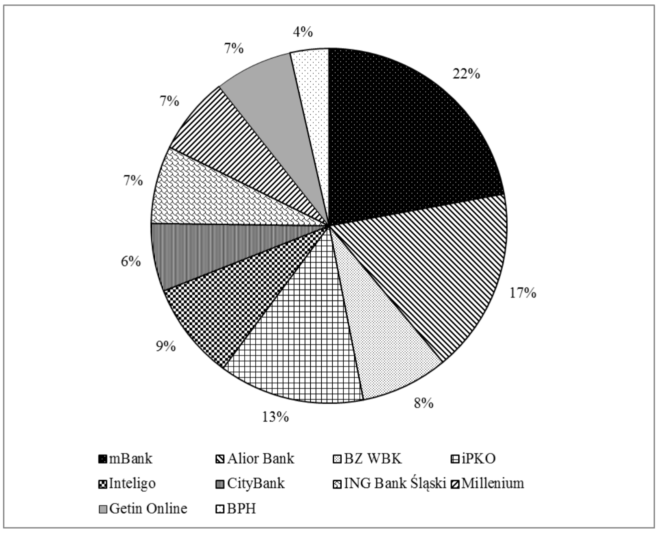

Fig. 2. The percentages of holders of accounts with electronic access in ten the most popular banks

The respondents filled in the tables evaluating e-banking websites of the banks where they had their accounts, performing the analysis and assessment of the obtained results. The tables which they completed were sent by electronic mail. In the second stage, they imposed preference coefficients on particular criteria and performed further calculations. The obtained findings were supplemented with comments. All calculations in the present study are carried out with the application of the authors own, though based on the literature and consultations with experts, set of criteria for a scoring evaluation and a selection of electronic access to services of selected banks.

Criteria applied in this study can be divided into two main groups:

- economic—annual nominal interest rate of personal accounts, account maintenance PLN/month, fee for a transfer to a parent bank, fee for a transfer to another bank, payment order, fee for issuing a debit card, fee for a card PLN/month, interest on savings accounts, interest rate on deposits of 10,000, interest rate on loans 10,000;
- technological—additional services (such as: insurance, investment funds, cross-border transfer or foreign currency account), functionality (set of function available for user), access channels to an account (branches, the Internet, Call Centre, mobile phone), security (ID and password, token, SSL protocol, a list of single-use passwords, a list of single-use codes), visualization (colours,

fonts, background, photos etc.), navigation, clarity and ease of use.

Considering the situation of the signs of economic crisis spreading, the authors applied a set of psychological criteria in addition to the criteria used previously in the evaluation of e-banking websites which were discussed above. The psychological criteria included the so-called anti-crisis criteria related to—according to the experts cooperating with the authors—all those activities, which were to counteract potential impact of the crisis on the banking sphere [6]. This additional group of criteria was also included in the previous evaluation of e-banking websites. The group of the considered anti-crisis measures includes:

- dynamics of interest rates on deposits (reduction, increase, differences in rates, tendencies),
- dynamics of interest rates on credits (reduction, increase, differences in rates, tendencies),
- stability of the policy related to basic fees (the number and the nature of changes),
- degree of customer confidence (the number of individual clients, its dynamics, how long the bank has been operating in the Polish market),
- the average places occupied in the rankings in the Internet and trade magazines last year.

In the scoring method the authors collected information on selected criteria; they were assigned values according to the assumed scoring scale and the results were analysed in a combined table. For the purposes of the evaluation the authors applied—as in previous studies—a typical R. Likert scale [8]. A scoring method was used in two variations: simple—where criteria were treated equivalently; and one with a preference scale—where sets of criteria were assigned indicator values differentiating their treatment by clients (the total of coefficients = 1).

In a simple scoring method you need to measure the distance from the maximum value to be obtained (according to the assumed scoring scale). It concerns the value of criterion measure and in the sense of a distance it is the same when we measure the distance from one criterion to another as the other way round. However, we do not define the relations between particular criteria. Assigning a preference scale to particular criteria (or sets of criteria) can be regarded as such a measure. A linear preference scale in a normalized form defines in turn the participation of particular criteria in the final score. It establishes a one-time relation between criteria in relation to the final score, it is also a specific "averaged" measure of criteria in particular cases, without the individualization of the evaluation for any of them. However, it does not specify to what degree one criterion is better/ worse than the other. It is merely a derivative of the normalized distance.

## III. Comparative Analysis of Internet Access to E-Banking Accounts Using a Scoring Method

To evaluate cost, functional, technological and anti-crisis criteria the authors used a preliminary table presenting bank offers related to internet banking services used by respondents and fees connected with using bank accounts operated via the Internet. This table has been generated on the basis of data obtained from websites of selected banks. On the basis of the surveys the authors created an averaged combined table for the criteria generated by users.

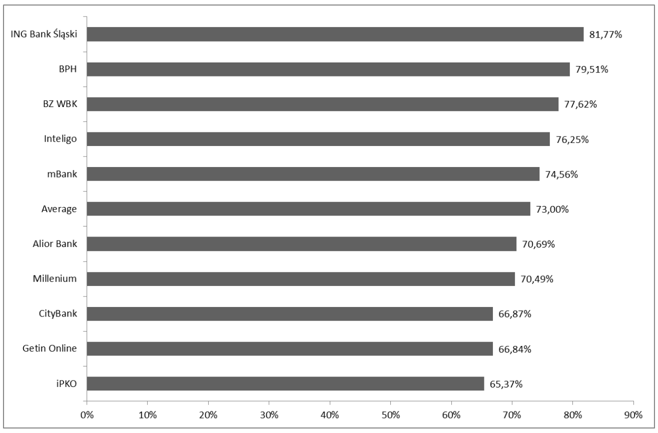

Fig. 3. Ranking of banks for assessing electronic access to individual accounts in selected banks in Poland

The spread in the respondents' evaluations of the analysed banks amounts to 16.4 percentage points (compared to 5.1 percentage points in 2011, and 2.3 points in 2008), which reflects the growing diversity of evaluations; which confirms the thesis that the period of crisis increased the radicalism of evaluations and heightened expectations concerning the tools used to access an account.

This time the best in the ranking were: ING Bank Şląski (81.77%) and BPH (79.51%). Directly behind are: BZ WBK and Inteligo. The low position of mBank (fifth position in the reverse order), came as a surprise because this bank so far occupied leading positions and it was very popular with the analysed group of people (22% of respondents). It is worth mentioning that in the rankings [17] till May 2011 it held the first position. There occurred a reversal of the situation from three years ago—the banks which two years ago fell in the rankings, at present, are trying to make up for the previous losses. Another issue which seems to be characteristic of this study—general scores for the quality of the websites increased (see Fig. 3.).

In the majority of analysed cases there are no obligatory payments for issuing a debit card; transfers to the parent bank are usually free of charge. The level of security can be regarded as satisfactory for clients. Actually, it has not changed from 2008. Based on the compilation, we can conclude that a fee for issuing a card (usually there is no fee for such a service) reached a level which, at present, may satisfy clients' needs almost in 100% (96%). Undoubtedly, the worst indicator is interest rate on savings accounts functionality (evaluated by the majority of users as too low—37.92% of the maximum scores). The interest rates on deposits reached over 57% of maximum score (Fig. 4). From the factors not listed within

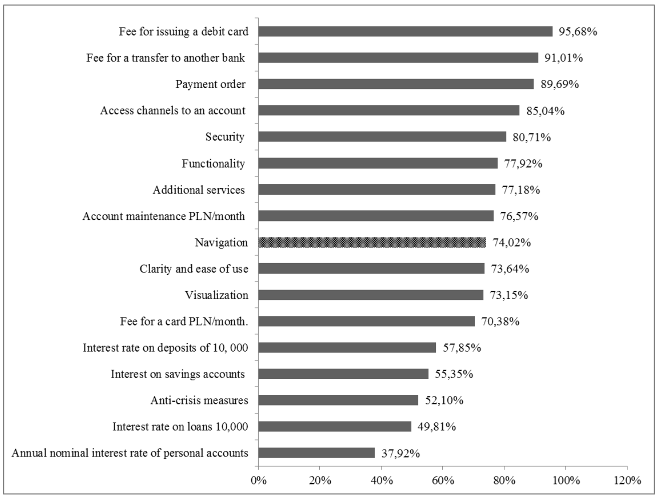

Fig. 4. Ranking of criteria for assessing electronic access to individual accounts in selected banks in Poland in the beginning of 2014

the criteria clients paid attention to the lack of possibility to make a cross-border transfer (e.g. SWIFT in Inteligo) or no possibility of fully automatic obtaining a credit—via the Internet. In 2008 there were no anti-crisis measures among the criteria; however, if we compare this study with the research carried out in 2011, we have to admit that during the crisis e-banking clients neither noticed any signs of the crisis nor were able to define anti-crisis measures undertaken by the banks, and at present they sometimes suggest criteria to be applied for their evaluation.

## IV. Comparative Analysis of Internet Access to E-Banking Accounts by Means of a Scoring Method With Preferences

One of the methods limiting a specific subjectivity in the experts' or users' evaluations (apart from the previously used averaging of scores) is applying unitary preferences with regard to particular criteria or sets of criteria. For each group the authors applied one dominant variant:

- economic (70% for economic criteria and 15% for the remaining ones),
- technological (70% for technological criteria and 15% for the remaining ones),
- anti-crisis (70% for anti-crisis criteria and 15% for the remaining ones).

In the first case the three leading positions are taken by ING Bank Śląski, Inteligo and BZ WBK. Next, BPH and mBank are among the best banks with regard to economic factors. iPKO, CitiBank, Alior Bank occupy the last positions of the ten analysed banks. In the leading positions (in the relation to research without preferences) Inteligo moves by two places, Millenium by one place. iPKO BP records the greatest fall.

In the second case the leaders are as follows: BPH, ING Bank Śląski and BZ WBK—further positions are taken by: Inteligo and mBank. The last positions were occupied by: Getin Online, iPKO and Citi Bank.

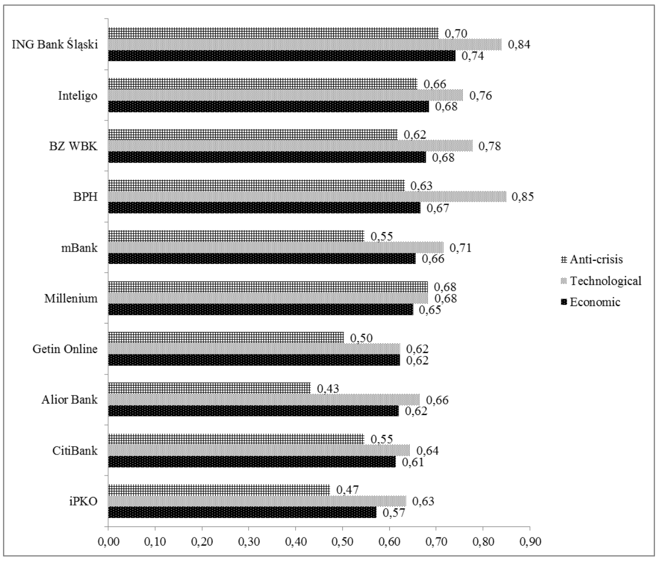

Fig. 5. Ranking of the scores according to various types of preferences for ten selected banks in Poland in the beginning of 2014, according to the order of economic criteria

In the third case the order is very similar to the other evaluations. The first is ING Bank Śląski, next—Millenium and Inteligo. The last positions are occupied by Alior Bank, iPKO and Getin Online.

All in all, multiplaying the values by preference coefficients did not bring about any significant changes in the analysed cases, because the order of the examined websites offering access to e-banking services remained basically the same. The results for the groups are presented in Fig. 5.

## V. Summary and Some Conclusions

The present analysis has shown that the crisis situation, whose signs are visible in various industries, does not apply to electronic banking. While in 2011 it could be a one-off phenomenon, after five years we may conclude that it starts to be seen as a clear trend. Also, it confirms the changes concerning the banking customers' awareness. The choice of the access to an account starts to be a matter of an informed choice, not a chance or habit. The decision is determined both economic and technical conditions. The result is the choices made by clients reflected in the presented study and commented on in the surveys. It is true that some of the opinions indicate—despite the awareness of certain shortcoming of the bank where they hold an account—resistance to changes, but it is the first step to move their account to another bank.

The selection of the research sample and its limitations affected the obtained findings. Students are a group which have relatively the greatest number of access to e-banking and use it most frequently. And know e-banking websites very well. Taking the above factors into consideration, it appears to be the best sample for carrying out the research. This group in the population also has a wide, and perhaps the greatest, knowledge concerning the newest technologies and their use. The selection of the student groups was random, the dominance of women and students of early years of study are accidental. However, it is a group which does not have considerable financial resources, and this may be the reason why the representatives of this group have relatively the cheapest access to the internet banking websites. Simultaneously, the awareness of the high usability of information technology means that this particular group is able to appreciate the practical (or entertainment) value of the offered e-banking services. In addition, the representatives of this group, after a few years of using e-banking websites designed for them, are less likely to be satisfied with a product or service—in the form of e-banking website for example—of lower quality.

Taking into consideration the conducted analyses, we may draw the following conclusions:

- in the minds of users of electronic banking a clear distinction between the virtual banks (electronic access only) and electronic access services of traditional banks lost its importance, and it appears to be a continued trend. It is caused by the following phenomena (quotation from a student's survey: ...as we can see the results are comparable. This is due to the large similarity of services offered by banks with regard to visualisation and "starting package", that is all for 0zł ...): virtual and traditional banks try to maximally increase the number of communication channels, it is difficult to separate a virtual bank from a traditional one, e-banking websites of traditional banks are just as technologically advanced and modern as those of virtual banks, we observe lowering of that prices of basic e-banking services in traditional banks, sometimes below the prices of virtual banks, we have a more possibility of access—phenomenon of mobile banking via mobile applications (smartphones, tablets),
- users have higher expectations with regard to the quality of e-services. The averages from the rankings—previously relatively constant—have become dynamic and fluctuate,
- entering the market (for example—the case of Alior Bank) and allocating significant resources to a clever advertising campaign does not guarantee an automatic promotion to the top position in the rankings (for example—Credit Agricole),
- having two or more accounts in two or more banks to perform various financial transactions is still a rare phenomenon,
- too few clients dynamically respond to changes in banking services market,
- vast majority of active bank customers consider economic criteria to be the most important criteria in the evaluation of electronic access to banking services—usually the prices of the most frequently used services. More and more people admit, however, that when selecting a website, to a certain degree, they tend to focus on user-friendliness and intuitiveness as well as the visual attractiveness of the website (quotation from a student's survey (original phrasing): ... personally, when selecting banking services, I am more influenced by economic factors than the visualisation or the simplicity or complexity of navigation. Visual qualities depend on a personal taste, and I think they should not be a decisive factor in the selection of a financial institution, to which we entrust our own money. With regard to the technical and functional level of the service, it does not determine my choice—especially since the current market seems to have developed a certain standard, below which banks can no longer operate because customers are bound to verify it quickly and leave ...),
- users of electronic banking services more frequently notice anti-crisis measures of banks and even though they do not influence their choices in any considerable degree, they can note and identify them.

This confirms the authors thesis about the inadequacy and a specific superficiality of standard, unified, quantitative methodologies used for evaluation and selection of e-banking websites. It also points to the need of further studies into constructing multi-dimensional, multi-criteria, hierarchical and multi-faceted system for websites' evaluation, with the consideration of additional, more specific information, e.g. customer profile [3].

Nevertheless, despite the problems related to using e-banking services, which the article presents, from year to year we observe that the Internet tends to assume the role of the main (also for an individual client) channel of communication with the bank. Undoubtedly, this development irrevocably changes the expectations, perceptions and habits related to using banking services which users have had so far, and also, simultaneously, it urges the banks to introduce quick changes of the medium which would take into account holders' requirements.

*Abstract*—**The article presents the approach to the conceptualization of the financial knowledge used for an Intelligent Dashboard for Managers. The content of the knowledge is focused on essential financial concepts and relationships related to the management of small and medium enterprises (SME). That includes the illustration of the conceptualization of the ontology. The designed ontology was split into six ontologies describing areas of Cash Flow at Risk, Comprehensive Risk Measurement, Early Warning Models, Credit Scoring, Financial Market, and General Financial Knowledge. The examples of the topic map of key financial indicators and their interpretation are given. The results of this research have been implemented in the Business Intelligence system.**

## I. Introduction

TO make optimal decisions, managers need very useful, adequate and easy to interpret information. They must analyse various economic indicators assessing the financial situation of an enterprise. Data for analyses are usually extracted from different information systems. To interpret a financial indicator, a manager should analyze relations between indicators and economic data which have influence on its value. However, available information systems concentrate mainly on providing information reflecting hierarchic relationships between examined indicators. Decision-makers evaluate semantic associations existing between them. Such an analysis of indicators can potentially ease and shorten the time needed, inter alia, to identify chances of advancement and threats of breakdown related to carrying out an activity. In order to facilitate the process of data analysis, the usage of the ontology is proposed as a model of financial knowledge about the analysis of indicators.

The decision-makers of small and medium enterprises (SMEs), in comparison to managers of big companies, may not have access to all essential strategic information. Usually financial expertise is either not available or too expensive. Big companies have at their disposal strategic consultation and possess standard procedures to solve problems in the case of essential changes in business environment. For financial and personnel reasons most SMEs cannot afford these types of facilities. It should be noted that SMEs operate in a definitely more uncertain and risky environment than big enterprises, because of a complex and dynamic market that has much more important impact on SMEs' financial situation than on big companies [1].

In general, most existing Business Intelligence (BI) and Executive Information Systems (EIS) provide the functionality of data aggregation and visualization. Many reports and papers in this domain underline that decision makers expect new ICT solutions to interactively provide not only relevant and up-to-date information on the financial situation of their companies, but also explanations taking into account the contextual relationships.

Our research concentrates on two essential issues: supporting decision makers in the area of analysis of economic and financial information using solutions for representing the ontology of economic and financial data (for example: topic map)[1], and using tools for visualization of the semantic network, which is based on an ontology model of the economic knowledge and data from all relevant information systems[2].

The aim of this article is to present the conceptual design of financial ontology. The structure of the paper is as follows. In the next section, the functional schema of the system is discussed. The main domain areas of financial knowledge are presented and detailed by the topic map of the main financial indicators. Section 3 describes the process of ontology development, in particular the actual design of the ontology. A case study in section 4 illustrates an example of financial ontology conceptualisation. To show the reasoning a case for explanation of financial data is specified. In the conclusion, the future research directions are indicated.

## II. Proposal widen Business Intelligence system functionalities

The Business Intelligence (BI) system is used for the analysis of all basic areas of an enterprise's activities, such as, e.g., finance and accounting, manufacturing, logistics, marketing, sales, and customer relationships. These applications provide many reports containing valuable information in each statement. Retrieval information from these reports is eased by the use of appropriate forms of its presentation, and of a friendly and easy user interface. Nowadays decision-makers want not only to look at static reports or even ad hoc reports, but also easy-to-use tools to assess goals and key performance indicators to identify any chances of advancement and threats of breakdown. The usefulness of the BI system is not related to the amount of generated information, but to the information which is required at the right moment. These were basic motives for developing and applying a new technology and knowledge representation in the BI system. In the literature, the development of BI systems towards BI 2.0 (using semantic search) is described (see [2]-[4]). This system is focused on the semantic analysis of data, using data and information from multiple sources (including external sources). One of the main artifacts to create a semantic network is the ontology, because the architecture of BI 2.0 has new components, such as ontologies and service ontologies (see [2]). The ontologies are used to create the necessary knowledge models for defining and explaining functionalities in analytical tools. Using ontologies and semantic networks for a visual interface supporting an information search in the BI system may help to reduce the following weaknesses of management information systems (see [4], [5]):

- lack of support in defining business rules for getting proactive information and support in consulting in the process of decision making;
- lack of a semantic layer describing relations between different economic topics;
- lack of support in presenting the information of different users (employees) and their individual needs;
- difficulty in rapidly modifying existing databases and data warehouses in the case of new analytic requirements.

In Figure 1 a functional architecture of the information system is presented, with ontology applications. Various mechanisms can be seen for extracting source data from transactional systems (ETL), its data warehouse, and external sources. However, the available solutions – in particular the standard analyses, reports and analytical statements generated by the system – are complemented by economic and financial knowledge (most importantly ontologies). This enables a dynamic, interactive analysis of key economic and financial indicators. Such architecture concept was used in the project InKoM (a wide review of the issue is presented in: [6], [7]). This solution will significantly extend existing BI and EIS functionalities.

To support the analysis, SMEs decision makers need economic and financial knowledge. The scope of required knowledge was divided arbitrarily by experts into six selected areas, namely: Cash Flow at Risk, Comprehensive Risk Measurement, Early Warning Models, Credit Scoring, Financial Market, and General Financial Knowledge (Fig. 2). They are described in [6]. Between these fields there are intersections, and some topics belong to two or three areas.

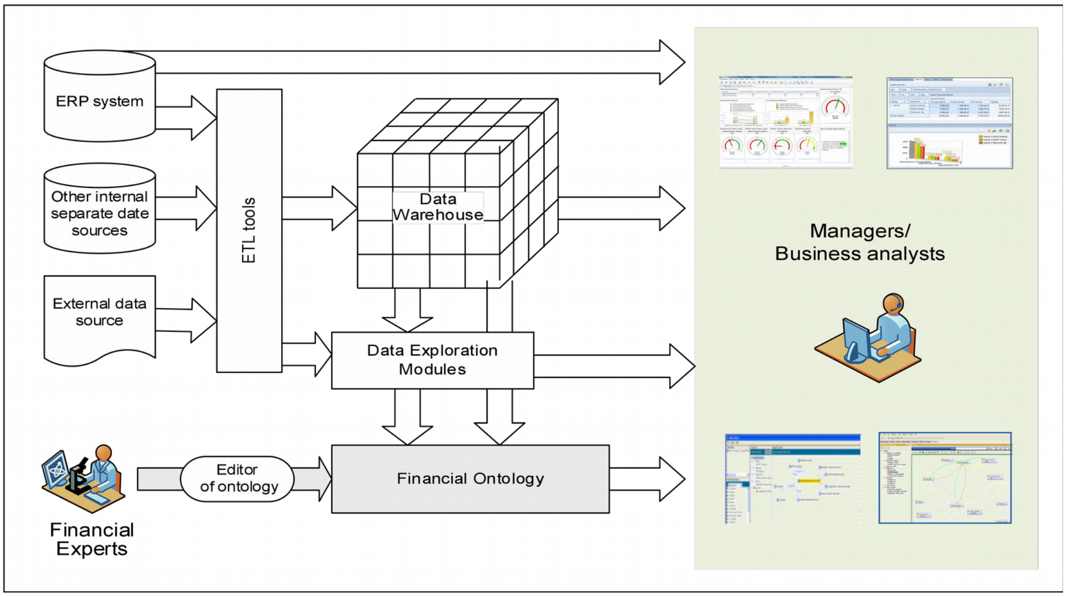

Fig. 1. Functional architecture of information system with ontology applications

Source: based on [1, p. 57].

The system that enables semantic information retrieval should be intuitive to use or easy to understand. For managers, the presentation layer is the most critical aspect of a BI system, since it broadly shapes their core understanding of the data displayed [8]. The basic assumption of navigation is that managers should be able to view focus and context areas at the same time to present an overview of the whole knowledge structure [9].

Ontology of financial knowledge is the foundation of creating a semantic network. In our project, special attention was paid to the role of the visualization of a semantic network, which is not only a tool for presenting data, but also provides an interface allowing interactive visual information retrieval (see inter alia [10], [11]). Working from the displayed semantic structure of a built-in ontology of financial and economic knowledge, it is possible to interactively choose analyzed topics or relations, to change the area of presented details, and to obtain relevant source data.

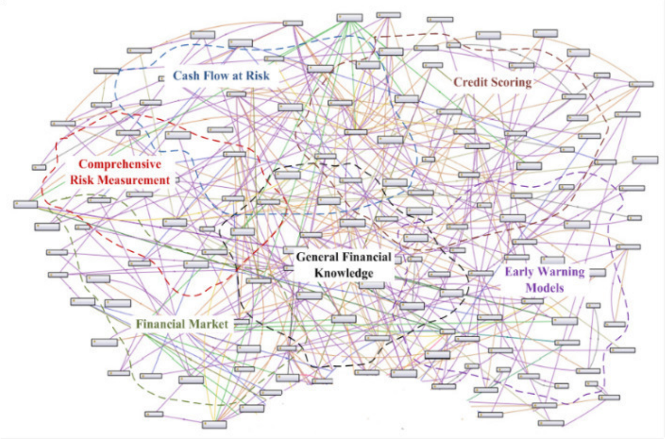

Fig 2. Six selected areas of ontology in the Intelligent Dashboard for Managers

Source: [1, p. 61].

In the years 2011-2013 we carried out four experiments with a created prototype and users participation. The results of these experiments are optimistic (discussed inter alia [12]). However, the usefulness of these solutions depends mainly on substantive content, that is, correctly building the ontology of financial or economic knowledge.

## III. Design process of financial ontology

In the literature many different approaches to design of an ontology can be found (a wide review of the issue is presented in: [13]). There are many methods describing the methods of creating ontology for information systems. These are inter alia: Cyc, KBSI, TOVE, EMA, HOLSAPPLE, HCONE, System KACTUS, SENSUS, UPON, METHAONTOLOGIA, On-To-Knowledge method (a wide review of the issue is presented in: [14], [15]). But so far there is no single approach accepted by all.

Based on the analysis of existing methodologies and our research, a method of creating an ontology of financial indicators has been proposed. In this method, the following stages are distinguished (see also: [1], [6], [16], [17]):

*1.* Definition of the goals, scope, and constraints of the created ontology. While creating an ontology, assumptions about the created model of knowledge that will apply during its building have to be provided. That requires an answer to the question: *what will the created ontology be used for?*

*2.* Conceptualization of the ontology. Independently of the field that is to be modeled by using an ontological approach, it is the most important stage in creating a model based on ontology (see inter alia [18, p. 2036]). It includes the identification of all concepts, definition of classes and their hierarchic structures, modeling relations, identification of instances, specification of axioms, and rules of reasoning.

*3.* Verification of the ontology's correctness by experts. In this stage, the constructed ontology is verified by experts who did not participate in the process of conceptualization. Verification is carried out in two steps. The first concerns a formal verification of the specified ontology (e.g. incorrect relations are indicated) with the use of a given editor. The second step is carried out by experts from the given field and concerns content verification which includes verification of the correctness of topics' definitions, correctness of taxonomic topics, and correctness of relational dependences between topics. In the proposed method of building an ontology of financial knowledge verification and validation were isolated in accordance with approach used in software engineering (see [19]).

*4.* Encoding the ontology is described in the formal language or editor of ontology. The result of this stage is the encoded ontology. Two basic stages of encoding of ontology are: (1) entering all topics and creating a taxonomy of these topics, and (2) entering all other types of relations between topics.

*5.* Validation and evaluation of the built ontology. In this stage, the encoded ontology is checked to ensure it meets the needs of the managers. Validation is carried out in three areas. Firstly, validation of usefulness and correctness of the created ontology by experts (managers) who will potentially use it. Secondly, evaluation of the application with a created ontology is carried out by managers. Finally, the validation of predefined use cases is carried out. That requires an answer to the questions: *will the created ontology be useful for the managers who will use it?*

Financial ontology

Fig. 3. Design process for an ontology of financial knowledge

Source: own elaboration.

The important stage in the described method is the conceptualization of financial indicators. The process of conceptualization of an ontology is an intellectual activity of organizing knowledge acquired from a given domain knowledge. This is carried out by the person, either an expert or in collaboration with an expert, responsible for creating the model of knowledge without the support of automated tools (see inter alia [18, p. 2036]). In the literature [14], [15]) the following phases in the conceptualization of the ontology of financial knowledge are shown (see also: [6]):

(a) Identification and definition of all topics. A topic, representing any concept, is "a syntactic construct that corresponds to the expression of a real-world in a computer system" [10, p. 60]. A topics' list is determined by experts in a given domain of economic knowledge. These topics include, beside their names, also their synonyms and descriptions.

(b) Creating a taxonomy of topics. Specification of taxonomic relations between distinguished topics and defining classes and subclasses. In general, these relationships describe the topics generalization. The description of a taxonomy can be presented in graphic or tabular form. An interesting approach to creating a taxonomy is proposed in METHONTOLOGIA (see i.e. [14]).

(c) Definition of all other types of relations between topics, notably the basic relationships aggregate of (*Aggregate – Member*) was defined. Moreover, within each ontology, additional relations were defined.

(d) The list of all the individual relationships existing in the ontology. The list includes: the name of the relationship, source topic, and target topic.

(e) Description of functions and rules. This description contains: name, input, output, initial and final conditions, and definition of operations.

(f) Description of usage scenarios. Usage scenarios, also called use case views, describe demonstration analyses of economic topics occurring in this ontology.

Building an ontology always denotes analysis and organizing of knowledge. That work has required multi-domain expertise, both theoretical and practical, in economics, finance, and informatics.

## IV. CASE STUDY - CONCEPTUALIZATION OF FINANCIAL ONTOLOGY

The important stage in the described method of creating an ontology is the conceptualization of ontology. We will illustrate it in the example of the analysis of Return on Sales (ROS) indicator. ROS is one of indicators that managerial staff analyses to evaluate a company's efficiency. This measure is helpful to management by providing insight into the profit structure of sales. An increasing ROS indicates that the company is growing more efficiently, while a decreasing ROS signals financial troubles. Managers often use the ROS indicator and sales analysis reports to identify market opportunities and areas where they could increase the volume of sales.

The conceptualization of the ontology of the ROS indicator was as follows:

*1.* Identification and definition of all topics. Table I presents the example of the topics list.

TABLE I.
THE EXAMPLE OF TOPICS LIST

| Name | Synonym | Description |
|---|---|---|
| Return on sales | ROS | A ratio widely used to evaluate a company's operational efficiency. ROS is also known as a firm's "operating profit margin". It is calculated using this formula:<br>Net_profit / Revenues_from_sales<br>Recommendation: Compare a company's ROS over time to look for trends, and compare it to other companies in the industry. |
| Net profit | NP | Net profit is calculated by subtracting a company's total cost from total income, thus showing what the company has earned (or lost) in a given period of time (usually one year). Also called net income. |

Source: own elaboration.

*2.* Creating a taxonomy of topics. Figure 4 shows the taxonomy for topic *Indicators* and topic *Profitability evaluation indicators.*

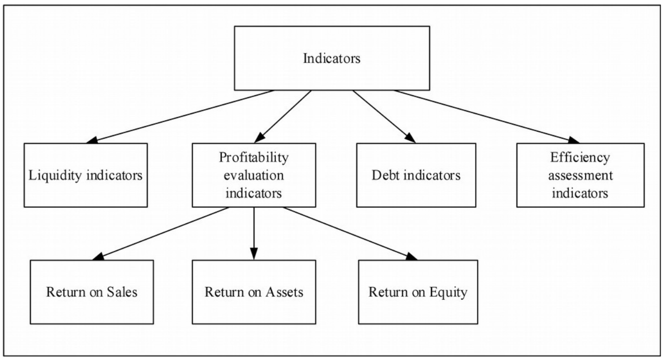

Fig. 4. Example of the taxonomy for topic *Indicators* and topic *Profitability evaluation indicator*
Source: [1, p. 64].

*3.* Definition of all other types of relations between topics. In this ontology, the basic relationship *aggregate of (Aggregate – Member*) is defined. Moreover, additional relations are defined, for example: *potential growth, proportional positive/negative change, is the sum, is the quotient.*

*4.* The list of all the user defined relationships existing in the ontology. The description of a taxonomy can be presented in graphic or tabular form. Figure 5 shows the relations existing between topic *Return on Sales* (in the class *Profitability evaluation indicators*) and topics: Net profit, and Revenues from sales ((in the class Total income). Solid lines denote taxonomic relations (relation *Subclass – of*), whereas broken lines denote domain-specific relations (e.g. relation *is the quotient*).

5. Description of functions and rules. The definition describes how to compute and interpret their values. This description can contain: name, input, output, initial and final pre-conditions, and definition of formula (see also: [9]). The following description specifies the example of the indicator *Return on Sales*:

***Name****:*
  *Indicator Return on Sales (ROS)*

***Input****:*
 *Result of Net profit (NP)*
 *type: value extracted from Balance Sheet*
*Revenues from sales (RS)*
*type: number, value extracted from Balance Sheet*

***Output****:*
*Return on Sales*
*Description/formula:*
    *ROS = NP/ RS*

```
Final conditions:
if (ROS < value_1)
  Interpretation_1
else if (value_1  > ROS  < value_2)
  Interpretation_2

else if  ....
  ....

else if ( ROS > value_n)
  Interpretation_n
```

6. Description of usage scenarios. Usage scenarios, also called use case views, describe demonstration analyses of economic topics occurring in this ontology. For example, a manager analyzes the ROS indicator and would like to identify causes of a decreasing value ROS:

*a.* The manager analyzes the semantic network, from which it follows that the *Return on Sales* indicator depends on two values: *Net profit* and *Revenues from sales*.

*b.* From the BI system the manager receives the values of the *Net profit* and *Revenues from sales*. It notices that the company's value of net profit is worse than for the previous period (Fig. 6).

*c.* The manager analyzes the semantic network of the *Net profit* to identify two parameters: *Total income* and *General costs*.

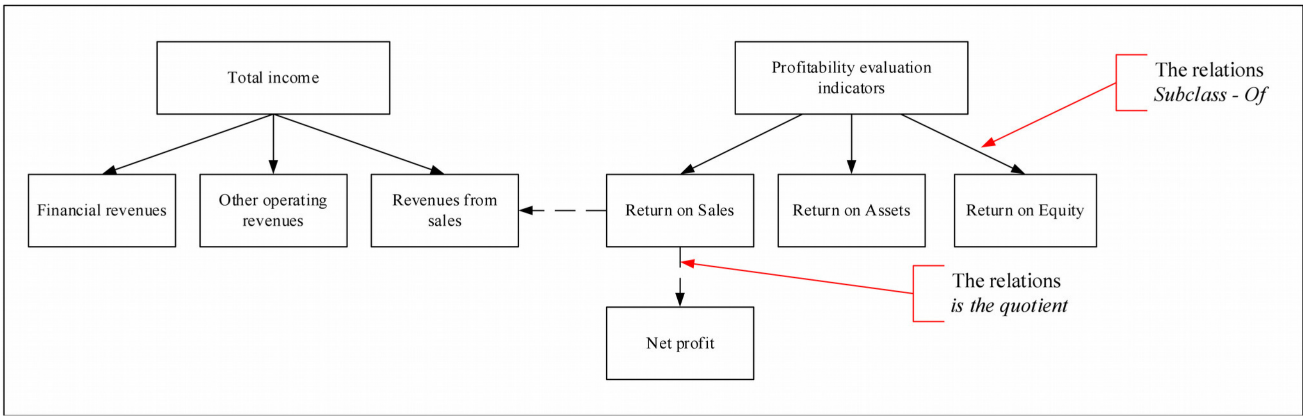

Fig. 5. The example of illustrated relationships *is the quotient*

Source: own elaboration.

*d.* From the BI system the manager receives the values of the *Total income* and *General costs*. It notices that the company's value for General costs is worse than the previous period.

*e.* The manager analyzes the semantic network of the General costs to identify causes of unfavorable values from the ROS indicator.

*f.* Based on the analysis conducted of economic indicators, the manager can undertake corrective actions which may potentially result in improving the company's *Return on Sales*.

Fig. 6. . Example of visualization of entered ontology of ROS indicator and of Balance Sheet extracted from the TETA BI system

Source: own elaboration

.

The scenario is presented in Figure 6. The screenshot shows the expansion of the selected topic: *General costs, Total income* and *Profitability evaluation indicators*. On the diagram, it is the area encircled by a dashed line, with new topics being a subclass of the topic *Total income*. A semantic search is provided to avoid difficulties related to decision makers' interpretation of financial information. This gives the user the opportunity to search data sources taking into account not only structural dependences, but also the semantic context. In this figure there are two types of lines between topics: (1) the solid line represents a relation *Subclass – of* and (2) the dashed line represents the experts' defined relations. Business data contains a lot of hidden relationships and dependencies that make their usage difficult. To interpret the values of financial indicators correctly, many measures and ratios need to be examined that either directly or indirectly influence the final result. Explicit visualization not only makes the interpretation of indicators easier, but it also contributes to finding explanations of current values of indicators.

## V. Conclusion

The use of a financial ontology seems to be a promising extension for Business Intelligence systems. It not only improves the efficiency of analysis, but also increases the capacity of understanding of financial data.

In this paper, the approach to the ontology of the financial knowledge design process was presented. The stages of ontology design were described and illustrated using the Business Intelligence system. In the case study, the topic map of key performance indicators is presented, with their structures and relationships. The financial ontology was implemented in the extended Business Intelligence system, which will be soon commercialized by TETA BI Center.

Many extensions and applications of this work are possible. Current work is directed toward the development of smart navigation throughout the very large field of ontological concepts, and the method of financial ontology updating by adding new concepts either through a SME manager or data mining modules. Suggested approach could be used in bigger enterprises too.

*Abstract* - **Performance Measurement Systems (PMS) have long captured the attention of organizational behavior and information systems (IS) research. The PMS in the study was implemented by public police forces, using advanced Business Intelligence (BI) technologies. The study examines the impact of enhancing that PMS, through analysis of the metric results over an 8-year time period that covered a transition between two major system versions. The analysis results indeed show a significant impact of transitioning to the new PMS in most (75%) performance metrics. A noticeable impact of the transition is the temporary performance decline, followed by some improvement that can be attributed in part to the redefinition of some metrics. Further, the results confirmed the preliminary assumptions that the improvement in the measured performance is positively and significantly associated with human-resource allocation; however, with some mediation effects of the crime category and the organization unit**.

## I. Introduction and Background

Today, PMS are broadly adopted across all industries and business domains, and their implementation is often supported by Business Intelligence (BI) technologies [1], [2]. PMS implementation is driven by the notion that consistent and well-organized measurement, reflecting past behavior and current state of organizational units, can serve as an important tool for supporting decision-support and driving continuous performance improvement [3]. PMS may back these goals by providing solutions for gathering, analyzing, and distributing relevant information [4]. Much of the PMS research so far is non-empirical, and not supported by rigorous evidence [5]. Further, PMS studies mostly focus on for-profit businesses [6], but less on organizations that are not necessarily driven by profit goals, such as governmental agencies or community-based groups [7].

This study explores the impact of a PMS in a real-world setting, within a governmental agency – the Israeli Police Forces. The research scope is examining the transition between two PMS: the “MENAHEL” that was used between 2006 and 2010, and the “MIFNE” that replaced it in 2010. Both PMS were implemented with advanced Business Intelligence (BI) technologies and embedded a number of performance metrics that reflect the police strategy and activities. Beyond enhancement of BI technologies, a key difference between the systems was the re-design of the metrics structure. While the "MENAHEL" offered a large number of metrics (over 150), some with low relative weight, the "MIFNE" offered a reduced and more focused set that was developed based on the knowledge and insight that were gained during the operation of the "MENAHEL". The focus of “MIFNE” is not the quantity of measures, as the quality and essence. The newer system exposes police officers not only to performance measures in their own stations, but in other stations as well for the sake of comparison. Further, the newer performance measurement system serves not only police stations, but rather all organizational police units. One new main module that is part of  “MIFNE” is “internal services”- as part of the comprehension of the importance of police officer’s and his family’s social satisfaction. Moreover, “MIFNE” is targeting every organizational unit specifically, compared to “MENAHEL” that defined a uniform target for all units. The new PMS enables to drilldown and investigation from high-level information to more detailed. It enables identification of exceptional trends or events that required an attention. According to research and statistics unit of the police, "MIFNE" brought a significant change in perception as part of a 3-years change program named “MIFNE” that has been started in 2011. Main guideline of this program is that public trust of the police, has an important and critical rule. In order to focus all organizational units on achieving “MIFNE” strategy, “MIFNE” program is based on a unique PMS named “MIFNE”.

A question that motivates this study is whether or not the transition to a new PMS promoted the desired improvement in police-units performance. Was the influence positive, or rather negative in some cases?  Is the influence moderated by certain characteristics of the organizational unit? This study suggests that these questions may have important implications for performance measurement in the Israeli police as for the adoption of PMS in other organizations.

This work was not supported by any organization

## II. Model Development

The transition between the two PMS systems raised questions that this study aims to explore: did the transition indeed gained the desired effect on performance measurement? What factors may possibly affect the actual contribution of replacing a PMS? One could expect that the actual contribution will be affected by factors such as the size of police station, socio-economic characteristics of its region, or the activity or crime category that the performance metrics reflect. These questions are reflected in the model that underlies this study (Figure 1), which is presented next.

The model observes the following constructs:

**Performance (P):** The dependent variable observed is the organizational performance as reflected in the values of the PMS metrics. Positive and/or negative trends in metric values reflect the influence transitioning to a new PMS and possibly other factors.

**PMS Replacement (R):** Transition to a new PMS is expected to have a significant impact on performance. Accordingly, the first set of hypotheses reflects possible manifestations of that impact:

- *H1a:* PMS Replacement will significantly affect performance.
- *H1b:* PMS Replacement significantly improves performance over time.
- *H1c:* PMS Replacement may result in a temporary performance decline during the transition period

***Resources Allocation (A):*** An alternative, or possibly complementary, explanation to the effect of PMS replacement on performance is the allocation of resources. Performance could have been enhanced not only by PMS replacement, but also by extending human-resource allocation, where the effect is expected to be positive:

- *H2:* Increasing human resource allocation will improve the measured performance

***Socio-Economic Ranking (S):*** The common assumption in literature is that socio-economic ranking may influence on the dependent variable in some researches as in politics and government [8] and entrepreneurship [9]. Certain demographic characteristics, such as the socio-economic ranking of the region in which the police station acts, are expected to moderate the effect of PMS replacement on the measured performance. We therefore assume that:

- *H3a:* Stations that act in regions with different socio-economic ranking will show difference in the influence of replacing PMS on the performance

***Performance Category (PC):*** PMS commonly arrange the performance metrics in clusters. For example, in PMS that are based on the Balanced Score-Card (BSC) methodology [10], the measurements are categorized under four key clusters. Such categorization could be detected in the police PMS as well, and the model assumes that this categorization will have some effect:

- *H3b:* Different performance categories will show different influence of PMS replacement on performance.

***Crime Category (CC):*** The police typically characterize different types of crime along different categories. The model assumes that different crimes category will show different effect of replacing PMS on performance:

- *H3c:* Different crime categories will influence of PMS replacement on performance differently.

***Police Station (PS):*** There is a different effect on measures among different police stations so stations differ from each other in PMS enhancing. Considering common qualities of police stations assist to divide them to clusters. Each Cluster is differ from other in internal and external characters. This examination helps assessing whether or not performance measures are effected from internal (HR allocation, socio-economic ranking) and external (crime records) police stations characteristics. The assumption is that the influence of replacement PMS on performance is expected to be different between different police stations. The model assumes that different police stations will show different effect of replacing PMS on performance:

- *H3d:* Influence of PMS replacement on performance is different between different police stations.

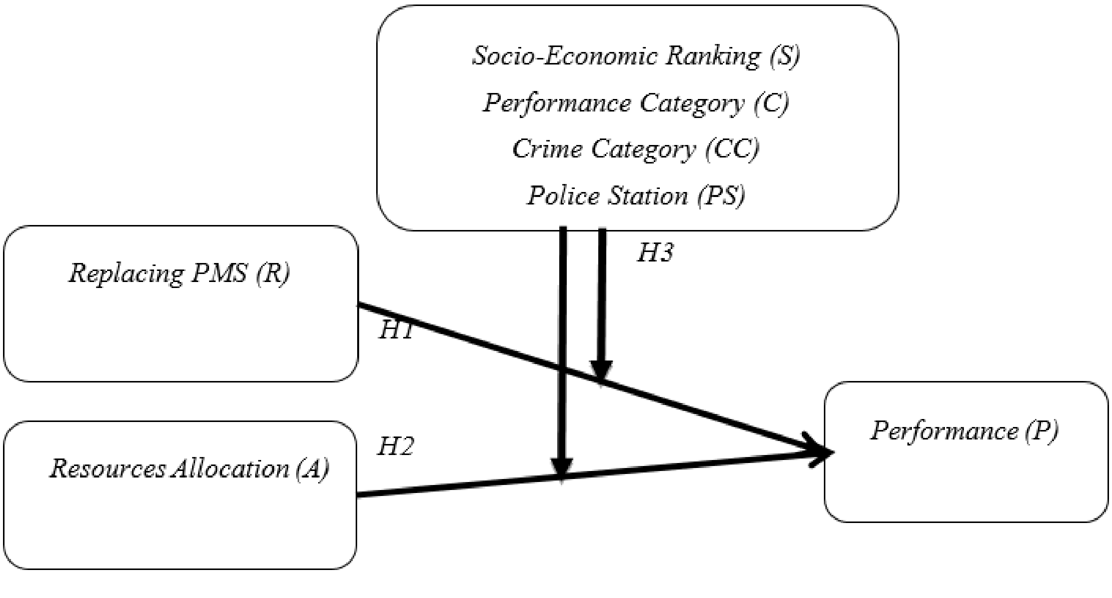

Fig. 1 Research Model

## III. Data Preparation and Preliminary Analysis

The study was based on performance measurements that were retrieved from the police database, with some additional pieces of data that were retrieved from other sources. The measurements covered an 8-year period (January 2006 to December 2013), 146 organizational units (districts, regions, special units, etc.), and 33 performance metrics - 8 annual measures, per metric and per unit. The 33 metrics can be classified to 3 main categories: a) crime records, b) charges, and c) arrests. Each category includes 11 crimes that could be divided to exposure offenses versus the rest. Exposure offenses are crimes with no previous complaint or report; hence, exposed only by initiated activity. Exposure-based crimes are considered to be more challenging to handle than the others; hence, get extended attention by the police. One of main goals the police has put as a focus in front of her is increasing the probability of the criminal to be caught in exposure offences. 3 crimes out of 11 are considered as exposure offenses: weapons, illegal stay and drugs.

Another data resource that was used includes human resource allocation for each organizational unit per year. The datasets also contain socio-economic ranking, which was calculated as an average for all cities and regional councils' socio-economic ranking that under the responsibility of a certain police station. After removing records with missing or inconsistent values, and keeping only police stations that have full information of HR allocation and performance measures over 8-year period- 2006-2013, 60 valid stations remained, and were included in the analysis. The final dataset include one annual record per police station.

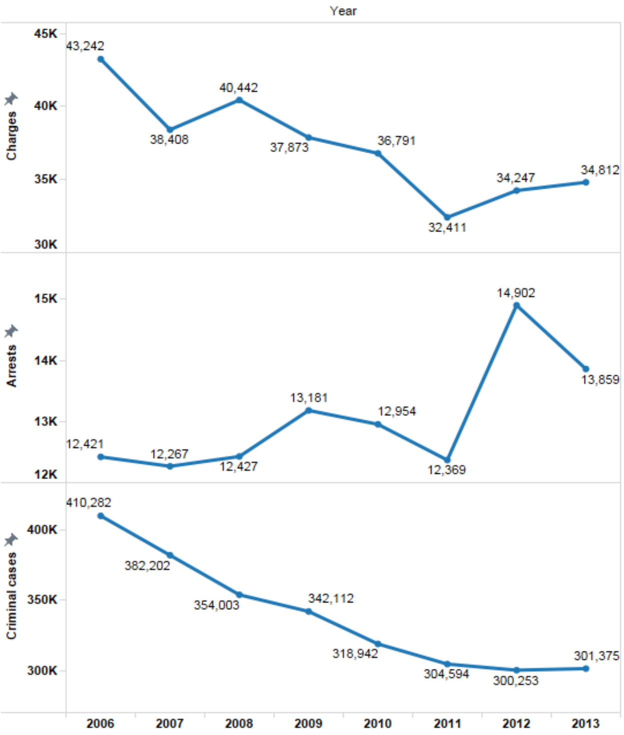

Fig. 2 Preliminary Performance Analysis

A preliminary analysis of 3 main categories: criminal cases, charges and arrests shows an improvement in metrics after the switch to the new system (2012); however, with some period of instability during the transition in 2011 (Figure 2). In addition, the ratio between arrests and crime records has a positive trend, and the ratio between arrests and charges is increasing as well over time. Among 15 performance measures out of 33 (45.45%) there is an increase in performance following the switch and among the 33 measures, only for 2 (6%) transition period (2011) is followed by improvement in performance, the rest of measures (94%) are followed by decline in performance. Furthermore preliminary analysis shows a positive relationship between HR (number of police officers in a station) and performance measures: crime records, arrests and charges. A preliminary examination shows a strong correlation between crime records and arrests especially (Figure 3); however the correlation with charges measure seems to be weaker.

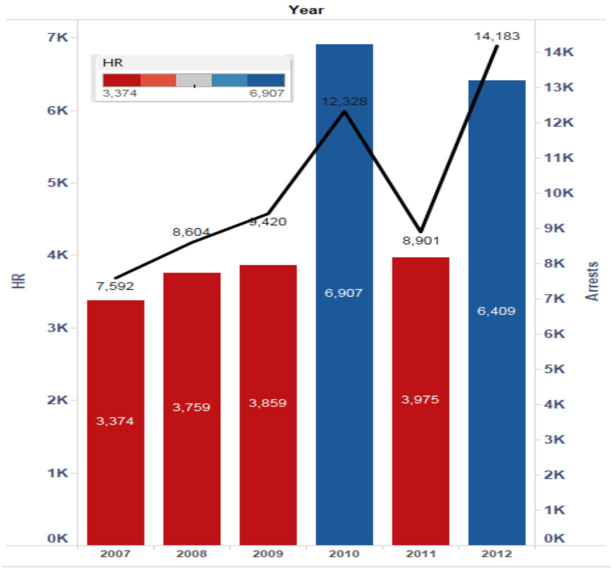

Fig.3 Arrests vs. Investment in Human Resources

## IV. Evaluation Results

This chapter reviews the analysis results of the model that is describes in chapter 3.

*Testing Hypothesis H1: The Impact of Enhancing Performance Measurement Systems*

The first hypothesis (H1) suggests that replacing the PMS will result in significant decline in performance during the transition period and also significant performance improvement following the replacement; the results support it partially. The datasets that were examined for this hypothesis is 3 year period between 2010 and 2012. In 2010 the former PMS was active. The transition to the new PMS system began in 2011. Then, the first version was active, followed by a year of the actual transition. By 2012, the transition was over and the new system became live in the organization.

The three derived hypotheses - H1a, H1b, and H1c - were tested by examining the rate of measures that had a significant effect (P-Value < 0.05) (Table 1). The H1a assumption that measures show significant change over time is largely supported, as for 25 out of 33 measures (75.7%). The H1b assumption that measures will significantly improve following replacement wasn't supported- 24 out of 33 measures have no significant improvement (72.7%). However most of the measures that were improved significantly are included in the arrests category. The H1c assumption that measures will significantly decrease during transition is also not fully supported. 31 measures among 33 had a decline in performance during the transition period (93%), however, 10 only (30%) had a statistical significant decrease.

TABLE 1.
CHANGE IN PERFORMANCE MEASURES (H1)

| Hypothesis | Significant measures | Ratio |
|---|---|---|
| H1a | 25 | 75.75% |
| H1b | 9 | 27.27% |
| H1c | 10 | 30% |

*Testing Hypothesis H2: The improvement in performance will be positively affected by human-resource allocation*

H2 suggests that performance will be improved with higher human-resource allocation. The results support this assumption significantly. A preliminary analysis shows consistently-high correlation between HR allocation and performance improvement in three key metrics (Tables 2).

TABLE 2.
CORRELATION BETWEEN HR ALLOCATION AND PERFORMANCE (H2)

| Crime Metric | Correlation with Crime Records Performance | Correlation with Charge Performance | Correlation with Arrests Performance |
|---|---|---|---|
| Regular violence | 83.58% | 57.98% | 61.22% |
| Aggravated violence | 73.7% | 62.1% | 61.70% |
| Total violence | 83.61% | 59.89% | 60.86% |
| Property | 63.81% | 51.86% | 53.86% |
| Sex | 54.67% | 43.60% | 39.73% |
| Regular attack | 78.74% | 54.45% | 56.56% |
| Aggravated attack | 69.53% | 61.20% | 50.67% |
| Weapons | 1% | 22.1% | 0% |
| Illegal stay | 11.2% | 0% | 21.0% |
| Drugs | 48.52% | 57.2% | 30.30% |

A more detailed analysis shows that the extent of improvement varies between performance types. For some measures (e.g., violence, aggravated attack, regular attack, etc.), the correlation is significant (P-Value < 0.05), while for others – "exposure offenses" (e.g., illegal stay, weapons, drugs trade) it is less significant (P-Value > 0.05). The most significant difference is between exposure offenses and the others. As seen in table 2, among the 30 indicators that demonstrated in 3 categories (a table is presented for each category), 7 (70% of all crime measures) have a significant correlation with HR allocation in all categories. All 3 exposure measures (30% of all crime measures) have a low and not significant correlation.

*Testing Hypothesis H3a: Station will show difference in the influence of replacing PMS, based on the socio-economic of the region under their control.*

Hypothesis H3a, suggesting that the impact of replacing the PMS on performance is moderated by the socio-economic ranking, is supported in part. A repeated-measures ANOVA test shows influence of replacing the PMS on performance measures for the 3 key measures (H1a). The test confirmed the assumption H1a with high significance (P-Value = ~0). However significant influence with respect to the interaction with Socio-Economic Ranking (H3a) could be found among 17 measures out of 33 (~50%). In crime records category, high significance (P-Value = ~0) interaction was found in 7 out of 10 crimes categories (~70%), however for arrests category only among 3 crimes out of 10 (30%) the interaction is significant and for charges category among 5 out of 10 can be seen a high significant interaction (50%).This interaction is found as significant in all categories for crimes like violence and attack more than other crimes. The main conclusion that derived is that different stations will show difference in the influence of replacing PMS, based on the socio-economic characteristics of the region under their control and crime category.

TABLE 3.
RATIOS BETWEEN SIGNIFICANT PERFORMANCE MEASURES (H3B)

| Impact | Category | Significant Metrics | Ratio |
|---|---|---|---|
| Total Change | Crime records | 7 | 70% |
| | Charges | 7 | 70% |
| | Arrests | 9 | 90% |
| Increase | Crime records | 1 | 10% |
| | Charges | 1 | 10% |
| | Arrests | 7 | 70% |
| Decrease | Crime records | 5 | 50% |
| | Charges | 4 | 40% |
| | Arrests | 1 | 10% |

*Testing Hypothesis H3b: The influence of PMS replacement on performance is will differ between metric categories*

The third hypothesis (H3b), is suggesting that the impact of enhancing PMS on performance will be moderated by performance category. This sub-hypothesis is derive from H1, which assumes that replacing PMS has an impact on the performance. This hypothesis (H3b) suggests that replacing the PMS will result in significant decline in performance during transition period and also significant performance improvement following the replacement is dependent on performance category; Results of examination the impact on performance by considering 3 performance categories are presented in Table 3.

For most crimes in all 3 categories some significant change in performance measures could be detected (P-Value < 0.05). For arrests, the ratio of crimes that had a significant change, is the highest- 90%, and for the other 2 categories the ratio is 70% which is pretty high as well. Regarding the increase in performance following the replacement, for both crime records and charges categories, the ratio is 10%, however for arrests category- ratio of crimes with significant improvement is 70%. It seems that there was no significant decrease in performance in transition period for none of the category in all crimes. For crime records category, 50% of crimes had a significant decline in performance, for charges category 40% and for arrests only 10% from crimes.

Table 4.
P-Value results (H3c)

| Category | Arrests | Charges | Crime Records |
|---|---|---|---|
| Regular violence | 0.00 | 0.00 | 0.00 |
| Aggravated violence | 0.01 | 0.08 | 0.02 |
| Total violence | 0.00 | 0.00 | 0.00 |
| Property | 0.02 | 0.316 | 0.05 |
| Sex | 0.588 | 0.55 | 0.115 |
| Regular attack | 0.05 | 0.01 | 0.00 |
| Aggravated attack | 0.11 | 0.14 | 0.187 |
| *Weapons | 0.06 | 0.06 | 0.01 |
| *Illegal stay | 0.00 | 0.00 | 0.638 |
| *Drugs | 0.00 | 0.14 | 0.00 |
| total | 0.00 | 0.00 | 0.00 |

*Testing Hypothesis H3c: The influence of PMS replacement on performance will be differ between crimes categories.*

The third hypothesis (H3c), is suggesting that the impact of enhancing PMS on performance will be moderated by the crime category. This sub-hypothesis is derive from H1 as well. This hypothesis (H3c) suggests that replacing the PMS will result in significant decline in performance during transition period and also significant performance improvement following the replacement, dependent on crime category; examination results of the impact on performance by considering 11 crime categories show that for sex and aggravated attack crimes there is no significant change in performance in none of the categories (Table 4). Also, for illegal stay – crime records category and for drugs charges, the change in performance is no significant; however for rest of crimes (80%) the change is significant in all categories for 6 crimes and for the rest 2, is significant in 2 categories out of 3. None of the above crimes has a significant improvement or a significant decline in all categories (Table 4).

*Testing Hypothesis H3d: Influence of PMS replacement on performance is different between different police stations.*

The third hypothesis (H3d), is suggesting that the impact of enhancing PMS on performance will be moderated by the police station. This sub-hypothesis is suggesting that the influence of replacing PMS is differ from one station to other. In order to test this assumption, all 57 police stations were divided to 6 clusters. One cluster included all “non-jewish” police stations and the rest of 45 police stations were classified to 5 clusters by k- medoids algorithm. This classification shows a partial support to the assumption; for sex crimes and illegal stay- charges and arrests categories there is a significant interaction with clustering (Table 5). Also, for aggravated attack crimes –charges, the interaction is significant. Cluster analysis was made according to measures: HR allocation, socio-economic ranking, and criminal charges in crimes: regular violence, aggravated violence, aggravated attack and property. After a cluster analysis was done, results of repeated measures ANOVA show that the only crime category with significant interaction is criminal charges. However this result is obvious since the cluster analysis is based on criminal charges measures, as mentioned above. Moreover it is clear (Table 5) that for some measures as sex and illegal stay in arrests and charges categories and also in aggravated attack charges, the influence on performance measures is dependent on the cluster attribute.

Table 5.
P_Value results- K=5 (H3d)

| Crime Metric | Crime Records | Charges | Arrests |
|---|---|---|---|
| Regular violence | 0.00 | 0.14 | 0.76 |
| Aggravated violence | 0.00 | 0.14 | 0.98 |
| Total violence | 0.00 | 0.09 | 0.90 |
| Property | 0.00 | 0.09 | 0.12 |
| Sex | 0.43 | 0.00 | 0.00 |
| Regular attack | 0.09 | 0.09 | 0.47 |
| Aggravated attack | 0.00 | 0.03 | 0.71 |
| Weapons | 0.69 | 0.985 | 0.92 |
| Illegal stay | 0.13 | 0.02 | 0.02 |
| Drugs | 0.08 | 0.498 | 0.11 |

Following repeated measures ANOVA, determining directionality of measures is defined as next step. Tukey HSD test was done in order to determine what police stations clusters achieved better performance in each year and who improved over time. Results of Tukey HSD test for *illegal stay arrests* measure show that cluster 2 is in total better than clusters 3 and 4; police stations that relate to cluster 2 perform better than those that relate to clusters 3 or 4. In addition, the performance is higher in 2012 than in 2010. Results of Tukey HSD test for *illegal stay charges* measure show that cluster 1 is in total better than clusters 4 and 5, so the number of illegal stay charges is higher in stations from cluster 1 than clusters 4 or 5. For conclude illegal stay crimes, one can say that there is significant difference between police stations that relate to different clusters in performance. Regarding *sex arrests* measure, cluster 1 is seen to be better than 4 and 5 in 2010-2012. Moreover, cluster 2 is better than 3,4 and 5 and 3 is better than 4 and 5. Police stations that related to cluster 3 improved in sex arrests measure significantly over time. Regarding *sex charges measure*, the results show that clusters 1 and 2 have higher performance than 3, 4 and 5. Moreover cluster 3 is better than 5 and also than 4 in 2011-2012. In sex charges, as in sex arrests, cluster 3 has improved in 2012. These results support the assumption that influence of PMS replacement on performance is different between different police stations however it's significant with dependent on crime category.

TABLE 6.
SUMMARY OF RESULTS

| Hypothesis | | | Supported? |
|---|---|---|---|
| H1 | H1a | PMS Replacement will significantly affect performance | Strongly |
| | H1b | PMS Replacement significantly improves performance over time. | Partially |
| | H1c | PMS Replacement may result in a temporary performance decline during the transition period | Partially |
| H2 | | Increasing human resource allocation will improve the measured performance | Partially |
| H3 | H3a | Stations that act in regions with different socio-economic ranking will show difference in the influence of replacing PMS on the performance | Strongly |
| | H3b | Different performance categories will show different influence of PMS replacement on performance. | Strongly |
| | H3c | Different crime categories will influence of PMS replacement on performance differently. | Partially |
| | H3d | Influence of PMS replacement on performance is different between different police stations. | Partially |

## V. DISCUSSION

This paper had discussed the implementation and enhancing of a PMS in the Israeli public sector organization.

The literature and case data presented clearly shows first, the importance of updating and enhancing performance measurement systems in organizations so that they change over time, and second the factors that affect the performance measures as a result of enhancing process. There is not a significant evidence in the literature to enhancing PMS process in organizations, and in particular not in the public sector. This paper discusses many of these issues in the context of case study data in Israeli police relating to performance measurement systems evolution. A considerable amount has been written about design and implementation of performance measurement systems in organizations. Moreover one can find many researches about performance measures methodologies, success and failure factors and PMS development over time; however, there is a little discussion in the literature of what are the influences of enhancing PMS, and in the public sector even less. Israeli police data show clearly that enhancing PMS may have a strong impact on performance- some decline during transition period and improvement after it.

It is also clear that for performance measurement systems to enhance effectively there are factors that an organization must consider as internal characteristics of organizational units and measures categories. Reviewing these factors is an important stage in management enhancing PMS process in organizations. This research provides a view of the factors that may influence a process of enhancing a PMS and the impact of that.

## VI. CONCLUSIONS

This research examined the impact of enhancing PMS and factors that are possibly involved in that impact. The study shows that, generally, there is a significant change in performance in most of crimes' categories following enhancing PMS. The only crimes' categories that weren't affected from PMS enhancing are sex, aggravated violence, drugs trade charges and illegal stay records. The study shows that the improvement in performance following the change is mostly expressed in crimes from arrests category (an output measure): violence, attack, and illegal stay. Furthermore, for most of crime categories a decrease in performance during transition period was seen, however it's statistical significant only for 30% of measures. For violence and aggravated attack crimes there is a significant decrease in performance for arrests and charges, for drugs trade there is a significant decrease in crime records and arrests. In addition, it confirmed that performance will be improved with higher human-resource allocation in most crimes categories, except from exposure crimes; main conclusion for the police is that no matter how resource allocation is high, the impact on performance wasn't significant. We can conclude that without any consideration in size of human-resource in a police station, its performance in dealing with crimes like illegal stay, drugs trade and weapons remains the same. Police officers can learn from this study that

The quantity of the police force staff in a police station will not dramatically improve the quality of those measures, so the focus should be on the quality of HR and less the quantity. Moreover, as suggested previously, the socio-economic ranking is shown to have a strong moderating effect on performance in crime records category, however for output measures as charges and arrests, it seems that changes in performance are not affected by socio-economic ranking.

The baseline assumption that a PMS system and, in particular, a BI-supported one has an influence on organizational change and improvement in performance has been confirmed. However, it's forbidden to neglect the negative incline in performance during the transition period that preceded the improvement.

## VII. Future Research

The literature claims that there is a need to a right management of performance measurement systems in both public and non-public sectors. Many researches are focusing on developing methodologies and reviewing the literature on PMS, however little empirical research has been carried out to assess their influence on performance measures, especially in the public sector. In order to better understand performance measurement in general and in the public sector in particular, this study can be extended in a few possible directions.

Some limitations are ought to be further addresses and explored since the study explores only a limited number of moderator variables that can influence the effect of replacing a PMS. Studies focusing on the following research questions would be of interest.

- Are the moderate variables that were analysed are the only main ones that can influence performance or other variables need to be considered?
- Is enhancing PMS improves performance over long period? How performance is influenced in the long term?
- Are other public organizations show same behaviour as the Israeli police? Is the influence of enhancing PMS is specific to this case study or common in other organizations as well?
- Is the influence on performance measures is the same on other measures that weren't included in this research but are part of the PMS?

To answer most of these research questions, additional academic and empirical research are required.

*Abstract*—**The article comprises the characteristics of traditional project management (TPM) and agile project management (APM) and indicates that when using a specific concept we should take into account the conditions of the sector in which the organization implementing or participating in IT projects is functioning. For it is not in all organizations that APM is more effective than TPM. Agility at the project level is one of the possibilities of which we should remember when seeking a tool for achievement of the organization's strategic objectives. However, such a tool becomes less effective if its use is not preceded by analysis of specific attainable benefits and conditions which have to be met to achieve such benefits. These conditions comprise, among other, the organizational and decision-making culture, projects financing method, as well as approach to change servicing, risk management or standardization of project management practices.**

## I. Introduction

AGILITY at the executive – project level was defined in the principles of Agile Manifesto [4], and in practice implemented in numerous agile methods [1]-[2]-[3], the most popular of which is SCRUM [5]-[6]-[27].

The main project benefits which when reached facilitate an agile approach involve: higher easiness to cope with variable priorities, abbreviated time to market, decreased project risk, better adjustment of the objectives of IT and business [10]-[17].

However, the use of one of the agile methods does not guarantee the appearance of the mentioned benefits in each project, or their contribution to a higher efficacy of the whole organization.

Both the public sector organizations and the ICT (Information and Communication Technology) organizations undertake the IT (Information Technology) projects. Yet, they are functioning in different conditions and implementing such projects differently [37].

IT projects exhibit many identical characteristics, as is the case with other measures. They also bear their own specificity. The information project management consists of many activities related to planning, management and control.

According to B. Lent, the information project (IT project) is the „temporary form of organization aimed at designing and performing of applications, data banks, organizational solutions, computer accessories, system platforms and other solutions within the computer science" [9].

The public sector[1] is connected with the provision of a number of public services. Thus, the public administration bears the nature of services and is functioning within the legal regulations system [12]-[15].

*The act on informatization of entities performing public tasks* [20], of 17 February 2005 (hereinafter referred to as the UINF), constitutes the e-activity of all offices from this sector.

Owing to defining in the UINF [20] the term of information project of public use (art. 3 §6) legal use of such projects was enabled and entered the road of the formal setting up projects in entities of governmental and self-governmental administration.

"Information projects should be established in this sector mostly to make available further e-services and teleinformation systems owing to which they may be provided" [38].

The ICT sector is defined in many ways by various organizations. In the simplest way it is understood as a combination of IT sector and telecommunication sector.

The core of the definition of ICT sector is International Standard Industrial Classification – ISIC [14] which applies product distinguishing that consists in specification of conditions which have to be met by the products of a given business activity in order to qualify it as an element of the sector.

ISIC defines ICT sector as a set of enterprises conducting production and services activities consisting in seizing, transferring and displaying the data and information electronically [11].

[1] According to the definition submitted by the Ministry of Finances the „Public sector is a part of the national economy which consists of:
1. State and self-governmental organizational units which are not corporate entities.
2. State and self-governmental special funds (State higher schools and State and municipal culture institutions as well as State enterprises are not included into the public sector)" (Art. 9 of the Act on public finances).

978-83-60810-66-8/$25.00©2015, IEEE

Organizations from ICT sector are usually suppliers of information solutions for the public sector. These organizations are much more experienced in using the Agile approach in IT projects implementation and may convince the public administration decision-makers to a more comprehensive use of APM in its future projects. First, however, suppliers from the ICT sector should try to gain trust through reliable indication that they had found a method to bend the rules without breaking them and that they can abide by them through co-implementation of IT projects in public administration entities.

Agile methods require such skills from project participants as: self-organization of teams, undertaking of group commitments and decisions, self-reliance, creativity and courage. These are elements of organizational culture, and not just project culture. The use of agile approach to project management in organizations from different sectors should also involve this aspect.

This paper is written from the perspective of the public and ICT sectors in Poland.

The comparison of traditional and agile project management in these sectors in Poland is based on the following criteria:

- legal consideration related to conducting of projects,
- approach to change and risk servicing,
- organizational and decision-making culture,
- project financing method,
- maturity in project management.

The public sector implemented from the private sector a form of management through the development of projects. Evaluation of the use of TPM and APM approach in Polish public administration entities was preceded by analysis of the most important legal acts [12]-[15]-[20] in this respect and positioning of our country in acknowledged European research within *eGovernment Benchmark Measurement* from the years 2004-2014 [21]-[22]-[23]-[24]-[25]-[26]-[31]-[32]-[33].

Opinions on the use of agile and traditional approach in IT project management was based on analysis of CHAOS reports [13]-[18]-[19] and conclusions from the research carried out by K. Jasińska and T. Szapiro [28]-[29] on the factors of success in project implementation processes management among Polish enterprises from the ICT sector.

## II. TRADITIONAL VERSUS AGILE PROJECT MANAGEMENT

R. Wysocki [16] singles out the following methods of project management:

- Traditional Project Management (TPM),
- Adaptive Project Framework (APF),
- Extreme project management (XPM).

The method allocation criterion is the basis for project implementation. And so in TPM such basis is a strictly defined plan. In APF the implementation is based on an earlier analysis and defining of the project structure. XPM – otherwise referred to as management in extreme conditions – is based on the principle of a fast response to ongoing changes and appropriate facing of complex, unplanned situations.

The project approach to changes appeared in public administration in Poland quite recently, so its modifications may seem unnecessary to some decision-makers. However, new proposals have already appeared on how to increase the efficiency and effectiveness of project management, therefore the earlier approach is referred to as the traditional project management, whereas the newer one – the agile project management (APM).

Both the TPM and the APM are focused on the golden triangle (also referred to as the main triad [8]) of the project management. This is an equilateral triangle whose sides are the following parameters:

- the project operations range (resulting from the project objective),
- cost (budget which is the project financial restriction),
- time (the time framework of the project implementation).

These parameters, which at the same time are the project’s main determinants, are the most important factors decisive of the success of the measure under implementation.

Assumed as a resultant of all the three parameters is the quality of the implemented project for which the project manager is responsible. It is his task to constantly monitor and improve the activities related to the project’s key parameters. Each appearance of deviations from assumed arrangements or even the risk of such deviations is reported to the project sponsor who may decide that it is legitimate to start introducing remedial plans.

The critical factors of the project’s success are strictly inter-related, they condition each other and determine the project implementation path and decide about the risk in a given project. Modification of the factors rests only with the project sponsor, and the relations between the parameters in case of such modifications should be as follows:

- lowering of the costs of the project – reducing the range of the project,
- abbreviation of the project implementation time – raising the costs of the project or/and decreasing the range of the project,
- increasing the range of the project – increasing the costs of the project and lengthening the project implementation time.

As early as at the stage of determining the project concept, the first requirements as to the project key parameters should be agreed between the sponsor and manager of the project. Furthermore, their priorities should be determined as early as possible. Such priorities indicate which of the factors may be subjected to more changes and which should rather remain unchanged. Therefore, the factors should be balanced together, because all unbalanced proposals of the project limitations cause a risk that the measure will not be performed at the set time, cost or range.

At the TPM the project manager does his best to determine, describe and „freeze" the project range so as to base on it the determination of the project time and budget. He carries out laborious analyses at the beginning in order to prepare a detailed plan and avoid as many changes in the future as possible.

When the change is unavoidable, it is subject to analysis and once approved the changed elements are added to the project range. This usually leads to extension of the implementation time and increase in the project budget.

At the APM the time and costs are considered to be constant parameters, whereas management is aimed at an appropriate adjustment of the range to the current situation. Simultaneous creation of the best possible conditions for the work performance yields very good effects and increases the teams' creativity on both the business and technical side.

The project implementing team's expectations differ from those of the future user. Contractors aim at the compliance with agreed parameters of the project, to the extent consistent with the specification. The user represents a different point of view. He expects the actual use of the created and implemented SI which will effectively support the organization's basic activity, pursuant to both identified and unspecified needs.

The project management involves also activities connected with the best use of available resources. The primary resource are the people, other resources are various tools, equipment or premises. Competent organization of the people's work, methods of motivating to everyday productivity is an important element of the project implementation and constitutes an indispensable condition of maintained consistency with the basic parameters of the project.

APM as compared to TPM is more similar to the not quite perfect human nature, because it follows the principle: „ Do not change people. Change systems". This is one of the greatest „soft" differences between the traditional project management and agile project management. In APM the so called time boxes were used, i.e. constant segments of time, in the form of sprints covering the periods from 1 to 4 weeks. The determined length of the sprint must not change even by one hour. This was meant to avoid the syndrome of the student who performs his tasks at the very end in situations when the objective is considerably remote. On the contrary: in APM the objective is close and precisely determined in time, while as the sprint's effect the ready-to-use value arises.

Truly enough, there were attempts to use similar mechanisms in TPM, such as for instance the division of the project life cycle into phases. But completion of a phase at a strictly determined time is not perceived restrictively [36].

In the traditional approach the push concept is used, whereas in the agile concept – the pull concept is used. In push the tasks are allocated to the contractors well in advance. In pull – to the contrary – the sprint tasks are selected by a self-organized team whose individual members may use their preferable method of implementation. This is an element which significantly contributes to the contractor's higher commitment. The team does what is most important in a given moment of the project for the client's best possible results. Every short sprint is a consequence of the following steps: planning, implementation, survey of effects and retrospection consisting in collection of the so far acquired experiences. This is motivated by the idea of faster learning and adaptation to new situations in result of better working conditions and increased involvement and creativity of the team.

The TPM and APM approaches perceive the risks to the project differently. For the traditional management the highest risk is exceeding the planned date of the project completion, while for agile management – the lack of involvement of the business party. Every sprint is planned with the Product Owner (PO) who is a business representative. PO must know exactly what is most important during planning of a concrete sprint at a given moment of the project and share such information with the team. An adverse aspect of the fact that the PO may make plans in short segments of time is an unexpected lack of PO, because then the team cannot continue its work. What is positive is that he may introduce changes appropriate to the current situation in the project environment [27].

There is a great difference between the two approaches in the project objective. In APM the project objective is not its termination on time and within the planned budget but what matters most is the product and its development. The point of view in this approach is oriented to execution of the product, and not the project itself. This is particularly important when a change characterized by a high innovation is planned [7].

The project team in APM consists of the same roles, apart from the project manager whose competencies were assigned to the PO. All roles have one objective, which is the project product that will „enrapture" the client. PO draws up a list – arranged according to the business value - of functionalities necessary for implementation of the product or functioning of the service, which is referred to as the backlog. The lower the position of a given functionality on the list, the lower its value and accuracy of description.

A complete backlog is delivered to the project's team's meeting at which the sprint is planned. The team is servicing only that segment of functionality from the backlog which it is capable to perform within one sprint.

On the other hand there is a stepwise implementation of the sprint which ends in acquisition of active single functionality (or functionalities) (it is not yet the whole product – e.g. SI because of the lack of other functionalities contained in the backlog) whose activity may be checked by the PO. At the same time PO is capable to recognize and prepare the next required functionalities. In the last step of the sprint – retrospection the team discusses its activities and the process and selects and can estimate the most important elements which might be improved in the next sprint[2]. With each consecutive retrospection the team empirically knows better and better the pace of its work and is able to estimate with a higher accuracy the time needed for implementation of the functionalities remaining still in the backlog.

The product owner has the right to introduce changes in the backlog according to the rule of choosing the required and most needed functionalities for the client, which may be accomplished within the fixed time and budget. The PO may also take a decision to withhold implementation of the effects of several sprints till the moment of creating a set of functionalities which are important for the client.

In each consecutive sprint the consecutive functionalities of the product are performed or those performed earlier are changed according to the feedback information from stakeholders. Such a mode of work requires a lot of commitment from the PO during continuous updating of the backlog and when work is allocated to the team. The backlog updating moment is very important because it is exactly at that time that the product owner may consider the product to be good enough so that there is no need to develop it any further. The PO may also give up the least important functionalities of the product to replace them with other functionalities, even such which initially were omitted in the backlog.

## III. Traditional and Agile Project Management in Public Sector

All public projects in Poland may be established owing to the *The act on informatization of entities performing public tasks* (UINF) [20], but they are also subject to the *Public Procurement Law* [12] hereinafter referred to as the UPZP. Most of the limitations and difficulties in project implementation result from the entries of that particular act.

Project implementation according to one of agile methodologies assumes the lack of precise specification of the final product parameters. Public administration institutions are obliged by the act of the Public Procurement Law [12] to specify in detail the subject of procurement (at SIWZ) prior to selection of the contractor.

It is impossible to determine complete functionality of the solution at the beginning of the project. However, no matter which approach to the project management is applied, we should absolutely specify precisely the key assumptions and parameters. It is of utmost importance to specify the project purpose in a measurable way which allows to check if it is achievable. To put it generally, we should specify as precisely as possible what has to be done, how it will be checked, if it is implemented, and then to offer relatively much freedom as to how it should be accomplished. Public projects at the very start demand a very detailed description of the solution, thereby making it difficult to introduce subsequent changes.

For the choice of the contractors of the largest public projects in Poland the same criterion is used, i.e. the criterion of experience and knowledge, as is the case with less complicated works. Success in every project depends not so much on technical skills, but rather on the offerer' skills within the project management. Meanwhile, the national public procurement law demands specification of the procurement subject according to European, Polish or international standards, but does not require any description of offerers' qualifications within the project management. This creates quite a high probability of choosing a company which will not cope with implementation of a huge project or will cause selecting a foreign contractor who does not know Polish conditions.

The more and more prevalent (irrespective of the UPZP entries) requirement that the project managers have certificates confirming their management qualifications meeting the PMI or PRINCE2® standards is insufficient. Legal sanctioning of such a requirement would not quite solve the problem either, because the project manager may undertake activities exclusively within the procedures of the public administration entity for which he works.

A severe problem connected with the UPZP is that the Terms of Reference (SIWZ) do not include the risks which may occur during implementation of a given project. The lack of if only preliminary estimation of the risks by the public sector contracting authority deprives the potential contractors from the ICT sector the important knowledge about the realities of implementation of a future project.

SIWZ should be supplemented not only with a list of risks to which the project is exposed, but also with indication for which of them the responsibility rests with the contracting authority, for which – with the contractor, and for which both participants of the project process are responsible. Exclusively the contractor should be held responsible for the risks connected with direct project management, including those resulting from cooperation

[2] Improvement - in a consecutive sprint – of the most important elements from the previous one is referred to as implementation of the Lessons Learned.

with sub-providers. The list of risks included in the SIWZ by the contracting authority would be specified by the contractor within the submitted bid. The contractor would be also obliged to estimate the consequences of all identified risks for the budget and schedule of works. Leaving the risk servicing almost exclusively on the contractor's side will probably make the offerers try and include their cost in the price they suggest. The cost of risk servicing should constitute a separated part of the bid's budget, to be launched at the moment a given risk occurs [7].

The use of agile approach to management of IT projects implemented in public sector is also exposed to difficulties caused by the principles of the provider selection and cooperation with him and also evaluation of the extent to which he managed to implement the project.

Presently, due to legal limitations, the complete departure from the cascade model of public IT projects implementation is impossible.

In the ICT sector we deal with clients, while in the public sector – with applicants or tax-payers. Contrary to the clients, the tax-payers have no choice and may not go to another provider when the product does not meet their expectations [3]. Consequently, the market pressure on improvement of public services is insignificant.

Introducing of project management into the public sector in Poland enables informatization of this sector, but first of all causes the development of eGgovernment, i.e. administration providing services electronically.

Analysis of the Polish eGovernment position in the research within the *eGovernment Measurement* [21]-[22]-[23]-[24]-[25]-[26]-[33] covering the years 2004-2013 (Table I and Table II) points to extensive backwardness of the public sector in Poland, as compared to other countries. This problem may be solved by effective management of IT projects financed with the EU support.

Successful IT project management in public sector is currently very important because more and more EU funds are obtained. It should be underlined, that not only the amount of EU funding is a measure of the beneficiaries success but the issues of effective project management ought to be the area of greatest engagement of executive management.

Before 2013 Poland participated six times in the *eGovernment Benchmark Measurement* [33]-[38]. For the first three years our country had one of the last positions on ranking lists, both in respect of the index of complete availability on-line of 20 basic public services and index of their maturity (Table I).

The last but one report on public services online has subtitle *Đigital by Default or by Detour* [26]. It states that public services must be designed and delivered not in administration-centric but in a customer-centric manner. The new benchmark framework was used in order to aligned it with the policy priorities of *the Digital Agenda for Europe* [31] and the current *eGgovernment Action Plan* (AP). One of four priorities of AP is „results driven government". „The results are based on a survey sample of more than 28 000 internet-using respondents in 32 countries who were questioned for this study" [26] and were named EU-27+.

TABLE I.
20 COMMON PUBLIC SERVICES IN POLAND IN RANKINGS
OF E-GOVERNMENT AUTHORIZED BY THE EC

| **The year when the report was prepared** | **Poland's position in view of full online availability of services** | **Poland's position with regard to services maturity** | **Number of states participating in the study** |
|---|---|---|---|
| 2004 | 26 | 27 | 28 |
| 2006 | 25 | 26 | 28 |
| 2007 | 30 | 30 | 31 |
| 2009 | 25 | 24 | 31 |
| 2010 | 19 | 20 | 32 |

„Results driven government" evaluates the efficiency and effectiveness of government on the basics of synthetic indicate *Effective Government* (which building is presented in Table II; counted according to formula: *Effective Government* = average of *(eGovernment efficiency* and *eGovernment impact)* * percent of eGovernment users scaled on 100). Value of this indicator shows the extent to which governments succeed in satisfying their online users.

The synthetic indicator *eGovernment efficiency* is an average of e-government users satisfaction and fulfillment of expectation. While *eGovernment impact* is average of *Likelihood of re-use* and agreement with *Perceived benefits.*

TABLE II.
INDICATORS BUILDING THE EFFECTIVE GOVERNMENT BENCHMARK
AND VALUES OF ITS COMPONENTS
FOR POLAND VERSUS EU-27+

| **EFFECTIVE GOVERNMENT – Poland / EU-27+**<br>**EFFECTIVE GOVERNMENT – 18% / 26%** | | | |
|---|---|---|---|
| **eGovernment efficiency** – Poland / EU 27+<br>**eGovernment efficiency** – 39% / 40% | | **eGovernment impact** – Poland / EU 27+<br>**eGovernment impact** – 64% / 71% | |
| **User Satisfaction – Poland / EU-27+** | **Fulfillment of expectations Poland / EU-27+** | **Likelihood of re-use Poland / EU-27+** | **Perceived benefits Poland / EU-27+** |
| Top level satisfaction scores (8-9-10) across 19 life situations | % „better" and „much better than expected" | % „likely" and „very likely" to re-use | % „agree" and "strongly agree" with 8 perceived benefits" |
| 37% / 38% | 42% / 41% | 83% / 86% | 45% / 56% |

The latest report from this series (subtitled *Future-proofing eGovernment for a Digital Single Market*) [31]-[32] accesses the state-of–play of the implementation of digital services in 33 European countries (including all countries of the EU, Iceland, Norway, Serbia, Switzerland and Turkey) who were named EU-28+.

A two-step clustering study has been carried out to place the performance of individual countries in the national context of exogenous factors such as eGoverment demand or the environment.

The first step of this study makes it possible to determine eGovernment maturity within countries and to identify different clusters of countries with similar eGovernment maturity performance. Five clusters have been identified: neophytes, high potential, progressive, builders and mature. Poland together with Austria, Germany, Bulgaria, Czech Republic, Italy, Latvia and Slovenia were qualified for the progressive cluster. Countries in this cluster have been working on a digital approach, but there are some factors that constrain full distribution of satisfying eGovernment services and the progressive cluster should focus on removing those barriers. Policies and innovation plans in countries from this cluster should specifically address and support deployment of a citizen - centric approach to further increase use of eGovernment services.

In the second step is taken into account that eGovernment maturity is affected by different variables. At the same time, undertaking an eGovernment project could have different meanings in different countries. Therefore, it is important to understand the impact of the national context on performance. Five groups of countries with a similar context are identified, based on the values of the context variables which were defined per country (eGovernment supply, eGovernment demand and environment).

Having categorised countries in terms of both absolute performance and their relative context, it is possible to analyze peers. The cross-analysis puts the individual performance of a country in its context. The purpose of mapping absolute performance clusters with clusters of countries with a similar context is to compare peers and to identify specific policy recommendations for each country that could support policy makers in moving forward. Although the background (e.g. economic, demographic and institutional factors) of European countries varies, all countries can find good example among their own peers. All contextual groups have at least one country in the well performing high potential, mature, progressive or builders cluster.

Poland was classified as a country of Group 2. Germany, Italy, France, the United Kingdom and Spain were also included in this group. Group 2 is composed of high income countries with the largest populations (and those populations are relatively older), level of education and the take-up of the internet are in line with the EU average. The ICT infrastructure is highly developed but the level of centralisation is low.

Clustering countries by contextual group and performance Poland found at the same cluster as Denmark and Italy (our peers). Policy recommendations received by our country are following: „Compared to the benchmark, in Poland context factors that limit digitisation may be the availability of digital skills and the difficulty to coordinate the efforts of the public bodies, although these factors are not likely to jeopardize the effectiveness of an appropriate eGovernment strategy. Similar considerations can be extended to Italy, although Poland may count on higher digital skills level" [31]-[32].

For the public sector entities as clients of the ICT sector enterprises the problems in project implementation are often tantamount to multimillion losses, disturbances in their functioning, and deteriorating their image in the society.

In the EU the public sector bureaucratization is increasing. It seems, however, that in Polish offices the projects will be managed pursuant to the APM principles. This, however, will demand bending the APM rules to one's needs and becoming creative. For example: if a public administration entity is required to conduct documentation related to the process or architecture of the implemented solution, such entity may prepare a video recording of the people creating on a board some graphic models of the system process or architecture. Such video recording is much easier to implement and understand. Actually, it may be also acknowledged as some type of documentation.

In public administration the projects are mostly managed in a traditional way. Effective implementation of projects requires continuous improvements. Even the division of a complex large project into smaller sub-projects while leaving the same budget, scope and general project imposed in advance, may yield the following effects: reduced risk and feedback information loop and encouraging people to extend their competences.

The on-going improvement of the project approach in public sector in Poland directly contributes to a change in public organizations management.

## IV. Traditional and Agile Project Management in ICT Sector

According to ISIC [14], the ICT sector enterprises may conduct production (e.g. production of office machines and computers, wiring and components, production of instruments and devices used for measuring, control, testing, navigation, and for other purposes, except for industrial use) or services (e.g.: telecommunication, services connected with hardware, wholesale of computers and their components and software, electronic and telecommunication devices).

The following types of enterprises may be singled out among the ICT sector enterprises:

- providers of IT devices and (or) software
- providers of IT services (from simple repairs and servicing to solutions in the cloud and professional services),
- software developers,
- distributors – companies specialized in logistics, having preferential price conditions for some goods, reached through framework agreements with selected providers,
- integrators – companies constructing complex solutions and specialized in specific ICT technologies,
- telecommunication operators.

The companies of this sector implement projects without such legal limitations as those identified in the public sector.

Representing the contractor's party in the public project with EU cofinancing, such companies are subject to evaluation carried out by the project financing institution. The criteria used by the European Union during evaluation are: relevance, drawing the project up and its plan, efficiency, effectiveness, impact and sustainability.

The relationships between the ICT sector enterprises are characterized by a high level of cooperation, temporariness and insignificant formalization.

The ICT market is the client's market where the supply of ICT solutions exceeds the demand. The decisive party in the provider-purchaser relation is the client with whom we should continually and mutually modify the project results and adapt to the changing conditions of the project implementation.

The conditions of companies functioning in the ICT sector, where the enterprises are not so significantly limited by legal regulations and often together on the client-provider line search for the best model of cooperation largely predestine this sector organizations to conduct projects with agile approach.

In many enterprises participating in IT projects a view prevails that project implementation is an individual and unique activity, therefore the project management processes are not subject of the process management concern. This view should be verified, especially among the ICT sector enterprises, because the project implementation process is not functioning in the organization alone but is a part of a large system of all its processes.

Although the project itself is an individual and unique undertaking, yet we can distinguish various types of projects in the ICT sector, which constitute groups of undertakings characterized by similar features. In the ICT sector these may be the following groups of projects:

- - information projects – their final products mostly consist in development of software or services related to its development, service and maintenance,
- - IT projects – their final products mostly refer to computer hardware or related services,
- - telecommunication projects – their final products are mostly related to the network infrastructure,
- - electronic projects – aimed at the production of electronic devices, therefore they are colloquially called hardware devices,
- - electrotechnical projects – their final products mostly refer to electrotechnical solutions; they are also called low-signal projects; the monitoring network project may serve as such a project,
- - ICT projects – combining all the mentioned categories of projects; they are interdisciplinary but we could hardly indicate a dominant domain in them; corporate network projects may serve as an example here.

Implementation of specific groups of processes bears common features and involves resources with specific competences. Therefore, aiming at standardization of project activities should be a natural aim of every enterprise from the ICT sector oriented towards project implementation. Those enterprises in this sector which would each time start project implementation individually would be ineffective, because in each newly undertaken project they would have to build its implementation structures and acquire new resources. Understanding a project management in ICT sector enterprises as a process, conforms with the concept of B. Lent [9] and additionally analyses project management in the context of operational project activities (e.g. drawing up documentation), supporting (e.g. legal or book-keeping services) and mostly managerial and administrative activities (all activities oriented to harmonization of operational and supporting activities; they include project management). B. Lent differentiates between the project conducting process and the notion of project management itself. He means as the project conducting process the process during which the project is implemented starting from its concept, through planning processes and implementation till its successful completion. Meanwhile, the notion of project management itself refers to single processes of the project of the type of activities following a cyclical pattern of measures.

The project implementation process involves additional input and output processes connected with new projects and their course after formal closure. These activities are strongly connected with the specificity of the project implementing enterprise.

Management of project implementation processes with reference to processes going on in the ICT sector enterprise requires a favorable internal environment in which the project and process activities integration is of key importance.

Perception of project management in ICT sector enterprises as a process increases the possibilities of enterprises of arranging repeatable elements of project implementation into systematized standards which form schemata ready for multiple use. Consequently, a project implementation process arises, which on the one hand enables carrying out unique projects, on the other hand it may be improved as any other repeatable process in the enterprise [29].

The studies carried out so far on the key factors of ICT project success are important, because they allowed not only for specification of the factors of success, but they were also an attempt of identification of implementation problems and searching for methods to limit or eliminate them.

As statistics of ICT projects failures, in Poland and elsewhere in the world, usually quoted are the research results of the Standish Group (tSG). The data presented by tSG should be interpreted with reference to established criteria of the project success. The Standish Group defines project success as on time, on budget, and with all features and functions as initially specified.

Observation of changes occurring on lists of key factors of ICT projects success allows to state that systematically growing is the importance of such factors as agile management processes and activities aimed at optimization of project operations.

Agile projects are successful three times more often than non-agile projects, according to the 2011 CHAOS report from the Standish Group. Exactly the report states that: “The agile process is the universal remedy for software development project failure. Software applications developed through the agile process have three times the success rate of the traditional waterfall method and a much lower percentage of time and cost overruns” [18]. Moreover, they do not report how many projects are in their database but say that the results are from projects conducted from 2002 through 2010.

When plans are established in the initial phase of the project, there is a need to increase the control processes which verify the consistency of the plan with actual requirements of the project at a given moment of implementation. This increases formalization which in turn absorbs time and budget. The complete departure from traditional planning is impossible and encumbered with a high risk of implementing the project ad hoc – only through responding to the ensuing events.

A higher flexibility in implementation of ICT projects expresses increased interest in the agile project management approach. Agile project management is presently treated as one of the most important ways of reducing the formalization and eliminating the difficulties with preliminary planning in projects.

In the latest tSG report of 2014 [19] the IT projects were classified into three types:

- successful projects,
- challenged projects (such projects are completed and operational but exceeded the funding package and time and offer fewer functions than planned),
- cancelled projects (at a certain moment during the development cycle).

The Standish Group further segmented successful, challenged and cancelled projects by large (any company with greater than 500 million dollars in revenue per year), medium (defined as having 200 to 500 million in yearly revenue) and small companies (from 100 to 200 million dollars).

Generally, on the part of the successfully completed projects the average reaches only 16.2% for IT projects completed on time and within the funding package (in smaller companies in total in 78.4% software projects at least 74.2% of their planned features and functions will be implemented, while in bigger companies only 9% of their projects are provided on time and within the funding package) [19]. The detailed data of such cross-analysis are presented in Table III.

TABLE III.
SUCCESSFUL, CHALLENGED AND CANCELLED PROJECTS BY LARGE, MEDIUM AND SMALL COMPANIES

| TYPES OF PROJECTS / TYPES OF COMPANIES | Large | Medium | Small |
|---|---|---|---|
| **Successful** – 16.2% | 9.0% | 16.2% | 28.0% |
| **Challenged** – 52.7% | 61.5% | 46.7% | 50.4% |
| **Cancelled** – 31.1% | 29.5% | 37.1% | 21.6% |

The three major reasons that a project will succeed are: user involvement (15.9% of responses), executive management support (13.9%), and clear statement of requirements (13.0%).

Software professionals from ICT sector are getting more and more knowledgeable about agile development and are now scaling it more broadly within their organizations, as compared to what officials could do [17].

The results of the studies carried out by K. Jasińska [28]-[29] among the Polish ICT sector enterprises indicate that the most significant limitation of ICT project implementation was the company’s internal organization maladjusted to project implementation. To identify the organization’s elements which generate the highest implementation difficulties, subjected to analysis was the area of processes, organizational structures and project management methods used in enterprises.

The highest percentage (92%) of respondents among those using the organization processes or their elements for ICT project implementation, used processes of planning the solution and sale and marketing. The fewest respondents (14%) used the technology development process, which may be associated with a limited need to develop technologies during the ICT project implementation. The processes with inherent most significant limitations in the decreasing order: processes of designing the solution, sale and marketing, implementation of the solution at the client and company management.

In the planning process most prevalent were the problems associated with the lack of knowledge about the client's needs, purposeful reduction of the scope, costs and time limits, and insufficient integration.

In the process of production and sale most errors were associated with the lack of support for selling activities, improper project qualification, and taking the selling decisions by managers without suitable consulting the project team.

On the other hand, in the company management process most errors resulted from conflicts between the project and formal structures, maladjustment of the project management methods to the specificity of implemented projects and communication problems.

In the organizational structures area of research the highest appraisal was granted to the linear-staff structure as such which to the highest extent supports the ICT project implementation, whereas the lowest appraisal was that of the linear implementation of projects with functional isolation.

Within the project management methods use in the ICT sector enterprises in Poland it was found out that the most often used methods were: the Project Management Institute, and next - PRINCE2®.

The enterprises of the highest project maturity [34] are the integrators (level 4 according to H. Kerzner model [35]), and the lowest – telecommunication operators (level 1).

The results of the studies [28]-[29] connected with the critical factors of successful project and difficulties in project implementation in ICT enterprises in Poland are similar to those connected with failures of IT projects obtained by tSG and do not differ from the average results obtained by other organizations (the OASIG Survey, The Robbins-Gioia Survey or The Conference Bard Survey). This enables to use the results of the studies on IT project management, carried out by large organizations specialized in this area, in Polish ICT sector enterprises, to increase the efficiency of project implementation using the APM or TPM approach, depending on their effectiveness in implementation conditions of a specific project and conditions of the sector from which the client and provider come.

## V. CONCLUSION

The development of project management seems to reflect evolution of management as a whole. Such development started from hard aspects in conducting of projects and aims at inclusion of more and more soft psychosocial aspects at the end of the 20th and the beginning of the 21st century. The development of an appropriate system of elements of hard and soft projecting largely depends on the project manager and the team he created.

The project management is a new approach in management, whose pillar has always been information but now it is also knowledge [8]. The most effective approach to project management is the project-resources approach which involves both the resources of information and the resources of the knowledge of the project-launching organization, furthermore – the intellectual capital is worked out owing to the people who use appropriate tools to accomplish specific project processes.

The greatest benefit of agile project management, as compared to the traditional management, is an increase in the risk management quality within the project. The agile – iterative approach allows to follow the project progress with a very high accuracy and gives a possibility to react in advance in case of risks of exceeding the budget, delays in implementation or supplying a solution the functionality of which differs from that expected by the client. Advance active response to risks finally translates into benefits in various areas of the project.

Many failures related to implementation of projects (especially large projects) in public sector point to the need for a profound reconstruction of the Public Procurement Office (UZP). For the largest projects, e.g. nationwide information projects, separate terms of their commissioning and implementation should be introduced. The criterion which qualifies a given measure to the group of large projects could be e.g. the preliminary estimation of the budget of works. It should not be important whether the budget of such a project amounts to 350 or 700 million PLN; what should matter is determination of specific valuating thresholds which would be the decisive factors as to whether a given project may be included into the cluster of large projects.

The Public Procurement Office (UZP) as a central institution most directly connected with implementation of public projects should first of all determine the projects management standards[3] as well as the ways of evaluating the contractors competencies (at best according to the project maturity models), and also supervise their subsequent use, at least in the largest projects. Actually, it is not important which of the internationally recognized standards (PMBOK® or PRINCE2®) and maturity models - Capability Maturity Model Integration® (CMMI) or Organizational Project Management Maturity Model® (OPM3) [34]-[35] will be selected as obligatory on the

[3] In Great Britain even the Highways Agency which is a counterpart of the Polish General Directorate of National Roads and Highways, and not of a higher level such as the UZP, cares about the level of project management and issues recommendations for the projects of highways construction.

Polish market, because they all performed well in the project implementation practice. Perhaps the UZP will be assisted by the International Organization for Standardization (ISO) which in September 2012 issued a new standard of project management, marked as ISO 21500[4].

The Public Procurement Law should also allow to specify the scope of works during the project implementation. The cooperation between the employer and contractor at a change of the scope of works would then express a partnership approach to project implementation. Such form of cooperation between the employer from the public sector and the contractor from the IT branch is more and more popular in Hong Kong, Great Britain and the USA.

There are several differences between TPM and APM. The greatest methodological difference between the traditional ad agile project management is the approach to the project management golden triangle. Information about other differences may be obtained directly from Manifest Agile [4]. These are, for example, the following values put above other in agile project management:

- „Response to changes above following the plan",
- „People and interactions above processes and tools",
- „Cooperation with the client above formal decisions",
- „Software over extensive documentation".

Statistically [13]-[17] the project implementation in the APM model in most cases lasts from 4 to 5 times shorter, as compared to the TPM model. This mainly results from the fact the APM is used to form the most important functionalities, whereas other functionalities are skipped, which decreases the range of the project. Efficiency of work at the team's level is increased by approx. 200-300%, similarly to the probability of success. Efficiency at the team's level grows, because each member of the team may have an individual impact on the product development and soon sees the effects of his work, but at the same time the whole team works for one common objective.

The *8$^{th}$ Annual State of Agile$^{TM}$ Survey* [17] emphasizes that agile project management gives the client who orders the IT solution the following benefits:

- he has a high freedom within introducing changes and adjusting his requirements to the changing business environment,
- the investment may bring profits as early as during the project implementation,
- comprehensive outlook on the project – not only during its implementation but also during its subsequent maintenance,
- relatively low costs of the project maintenance due to a respectively high quality,
- the work performance concept which is flexible and prone to changes (the provider continually aims at creating a product ready for the fastest possible use),
- better concept on the client-provider line, which enables the provider a possibility of actual involvement through searching for more advantageous solutions, reporting one's own suggestions, sharing one's specialized knowledge and using it for the client's activities optimization.

Owing to agile project management, both the client and the provider are less trustful and want to achieve success together. The final result of the project depends largely on how much the parties trust each other, and therefore – cooperate with each other.

The traditional project management may in turn lead to the situation in which the client and provider are less trustful towards each other, while every change and not quite specified requirements are perceived as an obstacle.

Educating the clients within social cooperation on the contracting authority line is inscribed into the Agile principles. In practice, the ICT sector contractors help the public sector clients in the process of acquiring experience and understanding their role in the project. The exemplary support forms may be as follows:

- training courses organized by the provider personally or by external consultants,
- close cooperation of leaders in the role of the Scrum Master on the provider's side with the Product Owner on the client's side,
- supporting the Product Owner by the Proxy's role on the provider's side.

**Abstract**–***Steadily increasing complexity of software systems makes them difficult to configure and use without special IT knowledge. One of the solutions is to improve software systems making them "smarter", i.e. to supplement software systems with features of self-management, at least partially. This paper describes several software components known as smart technologies, which facilitate software use and maintenance. As to date smart technologies incorporate version updating, execution environment testing, self-testing, runtime verification and business process execution. The proposed approach has been successfully applied in several software projects.***

***Keywords-Autonomic computing, smart technologies, self-managing systems, software maintenance***

## I. Introduction

Rapid development of information technologies has created systems of unprecedented complexity; some authors [1] refer to as „computing systems with complexity approaching boundaries of human ability". They indicate that the ultimate dream of a pervasive computing – billions of computing systems simultaneously connected to the internet – can quickly become unmanageable and may soon turn into evil "nightmare". The authors predict even further increase of information systems' complexity that would almost eliminate human ability to perform software installation, configuration, optimization and maintenance.

Solution to this problem certainly lies within prospects of information technologies. In complex systems operations that are too sophisticated to be managed by a regular user should be entrusted to the system itself. This can be executed by implementing respective components into software and setting environment, in which the system is used.

IBM has proposed a solution described in its autonomic computing manifesto in 2001. The main statement implies targeted development of information systems that were able to self-management thus overcoming gap between users and increasingly complex world of information technologies.

The manifesto listed four aspects of autonomic computing:

- Self-configuration - automated configuration of components and systems follows high-level policies, rest of system adjusts automatically and seamlessly;
- Self-optimization - components and systems continually seek opportunities to improve their own performance and efficiency;
- Self-healing - system automatically detects, diagnoses, and repairs localized software and hardware problems;
- Self-protection - system automatically defends against malicious attacks or cascading failures.

Achievements of autonomic computing movement during its first decade after publication of the manifesto have been explicitly demonstrated in [2], as well as in [3]. As of now, manifesto's targets have been met only to some extent.

The concept of smart technologies was created by authors [4], and its main objectives are similar to those of autonomic computing. The approach contains a set of practically applicable improvements of non-functional features to simplify the maintenance and daily use of information systems. Below are described five types of smart technologies, which need was identified in real software development projects. The proposed smart technologies cover only part of requirements outlined in the autonomic computing manifesto. Nevertheless they are suitable for practical implementations and can serve as valuable improvement of new and existing software systems.

The second chapter of this paper deals with related research and solutions. The third chapter describes the proposed architecture of smart technologies.

## II. Related works

The autonomic computing manifesto declares a vision of fully independent computer systems (not just software) that are able to self-management. It also defines evaluation criteria to check the maturity of autonomic systems [5] - from basic level (manually maintainable information systems) to completely autonomic systems that are able to function operate accordingly to guidelines set by humans.

The manifesto does not include any instructions about implementation issues, but some authors discuss ideas about essential components of autonomic systems. For instance R. Sterritt [6] describes an autonomic environment consisting of autonomic elements, which are mutually connected via

The research leading to these results has received funding from the research project "Information and Communication Technology Competence Center" of EU Structural funds, contract nr. L-KC-11-0003 signed between ICT Competence Centre and Investment and Development Agency of Latvia, Research No. 1.5 "Platform for business process description and modelling in event-oriented systems".

978-83-60810-66-8/$25.00©2015, IEEE

autonomous channels. Every autonomic element has a kernel, so called manageable component (the component implementing the business logic), and it is controlled by an "autonomous supervisor". The supervising component uses sensors and effectors, and its main functions are monitoring of internal and external states, accumulation of knowledge base and communication with other autonomic components using autonomous communication channels. A separate component in this system is so-called "heartbeat monitor" which communicates with any existing system components through autonomous communication channels and supervises the system as a whole.

The autonomic computing approach has also been criticized [7], and the main reasons are as follows:

- the lack of precise definitions;
- avoidance of the real complexity of the problem;
- ignoring of inter-componential links.

Despite these criticisms, autonomic system objectives are so attractive that there seemed to be no reason to abandon the ideas. In 2003 IBM extended the list of autonomic aspects to eight characteristic aspects [1]. The initial autonomic characteristics were enhanced by system's ability to "know itself" and manage its resources in a proper way. An autonomic system should know its environment as well as the context surrounding its activity and act accordingly – to adjust and operate in heterogeneous environment accordingly open standards - , as well as anticipate the optimized resources needed while keeping its complexity hidden. Some years later the, so called, self-management features were supplemented with new self-properties reaching a total of 24 features [3]. Continuing efforts on autonomic systems include both, theoretical research and practical implementation [2].

The concept of smart technologies created by authors [4] is consistent with the primary objective of autonomic computing. Unlike the traditional implementation of autonomic computing where universal autonomous software components are built, the smart technologies approach deals with embedding of specific system features into information systems directly but in a uniform way.

Although the smart technologies approach and the autonomic computing approach seemingly share some similarities, it should be emphasized that the smart technologies approach was developed independently. The practical results gained in IT projects provide evidence of the usefulness of the approach.

## III. Components of Smart Technologies

There are five fields of smart technologies where practical results were gained: embedded software versioning and data syncing, embedded dynamic business model, testing of external environment, self-testing, and runtime verification.

### A. Software Versioning and Data Syncing

Every successful software solution is being used and improved significantly longer than the development of its first version has taken. Information systems are in use for many years, and the software is gradually modified, updated with new features, improved to approximate to user needs.

To ensure reliability of software in long-term, the system should already in its initial development time include not only the required (customer specified) functionality, but also supporting mechanism – "updater" (see Fig. 1) for software, data structures and templates upgrading.

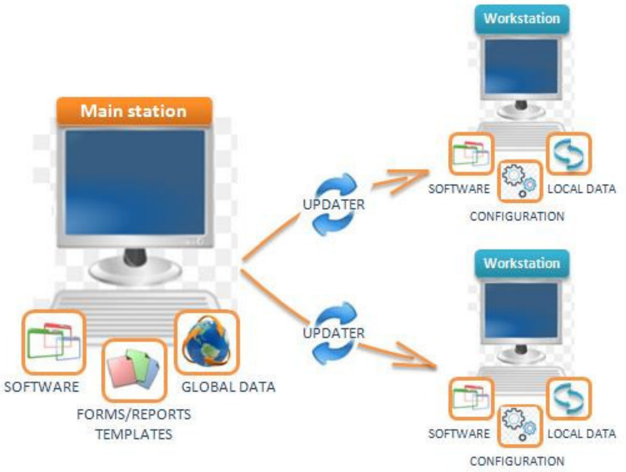

Fig. 1 Software versioning

The supporting mechanisms should be built into systems, and they should include features for deploying of new versions without any user intervention. The following should be ensured automatically during deployment process:

- check the compliance of the new software version with the external environment
- download and install a new software version
- update configuration and information about data structures, screen forms, report templates etc.
- migrate stored data into the new data structures of the database as well as the personalization and configuration data
- perform self-testing of the new system's version to check correctness of the essential system's functionality
- create backups to be able to recover the system in case of incidents

The majority of information systems today support some of the characteristics listed above, but in most cases - to a limited extent only. Authors of this paper have prototyped the characteristics in some projects, the research results are described in [8].

### B. Execution environment testing

One of the most spectacular smart technology solutions is described by the authors in [9]. It is quite common that programs have specific requirements for their successful operation at a given environment – the computer, network, operating system, etc. The proposed solution implies gathering these requirements in a "software profile" to be able to validate the execution environment before starting the information system. Such validation should be performed on demand, for instance, before each session; however, some authors propose validation during installation. Validation of execution environment allows avoiding failure in business processes in case the information system relies on properties of the environment.

Quite often, software is developed based on assumptions about other component's work, not on their specification [10], [11]. Similarly, developers sometimes assume that software, which works in development environment, will keep working after it is deployed elsewhere, hence encoding some assumptions about the environment into the program. As a result, when the software is installed in other environment, which is different from the development environment, the software may fail or work only partially correct.

The authors [12] propose a technology, which allows independent environment checks, performed by the software in order to validate if the execution environment is suitable for normal execution (see Fig. 2). Unlike the built-in test method, which validates the ability of software itself to fulfill its "contracts"; this technology measures livability of the external conditions. Only if the results of all checks are satisfactory, the program can be considered prepared for work at a given environment, otherwise the session is stopped, giving the user an explanation, why it is not possible to perform work.

A program execution profile is a document achieved when all the requirement descriptions of software are combined together. The profile can be formalized as a separate document and supplemented to typical software deliverables such as code and documentation. The main, but not the only use of the profile is validation of execution environment during program use.

The practical environment testing task is carried out by environment validation modules. Each module is an atomic unit, which enforces validation of a single type of requirement; this is done by reading information from the environment and comparing it to reference values. In a simple scenario, each requirement describes required value of some resource's attribute (for instance, data base server must be reachable). When the testing functionality of the module is invoked, it uses the information available in execution environment to do the "inspection".

To be able to modify the set of checks to be performed without modifying the program code, information about the checks (both the algorithms and reference values) must be stored outside the code. This concept is different from other approaches used in practice – both from the ones, which validate the environment straightaway after installation or updating, and from the others, which try to "hide" the checks in source code.

To be able to describe requirements regarding execution environment, a formal language is required to encode the requirements, moreover, the language must be extendable, when new kinds of requirements are defined. Such aspect complicates the construction of test coordinator, since it has to be compatible with a language, which is not fully defined during development of coordinator. The problem is solved by assigning the coordinator only the role of language syntax analysis, but the semantic analysis of requirements is performed in environment validation modules.

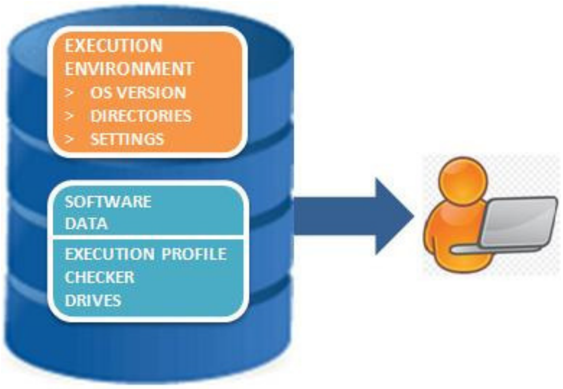

Fig. 2 Execution environment testing

The practical implementation showed that development of the proposed approach requires relatively little programming resources.

## C. Self-testing

The research of the authors [13] offers an original approach to software testing, named as self-testing. Self-testing is a software's ability to test itself automatically prior to operation, and it can be performed even in a productive environment. The self-testing feature in software is similar to hardware self-tests that are executed every time after the device is turned on. Instead of traditional testing that verifies correctness of software in testing environments using testing tools, the self-testing property is built-in software component that executes accumulated test cases using means of the information system. It helps to perform tests not only in testing environment, but also to verify software correctness in action with real data in production environment.

Self-testing contains two main components:

- test cases that are designed for checking of critical functions of the software
- built-in automated testing mechanism providing automatic execution of tests and result comparison with benchmark values.

Designing of test cases covering the critical functionality (lack of these essential functions causes inoperability of the whole system) is a part of requirement analysis.

Implementation mechanism of self-testing approach uses software instrumentation, and it has been offered quite a while ago [14], [15]. The idea is to supplement the source code with extra routines for self-testing purposes that are executed if the software is run in the testing mode. The points in source code where the routines are included are named as test points. Testing routines allow to monitor values of variables and to compare them with benchmark values therefore checking the correctness of the information system. Unfortunately, this solution is usable only for those information systems whose development is in the testers' influence sphere.

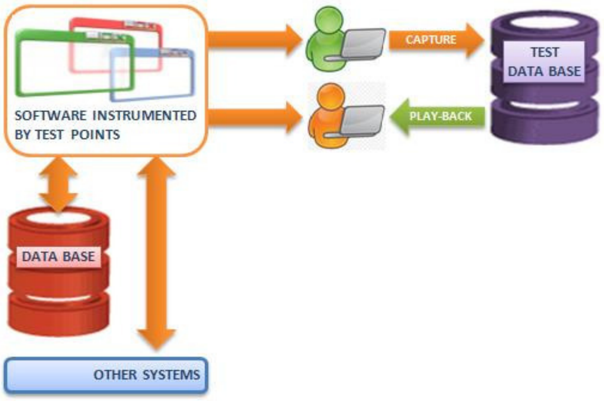

Fig. 3 Self-testing

Self-testing can be used in four modes (see Fig. 3):

1. test-capturing – running of software instrumented by test points and capturing of new test cases into test data base or editing of the existing ones;
2. self-testing – automated self-testing of software by automated execution of the captured test cases;
3. normal usage – running of information system without any testing activities;
4. demo mode – running of information system using pre-captured demo scenarios.

Comparison of self-testing implementations with automated testing tools leads to the following conclusions:

- Unlike the majority of globally recognized testing support tools, the self-testing approach offers some additional options: testing of external interfaces to other information systems and database management systems, testing in production environment, testing with the white-box method, possibility for users without IT knowledge to capture tests.
- The self-testing technology makes possible to test software throughout the whole life cycle of an information system – from early stages of software development till maintenance activities, because it is suitable for testing in all development, testing and production environments.
- The self-testing functionality should be integrated into software already during development of the software.
- The self-testing requires additional work to include the self-testing functionality in the software and to design test cases; on the other hand, self-testing saves time as repeated (regression) testing of the existing functionality is available
- Implementation of the self-testing functionality is useful in incremental life cycle models, in particular if information systems are improved gradually and maintained for many years; it is less useful in linear (waterfall) life cycle models.

Empirical studies show that 60% of information systems' problems would be possible to identify and rectify by self-testing approach [13].

### D. *Embedded business processes*

Development of software engineering tends to devote more attention to precise modelling and designing of information systems instead of extensive programming. Some researchers are even predicting development of information systems without programming at all in very near future. Business process modelling is a compulsory initial phase of every information system development project according to this concept [16].

Workflow based information systems is the area where business process modelling is an essential component for functioning of information systems. Business process of organization is described by a workflow model containing sequential business process steps – activities - together with performers of the activity, deadlines, the actual state of the object in the workflow etc. Documents and reports can also be created during the workflow execution, and this should be included in business process descriptions.

It is common to describe business processes using modelling languages. There can be used universal modelling languages or domain specific languages (DSL). When DSL is chosen, it must ensure two important features: a) the language should be easy understandable for the majority of users, b) it should include all necessary information for automated execution of workflow steps.

The first step in development of information systems is to describe business processes to be supported (see Fig. 4). A set of graphical diagrams are created using DSL, and it serves as business process model. After the model is created the information from the diagrams can be transferred to the database of an information system. The business process descriptions are embedded into the information system, and the engine of the information system can interpret information from the diagrams. Embedded business processes ensure that the information system behaves according to the business process model.

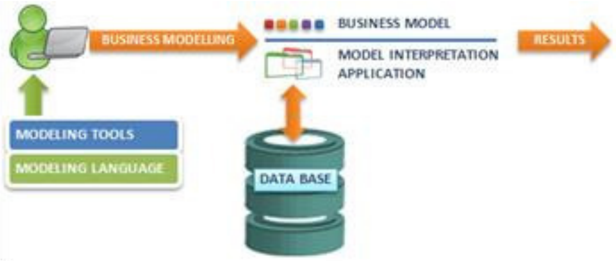

Fig. 4 Embedded business process

As practice shows [17], it is possible to create a special tool for transfer of model's data to executable application relatively quickly. The API of the graphical editor can be used to access the model's repository, to gather the information and to transfer it to applications database. This guaranties that the application operates according to the model developed in a graphical DSL. And the overall quality of the application – usability, reliability, performance etc. – is dependent on the application itself, not on the hypothetical ability of a code generator to create an application in the desired quality.

The authors have created the domain specific language BILINGVA [18] that is convenient for description of workflows. The approach was tested in practice, and particularly surprising was the positive feedback from users about the graphical representation and implementation of business processes. The diagrams served as some kind of information system's user manual that explained functioning of the information system in a more precise and understandable way than the conventional (written) user manuals.

### *E. Business process runtime verification*

From the beginnings of information systems the topical issues were: does the information system operate correctly?, are the system's results adequate?, and is the information system in the correct state in terms of the relevant business? Sometimes processes must be stopped as soon as possible after inadequate situation has occurred, otherwise more serious problems could rise [19].

Inadequate situations can be caused by many conditions. They can be caused by heterogeneous systems, which are developed at different times and used in a variety of companies. Problems can arise due to poor software quality and lack of testing. Problems may also occur due to incorrect user actions: incorrect execution of business functions, a breach of the input restrictions, or the timing and sequence of process steps.

For example, if warehouse system is not updated with payment information from accounting system timely, goods cannot be issued to customer. On the other hand, this situation is unacceptable for the customer, who has done payment according business process. Obviously, in this case there is no reason to look for errors in information system, but a person should monitor that payment data are imported timely. This is basic task of runtime verification – to verify systems execution in their runtime.

The authors [19] propose a solution for business process runtime verification (see Fig. 5). The basic idea of the solution is to run a separate verification process for each controllable business process (further – base process). Verification processes are described in DSL that has been developed in conjunction with the solution. A base process typically is executed by information systems, while verification processes should be executed on the basis of independent and external controlling software (further – a controller). The steps of the verification process are linked to base process steps and are described by events that acknowledge the execution of the each base process step.

Base processes can be executed manually or automatically by computer, and verification processes are executed independently. Each of base process steps makes some changes in the process "memory" (usually stored in database or file system). The verification controller receives acknowledgement from event agents about base process memory modifications, therefore identifying inconsistencies between the received information and the description of the verification process. If inconsistencies are detected, then they are reported to the support staff.

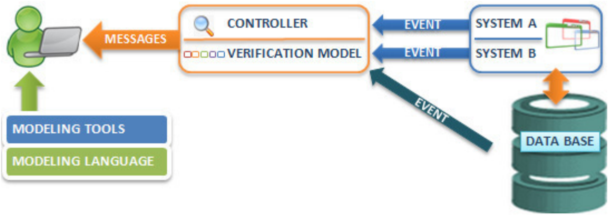

Fig. 5 Runtime verification

The solution provides a number of interesting possibilities, which bring us closer to the goal defined by ideas of autonomous computing:

- runtime verification can be done without modifications of the base process
- process verification can be added dynamically to legacy systems
- verification does not depend on modelling language used for process description, it depends only on possibility of verification agents to identity events of the base process.

Likewise, some solution limitations must be taken into account: verification mechanism can detect only those base process steps which leave some modifications in the systems „memory". Otherwise verification agents cannot work as external process, but must be incorporated into the base process.

However, it must be stressed that the proposed solution can significantly reduce monitoring load of information systems' operational staff. It automates business process runtime verification that typically is done manually and not continuously.

## IV. Conclusion

There were spent several years on research to achieve goals similar to autonomic computing – facilitating the use, maintenance and development of systems by including support components in them. The conclusions are as follows:

- several components, created using smart technologies, can provide good support in use, maintenance and development of information systems which are easy enough to implement for a small/medium size organization;
- there are quite many functions, which could be supported by respective smart technologies, for instance, data quality control, confidentiality control, built-in privacy protection [20], performance monitoring, availability monitoring, selecting environments for software compatibility testing [21], automatic testing of WEB services [22] and others;
- smart technology enabled systems are currently not very common due to the fact that these ideas are not popular enough yet; with increasing complexity of information systems, smart technologies will surely

grow in importance and will help to deal with complex system development and maintenance issues.

*Abstract*— **The paper sets out from a central proposition that the concept of adaptive case management (ACM) bears on the evolution of business decision support and knowledge management in modern businesses. While presenting the state of the art in efforts to blend enterprise resources planning/business process management (ERP/BPM) systems with knowledge management systems (KMS) and decision support systems (DSS), the authors observe that the classical platform combining ERP/BPM with KMS and DSS was based on the interaction of three separate layers/subsystems and that, throughout the past decade, that approach proved satisfactory. However, in the last few years it has been increasingly felt that the approach to business process management and enterprise resource planning, as well as to their integration with knowledge management and decision support, needs to be modified. The dynamic and adaptive nature of some business processes poses challenges that the classical BPM approach cannot adequately address. Adaptive case management has been developed to better cope with such challenges. It makes it, on the one hand, easier to align a business to rapidly changing requirements and conditions, and, on the other, it allows organizations to more effectively exploit the potential inherent in organizational knowledge and information resources. The paper discusses the evolution of KMS and DSS from the perspective of their application in ACM environments.**

## I. The Origins of, and Rationale for, Adaptive Case Management

WHAT has long been demanded of information systems is that they move away from the prevalent control flow perspective, commonly adopted in the BPM area, toward the data perspective[1]. Attempts to meet these expectations have led to the emergence of a new class of information systems built around the approach known as adaptive case management.

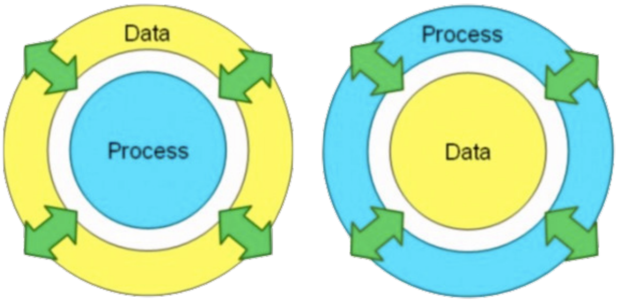

Fig. 1 The classical BPM approach vs. modern ACM.

The term “case” represents a generalization of any activity by so called “knowledge workers”, whose efficiency Peter Drucker sees as a principal challenge of the 21st century [2].

Unlike in classical BPM, under adaptive case management processes are of dynamic character, since they are not defined until at runtime. To master the unpredictability of processes and hence facilitate process management in contexts where processes are mostly complex and where relevant decisions are affected by a large number of factors, more and more organizations choose to switch to adaptive process management systems [3].

ACM allows perfect visibility and full control of each specific case, whether it is handled by a predefined or an ad hoc process, or by a combination of the two.

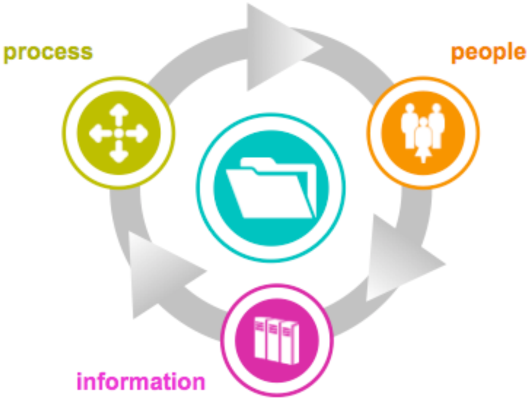

Fig. 2 A typical ACM implementation environment.

This work was not supported by any organization

In a dynamic process management environment, operators/managers, i.e. knowledge workers, can be creative and innovative in performing their work, in that way contributing to organizational knowledge management and creation.

To distinguish the role of process operator from that of temporary process participant, under ACM the former has been redefined and termed as the knowledge worker.
Van der Aalst uses the "blind surgeon" metaphor to illustrate the differences between the two [4]. Under the traditional approach to processes, a participant has a partial view of the whole process, usually limited to the step in the process at which the participant is supposed to make a business decision.

The knowledge worker, on the contrary, has a complete insight into information on the case or process. Knowledge workers constitute a new category of specialized staff whose job is, in the first place, to utilize and exchange knowledge in a productive manner. They are responsible for the generation and implementation of new ideas that enable organizations to align their strategies with the increasingly rapid changes taking place in the business environment; they do so, primarily, through searching, exchanging, combining and utilizing knowledge inside as well as outside the organization.

An enterprise that is run in compliance with the ACM concept will be able to seamlessly combine its core activities with an ability to generate and verify innovations daily [5]. Allowing operators to dynamically modify their processes (and business rules, too), the enterprise management system as a whole opens up to creative initiatives from staff at large, while at the same time preventing chaos that could arise as an outcome of unharnessed changes made to the operating properties. In addition, since it possible to examine the outcomes of changes as they emerge, information on which practices and solutions produce the best results and which yield the worst can be appended to organizational collective knowledge. This stands for actual day-to-day improvement and adaptation of business processes, relying on the best knowledge of a large portion of personnel and getting validated through feedback from customers.

The greatest benefit in deploying dynamic ACM-based business process management is that large enterprises can regain agility and responsiveness that makes them capable of operating and competing in a rapidly changing marketplace. Making it possible to actually delegate work and responsibility to process operators without the risk of losing control of the currently running processes, ACM permits large enterprises to manage their knowledge on an everyday basis through:

- creative, proactive experimenting based on continuous, even if modest, changes, introduced by a number of process operators and leading to gradual accumulation and dissemination of knowledge,
- validation of existing knowledge and elimination of outdated information that no longer meets customers' requirements or competitive challenges.

As a precondition, organizations must be able and ready to adjust their policies and operating properties on an everyday basis as well as to continually update their knowledge on the actual and likely needs of their customers. Adaptive management of business cases is an extension of classical process-based management and an attempt to bring it together with the concept of a learning organization.

One of the cornerstones of ACM is the overarching belief that any organization should continuously expand and process its knowledge on the mechanisms governing its business environment and that this management model is not only more effective but indeed a prerequisite for its ability to keep pace with the unprecedented dynamics of changes in present-day markets and customer expectations. It is often alleged that ACM aims to create a learning organization. Clearly, it streamlines the processes inside an enterprise at several levels, affecting managers as well as personnel.

In course of its business activity, a company creates, accumulates and validates knowledge, which is then used to evaluate and support business decisions. By this token, an ACM system can use business processes in the following ways:

1. As knowledge sources;
2. As a space for organization-wide, innovation-driven knowledge creation and limited experimentation;
3. For knowledge preservation and in database building to bypass the need to set up and operate another system.

## II. The legacy reference architecture

In business practice, the most common enterprise-level system architecture consists in mounting decision support and knowledge management subsystems on top of business process management and enterprise resource planning platforms.

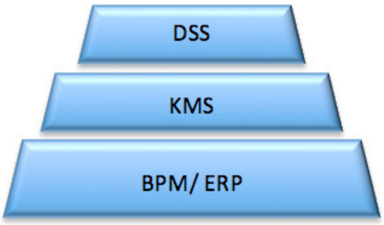

Fig. 3 The classical corporate work platform

Platforms designed in this way would make it possible to use information resources (business rules, workflow mappings, standardized management procedures, etc.) in order to build explicit knowledge and, consequently, develop knowledge management systems and address better support to decision making processes.

This approach involved several problems, the information flow being the fundamental one. Each layer had to be integrated with the others, which required months of analytical and design work focusing on a metadata model enabling the exchange of information between the component layers. For each layer, constituting a subsystem on its own, a specific conception had to be developed for its integration with the other components.

Another feature that users emphasized fairly often was the static mode in which knowledge and decision support were built. Where BPM processes had been defined and designed in advance, the values added by the DSS that the users mentioned the most often were decision process automation (the addition of another layer in the workflow) and instant updates to process flows to keep pace with external regulatory changes. Just like the DSS, beyond the stabilization phase of the underlying BPM/ERP system the knowledge management subsystem did not further contribute to increasing the corporate intellectual potential by expanding its knowledge base.

What users most complained about was that systems so designed were not adaptable enough. Decision support systems perform best in dynamic environments where decisions are complex and the response path cannot be defined in advance. However, in the architectures described above, most decisions are known at a very early stage (the BPM process map pre-defines all options to choose from, leaving no room for dynamic processing and decision making).

The same was, to a large extent, true about organizational knowledge building. In an architecture raised on a static foundation, a knowledge base is built most effectively at initial stages of the system's functioning, i.e. right after it has been put in place, while its subsequent use does not contribute much value to the knowledge base as no new, unique business cases come up.

The paper aims to demonstrate that that the ACM concept can successfully replace the classical approach involving a separate DSS and KMS mounted on top of a static BPM/ERP platform

A. Figure 3 shows architecture composed of three separate layers, which can be considered as the most mature and most tested solution to date.

## III. ACM FROM THE DECISION SUPPORT PERSPECTIVE

Just like the decision making process itself, the decision context and the process context will change dynamically in the course of decision making as the cases are being handled.

From a business perspective, DSS is often regarded as part of ACM. Fischer et al.[6] define the key DSS features as follows:

- developing socio-technical environments that support and empower users to engage in the process of system development not only at design time but also at use time,
- supporting social creativity by providing the technical and social conditions for the exchange of ideas during discussions, debates, brainstorming, co-creation sessions, and other forms of vivid collaboration,
- combining art and design in the processes of self-realization,
- use of meta-analysis for comparing, combining, synthesizing, summarizing, specifying, and generalizing of previous studies.

A popular definition of ACM asserts that it is "a collaborative process of assessment, planning, facilitation and advocacy for options and services to meet an individual's holistic needs through communication and available resources to promote quality cost-effective outcomes" [7]. Under this definition, ACM can be perceived as a platform comprising a decision support system.

Clyde Holsapple, one of the fathers of the DSS concept, commented that "… DSS architecture does not define what DSS is; rather, it functions as an ontology that gives a common language for design, discussion, and evaluation of DSS."[8] This perception of DSS corresponds with Lambert's opinion that "… the architectural design should set a common level of understanding among technical, non-technical and management participants." [9] Suresh Basandra, on other hand, believes that "… system architecture is the process of partitioning a software system into smaller parts." [10] These insights bring us to Holsapple's 2008 definition of the DSS architecture: "DSS architecture is a general framework that identifies essential elements of a DSS and their interrelationships." [11]

Substantial research conducted by the authors at the request of several business enterprises employing ACM systems indicates that most such systems have similar business goals concerning decision support:

- to support the knowledge worker in making optimal decisions in each and every case,
- to deliver faster and more accurate case resolution,
- to improve agility by following business rules in deploying decision support.

Within existing decision support systems, the control function is performed via meta-knowledge subsystems (like norms, axioms, ontologies, etc.). The development of a meta-knowledge subsystem is driven by the double loop pattern of knowledge development. The primary feedback loop, which is characteristic of adaptive learning, involves detection and rectification of deviations from operational norms. The secondary loop, found in the so-called generative learning, is responsible for creative modifications to operational norms.

Likewise, ACM system users will build up corporate knowledge using IT tools and social mechanisms to bring tacit knowledge (i.e. the staff's expertise and individual experience) to broader use in case processing.

It is essential in any DSS project to thoroughly analyze interactions among business owners. As Frederic Adam has it, "… [M]anagers are not seen as atoms but as active, purposeful agents. It is possible to visualize the Decision Making Network (DMN) and to investigate what happens within the networks as the organization tackles a Decision Situation." [12]

ACM could be viewed as an IT platform including an integrated decision support system. The DMN can be then identified with a process map that visualizes all possible case states and provides process managers/leaders with a profound insight into the business.

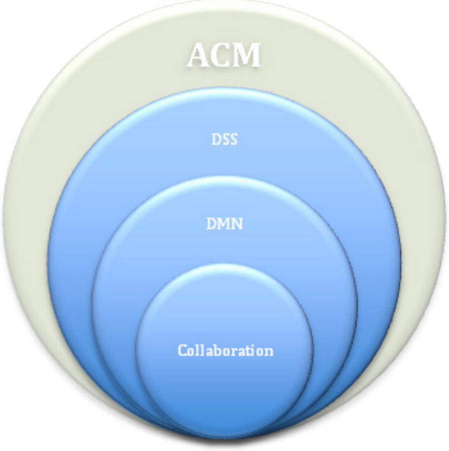

Fig. 4 A model of relationships between ACM and DSS

Those having to cope with less structured decision problems will normally need to have a good understanding of the problem solving process and to be familiar with the applicable techniques. Without this know-how, users situated beyond the operational level might not be able to use the system resources efficiently: even if an expert system is activated to provide them with support in choosing the most suitable tools (models) for their problem, the choice has to be ultimately made by the user. Observation reveals that the most common reason why some systems are not used in tactical or strategic problem solving is not the technology itself but the relatively high demand they put on users' competence (knowledge base).

ACM helps manage the unpredictable by enabling knowledge workers to effectively cooperate and share their knowledge, thus improving the functionality of a decision support system.

Users engaged in solving tactical and strategic problems will rather expect the system to become a "partner in problem solving." Interestingly enough, we have found that the lowest skill levels are associated with the highest expectations from the system, including a proactive attitude in assisting the user. Conversely, the expectations of most advanced and creative problem solvers are limited to being offered an efficient technology and a rich collection of presentation tools.

What is expected from the system in such circumstances is, in the first place, adaptability and expandability through appending new decision models. Not only does the DSS have to offer the requisite decision modeling tools but it also needs to be able to instantly integrate (owing to bidirectional data interchange) with dedicated external systems tackling specific business problems.

The ACM model typically includes a special resource containing knowledge on the business processes utilized in decision making (decision workflows). Identifying the key business processes and analyzing the decision making processes intrinsic to them makes it possible to accumulate knowledge needed to discover and assess relationships between decisions and their outcomes. This appears critical, in the light of our research, for decision analysis at all levels.

Our survey indicates that the most frequently used creative problem solving tools include:

- context-sensitive help along with access to historical data and similar cases,
- group work support tools, such as discussion forums or (widely popular) instant messengers.

## IV. ACM FROM THE KNOWLEDGE MANAGEMENT PERSPECTIVE

A company's body of knowledge is partitioned and distributed among staff and across worker groups; before it can be brought to productive use, it has to be properly organized. Any modern enterprise needs to have a knowledge management system, which can be described as a complex blend of understanding and experience, explicit and tacit knowledge, material and social technology [13]

The following are the principal goals of knowledge management in organizations:

- To make the most of the knowledge that is already available within the organization,
- To create new knowledge, and
- To increase the understanding of knowledge.

It has taken some time for companies and researchers to realize that, besides data as such and besides information that can be interpreted by humans, there exists another vital resource that becomes increasingly crucial to a company's performance but cannot be captured and managed via standard information management methods – and that is knowledge. It can be either explicit knowledge, readily accessible e.g. from an internet portal, or tacit knowledge that resides in the staff's minds and originates in their individual experience, training and talent.

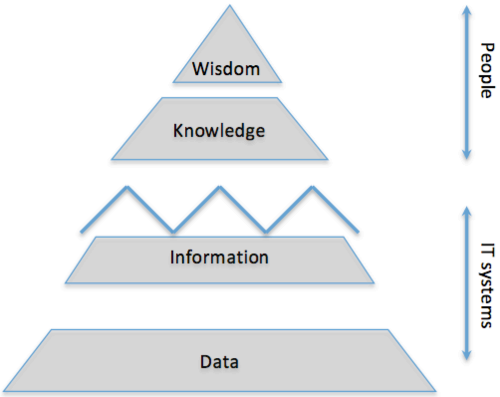

Fig. 5 A model of interrelationships between organizational resources.

Nonetheless, efficient knowledge management alone does not ensure success in business. David Pollard argues that businesses survive and achieve success not because they give a lot of attention to managing their knowledge but because they manage their operations better than their competitors do [14]. The ACM concept, and the instruments it offers, can help organizations optimally utilize their knowledge repositories as a resource and to run their business adaptively, thus increasing their competitive edge.

ACM tools, such as the IBM Case Manager or Pega SBPM, offer knowledge workers a wealth of opportunities to communicate their ideas, observations and suggestions, and to establish best practices, at the same time increasing their autonomy in the workplace.

A survey of industry leaders such as Ford Motor Company, PWC, LLP, Hewlett-Packard or Arthur Andersen, conducted by the American Productivity & Quality Center (APQC), has revealed the presence of processes and features typical of learning organizations [15]. Of these, the following five elements seem to be of critical importance:

Knowledge sharing that occurs in solving problems or with a view to delivering better business results. Different approaches are pursued; in some companies, executive management is involved, while in others preference is given to the use of internet-based knowledge bases or to knowledge sharing among staff during problem resolution.

This aspect of knowledge management has become a central element of the ACM concept. Information on each business case is stored in the system and retrieved by staff engaged in handling cases as they collaborate in case processing and closing. Modern information technologies can provide support for group work through communicators, messengers, social networks, and corporate portals, helping exchange insights, comments, and case processing information – thus facilitating knowledge creation and knowledge sharing.

There is a high degree of awareness of the relationships between knowledge acquisition, knowledge sharing, and achieving business objectives; the staff appreciate the importance of knowledge sharing and understand its contribution to the accomplishment of their company's strategic goals.

It should be noted that, from the ACM perspective, information (e.g. process-related data) is construed as a tool for knowledge creation rather than part of knowledge itself [16]. This is a fundamental difference that has practical consequences for the approach adopted toward knowledge management. Gilbert Probst, Steffen Raub and Kai Romhardt assert that knowledge is a collection of information and capabilities employed by individuals in problem solving [17].

Under ACM, the conception of knowledge management conforms to the definition adopted by the NASA: "Knowledge management is getting the right information to the right people at the right time, and helping people create knowledge and share and act upon information in ways that will measurably improve the performance of an organization and its partners." [18]

The company's principal values are closely related to self-development, cooperation and knowledge sharing; knowledge management is well deliberated and embedded in the organization's business strategy.

At a time of economic downturn, new challenges will arise for business enterprises, forcing them to seek improvements to flexibility, innovation, and responsiveness;

it is also necessary to take a new outlook on human capital – each company's prime asset – with its competencies, autonomy, and responsibility. Adaptive case management systems respond to companies' real needs by offering them dynamic handling of business processes on the one hand, and effective communication and knowledge management mechanisms on the other. In the world of today, success is founded not so much on a careful orchestration of corporate processes, but rather on an organization's ability to instantly adapt, make quick decisions, and use intuition and knowledge management in adjusting its process flows to changing business conditions.

In his 1999 typology, Skyrme proposes a distinction into six types of knowledge:

- Know-**how** – i.e. individual skills and familiarity with procedures,
- Know-**who** – the kind of knowledge that triggers access to required resources; acquaintance with people who can help find the answer or perform a task,
- Know-**what** – or structural knowledge, e.g. acquaintance with pertinent patterns,
- Know-**why** – or "deeper knowing" that enables one to interpret the information one already has and understand the broad context of whatever one does,
- Know-**when** – a sense of the right timing and rhythm for an action,
- Know-**where** – an awareness of the place and context in which an action would be best performed [19].

The latest ACM systems make use of all the above-mentioned types of knowledge. Within such systems, the knowledge of how, what, where and when is readily available and easy to access and modify.

The business owners of respective processes define instructions and types of documents required in process handling, as well as tasks and roles to be performed in solving business cases. Depending on the type of case being processed, relevant properties are displayed to the case manager. The know-how of every assignment (i.e. how it can be best completed within a specified time) is available throughout the system, easy and intuitive to find for each ACM user.

It is different with knowing **who** and **why**. ACM supplies knowledge workers with ample functionalities supporting e.g. task delegation or, notably, the creation of a hierarchy of experts whose assistance is instrumental to resolving a given case. Owing to social networking services (e.g. setting up a team room for experts designated by the system to sort out a specific problem), the knowledge of who can help process a case and why a particular decision should be taken is broadly utilized and dynamically expanded.

The knowledge management style, as well as its structure and language and the extent to which it has been formalized, are aligned with the organization's culture and work environment.

ACM software packages contain rich collections of personalizable tools providing whatever organizational and technical means it takes to raise organizational competence, improve the staff's education and learning capability, and boost up collective intelligence. It supports the development and use of state-of-the-art mechanisms for semantic content analysis and industry-specific glossaries aiding communication among knowledge workers within an organization. Owing to enhanced text analysis techniques, it makes it possible to discover trends, patterns and relationships in unstructured data as well as in related structured data. The resulting observations become part of organizational knowledge and can be used in decision making, forecasting, and setting business targets. In ACM environments such as the IBM Case Manager, the user interface and the system vocabulary are customizable and can be adapted to the language specific to a given professional/business area (e.g. medical or other discipline-specific terminology).

Managers engage in promoting attitudes and behaviors involving cooperation and knowledge sharing.

In organizations that are managed in line with the ACM concept, core activities go hand in hand with a drive for daily innovation. Given the process operators' ability to dynamically adjust and fine-tune their processes, the enterprise management system as a whole becomes open to creative initiatives from most staff while at the same time avoiding the risk of disorder that might result from spontaneous changes to operating norms. In addition, being able to observe the outcomes of changes, the organization can incorporate findings on best and worst practices into its body of collective knowledge. This stands for actual, day-to-day improvements and adjustments to business processes based on knowledge contributed by a large number of staff and on feedback from customers. Instead of hierarchical relations and work division, ACM offers autonomy that enables staff at lower levels to create knowledge and transfer it to higher levels, where new solutions are assessed and approved by senior executives in recognition of their staff's initiative and enthusiasm.

From the perspective of knowledge management, most ACM systems are characterized by several fundamental properties. Depending on specific organizational conditions and requirements, the system's design should embrace socially or technically oriented knowledge management tools. An ACM system framework must aim to integrate all of the company's functional areas as well as all of the existing management subsystems.

Knowledge Management
Collaboration
Adaptive Case Management

Fig. 6 A model of relationships between ACM and KM.

Benefits that can be expected in relation to the introduction of a support system for knowledge management (e.g. an ACM-compliant one) include improvements to organizational knowledge distribution, innovation management, and knowledge transfer (sale). Deloitte & Touche point out another two rewards:

- enhanced internal efficiency – dissemination of best practices, innovative concepts and valuable experiences,
- increased loyalty – establishing and strengthening ties between staff, customers, shareholders, and suppliers [20].

One can easily endorse Ernst & Young's definition of ACM as "a framework or system designed to help companies capture, analyze, apply, and re-use knowledge to make faster, smarter, and better decisions and achieve competitive advantage." [21]

## V. THE NEW ORDER.

The application of an ACM framework substantially increases the capabilities of platforms conforming to the classical architecture delineated in Chapter 2. Adaptive case management effectively combines BPM/ERP components with a dynamic approach to business case management.

In a world where business processes are unpredictable due to their complexity and the number of factors affecting decisions, more and more organizations choose to shift to adaptive process management systems such as adaptive/advanced case management [22] or dynamic case management [23].

The above can be illustrated by a business process involved e.g. in construction projects or loan application processing. Each must be tackled differently, in a manner specific to the type of project or suited to a customer's unique requirements. Since it is impossible to predict and model all types of projects and all customers' likely needs, there has to be a way to dynamically adjust a business process to specific contexts and individual requirements. Process management cannot be therefore reduced to merely reiterating a process according to an established routine, even if the process has been perfectly optimized. Attention to customers' individual tastes and requirements means that processes in an organization must be individualized, too. The advantages exercised by small, innovative and fast-adapting businesses over large international corporations demonstrates that the key to success is no longer in process optimization alone but that it should be sought in an ability to dynamically adjust a process to customers' requirements and address effective support to organizational decision making and knowledge management. Large companies spending enormous amounts of money on introducing new management methods and complex information systems cannot dream of the flexibility that comes as natural to small family businesses.

To overcome this increasingly evident paradox, it is necessary to extend the classical architectural model of a corporate platform described in Chapter 2. Given the need to deliver swift performance demanded by customers and the number of processes running parallel, process owners should not bear the sole responsibility and powers for analyzing and adjusting their processes. With ACM, that responsibility is shifted toward knowledge workers. Within their delegated powers, knowledge workers are allowed to make changes to the processes they are engaged in, just like process leaders would. This functionality, coupled with the integration of decision support and knowledge management subsystems into the ACM architecture, provides a vantage point over companies whose operations are based on the classical BPM/ERP+ DSS + KMS model.

Under the traditional approach, the staff tackling a process are forced to execute an algorithm developed on the basis of a standard process map, i.e. designed in accord with the knowledge workflow that was in place at the time the map was made. As the conditions for process execution will vary in practice (e.g. there do not exist two identical consulting or development projects) and no two processes are in fact performed in the same way, it is advisable that standard processes be adjustable to implementational requirements by their direct executors[24]. The classical process improvement cycle administered by process leaders, involving such subsequent steps as process modeling, performance monitoring, formulating conclusions and, eventually, utilizing the findings to improve the process, is far too slow and therefore inadequate. What is more, in the event that certain clients have conflicting expectations, it might be impossible to design a "universal" process that could be accepted by all the stakeholders.

The ACM approach, incorporating a DSS and a KMS working parallel, is particularly useful in designing processes that are not known in advance, which is what occurs e.g. in court proceedings or in medical treatment. In such processes users have to be given the capability of dynamically modifying and creating tasks within each process. These users are therefore referred to as knowledge workers. Owing to ACM, not only organizational knowledge is built in the KMS, but also the DSS becomes a much more valuable tool, helping make even the most difficult decisions concerning a wide variety of business cases.

A dynamic management strategy allows concentration and intensification of efforts directed at supporting decision processes and organizational knowledge building, while catering to the most unique expectations of clientele.

Under the classical three-layered architecture (BPM/ERP, DSS, KMS), platforms typically suffer from delays arising from the necessity to involve process leaders in making process-related decisions and from the very limited possibility to establish systemic, institutional links between the company's core activity and knowledge management via a process based system. Given the current pace of changes, top executives or process leaders are increasingly unlikely to be able to react timely.

At the heart of ACM is the belief that an organization must never stop expanding and refining the knowledge it already has on the mechanisms governing its business environment, and that management methods founded on this belief are not only more effective but simply constitute a precondition of an organization's responsiveness to the incredibly robust changes in present-day markets and in customers' expectations. Another distinctive feature of ACM, perhaps just as important, is that it can effectively and efficiently support knowledge workers in making business decisions. It is frequently stated that ACM enhances organizational learning to the extent that it represents a step toward the building of a learning organization, since internal process improvement takes place at several levels, affecting both personnel and managers. It should be also underscored that ACM comprises fully-fledged and fully integrated, tailor-made decision support and knowledge management subsystems that do not need to be integrated through individual system integration projects.

The benefits of ACM and the development potential of this methodology have already been recognized by software vendors (e.g. IBM Advanced Case Manager). A major emergent trend in software development is to remove inflexibilities attributable to the posture whereby processes, once identified, are treated as a binding blueprint for action. ACM is different in that it allows users of corporate software applications to take initiative in performing actions that have not been envisaged at identification and design stages. As a result, dynamic ad hoc processes are simpler and easier to model.

ACM systems account for better results in knowledge management and decision support owing to:

- reducing the process description stage to preliminary modeling or to the modeling of known, invariable elements, subject to subsequent supplementation and expansion via the learning mechanism built into the knowledge management system;
- significant acceleration of process improvement by allowing both process operators and process leaders to modify processes, whether in steps or leaps;
- enabling instant dissemination of the knowledge inherent in process innovations through the integrated knowledge management system.

When fully exploiting the potential of ACM-class systems, companies can extract process-related knowledge that has so far been tacit or hidden and in that way find out about processes that cannot be structured by defining straightforward, clear-cut algorithms (process maps). This makes it possible to substantially accelerate the acquisition of knowledge about processes, thereby reducing or eliminating the time required for their formal identification. In effect, organizations should be better prepared to seize emerging opportunities and make optimal decisions, which will affect not only their current performance, but their ability to survive in the market as well. Therefore, it seems that the classical approach is likely to be soon abandoned or modified, and business optimizations will be chiefly conducted using ACM.

## VI. A CASE STUDY

JM Family Enterprises, Inc., founded in 1968, is a diversified automotive company ranked by Forbes as the 27th-largest privately held company in the U.S. The introduction of an advanced case management platform has affected a number of its core businesses, including World Omni Financial Corp. – a major US car finance company.

At World Omni ACM has, in the first place, improved customer service by enabling service associates to access all relevant information concerning a customer's case and hence provide a quicker and more reliable response regardless of where the loan/lease servicing request is initiated. ACM helps the company manage information and knowledge as the customer requests arriving from multiple sources, such as phone, fax, mail or e-mail. When a loan/lease request is received, an associate initiates the process by completing appropriate electronic forms or templates and electronically attaching any associated documents. Such approach structures the case data and improves decision process. Inputting information into electronic forms removes the need to re-key data and, owing to integration, makes it possible to share data with mainframe and client-server systems that are part of the loan/lease servicing process.

At the same time, the elimination of paper-based documents has further streamlined the loan/lease process and resulted in a corresponding "green benefit" meaning that approximately 168,000 pages of paper are no longer printed annually. Moreover, it translates directly into the optimization of knowledge workers' daily duties. 360 degree view for the case information and data is used for decision support in key process steps.

Following is an overview of the key benefits obtained by JM Family in particular business areas through the deployment of an advanced case management system:

- **Customer service**. At its locations in Mobile, Alabama and St. Louis, Missouri, the World Omni call center employs more than 700 customer service associates and processes tens of thousands of automobile loans and leases annually. Originally, the customer service process was complex and involved sizeable volumes of paper documents, frequent interaction with customers, and multiple information sources and systems. Each loan/lease servicing transaction had to pass through a specified sequence of steps engaging many associates and including a number of approval and audit levels. Now all the necessary customer data, along with the requisite knowledge (information regarding a customer's case, transaction history, staff's comments and shared expertise), are available in each single case, providing for an ability to deliver a quick and reliable response/decision regardless of where the loan/lease servicing request is initiated. This is example for using ACM system for better knowledge utilization and making more accurate business decisions.

- **Better punctuality and efficiency** corresponding to shorter response times in handling customer inquiries. The implementation of case management has resulted in improved access to information and knowledge pertaining to a customer case. As a result, knowledge workers can make better-informed and timelier business decisions. Electronic document management and distribution enhances productivity by removing the delays arising from the need to wait for information required to complete a task.

- **Enhancing business outcomes**, which translates into increased customer satisfaction. Working with IBM, JM Family has achieved its primary goals of improving customer service and raising productivity. Customer service associates can now quickly determine the status of a loan or lease service transaction – a task that previously required significant manual effort. A comprehensive view of each customer's case allows associates to update account data and have changes applied consistently across all systems involved in the process. In addition, the ACM system lets knowledge workers collaborate and exchange their knowledge about optimal processing (automatically contributes to organization's knowledge base). As a result of business process automation, loan/lease transactions are now finalized more quickly. JM Family has also achieved its secondary goals relating to: improvements in data quality, paper reduction, better compliance with corporate reporting requirements, and the ability to monitor process performance metrics. JM Family estimates savings at approximately $202,000 annually and anticipates further savings as additional business processes become automated.

- **A better organizational culture**, underpinned by the characteristics of **lean manufacturing**. All of the customer content has been organized into dedicated information silos. This move has been applied consistently across the entire organization, and the idea of a single central backbone for information has led to the emergence of a better, more mature organizational culture. The benefits are reflected in reduced operating costs and increased efficiency that have been accomplished by improving the management and distribution of relevant information and knowledge. Not only has JM Family improved the loan and lease processes, but the company's progressive IT culture has motivated it to strive for continual process improvement with ACM.

- **Market forecasting, costs of decision prediction, business optimization**. Case managers need an insight into workloads and processes to optimize case handling and to be able to find out whether service associates are achieving key performance metrics. To support these objectives, JM Family utilizes the IBM FileNet Process Analyzer to record loan/lease servicing performance metrics. These data are then used by IBM BI software to generate daily performance reports, allowing continual monitoring of the automated loan/lease servicing process as well as of individual customer service associates participating in the process. Such approach is an example of directly contribution to DSS and to business performance overall.

- **Smart, rich data/content analysis**. The ability to dynamically analyze customer content means that it becomes possible to catalog and organize content from multiple sources by exploring and aggregating JM Family information. Content exploration leads to new knowledge and understanding for making instant decisions about business value, relevance, disposition and category schemes in order to take action. "Decommission what's unnecessary" means to cut down on costs and reduce risk by eliminating obsolete, over-retained, duplicate, and irrelevant content, along with the infrastructure that supports it.

**Employee productivity** has been improved by enabling service associates to access all relevant information and enterprise knowledge regarding a customer's case, which accounts for quick and reliable decision regardless of where the loan/lease servicing request is initiated.

**Annual projected savings** of approximately $202,000; faster and more accurate response to customer inquiries; much less paper used to print out documents, which results in significant environmental benefits; improved compliance with corporate records requirements. ROI: 64%, payback: 1.6 years.

**Improved data quality and reduced audit costs.** By eliminating many processes that involved re-keying of data across systems, JM Family has reduced data errors to help ensure consistency and accuracy of data that are transferred between systems. New business processes have been designed to automate World Omni approval procedures and implement firm controls, thereby reducing the amount of auditing required. JM Family estimates annual savings attributable to cost cuts in audit steps at $68,000.

**Savings in case progression and resolution**. JM Family's reputation for technical innovation implied that advanced case management could be a key enabler and driver in improving the quality of customer service as well as the productivity of customer service associates. Additionally, it was recognized that ACM could help the staff improve knowledge management, decision support and other business processes throughout the organization. JM Family has chosen to use IBM software to gain the advanced case management insights that it needed to make the customer experience seamless. The software contributes an integrated process approach that combines electronic forms, business process integration and systems integration to optimize process automation. A flexible framework provides customer service staff with access to all relevant content for each case at every step regardless of source.

**Improved business visibility and transparency** to further enhance compliance. JM Family has designed a process to automatically record the status of key processes as well as of the participants involved in reviews and approvals. JM Family employs the IBM Enterprise Records software to automatically capture and retain loan/lease documents in accordance with corporate compliance policies.

**Continuous improvement with case analytics**. The ACM system implemented at JM Family offers high performance analysis of customer content, hence better monitoring of the automated loan/lease servicing process as well as of individual customer service associates engaged in the process. The continuous improvement policy, coupled with process knowledge retrieved from case analytics, has led to better business decisions resulting in significant savings.

## VII. Conclusions

The paper has tried to highlight the reasons why adaptive case management could be considered as a valuable tool in both decision support and knowledge management. Admittedly, ACM is currently shaping trends in the evolution of both KMS and DSS – by adding vital dynamics to knowledge acquisition and management as well as to decision support.

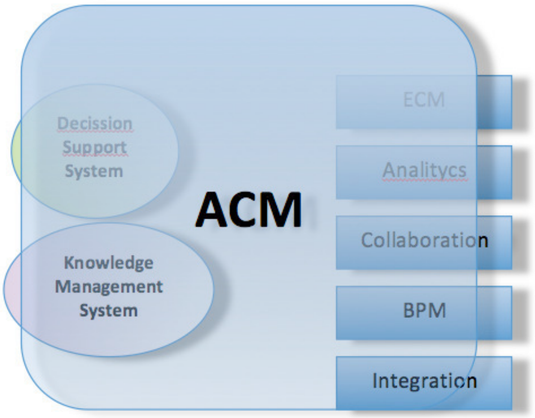

Fig. 8 ACM vis-à-vis organizational resources.

The new business model associated with ACM proves more effective and capable of satisfying most of the requirements of modern businesses.

A dynamic management strategy permits concentration and intensification of efforts aimed at supporting decision processes and organizational knowledge building, standing for an ability to respond to even the most extraordinary customer expectations.

The classical platform, whose architecture is divided into three layers (BPM/ERP, DSS, KMS), is clearly inferior to ACM in terms of efficiency. Furthermore, it offers limited possibilities of establishing systemic, institutional ties between a company's core business activity and knowledge management via the system's process-orientedness. Its adaptability is, on the other hand, increasingly compromised by executive and line managers', as well as process leaders', inability to deliver a timely response to rapid changes in the business environment.

ACM represents the most recent model that comprises integrated subsystems responsible for knowledge management and decisions support. Its very design accounts for superior performance over the traditional approach based on a combination of distinct ERP/BPM, KM and DS systems. Its primacy has been demonstrated by a number of business case studies.

***Abstract*—The article describes the levels of use of electronic business communities in the management of the city. The study was prepared on the basis of data, observations and investigation at Czestochowa City council, in April and May 2015. The research are related to the development of the concept of Regional Business Spatial Community (RBSC). City Council, along with service providers and providers of media for the residents work for regional development. Five basic levels were identified: informative, tender, negotiative, the level of projects and of processes. In addition to the characteristics of the levels, a qualification of the applied solutions and tools to specific levels has been made. The analysis shows that in the region of Czestochowa, relations at the level I to III occur. The summary indicates directions for further research on the developement of electronic business community.**

## I. Introduction

MORE and more new competencies are assigned to modern local self-government bodies. They affect the operation of more and more areas of local life. To accomplish the tasks assigned to the offices, IT tools are becoming increasingly necessary. One of the effects of the use of IT tools is the ability to create electronic communities.

Appointment of electronic communities in cooperation with the local administration aims to create a network of cooperation between different actors operating in the region. These communities can cover various thematic areas, can be open or closed, can serve to establish cooperation or continuous improvement of it.

This study takes the theme of development of electronic communities to support local development. Creating a regional electronic communities the assumption to facilitate the planning, organization and implementation of various projects. The assumptions of creating these communities is to encourage the increase of the activity of different types of entities functioning in the region [1].

In this consideration of these concepts for electronic development levels of the community were proposed. The arrangement of the shown levels is intended to indicate how they should evolve the built communities [2]. The proposed system of levels is the result of the analysis of several years of cooperation of the authors with Czestochowa City Council for the creation of these communities in order to implement selected urban projects.

## II. Idea of electronic communities

The essence of electronic communities is to join entities, enterprises, institutions and offices in one circle of interest with the use of ICT solutions (information on communication technologies). This idea reminds the use of social networking sites (e.g. Facebook, Twitter, Instagram) by individuals. These people voluntarily create an account in order to communicate and exchange their views. These portals also allow for focusing on specific tasks, objectives and events. Users shall provide one another with information and, this way, form interest groups.

In a similar way, around specific projects and initiatives, enterprises, institutions and offices can be focused. Due to the geographical spread and growing importance of information resources in modern economy and business processes, emerging electronic communities are electronic-virtual. Obviously, they will not use the already existing social networking sites for this. It is necessary to build specific environment - an electronic platform (e.g. Spatial Regional Business Community RBSC - see more [3]).

The basis of the platform of collaboration among electronic communities is an Internet service. Access to the site can be open or closed. This means that only entities that meet certain criteria can use it. Access to the website may also require an invitation by another entity or have the appropriate recommendations. Users of the service can create within its interest circles. These interests may affect ongoing projects, investments, management of the region, cooperation, etc. The implementation of these tasks requires to supply the system with appropriate data and information. The purpose of the scheme is therefore the integration of data from different sources and from many entities. The collected data, according to specific tasks and access rights, would be made available to participants in the electronic community in cloud computing technology.

The basis for the internet system agglomerating online communities can be data from government offices and local government, such as maps, records, information about entities operating in a given area, information about auctions, investments held, etc. On the base constructed this way users would have the option of applying their own information and data (which from the point of view of the community could help to increase the value of the service), from their systems, such as:

978-83-60810-66-8/$25.00©2015, IEEE

- ERP - selected information about the transactions, collaborators, owned resources [4],
- GIS - Spatial information on the nature concerning, for example, distribution of real estate, infrastructure course, scattering branches, commercial premises, the work carried out, etc. [5],
- CRM - selected information about contractors, collaborators, needs in terms of cooperation, missing resources for specific investment or project, etc. [6].

The created website, focusing on electronic communities in a given region becomes a kind of data warehouse. The system integrates data from different sources and in different formats. Then, after establishing rules for access integrated and aggregated data are made available to other participants in the community.

The sharing of data may be controversial and it can raise concerns. Data, information and knowledge are an important part of the organization's resources. They are protected, as this determines competitive advantage. Sharing of information resources within the electronic community therefore requires an appropriate approach and policy. So it is only possible to share such resources, which, in effect, will constitute value added for the electronic community, and, at the same time, can bring tangible economic effects, for example, will allow to gain a business partner, shorten the time of the investment, will help to identify inconsistencies or barriers.

## III. Levels of application of electronic communities

The terms of reference of local government are appointed by civil laws. In them they are contained lists of the areas whose functioning is the responsibility of specific levels of local government. The purpose of these offices is to organize the principles of functioning of the individual, identified areas of life, the creation of entities or cooperation with relevant organizations. In addition, in certain parts of the act, they govern the responsibilities and roles of acceptable administrative units. It is worth remembering that the tasks of the local government bodies are not limited to regulation of specific areas of social life and making administrative decisions, but they can also stimulate local activity, both social and economic. The aim is to stimulate local entrepreneurship in various fields of human activity.

The proper functioning of local government administration should be focused on cooperation with the environment. Electronic media may become one of the main channels of both cooperation and mobilization of potential partners. With it one can gain data about the needs occurring in the region, as well as collect the opinions of residents about the planned projects. It is also possible to keep appropriate information in terms of policy and activities of the office, as well as all types of projects carried out in the area. Electronic media can be an important channel of communication between the office, residents and all stakeholders in the area.

When planning the rational use of IT tools in the activities of the local administration and in the broader regional management thread, the application of criteria should be defined. In these considerations mainly two criteria for the areas of local community life and levels of cooperation were taken into account.

The basic tasks of the governments of cities with county rights in Poland include [7] :

- ensuring spatial order,
- estate management,
- environmental protection and nature conservation and water resources, construction of roads,
- building streets and bridges, traffic organization,
- protection of public transport,
- water supply and sanitation,
- tasks in the field of geodesy, cartography and cadastre,
- education, health and care of the third century people,
- culture (libraries, theatres and other institutions),
- protection of monuments of culture and nature,
- public safety,
- promoting the city,
- social activation of residents,
- creating the city's development strategy.

There are definitely more of the mentioned tasks. However, this citation is to indicate how many different tasks public administrations of cities with district rights have to carry out. To carry out these tasks, the office can create special units for specific tasks or order them to external actors. In some areas, the office can stimulate the construction of infrastructure, which is meant to enhance local entrepreneurship. It happens that in some cases the local government must define a strategy of development of the administrative unit, which may cause stimulation of one sector of the economy at the expense of another (for example, the conflict between cumbersome industry and tourism - especially characteristic for places situated in an attractive tourist area) [8].

In view of the fact that local authorities are elected, making decisions of a strategic nature for the development of the entity must be consulted with representatives of the local community and gather the opinions of residents, take into consideration local needs and ideas for the development of the unit. Very often local authorities are held accountable for actions they have taken for the development of the region and the results they have.

Therefore, their activities must be carried out in different areas and at different levels of cooperation. Analysing the contemporary principles of functioning of local governments, the following levels of cooperation can be indicated (compare to [9]):

1. Information.
2. Tender.
3. Negotiation.
4. Projects.
5. Process.

At the level of information offices collect data about the needs occurring in the region and inform themselves about their own activities. This may involve both information about the activities of local governments (e.g. The information of the topics discussed at sessions of the municipal), as well as planned and the measures taken in the city in various areas of social life. For example, BIP (Public Information Bulletin) can be used for this purpose.

At the level of tender subject matter exchanges of information refers mainly to the planned projects in the city. Offers can flow in two directions. On the one hand, the offer may flow from potential investors who plan to invest in the city and for this purpose are probing interest in the city and its residents planned investment. On the other hand, the local government may announce emerging ideas and plans for different types of initiatives to the residents to hear their opinions. In this case, you can use the systems to collect and transmit documents electronically, as well as the possibility of collecting public opinion through electronic methods in various vital issues residents.

The level of negotiation is related to the organization of projects implemented in the city. The role of the office may be threefold. The authorities may initiate the project (e.g. construction of the road). Using IT tools may carry out auctions, and then negotiate, it may also organize consortia made up of representatives of many entities, which in turn has to lead to take the project. The second type of the role of the office is to support people's initiatives to be implemented throughout the city. In this case, the city can be a shareholder or, in a variety of ways, support the project implemented, including seeking partners for cooperation. What it can also be accomplished by using IT tools. The third role is to control, which is on one side of verifying all documentation relating to the operation, on the other hand may consist of facilitating and promoting investments.

The level of projects is to create tools which will support the implementation of specific projects. This is particularly true for large projects that will require the cooperation of many entities. In this case, IT tools can be used to establish a communication medium between all the partners involved in the project.

Referring to the contemporary concepts of process management, many projects can be applied to specific procedures for implementation. Using the tools for process design, it is possible to design informatics support for processes carried out in the framework of the project [10]. This can apply both to investment processes and then to the control or management of entities arising as a result of the investments the city [11]. In this way, not only a tool for electronic document flow can be created, but also social tools can be used to create the development of the project's areas.

The above levels of cooperation are the basis for the creation of electronic communities. The thing is that created communities are not homogenous. Hence, it is unlikely to create a single community. As a part of the regional communities, may occur many community sectors (e.g. related to education, health services and municipal investments). Furthermore, many traders may belong to different communities. These communities may be closed and open. In addition, different rules may be accompanied by the possibility of joining the framework of the community. This may depend both on the specifics of the industry, where a community was established, as well as the level of cooperation.

Construction of electronic communities is a long process and can take many forms, which over time can be converted together with their development. The formation of regional electronic community usually takes place according to certain phases. A significant impact on its shape has also the purpose for which they arise. For the purposes of regional governance can be invoked various communities, which seeks different objectives and designed to satisfy the diverse needs of society.

Bearing in mind the diversity of the community and the objectives of their use in regional management in these deliberations levels of use of electronic community in accordance were adopted with accepted earlier levels of cooperation.

Information level is a kind of substitute for the community. Its aim is the presence of different information or initiatives. Information may involve various important issues in the life of the city. In contrast, initiatives on one hand inform about emerging initiatives, on the other objective is to obtain an opinion, and, above all, support for relevant projects. Generally, the information appears at the integrator (e.g. the town hall), which aims to send a message to the widest possible population. Usually, messages are transmitted to open community, though not excluded is the creation of news compasses closed. Information level may be interdisciplinary.

The level of bidding has been generally assumed by discipline. It refers to specific sectors of social life. It also requires interaction between the initiators of projects, and those who will give an opinion, in the long run, may take part in them. It is worth remembering that not always the initiators are entities that organize the project and in the future will be integrators. The level of bidding electronic community is usually open. Although they may also receive the offer (in particular of a business), which can be routed to a closed community.

The level of negotiating refers to specific planned projects. An electronic community will have to negotiate in order to organize the project from preliminary discussions by submitting comments and offers, and ending with the completion of electronic auctions and having conversations to the conclusion of a relevant investment agreements have in the future supplies. Generally, the community may be mentioned at the outset generally open, but with the implementation of further preparatory activities for the implementation of the project can be closed. It is also necessary to note that many similar communities can be invoked, each for a different project.

With the closure of community at the negotiating level, exclusively to the entities involved in the implementation of the project, it can be assumed that the community moves to the level of the project. At this level it is important to provide adequate communication to the smooth implementation of the project and its management. At this level you will be required a certain level of integration of information systems managed by participants in the community [12]. These communities typically will be closed. Also in this case there may be many different communities that support various projects.

The level of the process is a further development level of cooperation. It is based on the fact that the project is quite strictly formalized. First of all, procedures for implementation have been strictly defined. Thanks to it, it is possible to control the implementation of all processes within the project [13]. The condition for achieving this level is the right level of integration of information systems of all participants in the community, the availability of tools for modelling processes and their application. Communities are closed. Time may be limited for the time of investment or for the duration of the operation of the project. Comprehensive description of the various levels of use of electronic community are presented in Table. 1.

## IV. Technology used within electronic communities

Implementation of the indicated levels of cooperation within the electronic community requires a set of ICT tools. These tools require proper integration so as to form one coherent system. The functioning of such a system must be network service (Web Service) in database technology.

The simplest in the implementation seems to be the level of information. Technological solutions that can be used is news in the form of blogs, forums and other Web 2.0 tools. They allow the posting of information on existing activities, investments, tenders, etc. Other participants of the community can give opinions and comment on them. Even at this level of the system (such as on social networking sites) should enable the creation of groups and circles of interests around specific themes. Similar approaches may be used as a proposal. However, it is necessary to supplement the system with the possibility of submission of tenders in an automatic manner, e.g. Through a system of forms and attachments. Sent offers should be reliable, which is why the system can be completed with the need for registration, and in some cases it may be required to sign an electronic certificate.

Implementation of negotiation level builds the idea of groups and circles of interest. In the framework of specific initiatives, circles of interests are filled with participants. They become cooperators and collaboration platform offers the possibility of negotiations in the virtual space. The necessary technological solutions in this area appear to be advanced communication tools, video conferencing, workflow systems and groupware systems (e.g.. Microsoft SharePoint or Novell Open Workgroup Suite).

Implementation of joint projects within the electronic community web platform needs to be supplemented with tools to coordinate and assist in the definition of business factors, making the right decisions about funding and display the status of projects and resources across the enterprise. This type of software helps manage projects and allows collaboration from anywhere using tools for project managers, project teams and decision-makers. An example of such a platform are applications such as Microsoft Project version running in cloud computing technology - MS Project Online.

Support for business process level requires implementation of solutions allowing for the design, implementation and development processes in the context of groups and circles of interest. Applications supporting Business Process Management BPM can also be handled in the cloud. An example of such a solution may be IBM software. As declared by the manufacturer it allows for:

- optimizing operations, providing them with an excellent view of the ongoing work and ongoing tasks based on continuous monitoring and analysis of processes;
- faster execution of tasks through comprehensive collaboration tools;
- secure management of changes and taking them under intuitive supervision;
- offering customers valuable forms of interaction with the inclusion of mobile environments to business processes;
- continuous analysing the business through the integration of business processes with the basic enterprise systems.

Diagram of the functioning of the web service for electronic communities is presented in Figure 1.

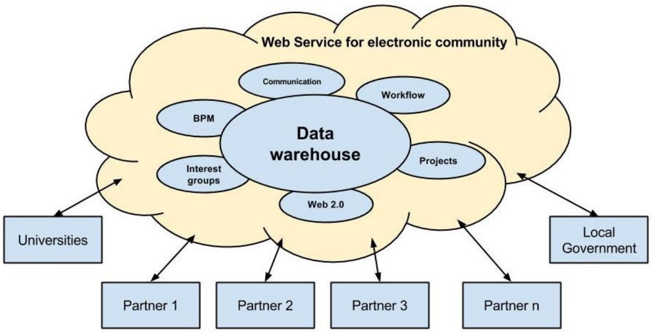

Fig. 1 Scheme of Web Service for electronic community
Source: Own study

Table I.
Characteristics of Cooperation Level in Electronic Communities

| Level | Availability | Participants | IT Tools | Range |
|---|---|---|---|---|
| 1. Information | Open, unidirectional | All actors in the region | Web 2.0, Web Services | Regional |
| 2. Tender | Open, two-way | Entities interested in a particular industry | Web 2.0, Web Services, e-forms, | Industry |
| 3. Negotiative | Open/closed | Entities interested in the project | Web 2.0, Web Services,, MS SharePoint, etc | Interested in the project |
| 4. Projects | Closed | Entities carrying out the project | ERP, GIS, CAD/CAM, CRM, – MS Project Online | Stakeholders of the project |
| 5. Process | Closed, formalized | Entities carrying out the project | ERP, GIS, CAD/CAM, CRM BPMN or BPEL | Stakeholders of the project |

An important element of web service is a data warehouse. Principles of the data warehouse is presented in Figure 2.

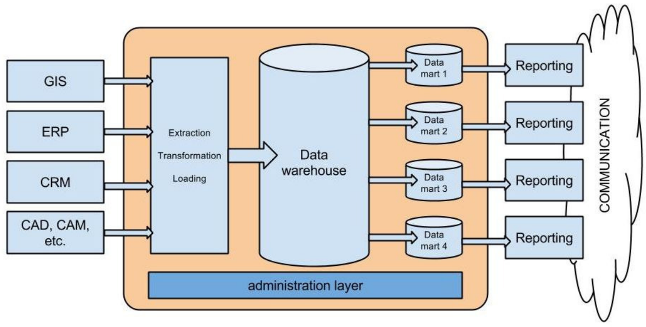

Fig. 2 Data warehouse model for electronic community

## V. Current status of the functioning of electronic community

In the first quarter of 2015 year, a number of discussions and consultations with the Office of Czestochowa, which concerned the current state of the electronic community were conducted. The aim of the study was also to identify potential technological and organizational solutions that can contribute to the development of this type of concept.

The Office, as the body responsible, and strongly interested in the development of the city and the region could potentially become an integrator and leader of this kind of technology. The more that has a large number of information resources, which could become the basis for the initiation of the said web service and data warehouse.

Most of the solutions operating at the moment in Czestochowa's offices, and which can be regarded as the nucleus of the electronic community function on the first level - information. That is, they operate on the principle of communicating information. Offices, institutions and firms have the ability to publish information about their activities, planned investments or needs. Some data is published in the activation of specific social groups. Web 2.0 technologies allow for interaction, feedback.

The most important solution in this aspect is the website of the City Council www.czestochowa.pl It has a thematic areas allowing you to create electronic germs communities in sections: economy, education, culture, sport and tourism,

Web service municipal office is also integrated with other thematic parties, e.g.:

- Public Information Bulletin (bip.czestochowa.pl),
- The electronic public administration services platform – (epuap.gov.pl),
- System of Electronic Communication in Public Administration (sekap.pl).

City Czestochowa also has solutions aimed at electronic integration of citizens through a system of public consultation, support local initiatives - konsltacje.czestochowa.pl

Due to the advantages of tourism and pilgrimage, Czestochowa has a developed system of City Tourist Information Service - info.czestochowa.pl.

Part of systems, in particular those which relate to areas of the economy and investment, has the characteristics of a second-level electronic community - level proposals. On the biznes.czestochowa.pl is a search system of investment offers. (Business and Real Estate Marketplace). It consists of a main areas: maps listings (map deals), offers base, make an offer and ask for offer.

This system could be a first step for potential investors looking for potential areas for investment location.

A similar function can be performed by geo investor (http://e.czestochowa.pl/geoportal-inwestora). Information about the city, the existing administrative procedures, planning and fiscal policy, as well as investment offers in Czestochowa can be found there.

Part of the systems managed by the Office of Czestochowa has elements of Level 3 - negotiation. In particular, it can be seen in GIS, whose task is to record geodetic resources of the city. These systems are at the moment there are models that allow for automation and virtualization negotiation processes, but in the case of the occurrence of such needs, there is the possibility of their development and software.

The study of information systems and web solutions managed by the City and discussions with officials revealed that at the moment no system supports electronic community at the level of implementation of projects and processes. This idea, however, aroused interest. Employees magistrate indicated their willingness to participate in the potential projects in this area.

## VI. Directions of development and conclusion

According to research conducted in the City Hall of Czestochowa it is known that a part of the management office is interested in creating electronic communities, which would facilitate contacts with potential petitioners, investors, stakeholders cooperating and various other organizations and residents. The electronic media allow not only the flow of documentation (eg. taking samples of the documents and their electronic submission), but also allow making contact with various actors. Already, employees of the relevant departments of the Municipal Office in Czestochowa are in contact with the representatives of various organizations, invite to participate in various training meetings and other events. Under mailing lists hides a kind of network of cooperation, especially when many of these entities interactively respond to sent invitations.

It seems that the problem lies in building a tradition of cooperation in the use of IT tools. It also seems that the participants of these forms of cooperation could take a more active part themselves by inspiring their own events, and invite representatives of other entities, including the town hall. In this way, it could be possible to create more circles of the electronic community.

In continued discussion it was noted that communities may be based not only on electronic communication, but also on data exchange. This data is usually registered in closed or only partially open systems of real or potential participants in the proposed community. In principle, from negotiating the level of communication between participants of the community can be enriched by the exchange of data which may facilitate subsequent cooperation.

At the level of projects, in particular data exchange processes between systems of the users already seems to be rather essential. However, achieving this requires the fulfilment of several conditions. The most important ones include:

- the existence of a genuine desire for cooperation, including the exchange of knowledge and resources between members of the community,
- building ventures involving many actors, where IT tools will become an essential part of management,
- supporting process management in organizations and shaping attitudes among managers of community participants, as well as rank and file workers conducive to the implementation of formalized business procedures
- awareness among others on the electronic community, proposed and submitted socio-economic initiatives, business process modelling tools.
- creating rational data collection systems to support the planning and implementation of regional projects.
- training of specialists in the construction of models describing the processes and selected regional issues, the use of which will require the use of data already collected.

These requirements have been defined basing on research conducted at the office of the city of Czestochowa and on the basis of contacts with companies supplying utilities (eg. plumbing companies, a provider of electricity and gas, etc.)together with other civil society organizations operating in the city of Czestochowa.

By analyzing the obtained results it can be stated that the office fulfils the obligations assigned to it by law. However, there is a will to activate the community of the town, which until then struggling among others with problems such as depopulation and a relatively high unemployment rate in the whole province of Silesia. Therefore, it seems that the establishment of regional electronic community can be one of the factors increasing the activity of residents and reverse adverse trends in development.

***Abstract*—Implementing management support information systems with the use of outsourcing is the prevalent method of completing this type of project in Poland. Agency theory is one of the significant categories of theories used in the analysis of IT outsourcing. Literature studies indicate a research gap concerning the phenomenon of moral hazard in IT projects consisting in the implementation of management support information systems. The scope of this article is to present research results on the phenomenon of moral hazard based on the case study method. The research results may be interesting for theoreticians of business informatics and for practitioners completing IT projects both in enterprises and government agencies.**

## I. Introduction

According to J. Lee [1], IT outsourcing means managing a company's IT infrastructure through administration mechanisms exercised in cooperation with external organizations. A particularly interesting area of IT outsourcing is the purchase of implementation services as part of the completion of IT projects consisting in management information system implementation. The author's research has shown that IT outsourcing linked directly to the implementation of management support information systems, i.e. ERP, BI, CRM and DMS, was used in 78% of Polish enterprises, while the remaining 22% completed this type of project themselves.[1] Consequently, the issue of outsourcing in this type of project is clearly visible in the majority of Polish companies and it requires further research by theoreticians of business informatics in Poland. Internationally, issues linked to IT outsourcing have been the subject of research by business informatics theoreticians for many years. J. Dibbern [2] analyzed 84 articles on IT outsourcing published between 1992 and 2000. 10 categories of theories used to analyze the question of IT outsourcing were identified, which were then divided into three groups: strategies, economy and social-organizational groups. Agency theory was ranked third in terms of the number of publications,[2] which shows that it is frequently used in research on IT outsourcing. Agency theory stems from the need to explain the behavior of participants in relations client-contractor, where both parties have different goals. The risk is known as agency problem, relations – as contract, and the parties of the relation – as principal and agent. Agency theory addresses the phenomenon of dependency, where the principal delegates tasks to the agent. Agency problem is considered in two aspects [3]. First, it refers to the contradictory goals of both parties, which result in different expectations dependent on classifying the risk priority differently – the so-called risk preferences, linked to the agent's activities carried out on the principals' orders. Both sides of the relation try to minimize the risk. Different goals may result from opportunism, where both sides enforce the realization of their own goals over common goals. The second problem refers to the mechanism which influences specific behaviors of the agent, according to the principal's expectations [4]. The unit which constitutes the basis of theory analysis is the contract defining the rules of cooperation between the principal and the agent. Important concepts introduced by the theory are: moral hazard, adverse selection and programmability. According to the research carried out by Dembe and Boden [5], the term "moral hazard" dates back to the 18th century and was widely used by British insurance companies until the end of the 19th century. The early usage of the term has negative connotations, linked to fraud or other immoral behavior – usually on the insuree's part. Renewed scientific interest in the phenomenon of moral hazard appeared amongst economists in the 1960s, and it was not applied to instances of fraud or immoral behavior. The term would be used to describe ineffectiveness, which could

[1] The research was carried out between 2012 and 2014 amongst 300 companies based in Mazovia, Greater and Lesser Poland, as well as Upper and Lower Silesia, which completed 370 projects consisting in management support information system implementation. The selected enterprises met the following criteria: number of employees between 80 and 1000, own IT department, minimal income: 40mln PLN.

[2] The ranking of theories applied to research of IT outsourcing with the use of 84 articles conducted by J. Dibbern, T. Goles, R. Hirscheim and B. Jayatilaka [2]. Theory of transaction costs—16, Strategic management theory—14, Agency theory—10, Group of resource allocation theories—9, Group of social exchange theories—7, Game theory—4, Theory of power group—2, Diffusion of innovations theory—2, Other theories, e.g. of knowledge management, risk management, psychological contract —13.

978-83-60810-66-8/$25.00©2015, IEEE

appear in case of bad risk management, rather than in the context of ethics.

We need to stress here that the agency theory, alongside institutionalism, the theory of contracts and the theory of transaction costs, constitutes a component of the new institutional economy [6], which is based on the idea of institution understood in three categories: *A*. social, defining the norms of human relations, *B*. legal, regulating the creation, duration and termination of legal relationship between legal entities and *C*. organizational, regulating the functioning of formal organizations, safeguarding certain norms.

J. M. Buchanan [7] confirmed that a new contractarian paradigm of a new institutional economy is forming, which he described by saying that "economics comes closer to being a 'science of contract' than a 'science of choice' [...] The maximizer must be replaced by the arbitrator, the outsider who tries to work out compromises among conflicting claims." This statement, as well as the concept of treating an enterprise as a cluster of contracts and making the project's success dependent upon the quality of contracts, fully confirm the rationale of a new institutional economy as a central element creating a model of IT services in the form of outsourcing.

The scope of the article is to present research results concerning the incidence of moral hazard in IT project completion as part of outsourcing. In the article, I focus on projects consisting in the implementation of management support information systems, i.e. ERP, BI, CRM and DMS. The article stems from an attempt to identify the conditions influencing the effectiveness of completing a given group of IT projects based on outsourcing. In my opinion, the factors influencing the effectiveness of IT project completion have been changing over the years and their character has become increasingly nuanced. This results from many factors, i.e. the rapidly changing technology, the evolution of project completion methods, the fast-growing saturation of IT system markets, the hypercompetition amongst suppliers, the behaviors and practices of suppliers during the process of sale or project completion. This is why I believe that researching the problem of outsourcing in IT projects is important, where the results will be beneficial both for theoreticians of business informatics and practitioners working in companies and government agendas. The article belongs to a cycle of over a dozen articles that I wrote to present the results of my research on IT project completion as part of outsourcing.

## II. Moral hazard in IT project completion

According to Y. Lichtenstein [8], agency theory describes the methods of completing IT projects during the whole life cycle of a project, i.e. as part of the following three stages:

*Stage 1*—Organization and completion of a tender aimed at selecting a management support information system and a company to implement it.

*Stage 2*—IT project completion.

*Stage 3*—Information system operation on the basis of an SLA contract.

Agency theory presents the contract for the service of implementation of a management support information system between the supplier and the customer as a relation between an agent and a principal. During the first stage of a project's life, an outsourcing agreement for the provision of IT system implementation services is established, and later on a Service Level Agreement is negotiated. Y. Lichtenstein [8] indicates that in case of negotiating IT project agreements, and later their implementation, an incompatibility of both parties' interests occurs. The client's goal and interest is the completion of an IT project within the planned time frame and budget, considering the Total Cost of Ownership (TCO) and meeting all the organizational and technological requirements designed for the project. The supplier's goal and interest lies in achieving a planned income in the whole life cycle of the project, meeting the planned quality of completed work. Table I (Source: Own Study) presents the contradictions between the client's and supplier's interest in case of completing an IT project consisting in the implementation of a management support information system.

Y. Lichtenstein [8] points out that a high level of information asymmetry between the supplier-agent and the client-principal means that at every stage of the project's life cycle, the supplier-agent may be prone to the abuse of trust: moral hazard, which results directly from the high level of information asymmetry concerning both the ERP, CRM, DMS and BI-class software as such, and the method of implementing the project. Especially in the case of projects completed on the basis of a fixed budget, the supplier-agent may have a strong motivation to push the cost below the planned budget, which can have an influence on the quality of services.[3]

[3] The research was carried out in 2013. It covered 500 enterprises where 895 IT projects consisting in the implementation of ERP, CRM, BI, DMS, BI and E-learning-class management support information systems were completed. The chosen enterprises were based in Mazovia and Lesser Poland and the research was conducted among enterprises employing less than 400 people. Research results showed that in the management support information system market in Poland, the structure of agreement types is as follows: 68%—fixed price contract, 27%—time and material contract, 5%—cost-reimbursable contracts.

TABLE I.
GOALS AND INTERESTS OF BOTH TRANSACTION PARTIES

| Client's goals and interests | Supplier's goals and interests |
|---|---|
| Fulfilling business goals<br>Fulfilling technological goals<br>Completing the project within the time frame<br>Completing the project within the maximum planned budget<br>Minimizing the total cost of software ownership (TCO)<br>Achieving functional and technological solutions creating a temporary competitive edge | Completing the project according to the planned quality<br>Maximizing the project's profitability in its entire life cycle, i.e. implementation and usage<br>Obtaining reference information after the completion of the project, which will allow the supplier to sell services to other projects |

The supplier-agent possesses all the information about their current activities and all their plans linked to project completion, while the client-principal has only a limited knowledge in this area. Knowledge concerning the completion of IT projects consisting in the implementation of management support information systems is increasingly robust and dynamically changing, which means that the client-principal is not able to effectively negotiate a favorable contract, and then supervise this type of project on their own. Due to the fact that both parties' interests are not equal, the supplier-agent may be prompted to take inappropriate action, i.e. abuse trust (moral hazard), in a situation where they are not controlled because the knowledge and experience of the client-principal limit the possibilities of effective control. The potential action of the supplier-agent aimed at securing the realization of their particular interests may result from their opportunism. Inappropriate behavior of the supplier-agent manifesting itself in trust abuse in the second stage, which is completed on the basis of a fixed budget, and in the third stage of a project's life cycle may lead to:

*A.* Guaranteeing full project profitability for the supplier-agent when it turns out that, already after signing the implementation agreement, the scope of the project is larger than originally foreseen at the bidding stage. This situation may occur when the client-principal was only guided by the price in their choices, while the competition amongst the suppliers was high. In the current situation of hypercompetition on the market, it may happen that this type of projects may be offered at a lowered price. In this situation, paradoxically, it is the client-principal who should make sure that the project price is not too low, with the assumption that they have given the supplier-agent all the requirements for the implemented IT system.

*B.* Increasing project profitability for the supplier-agent compared to the earlier plan of completing the project at a lower cost.

The result of the supplier-agent's trust abuse in the project's whole life cycle may be the occurrence of one, or a combination of several organizational complications impacting the effectiveness of an IT project, i.e.:

1. Lack of complete or partial fulfillment of project goals.

2. Unjustified exceeding of the budget in the completion of the second stage, as well as the third stage, the so-called Total Cost of Ownership.

3. Unjustified exceeding of the planned time frame for the completion of the second stage.

An important organizational aspect of the contract between the supplier-agent and the client-principal is an attempt to construct a mechanism which would effectively eliminate the possibility of trust abuse in the second and third stage of the project life cycle. Designing such a mechanism may turn out to be costly and difficult to complete [4]. My research results will allow us to indicate and describe selected attempts to abuse trust by the supplier-agent in IT projects consisting in the implementation of management support information projects, i.e. ERP, CRM, BI, and DMS.

## III. RESEARCH METHODOLOGY

In my research, I have used the multiple case study method. Four enterprises which implemented and are currently using management support information systems, i.e. ERP, CRM and DMS, constituted the subject of research. The goal of the case study is developing the agency theory, and especially a better understanding of the notion of moral hazard in management support information systems.

I analyze the case study, as it allows us to develop the existing theory and provide explanations of phenomena unrecognized before, such as moral hazard in IT projects. I focus on the client's perspective during the whole life cycle of an IT project in an enterprise, i.e. from the bidding stage to the operation of management support information systems. My choice of research method – case study, is motivated chiefly by two circumstances [9]:

1. The early stage of knowledge development in the given research area, i.e. agency theory in a specific group of IT projects.

2. Lack of recognition of moral hazard in real conditions.

As part of the multiple case study analysis, I would like to pose the following research question:

In what behaviors does moral hazard in the relation between the principal (client) and the agent (supplier) manifest itself in case of IT projects consisting in the implementation of management support information systems based on outsourcing?

The choice of studied cases was carried out through purposive sampling. According to B. Flyvbjerg [10], there are five main criteria of case selection. Table II (Source: [10]) presents the criteria along with their characteristics in the context of conducted research.

TABLE II.
FIVE MAIN CRITERIA OF CASE SELECTION

| **Criterium** | **Information on the fulfillment of the criteria** |
|---|---|
| Data availability | Guaranteed |
| Distinctiveness of the case, clearly illustrating studied patterns | Projects that ended in partial failure, but not interrupted during the implementation |
| Variation in the analyzed cases | Variation in the analyzed cases is expressed in the selection of:<br>- IT projects consisting in the implementation of four management support information systems, i.e. ERP, CRM, DMS<br>- Client profile<br>- The results of project implementation |
| Critical character of the phenomenon allowing to formulate a general statement | The incidence of moral hazard between the agent (supplier) and the principal (client) during the whole life cycle of project implementation influences the results of project implementation from the client's perspective. |
| Metaphor allowing to point the researcher's attention towards a specific course of the studied phenomenon | Aiming to analyze the phenomenon of moral hazard in the entire project life cycle, I selected cases that could be studied at the stages of: bidding, contract negotiations, implementation and information system operation. |

## RESEARCH RESULTS AND THEIR INTERPRETATION

Table III (Source: Own Study) presents the results of multiple case study research.

I analyzed the implementation of ERP, CRM, BI and DMS-class management support information systems completed as part of a contract based on a fixed budget. All the analyzed implementation projects ended in partial failure, although their implementation was not interrupted. I diagnosed three major types of supplier's behavior, through which moral hazard, resulting from the opportunism[4] of the supplier-agent and a high level of information asymmetry between the client (principal) and the supplier (agent) in IT projects, manifested itself.

*Behavior 1.* An attempt to minimize the supplier's cost of completing stage 2 and 3 of the project by:

- Engaging specialists with low competences and little experience, which is linked to their low salary.
- Lowering the actual workload of consultants working on specific tasks in the project in comparison to the workload declared in the agreement regulating the outsourcing of implementation services.

*Behavior 2.* An attempt to sell implementation services concerning stage 2 at a lowered price, which will allow them to win the tender in the conditions of hypercompetition in the market. The supplier's intention is to compensate for the possible losses in stage 2 with profits in stage 3.

*Behavior 3.* An attempt to intentionally complete chosen types of project tasks in stage 2 poorly, e.g. acceptance tests, training and project documentation in order to create a competence gap concerning system configuration amongst client's application users and make it impossible for them to introduce changes to the configuration independently, e.g. in stage 3, which will increase the number of client's orders from the supplier.

To sum up, in their entire life cycles, the analyzed projects did not end in full project success, however we need to stress that the projects were not interrupted and abandoned. Two main results of project complications were observed, i.e. exceeding the budget both in stage 2 and 3, and exceeding the time frame without justification while completing stage 2. In each case, the clients engaged external consultants, who in the first two stages of the project played the part of the "client's advocate", indicating the dangers linked to the supplier's behavior and the possible consequences of their materialization. Another role of the external consultants was suggesting counteractions to the client, in order to minimize the danger of the project ending in a total failure. Most probably, it was the engagement of external consultants that led to the projects' partial success and prevented them from failing completely. In spite of this, the respondents from the client's side clearly indicated that the supplier's behavior, through which the moral hazard manifested itself, was the source of project complications. Amongst the researched IT projects, there were three types of behavior that demonstrated moral hazard on the supplier-agent's side. In-depth analytical workshops with the representatives of the client-principal showed that the members of client's project group diagnosed the described behavior already

[4] *Polish Language Dictionary* (Warszawa: PWN, 1996), defines opportunism as concentrating on one's personal interest while ignoring common goals and generally assumed codes of behavior.

during stage 2 of the project. Moral hazard at this stage of the IT project leads to a deep crisis of trust and decreases the chances of a successful project completion. The mutual loss of trust influences the increase of transaction costs [11], especially the cost of monitoring the agreement implementation, the adjustment cost and the cost of terminating the agreement by the client, which can on its own lead to a complete failure of the project. In analyzed cases, increasing client's transaction costs was visible mostly in the increasing workload of the tasks. During in-depth workshops, the respondents on the client's side made suggestions that they would like to pass on to the future client's project managers, who will be responsible for the implementation of stages 1 and 2 of the IT projects:

- Engaging external consultants as client's "advocates" with the aim to support the completion of stages 1 and 2.
- Professional preparation for project implementation by the workers from client's project group:
  - o Specifying precisely (ex ante) the functional requirements of the system.
  - o Specifying precisely (ex ante) the direct and indirect benefits of the project.
  - o Specifying precisely (ex ante) the requirements for the supplier.
  - o Specifying precisely (ex ante) the requirements for the IT system.
- Designing an implementation agreement, which could eliminate the morally hazardous behavior of the supplier.

We need to stress here that the presented types of supplier's behavior are universal and they concern all the relations between the supplier and the client, also in case of contracts signed in public administration.

## IV. Conclusions

The respondents stressed that the agreements of software licensing purchase, service purchase and Service Level Agreement are not simple and even in the current economic structure there are very few specialized lawyers who, linking their legal and MIS knowledge, could secure the company's interests. During in-depth analytical workshops, the respondents indicated that many lawyers de-

Table III.
The results of multiple case study research

| | Company X | Company Y | Company Z | Company A |
|---|---|---|---|---|
| Client's (principal's) profile | Bank | Manufacturing company | Service company | Legal firm |
| Type of purchased IT system | BI | ERP | CRM | DMS |
| Supplier's (agent's) profile | Reseller of software designed by the market leader | Reseller of software designed by the market leader | Reseller of software designed by the market leader | Reseller of software designed by the market leader |
| System operation period | 5 years | 4 years | 7 years | 7 years |
| Implementation results | Project not completed on time without justification, stage 2 completed within the budget, operational costs increased significantly in stage 3 compared to the original estimate, not all the business goals completed. | Project not completed on time without justification, stage 2 not completed within the budget, operational costs increased significantly in stage 3, not all the business goals completed. | Project not completed on time without justification, stage 2 not completed within the budget, operational costs in stage 3 according to the plan, all the business goals completed. | Project not completed on time without justification, completed within the budget, not all the business goals completed. |
| Type of implementation services | Fixed budget | Fixed budget | Fixed budget | Fixed budget |
| How does the moral hazard in the principal (client) – agent (supplier) relation manifest? | The budget for the completion of stage 2 was calculated by the supplier on the basis of a lower hourly wage for the consultant than stipulated by the maintenance service budget in the SLA agreement regulating the system maintenance services in stage 3, i.e. the operation stage. The change of rates took place directly after the completion of stage 2. Thus, the total system maintenance cost (TCO) increased in relation to the estimates completed in stage 1. | Engaging people with low qualifications and little professional experience in the area of a specific ERP system in the given manufacturing company. Thus, the client does not obtain the benefits resulting from the knowledge transfer and good practice.<br>Decreasing the engagement of supplier's consultants in some implementation tasks, e.g. completing acceptance testing with system calibration in comparison to the obligations included in the agreement concerning the workload of this task. | The low quality of knowledge transfer carried out by the supplier, both regarding the configuration and operation of the system by its end users, with the aim of creating the client's competence gap.<br>The supplier's consultant-programmer programs the system to limit the workload during the completion of stage 2, e.g. by introducing constants instead of variables in the code, which results in eliminating the possibility of configuring a given function simply and without an excessive workload in stage 3. | Engaging people with low qualifications and little professional experience in the area of a specific CRM system implementation. The people engaged by the supplier as key consultants had only graduated from university 2-3 years beforehand. Decreasing the engagement of the supplier's consultant in certain implementation tasks (e.g. ensuring the quality of data migrated from the old system to the new system, training key system users) in comparison to the obligations included in the agreement regarding the workload of the task. |

signed the agreements trying to eliminate the moral hazard, struggling between two extreme approaches, i.e. case-specific agreement, which was supposed to foresee and eliminate the majority of dangers resulting from cooperation in stage 2 and 3, and a simplified agreement regulating only the basic aspects of the cooperation. In case of case-specific agreements, transaction costs increase dramatically[5]. The presented research results point towards three basic behaviors of the supplier where moral hazard occurred in IT projects, resulting from the opportunism of the supplier-agent and a high level of information asymmetry between the client (principal) and the supplier (agent). All the three types of behaviors increased the risk of an unsuccessful IT project implementation and influenced the transaction costs, also through the loss of mutual trust. Identifying the unwanted behavior of the supplier allowed the client's project group to react and to minimize the risk of the project's failure.

New institutional economy treats enterprises as a cluster of contracts and it makes the success of the projects dependent on the quality of agreements. We need to underline that institutional economy focuses not only on analyzing the available choices and making those choices, but also on solving conflicts as part of the enterprise's stream of contracts. Considering the current and projected saturation of the market with management support information systems, we need to stress that a cluster of contracts regulating IT outsourcing constitutes one of the most important agreement groups in a large group of enterprises. Until now, IT projects were rarely analyzed from the perspective of institutional economy by Polish theoreticians of business informatics, thus creating a research gap. Special attention in this area is owed to the work by J. Auksztol [3]. I believe that tightening the knowledge gap and promoting the knowledge, as well as practical skills in this area, may increase the effectiveness of implementing IT projects based on outsourcing, both in enterprises and government agencies.

*Abstract*—**The paper presents considerations on the concept of big data. The aim of the paper is to confront the attempts of defining big data with its common understanding by different groups of users. In this research the group of respondents are students of Warsaw University of Economics. The authors advocate that the student's opinion and attitude to big data can be important regarding the fact that they will probably become managers - business users of big data solutions. Another aim is the analysis of present educational offerings of Polish universities in the area of big data and suggesting the directions of the development of educational curricula to better fit the marked demand for big data professionals.**

## I. Introduction

THE attempt to demystify Big Data may on one hand lead to numerous definitions that can be found in academic literature, corporate and individual blogs of companies and people interested in latest advances, algorithms, and practical applications in this field [1] [2]. On the other hand some publications regarding better common understanding of Big Data and its social aspects can be found [3].

The term 'big data' is very simple in its construct, it is a combination of two frequently used words 'big' and 'data'. The simplicity of the term makes even non-specialists have their own idea on what big data really is. The term suggests gathering, processing and using large volumes of data.

'Big' is a relative term which changes its meaning along with technology development. Particularly performance and capacity challenges that are associated with big data systems evolve over time in their nature, scale and scope. Thus it is not surprising there is much confusion surrounding the term.

The phrase 'big data' has been extensively used in the recent years. For example analysis of keyword popularity with the Google Trends tool reveals the constant, systematic and regular growth of number of searches with the keyword 'big data'. This phenomenon has been taking place since the year 2012 (see. Fig.1). However the question about context of the searches stays open so the further research is sorely needed.

Over the past five years, the emergence of huge data sets and data-intensive science are fundamentally changing the way researchers work in virtually every scientific discipline. This phenomenon can be easily observed while analyzing bases of scientific publications (see. Fig.2.).

Big Data is currently understood as the term increasingly used to describe the process of applying serious computing power to seriously massive and often highly complex sets of information [4], data sets whose sizes exceed the capacity of

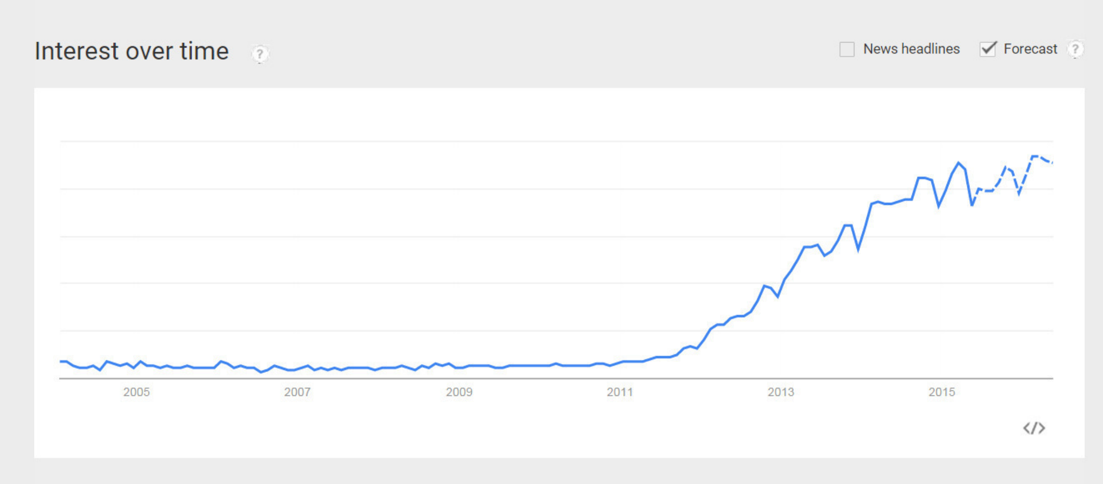

Fig. 1 Big data search term – interest over time with forecast, Source: Own elaboration

978-83-60810-66-8/$25.00©2015, IEEE

conventional database tools for gathering, storing, managing and analyzing data [5]. The above definitions are timeless and universal because they are not domain-specific and do not specify the typical big data features in any point of time, however they emphasize the change that has happened as compared to 'conventional database'. This point of view is highlighted for example by Dumbill [6] who states that: Big data is data that exceeds the processing capacity of conventional database systems. The data is too big, moves too fast, or doesn't fit the strictures of database architectures.

Other examples of definitions underline the unstructured character of data, i.e. accordingly to Rouse [7] big data is a general term used to describe the voluminous amount of unstructured and semi-structured data a company creates - data that would take too much time and cost too much money to load into a relational database for analysis.

Model 3V of META Group [8] is usually considered a starting point for describing big data in the modern sense. The big data notion was not considered then, but its 3 basic features were taken into account: Volume (very large volumes of processed data), Velocity (variability and dynamics of processed data), Variety (variety of processed data). Later various authors tried to choose other features characteristic for big data, which could enhance the 'v' model, particularly: Value – the processed data is valuable, Veracity – another way 'accuracy' or 'truthfulness', Visualisation – the possibility to present the vast amount of data in a way that would be comprehensible, easy to understand and read.

The 'Volume' feature is the most difficult to verify among the original 3V because the amount of data significantly increases with the IT development. The volume of large datasets may differ depending on the area of application. The remaining 'v' features seem very important: the possibility of real-time analyses of particular variables, such as stream data, sensor data (velocity) and analysis of various unstructured data (variety). These features are characteristic to contemporary big data in contrast to the previous approaches to massive data processing.

Attempts to define the term big data are as well very general and timeless as bringing up the technological aspects and trends which on one hand describe the concept in a more detailed way but on the other hand go obsolete very quickly. At the same time, because of dynamics of the discussed term different opinions can be found agreed that the concept is not yet fully definable.

## II. THREE-ASPECT APPROACH TO BIG DATA. THE AUTHOR'S WORK ON UNDERSTANDING OF BIG DATA CONCEPT

The lack of unified definition of the term big data coupled with the high recognition and popularity as well in scientific papers as in popular publications induced the Authors to investigate its common understanding by different professional and social groups.

The Authors conducted research on the context of using the term 'big data' in press articles from daily newspapers [3]. The analysis of online edition the newspaper of Agora (one of the biggest media companies in Poland) was conducted twice: in March and September 2014. The thematic context of 10 of the top search results for the key word 'big data' had been analyzed after excluding the incidental cases where the document's context was not relevant to the research subject.

The Authors proposed "three-aspect approach", identifying three essential aspects of big data: technological, business, social.

**The technological aspect** in the above classification represents a focus on the methods of big data analysis and information technology used. Considering the methods of analysis the big data concept is based first of all on well-grounded statistical methods, artificial intelligence, machine learning and data mining. Similarly to the latter, the aim of big data analysis can be exploration of implicit associations and patterns in large data sources. The big data approach is to analyze all the accessible transaction data rather than a representative sample. Such approach does not require a predefined model and hypothesis, but enables discovering

Fig. 2 Number and subject areas of scientific publications on big data in Scopus base, Source: Own elaboration

previously unknown patterns in all the accessible data. Moreover the big data approach gives a possibility to analyze unstructured data such as texts from internet pages.

**The Business aspect** of the described classification focuses on applications of big data. Considerably shrinking cost of data gathering and processing makes it worth to process the data which were previously not possible or economically not feasible. The new approach can be the solution for information overload which refers to the situation when there is enough accessible and relevant data but there are no capabilities to process or draw conclusions on the basis of the data [9]. The big data can be considered the next stage in evolution of business intelligence and predictive analysis. In this context the possibility of using transactional data directly for analysis seems to be very important qualitative change. This change is especially viable for implementation of new organizational solutions and methods. As Płoszajski [10] notices in history it was always so that when the prevalence replaced rarity, the necessity for new business models arose.

Part of the new applications are old but improved solutions for data mining, risk modelling, fraud detections, churn predictive modelling, load forecasting for electric power systems, stock technical analysis, optimization of logistics [11]. Combining the concept of big data with other ideas (e.g. GIS, cloud computing) allows many new benefits, for example in supporting public administration, regional electronic communities [12].

**The social aspect** of big data is in the Authors' opinion associated with social consequences of data processing results. These matters are often overlooked in definitions of big data concept. Alongside the clear and unquestionable advantages for society, there are also some threats, the first of which is associated with massive processing and using of personal data. In contemporary world every person leaves large amount of electronic traces such as records in the data bases or different archives of unstructured data. These are the data describing the activities of the internet user, in particular e-mails, posts on social networking websites, pages visited, keywords and phrases input into search engines, billings and geolocation data from mobile networks, data on financial transactions (payments with credit cards, bank transfers), data from loyalty programs, purchases, medical sensitive data, video from monitoring systems. The abovementioned data may have great commercial value (for example enable personalized targeting and displaying custom ads) and public value (i.e. protection of public security). The essential issue in question is the required level of privacy which can be different in commercial and public applications of big data processing.

Source: Own elaboration

The Author's researches on the concept of big data were focused on assigning the context to the press articles and notes. Because some of the papers were focused on several aspects, the total number of references in each text was over 10. The summarization of research results is presented in table I.

It should be highlighted that the research encompassed only nonprofessional press. Moreover what is puzzling is a very small number of references to technological aspect. The articles which were strictly economical were focused on the examples of big data applications. Most of the references were to the social aspect. The potential threats of privacy were often discussed especially in the contest of data processing by various institutions, the control of the internet and social networking websites by commercial units.

It is generally can be seen in the press articles that particularly interested for journalists is the social aspect, to a lower degree applications and least interesting were the technological and analytical issues. The reason for this lack of interest in technological aspects is probably the lack of expertise and competencies in technology and data processing. Most of the journalists were trying to follow popular, trendy topics. Popularizing big data the journalists often emphasize the influence of technological developments and economic changes on society.

## III. RESEARCH ON KNOWLEDGE BIG DATA CONCEPTS

The Authors decided to explore the knowledge and understanding of big data among students. The aim of the research was also to verify the hypothesis that the social aspect of new technologies is particularly important for the respondents. The studied community was a group of students from the Warsaw School of Economics.

Apart from openness to the new solutions, which is the typical feature of young people, it is vital to be broadminded and realize the potential of the new technologies applications. In particular the students of economic schools should have well-grounded, good idea about ICT applications in widely understood economy. This issue is especially important for this research. The future users of big data – based solutions will probably be today' students of economics, statisticians and analysts (so called data scientists). A broad group of big data users will probably be the management professionals from companies and institutions who will commission studies of big volumes of data. Therefore the group of respondents was intentionally chosen to draw conclusions about the desirable new directions for higher education in the area under consideration.

The group of 140 students underwent the survey using traditional paper questionnaires with closed questions. Among the surveyed persons 75 were first-year students and 65 second of third-year students. In the Warsaw School of

Economics the first-year students implement the standard study program including, inter alia, basic courses on technology and statistics.

In the next years of studies the students have more possibilities to choose the courses and their sequence depending on their interests. For this reason in the research procedure students are divided on two groups – the first year of study and higher (II and III) years of studies. The respondents were asked to state whether they are acquainted with the term 'big data' and more detailed questions regarding the understanding or the considered term (11 questions) and its characteristic features (8 questions) were asked. The data were gathered during the educational activities not relevant to big data concept. Such a form of survey ensured virtually 100% response rate.

The assumption was made that the students have enough knowledge on the basic level to understand the capabilities of modern information technologies and their applications (in particular in business), and also they should realize the social consequences of using big data.

For the question „Have you ever met the term 'big data' in contest of new possibilities of massive data processing?" there were 58% of positive answers. It should be noted that the number of positive answers is increasing. Among the students of the first year there were 40% of positive answers, while on the higher years of studies there was 77%.

Although it cannot be claimed clearly that the subject of big data is included in the obligatory courses for bachelor studies, the teachers may mention about it during the obligatory course of 'Statistics' on the first year of study. Moreover the concept can appear in the content of other courses however it is not fully discussed.

In this case the understanding of big data term is of special interest. The further analysis of survey results will only take into account the students who have acquaintance with the term big data. A clear majority of respondents (68%) understands big data concept very broadly, as every processing of large amounts of data. This group does not think of big data in terms of theoretical considerations and it can be supposed that they understand the term 'big' in a purely common way. However regarding the continuous theoretical considerations on the term big data and the lack of uniform definition it cannot be assumed that this 'shallow' understanding is not correct.

The students' faith in the efficiency of typical big data methods can be observed. Most of them (65%) claim that the characteristic feature of big data is quality of data processing: 67% of the first year students, and 62% of the higher years of study. In consequence most of the students do not see the problems of data quality which are in fact typical to big data. And again the awareness of importance of this problem increases along with the year of studies (17% totally, in which 7% for the first year and 24% for the second and third year).

The majority of the respondents stated that great business value of processed data is characteristic for big data (83% of all the respondents, 77% first year of study, 86% higher year of study). Because the respondents are students of economics it seems natural that they notice the significance of detailed data in management. However it can be noted that the students' attitude to the massive data processing tends to be slightly indiscriminate. And again the criticism increases long with the education level and is probably caused by improving knowledge. Considering the field of study, it can be assumed that the business aspect of big data is more clear for the respondents than the technological one. The technological issues are not explained in detail, similarly the analytical methods are discussed only on the selected study specializations on master degree.

The survey results on social aspect of big data are also interesting. According to most of the students a threat to privacy when using massive data processing for surveillance, monitoring of individuals and identification are not associated with big data (45% of positive answers). This is also the case with privacy law and personal data processing with IT tools (35%). Generally the number of positive answers is not low. Compared with the previous research on journalists, the students pay more attention to possibilities of using big data for economic purposes than on threats to privacy. It can be assumed that young people somehow used to partial loss of privacy, due to the fact they extensively use internet, in particular social networks that is necessarily associated with privacy issues. However to prove the hypothesis it would be necessary to conduct specific studies.

The above discussed results of the survey are related primarily to questions about the opinion: how wide is the concept of big data, which is practical importance and what could be the negative consequences of applications. Other questions allow for verification of the correct understanding of the concept. Most respondents correctly classified technology of high-performance computers into big data idea (62%) and very large amount of processed data (91%). These questions do not relate to technical terms and the answer seems to be intuitive. On the other hand, there is no knowledge of IT terminology associated with big data.

The results showed poor understanding of problems of big data (particularly in IT) among students of economics. There is also an increase in knowledge at the later years of study, mainly in statistics and the possibility of use of big data solutions.

## IV. Big data and education

The widespread use of Internet, mobile computing and sensor networks are generating massive amounts of data available for decision making. As the Internet of Things grows the data can be collected from more sources. The increasing storage capacity and cloud storage solutions allow the data to be gathered across longer periods of time, and a greater number of variables can be monitored, at a relatively low cost and with less effort than ever before.

This situation brings opportunities and challenges to many domains, so the educational institutions should definitely focus on this emerging field to satisfy the market demand for professionals in big data analyses, applications and technologies.

Given the broad scope of the issues covered by big data domain, higher education in economic schools should provide an overview of the possible uses of big data in business and administration institutions. The key aspect is to develop students' ability to critically evaluate the technologies, and consequences of their application. The Authors while browsing information about educational offering were attempting to identify academic courses which are related to any aspects big data.

Table II presents an overview of university courses that strictly or somehow referred to big data. The faculty name in the second column of the table provides a context for the course name. The short research on available courses was made by analyzing the online resources of the USOS systems of different universities where the detailed syllabi of the courses are available.  The syllabi contain content of subjects for each classes. The criteria to choose the course as somehow related to big data were that at least one of the topics has the keyword ‘big data’.

The 15 example courses have been identified among different levels of education: bachelor or master degree, post-diploma and also studies founded from Erasmus program. It is worth to notice that, the range of faculties and their specializations is quite broad from social sciences, through business oriented to strictly technological ones. Five of them refer directly to the phrase ‘big data’ in their titles and all of them are offered by information technology or economic faculties or specializations. These technical and economical faculties also some other courses related to big data such as programming, visualization of information, social networks etc. The term ‘big data’ also appears in descriptions of strictly humanistic subjects, for example offered by Faculties of Polish Studies in the context of social media.

Table II. Overview of university courses that referred to big data

| no. | Course name | University / faculty or institute |
|---|---|---|
| 1 | Big data | Warsaw School of Economics |
| 2 | Big data | Wrocław University of Economics / Management IT and Finance |
| 3 | Big data and business analytics | University of Zielona Góra / IT |
| 4 | Big data processing | University of Warsaw / Mathematics, Informatics and Mechanics |
| 5 | Big data processing | University of Wrocław |
| 6 | Business intelligence systems | Nicolaus Copernicus University in Toruń / Management |
| 7 | Concurrent and Distributed Programming | University of Warsaw / Mathematics, Informatics and Mechanics |
| 8 | Culture 2.0: social media | Jagielonian University in Kraków / Polish Studies |
| 9 | Design and visualization of information | Nicolaus Copernicus University in Toruń / History |
| 10 | International Forecasting and Simulations | University of Warsaw / International Relations |
| 11 | Landscape of today's Polish Internet | Kazimierz Wielki University in Bydgoszcz / Administration and Social Science |
| 12 | Mass media | Universitas Opoliensis / Polish Studies |
| 13 | R and Big data | Warsaw University of Technology / Mathematics and Information Science |
| 14 | Social networks and multi-agent systems | University of Zielona Góra / IT |
| 15 | Social portals - the role and importance | University of Social Sciences / IT |

Source: Own elaboration

The presented research shows that the term ‘big data’ is applied in broad range of domains. The technological aspect (in the context of applied IT solutions) is mainly visible on IT oriented fields of study and in the context of analytical methods, also can be met on IT and economic studies. The business aspect of the analyzed courses is mainly considered from the social media on humanistic studies.

The social aspect of big data is also considered. It should be noted that among the identified courses commercial applications or public administration point of view are not present. We can suppose that there are some courses that deal with business data processing but this is not exposed in the course syllabi as ‘big data’. However it cannot be said that the term ‘big data’ is used only on technical studies.

There are first attempts to create the fields of study addressed to future big data specialists. One of those efforts is the master-level study in SGH (Warsaw School of Economics). “Advanced Analytics – Big Data” has interdisciplinary character and it is placed in scientific disciplines: economics, management sciences, mathematics and informatics. Competencies of the graduates are focused on the problems of acquiring, ordering, storing and analysis of large data volumes using advanced tools. The competencies of the graduates are planned to be the focused on business and economic phenomena and processes.

The new field of study will educate the specialists in data acquiring – as well structural as unstructured – from many resources (i.e. data bases, data warehouses, internet, text files, sensor data and geolocation data) and their analysis which encompasses searching for hidden associations, knowledge extraction, creating prognostic and simulation models and interpretation of the results.

Among the specialization courses apart from detailed economics, there are some courses on data bases and data warehouses, decision rules, optimization methods, graph and network theory, data mining, text mining, data visualization and concept of big data. Moreover the large number of computer laboratories was foreseen with SAS software. [13]

It should be noted that the field of study described above is aimed at educating relatively few analytics and big data professionals. Another issue is education of many specialists of management, finances, administration and other fields, who should have general knowledge on big data, directed on the ability to use this concept.

## V. Conclusions

Above considerations show the multiaspect and relative immaturity of big data concept. The concept is constantly evolving due to the very relative term 'big' and can be understood in many different ways. The research of popular paper articles, survey among students and research on educational curricula of Polish universities also confirm this hypothesis on multiaspect and nonuniform understanding of the big data concept. As the research shows, in spite of high recognition of big data term, its understanding among students of economic studies is mainly intuitive and associated with everything that is related to data storage and processing of large data volumes. The specific big data features poorly recognized by students and often highlighted by big data professionals are: lack or poor structuring of data and their processing for analytical purposes in a real-time.

Apart from poor understanding of the concept, the interesting aspect is the respondents' faith in the business utility of big data solutions. The business aspect for this group is most important. Such attitude is differs from the attitude represented by most of the journalists for whom the business aspect in most cases is an occasion for discussing and describing potential problems of privacy violation and its social repercussions.

The analysis of academic curricula related to big data also indicates its broad conceptual scope. Depending on the field of study various aspects are discussed. At present the students of economic studies are supposed to be future managers. Once on the labor market they will probably expect to have information technologies and analytical methods to bring them valuable data to help them improve business performance. This can bring positive effects in the form of increased IT investments for data analysis and big data applications. In this situation the interest in big data technologies should be used as a chance to improve the level of education in this area, so the future managers could understand real capabilities offered by massive data processing. The education in this field is necessary not only for small group of data analysis specialists/data scientists but also (to some certain degree) to all the students of economic studies. Simultaneously, apart from providing technological knowledge the care should be taken to understanding the social aspect of big data. Improper use of personal data may lead to society's reluctance and in consequence for example to establishment of legal regulations significantly limiting the applications of new technologies of massive data processing what could be harmful for the country economy.

*Abstract*—**This paper is devoted to the cloud computing model and the opportunities and challenges connected with its utilization by business organizations, including the most significant issues related to the cloud migration strategy. It is composed of five parts. In the first, some facts concerning cloud computing as a new technology and the reasons for organizations using this type of computing model are provided. Next, the notion of cloud computing is briefly defined and the most significant opportunities and possibilities linked with cloud-based solutions are presented and discussed. The following part is focused on the analysis of the most important problems and challenges connected with the cloud computing model. The penultimate part of the paper deals with the issues connected with the cloud migration strategy, focusing on the most important elements. In the final part of the paper, the most significant conclusions and suggestions are offered.**

## I. Introduction

THE dynamic development of solutions available using the cloud-based model and the growing interest in them can be noticed taking place over recent years. Cloud computing is perceived as one of the components of the next-generation IT infrastructure (NGI) of contemporary organizations and a very important technology of the future [1]. According to the report by the McKinsey Global Institute, it is regarded as one of twelve potentially disruptive technologies that will transform business and the global economy [2].

The importance of cloud computing as a technology has been confirmed by various studies. The results of the 18th Annual Global CEO Survey (1322 company leaders from 77 countries) conducted by PwC indicate that cloud computing is considered by CEOs as one of the six most strategically important developments in digital technologies [3]. According to the results of the 2014 Technology Innovation Survey, conducted by KPMG among almost 800 global technology industry leaders, cloud computing is a top technology that will have the greatest impact in driving business transformation for enterprises [4]. In addition, the results of a survey of ICT professionals, carried out by the German Federal Association for Information Technology, Telecommunications and New Media (BITKOM), confirms the importance of this technology. 64% of those surveyed consider cloud computing as the leading information and communication technology trend [5].

The significance of cloud computing additionally increases because of the fact that it enables other highly impactful technologies, including: mobile Internet, automation of knowledge work, the Internet of Things, and Big Data [2], [6], [7].

So, in the context of the importance of this technology and its transformational potential, it is pertinent to analyze a few of the key issues connected with it, which this paper will proceed to do. They include the following aspects:

- the opportunities and benefits connected with cloud computing utilization,
- challenges and concerns connected with cloud computing usage,
- the cloud computing strategy and its key elements.

## II. Opportunities and benefits connected with cloud computing utilization

There are many diverse benefits and opportunities arising from the adoption of a cloud computing model and different mixes of the delivery (SaaS, PaaS, IaaS) and deployment (public, community, private and hybrid clouds) models. Although cost is very often indicated as a key benefit, ([8], [9]) in fact there are much more important advantages associated with this approach. According to the results of the above mentioned 2014 Technology Innovation Survey, there are four main categories of benefits connected with this technology. They include [4]:

- improved business efficiencies/productivity (37%),
- cost reductions (22%),
- faster innovation cycle (11%),
- accelerated time to market (10%).

Other reports also often indicate considerations such as [2], [10], [11]: increased agility, opportunities connected with the implementation of new business models, improved collaboration among business units and partners, geographic expansion, creating new opportunities for SMEs. If the issues connected with an organization's productivity are concerned, there are two main considerations. They are [2]:

978-83-60810-66-8/$25.00©2015, IEEE

- infrastructure and operating expenses,
- application development and packaged software.

According to estimates by the McKinsey Global Institute, in relation to the first of these, productivity gains could reach 20-30%. They result from [2]:

- reduced infrastructure and facilities footprint,
- high task standardization and automation.

In the second case the McKinsey Global Institute estimates that productivity gains could reach 10-15%. They result from [2]:

- standardization of application environment and packages,
- faster experimentation and testing.

There are many aspects of the cloud computing model which can result in lower costs. For example, if the physical IT infrastructure is considered the most important aspects include [2], [8], [9], [12], [13]:

1. Reduction or elimination of waste related to the low level of hardware utilization.
2. Reduction of costs connected with hardware maintenance.
3. Lowering costs related to energy consumption.
4. Possibilities for the permanent analysis of costs and the selection of the optimal service level.

In the case of software utilization, the cloud computing model can lead to the reduction or elimination of costs connected with:

1. Purchase and installation of software, its maintenance and upgrade.
2. Purchase of wrongly selected software (see [14]).
3. Low level of software usage.
4. Developing and testing of applications.

There are many new factors connected with cloud computing which have an impact on faster innovation cycles. Easy and cheap access to tools for the development and testing of new products or services, e.g. cloud-based Big Data tools, is a good example in this context [7]], [15]. Big Data tools are already being used for this purpose by a growing number of companies [16].

Simultaneously, the implementation of cloud-based solutions leads to a diminishing demand for IT department employees to be responsible for the maintenance of an organization's physical IT infrastructure and, correspondingly, the possibility to release some of the budget previously allocated for this purpose. This allows for the reinvestment of the savings on innovative products or services. According to the results of the earlier cited survey conducted by the Manchester Business School and Vanson Bourne, this occured in the case of 62% of the companies surveyed [9].

Use of the PaaS model is a good example as far as accelerated time to market is concerned. In this case companies which develop their own software instead of creating their own environment can instantaneously use ready-made tools for the application building process, delivered to them as a service.

If company agility, understood as the capacity of an organization to identify and capture opportunities more quickly than competitors, is considered, cloud computing significantly increases the possibilities of companies in this respect, due to the fact that utilization of the cloud-based model considerably broadens opportunities for the quick and flexible adjustment of an organization's IT infrastructure to new needs or new market situations. Such situations can require the implementation of new applications, adding new services or increasing computational capacity. In addition, using cloud-based solutions can be quicker than using a company's own staff [2].

Utilization of the cloud computing approach also provides organizations with numerous new opportunities to implement new business models. In many cases, these business models would not be feasible without usage of this computational model. An innovative business model called car sharing, implemented by the Zipcar company, is an example of such a situation. This business model is based on a complicated management system of a single set of cars which are shared by many users, which would not be possible without an advanced IT system where one of the key elements is the utilization of the cloud computing model [17].

Improved collaboration among business units and partners is made possible by the provision through the cloud of easily accessible, continually developing, applications. This aspect, combined with the above mentioned opportunities to build and implement new business models, provides organizations with new possibilities for geographic expansion.

The cloud computing model also provides small and medium enterprises (SMEs) with significant opportunities, especially in respect of costs. In the case of the smallest SMEs or start-ups with only small levels of capital at their disposal, this is not in relation to the reduction of costs previously incurred for IT infrastructure but rather opportunities to access hardware and software which would not be achievable in the traditional computational model, owing to financial barriers, particularly around the purchase of hardware and software and the employment of skilled IT workers to cover maintenance. The cloud model and the associated possibilities of "hiring" services connected with physical IT infrastructures or applications, enables smaller firms to more effectively compete with large organizations [8]. They can also access sophisticated solutions such as the above mentioned Big Data tools or the programming environment in the PaaS model.

## III. The most important challenges and concerns connected with cloud computing utilization

As is the case of all IT solutions, those offered in the cloud model bring not only benefits and opportunities but also problems and challenges. According to the results of the above mentioned 2014 Technology Innovation Survey, there are three main groups of challenges connected with the cloud computing model. They include [4]:

- security (23%),
- technological complexity (16%),
- risk management (15%).

Security anxiety is undoubtedly the key concern connected with this technology, and is confirmed by the results of other studies [2]. According to the Cloud Security Alliance there are various types of security concerns including such aspects as: data loss/leakage; account, service, and traffic hijacking; shared technology vulnerabilities or insecure application programming interfaces [18]. Of course the level of the potential risk depends on many factors, including the type of cloud being used, the service provider, the technologies being used (including data encryption) as well as the procedures it uses, or the procedures applied by a client-organization. In the latter case, it also relates to the phenomenon called shadow IT, which is the use by employees of cloud-applications not approved by their IT departments for business purposes [19].

The spread of the cloud computing model should also reduce the issue of technological complexity, due to the fact that service providers are likely to do everything to make their solutions as simple and as easily manageable as possible. Such a trend is already perceivable (see [20]).

The third issue which causes the biggest anxiety among managers is risk management connected with the utilization of the cloud computing model. Apart from the above mentioned security-related issues, some of the most import challenges are those connected with the availability of services. The deeper the dependency of an organization on cloud-based solutions, the more important this issue is. In spite of numerous publicized cases of problems with the availability of cloud services from well known providers, availability of this type of service is generally at a very high level. This fact is confirmed by the results of various studies (see [21]). Regardless of the level of availability of cloud services, every organization which utilizes the cloud computing model has to have appropriate procedures and technological solutions in place in case of problems with access to services. The same relates to the management of other types of risks.

Apart from the above mentioned issues, there are other challenges and limitations connected with the implementation and utilization of the cloud computing model. In the case of technical issues, one of the most important, and often underestimated issues, is network capacity. This is due to the fact that cloud-based technology is deployed through massive data centers that necessitate high-capacity bandwidth [2]. Simultaneously bandwidth requirements can significantly differ depending, for example, on the type of cloud-based application (basic, intermediate or advanced) [6].

The next element can constitute a significant hurdle in the process of adoption of a cloud computing approach, which is a reservation regarding the usage of the cloud-based model (lack of trust in cloud-based solutions). Such reservations are typically connected with issues such as concerns about placing sensitive data on third-party servers somewhere in the world. An important element of these concerns is the earlier mentioned issue relating to the reliability of cloud-based solutions. In spite of improvements in cloud technology, high-profile downtime accidents continue to take place. As a result, they affect public perceptions concerning the reliability of cloud-based solutions.

The next significant challenge which can constitute an important barrier to the implementation of cloud-based solutions are structural issues and cultural resistance in organizations' IT departments. It is connected with the fact that usage of such computation models causes deep changes in IT management practices and the functioning of IT departments. It can, and in many cases does, lead to raising concerns about loss of control and the lowering of significance and position of these departments in companies. In fact, in the new "cloud realities", their role will be significantly different, moving to that of broker of IT services [22].

The newly required skill sets are the next issue which can be a source of fear and which can cause resistance. It relates to the skills of the employees of IT department and not only of technical nature. In this context a demand for a new type of manager, called "true program managers", has been indicated. They should be leaders who know how to cooperate with internal technologists and third-party vendors in order to pull together a particular solution and deliver it as an overall program [1]. Another significant factor is connected with the complexity of migrating enterprise IT systems to the cloud [2].

There are also many legal challenges. They relate to such aspects as: regulations concerning the place of data storage and access to that data, data ownership, privacy and data protection issues, the applicability of the law connected with data protection and the scope of vendors' responsibility (including liability for data residing in a particular online location). These issues have yet to be settled by policy makers, and a significant barrier is the fact that the law in many countries does not address these issues. An important constraint in the ability to take advantage of some of the benefits of cloud-based solutions (especially those connected with public clouds) is the fact that in many countries data protection laws restrict the possibility of storage and transfer of some types of data outside their borders [2], [23]. A further legal issue constitutes a significant concern in the case of the utilization of public clouds. It relates to inquiries from governmental agencies (e.g. the National Security Agency in the U.S.). Namely, public cloud providers can be obliged to provide information concerning their customers, but may be legally barred from informing them about this fact [1].

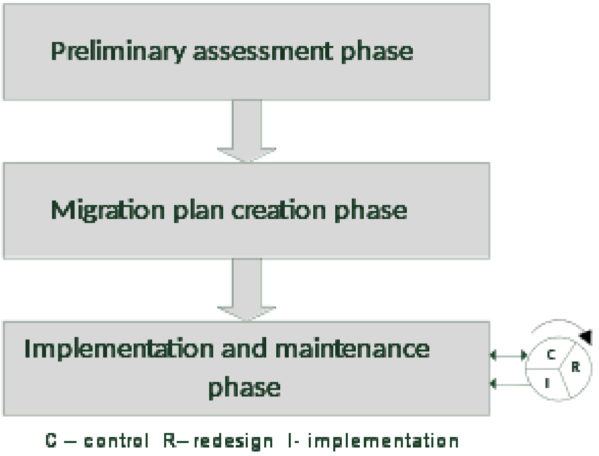
## IV. The most important elements connected with the cloud strategy

In spite of the growing interest of organizations of various sizes in adopting cloud-based solutions it does not mean that they have a cloud strategy. According to research conducted by IDC only 17.9% of young organizations (fewer than five years of operation) and 10.2% of mature ones (more that five years of operation) have an optimized cloud strategy. That is:

- a broadly implemented, cloud-first strategy which is proactively managed,
- clearly driving business innovation while improving IT operational efficiency [24].

Although one could perceive the utilization of the cloud computing model as a relatively simple issue, this is in fact not the case. There are numerous potential problems and challenges connected with its implementation and many aspects have to be carefully analysed and planned. It is obvious that implementation of cloud-based solutions is simplest in the case of companies without any previous “burdens” and legacy systems i.e. start-ups. But the bigger the company is, with many complicated business processes, the greater the scale of the challenges. Because of this fact it is especially important for organizations to have clear and comprehensive cloud strategies, including the cloud migration plan, in case they decide to utilize a cloud-based model.

Generally a strategy for the utilization of cloud-based solutions and migration to this computation model should be based on three key phase (see Fig. 1).



Preliminary assessment phase
Migration plan creation phase
Implementation and maintenance phase
C
R
I
C – control R– redesign I- implementation

Fig. 1 Cloud utilization strategy and its three phases (source: own source)

In the preliminary assessment phase a management board, or especially established special committee, should make a preliminary assessment of the usefulness of using a cloud computing model in the context of its impact on the organization’s functioning.

This relates to such issues as:

- assessment of whether the cloud computing approach aligns with the organization’s culture e.g. in terms of  outsourcing or not outsourcing any of its own operations (a culture of risk avoidance [25]),
- assessment of whether the cloud computing approach aligns with the organization’s objectives and what would be the migration goals (improvement of productivity, cost reduction, increased agility, new business models implementation etc.),
- appraisal of the risk connected with the migration process in the context of the potential impact on it of internal and external factors,
- assessment of which key stakeholders would be impacted by the migration process and how.

In the context of the above mentioned issues, it is evident that many organizations, for various reasons, do not decide to move to the cloud. According to the results of Computerworld’s Forecast survey conducted among 194 IT executives in May and June 2014, almost one third of those surveyed declared that their companies had no such plans (see Fig. 2).

And there is one more significant element of this phase - a comprehensive assessment of the readiness of the organization for the migration process. It is concerned with issues such as technical, human and organizational aspects. According to the results of the Chief Infrastructure Technology Executive Roundtable (CITER) organized by McKinsey, there are six key elements important in the context of an organizations’ “cloud readiness”.

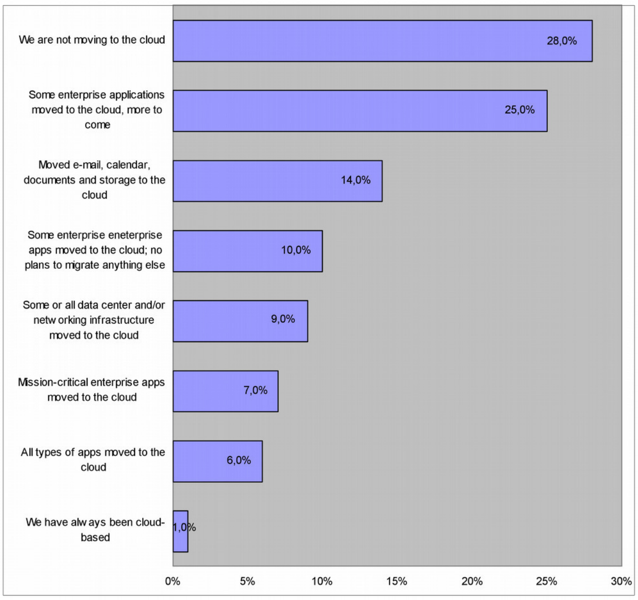


Fig. 2 Organizations’ strategies for cloud computing (source: [11])

They include such issues as [1]:

- well defined and well understood workflows to support cloud offerings,
- highly automated IT infrastructure,
- the right technical skills and training to support cloud of company’s IT department,
- effectively broken down/collapsed by company's IT department technological silos (e.g., Windows, UNIX, storage, networking),
- extensive self-service options (e.g., development/test servers) offered by the company’s IT infrastructure,
- a strong understanding of the issues connected with forecasting the demand for cloud offerings.

In the case of a positive assessment of the sense and advisability of using a cloud-based solution, it is then necessary to move to the second phase - development of a migration plan. In its scope it is necessary to analyze the more detailed issues (including technical, legal and organizational ones) and make final choices, such as:

- determination of the final migration goals and choosing the business processes which should be cloud-supported,
- selection of the deployment model (cloud type) which will be used by the organization,
- selection of the delivery model(s) (SaaS, IaaS, PaaS) which will be applied and determination of the scope of their utilization (type of cloud-based applications, elements of the infrastructure which will be moved to the cloud etc. – see Fig. 2)
- selection of the approach for adopting cloud-based solutions.

In the case of this last issue there are two basic approaches which can be chosen by an organization i.e. “brownfield” and “greenfield”. The first one concerns the piloting of individual technologies and next deploying them in the current IT environment in order to replace solutions used so far. The second one relates to situations in which an organization deploys a separate standalone environment for new applications, and legacy applications are migrated to this new environment [1]. In the context of decisions concerning deployment and delivery models organizations should remember that such choices have a significant impact on issues relating to the level of direct control of the organization over the solution and risk connected with it (see Fig. 3).

Knowing the specific elements connected with the planned delivery and deployment model, the organization can then start the process of selection of a provider of cloud services. In this context an important aspect is to determine the provider’s role and scope of engagement in the migration process as well as the parameters which should be fulfilled by the services delivered in the cloud mode. As far as the first aspect is concerned, according to the results of the above mentioned Chief Infrastructure Technology Executive Roundtable (CITER) organized by McKinsey, there are four important roles of vendors in the process of cloud migration.

They include such issues as [1]:

- implement and integrate solutions,
- provide managed services (e.g. hosting, storage, incident monitoring/response),
- provide IT staff augmentation for ongoing operations,
- design a company's architecture and/or IT infrastructure environment.

As far as the second aspect is concerned, in this case it is necessary to determine the parameters which should be fulfilled by the services delivered in the cloud mode and working out the metrics (Key Performance Indicators) as precisely as possible, allowing for their control [10]. It is also extremely important to determine requirements for such issues as: data security, back-up procedures, location of data, ownership of data or the scope of the provider’s responsibility.

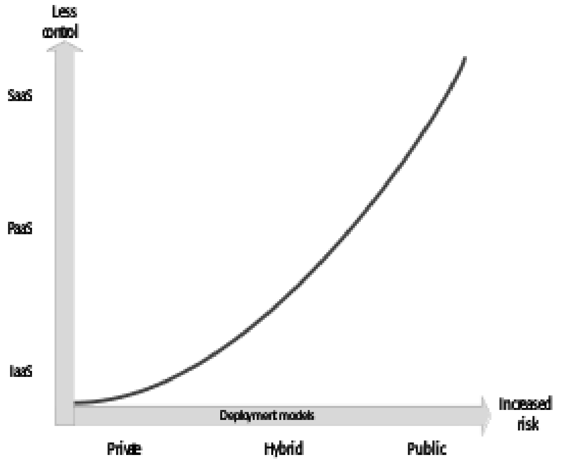

Fig. 3 Inherent risk relationships with cloud service delivery and deployment models (source: [25])

Other important issues which have to be planned include:

- the means of integration of the cloud-based solutions with those which will remain functioning in the traditional way,
- determination of a disaster recovery plan and procedures including a risk management program and incident management,
- organizational changes (especially in the IT department) i.e. their scope, their implementation and overcoming potential cultural resistance,
- necessary training and its scope,
- a cloud governance model.

The third and final phase of activities connected with the introduction of cloud-based solutions to an organization is the implementation phase, the maintenance and monitoring of their functioning in the context of the performance of the organization as a whole. The key issues which have to be realized in this phase include:

- final selection of the service provider and signing the contract including a Service Level Agreement (SLS),
- elaboration, together with the vendor, the migration plan based on the selected approach of adopting cloud-based solutions, including the scope and dates of necessary trainings,
- execution of the planned trainings,
- implementation of the planned cloud-based services and their integration with those functioning in the “traditional” way, as according to the plan,
- testing the functioning of the implemented solutions and making required corrections,
- monitoring the functioning of the implemented solutions based on a previously prepared cloud governance model and making necessary improvements and corrects.

## V. Conclusion

The results of numerous surveys clearly indicate the growing interest of organizations of varying types in IT solutions available using the cloud computing model. This fact is also confirmed by the data concerning the dynamic growth of the cloud computing market and cloud data center IP traffic [6].

Undoubtedly, utilization of cloud services provides organizations with many opportunities. They are not only connected with such issues as the reduction of IT-related costs or productivity improvements, but they also have significant influence on a faster innovation cycle, increased agility or implementation of new business models. Also more and more organizations discern that without cloud-based solutions it would be more difficult to be able to store, analyze and use the rapidly increasing amounts of data critical for their market success and development.

But utilization of cloud-based solutions also brings numerous potential challenges and concerns related to such issues as the reliability of cloud services, data security, privacy or cloud-platforms compatibility. Also the migration process to cloud solutions includes many aspects which have to be well thought out and carefully planned. It relates not only to purely technical issues but also to legal and organizational ones. In the context of the last aspect, one should remember that implementation of a cloud-based approach, especially when it is a larger scale program, will be a type of reengineering project, as it is connected with a deep rethinking of the way an organization conducts its own operations. In this case problems of the various types of potential resistance (especially connected with the IT department and its changing role) and overcoming it, should be carefully addressed. An important challenge is also the lack of so called "best practices" which could be applied by organizations in their migration process (see [11]). In this situation properly planned and executed cooperation with vendors is a very important aspect and one of the success factors.

Taking into consideration the above mentioned remarks, it is necessary to stress that an incorrect and ill-considered approach to the cloud computing phenomenon can lead to a situation where, instead of expected benefits, numerous problems arise, negatively or even destructively influencing an organization's functioning and the realization of its goals. This results from the fact that cloud-based projects are connected to the IT infrastructure, a crucial component of every contemporary organization and the foundation of their functioning.

***Abstract*—The aim of this study is to answer the question about risk factors for the information system (IS) projects in public organizations in Poland. These factors were identified based on a critical review of literature, practical collaboration, the case study and logical deduction. The paper continues as follows. Firstly, a relationship between risk factors and a project success is explained and risk factors presented in the literature are shown. Secondly, a methodology of examining risk factors for the IS project in public organizations is presented. Thirdly, the risk factors for the IS projects in public organizations in Poland are identified and the framework of risk factors presented in the literature is improved. In this framework the factors are classified into eleven groups, namely (1) top management support; (2) manage processes in organization; (3) involve end users; (4) manage information system development process; (5) make system requirement analysis; (6) plan the project; (7) manage, monitor and evaluate the project; (8) manage project team; (9) manage team experience; (10) manage team communication; and (11) public sector procedures and processes. This paper concludes with a presentation of the study's contribution and limitations, implications for the findings and the stream of future work**.

## I. Introduction

THE information systems (IS) projects are always connected to substantial risk. A considerable number of IS projects still use more resources than planned, take longer to complete and provide less quality and functionality than expected [1], [2]. The questions are, what are risk factors for IS projects and how manage risk in IS projects? Among some most common risk factors for IS projects are: unrealistic goals, inaccurate estimation of necessary resources, badly defined requirements, poor presentation of a project status, and unmanaged risk [3], [4]. It has been identified that a poor risk management (RM) of IS projects often leads to failure in IS projects both in public and business organizations [5].

Although some managers claim that they manage risk in their projects, there is evidence that they do not manage it systematically [6]. This shows that public and business organizations should improve not only their ability to identify, but also manage the risk associated with projects [7].

The existing studies mostly examine risk factors for IS projects in business organizations [8]-[10]. There are only few studies concerning risk factors for IS projects in public organizations [11], [12]. This portrays the need for studying risk factors influencing the success of IS projects in public organizations. Therefore, conducting research among Polish public organizations should contribute to greater understanding of risk factors for IS projects and should help fill the gap in the existing body of knowledge.

This article focuses on analyzing risk factors in IS projects in public organizations in Poland. Its aims are to: (1) indicate risk factors for IS projects in public organizations in Poland, and (2) define a risk factor framework for IS projects in public organizations.

The article is structured as follows. Section I is an introduction to the subject. Section II states the theoretical background of risk factors for IS projects. Section III describes a research methodology. Section IV presents the research findings on risk factors for two IS projects in Polish public organizations and the risk factors framework presented in the literature is enhanced. Section V provides the study's contributions and limitations, implications for the findings and the stream of future works.

## II. Literature Review

### *A. IS Project Success and Its Risk Factors*

Is there a relationship between risk factors and project success? This question has been considered relevant by people from both academic and practitioners' communities already for a long time, especially in the area of IS, where projects have a long history of failing [13]-[16]. What exactly is defined as risk? Risk is the occurrence of any event that has consequences for, or an impact on the success of an IS project [17]. Many authors define that all projects involve risk of some sort [18]. There is no project without a risk. Risk management (RM), therefore, is one of the main issues of a project. Its positive impact on planning, decision making, avoiding bad events, and giving a proper response to a risky situation is remarkable [19]. RM is both a science and an art for identifying the treats, assessing and controlling them by applying the most effective manner [20].

The success of IS projects is traditionally measured by time, budget and requirements criteria. Many researchers define a project success in terms of compliance with time limits, cost limits and meeting requirements [21]. The significant impact on projects success has RM [22]. It helps to identify and manage risk, and thereby prevent IS projects from getting off the track. RM involves identifying the potential risk, measuring, monitoring and controlling them

978-83-60810-66-8/$25.00©2015, IEEE

in an organization to meet its strategies and objectives, and leads to decrease the undesired effects in project life cycles.

There is a general consensus that effective planning and implementation of a RM methodology both positively affect the success rate of any project [23]-[26]. There are several methodologies of project RM that represent the course of actions required to manage risk during IS projects [27]. However, the main point is to identify the exact risk factors for IS projects [28]. We found only five papers published after 2010 defining risk factors. Characteristics of the publications are presented in Table I.

Based on the literature findings, there have been identified ten risk groups (RG). Namely, (1) top management support; (2) manage processes in organization; (3) involve end-users; (4) manage information system development process; (5) make business requirement analysis; (6) plan the project; (7) manage, monitor and evaluate the project; (8) manage project team; (9) manage team experience; (10) manage team communication. Each of risk groups is clearly defined by particular risk factors. The compilation of risk factors grouped into risk groups is presented in Table II.

### *B. Risk Factors for IS Projects in Public Organizations*

In the literature, researchers are conducting studies on identifying risk in public organizations. Patanakul [11] conducted research on large-scale IS projects in the public sector. There were defined the exact risk factors:

- system design and implementation;
- problems in requirement identification;
- project management and governance;
- problems in managing project risk;
- problems in project monitoring, control and managing changes;
- problems in project governance; and
- contract management.

Aritua, Smith and Bower [12] run research on risk factors in public sector in the UK. The research focused on public organizations' projects in general, not in the context of IS projects. According to them, rejecting the risk of a general nature, specific to certain sectors of the economy, the risk factors can be distinguished as follows:

- linking strategy and projects;
- difficulties in project delivery;
- skills shortage and resources;
- cash flow and funding problems;
- sustainability and environmental legislation;
- challenges of procurement;
- competition for contractors; and
- change in government policy.

Analyzing the above risk factors, it can be noticed, that some of them are the same as defined in the risk groups presented in Table II. However the risk, namely: contract management, challenges of procurement, and change in government policy are not included among the risk defined for business organizations.

### *C. Risk Factors Framework for IS Projects*

Risk usually comprises a lot of factors interacting with each other. Researchers have built several frameworks to classify the factors and present relations between them [34], such as the MIT90s framework of Morton [35], the project life-cycle framework of Markus and Tanis [36], the strategic-tactical framework of Holland and Light [37], and the process-control-information (PCI) framework of Bemelmans [38]. The literature presents, that the success of IS projects is dependent on the dynamics and interaction of the organizational and technical factors [39]-[40], [41]. The authors structure and classify the risk factors in the MIT90s framework which covers organizational as well as technical issues. The framework is simple and easily extendable and can, therefore, be used in different settings for multiple purposes [34]. For instance, the framework was applied for supply chain information systems critical success factors [34], [42].

The MIT90s framework contains the following dimensions [35]:

- Project strategy – project goals and how the organization fulfills these goals;
- Structure – process, functions, and structure of the project in organization;
- Individual and roles – the roles, skills, knowledge, social ties and attitudes of people;
- Management process - the management process that steers the implementation project; and

TABLE I.
CHARACTERISTIC OF THE PUBLICATIONS

| Publication | Research characteristics | Research result |
|---|---|---|
| S. Liu, L.Wang (2014) | survey, 26 respondents (IS managers) | identified 27 risk factors |
| S. Sundararajan, M. Bhasi, P. K. Vijayaraghavan (2014) | 1 case study | identified 20 risk factors |
| C. Lopez, J.L. Salmeron (2012) | interview, 12 respondents (IS/IT projects experts);<br>risk evaluation using IPA method | identified 46 risk factors |
| L.Jun, W. Qiuzhen, M. Qingguo (2011) | survey, 93 respondents;<br>the influence between factors were measured | identified 7 risk factors |
| P.K. Dey, B.T. Clegg, D.J. Bennett (2010) | 1 case study | identified 41 risk factors |

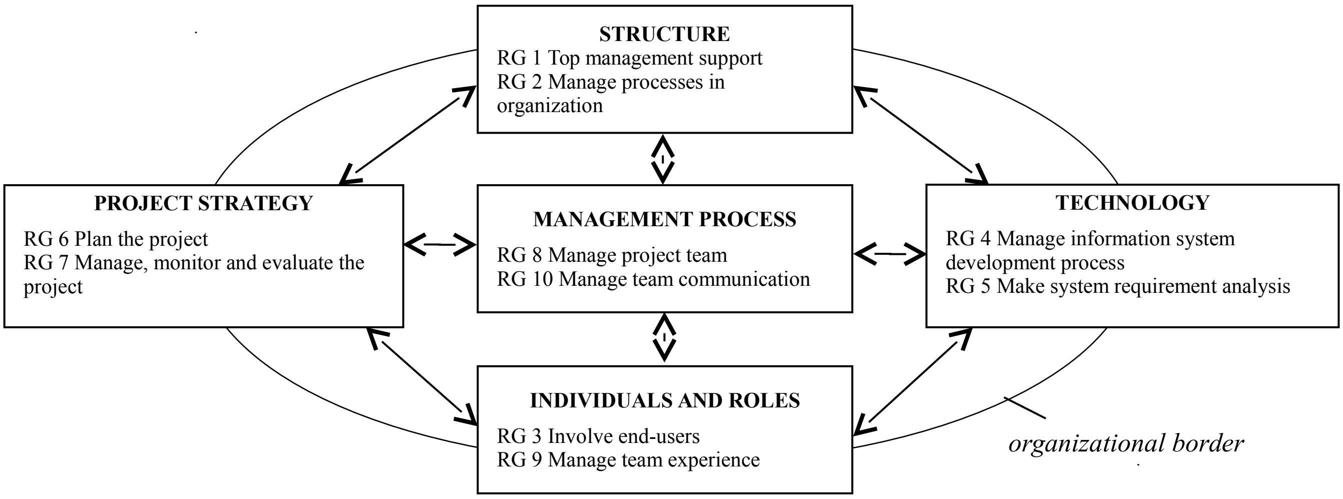
RISK FACTORS FOR IS PROJECTS

| Group of risk | Risk factor | | Source |
|---|---|---|---|
| RG1<br>Top management support | R01 | Lack of top management commitment to the project | [29] [30] [32] |
| | R02 | Top managers make important IT decisions without consulting the others | [29] [32] |
| | R03 | Unrealistic projects outcomes | [30][33] |
| | R04 | Excessive project size | [29] [31] |
| | R05 | Change in ownership or senior management during the process of development | [30] |
| | R06 | Time too short/too long | [29] |
| | R07 | Unrealistic schedule | [29] |
| RG 2<br>Manage processes in organization | R08 | Resources shifted away from the project because of changes in organizational priorities | [29] [30] |
| | R09 | Major effect of project implementation on organizational structure | [30] [33] |
| | R10 | Mismatch between organization culture and required business process changes needed for new system | [30] |
| | R11 | Changes in organizational priorities | [29] |
| | R12 | Continuous changes in the organizational environment | [29] |
| RG 3<br>Involve end-users | R13 | Lack of user participation | [29] [30] [31] [32] [33] |
| | R14 | Users resistant to change | [29] [30] [32] |
| | R15 | Target users are unfamiliar with the technology and require additional training | [29] [30] [31] |
| | R16 | Users with negative attitudes toward the project | [30] [32] |
| | R17 | User is not committed to the project | [29] [30] |
| | R18 | Users constantly request further changes | [29] |
| | R19 | Conflicts between users departments | [29] |
| RG 4<br>Manage information system development process | R20 | High level of technical complexity | [29] [30] [31] [32] |
| | R21 | Immature technology | [29] [30] [32] [33] |
| | R22 | New technology and use of technology that had not been used in prior projects | [29] [30] [32] |
| | R23 | Lack of effective development methodology | [30] [32] [33] |
| | R24 | Large number of links to other system required | [29] [30] |
| | R25 | Inadequate system documentation; incomplete or non-existent | [29] [32] [33] |
| | R26 | Lack of proper tests | [29] [32] |
| | R27 | Lack of integration between systems | [29] [32] |
| RG 5<br>Make system requirement analysis | R28 | Continually changing scope and system requirements | [29] [30] [32] |
| | R29 | Unclear or incomplete system requirements | [29] [30] [33] |
| | R30 | System requirements not adequately identified | [29] [30] [32] |
| | R31 | Conflicting system requirements | [30] |
| | R32 | Failure to manage end-user expectations | [29] |
| | R33 | Lack of frozen requirements | [29] |
| RG 6<br>Plan the project | R34 | Poor project planning | [29] [30] [31] [32] |
| | R35 | Inadequate estimation of required resources | [30] [32] [33] |
| | R36 | Critical activities are not identified | [29] |
| RG 7<br>Manage, monitor and evaluate the project | R37 | Project progress not monitored closely enough | [29] [30] [31] [32] [33] |
| | R38 | Lack of an effective project management methodology | [29] [30] [32] [33] |
| | R39 | Ineffective communication | [29] [30] [32] [33] |
| | R40 | Inexperienced project manager | [29] [30] |
| | R41 | Project manager lacks required skills | [29] |
| RG 8<br>Manage project team | R42 | Lack of knowledge management | [33] |
| | R43 | Frequent turnover within the development team | [29] [30] [32] [33] |
| | R44 | Team members are unmotivated | [29] [32] [33] |
| | R45 | Inadequate composition of project team | [29] [32] |
| | R46 | Improper definition of roles and responsibilities | [29] [33] |
| RG 9<br>Manage team experience | R47 | Team members lack of specialized skills required by the project | [29] [30] [31] [32] |
| | R48 | Inadequately trained development team members | [30] [32] |
| | R49 | Team members are unfamiliar with the technology | [29] |
| RG 10<br>Manage team communication | R50 | Conflict and no cooperation between the team members | [29] |
| | R51 | Team member are in many localizations | [33] |
| | R52 | Inadequate team size | [33] |

- Technology – the information system being implemented.

The MIT90s framework indicates that the success of IS projects dependents on the interaction of the organizational and technical system. The framework (Fig. 1) provides opportunities for better understanding of dependency among risk factors. Firstly, risk factors can be grouped into five dimensions of the MIT90s framework which is easy to present from a management perspective. Secondly, the framework of risk factors also provides an understanding of the dynamics and cause-effect relationships of a complex IS projects. The arrows in Fig. 1 indicate that changes in one of the five interacting dimensions are influencing the other. The risk identified in one dimension will cause the higher probability of risk in the other dimension. For example, RG6 Plan the project – the factor R34 Poor project planning, will influence RG8 Manage project team, R45 Inadequate composition of project team. Poorly planned project



STRUCTURE

generates risk of underestimation or overestimation of resources.

## III. Research Methodology

The goal of this research was to analyze risk factors for IS projects, described in the literature, in the context of public organizations and identify the most critical ones. The following research questions were posed:

1. What are the risk factors for IS projects?
2. What are the risk factors for IS projects in public organizations?
3. Is there any significant influence between risk factors?

Research methods included a critical review of literature, the case study, practical collaboration and logical deduction. The following steps were taken.

The first step. The empirical evidence was searched aimed at peer-reviewed journal publications from 2010 to 2015. The process was supported by the use of electronic tools for the search and selection of publications. The search included journals indexed in bibliographic databases, i.e. Ebsco, ProQuest, Science Direct. The search was conducted using a relevant set of keywords and phrases such as ''software project'' or ''information technology project'' and ''risk management'' or "risk factors", and ''project success'' included in paper abstracts in all possible permutations and combinations (taking into consideration the logical AND, and OR as appropriate). A search was done on the appearance of any combination of these terms, with a result of 933 hits. All hits of 4 pages or less were excluded and narrowed to reviewed academic journals in English. Then, a second selection was made by evaluating the abstracts of the publications selected in the first round of selection. This second round, it was necessary to make sure that the publications included all three topics: software/IT project, project success, and project risk management. The search process resulted in a total of 13 journal publications, published between 2010 and 2015.

The second step. Risk factors for IS projects were improved on the basis of practical collaboration the authors with IT companies that develop IS systems for business and public organizations.

The third step. After careful evaluation of the literature findings, practical collaboration and logical deduction, risk factors for IS projects were further refined, classified and presented based on MIT90s framework. In the framework, the risk factors were considered in five groups as (1) project strategy, (2) structure, (3) individual and roles, (4) management process, and (5) technology.

The fourth step. Using the case studies approach, the risk factors for IS projects in public organizations in Poland were defined. Moreover, semi-structured interviews with end-users and project team members were conducted as well as shareable documentations related to IS projects management were analyzed during the study. Data was obtained from documents and records such as statement of work, project plan, risk management plan, minutes of meetings, review meetings, reports, project overview presentations and project closure reports. This study was conducted in 2010 and 2013. It concerned IS projects in two Polish public organizations. The IS projects included development and implementation of integrated IS.

The fifth step. The risk factors included in MIT90s framework were evaluated and further developed. The framework was supplemented by additional risk factors defined for RM of IS projects in the public organization.

## IV. Research Findings

### *A. Case Studies of IS Projects in Public Organizations*

Public organizations in Poland, due to territorial scope of their operations are divided into public organizations at the state level, embracing the whole Poland, and public organizations at the local levels, district or county. The described case studies of IS projects refer to the state level, where project management took place and the local levels, where IS was implemented.

Two similar projects, one successful and one not, will be used to present the application of risk factors in IS projects [43]. Information about a project was gathered by participation in those projects and conducting series of semi-structured interviews. Data was obtained from documents and records such as statement of work, project plan, risk management plan, minutes of meetings, review meetings, reports, project overview presentations and project closure reports.

Table III shows that those two projects were similar in terms of scope and size. As a result, the outcomes of the projects were different. Project A ended only as a partial success. Finally, IS was implemented but it was not fully used by the end-users after 12 months. The completion of Project A was also significantly delayed. Project B was fully successful. IS was implemented and it is fully used by its end-users.

Project A was carried by a public organization at the state level. The aim of the project was to improve and automate government processes and to implement an integrated information system, i.e. an ERP system in sixteen public organizations at the local levels. The ERP system used to this point of time was out of date. The results of change were to centralize management of the organizational structure of all sixteen public organizations and automation of supporting government processes for finance and accounting, human resources management, payroll management, inventory management, and fixed assets management. The expected benefits of the project were to eliminate unnecessary documentation, systemize document circulation, ensure a smooth flow of information, and make information accessible (which is relevant, timely to appropriate users and in an appropriate form). A specifically set up project team of the central public organization was responsible for the implementation of the ERP system. The project team was composed of people from the departments of the central public organization, such as: accounting, human resources, payroll, fixed assets, and inventory management, and from the IT department. Moreover, the project team was supported by the members of IT company, especially business analysts, systems analysts, and project team leaders.

Project A was managed using PRINCE2 methodology, however only few documents were created. There was created a risk procedure, however the risk was never escalated to steering committee. The risk registry was fulfilled at the beginning of the project, but was not updated during the project. The project team was not properly instructed about necessity of risk reporting. The basic risk management approach was missing. The risk was not properly managed. Often the risk was not identified but happened as an issue.

Project B was also carried out by a public organization. The aim of the project was to implement IS for supporting processes of service provision for citizens. As a result of the project the following types of IS were implemented: integration platform, business intelligence, enterprise portal, web based information portal and mobile terminal software. The project was undertaken as a consequence of the diagnosed problems arising from the lack of IT system integration. The lack of integration made it impossible to have quick access to information indispensable for effective functioning and monitoring of operations of public organizations and caused an ineffective flow of information between the public organizations and the cooperating institutions. The lack of system cooperation compounded the difficulties in monitoring funds allocation and expenditure, and the difficulties in monitoring the use of funds by individual public organizations.

Project B was managed using PRINCE2 methodology, where all necessary documents essential for effective project management were created. The project team was formally established. Particular people were permanently assigned to particular parts of the project. Their scope of responsibilities was explicitly defined. The project team consisted of an IT specialist group and a government group made up of specialists who were the main users of the system. Risk management was conducted concurrent with the project implementation. The end-users participated in a series of conferences, where a clearly defined project goal and

| Project management methodology | PRINCE2<br>(only few basic documents where created) | PRINCE2<br>(full documentation needed were created) |
| Risk management | No (no risk registry provided) | Yes (risk registry provided) |
| Project result after 12 months | Software was made but not fully used after 12 months | Software was made and fully used after 12 months |

successively accomplished tasks were presented. Moreover, they actively participated in analysis meetings where they defined the system requirements. The project had a coherently worked-out schedule that also included a business team meeting schedule. The business team was kept informed about the project progress and participated in the final IS testing.

### *B. Risk Management of IS Projects in Public Organizations*

In project A, the risk was not identified and managed. Whereas, RM was applied to project B in a methodologically correct manner.

Based on the examination of the case studies, the authors can draw the same observations (Table IV). Obviously, it can be stated that in case of project A, 27 risk factors did not occur, although 25 risk factors occurred and they were not managed. The lack of RM could have contributed to the failure of the IS project. Finally, IS was created and implemented with a significant delay. In case of project B, 38 risk factors did not occur, and 14 risk factors occurred and they were managed. Project B was completed on the schedule. It can be assumed that RM played a significant role in the IS project success.

However, there were several other risk factors which were not included in the risk factors framework for business organizations (Fig. 1). They were:

- changing government processes during project implementation;
- changing and inconsistent legal regulatory framework;
- challenges of procurement procedure;
- financial capability of project contractor; and
- managing contract.

**Changing government processes during project implementation**. Changes in government processes during the project always generate the need to change the IS requirements. The changes of IS requirements are one of the most frequent reasons of IS project failures. The change of requirements influences the scope of the project and its functionalities and can extend the project duration.

**Changing and inconsistent legal regulatory framework**. Changes to the rule of law which take place during the project can affect and often affect IS requirements. As it was mentioned above, the change to the requirements influence the scope of the project and its functionality and can extend the project duration. Unfortunately, the changes to Polish legal system are frequent. It is partially connected with the fact that recently the Polish economy has gone through the transition from a central planned economy to a market economy and it had to adjust and is still adjusting the legal system to the market economy.

**Challenges of procurement procedure**. There are several factors which must be met in a procurement procedure. One criterion of offer evaluation must be a price. Other criteria may be freely chosen depending on the object of the contract, e.g. quality, technical merit, functionality, usability. Typically, a tender is chosen using the price criterion. In Poland, the cheapest offer is often chosen. As a result the ratio of price to quality is not always maintained.

**Financial capability of project contractor.** The payment for the contractor for the works done within the IS project framework takes place after the final IS technical acceptance. In practice it may take from few to several months. During this time the contractor has to cover the running costs from own resources. This creates the risk of losing financial liquidity if the contractor does not have appropriate financial backing.

**Managing contract.** An effectively managed contract can impact on a timely completion of IS project. However, it is extremely difficult to predict all conditions that may occur during the contract realization process. There is a need for long term planning and considering, e.g. identifying all current and future systems that must be integrated. There is a high risk that some minor requirements might be omitted in the contract. The contract cannot be significantly changed

during the project, as it is one of the procurement procedures.

### C. Risk Factors Framework for IS Projects in Public Organizations

The above identified risk factors for IS projects in public organizations are creating the new risk factors group: public sector procedures and processes. This group is included in the risk factors framework proposed by Morton and presented in Fig. 1. The new group of risk factors was classified into the framework dimension named Structure. The factors are the part of this dimension, because they are related to processes and functions of IS projects in public organizations. Furthermore, they influence project strategy, management process and technology. The enhanced risk factors framework for IS projects in public organizations is presented in Fig. 2.

As mentioned above, public sector procedures and processes have an impact on project strategy. Especially, they affect project planning which has to account for such identified risk factors as a procurement procedure, changing government processes and financial capability of project contractor. Public sector procedures and processes also influence managing, monitoring and evaluating IS project as they are more complex and have to account for additional identified risk factors. Public sector procedures and processes have an impact on management process. Managing contracts, in particular, requires from managers specialist experience and the knowledge of the rule of law.

Public sector procedures and processes also influence technology. Changes to the requirements caused by changing government processes or a legal regulatory framework must be reflected in IS projects, especially in IS functionality. Moreover, these changes often result in delays in the IS project implementation. The potential changes to the IS project lead time are limited by the procurement procedure.

In conclusion, public organizations must take into account more risk factors in the risk management of IS projects than business organizations. Fig. 2 presents the framework of risk factors for IS projects in public organizations.

## V. Conclusion

Identifying and understanding risk factors is crucial for the success of IS projects in public organizations. The paper enhances the framework of risk factors identified in the literature and proposes a comprehensive risk factors framework for IS projects in public organizations.

This study contributes to the research on risk factors for IS projects in two ways. Firstly, the risk factors for IS projects in business organization are analyzed and presented. Secondly, the unique risk factors for IS projects in public organizations are identified based on the case studies approach. In summary, there are eleven groups of risk factors for IS projects in public organizations, namely (1) top management support; (2) manage processes in organization; (3) involve end users; (4) manage information system development process; (5) make system requirement analysis; (6) plan the project; (7) manage, monitor and evaluate the project; (8) manage project team; (9) manage team experience; (10) manage team communication (11) public sector procedures and processes. Moreover, the proposed risk factors framework for public organization is based on MIT90s framework. The framework indicates that risk factors are not standing alone, but they influence each other.

In this research, public organizations could find knowledge related to the risk factors impacting on successful IS projects. Especially, this research can be useful for the Central and Eastern European countries. This is because the countries are similar. Their similarity concerns their analogous geopolitical situation, their joint history, traditions, culture, and values. In addition, the similarity reflects in building democratic state structures and a free-market economy, participating in the European integration process, the levels of information systems implementation in public organizations. Moreover, they have to resolve the same problems and overcome the same political, economic, social, technological obstacles in their transition from traditional public organizations to organizations based on information systems.

As with many other studies, this study has its limitations. The main is that, it is only based on two case studies in Poland. Caution should be taken when generalizing our findings. The issues of risk factors for IS projects in public organizations, therefore, should be explored in greater depth. There is a need to examine other case studies, and verify and enhance the risk factors framework. This will be considered as a future work.

***Abstract*—Many methods can be used for the evaluation of website quality. While they can be used for different purposes and require different assessment approaches it is not easy to select proper method adequate to the needs. Presented research is focused on building a repository of knowledge about the methods for the assessing the quality of website. The repository in the form of ontologies covers various methods of quality assessment and makes possible their proper selection. Proposed approach was verified with main methods and the resulting ontology can act as a repository of domain knowledge.**

## I. Introduction

In the sectors related to e-commerce and online advertising, the number of users visiting corporate websites, blogs, portals and social platforms directly determines revenue. More users increase the potential of advertising, which has a direct impact on the number of transactions, the amount of revenue, and the ability to engage new customers [1]. In the United States, recent revenues from online advertising amounted to 42.78 billion dollars [2], while in Europe, it amounted to 27.3 billion euros in the advertising sector [3] and 363,1 billion euros in e-commerce [4]. It is worth noting that for businesses using a website to generate transactions, the website's quality can have a major impact on sales [5]. Poor quality of service and user experience can cause existing Internet customers [5], potential sales, and repeated visits to be lost [6]. Therefore, in order to maximize profits from e-commerce or online advertising, website owners should only offer the highest quality experience and services.

The quality of a website can be understood as the qualification of how well it meets the needs of users [7]. It should be noted that quality is defined by a model composed of characteristics and features/criteria describing its various components [8]. In the literature, there are many methods used to assess the quality of Internet websites, with the most formalized of those including: eQual [9], Ahn [10] SiteQual [11], Web Portal Site Quality [12] and Website Evaluation Questionnaire [13]. They have been widely used in both academic work [14] and business practice [15]. By examining the different methods was observed similarity between them. Characteristics and criteria for quality assessment based on a Likert scale were used and for the getting knowledge about quality of services surveys were explored. The reason for these similarities is that different methods are often based on the same scientific theories and source references.

Analysis of the literature and areas of practical use of methods and models for the assessment of website quality indicates a gap in the area of knowledge repository construction. Namely, there is no repository of knowledge covering some important methods for assessing the website quality. The possible construction of such a repository in the form of ontology allows formal specification and analysis of the various methods of assessment and factors affecting the quality of website [24], as well as consequent sharing and reusing that domain knowledge [17]. The ontological form provides access to the knowledge gained from individual assessment methods and enables the processing of this knowledge. It is also important to enable the integration of heterogeneous data [18] from a variety of assessment methods. As a result, it will also be possible to assess websites through a variety of methods defined in the ontology and compare individual results of that assessment in a single terminology and a reference plane. In this approach, the problem of building such a repository is divided into two subproblems. They successively concern (1) the construction of the source ontologies, reflecting the

978-83-60810-66-8/$25.00©2015, IEEE

specific methods for quality assessment; (2) the integration of source ontologies in the target ontology, which is a complete repository. This approach is justified by the above-mentioned similarities between the different methods, so that individual source ontologies are close to each other in terms of structure and concepts. Proposed approach of building a repository of knowledge is graphically represented in Figure 1.

This article presents guidelines on how to design an ontology reflecting the various quality assessment methods and their integration in the repository of knowledge. Then, using these assumptions new algorithm was proposed based on the integration of the five methods in the repository. The article concludes with a presentation of research findings and possible future directions for work.

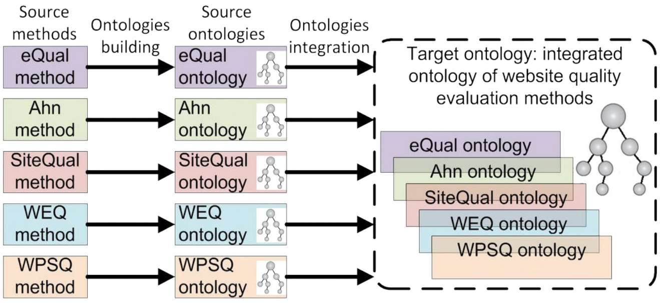

Fig 1. Proposed approach to building repository of knowledge by integration of ontologies

## II. Literature review

The possibility of constructing a repository of knowledge on the methods and models of assessing the quality of Internet services in the form of ontologies confirms its definition, as the term "ontology" in computer science is defined as the "formal specification of conceptualization" [19]. Essentially, it allows concepts and domain knowledge to be captured. A similar definition states that ontology is treated as a form of data structure and a tool for data representation, allowing knowledge to be shared and reused in artificial intelligence systems that use a common vocabulary [20]. Therefore, ontology seems to be a natural form of representation for the repository of knowledge concerning methods of quality assessment. This is due to the fact that the use of ontologies will create conceptual models that explain the structure of the different methods of evaluation criteria. The use of ontologies will also be shared, making it possible to repeat the use of such structures and facilitate better management.

The possibility of using ontologies as a repository of knowledge is confirmed by various studies where among others a biomedical knowledge base was created using ontologies [21]. Ontologies are also implemented in the knowledge bases of various systems, e.g. an expert system for the study of company financial ratios [22] and a decision support system for the construction of railway infrastructure [23]. Analysis of the literature shows that ontologies are also used in the systems and methods of quality assessment. For example, [24] presents an ontology quality that formalizes the knowledge necessary to evaluate the quality of e-government. In contrast, [25] proposes the use of ontologies in the quality assessment of tourism services websites. In this case, the ontology serves as a repository of knowledge on issues related to the tourism sector. However, analysis of the literature showed that there is no repository of knowledge covering some important methods for assessing the quality of website. Meanwhile, the reasons discussed above and the use of ontologies both demonstrate that the construction of a repository of knowledge about the methods of assessing website quality based on ontologies is justified.

The ontology construction methodology is frequently used, although it differs in the degree of formalization, destination and detail [26]-[30]. The most formal and detailed methodology includes Methontology [31] and NeOn [32]. Methontology proposed an "ontology life cycle" based on the so-called "evolving prototypes" [29]. This approach assumes that the individual steps of this methodology, namely I specification, II conceptualization, III formalization, IV implementation, and V maintenance, are performed continuously, and each cycle is replaced by a new version of the ontology. The NeOn methodology is focused on developing an ontology network instead of a single ontology. An ontology network is understood here as a set of related ontologies through a variety of compounds, e.g. mapping and versioning [26]. Methontology defines the process of conceptualization in detail, while NeOn largely formalizes the problem of ontology specification.

Concerning the integration of ontologies, it should be noted that the concept of integration is not clearly defined in different works. Reference [33] distinguishes three types of ontology integration: integration of ontologies into applications, integration and reusing, and integration by merging. Integration and reusing is defined as the construction of a new ontology by using existing ontologies. Merging is the unification of multiple ontologies from a given field into a new ontology. Merged ontologies may vary in appearance and function, including taxonomy of concepts, method of implementation, etc. Conflicts arising from these differences should be resolved when merging ontologies [33]. Reference [34] stated that ontology created by such a merger should capture all the knowledge contained in the original ontologies. Two approaches may be used: a new ontology can be created that reflects the source ontologies, or what is known as bridge ontology can be created. Bridge ontology contains the original ontologies and the relationship between them. In [35] integrating and merging operations are defined as equal. They include the creation of a new ontology from two or more existing ontologies with overlapping parts. In addition, reference [34] defines the terms being similar to integration, i.e. alignment and mapping. Alignment is a preliminary process by which it is possible to integrate ontology in a widely understandable way. It is a process of discovering similarities between ontologies. These similarities may occur between the concepts, their instances, or a similarity in the ontology structure. Mapping, on the other hand, refers to representing the relationships that exist between ontologies. As result a specification of the semantics of one ontology coverage by another is obtained which can be represented as a map describing the mutual relations between the elements of mapped ontology). Relationships between ontologies are stored separately from the ontology and are not part of them. Therefore, the mapping does not change in any of the ontology. Mapping allows to get a result somewhat similar to bridge ontology. However, in bridge ontology, as opposed to mapping, source ontologies and connections between them are stored in one entity.

## III. Construction of the source ontologies

In order to successfully complete integration, it is necessary to construct an appropriate source ontologies, reflecting the various website quality assessment methods. Consequently, the design of the source ontology is affected by the structure of the quality models included in the assessment methods and aspects relateted to their future integration. As indicated in Paragraph 1, each of the methods of evaluation is based on the quality model composed of characteristics and features/criteria describing its various components. Each of the source ontologies should reflect the quality model, which can be represented by a general structure, as illustrated in Figure 2.

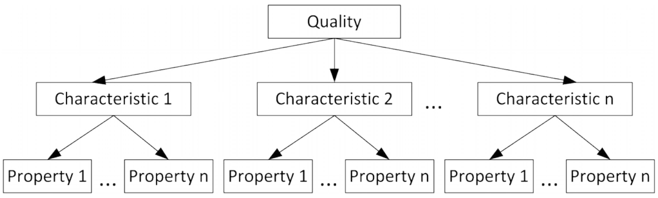

Fig 2. General quality model

With regard to the structure of the ontology generated by integration, it is assumed that the target (integrated) ontology should contain a unified model, including all the characteristics and evaluation criteria, and simultaneously contain therein quality models derived from different methods. The purpose of storing individual quality assessment models (source ontologies) in the target ontology is to determine which method and characteristics derives a given criterion. Ability to determine the source method of a given criterion allows the integration of heterogeneous data from a variety of assessment methods into knowledge base. The inclusion in the ontology of a unified model allows to use it as a knowledge repository on evaluation criteria. Therefore, the ancestor of each criterion should be a model from which the criterion is derived together with the characteristics. In addition, if certain criteria are found in many different models of assessment contained in the ontology, then it will take more than two direct ancestors. This problem is illustrated in Figure 3.

Figure 3 shows part of the quality characteristics contained in Ahn and eQual methods. Moreover Figure 3 also includes a hypothetical model, which is a result of the unification of the ontologies of these methods. Three further examples of criteria are included, of which "availability" is derived from the Ahn method, "ease_of_learn_to_operate" comes from the eQual method, and "ease_of_navigation" occurs in both methods. Given that a unified model for the assessment will include the union of assessment models included in the methods eQual and Ahn, it should also include the criteria found in these models. Therefore, ancestors of the criterion of "availability" should be characteristics included in the Ahn and unified model. The criterion "ease_of_learn_to_operate" should be in the form of ancestral characteristics in eQual model and the unified model. In contrast, the ancestors of the criterion “ease_of_navigation” should be the characteristics of each of the three models. However, such a link between criteria with multiple characteristics using subsumption relations should not occur, as this would mean redundancy. A redundant

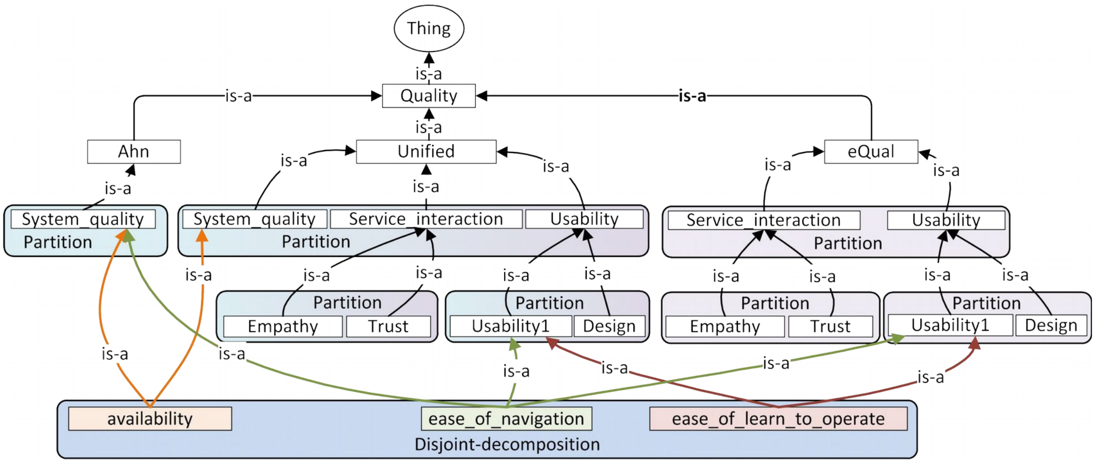

Fig 3. The problem of criteria membership for the evaluation models included in the target ontology

occurrence of a subsumption relationship is in turn treated as an error in the method of integration formulated in [35]-[38].

The problem presented above can be solved through the method of use adopted by the authors of the ontology. Namely, at the stage of the source ontology specification, it was found that the constructed ontology criteria would be separated from the characteristics. This approach allowed for applications with greater transparency of the ontology. This is also consistent with the representation of open and closed world assumptions in the ontology [39]. Namely, the each quality model contained in the various assessment models is a closed model. This means that it is complete, and a new one cannot be added to it. The quality evaluation criteria are the open portion of the world, which means that there may be additional criteria that are not yet included in the ontology. For these reasons, the part of ontology reflecting the quality model was used to partition taxonomic relationships between concepts occurring at the same level of hierarchy. In contrast, disjoint-decomposition taxonomic relationship was among the criteria used, as these criteria describe the different parts' quality, but there may be other criteria for describing the quality. This solution allows for independent criteria of quality models in certain ways. In addition, it allows for inclusion in the ontology of many quality models, including the unified model. Therefore, the hierarchy of concepts of a target ontology should be similar to structure shown in Figure 4, which is the result of the integration of ontologies eQual and Ahn. Figure 4 shows a hypothetical ontology with three quality models eQual, Ahn and model obtained as a result of their unification. Furthermore, in the illustrated ontology, regardless of the quality models the criteria belonging to these models were incporporated.

To get a similar structure as that shown in Figure 4, a compromise between a fully integrated ontology and so called bridge ontology was chosen [34]. Namely, the target ontology should include a fully unified model of quality, including the characteristics derived from the source ontologies, along with the methods of assessment, for which the source ontologies were built. Additional models, such as eQual and Ahn, as well as quality characteristics, should be included in the target ontology in the form of components, which can be simply described as external. This will avoid any inconsistencies, where the same quality characteristics will occur in the different models. An example may be the characteristics of "Information_quality" appearing in the eQual and Ahn models. As a result of the full integration, only one such characteristic appears in the resulting ontology, and it would be included in the unified model and the eQual and Ahn models. This would include criteria that belonged to both eQual and Ahn model. Consequently, in each of these models, union of information quality criteria has existed. These models would not be as consistent with their actual structure, as defined in the relevant methods of quality assessment. The solution of this problem, which allows for the incorporation of quality models (eg. eQual and Ahn) as "external", but simultaneously makes it possible to include them in the target ontology, is go find a use for them other than for IRI identifiers' unified ontology.

Separating the criteria of the quality characteristics of ontology concept hierarchies' source requires that the reasoner infers membership criteria for the relevant characteristics of the subsumption relation linking them. For this purpose, the criteria should be linked to the characteristics using the appropriate relationship, as shown in Figure 5.

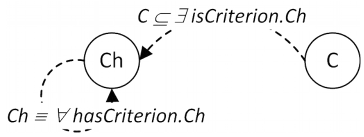

Fig 5. Proper configuration of relation “isCriterion” and “hasCriterion”

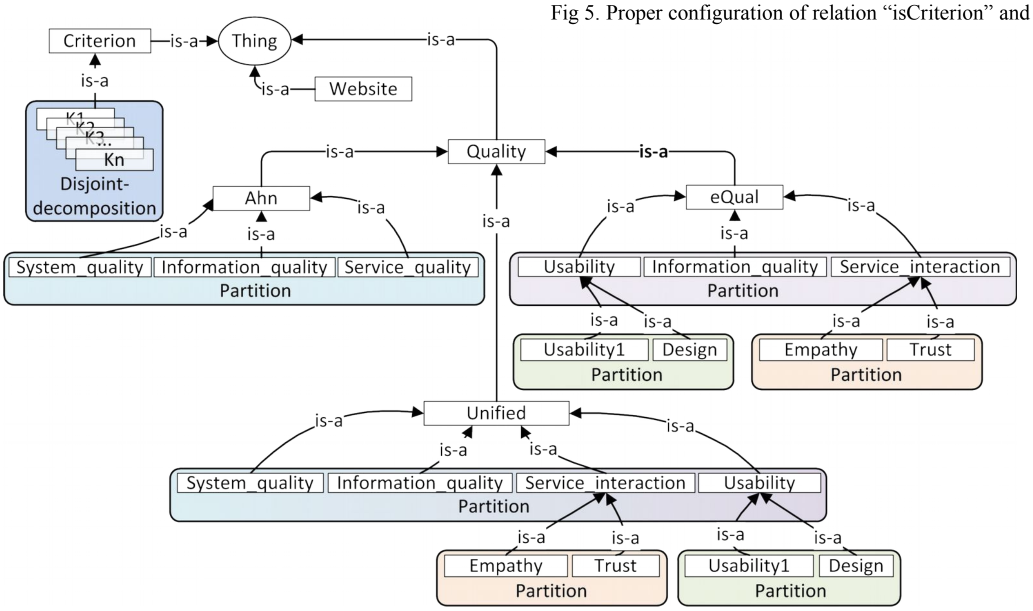

Fig 4. Hypothetical effect of eQual and Ahn integration in the target ontology

The diagram shown in Figure 5 contains concepts Ch and C, where Ch represents any quality characteristics, and C defines any criterion. By analyzing Figure 5, it can be seen that the relation "hasCriterion" with a universal quantifier is established as a necessary and sufficient condition (≡) Ch concept, which is also the domain and scope of this relationship. The relationship "isCriterion" of the existential quantifier is a necessary condition (⊆) criterion C, for which coverage is a quality characteristic Ch. This solution can be understood as follows: (a) there are certain criteria in the C group that belong to the characteristics of the Ch group ("C isCriterion some Ch"), (b) the characteristics of Ch are only those criteria that belong to the characteristic ("Ch hasCriterion only Ch"). This configuration relationship between "isCriterion" and "hasCriterion" allows for the exploration of membership criteria to the characteristics and describe this kind of membership as a comprising specific criteria in the relevant characteristics. Presented in the form indicated, the relationship is very important, as our study showed that a different configuration could lead to erroneous conclusions inferred by the reasoner. An example of such a configuration error in the indicated relationships is included in Figure 6.

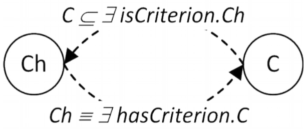

Fig 6. Wrong configuration of relation “isCriterion” and “hasCriterion”

Figure 6 shows a configuration in which the relationship "has Criterion” is marked as a necessary and sufficient condition (≡) with an existential quantifier, and the scope of this relationship is criterion C. This formulation relationship "hasCriterion" could cause inconsistent ontology at the level of the relationship. This will be explained by the example provided in Figure 7. In addition, will be used to clarify the description of the reasoning process, saved using descriptive logic expressions (1) - (12).

$$\text{Usability} \equiv \text{Design} \cup \text{Usability1} \tag{1}$$

$$\text{from(8),(10)} \qquad \text{Design} \equiv \text{System\_quality} \equiv \text{Usability1} \tag{11}$$

$$\text{from(2),(11)} \quad (\text{Design} \equiv \text{Usability1}) \wedge (\text{Design} \equiv \neg\ \text{Usability1}) \equiv \emptyset \tag{12}$$

Figure 7 shows a portion of the target ontology, which is a hypothetical result of the integration of eQual and Ahn. The contents of Figure 7 include the quality characteristics eQual, i.e. "Design" and "Usability1", which make up the partition (i.e. they are disjoint and fully fill the space of eQual concept), which describes the axioms (1) and (2). In addition, Figure 7 contains the concepts of "ease_of_navigation", "appropriateness_design" and "appropriateness_design_style", which are some of the criteria. The criterion of "ease_of_navigation" is used in the Ahn method in the characteristics of "System_quality" and the method eQual characteristics "Usability1". The criterion of "appropriateness_design" occurs in the characteristics of the "Design" eQual method and an

Fig 7. Relationships between criterion and characteristics which raise the inconsistency inference

"appropriateness_design_style" functions in the characteristics of "System_quality" Ahn method. In addition, the concepts of "appropriateness_design" and "appropriateness_design_style" were considered to be equivalent to (7). Therefore, the concepts relating to design in an integrated ontology will be linked to the relationship "isCriterion" both with the concept of "System_quality" as well as "Design". The concept of "ease_of_navigation" in an integrated ontology will be linked to the relationship "isCriterion", the concepts "Usability1" and "System_quality". Assuming that:

- the concepts "Design" and "System_quality" are necessary and sufficient conditions include relations "hasCriterion some appropriateness_design" and "hasCriterion some appropriateness_design_style" (expressions (3) and (6)),
- then the concepts "Usability1" and "System_quality", as necessary and sufficient conditions, would cover the relationship "hasCriterion some ease_of_navigation" (expressions (4) and (5)),

during the integration of ontology, inconsistency would arise if the reasoner effect and "hasCriterion" relationships are defined as the necessary and sufficient conditions. If, for example the concept of "System_quality" has the necessary and sufficient condition "hasCriterion some ease_of_navigation", then it shall be deemed to be equivalent to the reasoner, the other concepts having the same condition. Therefore, it will be deemed to be equivalent to the concept of "Usability1" (8). On the other hand, based on a necessary and sufficient condition, "hasCriterion some appropriateness_design_style" shall be deemed equivalent to the concept of "Design", which has an equivalent condition "hasCriterion some appropriateness_design" (9), (10). The situation will appear when the concept of "System_quality" is equivalent to the concepts "Usability1" and "Design" (11). Accordingly, the reasoner also recognizes that these concepts are equivalent (12). The fact that the concepts of "Usability1" and "Design" create a partition is important, so that they are mutually exclusive and can not be considered equivalent to (12). This raises the inconsistency inference. The example given there is that there is no inconsistency in the target ontology due to the fact that the relationship "hasCriterion" and "isCriterion" between concepts of characteristics and quality criteria are defined as shown in Figure 5.

During integration there may be other inconsistencies that must be addressed on a regular basis. This will be discussed using the example of concepts called "Criterion" coming from the ontology eQual and SiteQual. In view of the fact that the method eQual grading scale covers a range of values from 1 to 7, a restriction should be imposed on the concept of "Criterion" in the ontology eQual " hasEvaluationValue only integer [> = 1, <= 7]". Meanwhile, in the SiteQual method the evaluation of criteria includes the values from 1 to 9, so that the concept of "Criterion" in the ontology describing this method will be limited to "hasEvaluationValue only integer [> = 1, <= 9]". While the integration of ontologies these concepts should be unified, the question arises: "What range of values should include restricting the concept of "Criterion" in a unified model of the target ontology?". In order to solve the conflicts mentioned, we decided to adopt a solution from the PROMPT algorithm. It occurs when one of ontology is considered to be the preferred one and conflicts of this type are resolved in its favor [40]. During the integration, target ontology that unifying source ontologies will be the preferred. Therefore, the order of the integrated source ontology will have a partial effect on the resulting form, a unified model of the target ontology.

Based on these observations, conclusions and guidelines, the source ontologies was built, reflecting the website evaluation quality methods. These ontologies, in the form of primary evidence, and inferred by the reasoner, are presented in: eQual [41], Ahn [42] SiteQual [43] Website Evaluation Questionnaire [44] and Web Portal Site Quality [45]. More of the construction process of source ontologies is described in [46]. Based on the literature analysis presented earlier, feedback and observations, we formulated the integration algorithm that was then applied in the process of ontology integration of website quality evaluation methods.

## IV. Source ontologies integration algorithm in the target ontology

The developed ontology integration algorithm is closely related to refactoring and ontology merging support tools offered by Protégé editor [47]. These tools make it much easier to carry out the integration process. The integration algorithm is divided into three parts. Part I is performed only once as part of the integration process. It concerns the preparation for the integration and the integration of the first source ontology in the target ontology. Part II includes the integration of the criteria and the placement in the target ontology the individual models of evaluation coming from the integrated ontology, as with the methods that are reflected by the different source ontologies. Part III deals with the construction of a unified quality model in the target ontology.

Part I: Preparing for the integration and integration of the first ontology. As a result of the first part of the algorithm, contained in the target ontology is the first source ontology. This part consists of four steps.

1. In order to prepare for integration, new empty ontology should be created in the Protégé editor, which are then integrated source ontologies. The created ontology IRI identifier must be given a value of "Integrated".
2. Then the first source ontology for integration should be selected; open the target ontology "Integrated" in editor Protégé and import the selected source ontology (e.g. "eQual").

3. The next step is to use the "Merge ontology" option in order to merge the source ontology (e.g. "eQual") and the destination ("Integrated"). In this way, the two ontologies will be included in the same file ontology.
4. Then, using refactoring tools, change the IRI identifier of the source ontology elements to "Integrated" value, which is the IRI identifier of the target ontology. This should be performed for all elements of the source ontology, with the exception of the concepts contained therein describing the quality model (for "eQual" the following concepts should be left unchanged: "eQual", "Service_interaction", "Empathy", "Trust", "Information_quality", "Usability", "Design" and "Usability1"). This action will preserve the quality model of the source ontology in the target ontology.

Part II: Integration of another source ontology in the section containing the criteria and quality model. As a result of this part of the algorithm, another source ontology will be placed into the target ontology (another website evaluation quality model and their criteria). It consists of two stages, having in total six steps.

Stage I: Selection of another source ontology to integration and alignment of parts of the source and target ontologies containing criteria.

1. Next source ontology for integration should be selected.
2. Then, to align the parts of the ontologies containing criteria, identify the relationship between the quality criteria present in the target ontology (i.e. "Integrated" in accordance with its current content) and in the source ontology to be integrated into the next stage. To do this, use the dictionaries, thesaurus, toolsof the Protégé editor and source literature concerning approaches represented by ontologies.

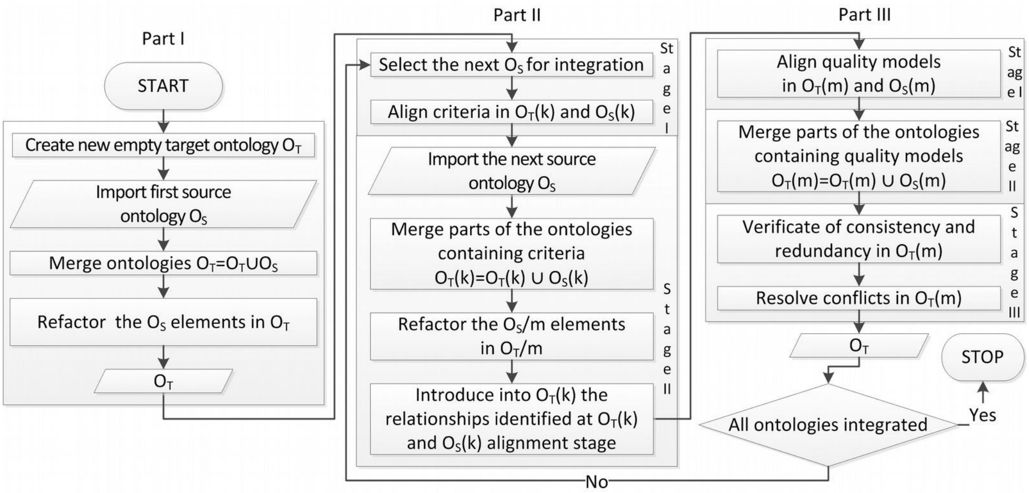
Stage II: Integration of another source ontology.

1. With Protégé editor open the target ontology "Integrated", perform another source ontology imports (e.g. "Ahn").
2. Using the tool "Merge ontologies", connect the source ontology (e.g. "Ahn") and the target (e.g. "Integrated", which already contains concepts from "eQual").
3. The next step is to change the IRI of the previously assigned values (e.g. "Ahn") to "Integrated" for all elements from the source ontology except those that describe the quality model (for Ahn they are concepts, "Ahn", "Information_quality", "System_quality" and "Service_quality"). This action will fit together just called concepts of criteria of source and target ontologies. The relations and concepts that are rooted in the ontology, i.e. "Criterion", "Quality" and "Service", will also be matched in this way.
4. The next action is to introduce the relationships of equivalence and subsumption between concepts of criteria derived from the source and the target ontologies. These relationships should be identified at the stage of aligning criteria (Part II, Phase I, Step 2).

Part III: Building a unified model of quality. This part consists of three stages, having in total 4 steps that should be done at the end of Part II of the algorithm.

Stage I: Aligning quality models. You need to specify the link between quality characteristics included in the unified model. As in the alignment step occurring in the second part of the integration algorithm, a number of tools must also be used here to facilitate the identification of links.

Stage II: Construction of a unified model of quality. This model should include the characteristics contained in the source and target ontology. After determining its structure, the previous unified model contained in the target ontology should be replaced. Quality characteristics of a unified model should contain relationship "hasCriterion". The criteria should be related to the characteristics of the model relationship "isCriterion".



Part I
START
Create new empty target ontology $O_T$
Import first source ontology $O_S$
Merge ontologies $O_T$=$O_T$U$O_S$
Refactor the $O_S$ elements in $O_T$
$O_T$
Part II
Select the next $O_S$ for integration
Align criteria in $O_T(k)$ and $O_S(k)$
Stage I
Import the next source ontology $O_S$
Merge parts of the ontologies containing criteria $O_T(k)$=$O_T(k)$ ∪ $O_S(k)$
Refactor the $O_S$/m elements in $O_T$/m
Introduce into $O_T(k)$ the relationships identified at $O_T(k)$ and $O_S(k)$ alignment stage
Stage II
Part III
Align quality models in $O_T(m)$ and $O_S(m)$
Stage I
Merge parts of the ontologies containing quality models $O_T(m)$=$O_T(m)$ ∪ $O_S(m)$
Stage II
Verificate of consistency and redundancy in $O_T(m)$
Resolve conflicts in $O_T(m)$
Stage III
$O_T$
All ontologies integrated
Yes
STOP
No

Fig 8. Algorithm for ontology integration

Stage III: Verification of consistency and absence of redundancy and resolving conflicts.

1. This should focus on the consistency of the target ontology obtained using reasoner.
2. Conflicts involving two equivalent characteristics having different names can also occur here. Then you need to decide what the characteristics that will be included in the model should be called. Furthermore, one criterion may be associated by the relationship "isCriterion" with two characteristics included in the unified model. Such conflicts must be resolved by selecting the preferred characteristics and relationships derived from a previous version of the unified model.

A block diagram of the integration algorithm is shown in Figure 8.

## V. Results

In order to integrate the source ontology built earlier, according to the algorithm presented in point IV, the first part of the process of integration was completed, i.e. the creation of an empty target ontology, and integrated in there the eQual source ontology. Then a second ontology was selected for integration, which was Ahn ontology, and the alignment of concepts representing criteria was carried out. In this step links were identified between the target ontology, which already contains eQual, and the source ontology Ahn. The links detected are shown in Table 1. It should be noted that the alignment of the ontologies created some problems. Namely, certain relationships between concepts may not be obvious. Therefore, in order to determine the relationships between concepts of criteria, dictionaries, thesauruses and source literature concerning methods of integration represented by ontologies were used. The second problem results from the the fact that the integrated ontologies are creations of secondary structures, developed on the basis of quality assessment methods. The criteria contained in the individual methods are typically in the form of sentences, so that their names are in the long form. Therefore, in the analysis of the links there may appear to be some confusion regarding the full wording of the concept.

Based on the identified relationship between the criteria set out in Table 1, the next stage of integration was carried out, i.e. a merging ontologies in Protégé editor. In this framework the following things were achieved: import Ahn source ontology to target ontology, ontology merging with the use of the tool "Merge ontologies", the change values of IRI identifiers for concepts / criteria in Ahn ontology, linking respective pairs of concepts with equivalent relationships. Therefore, the target ontology, which is a unified ontology eQual and Ahn at the level of criteria, was achieved.

Then the concepts representing the characteristics of quality models Ahn and eQual were aligned, as shown in Table 2. The relationship between the characteristics set out in Table 2 is presented in that way due to the fact that the criteria included in the particular characteristics were symlinked in it at the same level of hierarchy. For example, if the "Service_quality" has been recognized as being equivalent to the characteristics of "Service_interaction", then e.g. the criterion of "instills_confidence " (belonging to the ”Service_quality”) would occur on the 3rd level of the proposed hierarchy along with the characteristics of the "Trust” (including the ”Service_interaction"). The criterion of "reputation" (belonging to the "Trust") would be at level 4, resulting thus in a hierarchy in which on one level in the context of the characteristics of "Service_interaction" are both criteria and subcharacteristics. This could cause problems with inconsistency during the inference by the reasoner, so in this case these characteristics associated with subsumption relationship.

The last step was to check the consistency and lack of redundancy in an integrated ontology. Such redundancy appeared as a result of the reasoner, in the case of the criteria from the target and source ontology having the same name or having been recognized as equivalent, and belonging to two different characteristics included in the unified model. In each of these cases, there was a redundancy of subsumption relationship between the criteria and characteristics of the

Table I. Aligning the concepts of criteria in the target ontology containing the eQual model and source ontology Ahn

| No. | Relation type | Target ontology (containing eQual) | | Source ontology Ahn | |

| 5. | equivalence | Information quality | information accuracy | Information quality | information accuracy |
| 6. | equivalence | Information quality | information believability | Information quality | information reliability |
| 7. | equivalence | Information quality | information timeliness | Information quality | information timeliness |
| 8. | equivalence | Information quality | appropriate format of information | Information quality | appropriate format of information |
| 9. | equivalence | Trust | security of personal information | System quality | security of personal information |
| 10. | equivalence | Empathy | personalization | Service quality | adaptation to the user's needs |
| 11. | equivalence | Trust | confident about delivery goods and services | Service quality | providing whatever promised |

TABLE II. ALIGNING THE CONCEPTS OF QUALITY MODEL IN THE TARGET ONTOLOGY CONTAINING THE EQUAL MODEL AND SOURCE ONTOLOGY AHN

| No. | Relation type | Target ontology (containing eQual) | | Source ontology Ahn | |
|---|---|---|---|---|---|
| | | Parent concept | Characteristic | Parent concept | Characteristic |
| 1. | equivalence | Quality | Information quality | Quality | Information quality |
| 2. | reverse subsumption | Quality | Service interaction | Quality | Service quality |

unified model. Selected examples of such redundancy are presented in Figure 9, which shows both the redundant relationship within one sheet, as well as within different characteristics.

For example, a couple of equivalent concepts "personalisation" and "adaptation_to_the_user's_needs" belongs to the characteristics of the "Service_quality" and "Empathy". On the other hand, the subcharacteristics are included in the single characteristic "Service_interaction". So here there is a redundancy in a single sheet. This redundancy resulted from the fact that the criterion of "personalisation" in the ontology eQual being part of the category of "Empathy" and the criterion of "adaptation_to_the_user's_needs" in Ahn ontology being one of the characteristics of "Service_quality". As a result of the recognition of these criteria as being equal to each other, they take the relationship between them and the characteristics to which they belong. A similar situation occurs, for example, in the case of matched pairs of concepts "sense_of_competency" and "professionalism_and _competence", which are among the characteristics of "Service_quality" and "Design" as a result of the equivalence that exists between them. This type of redundancy relationship is resolved in accordance with the assumptions described in Section III of the article, i.e. for the benefit of the target ontology, keeping derived from the relationship, and removing accounts from the source ontology (in this case from the ontology Ahn). Integrating ontology models eQual and Ahn and including the quality model unifies these two methods, presented in the elementary form [48], in the form deduced by the reasoner [49].

Other iterations of the process of integration of the various source ontology and of the target ontology integration proceeded analogously to those presented above. Previously built ontologies accompanied the target ontology in turn systematically: SiteQual, Website Evaluation Questionnaire and Web Portal Site Quality [50]. Therefore, the ontology [50] contains five source ontologies. For the unified model of quality, consisting of five basic models as deduced by the reasoner, each model is presented separately in [51].

## VI. CONCLUSION

Even a cursory analysis of [50] and [51] shows a very high level of complexity in this built ontology. At the same time, it can be concluded that the construction of such an extensive ontology, as a result of the integration of the source ontologies, is much less complex than its construction process from scratch, even with the use of formal ontology construction methodology. Thanks to the presented approach, the problem of ontology construction unifying quality assessment methods was decomposed for a few minor problems involving construction of the source ontologies were integrated. This resulted in an ontology containing quality models used in the various methods and a model that unifies the different methods. It is worth noting that in all of the integrated methods a total of 115 criteria were used. In the integrated ontology, 94 criteria are listed, due to the fact that part of the criteria are repeated in the various methods. However, when one takes into account the fact that some criteria are equivalent to those of others, one can consider there to be 70 different quality criteria in an integrated ontology. Therefore, we managed to limit the number of applied ontology criteria by almost 40%. The resulting

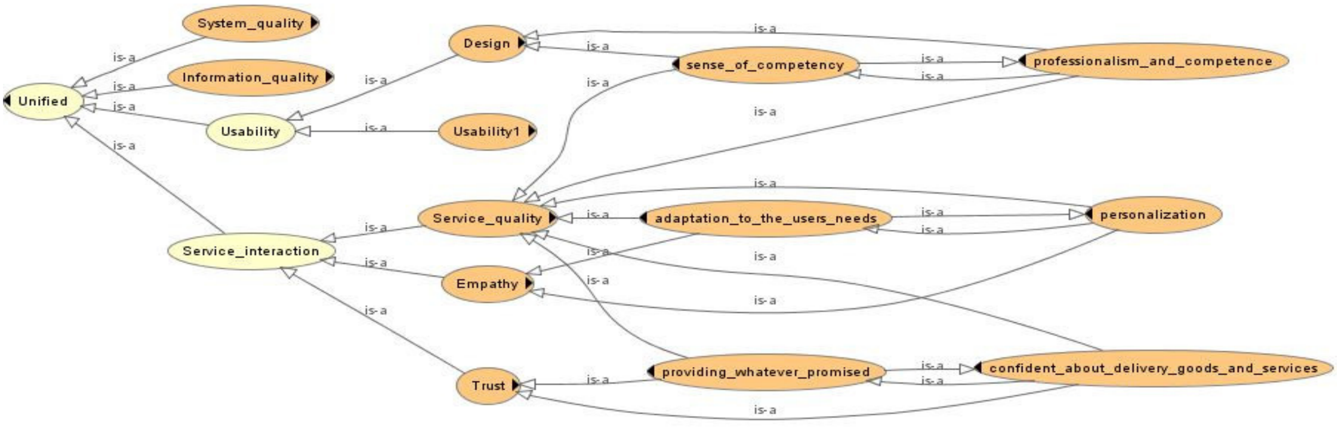

Fig 9. Redundancy of relationships in the target ontology containing the source ontologies eQual and Ahn

ontology presented in [51] can act as a repository of domain knowledge, due to the fact that it includes a number of methods and models that evaluate the quality of websites. It may also allow for the integration of heterogeneous data from a variety of assessment methods, and thus assessment websites through a variety of methods defined in the ontology, so that the individual results of the assessment can be compared in a the same terminology and a reference plane. Constructed repository of knowledge, together with presented in [16] website assessment criteria selection process could be at the core of the expert system of website quality assessment, which should be the direction of further research. In addition, further work should include the development of ontology about the possibility of environmental data records about ontology users.

*Abstract*—**The paper presents the method of a group decision making in a competitive environment. We deal with a group decision when the group of people with different preferences are to make one single decision. The group decision selection process is modeled with the use of multi-criteria optimization task. It is solved with the use of reference point method. This method is an interactive method in which every person specifies its requirements in the form of a reference point, expressing the desired values for its evaluation function. On the basis of the provided reference point, a scalar achievement function is built. Maximization of this function generates a solution of the multi-criteria task. This solution is presented to every person for acceptance or as a basis for the modification of the reference point. The paper contains the example of application of the proposed method to support a group decision by three people with different preferences.**

## I. Introduction

The paper presents the method of a group decision making in a competitive environment. A group decision means that several people, whose interests are conflicting, are supposed to make one decision. One should conjoin divergent interest of all people, in order to arrive to a compromise solution for all. The aim of the selection decision is the best solution for the group, and not for individual members of that group. No solution is selected for a single person, it is looking for all persons in a group.

The selection process of a group decision can be modeled with the use of game theory {5], [6], [11], [14].

The process of a group decision making is modelled with the use of multi-criteria optimization with a vector evaluation function. Each coordinate of this vector is the value of decision evaluation function for each person. The decision selection is performed with the use of an interactive computer system. Each person provides his proposition of the decision result for his/her evaluation function. These propositions constitute parameters of the multi-criteria optimization task and that is then solved. Then, each person evaluates the solution. Each of them may agree to the obtained result or not. In the second case the person or persons provide a new value of the parameter - their new propositions and the problem is solved again for the new parameters. The selection process is not a one-time process, but an iterative process of learning about the decision making. The process of a group decision making is to support the members of a group to obtain as much as possible.

## II. Modeling of a group decision making

Our aim is to find an adequate group decision in a competitive case. The process of making a group decision is modeled by introducing a respective decision variable. Moreover, there are the s. c. decision evaluation functions, which constitute criteria evaluating the solution from the point of view of each person. Each person has its own evaluation criterion - its evaluation function. These functions are a measure of satisfaction of every person by a given solution; they evaluate a degree of achieving a goal by every person. The bigger value of the function means a bigger satisfaction, so every function is maximized. The basis for evaluation and selection of a group decision are all evaluation functions – the criteria for all persons.

The group decision selection problem is modeled as a multi-criteria optimization task:

$$\max_x\{(f_1(x), f_2(x),\ldots,f_k(x)): \quad x \in X_0\} \quad (1)$$

where: $1,2,\ldots,k$ – particular persons,

$X_0 \subset R^n$ - the feasible set,

$x = (x_1, x_2,..., x_n) \in X_0$ - a group decision,

$f_i : X_0 \to R$ – the decision evaluation function by a person $i$, $i = 1,2,\ldots,k$.

Task (1) relies on finding such a feasible decision $x \in X_0$ for which $k$ evaluations attain the best possible values. There is a common restraining of decision which constitutes a solution.

The vector functions $f = (f_1, f_2,..., f_k)$ defines the correspondence of any decision variable vector $x \in X_0$ and

978-83-60810-66-8/$25.00©2015, IEEE

the respective evaluation vector $y = (y_1,..., y_k)$. They measure the decision quality from the point of view of decision evaluation. Particular coordinates $y_i = f_i(x), \quad i = 1,..., k$ are scalar functions of decision evaluation for $i - th$ person, $i = 1,2,...,k$. The image of the feasible set $X_0$ by the function $f$ constitutes a collection of achievable evaluation vectors $Y_0$.

Task (1) is formulated in the domain of evaluations, i.e. the following task is considered:

$$\max_x\{(y_1,...,y_k): \quad y \in Y_0\} \tag{2}$$

where : $x \in X$ – a vector of decision variables,

$y = (y_1,..., y_k)$ – a vector of evaluations, particular coordinates $y_i$ representing the results of the decision $x$ for the person $i$, $i = 1,2,...,k$,

$Y_0 = f(X_0)$ – the set of achievable evaluation vectors.

The set of achievable evaluation vectors $Y_0$ is provided in a non-explicit way – through the set of feasible decisions $X_0$ and the model $f = (f_1,..., f_k)$. In order to calculate the value $y$, a simulation of the respective model is necessary: $y = f(x), x \in X_0$.

The aim of task (1) is the aid in finding a decision that would be the most compromising for all persons.

## III. Equitably efficient solution

The solution in the selection decision process should satisfy certain properties that persons accept as reasonable. Namely, such a solution should be:

- an optimal solution in the sense of Pareto – i.e. such that you can not improve the solution for one person without worsening the solution for the other persons,
- symmetric solution – i.e. that it should not depend on the way the persons are numbered; as no one is more important that the others. Persons are treated in the same way in the sense that the solution does not depend on the name of person or on other factors specific to a given person,
- equalizing solution - that is, a vector that has less variation of coordinates of evaluation is preferred in comparison to a vector with the same sum of coordinates, but with a greater diversity of coordinates.

Any decision, that satisfies the above conditions is an equitably efficient decision. Hence, this Pareto-optimal decision satisfies additional conditions – anonymity and the axiom of equalizing solution.

The non-dominated results ( Pareto - optimal) are defined as follows:

$$\hat{Y}_0 = \{\hat{y} \in Y_0 : (\hat{y} + \tilde{D}) \cap Y_0 = \varnothing\} \tag{3}$$

where: $\tilde{D} = D \setminus \{0\}$ – a positive cone without the top. As a positive cone, it can be adopted $\tilde{D} = R^k_+$. Appropriate acceptable decisions are specified in the decision space. The decision $\hat{x} \in X_0$ is called efficient decision (Pareto - optimal), if the corresponding vector of evaluations $\hat{y} = f(\hat{x})$ is a non-dominated vector [7], 16], [17].

Finally, in the multi-criteria problem (1), which is used to select a group decision, the relation of preferences should satisfy additional properties: anonymity property and the property of equalizing solution.

The relation is called an anonymous relation if, for every vector $y = (y_1, y_2,..., y_k) \in R^k$ and for any permutation $P$ of the set $\{1,...,k\}$, the following property holds:

$$(y_{P(1)}, y_{P(2)},..., y_{P(k)}) \approx (y_1, y_2,..., y_k) \tag{4}$$

No distinction is made between the results that differ in the arrangement of coordinates. Evaluation vectors having the same coordinates, but in a different order are identified and that is the anonymity property.

Moreover, the relation of preferences satisfies the axiom of equalizing transfer, if and only if the following condition is satisfied:

for the evaluation vector $y = (y_1, y_2,..., y_k) \in R^k$:

$$\begin{gathered} y_{i'} > y_{i''} \Rightarrow y - \varepsilon \cdot e_{i'} + \varepsilon \cdot e_{i''} \succ y \\ \text{for } 0 < y_{i'} - y_{i''} < \varepsilon \end{gathered} \tag{5}$$

Equalizing transfer is a slight deterioration of a better coordinate of evaluation vector and simultaneously improvement of a poorer coordinate. The resulting evaluation vector is strictly preferred in comparison to the initial evaluation vector. This is a structure of equalizing – the evaluation vector with less diversity of coordinates is preferred in relation to the vector with the same sum of coordinates, but with their greater diversity.

Non-dominated vector satisfying the anonymity property and the axiom of equalizing transfer, is called equitably non-dominated vector. The set of equitably non-dominated vectors is denoted by $\hat{Y}_{0W}$. In the decision space, the equitably efficient decisions are specified. The decision $\hat{x} \in X_0$ is called equitably efficient decision, if the corresponding evaluation vector $\hat{y} = f(\hat{x})$ is an equitably non-dominated vector. The set of equitably efficient decisions is denoted by $\hat{X}_{0W}$ [2], [9], [13].

The relation of equalizing domination can be expressed as the relation of inequality for cumulative, ordered evaluation vectors. This relation can be determined with the use of mapping $\overline{T}: R^k \to R^k$ that cumulates nondecreasing coordinates of evaluation vector.

The transformation $\overline{T}: R^k \to R^k$ is defined as follows:

$$\overline{T}_i(y) = \sum_{l=1}^{i} T_i(y) \quad \text{for } i = 1,2,...,k \tag{6}$$

Define namely by $T(y)$ the vector with decreasing ordered coordinates of the vector $y$, i.e.. $T(y) = (T_1(y), T_2(y),..., T_k(y))$, where $T_1(y) \le T_2(y) \le ... \le T_k(y)$ and there is a permutation $P$ of the set $\{1,...,k\}$, such that $T_i(y) = y_{P(i)}$ for $i = 1,..,k$.

The relation of equalizing domination $\succ_e$ is a simple vector domination for evaluation vectors with nondecreasing coordinates of evaluation vector [2], [9], [13].

The evaluation vector $y^1$ equitably dominates the vector $y^2$ if the following condition is satisfied:

$$y^1 \succ_e y^2 \Leftrightarrow \overline{T}(y^1) \ge \overline{T}(y^2) \tag{7}$$

Solving the problem of decision selection in the group decision process consists in determination of the equitably efficient decision which satisfies the preferences of every persons.

## IV. Scalaring the problem

For determination of equitably efficient solutions of multi-criteria task (1), a specific multi-criteria task is solved. It is the task with the vector function of the cumulative, ordered evaluation vectors, i.e. the following task:

$$\max_y \{(\overline{T}_1(y), \overline{T}_2(y),..., \overline{T}_k(y)): \quad y \in Y_0\} \tag{8}$$

where: $y = (y_1, y_2,..., y_k)$ – an evaluation vector,

$\overline{T}(y) = (\overline{T}_1(y), \overline{T}_2(y),..., \overline{T}_k(y))$ a cumulative, ordered evaluation vector,

$Y_0$ – the set of achievable evaluation vectors.

Effective solution of multi-criteria optimization task (8) is an equitably efficient solution of the multi-criteria task (1).

To determine the solution of a multi-criteria task (8), the scalaring of this task with the scalaring function $s: Y_0 \times \Omega \to R^1$ is solved:

$$\max_x \{s(y, \overline{y}): x \in X_o\} \tag{9}$$

where: $y = (y_1, y_2,..., y_k)$ – an evaluation vector,

$\overline{y} = (\overline{y}_1, \overline{y}_2,..., \overline{y}_k)$ – a control parameters for individual evaluations.

It is the task of single objective optimization with specially created scalaring function of two variables - the evaluation vector $y \in Y$ and control parameter $\overline{y} \in \Omega \subset R^k$; we have thus $s: Y_0 \times \Omega \to R^1$. The parameter $\overline{y} = (\overline{y}_1, \overline{y}_2,..., \overline{y}_k)$ is available to each person. That allows any person is capable to review the set of equitably efficient solutions.

The optimal solution of task (9) should be a solution of the multiple criteria task (8). Scalaring function should satisfy certain properties - the property of completeness and that of sufficiency. The property of sufficiency means that for each control parameter $\overline{y}$ the solution of the scalaring task is the equitably efficient solution, i.e. $\hat{y} \in \hat{Y}_{0W}$. The property of completeness means, that by appropriate changes of parameter $\overline{y}$ any solution $\hat{y} \in \hat{Y}_{0W}$ can be achieved. Such a function completely characterizes equitably efficient solutions. Inversely, each maximum of such a function is an equitably efficient solution. Each equitably efficient solutions can be obtained with appropriate value of control parameter $\overline{y}$.

Complete and sufficient parameterization of the set of equitably efficient solutions $\hat{Y}_{0W}$ can be achieved, using the method of the reference point for the task (8). In this method the aspiration levels are applied as control parameters. Aspiration level is such value of the evaluation function that satisfies a given person.

The scalaring function defined in the method of reference point is as follows:

$$s(y, \overline{y}) = \min_{1 \le i \le k} (\overline{T}_i(y) - \overline{T}_i(\overline{y})_i) + \varepsilon \cdot \sum_{i=1}^{k} (\overline{T}_i(y) - \overline{T}_i(\overline{y})_i) \tag{10}$$

where: $y = (y_1, y_2,..., y_k)$ – an evaluation vector,

$\overline{T}(y) = (\overline{T}_1(y), \overline{T}_2(y),..., \overline{T}_k(y))$ - a cumulative, ordered evaluation vector,

$\bar{y} = (\bar{y}_1, \bar{y}_2, ..., \bar{y}_k)$ – a vector of aspiration levels,

$T(\bar{y}) = (T_1(\bar{y}), T_2(\bar{y}), ..., T_k(\bar{y}))$ - a cumulative, ordered vector of aspiration levels,

$\varepsilon$ – an arbitrary small, positive adjustment parameter.

Such scalaring function is called a function of achievement. The aim is to find a solution that approaches as close as possible the specific requirements – the aspiration levels [2], [7], [13].

Maximizing this function w. r. to $y$ determines the equitably efficient solution $\hat{y}$ and the equitably efficient decision $\hat{x}$. Note, the equitably efficient solution $\hat{x}$ depends on the aspiration level $\bar{y}$. A solution of the multicriteria optimization problem makes correspond of solution proposals of particular members of the group to the respective levels of aspiration.

## V. Method of supporting the group decision

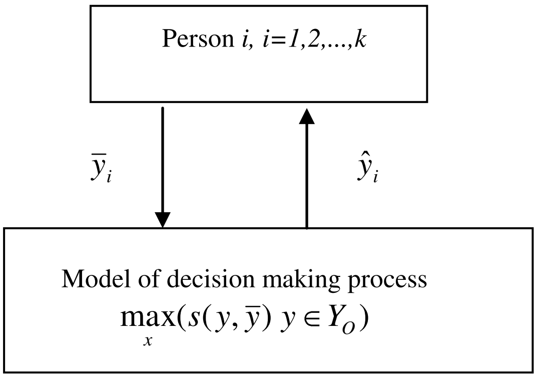
The solution of the multi-criteria task (8) is a set of equitably efficient solutions. In order to solve a given problem it is necessary to pick one solution which will be evaluated by all persons. Due to the fact that the equitably efficient solution is a whole set of solutions, the persons perform the selection with the help of an interactive computer system. Such a system makes possible to have a guided overview of a whole set of solutions. The tool used to view this set of solutions is function (10). Maximum of this function depends on the parameters $\bar{y}_i, i = 1,2,,...,k$, which are applied by all persons. In the reference point method each person expresses its preferences by specification, with the aid of his/her evaluation function, of such a value that would be fully satisfactory. That is the value of the aspiration level for his/her evaluation function. For any stage of the selection process the persons may provide different aspiration levels. Such levels of aspiration constitute steering parameters of the scalarization function. On this basis the task is solved and the system proposes the solution corresponding to the current values of those parameters - for further analysis.

The method of supporting the group decision is the following:

1. Iterative algorithm - propositions of particular decision.
   1.1. Interaction with the system - each person provides his/her own proposition of the decision for its evaluation function as his/her level of aspiration $\bar{y}_i, i = 1,2,...,k$.
   1.2. Calculations – computing particular values from the equitably efficient solution $\hat{y} = (\hat{y}_1, \hat{y}_2, ..., \hat{y}_k) \in \hat{Y}_{0W}$ and the equitably efficient decision $\hat{x} = (\hat{x}_1, \hat{x}_2, ..., \hat{x}_k) \in \hat{X}_{0W}$.
   1.3. Evaluation of the obtained solution - each person may accept the solution or not. In the second case - each person provides his/her new proposition and provides a constant value of his/her level of aspiration $\bar{y}_i, i = 1,2,..,k$ and another equitably efficient solution is set out. (Return to sub-point 1.2).
2. Establishing the decision, when the decision fulfills the requirements of all persons.

This is not a single optimization act but a dynamic process of looking for solutions, during which the persons learn and may change their preferences. Comparing the result of the decision $\hat{y}_i, i = 1,2,...,k$ with the aspiration point $\bar{y}_i, i = 1,2,...,k$, each person finds what is not achievable and how his/her proposition $\bar{y}_i, i = 1,2,...,k$ is far from a possible solution $\hat{y}_i, i = 1,2,...,k$. This allows for a proper modification of their own propositions – with regard to their own levels of aspiration. These levels of aspirations are specified adaptively in the process of teaching. This process finishes when such decisions are found, which allow to fulfill the aspirations of persons in a maximum possible degree.

Method of supporting the group decision is presented at diagram 1.



Person *i, i=1,2,...,k*
$\bar{y}_i$
$\hat{y}_i$
Model of decision making process
$\max_x(s(y,\bar{y})\ y \in Y_O)$

Fig. 1. Method of supporting the group decision making

Such a manner of making decisions does not impose any strict scenario and allows for the possibility of modifying the preferences for every person in the decision making process. Persons learn during the selection process about the decision making problem. The persons may check the results of every allowed proposition. All members of a group have an equal part in the decision making process. They all have an equal possibility for eventual changes of their preferences. The computer will not replace people in the decision making process; the whole process of selecting a decision is guided by all persons.

## VI. Example

To illustrate the support of the group decision making the following example is presented - selection of a group decision by three persons [3].

The problem of selecting the decision is the following:

1,2,3 –persons,

$X_0 = \{x \in R^4 : 2\cdot x_1 + x_2 + 4\cdot x_3 + 3\cdot x_4 \le 60,$

$3\cdot x_1 + 4\cdot x_2 + x_3 + 2\cdot x_4 \le 60,$ -

$x_1 \ge 0,\ x_2 \ge 0,\ x_3 \ge 0,\ x_4 \ge 0\}$

the feasible set,

$x = (x_1, x_2, x_3, x_4) \in X_0$ - a group decision,

$f_1(x) = 3\cdot x_1 + x_2 + 2\cdot x_3 + x_4$ – the decision evaluation function by person 1,

$f_2(x) = x_1 - x_2 + 2\cdot x_3 + 4\cdot x_4$ – the decision evaluation function by person 2,

$f_3(x) = -x_1 + 5\cdot x_2 + x_3 + 2\cdot x_4$ – the decision evaluation function by person 3,

The problem of selection of a group decision is expressed in the form of multi-criteria optimization task with three evaluation functions:

$$\max_x\{(3\cdot x_1 + x_2 + 2\cdot x_3 + x_4,\\ x_1 - x_2 + 2\cdot x_3 + 4\cdot x_4,\\ -x_1 + 5\cdot x_2 + x_3 + 2\cdot x_4): \quad x \in X_0\} \tag{11}$$

where: $X_0$ - the feasible set,

$x = (x_1, x_2, x_3, x_4) \in X_0$ - a group decision

To select the solutions of (11), the reference point method is used for the task with cumulated coordinates of the evaluation vector ordered in a non decreasing manner.

The first step of the vector analysis is to use the one-criteria optimization for evaluation function of every person separately. As a result there is the so-called matrix of goal realization including the values of each criterion, received by solving one of the three one-criteria problems. This matrix allows for evaluation of the scope of changes of particular evaluation function on the allowed set; it provides a certain information about the conflict of the evaluation functions. Matrix of goal realizations generates the utopia vector that represents the best values of each separate criterion.

Table 1. Matrix of goal realization with the utopia vector.

| Optimization criterion | | Solution<br>$\hat{y}1$ | <br>$\hat{y}2$ | <br>$\hat{y}3$ |
|---|---|---|---|---|
| Person's Evaluation 1 | $y1$ | 66 | 30 | -12 |
| Person's Evaluation 2 | $y2$ | 20 | 80 | 40 |
| Person's Evaluation 3 | $y3$ | 15 | -15 | 75 |
| Utopia vector | | 66 | 80 | 75 |

When analyzing the table 1 it might be observed that the biggest selection possibilities has person 2, lower - person 3 and the lowest one - person 1.

People in the group do control the process by means of aspiration levels. The multi-criteria analysis is presented in table 2.

Table 2. Interactive analysis of looking for solutions.

| Iteration | | Pers. 1<br>$\hat{y}1$ | Pers2<br>$\hat{y}2$ | Pers.3<br>$\hat{y}3$ |
|---|---|---|---|---|
| 1 | Aspiration point $\bar{y}$ | 66 | 80 | 75 |
| | Solution $\hat{y}$ | 24 | 66 | 66 |
| 2 | Aspiration point $\bar{y}$ | 55 | 65 | 60 |
| | Solution $\hat{y}$ | 26,76 | 65 | 60 |
| 3 | Aspiration point $\bar{y}$ | 50 | 60 | 55 |
| | Solution $\hat{y}$ | 30,17 | 60 | 55 |
| 4 | Aspiration point $\bar{y}$ | 48 | 58 | 53 |
| | Solution $\hat{y}$ | 31,54 | 60 | 55 |
| 5 | Aspiration point $\bar{y}$ | 45 | 55 | 50 |
| | Solution $\hat{y}$ | 33,59 | 55 | 50 |
| 6 | Aspiration point $\bar{y}$ | 43 | 53 | 48 |
| | Solution $\hat{y}$ | 34,5 | 53 | 48 |

At the beginning of the analysis every person specifies its preferences as the aspiration point equal to the utopia vector coordinate. The obtained solution prefers by person 2 and person 3 and is too small for person 1. The group wants to improve the solution. Therefore, all the people in the group decrease their requirements in the next iteration. One obtains a slight improvement for person 1 and deterioration for person 2 and person 3, but the group wants to improve the solution for person 1. In subsequent iterations all individuals reduce their requirements and improve the value obtained for the assessment of persons 1, at the cost of two other person. For iterations 5 and 6 the following decisions are found: $\hat{x}^5 = (3{,}78;\ 5{,}12;\ 2{,}02;\ 13{,}07)$ and $\hat{x}^6 = (4{,}27;\ 5{,}07;\ 2{,}41;\ 12{,}24)$. The analysis reveals that there is deep influence of person 2 and 3 on the solution; however, for person 1 it is far less significant.

The final selection of the specific solution depends on the preferences of all persons. The presented example shows that the method allows the persons to learn about their decision-making possibilities. The search for compromise for everyone is continued in this method.

## VII. Conclusion

The paper presents the method of supporting the group decision making. The selection of decision is performed by solving the multi-objective task according to the optimization criteria. This method is characterized by:

- the use of information about everyone's preferences in the form of aspiration points - values of goal function that are fully satisfactory to them and the optimal option of the scalar achievement function in order to organize the interactions with all persons,
- the assumption that the preferences of persons are not completely fixed and they may change during the decision making process.

Reference point method applied to the of multi-criteria problem indicates a solution which would be suited to the preferences of all individuals in the group.

The participation of any members of the group in the decision making implies acceptation of a final choice. In such a course of action one does not replace people in decision making. The whole process of decision making is guided by all persons.

***Abstract*—Modern organizations, knowledge-based organizations in particular, seek new IT solutions supporting business processes and knowledge management realized by them. One of the solutions, postulated by the authors supporting the actions of such organizations may be computer software in the form of software agents, considered in our study in terms of software agents society. The purpose of this article is to analyze the results of authors' three-year study on the modeling aspect of the software agents society in knowledge-based organizations. The paper presents theoretical issues connected with the use of knowledge management systems in organisations, partial results of interviews with developers of agent solutions in Poland, a proposal of a methodology for designing agent societies, elements of a developed prototype of an agent solution and findings of qualitative research in the area of usability of software agents.**

## I. Introduction

DEVELOPMENT of organization's theory for modern forms of management of the company's action results in that solutions need to adapt their structure and functionality to meet the specific needs of the organization. One example is to look at the management-oriented approach to knowledge, which is seen as an important organization's resource. Such knowledge, perceived in the literature as an overt or covert knowledge, is an essential part of business processes that such organizations implement. Information systems, which will support organizations aware of the knowledge processing content, should support on one hand its codification, so that the knowledge partnership could be stored as a resource system used by the organization and its employees, and on the other hand the methodology to support the modeling of such systems should support its codification changing tacit knowledge into overt. Solutions, which according to the authors have the indicated characteristics, are agent systems.

The purpose of this article is to analyze the results of the authors' three-year study on the modeling aspect of software agents society in knowledge-based organizations. The study conducted by the authors, initiated in 2012, on the modeling of software agents' society in organizations based on knowledge, were focused on the search for forms of use of software agents in the context of their use in modern organizations and to determine whether these solutions, aided by semantic knowledge representation, contribute to the improvement of business processes. Due to its complexity, first an analysis of the literature in this area was conducted in order to arrange a society of agents in the registration system used in organizations [1] [2] [3]. Further the IT companies, which offer agent-based solutions, have been asked to indicate their main problems of modeling and implementation [4] [5]. As a result, studies on currently used multi-agent platforms [6] and agent systems design methodologies [7] allowed us to propose a modeling methodology of software agents' society [8] [9] [10], it's possible architecture [11][12] and to assess their impact on organizations [13][14][15]. As part of the qualitative research, indepth interviews and research experiments were used. The presented issues have been addressed in chapters.

Chapter 1 and 2 will present the introduction to the theory of knowledge-based organization and knowledge management. In Chapter 3 the results of the 2013 qualitative research in the form of in-depth interviews with companies forming agent-based solutions on the Polish market will be given. Later in Chapter 4, the methodology of modeling software agents society will be shown, focused on the organization's knowledge for agents specification. Chapter 5 will depict partial results of research, carried out in 2014, related to the software agents' usability analysis in promoting knowledge about the organization and the processes occurring in it.

## II. Knowledge Management in Organizations

The concept of knowledge management (KM) was developed to discover tools and methodology of management of knowledge, which was described as one of classical factor of production with land, labor and capital by Drucker [16] . The term of knowledge management is one of the most promotes an integrated approach to identifying, capturing, evaluating, retrieving, and sharing all of an enterprise's information assets. These assets may include databases, documents, policies, procedures, and previously uncaptured expertise and experience in individual workers [17].

Knowledge management system (KMS) is dedicated to help organization to meet its goals and to increase its effectiveness. The literature review shows that there are a multiple definitions of knowledge management system have been proposed in the literature, and debates about this concept have been expressed from a variety of perspectives and positions [18][19][20]. Also there are some models of life cycle knowledge management in organization [21][22].

978-83-60810-66-8/$25.00©2015, IEEE

Information and communication technologies (ICT) may play an important role in effectuating the knowledge-based view of the organization to manage the knowledge it possesses [21][17]. KMSs are technologies that support knowledge management in organizations, specifically, knowledge generation, codification, and transfer. Nowadays the impact of modern ICT (interactive communication channels, agent oriented technologies, etc.) in the company due to developing of Web 2.0/3.0, i.e., social media, blogs, micro blogs, forums, wikis, and others, make the impact in knowledge-based organization.

Knowledge-based organizations understand the importance of knowledge in the process of creating a competitive edge and focus on creating value added based on an effective use of knowledge [23]. ICT solutions focused on the aspect of supporting. Such organizations should support business processes that take place in them in the area of creating, processing and sharing a contextual knowledge about them. This results from the fact that knowledge-based organizations focus not only on business processes but also on knowledge management processes which should be treated in such organizations equivalently. Nowadays knowledge management system is facilitated by Web-based ICTs. It is worth underlining, that the majority of companies use well known ICTs, for example: e-mails, online surveys, social networks, Internet forums, business blogs, comments posted on a producer website, business (specialized) portals, online price comparison [24] [25].

The main tools of Web 2.0 allow users to share content with each other and collaborate online. Web 2.0 features are commonly known as postulates, namely the idea that describes the people-oriented approach [26]. The next generation of the Web is Web 3.0 [27], which is no longer focused on the people but on the machine. The idea of Web 3.0 requires not only data, but also the metadata, which is information about the data; it is reflected postulate transformation into a computer network database. This allows data binding on the Internet, taking into account the aspect of meaning, differentiating the data by the machine with the identical record, and also carried out on these data inference. It is an extension of the existing web, but has better connections between the blocks of information by defining the importance of accurate data available. As a result, programs that read the information, called agents, can analyze data, understand their meaning and find the relationships between them, and perform complicated tasks assigned by the users [28]. It is the main reason of implementation Web 3.0 into knowledge management systems in organization. One of the solutions, that can help such organizations, are software agents societies which can support the different stages of knowledge management systems life cycle.

The study shows the kind of models of agent supported organizations [1]:

- Information allocation model - an agent model refers to the way information flows between the organization and its environment, and additionally the influence of the information on the organization, using a software agent.
- The presence of authority's model - the participation of agents as the authorities in a decision making process relied on two features: modularity and decentralization.
- Organizational norms and culture model – an agent's behavior depends on the organization's historical factors which are contained in the organization's norms and culture,
- Motivating model – the human factor can be subjected to various influences which in the case of the use of agent-based solutions come down to a certain decision imperative of an agent.

There are different functionalities of knowledge management in such a kind of agent supported knowledge-based organization, e.g. in business context, health care context [29], etc. In the context of health care, multi-agent software (MAS) may play an important role in effectuating the knowledge-based view of the e-health organization by enhancing the capability to manage the knowledge it possesses [30] [31]. There is the method of evaluating MAS in e-health knowledge management system. The model of multi-agent knowledge management system is based on [32]:

- knowledge creation about the user,
- knowledge sharing of the presented problem,
- contextual knowledge about the course of the conversation during knowledge distribution,
- knowledge application in the organization.

There is a diversity of areas in medical industry and health care systems that could benefit from systems based on agent technology (especially MAS) [33] [34]: 1) systems diagnosing diseases, 2) systems that recommend treatment, 3) patient history examination systems, 4) the support of palliative care units.

## III. Program Agents' Societies And Problems With Their Implementation

One of the metaphors of embracing agent technologies is to look for purposeful solutions in terms of software agent society [35]. Agent societies used in knowledge-based organizations operate in an environment of ubiquitous communication and are usually aimed at supporting the organization by supporting the processing and distribution of information and knowledge using semantic knowledge representation mechanisms. In the process of developing agent solutions supporting the improvement of business processes in knowledge-based organizations a variety of approaches, depending on their architecture and construction, are used. The use of semantic knowledge representation mechanisms requires that, at the design stage of the system, methods for acquiring and processing knowledge necessary for the operation of agent solutions are set out.

Conducted in 2013 qualitative research have been realized in the form of a series of in-depth interviews with companies which are the creators of agent solutions on the Polish market [4][5]. A dozen of companies were invited for the study but only 5 of them decided to participate.

Studies have shown that the solutions used by respondents overwhelmingly support the human - computer interaction in the context of their possible use as an element of knowledge management systems, and thus can be considered in the context of the interface agents with their own codified knowledge base, associated with organizations' information systems and actively participating in the ongoing business processes. As part of the study different manufacturers' approach towards agent solutions supporting the improvement of business processes in organizations based on knowledge have been analyzed and compared. Among the solutions offered to the market in the use of agent technologies in the sphere of supporting business processes in organizations managed by knowledge, the vast majority are so-called "virtual advisors" showing, in accordance with the adopted typology, lowest level of socialization [30]. One of the important issues raised in the context of the study was to identify the workshop used by vendors of agent solutions on the stage of their development. In this context, the focus was mainly concentrated on methodologies of creating agent solutions. Methodologies used in the construction of agent systems, what was highlighted by the creators of solutions examined, are focused mainly on their architecture, but only to a small extent allow the modeling of system knowledge. There are no proven solutions that are using a methodical approach to the modeling of knowledge representation semantic mechanisms to the needs of agent structures. Respondents confirmed the heterogeneity of methodologies appropriate to the solutions they use, the design of which requires, on one hand the reference to the issues of software development methods, and on the second engineering theory of knowledge, which is required in the context of agents' knowledge base modeling. In addition to the problems of methodology, the respondents pointed to the need for finding methods to assess the impact of the solutions they create on the organization and its environment operation.

Despite differences in the details of the used methodologies design, or the tools used, companies generally agree on the stages of agent-based solutions implementation. In simple terms it can be assumed that this process is based on four main processes. The first one is to analyze and gather information from a user under which the knowledge an agent will have will be worded. Since the information comes from a variety of sources such as individual interviews, search for paper and electronic documents related to the user, and acquired knowledge is not always codified in clear and understandable manner, it is necessary to systematize this information. The next step is to design a model of this knowledge, systematization and arrangement in a certain and clear structure for the agent which will enable it to recognize the thread and giving the user the right answers. The next step is to implement the agent system. The last stage of testing the system is usually the user's input and feedback concerning its functioning. Feedback information from the customer allow us to evaluate whether the knowledge, which was introduced to an agent is correct, if something has been omitted, supplemented, whether the range or essence of knowledge was in some way changed. Then this knowledge should be updated. However, despite applying own methodologies the companies base on proven tools based on UML modeling structures to facilitate knowledge sets, allowing for structuring knowledge to describe some of the relations in the knowledge base, the design of systems architecture of agent.

Virtually all respondents covered by the conducted survey declared that the process of developing agent solutions in their company is more or less consistent with the outlined above methodological scheme. However, even if any particular methodology was not specified, it does not mean taking chaotic and random actions, but consistent common-sense approach, using necessary resources. Most differences in the used approaches are declared in the process of knowledge acquisition.

After implementation of the solution manufacturers attach great importance to feedback from the customer, confirming the correctness of topicality and completeness of the knowledge that was introduced to agent.

With the increasing number of implemented agent systems and their complexity merits, there is a natural need to systematize the knowledge concerning the activities undertaken and their standardization. The use of established methodologies in the implementation of solutions is not disputed by principle, but the very process of implementing the chosen methodology into force is not carried without complications. Among the fundamental problems that arise in the implementation of methodologies indicated by the respondents two groups were dominating:

The first group of problems of objective nature related to the need of increasing the workload associated with the introduction and updating adopted methodological solutions and methods and tools for their implementation. Even recognized methodologies, including a set of procedures, are subject to constant alteration forced by changing organizational and economic conditions resulting in assembly and aggregating new knowledge. According to the respondents implementation of the new system, as well as an agent system, often creates necessity to abandon the previously developed business process execution mode. According to the respondents, implementation and then maintaining particular solution require additional labor, which generally is not enthusiastically accepted by both the contractors of project tasks and team management

The second group of difficulties are the unpredictable problems subjectively linked to specific persons associated with the solutions' life cycle. Indicated by the respondents fear of change, loss of autonomy, wont to existing, not always fully formalized mode, the impression of redundancy of seemingly unnecessary documents required for the execution of implementation makes it difficult to maintain and care for the implemented solution.

A very important aspect in the context of the use of approved methodologies for projects involving complex, partly autonomous structure of software agents society, is their specificity and complexity that result in multiplication of methodological problems encountered in the implementation of individual solutions. At the same time manufacturers of commercially available software emphasized the lack of experience while working on more complex systems. None of the respondents did not declare directly of the implementation of solutions involving cooperation of more agents within a specific software agents' society.

Depicted here problems caused, that the authors' study have been directed to the aspect of modeling agents' society in the context of the methodological design aspect of such solutions and to develop a method to assess the impact of software agents on the environment in the context of the human - computer interaction. For this purpose, it became reasonable to conduct a comprehensive analysis of the available methodologies and propose the best possible methodology allowing for the implementation of software agents' society. The specificity, diversity and complexity of software agents' society designed to stimulate organizational processes in an organization managed by knowledge, forces the establishment of a transparent and universal model. Options include the use of ready methodologies developed by the companies with years of experience in developing agent solutions, or to create a proprietary methodology based on own experience, supplemented with elements taken from corporate methodologies. To conclude this aspect of research, three main aspects should be noted, which according to the authors should support the defined methodology, supporting the implementation of the agent system in organizations. First is the focus on supporting the business processes modeling in organizations. Its purpose is to better understand business conditions for which the organization's agent system is created by the designers and future users of the solution. Second aspect is the agents society architecture modeling which will be aiding this business process. Targeting organizations for the classic methods of semiformal defining the architecture of the system in the form of UML causes that in case of modeling agents' society it should also be used. The final element is the modeling of knowledge that must be considered in the context of the business process involving people and software agents. Methodology applied here should support the codification of knowledge in a way that allows its understanding and application by both: the users and agents. This aspect is crucial in the context of business process integration and knowledge management systems, where the task of developed methodology should be an indication of the use of codified knowledge in the framework of business processes in the organization.

## IV. Methodological Aspects of the Software Agents' Societies Designing

Conducted interviews indicated that currently created agent-based solutions offered by the companies relate to individual agent solutions. One of these aspects, that caused the lack of implementation in the area of multi-agent systems, was to identify the problems with the integration of knowledge abstracted within the agent system. Therefore, one of the research aspects was to develop proposals for taking up modeling methodology of software agents' society in the context of highest level of agents' socialization, which will focus on the aspect of system's semantic knowledge codification methods and business processes organization. In order to develop such methodology a number of multi-agent platforms [6] and methodologies [7] available in the literature and methods of agent design solutions [11] were tested. From the modern organizations' point of view, where organizational knowledge is a key aspect of system design, an indication of how multi-agent modeling environment with a strong focus on knowledge of the system becomes necessary, which the methodologies presented here do not show. None of analyzed methodologies [7] fully define organization's ontology, social relationships. Only three do this in limited way where designer is usually able to define only concepts of agent ontology. Also the mechanism of agent's interaction with the environment is not well realized by analyzed methodologies. Comparative analysis, at the stage of the assumptions related the to design of multi-agent system indicated, that the agent society, through the used methodology, will have limited functionality. The result of the study was to offer the methodology shown in chapter [8].

This methodology was created as a combination of software agents' society design good practice, ontologies design methods and BPMN notation used for the purpose of analyzing the requirements for the created agents' society in the context of the organization it's supposed to support.

The proposed methodology consists of 8 stages, which include:

1. Analysis and development of business process
   - 1.1. Specification of organizations involved in the process and the posts performing the tasks.
   - 1.2. Determination of relationships inside the organization. At this stage the relationship is defined within the organizational structure that supports the system. In case of an organization it is a structure linking the different departments and the process' participants positions.
   - 1.3. Defining the rules of starting and ending the process.
   - 1.4. Diagnosing the business process' tasks.
   - 1.5. Diagnosing the business process' events.
   - 1.6. Defining the conditions governing decision gates.
   - 1.7. Determining the extent of agent's support of a specific task (realization of tasks, assisting the task, none)

2. Resources' identification of in agents' society setting
   - 2.1 Identification of inputs and outputs of the main task
   - 2.2 Identification of resources in the form of services or external data

3. Analysis of the roles and responsibilities of agents' society
   - 3.1 Defining the tasks carried out in the agent society
   - 3.2 Defining the roles of agents in the system
   - 3.3 Diagnosing emergency situations (events)
   - 3.4 Defining the inputs and outputs based on events

4. Determining the hierarchical structure of the relationship inside the organization

4.1 Reference of the organizational structure with the main tasks carried out by agents
4.2 Determination of organization's internal relationships within the agent society

5. Determination of the extent of agent societies' knowledge
   5.1 Identification of knowledge range of agent society
   5.2 Identification of the resources provided by agent societies

6. Preliminary definition of agents' internal architecture
   6.1 Determining agent's classes
   6.2 Assigning agents' classes to roles
   6.3 Assigning agents' classes to resources

7. Essential definition of the agents' internal architecture
   7.1 Agent knowledge specification
   7.2 Defining agent's behavior

8. Designing the interaction between agents

The proposed approach for agents' society modeling is considered in terms of the heterogeneous construction agents' societies and determines the combination of best practices for agent solutions modeling to support business processes within the organization's information systems. In particular, this methodology is dedicated for knowledge-based organizations through its focus on modeling of the organization's knowledge using semantic mechanisms of representation.

The proposed methodology has been developed upon the experience regarding the developed prototype of agent-based solutions supporting the operation of the organization and developed in the context of building solutions supporting the interaction of users within the business processes in which they participate [12].

Depicted in the [12] prototype of agents' society was used to evaluate elements of the methodology and pointed to possible applications of agents' society to assist the interaction processes between users.

For the purpose of prototype solution realization BPMN process models were paid and extending the BPMN notation was proposed by a number of new artifacts used in the agents' society modeling process, based on the methodology presented previously. Table 1 present the main artifacts.

As a result, it became possible to develop elements of a modeler supporting the codification of knowledge about processes which involve users in accordance with BPMN notation and allowing to define the knowledge resources of the organization. Figure 1 presents such example.

Elements of the proposed methodology also served to develop a tool that aids software agents' usability analysis in the process of sharing knowledge in the organization's environment. The approach proposed herein offers the following advantages:

- Extending currently used standards for describing business processes to include sources of knowledge that supports the performance of users' tasks (in the context of the process, place and time).
- Enabling direct integration of organisational knowledge within any business processes taking place in an organisation within the scope of the process in which this knowledge should be used and the task that it supports.
- Automating processes of assessing the functioning of knowledge management systems in terms of their usefulness in supporting business processes.
- Generating new organisational knowledge at the interface of business processes and knowledge management.
- Using semantic mechanisms for knowledge description for easier integration of possessed knowledge with internal organisational knowledge.
- Independent operation from used IT solutions and enabling integration of any knowledge management systems and a process-oriented solution.

In order for agent systems to support business processes, it is necessary to develop tools facilitating the evaluation of an agent's usability in the process of performing users' tasks.

TABLE 1.
PROPOSED ARTIFACTS

| | |
|---|---|
| 👤 | Interface agent - designates possible applications of an interface agent as an element supporting the performance of a specific task by the user. It allows the user to go into the mode of evaluation of an agent's usefulness and use it to support the user's actions. |
| 👥 | A multi-agent system - designates a possible application of a multi-agent system to substitute the user or prepare a specific knowledge resource that will be necessary in the decision making process. |
| 🗄 | Knowledge resource - designates a specific knowledge resource in knowledge portal or the Internet that can be indicated to the user. It can be a document, web service, URL identifier. |
| 🧍 | Consultant - designates a specific person who has the relevant knowledge about the performance of this task. |

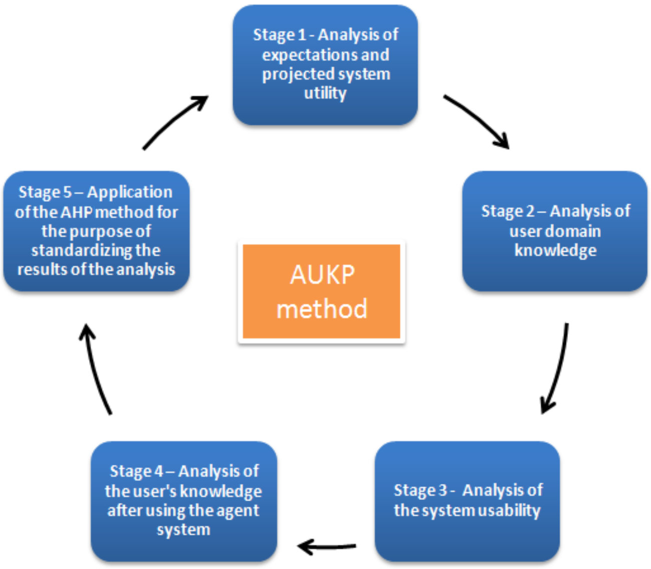
## V. Software Agents' Usability

As part of the conducted qualitative research it was necessary to determine how software agents' societies improve business processes in organizations based on knowledge. On the basis of the study, creators of agent solutions in Poland were diagnosed and a test method allowing for evaluation of the usefulness of agents in the context of human - computer interaction was proposed - AUKP - Agent Usefulness and Knowledge Propagation analysis method (figure 2).



Stage 1 - Analysis of expectations and projected system utility
Stage 2 – Analysis of user domain knowledge
Stage 3 - Analysis of the system usability
Stage 4 – Analysis of the user's knowledge after using the agent system
Stage 5 – Application of the AHP method for the purpose of standardizing the results of the analysis
AUKP method

Figure 2. Agent Usefulness and Knowledge Propagation analysis method

During the tests of usability of software agents implemented in organizations, the analysis was conducted in the following stages [15]:

- Analysis of expectations and projected system usability. Aim: determine the expectations of the users in relation to the agent system and its functionality. Proposed method: research survey analyzing the significance of the basic indicators of the system usability.
- Analysis of user domain knowledge. Aim: determine the user's base knowledge in terms of the domain aided by the agent system. Proposed method: survey of knowledge which the user obtains as a result of working with the agent system.
- Analysis of the system usability. Aim: determine the values of the specific indicators of the assessment of the system usability for the user and the organization. Proposed method: direct analysis of the agent system's operation.
- Analysis of the user's knowledge after using the agent system. Aim: to determine the user's knowledge in the field supported by the agent system after using the system. Proposed method: survey of knowledge obtained by the user as a result of working with the agent system (as in stage 1).
- Application of the AHP method for standardizing the results of the analysis. Aim: standardization of the results with regard to users' expectations for a comparative analysis of agent systems. Proposed method: application of the AHP method based on the results obtained in stage 1 and stage 3.

First, an analysis of previously conducted research on the human - computer interaction in the context of agent usability testing environments was performed. These studies have shown objectivity of examining the usability in terms of the agents' impact on the users. The assumptions concerning the developed method and the results of the conducted experiments are discussed in more detail in the works [13][14][15]. In these studies researchers assumed, that in accordance with the concept of utility, it is necessary to refer to the analysis of effectiveness, efficiency, satisfaction and propagation/dissemination of agent system's knowledge. For this purpose, the process evaluation model for specified factors within the HCI theory was developed and 102 research experiments were carried out, which aim was to evaluate the operation of three software agents. The results confirmed, that in the group of users and agents can be indicated, that the agent-based solutions contribute to the improvement of business processes in which they participate by improving customer satisfaction and propagation/dissemination of knowledge among users regarding the organization and the processes, in which the organization and the business process recipient participate.

The final results was given: analysis of the general level of satisfaction shows that for users of software agents that were used for experiment satisfactory level was above 0,6; also all agents reached knowledge propagation indicator above 0,75.

Satisfaction and knowledge dissemination assume values from 0 to 1, where 1 is the highest indicator of satisfaction and the highest level of knowledge propagation/dissemination.

Next two parameters (main effectiveness and partial effectiveness) assume values from -1 to1. Values above 0 mean that the system is effective, whereas values below 0 – lack of the agent's effectiveness. All agents gained measures of effectiveness (main) >0 and effectiveness (partial) >0, which can be interpreted as the possibility of implementation of indicated main goals by users and shows that the answers generated by an agent were correct.

The last parameter indicates the number of agent objectives performed per a minute. The conducted research has also showed that agent C (with the result of 3.5 of an objective per minute) achieved the highest performance compared to agent B (3 objective per minute) and agent A (2.5 goal per minute).

All aggregate results shown here revealed, that in the case where it is possible to identify high efficiency of agents and their productivity, users indicated high levels of satisfaction and knowledge gain. What is characteristic, increased productivity of agents and their effectiveness, influenced the increase of user's satisfaction and the amount of knowledge they acquired.

## VI. Conclusion

As indicated in the article, the theory of modeling the software agents' society is a complex research problem, particularly in the context of their use as a solution supporting the selected type of organization. Developing the assessment methods of the agents' impact on the processes taking place in organizations and supporting their modeling methodologies, required to refer not only to the current state of research in this area, but also to focus on the essence of organizations for the purpose for which they will be developed. The developed methodology, from the organization's point of view, supports the codification of knowledge that is contained herein and contributes to a better understanding of business processes that take place within. Such an approach improves the process of organisational knowledge integration within the modelled society of software agents and allows the relationships of the company's organisational structure to be mapped within a specific society of agents. The next step in the development of this methodology may be extending it by elements of modelling trust and reputation within the agent society being developed.

The proposed assessment method allows for indication whether the influence of agents on the processes that are related to the operation of the organization is visible. The conducted experiments proved that the currently used agent systems in organizations improve ongoing business processes, allow for the improvement of customer satisfaction and help to propagate the knowledge about the organization and its processes. The proposed method, which is based on the assumptions of agents' interaction with users, can be used with any software agents that have an interface ensuring communication with the user. The proposed approach, in accordance with the accepted criterion of usability, indicates validity of an analysis of knowledge propagation and satisfaction indicators, by which the impact of agents on business process participants can be determined, as well as effectiveness and performance indicators, which allow the agent itself to be assessed. The experiment examined the interaction between the human being and computer, but the developed indicators of agents' effectiveness and performance can be also used in the process of interaction between agents in a given society.

## Acknowledgment

The project was financed from the funds of National Science Centre 2011/03/D/HS4/00782.

# 4th Workshop on Information Technologies for Logistics

THE main purpose of the workshop is to provide a forum for researchers and practitioners to present and discuss current issues concerning use of ICT in logistic applications (hardware and software). There will be also an opportunity for hardware integrators, software developers and logistics companies to demonstrate their solutions, as well as achievements, in different logistic systems.

## Topics

The topics of interest include but are not limited to:

- Innovations in information systems supporting logistics and its management (WMS, SCM, TMS, LIS, VMI, CRP, PLM, and others)
- Innovative technologies in warehouse management: RFID, Voice Picking, Image Recognition, Pick Radar, etc.
- Logistics process modeling, including influence of warehouse automatic
- Optimization of logistics processes:
    - optimal vehicle routing and management, boundary conditions
    - optimal picking routing (global optimization, fast search, collision prediction and prevention)
    - shared mobility systems
    - day-to-day dynamic traffic assignment models
    - effective methods of picking (multi picking, batch picking ect.)
    - relationships between picking efficiency and products decomposition in warehouse area
- Environmental protection (for example carbon-aware transportation)
- Artificial intelligence systems and decision support systems in logistics
- BI, data mining and process mining in logistics
- Quality management algorithms and methods
- Material Flow Theory and applications

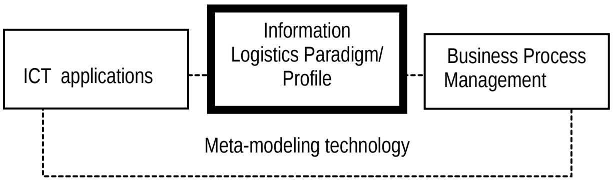
*Abstract*—**This paper presents a paradigm-based approach to information logistics. The approach deals with extracting concepts specific to information logistics in categories typical to paradigms. The resulting description should be easily connected to complementary components which are based on other paradigms, e.g. business process management and information systems development. Empirical part aims at checking and enhancing features typical to information logistics. It is conducted with action research of applying information logistics paradigm in coordination of Erasmus+ program.**

## I. Introduction

INFORMATION logistics has been a topic of research for about three decades with more than hundred contributions nowadays [1], [2]. It has several definitions with focus on a variety of issues in different contexts of use. A common motive for information logistics is transfer of the right information to the right place in the right time. The main active research directions are user-demand information supply [3], [4], efficiency of information flow [5], [6], cross-functional supply of analytical information [7], [8] and process improvement via information flow [9]. About two dozens of organizations offer their information logistics products for real-life solutions. One can observe that information logistics in real-life applications cannot be separated neither from defining chains of information processing and delivery nor from automation of information processing by software systems. Many information logistics products are based on Information and Communication Technologies (ICT) and support Business Process Management (BPM). Therefore, there is a need to explore relationship between information logistics, business process management and software engineering.

The goal of this paper is to analyze information logistics from the perspective of paradigm theory. It deals with extraction of concepts specific to information logistics and connection of resulting descriptions to components of solution which use other paradigms. Fig. 1 presents a schema of paradigm-based approach to integrating information logistics to other components using meta-modeling technology.

This approach is motivated by the following reasons. First, information logistics, business process management and software systems are complementary components of real-life solutions. They focus on different aspects and can be captured more precisely in terms of paradigms. The notion of paradigm is related to extraction of basic concepts specific to a given area and it allows to avoid uncontrolled overlapping with basic concepts from other paradigms. Second, the use of paradigm-based approach makes a difference in viewing information logistics. It makes a shift from entire information logistics solution (which informally defines enterprise processes and uses information systems) to a kind of specific component which can be connected to components which are based on other paradigms. The benefit of such approach is in solving each class of problems in the most effective technology and then connecting them in complete solution of real-life problems. Third, information logistics paradigm constitutes foundations for formalization of the paradigm with the meta-modeling technology provided by Object Management Group (OMG), especially in terms of UML profiles. OMG Unified Modeling Language (UML) [10] defines object-oriented software development perspective and OMG Business Process Model and Notation (BPMN) [11] defines business process management perspective. OMG offers UML profiles as extension mechanism and defines a profile diagram for the purpose of defining new UML profiles [12]. With use of this technology, formalisms which define all these complementary paradigms are expressed with the same meta-meta-models, which provides a strong common ground for integration and interoperability. This research shows that information technologies can offer to logistics not only methods and environments for computations or methods of information systems engineering, but also benefits from applying advanced meta-modeling technologies.



ICT applications
Information Logistics Paradigm/ Profile
Business Process Management
Meta-modeling technology

Fig. 1 A schema of integration of information logistics profile with other components of solution with use of meta-modeling technology

This paper is structured as follows. Section 2 presents and exploits paradigm-based approach. It explains the role of paradigms in computer science adhering to Kuhn's paradigms in philosophy of science, attempts to apply paradigms in computer science as well as multi-paradigm modeling approach and defines categories typical to paradigm description (paradigm template). Then, it describes analysis of information logistics definitions in literature made in order to capture core concepts and issues in information logistics. Section 3 contains description of action research in which features specific to information logistics are checked and en-

978-83-60810-66-8/$25.00©2015, IEEE

hanced when solving real-life problems in the area of coordination of Erasmus+ program. Section 4 makes an attempt to describe information logistics paradigm on the basis of both analytical and empirical parts. Section 5 presents conclusions and plans for further work.

## II. Information Logistics as a Paradigm

### A. Fundamentals of Paradigms

The popularity of the term paradigm, which has its roots in ancient Greak παραδειγμα meaning `pattern, examplar, example`, has been a contribution of a philosopher of science Thomas Kuhn, who explained incommensurability of theories in science by adhering to their diversified fundamentals. A paradigm in mature science stands for a set of fixed key theories, scientific language, values and metaphysical assumptions as well as procedures and instrumentation needed to solve practical problems [13].

The notion of paradigm corresponding to software has first appeared as paradigms of programming [14] with decreasing scope of paradigm as a side effect of moving the term of paradigm from science to technology. Then, it was elaborated in context of several reuse approaches to software development including design patterns, components, software architectures and frameworks [15]. Another use of this term can be found in multi-paradigm modeling approach [16], [17] which aims at dealing with heterogeneous solutions. The need for effective solutions has made a difference in viewing paradigm. It has replaced initial incommensurability of theories in science by the request for pragmatic integration of technologies which are based on different paradigms.

A paradigm-based approach is based on the following assumptions. Different classes of problems have effective solutions in technologies which use different paradigms. In order to develop software applications which deliver business value to customers there is a need to integrate technologies which are based on different paradigms.

When comparing paradigm-based approach with typical systems development the following differences can be identified. Typical development may be easier in simple cases whilst paradigm-based approach may require extra effort on interface definitions and collaboration between components based on different paradigms. On the other hand, solutions made with paradigm-based approach are easier to maintain especially when integral components need to be updated. It can deal more effectively with heterogeneous cases. Additionally, it is easy to connect to newly added components. It can provide more precision with traceability to sources. The challenge is in assessing global features of solutions. As this is a quite new approach, few experience reports from its applications are available.

### B. Questions and Methods

In order to capture information logistics as a paradigm there is a need to define knowledge gathered in this field of study in categories specific to paradigms. Thus, the following questions can be posed for information logistics: What are its values and (metaphysical) assumptions? What are its scientific language and key theories? What is the class of problems that can be solved effectively in this paradigm? What are instrumentation and procedures, i.e. methods and technologies, needed to solve these problems? How to integrate it with technologies which use other paradigms in context of paradigm-based approach?

We assume that information logistics paradigm should be based on its strong connotations to logistics. The intuitive understanding of information logistics is a kind of logistics which is related to information instead of material goods and services.

In order to capture the essentials of information logistics we have searched for common themes in information logistics definitions and notions provided by both researchers and practitioners collected in literature overview [1], [2]. Number of appearance of a given common theme against total number of definitions analyzed is presented in brackets.

Then, we have conducted a cross-analysis of these common themes with themes in logistics management definition provided by the Council of Supply Chain Management Professionals in order to check whether the common themes are strongly related to logistics and thus they have appropriate connotations to logistics.

A related field of study is information management. Therefore, we have compared our approach with the approach presented in Information Management Body of Knowledge.

### C. Common Themes of Information Logistics

Common themes of information logistics include:

- right information (20/33) with more precise specification of what is right information in terms of content or format (8/33), way or channel (3/33), size (1/33), quality (6/33) and requirements, needs or demands (6/33);
- right time (20/33) with adhering to "just in time" philosophy (3/33) or efficiency (5/33);
- right place or location (16/33) with additional distinction to recipient or person (7/33) or target group (3/33);
- information flow (9/33) or information value chains (5/33);
- right cost or optimization of costs (6/33);
- two cases: information distribution and information about logistics of goods and services;
- operational activities (8/33) of gathering (2/33), selecting (2/33), production, receiving, processing, organization, optimization, storage (3/33) and distribution (6/33); focusing on dissemination rather than production and classification;
- managerial activities of planning (2/33), control and implementation (1/33);
- infrastructure in terms of network of suppliers-requestors (1/33) or information logistics infrastructure with information systems support (13/33);
- relationship to other fields (2/33), such as information management, knowledge management, communication management and business networks.

The above classification of themes may be biased in several ways. Definitions and notions may not cover full range of issues addressed by research results or products. The analysis was made on the basis of selection of issues in cited literature overview. There are probably implicit relationships between research results, research bodies statement of notion and information logistics product providers. Therefore, the generalization of the common themes coverage to quantitative coverage of themes in the area of information logistics may be unjustified. However, they reflect quite well essentials and issues in this area.

### *D. Cross-Analysis with Logistics Management*

Council of Supply Chain Management Professionals (CSCMP) provides the following definition of logistics management [18]: "Logistics management is that part of supply chain management that plans, implements, and controls the efficient, effective  forward and reverse flow and storage of goods, services, and related information between the point of origin and the point of consumption in order to meet customers' requirements. Logistics management activities typically include inbound and outbound transportation management, fleet management, warehousing, materials handling, order fulfillment, logistics network design, inventory management, supply/demand planning, and management of third party logistics services providers. To varying degrees, the logistics function also includes sourcing and procurement, production planning and scheduling, packaging and assembly, and customer service. It is involved in all levels of planning and execution-strategic, operational, and tactical. Logistics management is an integrating function which coordinates and optimizes all logistics activities, as well as integrates logistics activities with other functions, including marketing, sales, manufacturing, finance, and information technology."

Table I presents a comparison of the common themes in information logistics with related logistics management themes. It shows that in almost all categories some equivalents can be found although they have different focus. The common themes of information logistics focus on provision and distribution of right information at the right time to the right place. Explosive speed of information available via global ICT applications, the need for gathering crucial business information and chaos of information in organizations are the main motivations for such statements of expected effects. Less attention is paid to the core term of logistics which is supply chain (similar to information flow and information value chain). In fact, logistics definition contains a suggestion that right information, time and place should be placed in a broader perspective of flows which contribute to a more complex enterprise.

For many logistics operations one can find equivalents in information logistics although they have their specifics or smaller importance. Equivalents of transportation are distribution, dissemination, gathering and receiving depending on context. Warehousing corresponds to storage. Logistics network design and fleet management are related to infrastructure management. Supply/demand planning finds its implementation in information flow design. Similar to auxiliary production planning and scheduling may be production, processing and optimization. Thus, on operational level, the analogy is quite strong. Logistics management can broader horizons of information logistics management. Although managerial activities of planning, control, implementation as well as relationships to other fields have been identified in scope of common themes for information logistics, logistics management is involved in all levels of planning and execution, i.e. strategic, operational, and tactical and it covers integrative activities of coordination and optimization of all logistics activities as well as activities in related fields.

TABLE I.
COMPARISON OF COMMON THEMES IN INFORMATION LOGISTICS WITH RELATED LOGISTICS MANAGEMENT THEMES

| COMMON THEMES IN INFORMATION LOGISTICS | LOGISTICS MANAGEMENT THEMES |
|---|---|
| information flow or information value chains | a part of supply chain management |
| managerial activities of planning, control and implementation | actions: plan, implementation and control |
| two cases: information distribution and information about logistics of goods and services | efficient, effective  forward and reverse flow and storage of goods, services, and related information |
| right place (location) with additional distinction to person  or target group | between the point of origin and the point of consumption |
| right information in terms of content or format, way or channel, size, quality or requirements, needs or demands | in order to meet customers' requirements |
| operational activities of gathering, selecting, production, receiving, processing, organization, optimization, storage and distribution; focusing on dissemination rather than production and classification;<br>infrastructure in terms of network of suppliers-requestors or information logistics infrastructure with information systems support | typical activities: inbound and outbound transportation, fleet management, warehousing, materials handling, order fulfillment, logistics network design, inventory management, supply/demand planning, and management of third party logistics services providers |
|  | all levels of planning and execution: strategic, operational, and tactical |
| right cost or optimization of costs; right time with adhering to "just in time" philosophy or efficiency | integrating function which coordinates and optimizes all logistics activities |
| relationship to other fields, such as information management, knowledge management, communication management and business networks. | integrates logistics activities with other functions, including marketing, sales, manufacturing, finance, and information technology. |

### *E. Comparison to Information Management*

One could ask questions: What is the relationship between information logistics and information management? Don't they deal with the same problems? (It seems similar to questions: What is the relationship between logistics and resource management? Don't they deal with the same problems?) In our opinion, information logistics and information management represent different traditions of research which address overlapping problems and deliver overlapping results. Additionally, both terms are broad and abstract, which makes difficulty in comparisons. One can expect that internal inconsistencies in both fields are encountered. In this situation, we compare only proposed paradigm-based approach to information logistics with a concrete representation of information management  in Information Management Body of Knowledge (IMBOK) [19].

IMBOK addresses problem of "huge complexities in the territory where information technology, business and society meet". It divides information management to six knowledge areas: information technology, information systems, business processes, business information, business benefits and business strategy. It describes four types of information management processes:

- projects related to information systems development with use of information technology,
- business change which makes changes in business process and business information areas with information systems,
- business operations which lead to accomplish business benefits,
- performance management where business strategy and business benefits meet.

Table II presents a comparison of paradigm-based approach to information logistics with IMBOK. Although the terms information logistics and information management seem to have a similar meaning, both have a broad scope and both include several approaches. The comparison which was made, shows that the differences might be on the level of fundamental assumptions, such as goals, focus, scope and values. (Information logistics solutions which use a more holistic approach could have more similarities to information management.) In fact, this is an example of incommensurability of theories in science, as Thomas Kuhn would call it. To continue his thought: established scientific paradigms, committed groups of researchers and consistent research results are the signs of mature science.

One of the common themes includes information management on the list of fields to which information logistics has relationships. This relationship may take form of appropriate application of relevant theories and techniques in concrete cases of information logistics solutions.

TABLE II.
COMPARISON OF PARADIGM-BASED APPROACH TO INFORMATION LOGISTICS WITH IMBOK

| PARADIGM-BASED APPROACH TO INFORMATION LOGISTICS | IMBOK |
|---|---|
| Information logistics profile as a component to be connected with others | Framework to cover complexities on the edge of IT, business and society |
| Focus on extracting and formalizing specific features of information logistics | Focus on a big picture, i.e. "everything that has anything to do with information in business" |

## III. ACTION RESEARCH BASED ON COORDINATION IN ERASMUS+ PROGRAM

### *A. Motivation*

Information Logistics paradigm seems to be helpful in coordination of Erasmus+ program [20]. There is a need to define rules and procedures, but business process perspective is not sufficient for capturing all aspects of the reality. Many parties are involved with their specific information needs. Changes are made outside of control of coordinators. There are several regulations of different kinds which need to be satisfied. Long documents which sometimes require interpretations and informal rules applied in order to unify action in similar exceptional cases cause difficulty to clearly understand the rules for those who just occasionally are involved in the program. The perspective which suggests to pose questions: What is the right information? What is the right time? What is the right channel to get to a given target? is helpful in systematic elaboration of the right solution in this complicated situation.

### *B. Action Research Description*

The goal of the action research is to check common themes of information logistics in a practical case and to enhance them by extracting new features specific to information logistics. The objective of the actions is to improve information logistics processes during coordination of Erasmus+ program in terms of analysis and explicit definition of the needs for information transfers, their content, channels and feedback. It should lead to a higher level of satisfaction of the parties involved in the processes. As the author fulfills duties of Faculty Erasmus+ coordinator, practical benefits resulting from process improvement this area are expected.

It is expected that the common themes of information logistics drive attention to several useful features which can be analyzed for process improvement. After validation and enhancements, they should be included in paradigm description. Managerial tasks should help in building framework for management. Operational activities are expected to help in extracting stereotypes of activities. Important issues of analysis are how to develop infrastructure and how to optimize effort related to its construction.

In the next section, an attempt to capture complexity of actions with traditional techniques and some limitations of their application are presented. In the further part, information logistics issues are analyzed. The following issues are discussed in details:

- goals of information transfer,
- management of group dynamics,
- flexibility of processes depending on diversity and changes in areas controlled by external participants,
- promotion via different channels,
- the right information at the right time and in the right place.

The descriptions are made according to the following template:

- description of the issue under consideration,
- comparison to business process management (BPM) perspective, especially to elements of BPMN,
- examples from the area of actions.

The comparison to BPM is made because business process and chain of information flow are similar concepts. Furthermore, analysis of relationships between information transfer and business process management is important from the perspective of making relationships between complementary paradigms which must work together in order to deliver solution.

### C. An Attempt to Capture Complexity of Actions

In order to deal with complexity of actions related to coordination and management of Erasmus+ program, several techniques available for project managers or business analysts can be applied with quite satisfactory results, e.g. stakeholder analysis, document analysis, organization modeling, process modeling, checklists, regulations and checking their compliance with framework regulations, metrics and key performance indicators. However, due to large diversity of cases, large dynamics and coordinative specifics, the application of these methods reveal some limitations. They are useful at higher level of abstraction, but it seems to be impossible to cover and trace all details of changes in a reasonable time. The resulting need for flexibility reduces the applicability of methods which tend to unification and formalization.

Fig. 2 presents stakeholders who require coordination during the Erasmus+ exchange actions. Erasmus+ agencies at European and national level as well as university authorities provide a variety of rules and regulations and then require documents and several kinds of reports. They influence mainly strategy and tactical levels. Other stakeholders are interact at operational level. The diversity of rules at partner university (including national regulations, university processes and on-line systems) has impact on all processes of exchange. It is reasonable that the work on information logistics is based on the results of stakeholder analysis.

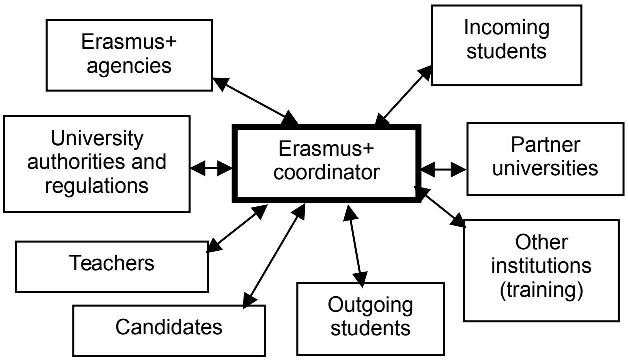

Fig. 2 Stakeholders who require coordination during the Erasmus+ exchange actions

High-level business process descriptions are useful for organizing and ordering the actions. However, due to coordinative specifics of these actions, low level business process descriptions does not reduce much complexity, i.e. it does not reduce neither the number of participants of a specific interaction nor helps in defining a single sequential course of actions. Furthermore, it seems that business process management paradigm has been invented to solve a slightly different problems than these appearing in coordinative actions.

### D. Goals of Information Transfer

*Description:* Goals of information transfers need to be defined because they are not default and they can be related to several actions with different effects. The goals organize related information transfers and they can be divided in sub-goals.

*Comparison to BPM:* A given business event usually starts business process which is strictly defined and formats of documents are fixed. Business goals and objectives are defined at higher level of business policy and strategy or they result from business process decomposition. Information transfers may be more flexible and thus more creativity can be involved in action. The goal acts as a frame of reference.

*Example:* Let's assume that the `goal` is to inform students about possibility to take part in Erasmus+ program, about the rules and recruitment procedure. It can be implemented via several actions which can be stated as `sub-goals` such as:

- provide short information via posters,
- organize a meeting,
- provide detailed information on the website,
- send e-mails to the students who expressed their interest,
- send short message via existing information systems.

Each of the sub-goals can be decomposed to several actions and information transfers which need proper management.

### E. Management of Group Dynamics

*Description:* Information logistics defines target in terms of both individuals and groups. Formation of groups and sub-groups allows for increasing efficiency comparing to individual treatments. It is worth to mention that these groups and sub-groups might be very dynamic. Therefore, group management and customization of messages is necessary. The benefits are visible when rapid reaction on changes is possible and when right information goes to the right target group. This action can be classified as an infrastructure management action.

*Comparison to BPM:* Participants and their responsibilities in business process can be specified in terms of swimlanes. BPMN allows to specification of multi-instance pools on conversation diagram, multi-instance participant on choreography diagram and multi-instance task on collaboration diagrams. However, no support for modeling dynamic change of participant's role is provided, i.e. phenomena that the same physical participant becomes a participant on a different pool.

*Example:* Let's consider a group of students interested in Erasmus+ exchange. Some of them can belong to a sub-group of students interested in bilateral agreements related to mobility. Another sub-group may be interested in offers of training. New students can be added to these groups as well as some students might want to withdraw. Another group of students are candidates for exchange, who can be divided with recruitment decisions for these nominated and those who are not. The sub-group of nominated students can be further divided for a sub-group of these who fulfill all requirements of application procedure and get accepted on one hand and a sub-group of those who do not achieve it on the other hand. All these changes happen dynamically in process and they cannot be predicted from the start.

### *F. Flexibility of Processes Depending on Diversity and Changes in Areas Controlled by External Participants*

*Description:* The difficulty in defining fixed processes with strictly defined information transfers might be caused by dependence on external participants who act according to the diversity of processes and they can make changes without notification. Thus, goals can be achieved via flexibility of action together with active processes of information acquisition.

*Comparison to BPM:* Business processes are usually fixed with limited number of routes connected by appropriate gateways. It is assumed that external data are inserted by participants within the defined processes. The difference in information logistics approach is in the need to customize the process and the content of information transfers to the requirements and specifics of external participants.

*Example:* The processes of sending nominations for exchange students and rules of application procedures are good examples of the diversity. Most universities accept nominations of exchange students by e-mail, but there are some exceptions, e.g. nominations via their on-line system or application by students themselves first with confirmation by coordinators later on. The number of combinations of online systems and kinds of required documents in paper in a variety of formats and ways of delivery is really large. Furthermore, these actions are spread over time adhering to different schedules and they are performed for a large numbers of students. These circumstances cause that they are really difficult to manage without systematic information logistics methods.

### *G. Promotion via Different Channels*

*Description:* Information logistics may require promotion management in order to reach target group. It needs to be done via different channels and insights from marketing studies are useful in order to make it effectively.

*Comparison to BPM:* This issue is specific to marketing and it is not present in BPM.

*Example:* Typical promotion is made in order to inform students about Erasmus+ program. In section III.D several sub-goals related to different channels were described. It is worth to mention that is should be a consistent campaign with use of creative methods as well as traditional ones.

### *H. The Right Information at the Right Time and in the Right Place*

*Description:* This statement could be a motto for information logistics as it covers the most popular common themes. It is good to understand that these are main dimensions of each information transfer and they should be assured all together.

*Comparison to BPM*: BPMN contains element called `data object` which represents information flowing through the business process. Timing and participants are described on collaboration diagram in context of the business process. The difference is in focus indicated by the word `right`, i.e. in information logistics one should analyze the needs for the right information at the right time and in the right place from the perspective of participant rather than optimization of request processing.

*Example:* In context of large amounts of rules and regulations the idea to provide the right information at the right time really promises to save participants time, increase confidence of action, and thus increase their satisfaction. Apart from general orientation, exchange students have different needs for detailed information on several stages of preparation to exchange. Before recruitment they need information about the rules and deadlines of recruitment. Then, they need details of other stages: application, actions after acceptance, actions during their stay and actions at departure. It is easier to prepare just one presentation for all, but the perspective of information logistics suggests that there should be separate information packages adhering to the paradigm of the right information at the right time to the right participants.

### *I. Discussion*

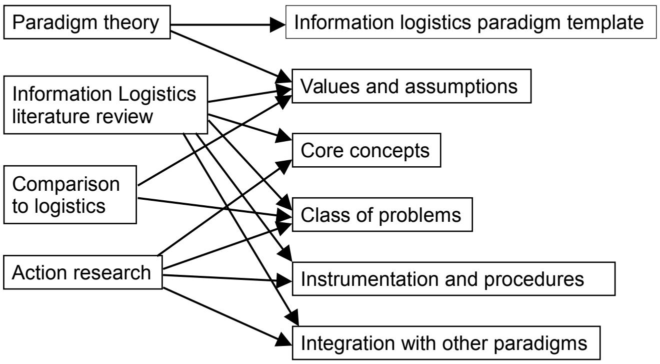
This action research was conceptually inspirational. It allowed to see the reality of Erasmus+ program coordination in the new perspective of information logistics. The connotations to logistics, transfers of right packages of information to right target just in time and the notion of infrastructure activate imagination to work on innovations in the coordination processes. Analysis according to the common themes in information logistics has driven attention to the aspects which were not analyzed in detail before and allowed to see them more clearly. The dimensions of the right information transfers, details of group dynamics and more clear understanding of changes controlled by external participants with related need for flexibility of processes should be taken into consideration when making changes in the process together with traditional techniques of business analysis and project management. To conclude, this action research (from the perspective of process improvement) has provided inspiration, useful terminology and solid bases for making decisions about improvements.

From the perspective of research on information logistics, it has appeared that the common themes are at very different level of abstraction. Some of them are very concrete and they can be transformed to an attribute of information transfer, e.g. content of information transfer. On the contrary others are extremely general without indication on operational action, e.g. relationship to other fields such as information management, knowledge management, communication management and business networks. These common themes which are concrete have led to more detailed results in analysis. Those more general require an extra effort to make them work. Regarding the enhancement to common themes, the examples of issues are hierarchy of goals of information transfers, management of group dynamics, and flexibility of processes depending on diversity. The question arise whether they are typical to several information logistics problems or they are specific just to the domain of this action research.

It seems that the common theme of `information flow or information value chain` is a good proposition for a common ground between information logistics and business process management. Actions related to sequences of information flows can be described by business processes. Information transfer details, such as channel, demands, content, time, size and quality constraints, can be provided by information logistics perspective. This action research has confirmed that business process management perspective is not sufficient to cover all aspects specific to information logistics. The issue of `the right information at the right time and in the right place` (III.H) shows that these approaches can be complementary. The goals of information transfers (III.D) sometimes correspond to business process but sometimes to a more general concepts in business strategy. Flexibility of processes and their changes (III.F) might be represented in their description, however this activity is profitable only when the cost of process update is lower than the cost of acquiring updated information when it is needed. The changes in assignments of individuals to group and dynamic change of roles (III.E) seem to be in opposition of business process fundamentals of having clearly defined participants of interaction. Promotion via different channels (III.G) is an example of issue which is outside of area of business process management. Therefore, this action research has revealed several shades of relationship between information logistics and business process management.

## IV. Towards Information Logistics Paradigm

The following attempt to define information logistics paradigm is based on both analytical results and action research insights with the categories of paradigms identified on the bases of paradigms in philosophy of science adjusted to technological context. Fig. 3 shows the contribution of the parts of presented research for the components of information logistics paradigm description.



Paradigm theory
Information Logistics literature review
Comparison to logistics
Action research
Information logistics paradigm template
Values and assumptions
Core concepts
Class of problems
Instrumentation and procedures
Integration with other paradigms

Fig. 3 Relationship between the parts of research and the components of paradigm template

### A. Values and Assumptions

Values come from two kinds of sources. The first one is paradigm-based approach with its tendency to define typical solutions in terms of paradigms and allow for integration of different paradigms for real-life solutions. The second source is the area of information logistics which has identified several concepts and issues related to information logistics. In the diversity of the field, the value of strong connotations to logistics acts a point of reference when making decisions.

### B. Core Concepts

Mature paradigms have their scientific language and key theories. The first step to define them for Information Logistics is a common language expressed as core concepts presented in Fig. 4. It details concepts related to information transfer and envisages the need for further elaboration with two packages of Activities and Infrastructure.

### C. Class of Problems

Information logistics can effectively solve problems which appear as information chaos in organizations or during collaboration with other organizations. They usually happen in context of large amounts of information, large numbers of stakeholders with different information needs, changes of information outside of control of those who manage it, needs to access to crucial business information at the right time, needs for flexible and informed customizations to external parties as well as dynamic emergence of new information suppliers, requestors or channels.

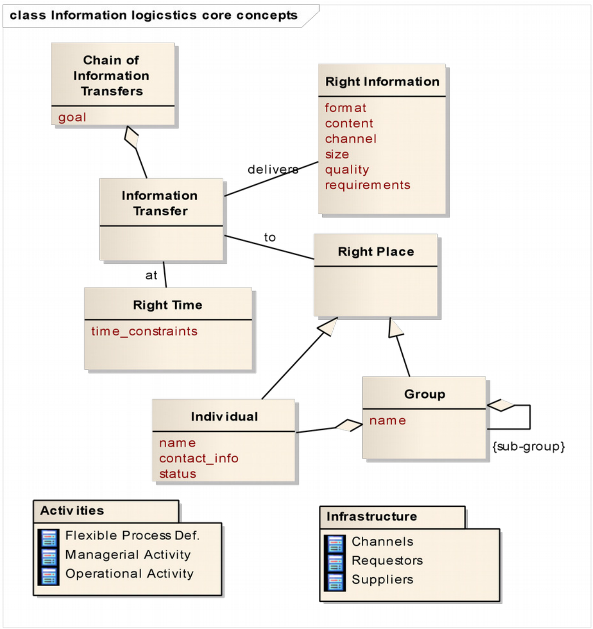


Fig. 4 Core concepts of Information Logistics

### D. Instrumentation and Procedures

Methods and technologies constitute technical equivalents for instrumentation and procedures in scientific context. They include ICT applications as well as techniques for visualization, case management, information transfer optimization, etc. In this approach a few kinds of methods can be distinguished. These can be methods specific to information logistics and methods for integration with other fields of study. Another classification can distinguish between methods for defining, elaborating and improving solution and methods for working with solution.

### E. Integration with Other Paradigms

The main connection point needs to be defined to business process management. The chains of information transfers are complementary to operational activities related with information acquisition and processing in context of circumstances which can be defined as stages of processing. The second connection point should direct to effective ICT systems which support users in performing their tasks. Other connection points can be made to results from related fields of study, such as marketing studies, information management, knowledge management, communication management and business networks. They address connection points related to solution. Other connection points can be made to techniques for elaborating solution, e.g. in the areas of business analysis and project management.

## V. Conclusions and Further Work

The paradigm-based approach is based on assumption that different classes of problems have effective partial solutions in technologies which use different paradigms and there is a need to integrate technologies which are based on different paradigms when developing real-life solutions. Information logistics can be viewed as a paradigm. This paper has addressed the first task on the way towards information logistics paradigm, which was the extraction of concepts specific to information logistics and the attempt of their description in categories specific to paradigms.

A frame of reference for categories specific to paradigms was elaborated on the basis of paradigms in philosophy of science and contemporary uses of the term of paradigm in computer science. When taking into account a large number of diversified definitions of information logistics in literature, the decision was made to build information logistics paradigm with the value of strong connotations to logistics, i.e. information logistics is a kind of logistics which is related to information instead of material goods and services.

Core concepts were extracted with analysis of common themes of information logistics definitions and notions provided by both researchers and practitioners. The essentials of information logistics appeared to be transfer of the right information at the right time to the right place. Common themes allowed to identify several issues, such as chains of information flow, cost optimization, distinction between two cases: information distribution and information about logistics of goods and services, types of operational activities with focus on dissemination rather than production and classification; managerial activities and infrastructure management, and relationships to other fields of study such as information management, knowledge management, communication management and business networks.

In order to keep compliance to the value of strong connotation to logistics, the cross-analysis was made in which the common themes were compared with themes of logistics management definition provided by the Council of Supply Chain Management Professionals. It has shown that in almost all categories some equivalents can be found although they have different motivation and focus. A brief comparison to Information Management Body of Knowledge was also made because information management and information logistics are related areas. The comparison has shown that, despite of similarities, diversity in approaches still exists.

The empirical part was made as action research in the area of coordination of Erasmus+ program. With the experience of facing real-life problems, the following issues have been discussed: need to set up a hierarchy of goals of information transfers, management of group dynamics, flexibility of processes depending on diversity and changes in areas controlled by external participants, promotion via different channels, and problems with the right information at the right time and in the right place. Each issue has been illustrated with the examples and comparison to business process management perspective has been discussed. A summary of issues on the edge of information logistics and business process management shows diversity of cases starting from clear complementary relationship, via issues which require consideration according to criteria from yet another perspective, to the situation where business process cannot help because they do not deal with these issues.

Both analytical research results and action research have contributed to an attempt to formulate information logistics paradigm. Within further work it is planned to supplement the model with more concepts specific to information logistics, formulate a proposal of UML profile for Information Logistics and provide connections to related technologies which are based on other paradigms. The concepts specific to information logistics can be gathered with more detailed review of related work in information logistics area. A proposal of UML profile for information logistics can be done with application of meta-modeling technology delivered by OMG. The most challenging task is providing connection to technologies which are based on other paradigms since there is no certainty whether it can lead to general results or these relationships are specific to a case at hand. Additionally, the research could benefit from more empirical research results conducted also in different domains.

*Abstract*— **A supply chain is a network of suppliers, factories, warehouses, distribution centers and retailers, through which raw materials are acquired, transformed, produced and delivered to the customer. A supply chain management system (SCMS) manages the cooperation of these system components. In the computational world, roles of individual entities in a supply chain can be implemented as distinct agents [1]. In this paper we present supply chain coordination between Autonomous Agents. Moreover, we present a cooperative game theory approach to describe the SCM coordination. Numerical and theoretical game examples are detailed in this paper, which help to understand the usefulness of cooperative game theory in SCM.**

## I. Introduction

Coordination between agencies during multi-agency emergency responses, although a key issue, remains a neglected research area [2]. Coordination between the different agencies (enterprises) involved is a major challenge. Most of the components in Supply Chain Management (SCM) work in isolation and achieving coordination among Supply Chain Management partners turns out to be a difficult proposition. A supply chain typically extends across the multiple enterprises including suppliers, manufactures, transportation carriers, warehouses, retailers as well as customers and entails sharing forecast, order, inventory, and production information to better coordinate management decisions at multiple points throughout the extended enterprise [3].

The game theory approach is one of the best tools for modelling this complex system; and for modelling the cooperation between intelligent decision makers, the co-management and the autonomous agents. We know the players of the game, the information and actions are available to each player at each decision point, and the payoffs can be calculated for each outcome. In this paper, the cooperative game theory approach is detailed, through its main features.

The paper is organized as follows: Section (II) discusses the Supply Chain Coordination and co-management. Section (III) discusses the Multi-level Governance. Section (IV) introduces the construction of Supply Chain with the help of an agent. Section (V) presents the different types of games used in supply chain management. In section (VI) discusses the main features of cooperative games. And finally, section (VII) and section (VIII) detail numerical and theoretical SCM examples, in section (IX) can be read the conclusions.

The main goal of the paper is merging the up-to-date knowledge of supply chain coordination and the game theory. So, it contains a large number of reviews, but as an outlook, as an own contribution, it gives a usage example too. This paper integrates the SCM logistic and mathematical modelling knowledge.

## II. Supply chain coordination and Co-management

Supply chains (SC) are a system with "multiple actors". The supply chain is commonly seen as a collection of various types of companies (raw materials, production, trade, logistics, transport, etc.) working together to improve the flow of products, information and finance [4], [5]. Supply chains are complex systems, dynamic, dispersed and open. Those elements together with other factors (e.g. multiple subjects, independence of cooperating enterprises) determine difficulties in the field of management, or more broadly, of coordination of commonly take up and independently realized actions. The discussed systems are affected, as a whole, by a lack of internal rationality, unverified information and insufficient knowledge. The problem is also posed by uncertainty and a lack of precision [6]; [7], indispensable in the realized projects and complex undertakings.

Co-management is of growing interest among researchers. Centralized, top-down resource management is ill-suited to user participation. Centralized management are limited in their ability to respond to changing conditions, an anachronism in a world increasingly characterized by rapid transformations [8]; [9]. Changing ideas about the nature of resource management, ecosystems, and social-ecological

□ This work is supported by Poznan University of Technology and Budapest University of Technology and Economics

systems (integrated systems of people and environment) have been catalyzed by insights from complex adaptive systems thinking.

Selected features of adaptive co-management:

- Shared vision, goal, and/or problem definition to provide a common focus among actors and interests;
- A high degree of dialogue, interaction, and collaboration among multi-scaled actors;
- Distributed or joint control across multiple levels, with shared responsibility for action and decision making;
- A degree of autonomy for different actors at multiple levels;
- Commitment to the pluralistic generation and sharing of knowledge;
- A flexible and negotiated learning orientation with an inherent recognition of uncertainty [9].

Plummer and Fennell [10] build upon initial efforts to capture how adaptive co-management is being understood [11, 12, 13] to arrive at the following attributes.

- Pluralism and communication. Actors from diverse spheres of society (and at multiple levels) and who have varying principal interests enter into a process to generate shared understanding of an issue or problem. This process is grounded in communication and negotiation. Conflict is viewed as an opportunity.
- Shared decision-making and authority. Transactive decision-making is employed as a basis for achieving decisions. Multiple sources of knowledge are acknowledged. Authority (power) is shared in some configuration among the actors involved.
- Linkages, levels and autonomy. Actors are connected or linked both within levels and across scales. Despite shared interests and commitments, actor autonomy is appropriate at multiple levels. Institutional arrangements therefore encompass multiple levels as well as retain flexibility.
- Learning and adaptation. Actions and policies are considered experiments. Feedback provides opportunities for social learning in which outcomes are collectively reflected upon and modifications to future initiatives are based. Learning may concern routines, values and policies, and/or critical questions of the underlying governance systems; referred to as multiple-loop learning. Develops as trust and knowledge [14].

Conjoint Stage

Fig. 1 A model of the adaptive co-management process [14]

Co-management is not a fixed unitary entity, rather it is a set of principles for institutional design that can assume various organizational forms depending on particular circumstances [15].

Coordination defined as the process of managing dependencies among activities. Starting with the individual activity it is easily recognized that the industrial reality contains a multitude of various activities. When focusing solely on individual activities, these might seem to have a generic value, for example considering a production or exchange activity [16].

## III. Multi-Level Governance

The chief benefit of multi-level governance (MLG) lies in its scale flexibility. Its chief cost lies in the transaction costs of coordinating multiple competence. The coordination dilemma confronting multi-level governance can be simply stated: To the extent that policies of one competence have spillovers (i.e. negative or positive externalities) for other jurisdictions, so coordination is necessary to avoid socially perverse outcomes. We conceive this as a second -order coordination problem because it involves coordination among institutions whose primary function is to coordinate activity [17]. Type (I.) multi-level governance describes jurisdictions at a limited number of levels. That is to say, they bundle together multiple functions. Type (II.) multi-level governance is distinctly different. It is composed of specialized competence. The number of such competence is potentially huge. They tend to be lean and flexible – they come and go as demands for change [17]. Multi-level governance is the domain of the European Union.

Multi-level governance characterizes the changing relationships between actors situated at different levels. MLG contributes to a growing awareness that many contemporary issues and challenges require analysis that transcends traditional disciplinary boundaries.

Multi-level governance:

- Decision-making competencies are shared by actors at different levels rather than monopolized by executives;
- Collective decision-making significant loss of control for individual executives.

## IV. Construction of Supply chain with the help of an agent

It should be assumed that this is one of the simplest coordination mechanisms. It assumes that the enterprises in the built structure possess a hierarchy, previously provided. In order for it to function effectively, the execution of the following tasks is necessary:

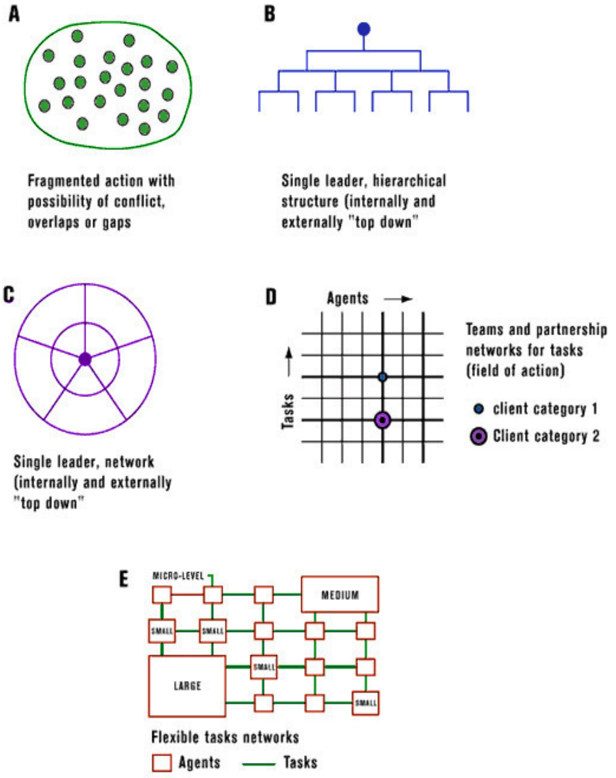
- Initiating the creation of a database of enterprises that will operate within the structure;
- Defining the scope of activities of the individual entities;
- Specifying the rights and obligations of the individual entities (regulations);
- Expanding the database of enterprises through own actions (sending information through the available communication channels, i.e. e-mail, press, internet...);
- Registration of structure participants;
- Approving the participants;
- Agreement;
- Establishing priorities and dependencies between the enterprises.

The agent should be understood and treated as coordinating activities of the organization. The agent should be:

- reactive – agent-coordinator identifies and responds to the tasks; It has current knowledge about the business,
- pro-active – agent-coordinator takes the initiative in order to carry out tasks,
- able to cooperate – agent-coordinator interacts with others in order to carry out the task.

The benefit of relations between enterprises defined in such a manner is the legible and explicit indication of the role that each enterprise is to play in the created structure. The building of structures with the help of an assistant most often assume the hierarchical master/slave structure. In such a case the agent master plans and sends out information on the orders to the individual subordinate agents (slave). And each of these agents transfers return information on the status of the completion of their order. The defect of such an approach is the small amount of autonomy for the slave agents. Coordination through the organization works ideally in the coordination of the tasks of agents connected by strong hierarchical relations [18].

Bennett and McCoshan (1993) [19] have suggested a typology of networks (Figure 1) which describes a range of relations between agents at the local or regional level. As they note, the networks A-D are derived from management science, and each has advantages and disadvantages in delivering economic development activities efficiently and sustainably. The introduction of the fifth form, E, is meant to be flexible and responsive to the needs of different agents [20].



A
Fragmented action with possibility of conflict, overlaps or gaps
B
Single leader, hierarchical structure (internally and externally "top down"
C
Single leader, network (internally and externally "top down"
D

Fig. 1 Network of relations between agents at a local level [20]

## V. The different types of games used in Supply Chain Management

Game theory is a powerful tool for analyzing situations in which the decisions of multiple agents affect each autonomous agent's payoff. The elements and rules mentioned in the previous section of this paper are the SCM conceptual basis: the decision-making, the coordination, the governance and the agents are the main subcomponents. The following game theory approach gives the opportunity of the mathematical modelling.

As such, game theory deals with interactive optimization problems. While many economists in the past few centuries have worked on what can be considered game-theoretic models, John von Neumann and Oskar Morgenstern (1944) [21] are formally credited as the fathers of modern game theory. Their classic book summarizes the basic concepts existing at that time. Game theory has since enjoyed an explosion of developments, including the concept of equilibrium by Nash (1950) [22], games with imperfect information by Kuhn (1953) [23], cooperative games by Aumann (1959) [24] and Shubik (1962) [25].

There are many game theory concepts, but this paper focuses on concepts that are particularly relevant to supply chain management (SCM) and, perhaps, already found their applications in the literature. The main state of the art: Myerson (1997) [29], Friedman (1986) [26], Fudenberg and Tirole (1991) [27], Topkis (1998) [30] and Vives (1999) [31], Moulin (1986) [28]. Some previous surveys of game theory models in management science include Lucas's (1971) survey of mathematical theory of games [32], Feichtinger and Jorgensen's (1983) [33] survey of differential games and Wang and Parlar's (1989) survey of static models [34], Porteus and Whang (1999) [38] survey of screening game. In addition, Fudenberg and Tirole (1991) [27] for more information on Bayesian games, Cachon and Lariviere (2001) [35] survey of signaling game, Brandenburger and Stuart (1996) [39] for more information of business process games, and [40], [41], [43], [44] about the core of the game, [44] about the Shapley value.

## VI. The main features of cooperative games

Cooperative game theory focuses on the outcome of the game, where the outcome is measured in terms of the value created through cooperation of a subset of players [35]. In what follows, we will cover transferable utility cooperative games (players can share utility via side payments) and three solution concepts:

- the core of the game;
- the Shapley value;
- and the nucleolus.

### A. Games in characteristic form and the core of the game

The cooperative game consists of the set of players $N$ with subsets or coalitions $S \subseteq N$ and a characteristic function $v(S)$ that specifies a (maximum) value (which we assume is a real number) created by any subset of players in $N$, i.e., the total pie that members of a coalition can create and divide. A frequently used solution concept in cooperative games is the core of the game. The utility vector $x_1, \ldots, x_N$ is in the core of the cooperative game if

$$\forall S \subseteq N,\ \sum_{i \in S} x_i \geq v(S) \text{ and } \sum_{i \in N} x_i = v(N)$$

A utility vector is in the core if the total utility of every possible coalition is at least as large as the coalition's value, i.e., there does not exist a coalition of players that could make all of its members at least as well off and one member strictly better off.

### B. Shapley value, nucleolus

The concept of the core, though intuitively appealing, also possesses some unsatisfying properties. Shapley (1953) offered an axiomatic approach to a solution concept that is based on axioms [45]. One of the most important is that: if $v_1$ and $v_2$ are characteristic functions in any two games, and if $\phi_1$ and $\phi_2$ are a player's Shapely value in these two games, then the player's Shapely value in the composite game, $v_1 + v_2$, must be $\phi_1 + \phi_2$.

An alternative equivalent formula for the Shapley value is:

$$\varphi_i(v) = \frac{1}{|N|!} \sum_{R} \left[ v\left(P_i^R \bigcup \{i\}\right) - v(P_i^R) \right]$$

where the sum ranges over all *INI!* orders $R$ of the players and $P_i^R$ is the set of players in $N$ which precede $i$ in the order $R$.

Another interesting value function for cooperative games may be found in the nucleolus, a concept introduced by Schmeidler (1969) [47]. The main idea: we look at a fixed characteristic function, $v$, and try to find an imputation $x = (x_1, \ldots, x_n)$ that minimizes the worst inequity. As a measure of the inequity of an imputation $x$ for a coalition $S$ is defined as the excess:

$$e(x, S) = v(S) - \sum_{i \in S} x_i$$

which measures the amount (the size of the inequity) by which coalition $S$ falls short of its potential $v(S)$ in the allocation $x$.

## VII. Numerical example

There are three enterprises (A, B, C; logistics providers – e.g. freight, storage, complex logistics processes, transhipment processes, with using roads and rails too -), the core of the game based on the following constraints (Fig. 2):

$$v(A)=v(B)=v(C)=0$$

$$v(AB)=3$$

$$v(AC)=5$$

$$v(BC)=4$$

$$v(ABC)=7$$

Here, individually, none of the players can receive any payoff. But if they cooperate, different coalitions result in a positive payoff for each coalition. If they all cooperate, then the grand coalition receives an amount $v(ABC)$ higher than any other coalition. Other words: they have to perform a multimodal logistics task.

The core of a game in characteristics form is defined as the set of all imputations $(x_1, x_2, \ldots, x_n)$ such that for all

$S \subseteq N$, $\sum_{i \in S} x_i \geq v(S)$. The core is the set of all $(x_A, x_B, x_C)$ satisfying:

$$x_A+x_B\geq v(AB)=3$$

$$x_A+x_C\geq v(AC)=5$$

$$x_B+x_C\geq v(BC)=4$$

$$x_A+x_B+x_C= v(ABC)=7$$

The set of imputations in this game can be represented by an equilateral triangle with high equal to $v(ABC)=7$. For any point $(x_A, x_B, x_C)$ in the triangle, $x_i$ is the distance to side of the opposite corner, $i=A, B, C$; as indicated in Figure 2.

Thus, player $i$ prefers imputations that are close to corner $i$. Since

$$x_i+x_j\geq v(ij) \leftrightarrow x_k\leq v(ABC)- v(ij)$$
$$for\ i\neq j\neq k$$

the latter inequalities can be drawn to obtain the core – provided that is nonempty.

The core in this game is obtain by drawing the regions

$$x_A\leq 3$$

$$x_B\leq 2$$

$$x_C\leq 4$$

These give rise to the area indicated by interrupted lines in Figure 2.

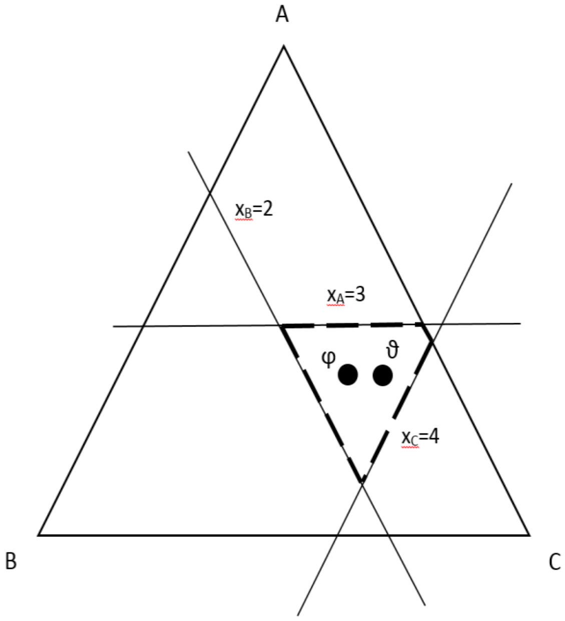

Fig. 2 The core of the game, the Shapley value and the nucleolus

Table 1. shows the marginal contributions of players, based on this, we can calculate the Shapley value.

TABLE I.
THE MARGINAL CONTRIBUTIONS OF PLAYERS

| Orders of the players | Marginal contributions of A | Marginal contributions of B | Marginal contributions of C |
|---|---|---|---|
| ABC | v(A)-v(0) | v(B)-v(0) | v(C)-v(0) |
| ACB | v(A)-v(0) | v(B)-v(0) | v(C)-v(0) |
| BAC | v(AB)-v(B) | v(AB)-v(A) | v(AC)-v(A) |
| BCA | v(ABC)-v(BC) | v(ABC)-v(AC) | v(ABC)-v(AB) |
| CAB | v(AC)-v(C) | v(BC)-v(C) | v(BC)-v(B) |
| CBA | v(ABC)-v(BC) | v(ABC)-v(AC) | v(ABC)-v(AB) |

The Shapley value for the three players are found as

$$\varphi_A(v) = \frac{14}{6} = 2{,}33$$

$$\varphi_B(v) = \frac{11}{6} = 1{,}83$$

$$\varphi_C(v) = \frac{17}{6} = 2{,}83$$

Based on Leng and Parlar (2010), we can use explicit formula to compute the nucleolus [46]:

$$xi = \frac{v(123) + v(ij) + v(ik) - 2v(jk)}{3}$$

$$for\ i,j,k = 1,2,3\ and\ i \neq j \neq k$$

The nucleolus $\vartheta(x_A, x_B, x_C)$ for the three players are found as (Table 2. shows $e(x,S)$):

$$x_A = \frac{7}{3} = \frac{14}{6} = 2{,}33$$

$$x_B = \frac{4}{3} = \frac{8}{6} = 1{,}33$$

$$x_C = \frac{10}{3} = \frac{20}{6} = 3{,}33$$

TABLE II.
THE E(X,S) IN THE NUCLEOLUS

| S | v(S) | e(x,S) | (14/6; 8/6; 20/6) |
|---|---|---|---|
| A | 0 | 0-$x_A$ | -2,33 |
| B | 0 | 0-$x_B$ | -1,33 |
| C | 0 | 0-$x_C$ | -3,33 |
| AB | 3 | 3- $x_A$- $x_B$ | -0,67 |
| AC | 5 | 5- $x_A$- $x_C$ | -0,67 |
| BC | 4 | 4- $x_B$- $x_C$ | -0,67 |

In this example, the Shapley value and the nucleolus is also in the core. They give solution alternatives of game, which are relatively close to each other.

Based on this numerical example, we can calculate the tangible benefits of a virtual logistics alliance. Moreover, there are three indicators (core of the game, Shapley value, nucleolus), to evaluate the benefit of this alliance, and the personal effects too. The great advantage of this solution is the quantifiability and the opportunity of the multi criteria decision making.

## VIII.THEORETICAL SCM EXAMPLE

The previous numerical example could be good for modelling cooperation in the freight and warehouse exchanges Kovács (2009) [49], Grzybowska and Kovács (2012) [50], Grzybowska and Kovács (2014) [51]. The simplified system model of the supply chain supported by electronic freight and warehouse exchanges is shown in Figure 3.

In this system, the electronic freight and warehouse exchanges perform the supply-demand (freight/storage capacities/tasks) harmonization; the decision supporting, the optimization and the whole software/hardware support. The logistics providers (storage providers, transportation providers, logistics centres) perform the physical freight/storage/transhipment tasks; whereas they have: suitable stock capacities, suitable freight capacities, equipment's, and logistics know-how. The wholesalers are responsible for the information processes; they manage the demands of retailers. This supply chain may be optimal, through using cooperative game theory, pollution or cost point of view. Consequently, green logistics systems, e.g. green city supply chains or combined transportation systems can be realized. In addition, this system is beneficial not only for the individual actors (e.g. retailers, wholesalers, logistics providers, manufacturers) but also for the national economy (reduce traffic flow, pollution, noise). The future plans include further development of algorithms and tests in real supply chains.

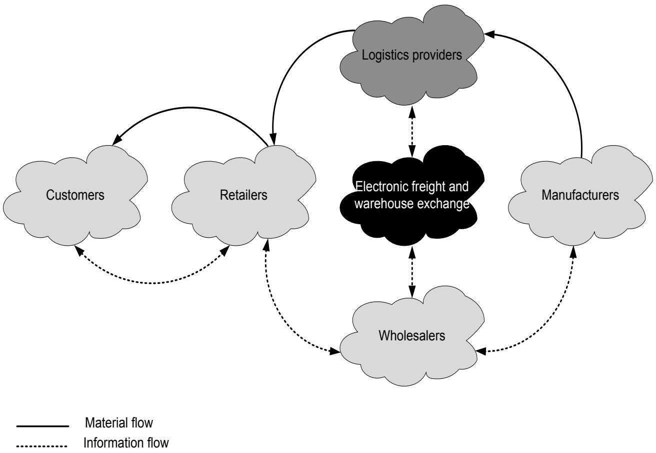

Fig. 3 The simplified system model of the supply chain supported by electronic freight and warehouse exchanges

As another example of potential SCM modelling, research at the Department of Material Handling and Logistics Systems in Budapest is aimed to help logistics processes at the construction industry. This work has been developed in the framework of the project "Development of construction processes from logistical and informatical aspects". This research is part of a project (KTIA-AIK-12-1-2013-0009) financed by the National Development Agency of Hungary. This project concentrates on the logistics aspects, where organization of the material flow is an important task. Based on this research, we can create flowcharts (for top-down modelling and for low-level modelling too), which help to analyse the real construction processes, and thereby we can build up realistic game models too.

## IX. CONCLUSIONS

The main result of this article is merging the supply chain coordination and the cooperative game theory approach. By the explanations and the numerical example, this logic modelling is reasonable. The occurring decision supporting problem can be modelled well, the branching points and a variety of outputs can be understood and managed. The main contribution is the combination of SCM and mathematical principal founds, by the addition of numerical and theoretical examples too.

One of most interesting application is the virtual alliances in the supply chain, such as freight exchanges, but other areas also may be promising. The next step in the research will be to make essential progress in the field of supply chains, e.g. a freight and warehouse exchange game model structure.

# A Hybrid Multi-Objective Programming Framework for Modeling and Optimization of Supply Chain Problems

Paweł Sitek
Institute of Management Control Systems, Kielce University of Technology Al. 1000-lecia PP 7, 25-314
Kielce, Poland,
Email: sitek@tu.kielce.pl

*Abstract*—**This paper presents a hybrid programming framework for solving multi-objective optimization problems in supply chain. The proposed approach consists of the integration and hybridization of two modeling and solving environments, i.e., constraint logic programming and mathematical programming, to obtain a programming framework that offers significant advantages over the classical approach derived from operational research. The strongest points of both components are combined in the hybrid framework, which by introducing transformation allows a significant reduction in size of a problem and the optimal solution is found a lot faster. This is particularly important in the multi-objective optimization where problems have to be solved over and over again to find a set of Pareto-optimal solutions. An over two thousand-fold reduction in size was obtained for the illustrative examples together with a few hundred-fold reduction in the speed of finding the solution in relation to the mathematical programming method. In addition, the proposed framework allows the introduction of logical constraints that are difficult or impossible to model in operational research environments.**

## I. Introduction

SUPPLY chain (SC) is an integrated process in which a group of several organizations and/or companies, such as suppliers, producers, distributors and retailers, work together to acquire raw materials with a view to converting them into end products which they distribute to retailers [1]. Decision and optimization problems occurring in the real-world supply chain are characterized by multiple objectives, constraints and many different decision variables. The presence of multiple conflicting objectives and constraints is natural and results from the complexity and interrelated character of problems and different interests of individual supply chain participants. Environmental aspects such as CO2 emissions, noise, etc., which are a new type of constrains in SC, are emerging to become an important factor in the design of supply chains. Operational research models, with mathematical programming (MP) in particular, are most often used. They include MILP (mixed integer linear programming), MIP (mixed integer programming), IP (integer programming), etc. and MOOP (multi-objective optimization problem) [2]. The vast majority of these models have a very large number of constraints, and two major difficulties appear in their application. First, discrete optimization problems, both single and multi-objective, contain many discrete decision variables. This increases their computational complexity and the finding of the optimal solution is long and costly. Second, mathematical programming models have linear constraints, which is insufficient for the description of many of the SC problems. This paper deals with a problem of supply chain modeling, multi-objective optimization and solving. An important contribution of the presented approach is to propose a programming framework that supports the hybrid modeling, hybrid multi-objective optimization and analysis of decision problems in the supply chain. In this programming framework two environments are hybridized, constraint logic programming (CLP) and mathematical programming (MP), in which constraints are treated in different ways and different methods are implemented to use the strengths of both for solving complex and constrained problems. The hybrid approach offers a lot more possibilities and higher efficiency in both the modeling and multi-objective optimization. The concept of hybridization is complemented by the interaction algorithm and a complete transformation of the problem and together creating an application programming framework. The rest of the paper is organized as follows: Section 2 describes literature review. Next Section presents Methodology. Section 4 is about our motivation. Section 5 gives the concept of the novel constraint logic programming approach with MP-based solver and implementation platform. The optimization models as the illustrative examples are described in Section 6. Computational examples and tests of the implementation platform are presented in Section 7. The discussion on possible extensions of the proposed approach and conclusions is included in Section 8.

## II. Literature review of supply chains models and multi-Objective optimization

The build-to-order supply chain (BOSC) model, a key operation model for providing services/products, has received more attention in recent years, car manufacturers

This work was not supported by any organization

including [3]. In the BOSC model, production activities are not executed until orders from customers have been received, which can effectively reduce the costs of demand prediction and inventory and credibly reflect market demands. When BOSC is started, the selection of suppliers becomes the priority. Product assembly begins after this selection. Based on the findings reported in the literature [4],[5]. BOSC is a successful supply chain model that is currently widely in use. There are two most widely encountered objectives of the objective function in multi-objective programming models for SC. The first objective is the cost of activity in the supply chain, including the cost of particular chain link, transport, work and even product design, etc. The second objective is associated with the costs or volumes of CO2 emission and other environmental aspects [6]. The second objective may also comprise delivery time [7] or, calculated in many different ways, the level of customer satisfaction [8],[9]. In [10] the multi-objective optimization mathematical model of BOSC has been presented. There are three objective functions. The first is cost minimizing including order cost, purchase cost and transport cost. The second is minimizing the maximum time of transporting the purchased parts to customers (delivery). The last is the part quality. Many researchers have recently reported the results of their multi-objective optimization studies. For example, a multi-objective programming model is proposed in [2],[11] to analyze solid waste management. The model for simultaneously optimizing the operations of both integrated logistics and its corresponding used-product reverse logistics in a close-looped supply chain has been presented in [12]. The common feature of these problems is the number of decision variables resulting from the allocation of resources, choice of location, route selection, choice of factory and distribution center, choise o mode of transport etc. These are usually binary and/or integer decision variables. Besides, all the problems are characterized by a large number of constraints binding decision variables. The overview of the models and algorithms of these problems is shown in [2],[27].

### A. Multi-objective optimization

The multi-objective optimization problem (MOOP) can be defined as the problem of finding a vector of decision variables $\hat{x}$, which optimizes a vector of $N$ objective functions $f_i$ $(\hat{x})$ where $i = 1, 2, .. ,N$; subject to inequality constraints $g_j$ $(\hat{x}) \geq 0$ and equality constraints $h_k$ $(\hat{x}) = 0$ where $j = 1, 2, .. , J$ and $k = 1, 2, .. ,K$.

A set of objective function is a multi-dimensional space, in addition to typically the decision space. This additional space is called the objective space Z. For each solution $\hat{x}$ in the decision variable space, there exists a point in the objective space:

$$\hat{f}\ (\hat{x}\ )=Z\,(z_1\ , z_2\ ,..., z_N\ )^T$$

In a MOOP, we want to find a set of values for the decision variables that optimizes a set of objective functions. A decision vector $\hat{x}$ is said to dominate a decision vector $\hat{y}$ (i.e. $\hat{x}{>}\hat{y}$) if:

$$f_i\ (\hat{x}\ )\ \leq\ f_i\ (\hat{y})\ \forall\ i \in \{1,2,..,N\}$$

and

$$\exists i \in\ \{1,2,..,N\}\ |\ f_i\ \ (\hat{x}\ )\ \leq\ f_i\ (\hat{y})$$

All decision vectors that are not dominated by any other decision vector are called non-dominated or Pareto-optimal and constitute the Pareto-optimal front/set. There are several methods for find the Pareto-optimal set of these optimization problems. Among the most widely techniques are: ε-constraint method, weighting method, goal programming, sequential optimization etc. [13].

## III. Methods and Methodology

The key problem in the modeling and optimization of problems in the supply chain are multiple constraints of different types and character-linear, integer, non-linear, logical etc. Constraints are logical relations between variables, each variable taking a value from a specific domain. Thus a constraint restricts the possible values that a variable can take, i.e. it represents some partial information about the variables of interest. Constraints are:

- declarative, they specify a relationship between entities (decision variables) without determining a specific computational or programming procedure;
- additive, we are interested in the conjunction of constraints and not in the order in which they are imposed;
- rarely independent, normally constraints share decision variables.

Thus constraints are a natural medium and form to express problems in many fields, especially in logistic, transport, manufacturing, scheduling, distribution, supply chain etc. by all (researchers, practitioners, professionals, end-users etc.). In the above problems, there are resource, financial, capacity, time, transportation, environmental, multimodal, sale etc. constraints. Based on numerous studies and our own experience, the constraint-based environment [14], [15], [16], [17], [29] is believed to offer a very good framework for representing the knowledge, information and methods needed for the decision support and optimization. The central issue for a constraint-based environment is a constraint satisfaction problem (CSP) [14]. Constraint satisfaction problem is the mathematical problem defined as a set of elements whose state must satisfy a number of constraints. Constraint satisfaction problems (CSPs) on finite domains are typically solved using a form of search. The most widely used techniques include variants of backtracking, constraint propagation, and local search. Constraint propagation embeds any reasoning that consists in explicitly forbidding values or combinations of values for some variables of a problem because a given subset of its constraints cannot be satisfied otherwise [15]. CSPs are frequently used in constraint programming. Constraint programming is the use of constraints as a programming language to encode and solve problems. Constraint logic programming (CLP) is a form of constraint programming (CP), in which logic programming is extended to include concepts from constraint satisfaction. A constraint logic program is a logic program that contains constraints in the body of clauses (predicates). In CLP the declarative approach and the use of logic programming provide incomparably greater possibilities for decision problems modeling than the pervasive approach based on mathematical programming. Unfortunately, discrete optimization is not a strong suit of CP-based environments. This weakness is more pronounced in multi-objective optimization problems, where a parameterized problem of a single-objective optimization problem has to be solved multiple times depending on the size of Pareto set. Based on [14],[15] and previous work on hybridization [16],[17],[18] some advantages and disadvantages of these environments have been observed. The hybrid approach of constraint logic programming and mathematical programming can help to solve optimization problems that are intractable with either of the two methods alone [19],[20],[21]. In both MP and CLP, there is a group of constraints that can be solved with ease and a group of constraints that are difficult to solve. Both MP and finite domain CP/CLP involve variables and constraints. However, the types of the variables and constraints that are used, and the way the constraints are solved, are different in the two approaches [21]. MP relies completely on linear equations and inequalities in integer variables, i.e., there are only two types of constraints: linear arithmetic (linear equations or inequalities) and integrity (stating that the variables have to take their values in the integer numbers). In finite domain CP/CLP, the constraint language is richer. In addition to linear equations and inequalities, there are various other constraints: disequalities, nonlinear, symbolic (alldifferent, disjunctive, cumulative etc.) [14]. Integrity constraints are difficult to solve using mathematical programming methods and often the real problems of MP make them NP-hard. In CP/CLP, domain constraints with integers are easy to solve. The system of such constraints can be solved over integer variables in polynomial time. The inequalities between many variables, general linear constraints, and symbolic constraints are difficult to solve, which makes real problems in CP/CLP NP-hard [21]. This type of constraints reduces the strength of constraint propagation. As a result, CP/CLP is incapable of finding even the first feasible solution [16].

## IV. Motivation and Contribution

The motivation and contribution behind this work was to apply a hybrid approach as a hybrid multi-objective programming framework for supply chain problems. The hybrid multi-objective programming framework is a concept that combines hybrid approach with iterative algorithm (Appendix A) in the context of multi-criteria optimization. The hybrid approach proved to be very effective when applied to a single objective optimization problems [17],[18]. This hybrid approach is an original concept whose elements and outline are presented in [16],[17],[18]. Application of this approach to multi-objective optimization has not been presented before. The best structure for the implementation of the above approach is a declarative CLP environment with operation research MP as a hybrid system. Furthermore, such a hybrid approach allows the use of all layers of the problem (data, structure, methods) to solve it. Finally, it allows the transformation of the problem (Section VIC) to such a form that can fully exploit the strengths of the constraint propagation and data instances. It is well-known that there exist multiple non-dominated solutions for a multi-objective optimization problem. Those solutions are called "Pareto-optimal" solutions. In this paper, our objective is to obtain a "Pareto-optimal" set which provides evenly distributed Pareto solutions and it is convenient for the decision maker to select a suitable costs between production, distribution and environmental (F1 and F2) or between all costs and total distributor capacity (F1' and F2') etc. (Section VIA and Section VID). This hybrid programming framework is not just a blind attempt to integrate two environments, CLP/MP. The proposed approach is reinforced with the transformation, different representation of the problem (Section VIC) and using the algorithm for finding a "Pareto-optimal" set. In addition, hybridization refers to the class of decision problems which has certain property (This property is characterized by the constraints of many discrete decision variables and their summation).

## V. The concept and implementation aspects of the hybrid multi-objective programming framework

In this approach to the modeling and multi-objective optimization of supply chain problems, the hybrid multi-objective programming framework has been proposed, where:

- the decision and optimization models solved using the proposed framework can be formulated as a pure model of MOOP/MOLP or a hybrid model (with logical and non-linear constraints);
- knowledge related to the problem can be expressed as facts and constraints (linear, non-linear, logical and symbolic etc.);
- the problem is modeled in the constraint logic programming environment by CLP predicates, which is far more flexible than the MP environment;
- transforming the optimization model to explore its structure and data has been introduced by CLP predicates;
- optimization is performed by MP-based environments.
- the effective algorithm for finding a "Pareto-optimal" set has been introduced.

The schematic diagram of the implementation framework for the hybrid approach is presented in Figure 1. The names and descriptions of the predicates and procedures are shown in Table 1. From a variety of tools for the implementation of the CP-based environment, ECL$^i$PS$^e$ software [22] was selected. ECL$^i$PS$^e$ is an open-source software system for the cost-effective development and deployment of constraint programming applications. MP-based environment in implementation platform was LINGO by LINDO Systems [23]. LINGO Optimization Modeling Software is a powerful tool for building and solving mathematical optimization models. ECL$^i$PS$^e$ was used to implement the following predicates of the framework: CLP1, CLP2, CLP3 and CLP4 (Fig. 1, Table 1.). CLP predicates significantly restrict the space of feasible solutions (Fig. 1). The transformed files of the model were transferred from ECLiPSe to LINGO where they were merged (MP1). Then the complete model was solved using LINGO efficient solvers (MP2). After that the model was modified for next step in procedure MP1 and solved again and again by MP2 in order to find a set of Pareto-optimal solutions (algorithm see appendix A).

TABLE I.
THE NAMES AND DESCRIPTIONS OF THE PREDICATES AND PROCEDURES

| Symbol | Description |
|---|---|
| CLP1 | The implementation of the model in CLP, the term representation of the problem in the form of predicates. |
| CLP2 | Constraint propagation for the model or transformed model. Constraint propagation is one of the basic methods of CLP. As a result, the variable domains are narrowed, and in some cases, the values of variables are set, or even the solution can be found. |
| CLP3 | The transformation of the original problem aimed at extending the scope of constraint propagation. The transformation uses the structure of the problem and data. The most common effect is a change in the representation of the problem by reducing the number of decision variables, and the introduction of additional constraints and variables, changing the nature of the variables, etc. |
| CLP4 | Generation the model for mathematical programming-MOOP; |
| MP1 | Merging files generated by CLP4 into one file. It is a model file format in LINGO system. |
| MP2 | The solution of the model from the MP1 by MP solver. Sending the new solution to MP1 as a new constraint. Modification of the model. The process is repeated until the whole Pareto set is found (algorithm Appendix A). |

## VI. ILLUSTRATIVE EXAMPLES OF SUPPLY CHAIN MODELING AND MULTI-OBJECTIVE OPTIMIZATION - THE HYBRID APPROACH

The proposed approach was used and tested on two illustrative supply chain multi-objective optimization models. The model was formulated as a multi-objective mixed-integer optimization problem (MOOP) problem based on under constraints (2) .. (23) in order to test the proposed approach (Fig. 1) against the classical operation research approach. The models differ from one another objective functions (Section 6.A). Indices, parameters and decision variables used in the models together with their descriptions are summarized in Table 2 and [16],[17]. The simplified structure of the supply chain network for this model, composed of producers, distributors and customers is presented in Figure 2. Both models are the cost multi-objective models that take into account other types of parameters, i.e., the spatial parameters (area/volume occupied by the product, distributor capacity and capacity of transport unit), time (duration of delivery and service by distributor, etc.), the transport mode and environmental aspects.

These models are based on optimization models taken from [16],[17].

TABLE II.
INDICES, PARAMETERS AND DECISION VARIABLES

| Symbol | Description |
|---|---|
| | *Indices* |
| k | product type (k=1..K) |
| m | delivery point/customer/city (m=1..M) |
| n | manufacturer/factory (n=1..N) |
| e | distributor /distribution center (e=1..E) |
| d | mode of transport (d=1..D) |
| N | number of manufacturers/factories |
| M | number of delivery points/customers |
| E | number of distributors |
| K | number of product types |
| D | number of mode of transport |
| | *Input parameters* |
| $F_e$ | the fixed cost of distributor/distribution center *e* |
| $C_{n,k}$ | the cost of product *k* at factory *n* |
| $K1_{n,e,k,d}$ | the variable cost of delivery of product *k* from manufacturer *n* to distributor *e* using mode of transport *d* |
| $A_{n,e,d}$ | the fixed cost of delivery from manufacturer *i* to distributor *s* using mode of transport *d* |
| $K2_{e,m,k,d}$ | the variable cost of delivery of product *k* from distributor *e* to customer *m* using mode of transport *d* |
| $G_{e,m,d}$ | the fixed cost of delivery from distributor *e* to customer *m* using mode of transport *d* |
| $Od_d$ | the environmental cost of using mode of transport *d* |
| | *Decision variables* |
| $X_{n,e,k,d,m}$ | delivery quantity of product *k* from manufacturer *n* to distributor *s* using mode of transport *d* to customer *m* |
| $Xa_{n,e,k,d,m}$ | if delivery is from manufacturer *i* to distributor *e* product *k* using mode of transport *d* to customer <u>*m*</u> then $Xa_{n,e,k,d,m}$ =1, otherwise $Xa_{n,e,k,d,m}$ =0 |
| $Xb_{n,e,d}$ | the number of courses from manufacturer *n* to distributor *m* using mode of transport *d* |
| $Y_{e,m,k,d}$ | delivery quantity of product *k* from distributor *e* to customer *m* using mode of transport *d* |
| $Yb_{e,m,d}$ | the number of courses from distributor *e* to customer *m* using mode of transport *d* |
| $Tc_e$ | if distributor *e* participates in deliveries, then $Tc_e$=1, otherwise $Tc_e$=0 |

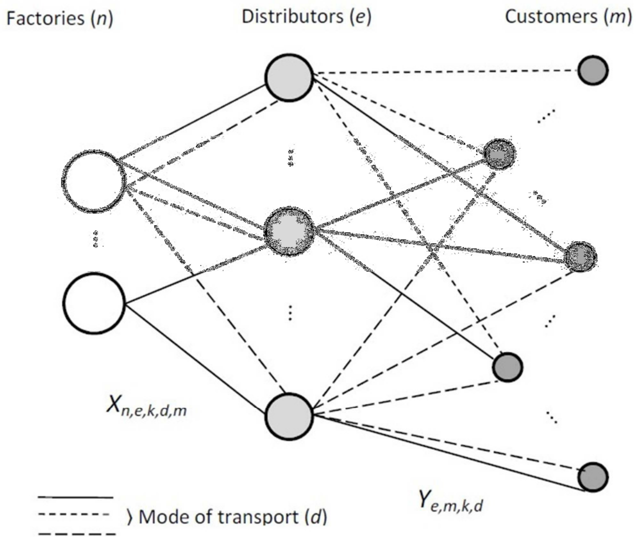

Fig. 2 Simplified supply chain network

### A. *Objective function*

Two typical objective functions, F1 and F2, are commonly used in optimization issues. Objective function F1 (1a) defines the aggregate costs of the entire chain and consists of four elements. The first element comprises the fixed costs associated with the operation of the distributor involved in the delivery (e.g. distribution centre, warehouse, etc.). The second component determines the cost of the delivery from the manufacturer to the distributor. Another component is responsible for the costs of the delivery from the distributor to the end user (the store, the individual client, etc.). The last component of the objective function F1 determines the cost of manufacturing the product by the given manufacturer. The second objective function F2 (1b) corresponds to environmental costs of using various means of transport. Those costs are dependent on the number of courses of the given means of transport, and on the other hand, on the environmental levy, which in turn may depend on the use of fossil fuels and carbon-dioxide emissions [8]. This hybrid approach and its implementation can be successfully used for other objective functions, including those named in Section 3. For the numerical examples from Section 7, in addition to the objective function formulated as above, the objective functions where F1'=F1+F2 (sum (1a) and (1b), whereas F2'=V (total capacity of distribution centers) were formulated.

$$\begin{aligned} F1 = {} & \sum_{e=1}^{E} F_e \cdot Tc_e + \sum_{n=1}^{N}\sum_{e=1}^{E}\sum_{d=1}^{D}(A_{n,e,d} \cdot Xb_{n,e,d} + \sum_{k=1}^{O}\sum_{m=1}^{M}(K1_{n,e,k,d} * X_{n,e,k,d,m})) + \\ & \sum_{e=1}^{E}\sum_{m=1}^{M}\sum_{d=1}^{D}(G_{e,m,d} \cdot Yb_{e,m,d} + \sum_{k=1}^{O} K2_{e,m,k,d} \cdot Y_{e,m,k,d}) + \sum_{n=1}^{N}\sum_{k=1}^{K}(C_{nk} \cdot \sum_{e=1}^{E}\sum_{d=1}^{D}\sum_{m=1}^{M} X_{n,e,k,d,m}) \end{aligned} \tag{1a}$$

$$F2 = \sum_{d=1}^{D} Od_d (\sum_{n=1}^{N}\sum_{e=1}^{E} Xb_{n,e,d} + \sum_{e=1}^{E}\sum_{m=1}^{M} Yb_{e,m,d}) \tag{1b}$$

### B. *Two typical objective functions, F1 and F2, are commonly*

The model was based on constraints (2) .. (23). Constraint (2) specifies that all deliveries of product *k* produced by the manufacturer *n* and delivered to all distributors *e* using mode of transport *d* do not exceed the manufacturer's production capacity. Constraint (3) covers all customer *m* demands for product *k* through the implementation of delivery by distributors *s* (the values of decision variables $Y_{e,m,k,d}$). The flow balance of each distributor *e* corresponds to constraint (4). The possibility of delivery is dependent on the distributor's technical capabilities (5). Time constraint (6) ensures the terms of delivery are met. Constraints (7), (8), (9), (10), (11) guarantee deliveries with available transport taken into account. Constraints (12), (13), (14) set values of decision variables based on binary variables $Tc_e$, $Xa_{n,s,k,d,m}$, $Ya_{e,m,k,d}$, $X_{n,e,k,d,m}$, $Y_{e,m,k,d}$. Dependencies (15) and (16) represent the relationship based on which total costs are calculated. In general, these may be any linear functions. The remaining constraints (17) .. (23) arise from the nature of the model (MILP). A detailed description of the constraints and their formalization have been presented in [16],[17].

### C. *Model transformation*

The ability to transform the problem using CLP is one of the most important features of the hybrid programming framework. Due to the nature of the decision problem (adding up variables in the objective function and constraints), the constraint propagation efficiency decreases dramatically. Constraint propagation is one of the most important methods in CLP affecting the efficiency and effectiveness of the CLP and hybrid programming framework (Fig. 1). For that reason, research into more efficient and more effective methods of constraint propagation was conducted. The results included different representation of the problem and the manner of its implementation. The classical problem modeling in the CLP environment consists in building a set of CLP predicates with parameters. While modeling problem (1) .. (23), quantities *n, e, k, d1, d2, m* and decision variables $X_{n,e,k,d1,m}$ and $Y_{e,m,k,d2}$ were predicate parameters (Fig. 3a). The process of finding the solution may consist in using the constraints propagation methods, labeling of variables and the backtracking mechanism [15]. The quality of constraints propagation and the number of backtrackings are affected to a high extent by the number of parameters that must be specified/labeled in the given predicate. In the models presented above, the classical problem representation included four parameters (Fig. 3b): n, e, d1, d2, and two decision variables $X_{n,e,k,d1,m,j}$, $Y_{e,m,k,d2}$. Considering the domain size of each parameter, the process is complex and time-consuming. The idea was to transform the problem by changing its representation without changing the very problem. All permissible routes were first generated by CLP3 predicate based on the fixed data (factories, distributors, mode of transport etc.) and a set of orders (Fig. 4a), then the specific values of parameters *n, e, k, d1, d2*, m were assigned to each of the routes. Thereby only one parameter of the transformed decision variable $X^T_{n,k,e,j,d1,d2}$ (deliveries) had to be specified (Fig. 4b). This transformation fundamentally improved the efficiency of the constraint propagation and reduced the number of backtracks.

Symbols used in descriptions are presented in Table III.

TABLE III.
INDICES, SYMBOLS USED IN THE REPRESENTATION OF THE PROBLEM

| Symbol | Description |
|---|---|
| $V_{FC}$ | Value of the objective function calculated on the basis of the vector of parameters. |
| O_n | Order number. |
| P | Products, P ∈ {$p_1$,$p_2$, ... ,$p_o$}. |
| M | Customers, M ∈ {$m_1$,$m_2$, … ,$m_m$}. |
| D | Distributors, D ∈ {$c_1$,$c_2$, … ,$c_e$}. |
| F | Factories, F ∈ {$f_1$,$f_2$, … ,$f_n$}. |
| Tu | Transport unit, Tu ∈ {$s_1$,$s_2$, … ,$s_l$}. |
| T | Delivery time/period. |
| Oq | Order quantity. |
| X/Y/$X^T$ | Delivery quantity. |
| route_n | Routes name-number. |
| , | Separates predicate parameters. |
| :- | Separates predicate heading from its definition. |
| _ | Unknown value of the variable. |

The obtained multi-objective optimization model after the transformation (MOOPT) has different decision variables and different constraints than those in the MOOP (1) .. (23). Some of the decision variables are redundant; other variables are subject to aggregation. This results in a very large reduction in their number. Decision variables before and after the transformation are shown in Table IV. The transformation also reduces or eliminates some of the constraints of the model. Thus constraints (4), (6), (12), (13), (14), (15) and (16) present in the MOOP (1) .. (23) are redundant in the MOOPT. Balance constraint (4) is unnecessary because the route defines the specific distribution center. Only those routes are generated that meet the time constraints, therefore constraint (6) does not make sense. Binarity ensures whether or not the route occurs, thus constraint (12) is redundant. Reduction of certain variables also affects the reduction of constraints, hence lack of constraints (13), (14) in the model. Constraints (15) and (16) are unnecessary, because the delivery costs are now calculated for the entire route.

TABLE IV.
DECISION VARIABLES USED IN THE MOOP AND TRANSFORMED MOOPT MODELS

| MOOP | MOOPT | Description of the decision variables after the transformation |
|---|---|---|
| $X_{n,e,k,d1,m}$<br>$Y_{e,m,k,d2}$ | $X^T_{n,k,e,m,d1,d2}$ | Decision variable $X^T$, unlike the initial decision variables X,Y, is generated only for technologically possible indices combinations. It defines the allocation size of product k to the route of deliveries. |
| $Xa_{n,e,k,d,m}$ | unnecessary | After transformation replaced by the appropriate factor for the route - generated by the CLP. |
| $Xb_{n,e,d}$ | $Xb_{n,e,d}$ | Without change, the same sense. |
| $Ya_{e,n,k,d}$ | unnecessary | After transformation replaced by the appropriate factor for the route - generated by the CLP. |
| $Yb_{e,m,d}$ | $Yb_{e,m,d}$ | Without change, the same sense. |
| $Tc_e$ | $Tc_e$ | Without change, the same sense. |

After the transformation in the MOOPT model, the objective functions F1 and F2 were re-formulated. New objective functions, F1T (A1a) and F2T (A1b) were obviously formulated using new decision variables (Table IV) and calculated parameters by CLP (Table V). These parameters were determined as a result of constraint propagation and the transformation itself using CLP2 and CLP3. Owing to these quantities, it is possible to introduce to the MOOPT model additional constraints (A2) ... (A7). These constraints affect the efficiency of the search for a solution by narrowing down the search area. Table VI describes these constraints.

$$\begin{aligned} F1T = &\sum_{e=1}^{E} Tc_e \cdot F_e + \sum_{n=1}^{N}\sum_{e=1}^{E}\sum_{d=1}^{D}(Xb_{n,e,d} \cdot Ksc_{n,e,d}) + \\ &\sum_{e=1}^{E}\sum_{m=1}^{M}\sum_{d=1}^{D}(Yb_{e,m,d} \cdot Ksm_{e,m,d}) + \\ &\sum_{n=1}^{N}\sum_{k=1}^{K}\sum_{e=1}^{E}\sum_{m=1}^{M}\sum_{d_1=1}^{D}\sum_{d_2=1}^{D}(X_{n,k,e,m,d_1,d_2} \cdot Kz_{n,k,e,m,d_1 d_2}) \end{aligned} \tag{A1a}$$

$$F2T = \sum_{d=1}^{D} Od_d \cdot (\sum_{n=1}^{N}\sum_{e=1}^{E} Xb_{n,e,d} + \sum_{e=1}^{E}\sum_{m=1}^{M} Yb_{e,m,d}) \tag{A1b}$$

$$\sum_{n=1}^{N}\sum_{e=1}^{E} Xb_{n,e,d} + \sum_{e=1}^{E}\sum_{m=1}^{M} Yb_{e,m,d} \geq R\,min_d \text{ for } d = 1..D \tag{A2}$$

$$\sum_{n=1}^{N}\sum_{e=1}^{E} Xb_{i,s,d} + \sum_{e=1}^{E}\sum_{m=1}^{M} Yb_{e,m,d} \leq R\,max_d \text{ for } d = 1..D \tag{A3}$$

$$\sum_{n=1}^{N}\sum_{e=1}^{E}\sum_{d=1}^{D} Xb_{n,e,d} \geq Min\_F\_C \tag{A4}$$

$$\sum_{e=1}^{E}\sum_{j=1}^{M}\sum_{d=1}^{D} Yb_{e,m,d} \geq Min\_D\_C \tag{A5}$$

$$\sum_{n=1}^{N}\sum_{e=1}^{E}\sum_{d=1}^{D} Xb_{n,e,d} + \sum_{n=1}^{N}\sum_{m=1}^{M}\sum_{d=1}^{D} Yb_{e,m,d} \geq Min\_TU \tag{2}$$

$$\sum_{e=1}^{E} Tc_e \geq Cn \tag{A7}$$

TABLE V.
CALCULATED FIGURES FOR MOOPT

| Symbol | Description |
|---|---|
| $Rmin_d$ | Minimum number of transport units d (CLP – propagation). |
| $Rmax_d$ | Maximum number of transport units d (CLP – propagation). |
| Min_F_C | Minimum number of transport units in the route Factories – Centers (CLP – propagation). |
| Min_D_C | Minimum number of transport units in the route Distributors – Customers (CLP – propagation). |
| Min_TU | Minimum number of transport units (CLP – propagation). |
| Cn | Minimum number of active centers (CLP – propagation). |
| Ksc | The fixed cost of delivery from manufacturer to distributor by using transport mode (CLP-calculated based on fixed data). |
| Ksm | The fixed cost of delivery from distributor to customer by using transport mode (CLP-calculated based on fixed data). |
| Kz | The variable cost of delivery (CLP-calculated based on fixed data). |

TABLE VI.
ADDITIONAL CONSTRAINTS FOR MOOPT

| Constraints | Description |
|---|---|
| A2 | narrowing the size of the transport unit domain from the bottom |
| A3 | narrowing the size of the transport unit domain from the top |

| A5 | the minimum number of all transport unit types necessary for the shipment from the from the center to customers |
| A6 | the minimum number of transport units in routes |
| A7 | the number of working distribution centers |

### *D. Decision support*

Implementation of the presented models using implementation hybrid programming framework can support decision-making in the following practical areas of supply chain (not limited to the following):

- the multi-optimization of total cost of the supply chain (objective functions F1 and F2/ F1' and F2' -Table VII) in the form of the Pareto-optimal solution set (Fig.5.);
- analysis of delivery costs with environmental cost optimization;
- the selection of the transport fleet number, capacity and modes for specific total costs (Fig.6, Fig.8);
- the sizing of distributor warehouses and the study of their impact on the overall costs (objective functions F1' and F2' -Table VII and Fig.7);
- the sizing production capacity and the study of their impact on the overall costs;
- the selection of transport routes for elements of the Pareto-optimal solution set;

## VII. NUMERICAL EXPERIMENTS AND ANALYSIS

In order to verify and evaluate the proposed hybrid approach and implementation platform, many numerical experiments were performed. All the examples relate to the supply chain with seven manufacturers (*n=1..7*), three distributors (*e=1..3*), ten customers (*m=1..10*), three modes of transport (*d=1..3*), and twenty types of products (*k=1..20*). The numerical data were taken from the trans-regional distributor FMCG and transportation fleet parameters available online. Experiments began with four examples of P1 .. P4 for the optimization MOOP model (1) .. (23). The examples differ the number of orders (No). The first series of experiments was designed to show the benefits and advantages of the presented approach. For this purpose the model was implemented in both the hybrid programming framework (MOOPT) and mathematical programming environment (MOOP). In the next stage of the experiments, the objective function was changed (Section 6.A). Its first element F1' refers to the total cost of deliveries whereas F2' defines the distributor's total storage capacity available.

Due to the nature of the optimization problems considered here, a new algorithm based on the ε-constraint method was proposed in the final phases of MP1 and MP2. This algorithm (Appendix A) helped determine a set of Pareto-optimal solutions. The algorithm has been implemented in LINGO by using meta-modeling and programming language LINGO package.

The detailed results for a 20-order example (P4) are shown in Table 7. Figures 5 and 6 show the corresponding sets of Pareto-optimal solutions for a 20-order example. It is evident that only the hybrid approach provides the results within the acceptable time (Table VIIIA and VIIIB).

This is possible owing to the reduction of the problem size and, in particular, transformation of the problem with the use of methods from both environments, MP and CLP. For the illustrative examples discussed here, a 23-fold reduction in the number of constraints (C) was obtained with an over 130-fold reduction in the number of decision variables (V). This gives the size of the combinatorial problem calculated as VxC reduced by more than 2600 times. Comparison of the results (Table 8a and 8b) from the hybrid approach with those from mathematical programming indicates that, first, when the same model and data are used in the classical manner (mathematical programming), the Pareto-optimal solution was obtained only for the smallest example P1 (5 orders). Second, for larger examples P2, P3, P4, it was hardly possible to find at least one point of the Pareto-optimal solution in acceptable time (computing stopped after 600 s). Comparing the proposed approach to modeling and solution in only CLP environment is pointless due to the nature and weak capacity of the CLP relative to the optimization of problems where many variables are added up, which is illustrated in [16].

TABLE VII.
THE DETAILED RESULT FOR EXAMPLE P4 (NO=20)

| PP | F1 | F2 | PP | F1' | F2'=V |
|---|---|---|---|---|---|
| 1 | F1≥26540 | F2=3775 | 1 | F1'=0 | F2'≤0 |
| 2 | F1≥29345 | F2=3725 | 2 | F1'=0 | F2'≤500 |
| 3 | F1≥32150 | F2=3725 | 3 | F1'=0 | F2'≤1000 |
| 4 | F1≥34955 | F2=3655 | 4 | F1'=0 | F2'≤1500 |

## VIII. CONCLUSIONS

This hybrid programming framework is especially significant and suited for multi-objective optimization, where a slightly changed single-objective problem has to be solved multiple times and where the modeling efficiency and ease are essential. The efficiency of the proposed approach is based on the reduction of the combinatorial problem. This means that using the hybrid approach practically for all models of this or a similar class, the same or better solutions are found even up to two hundred times faster (the optimal instead of the feasible solutions). Another element contributing to the high efficiency of the method is a possibility to determine the values or ranges of values for some of the decision variables (predicate CLP2). The presented transformation of the problem (predicate CLP3), characteristic of the problems that have the structure as in Fig. 2, is an important aspect of this approach. It should be emphasized that with this approach it is possible not only to solve optimization problems faster, but also to solve much larger problems than in the [24]. The proposed solution is highly recommended for all types of decision problems in supply chain or for other problems with a similar structure. This structure is characterized by the constraints of many discrete decision variables and their summation. Furthermore, this method can model and solve problems with logical constraints. Therefore the implementations in the form of hybrid platform can be applied to various practical decision problems in the area of logistics, transport, production, scheduling or project management. In addition to the undoubted effectiveness of the proposed declarative hybrid approach, we should underline the possibility of modeling decision problems.

Further work will focus on running the optimization models with non-linear and other logical constraints, uncertainty, fuzzy logic [25] etc., numerical test with hybrid models (HM) and different scheduling problems and resource allocation and activity coordination in the supply chain [26]. It is also planned to implement the framework in the form of cloud applications [28].

***Abstract*—*In this paper we consider a hub location problem in a real multimodal public transportation network. This problem is also known as the park-and-ride problem. Hubs stations are special facilities that serve as switches in such a network. In practice the set of hubs has a strategic importance, because all of the traffic that passes through the network can be controlled by these elements. From the theoretical point of view, the minimal hub problem is NP hard. Two different approaches to this problem are presented. The first group of methods bases on the greedy algorithms. In the second group the evolutionary strategy is used. The computational results for these algorithms proved a significant efficiency, what can be clearly expressed in terms of an input data reduction and also in quality measure values for the obtained solutions of this problem.***

## I. Introduction

LET US consider a real public transportation network. This network can be described as a graph [3], [8], [9]. In this graph, each tram/bus stop corresponds to one vertex and any two vertices are adjacent iff they belong to at least one common public transport line. Hence, the set of vertices along a route forms a connected subgraph of the entire graph. Each vertex in this graph is characterized/labeled by a set of numbers of tram/bus lines passing through it.

In such a graph, a hub set is a subset of vertices, such that any two vertices are connected by a path whose vertices lie in it. Let us define the minimum hub set problem as the problem of finding the hub set of minimal cardinality for a given graph. This collection has a strategic importance for the transportation system, because all the traffic that passes through the network can be controlled by these vertices. Communication hubs are excellent candidates for park-and-ride (P&R, sometimes P+R) points ([4]) with good connections to the center and other parts of the city and this idea is a basis of presented work. This problem is well known and is commonly used in industry, in particular in such areas as transport, telecommunication, and distributed computing [1], [2], [11], [13], [16].

Let us observe that we can try to find the minimum hub set for a given network in two different ways. This problem would be directly reduced to the task of designation the minimum dominating set [6], [14], [15]. Alternatively, we have a possibility of creating a hypergraph, such that its set of vertices is the same as in the original network, and for each set of vertices, which correspond to stops lying along a tram/bus route, we form the hyperedge. In this case, we reduce the considered problem to the search for the minimal transversal in a constructed hypergraph.

## II. Basic mathematical definitions

This section provides some basic notation. A **graph** is a representation of a set of objects, where some pairs of objects are connected by links. The interconnected objects are represented by mathematical abstractions called vertices, and the links that connect some pairs of vertices are called edges. More formally, a **graph** is an ordered pair G=(V, E) comprising a set V of **vertices** or **nodes** together with a set E of **edges**, which are 2-element subsets of V (E is a subset of VxV). An **undirected** graph is the one in which edges have no orientation. The edge (a, b) is then identical to the edge (b, a).

Let N(v)={u ∈ V: (v, u)∈E} be an open **neighborhood** for a given vertex v.

A **dominating set** for a graph G is a subset D of V such that every vertex not in D is adjacent to at least one member of D. This problem is strongly related to a problem well known in computational geometry, the **art gallery problem.** The **domination number** $\gamma(G)$ is the number of vertices in a smallest dominating set for G. The k-**dominating set problem** concerns testing whether $\gamma(G) = k$ for a given graph G and natural number k; it is a classical NP-complete decision problem in computational complexity theory (Garey & Johnson 1979) [3], [8], [9].

**Theorem** (Ore): If G=(V, E) is a graph without isolated vertices, then the complement of a minimal dominating set of G is also a dominating set of G. This implies that every such graph has two disjoint dominating sets and hence, $\gamma(G) \leq ½$ Card(V) [3], [8], [9].

**Theorem** (Arnautov 1974, Payan 1975, Alon 1990) : If G=(V, E) is a graph with minimum degree d > 1, then $\gamma(G) \leq [(1 + \ln(d+1))/(d + 1)]$ Card(V) [3], [8], [9].

978-83-60810-66-8/$25.00©2015, IEEE

An **independent set** is a set of vertices in a graph, such that no two of them are adjacent. The size of such a set is called the **independence number** of G, and is denoted $\alpha(G)$. The problem of finding the set such that $\alpha(G) = k$ is called the k-**independent set problem** and is an NP-complete decision problem. The dominating sets are closely related to independent sets (e.g. the 8-**Queens Problem** Puzzle). Namely, an independent set is also a dominating set if and only if it is a maximal independent set, so any maximal independent set in a graph is necessarily also a minimal dominating set.

A **hypergraph** is a generalization of a graph in which an edge can connect any number of vertices. Formally, a hypergraph H is a pair H=(X,F), where X is a set of elements called **vertices**, and F is a set of non-empty subsets of X called **hyperedges**. Let F be a subset of P(X)\{Ø}, where P(X) is the power set of X and F(x) = {f ∈F: x∈f } for x ∈ X. A hypergraph is also called a **set system** or a family of sets drawn from the universal set X. The **rank** of hypergraph H is the size of the largest hyperedge in H. A **set covering** of a hypergraph H=(X, F) is a subfamily C of F, such that the union of hyperedges from C equals the universe of vertices. A **transversal** (or **hitting set**) of a hypergraph H=(X, F) is a subset T of X that has a nonempty intersection with every edge. The notions of hitting set and set covering are equivalent. The **decision versions** of **hitting set** and **set covering** problems are NP-complete.

For any given graph G=(V, E) with V={1, 2,..., n}, construct a hypergraph H=(X, F) as follows: the universe X is V, and the family of hyperedges F is {F1, F2, ..., Fn} such that Fv consists of the vertex v and all vertices adjacent to v in G. Hence, if D is a dominating set for G, then S={Sv: v∈D} is a feasible solution of the set cover problem, with Card(C)=Card(D). Conversely, if S={Sv: v∈D} is a feasible solution of the set cover problem, then D is a dominating set for G, with Card(D)=Card(C).

The **greedy algorithm** for set covering chooses the sets according to one rule: at each stage, choose the hyperedge that contains the largest number of uncovered elements. This algorithm actually achieves an **approximation ratio** Card(C)/Card(Opt) (Opt – is an optimal set covering) of **h(rank)**, where h(n) is the n-th harmonic number. This value is approximately given by: ***O*((*1*+ *log*(*Card*(*V*)))**. We can construct dual algorithm for hitting set problem for which performance ratio is: ***O*((*1*+ *log*(*Card*(*F*)))**.

**Algorithm 0 – Greedy set covering method**

```
input:   a hypergraph H=(X, F);
output:   a set covering C;
 U := X; C := Ø;
 while( C ≠ X )do{
    select S from F such that maximizes Card(S ∩ U);
    U := U \  S;
    C := C ∪ {S};
  }
return: C;
```

It is interesting that there exists a pair of **polynomial-time reduction** between the **minimum dominating set problem** and the **minimum set covering problem** (Kannan 1992 pp.108–109). These reductions show that an efficient algorithm for the minimum dominating set problem would provide an efficient algorithm for the set cover problem and vice versa. According to the above presented facts, the greedy algorithm provides a factor 1+ log(Card(V)) approximation of a minimum dominating set.

**Algorithm 1 – Greedy hitting set method**

```
input:    a hypergraph H=(X, F);
output:   a hitting set – transversal T;
T := Ø; E := F;
while( E ≠ Ø )do{
   select x from X such that maximizes Card(F(x) ∩ E);
   T := T ∪ {x} ;
   E := E \ F(x);
}
        return: T;
```

Consider another approach to the hitting set problem, I.e. **algorithm 2** (**MSBT**) [12]. It seeks the vertices with the lowest degree and removes them from the set of vertices. If (without a removed vertex) the vertex set is not a transversal, then this vertex should be added to the transversal under construction, and the edges incident with it are eliminated from the hypergraph – they are deemed to be covered.

Yet another method (**algorithm RSBT**) [12] seeks a maximum transversal in the sense of cardinality. Contrary to the MSBT algorithm, the RSBT removes vertices with the biggest degree as long as it can. All the rest is the same as in the MSBT algorithm.

**Algorithm 2 - MSBT**

```
input:     a hypergraph H=(X, F);
output:   a hitting set – transversal T;
T :=  Ø V := X; Q := X; E := F;
while( V ≠  Ø & E ≠  Ø) do
 {      x := vertices with the lowest degree; V := V \ {k};
    if( V is not transversal of hypergraph (Q, E) )
    then {  T := T ∪  {x}; E := E \ F(x); V := V \ { v □ V: F(v) = Ø};}
       else
          for( each edge covers by exact one vertex v )do
              {T := T ∪  {v}; E := E \ F(v) ; V := V \ {v};}
       Q:=V;
 }
```

The algorithms MSBT and RSBT are the algorithms designed by authors as a complement of the Algorithm 1.

Let us consider a **reduction** from the dominating set problem to the set covering problem. For any given graph G=(V, E) with V={1, 2,..., n}, construct a hypergraph H=(X, F) as follows: the universe X is V, and the family of hyperedges F is {F1, F2, ..., Fn} such that Fv consists of the vertex v and all vertices adjacent to v in G. Hence, if D is a dominating set for G, then S={Sv: v∈D} is a feasible solution of the set cover problem, with Card(C)=Card(D). Conversely, if S={Sv: v∈D} is a feasible solution of the set cover problem, then D is a dominating set for G, with Card(D)=Card(C).

According to the above presented facts, the **greedy algorithm** provides a factor 1+ log(Card(V)) approximation of a **minimum dominating set.** Additionally, Raz and Safra (1997) show that **no** algorithm can achieve an approximation factor better than clog((Card(V)) for some c > 0 unless P = NP. Fomin, Gradoni and Kratsch (2009) show an **exact** algorithm which can be used to find a minimum dominating set in time *O*((1.5264)^n) and polynomial space. In parallel, a faster algorithm, using *O*((1.5048)^*n*) time was found by van Rooij, Nederlof and van Dijk (2009).

## III. Evolutionary algorithm

Graph problems such as graph coloring, TSP, graph partitioning, maximum clique search, etc. (**NP-hard optimization problems**) are often solved using computational intelligence methods due to the lack of efficient polynomial algorithms. Among them, the **evolutionary algorithms** (EAs) are often applied; thus, it seems fully justified to use the EA in the present graph transformation problem. The EA approach is quite different than the described earlier hypergraph method. The EA method tries to find hubs, which are strongly connected (in the sense of high capacity of connections – see formula (4)) among them and allow for fast mass travel to the center of the city and other hubs. It is very likely that such hubs are good candidates for the park-and-ride locations.

In our approach, information about the transformed graph is stored in an array of data describing all connections among graph nodes – public communication stops. This array is an adjacency matrix of undirected graph with stored values – weights, denoting the capacities of connections.

The idea of our approach is based on the hub and spoke paradigm. The spokes, which in this case represent public transport stops of minor importance, constitute groups of nodes connected with their hubs. The size of the subgraph of hubs is known in advance. Hubs (should) represent important public transport stops with fast and frequent connections with other important stops and the center of the city.

Algorithm 4. shows how the typical EA work, but this general framework requires several improvements to work efficiently and thus a specialized evolutionary method, developed by authors is used to solve the problem.

To adjust the EA to the solved problem it is necessary to apply proper, problem-specific **encoding** of solutions (sometimes called also population members, individuals or even agents), to develop specialized **genetic operators** tailored for the analysed data structure and the solved problem and, finally, to formulate the problem-dependent **fitness function** to be optimized by the algorithm.

**Algorithm** 4 - **The standard evolutionary algorithm**

```
input:   a given problem;
output:  solution of problem;
{   while( not stop condition )do
        { reproduction and modification
          of solutions using genetic operators;
          valuation of obtained solutions;
          selection of individuals for the next generation;
        }
}
```

The first step to obtain efficient evolutionary method is to choose an appropriate encoding method. It is obvious that there are plenty of possible solutions with different advantages and drawbacks. In presented approach the solution is stored as a vector of selected hubs with lists (or variable length vectors) of attached to them spokes.

An important problem in developing an efficient EA is the design of **genetic operators** for the adopted data structure, taking into account the constraints imposed on solutions. In the case here considered, the standard crossover and mutation operators are not proper, so the problem-specific, specialized operators must be prepared to efficiently solve the problems considered. When one element of a modified solution (for instance one node) is to be moved to another place (e.g. to the cluster of another hub), it must first be checked if it has a connection with this new hub. If not, the operation is canceled to avoid creation of infeasible solutions. Altogether, here, the set of genetic operators is:

- mutation – exchange of randomly chosen nodes in different sets of spokes,
- relocation of a randomly chosen node to a different set of spokes,
- exchange of a randomly selected hub for randomly selected spoke.

Application of several specialized genetic operators requires a method of selecting and executing them in all iterations of the algorithm. In the approach used in [17] it is assumed that an operator that generated good results for some population member should have bigger probability of execution for its possible offspring and more frequently affect them than the remaining operators. But it is very likely that the operator that improves one individual and its descendants may give worse effects for other individuals, because of its location in the domain of possible solutions. Thus, every individual should have its own preferences and could be treated as an agent, whose role is to select and call one of the evolutionary operators (or to perform an action) to obtain improvement of solution (or its income) as high as possible. In the EA here used, every individual has an additional vector of floating point numbers, besides the encoded solution. Each number corresponds to one genetic operator and is a measure of its quality (a quality factor). The higher the factor, the higher the probability of calling and executing the operator. Simple normalization of the vector of quality coefficients turns it into a vector of operator execution probabilities. This set of probabilities is also an expression of experience of every individual and according to the experience gathered one can maximize the chances of its offspring to survive.

The method of computing quality factors is based on **reinforcement learning**. When the selected by the individual-agent $i^{th}$ operator is applied, this can be regarded as an agent performing action $a_i$ leading to a new state $s_i$, which, in this case, is a new solution. The **agent** (or individual, solution or population member) receives reward or penalty depending on the quality of the new state (solution). The aim of the agent is to perform the actions, which give the highest long term discounted cumulative reward $V^*$, maximizing its chances to have offspring in next generations:

$$V^{\Pi}=E_{\Pi}\left(\sum_{k=0}^{\infty}\gamma^k r_{t+k+1}\right) \quad ,(1)$$

$$V^*=\max_{\Pi}\left(V^{\Pi}\right) \quad .(2)$$

The following formula, derived from (1) and (2), is used for evaluation purposes:

$$V(s_{t+1})=V(s_t)+\alpha\left(r_{t+1}+\gamma V^*(s_{t+1})-V(s_t)\right) \quad ,(3)$$

where:

*Π* - the set of possible strategies of the agent,
*V*⏭ - the discounted cumulative reward obtained using strategy *Π*,
*E* - expected value,
*k* - consecutive time steps,
*t* - current time,
$V(s_t)$ - quality factor or discounted cumulative reward,
$V^*(s_{t+1})$ - estimated value of the best quality factor
(in our experiments we take the value attained
by the best operator),
$\alpha$ - the learning factor,
$\gamma$ - the discount factor,
$r_{t+1}$ - reward for the best action, equal to the improvement
of the quality of solution after execution
of the evolutionary operator.

In the here presented experiments, the values of $\alpha$ and $\gamma$ were set to 0.1 and 0.2, respectively.

The **fitness function** in the EA is closely connected with problem specific quality function. The fitness function evaluates the members of the population. It is a modified (scaled, translated, etc.) problem quality function, prepared for computational purposes in the EA. The quality function directs evolutionary computations to obtaining the proper graph structure. In the considered problem the quality function is formulated to direct the EA towards the desired structure of potential P&R, taking into account weights among the graph vertices. Several quality functions can be used, depending on input data (binary, integer or real) or what kind of set of P&R nodes one wants to obtain. The formula presented in this paper was obtained on the basis of experiments. Usually, such formulas contain a penalty part for the potential invalid or improper structure of the obtained solutions.

For the **hub and spoke** structure with the predetermined number of kernel nodes the quality function promotes solutions where a rather small subgraph of hubs is (almost) fully connected and the sets of spokes attached to their hubs have medium sizes:

$$\max Q=\sum_{i=1}^{n}\left(a*\sum_{j=1}^{k_i}w_{ij}+b*w_{iC}+c*\sum_{m=1}^{k-k_i}w_{im}\right) \quad , \qquad (4)$$

where:

$w_{ij}$ – weight between candidate for P&R (hub) and its subgraph
of communication stops (spokes),
$w_{iC}$ – weight between candidate for P&R (hub) and
the center of the city[1],
$w_{im}$ – weight between candidate for P&R (hub)
and remaining communication stops,
*n* – predetermined (constant) number of hubs (candidates for P&R)
in the solution,
$k_i$ – number of nodes attached to $i^{th}$ hub,
*k* – number of nodes in the whole graph,
*a, b, c* – non-negative constants values that emphasize the influence
of corresponding factor.

## IV. Data base & computational environment

For the computational experiments a set of data files was obtained from the **www page**: http://www.ztm.waw.pl/. The description of the structure of public transport in Warsaw and full list of bus, subway and tramway stops and all lines of these means of transport are collected in the data files. The data include more than 5600 stops, but the majority of them are stops located not far from each other, with the same names but different minor numbers (like Centrum 01, Centrum 02,...), which indicate the opposite direction or different transport mean or extensions for bigger numbers of vehicles boarding passengers simultaneously. Thus, first the stops were aggregated: all of them with the same names and different minor numbers were treated as one. This allowed to reduce the size of the communication network to 1883 stops.

We prepared computation experiments for this article based on typical **personal computer** (with an Intel i5 4 x3.2 GHz microprocessor) running Linux OS. All our programs were written in the C language and compiled with the g++ compiler application.

## V. Data reduction

At the second step, some preliminary computations for the considered data allowed to reduce the size of the problem even more. This **preprocessing** was oriented to **reduce** input data (filtering method). We can treat the graph G as a representation of Warsaw **transportation network** being an input data for our programs.

Looking at this graph one can observe that it is possible to remove some of the redundant edges. It is clear that if two vertices, a and b, are **adjacent** in G and the sets of bus/subway/tram lines passing through them are the same, then we can apply the edge (a, b) contraction operation. An **edge contraction** is an operation which **removes** an edge from a graph while simultaneously **merging** the two vertices that it previously joined. More precisely, the edge (a, b) is removed and its two incident vertices, a and b, are merged into a new vertex c, where the edges incident to c correspond to edges incident to either a or b. Obviously, it is possible to apply these contraction operations several times, in polynomial time. After executing this procedure an obtained graph consists of 1003 vertices (reduction of 880 vertices).

## VI. The results of presented approaches

Given the above, we can try to find the **minimum hub set** for the given network by applying the presented algorithms.

[1] We decided to emphasize a central communication stop in the city as a virtual aim of the majority of commuters.

At the beginning we construct a hypergraph, such that its set of vertices is the same as it is in the input network. Let for each set of vertices, which correspond to stops lying along a tram/bus route, form a hyperedge. In this case, we **reduce** the problem considered to the **minimal transversal** construction for this hypergraph. Therefore, two different approaches are possible - deterministic and random:

(**a**) application of **greedy methods**
(in different versions);

(**b**) use of **evolutionary algorithms.**

In order to compare these methods we also made computations with and without the preliminary reduction. In the first approach **(greedy method),** algorithm 2 found 35 vertices. The **RSBT** found smaller transversal – 140 vertices instead of 152 vertices found without the reduction. Considering the obtained results it looks like the reduction could be used for the EA approach. There was no change as to the result obtained in the evolutionary algorithm, but there was a significant reduction of time needed for computation.

Due to a smaller graph of public communication stops considered each iteration of EA last significantly shorter, while the number of them remained unchanged. For the greedy method the time of computation is very short (less than 1 s.) with and without the reduction, thus it is no use to compare them with EA and with or without the reduction.

TABLE 1.
COMPUTATIONAL RESULTS

| Number of hubs | Time of 10 000 EA iterations (average of 10 trials) | |
|---|---|---|
| | Before reduction | After reduction |
| 50 | 5 854 s | 2 478 s |
| 100 | 13 433 s | 5 895 s |
| 152 | 27 231 s | 14 256 s |

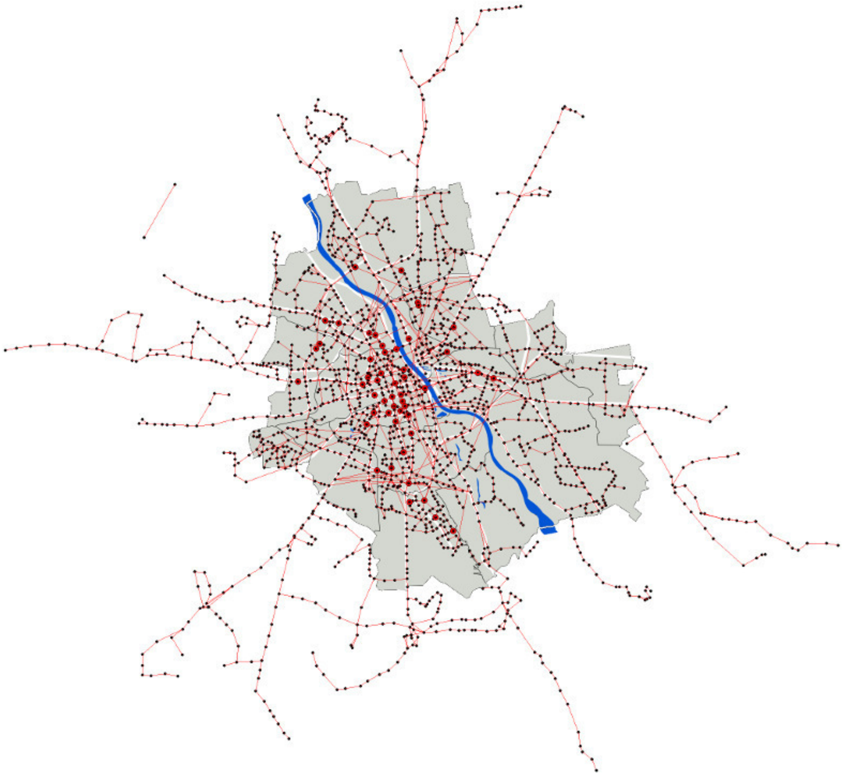

**Figure 1**: Result obtained by the EA with the imposed number of 50 hubs

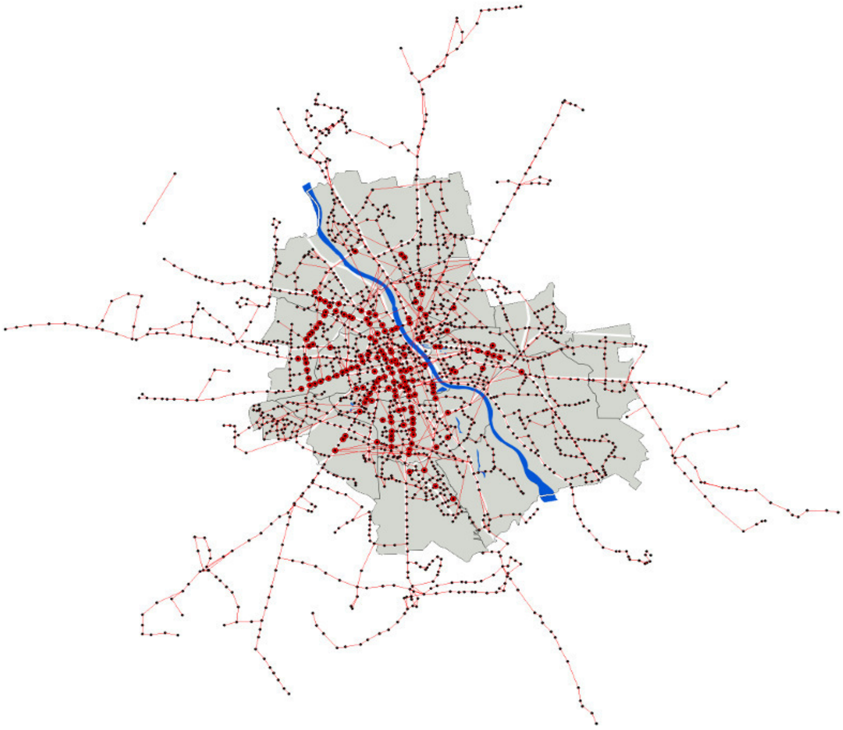

**Figure 2**: Result obtained by the EA with the imposed number of 152 hubs

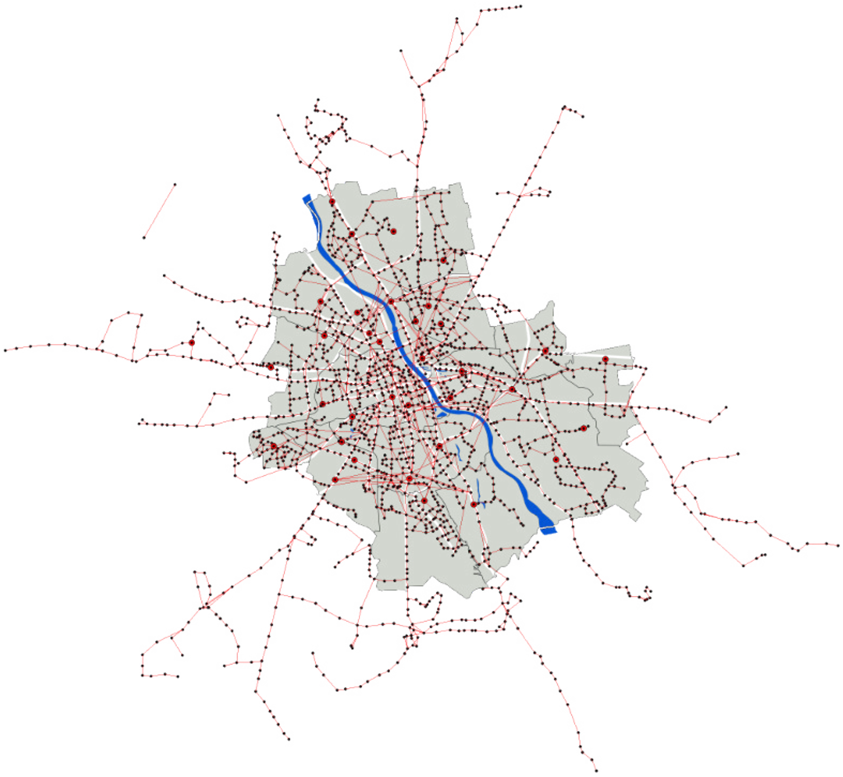

**Figure 3**: Result obtained by the MSBT algorithm - 35 points selected

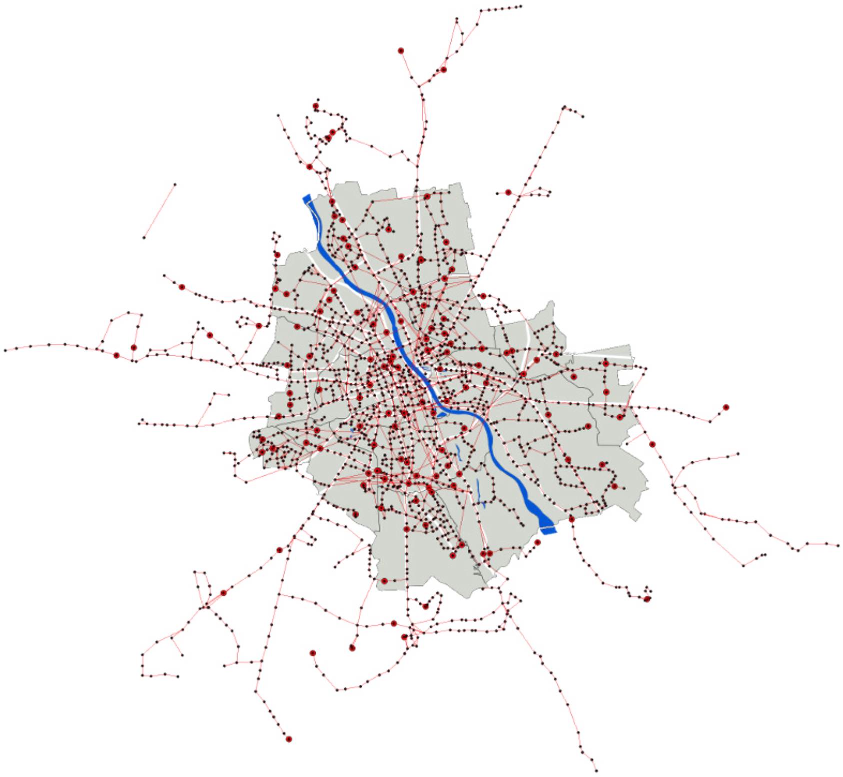

**Figure 4**: Result obtained by the RSBT algorithm - 140 points selected

## VII. Conclusions

This article is devoted to the problem of locating hubs in a public transportation network. Two different approaches to this problem are presented. Namely, the first group of considered methods are based on greedy strategies, and the second group, using evolutionary strategy. In the computational experiments the model of the transportation network of Warsaw was analysed. The obtained results showed for this model the potential P&R set of 34 stations using the MSBT greedy method and of 140 potential points using the RSBT greedy method. Using the EA with imposed number of hubs, satisfactory solutions for 50, 100 and 152 predetermined numbers of candidates were obtained. Additionally, it must be concluded that the graph reduction could be used especially for the evolutionary approach as a filtration method significantly reducing the size of the solved problem. Almost always the preliminary reduction of the stop number speed up the computational process by about 46%. According to the quality of solutions obtained with and without the preliminary reduction it appears that the use of the proposed preprocessing method seems to be justified.

This work is the first step towards obtaining a more complete model of communication in Warsaw, which would be a base to find and project communication hubs with proper places for P&R facilities.

# 21$^{th}$ Conference on Knowledge Acquisition and Management

KNOWLEDGE management is a large multidisciplinary field having its roots in Management and Artificial Intelligence. Activity of an extended organization should be supported by an organized and optimized flow of knowledge to effectively help all participants in their work.

We have the pleasure to invite you to contribute to and to participate in the conference "Knowledge Acquisition and Management". The predecessor of the KAM conference has been organized for the first time in 1992, as a venue for scientists and practitioners to address different aspects of usage of advanced information technologies in management, with focus on intelligent techniques and knowledge management. In 2003 the conference changed somewhat its focus and was organized for the first under its current name. Furthermore, the KAM conference became an international event, with participants from around the world. In 2012 we've joined to Federated Conference on Computer Science and Systems becoming one of the oldest event.

The aim of this event is to create possibility of presenting and discussing approaches, techniques and tools in the knowledge acquisition and other knowledge management areas with focus on contribution of artificial intelligence for improvement of human-machine intelligence and face the challenges of this century. We expect that the conference&workshop will enable exchange of information and experiences, and delve into current trends of methodological, technological and implementation aspects of knowledge management processes.

## Topics

The following group topics, concerning both theory and applications, will be included (unavoidably incomplete):

- Knowledge discovery from databases and data warehouses
- Methods and tools for knowledge acquisition
- New emerging technologies for management
- Organizing the knowledge centers and knowledge distribution
- Knowledge creation and validation
- Knowledge dynamics and machine learning
- Distance learning and knowledge sharing
- Knowledge representation models
- Management of enterprise knowledge versus personal knowledge
- Knowledge managers and workers
- Knowledge coaching and diffusion
- Knowledge engineering and software engineering
- Managerial knowledge evolution with focus on managing of best practice and cooperative activities
- Knowledge grid and social networks
- Knowledge management for design, innovation and eco-innovation process
- Business Intelligence environment for supporting knowledge management
- Knowledge management in virtual advisors and training
- Management of the innovation and eco-innovation process
- Human-machine interfaces and knowledge visualization

# What technology for efficient support of sustainable development?

Eunika Mercier-Laurent
University Jean Moulin, Lyon 3
Lyon, France
eunika.mercier-larent@univ-lyon3.fr

*Abstract*—**Sustainable development is among the greatest challenges of this century. Sustainability and development are apparently opposite. The traditional approaches try to manage the planet protection without taking the best from technology while eco-innovation focus mainly on smart transportation, smart use of energy and water and waste recycling. Many new concepts such as Smart, Intelligent, Green or Wise City were invented to promote … old technology. All these initiatives use data bases and machine to machine communication. The AI approaches and techniques may be very useful not only for process optimization but also for simulation before doing and education of new behaviors. This talk will present the principal advantages of using AI for balancing planet protection and technological progress.**

*Index Terms*—**Sustainable develoment, Intelligent technology, e-co-innovation, knowledge.**

## I. Introduction

TECHNOLOGICAL progress is considered as a powerful engine of economy but, despite partial recycling, it generates a lot of waste and contributes to climatic changes. Computers and smartphones are quickly out of date; new software versions are available only on new devices. Most of these devices are not eco-designed.

The quickly growing population of the cities represents a lot to feed it is also a huge global market facilitated by communication technology, e-business, and transportation means. Google business model based on advertisements generates intellectual and visual pollution and is an important theft of time – time to find how to close the advertisement window or 30 seconds if this facility is not provided. The mass media promotes the “to have more and to show” mentality, through advertisements and various entertainment programs. “Buy more, throw away and buy new” are the engines of today business. Opening to business and quick development of China and other Asian and South American countries offering the low labor cost increases the relocation-out from origin countries, mainly US and Europe, in search of quick business – in aim to offer more for less and increase the firms’ income. This way of doing increases also pollution in developing countries and the unemployment in Europe and other developed countries. Besides, we have to recycle products, often of poor quality, made somewhere else and travelling around the world by ships and airplanes.

Innovation is among contributors to planet disaster, because the inventors and designers think about functionality, shape, look and attractiveness and not about the overall behavior inside the environment. Business people want to sell more; nowadays a global market is addressed without thinking about the right values and right benefits.

The eco-innovation movement claims to generate new businesses and jobs but the use of technology in the related activities is moderate. Corporate Social Responsibility aims to balance environmental, economic and social impacts with a little use of traditional technology. Based mainly on norms, it aims in having an impact on products design via Product Lifecycle Management (PLM) software. Intelligent technology has a significant role to play in balancing all these components. A condition however is a capacity of different thinking and managing all available knowledge and experience that apply.

After describing main trends some perspective will be given on another way of doing and the role of intelligent technology in the transformation of society.

## II. From sustainability to sustainable development

In biological systems sustainability means long life. Systems components influence each other and the balance of the whole system is the condition to survive. Human activities have affected the balance of natural ecosystems [4, 5, 6].

Sustainable development is a principle that many people claim to have invented. The definition of the European Union is following:

“Sustainable Development stands for meeting the needs of present generations without jeopardizing the ability of futures generations to meet their own needs – in other words, a better quality of life for everyone, now and for generations to come. It offers a vision of progress that integrates immediate and longer-term objectives, local and global action, and regards social, economic and environmental issues as inseparable and interdependent components of human progress.”

“Sustainable development will not be brought about by policies only: it must be taken up by society at large as a principle guiding the many choices each citizen makes every day, as well as the big political and economic decisions that have to be taken. This requires profound changes in thinking, in economic and social structures and in consumption and production patterns”[2].

Sustainable development can be seen as a process for meeting human development goals while maintaining the ability of natural systems to provide the required natural resources and ecosystem services upon which the current

978-83-60810-66-8/$25.00©2015, IEEE

economy and society depend. The greedy economic system is not compatible with sustainable development. In this context sustainable development is oxymora – it is impossible to be sustainable without deep understanding of our natural ecosystems (multidisciplinary knowledge) and without radical change of behaviours, objectives, values, political and economic system. Sustainable development is an attitude to learn and cultivate.

Various actions aiming in changing the way of acting and doing things are engaged, mainly by individuals and organizations. Many of them are supported by social networks and have potential to influence behaviours. For example, Uber platform (and some others) connects people offering services with those who need them. It is quick and effective, but out of the current economic practices (taxes, companies…) and raise conflicts between “old” and “new”. Serious games try to push people to act [7].

Introducing the environmental principles into a design of products and services is a step forward. However the traditional PLM tools should evolve to take into consideration a new way of doing [8] by using simulators and optimizers. Technology is able to provide a considerable help, but the way of thinking should evolve to global, holistic and system [9]. For example, aeronautic and automotive industries focus on lightening weight and reducing carbon footprint, while other aspects can also be considered.

Corporate Social Responsibility requires the integration of environmental aspects into design. While it constraints companies to take care about social and environmental impact, they should also focus on economic performance. Environmental norms (ISO 26000) are very heavy; it is impossible for a small company to check and respect all these norms without loosing business. The intelligent technology can help checking and optimizing things; such systems are prototyped [12].

To remain sustainable, development requires the intensive use of available knowledge – individual and collective, from related domains, from the past and currently gained from experience.

## III. From eco-innovation to e-co-innovation

According to European Union [3] there are many fields and activities concerned, such as air, chemicals, green public procurement, industry, marine and coast, biodiversity, noise, soil, urban development, waste and water. The areas that should be greened are agriculture, employment, energy, fisheries, research, trade, transport…All are potential source of growth and job creation. But in existing system and with current goals, attitudes and practices, it can not work as expected. The greedy economic system aims in producing and selling more. The industrial giants impose their products and absorb competitors.

Circular economy is promoted by some wise economists and recently by European Union: “This means re-using, repairing, refurbishing and recycling existing materials and products. What used to be regarded as ‘waste’ can be turned into a resource. The aim is to look beyond waste and to close the loop of the circular economy. All resources need to be managed more efficiently throughout their life cycle” [16]. How they face the current practices of planned and perceived obsolescence [17]?

Circular economy is just new business concept, but nothing new – it has been practice in Poland in the 1950s and it is still practiced in poor countries. Despite generating activities, recycling uses the energy and generates pollution in many cases. Repairing involves education of new know how and another design, that should be encouraged – those of modular and reparable and reusable products (back to the 1950). AI approaches and techniques are very well suites to do that.

Another approach, connecting the best from technology and the best human capacity is those of e-co-innovation, considering all components, see Figure 1.

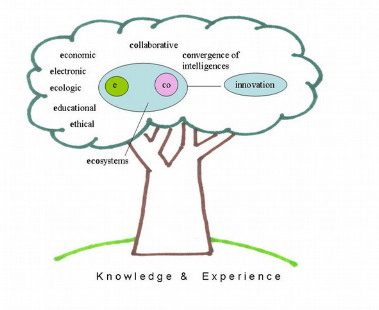

Fig. 1. e-co-innovation principles [9]

E-co-innovation is based on past and present knowledge as well as on a vision for the future. Its facets are ecological, economic, educational, electronic and ethical. It is collaborative and enables a convergence of intelligences. Inspired by nature, respecting natural and digital ecosystems it is centered on humans; such dynamics will certainly contribute to avoiding unbalance and a loss of competitiveness leading to economic, ecological and social decline.

## IV. Contribution of AI – example of wise city

The recent trends of Smart City, Intelligent City, Green and recently Wise City aim in providing services to citizens of becoming bigger and bigger cities. Actually, the population of cities is growing for different reasons, among them job offer, access to services, culture, immigration…This kind of initiatives is based on linear approximation that in 2050 70% of world population will be living in the Megapoles. The other factor is the ambition of politics to grow their territory. As consequence regional economy collapses in many cases and should be reinvented using local talents and resources.

The concept of Smart City was probably born in early 2000s. In aim to reboost their existing technology IBM changed in 2010 a slogan to Smarter Planet. Cisco as network provider is also involved. Intelligent City tries to be different and defines integrated model of intelligent economy, transportation, environment, governance and services for citizens [13]. The city of Nice (French Riviera) runs annually a conference on Innovative City [14]. Growing cities want to offer well being to citizens by initiating Green City which main interest is in architecture, gardening and social cohesion [15].

Among the lastest trends the Wise City of Hong Kong brings together large companies: Schneider Electric, Alstom, Veolia, Thales and KPMG, no room for small ones. KPMG claim to be integrator of all offers. They focus on improvement of living conditions: pollution, access to clean water, waste treatment…Hong Kong with over 7 million of habitants produces 15,000 tones of waste daily and uses 60% more water than New York. Buildings are heavy consumers and air pollution is 53% local.

The Figure 2 gives some details on main project components which are: smart energy, smart mobility, smart water, smart public services, smart buildings, smart data centers and smart integration. Public services offer seems very poor. We can notice that the offers for energy and water are a part of smart buildings. Data Center is certainly related to city management and we hope there is only one for all applications proposed by partners.

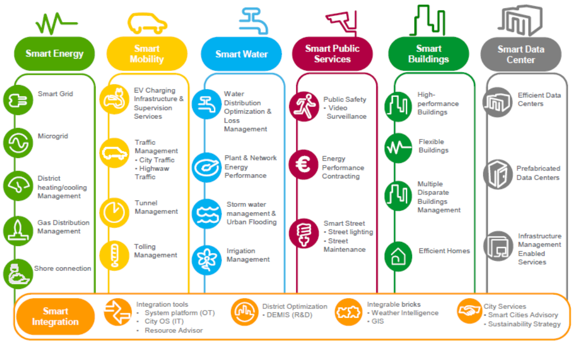

Fig. 2. Principal components of Wise City (source Schneider Electric, 2012)

Waste processing is not shown in this figure, because it is managed by another company. Such a separation generates more business for each company. They do not try to build an optimal (and cheaper) solution for the city in function of their needs; they just adapt their respective offers. The analysis of current situation and real needs is not published.

### A. *What could be done*

The Digital Agenda for Europe [15] points out the links between domains: "Information and Communication Technologies (ICTs) enable us to see the connections between seemingly disparate issues, like transport and energy or health and economic growth, and help us find comprehensive solutions, for example in the European Innovation Partnerships on Smart Cities and Communities and on Active and Healthy ageing" [15]. Such thinking is vital for building integrated and reusable solutions.

"Sensors and embedded software make objects increasingly interactive. Computer simulation makes a direct contribution to sustainability issues, particularly with regard to environmental protection, the scarcity of raw materials, and the emergence of a low-carbon economy. Smart city ambition is offering their inhabitants increased comfort, employment and economic development."

Since over 50 years now Artificial Intelligence developed methods and techniques that are now embedded in many decision support systems, diagnostic and simulation tools, educational software, innovative electronic commerce, data, text and image mining tools, creativity "amplifiers", robots and drones.

Combination of Knowledge Management method and Artificial Intelligence techniques are available to guide and enhance the architecture of an adapted, innovative and reusable system for city management. The comprehension and common discovery of needs may help innovating the both city and involved companies. Implication of local people (citizens and companies), sharing their talents, knowledge and experience may be beneficial for all. Knowledge base of experience of smart cities around the word will avoid the waste on energy and money for developing again and again the similar and not connected data bases.

New attitudes can be influenced via peaceful and knowledgeable games such as intelligent purchase for less waste, reusing the packaging, intelligent use of water and energy, avoiding or combining the transportations and other are a part of fun learning for all. Behind there is strategy, problem solving, thinking and multisystem agents.

While robots were conceived to copy human intelligence there are some useful robots designed to help human as industrial or surgery robots, those able to diagnostic and fix complex equipments in places difficult or dangerous to access, such as control and monitoring cabinets, nuclear power plants or high voltage stations.

Despite of available technology for distance meetings the number of people travelling is still growing. Optimization techniques such as constraint programming are helpful for optimizing travel. However air transportation companies have their own hub and an intelligent optimizer of travels is still missing. The available "optimizers" such as kayak, sky scanner and others works for their clients and not for travelers.

Smart cities open their data and wish to make business on it. Data is as raw materials, but intelligent access to relevant information allows the large-scale dissemination, analysis and use of data for the benefit of consumers and citizens. Analytics are mainly used to find information in large amount of data. The AI techniques of knowledge discovery, such as neural networks, genetic algorithms, induction or other multi-strategy machine learning hybrid tools are available but underused.

Offering the targeted services, corresponding to the real user's needs could be a great value. The effective matching of offer and demand in many domains saves our time and help in capturing opportunities. Smartphones and future devices embedded with machine learning techniques shall learn from real-time interaction with the user and not from navigation (too many errors) or published profile only.

## V. Conclusion and Future Work

Only few examples of what can be done on city level were presented here. The main rule is to apply suitable knowledge management approach, involve the end users from the beginning and use the best adapted techniques. The principle of modularity, reusability and genericity is still valuable for defining and building an effective and replicable system that really support city management and offer expected services to citizens, organizations and companies being a part of the city (holistic approach).

The evaluation of the impact of city activities may lead to right metrics for measuring progress and leadership. However the balance between the use of technology and human capacity should be preserved. Technology producers have tendency to produce software and devices that think instead of the human and take decisions for him/her. This kind of applications may replace human at the long run and reduce his cognitive capacity. That's why we have to produce the applications that enhance human intelligence without switching it off.

The future work is about evaluating 6D impact (technological, environmental, economic, social, cultural and cognitive) of technology.

Email: marcin.amarowicz@polsl.pl

*Abstract*—**The paper deals with the problem of designing diagnostic systems for technical objects such as power plant, machining etc. The new approach for this problem that is based on the methodology that are used in the design of machines and some aspects of requirement engineering that derived from the software area is considered in the article. In general case the requirements may be used to formalized notation of the project need, that described the designed diagnostic systems. The evaluation of gathered set of requirements may be done by using the specialized expert systems, that may be developed as part of proposed approach. The whole process related to gathering, writing and evaluation of requirements for the purpose of designing diagnostic system is presented in the article.**

## I. Introduction

DURING the operation of technical objects, exists the danger of occurrence various kinds of events, usually summary called as faults, that may have the negative consequences to the considered technical object and its immediate vicinity. These faults may be caused by different factors including the constructional errors committed during the design process, production errors associated with inaccuracy of technological processes, operational errors related to noncompliance with the prescribed terms of operation of the object and obsolescence errors that are the results of natural changes of object's state e.g. decreasing of strength etc., [15]. Probability of occurrence of particular faults and their consequences are interpreted as technical risk associated with the operated object. From the mathematical point of view, the technical risk may be written as:

$$R_i = P_i \cdot c_i, \tag{1}$$

where $P_i$ is the probability of occurrence of $i$-th fault and $c_i$ is the possible costs/consequences connected with the occurrence of this fault. In order to ensure the proper operation of a technical object it is necessary to minimize the technical risk. This can be achieved by diagnose the current technical state of the considered object. This process can be perform by using the diagnostic system that is designed specially for this object.

In technical diagnostics area it is assumed, that the technical state of an object is a function of faults [10]. Therefore, in order to correctly determine the state of the object it is necessary to detect particular faults. Process of their detection is performed based on available information about the existing relationships between the value of selected signals, recorded on considered technical object, and the possible faults. The occurrence of specific values of signal, values of several signals or e.g. values of selected features of these signals (e.g. medium, standard deviation etc.) is called a symptom of this fault. In the simplest case, the information about the exceeded of permissible value of some signal (e.g. exceeding the permissible rms value of vibration signal in the bearing node) could be the symptom of the fault [13].

In the structure of typical diagnostic systems, the two parts, the measurement and the software one can be distinguished [3]. The main purpose of the measurement part is to record the value of selected signals and save them, according to the assumed scheme, in the database e.g. in OPC servers. The software part of diagnostic system is responsible for the appropriate detection of faults. It consists of analysis of recorded signals, including the designation of the necessary features of these signals, and the inference about the technical state of the object. In many cases, this process is carried out by using advanced computational algorithms including the artificial intelligence methods. The results of performed analysis are presented (depending on the class of the diagnostic system) through various techniques e.g. sound and light alarms, synoptic screens, sms and email notifications etc.

The purpose of this article is to present the new approach to the designing of the diagnostic systems. This approach will be based on general methodology that are used in the design of machines and the introduction to it a some modifications. They are necessary because the specificity of the field which is the technical diagnostics must be taken into account [1], [2].

## II. Diagnostic systems design method

In general case the process of design machines is a multistage. It begins from the definition of the need. At the general level of detail it expresses the expectations that should be met by the developed technical object. It is important to note, that the need cannot impose any restrictions and itself cannot define any potential solutions. In the next stage, with using various techniques such as brainstorming, teamwork, morphological table etc., the set of possible solutions is generated. After appropriate analysis and evaluation, the optimal solution is selected from this set. This one best meets the evaluation criteria and housed in imposed or adopted project limitations [7].

978-83-60810-66-8/$25.00©2015, IEEE

Taking into account that the need to develop a diagnostic system is the main project's need, it may be seen that the direct use of this approach to the design of diagnostic systems, encounters to the some problems at the stage of development possible solutions of this system. This is due to the necessity to take into account the wide knowledge about technical object, the ways of its diagnosis (methods of measurement, signal analysis etc.), accepted limitations etc., [5]. For this reason, it is not possible to define the set of potential solutions of the diagnostic system directly from the defined need. This problem can be solved by using an additional project's stage, during which the formalized description of the need is prepared. Due to the fact that the diagnostic system contains the software part that is responsible for analyzing of the signals and inference about object state, it seems reasonable to use certain design techniques that are directly derived from the software engineering area. The sets of requirements that describe the expected functionality of the designed systems are one of them.

In the process of designing the diagnostic systems requirements can be used to formalize the notation of the project's need. Within the defined need, some characteristic functionalities that are necessary from the diagnostic system point of view may be extracted. These functionalities can be accurately characterized by applying the requirements with the hierarchical structure. Stored in such way the need, would be better expressed/described expectations about the potential diagnostic system solutions, because it will take into consideration the specificity of the field which is the technical diagnostics and the characteristics of the technical object for which there is a need to develop a diagnostic system. Based on such formalized need it is possible to develop/generate a set of possible solutions of the diagnostic system. In the next stage of the design process, these solutions will be evaluated on the basis of the set of established criteria, wherein these criteria may be defined/derived from a set of defined requirements.

Individual requirements may be defined based on the available diagnostic and operation knowledge, knowledge about the considered technical object etc. An important advantage of the use of requirements in the design process is the ability to define the individual requirements by independent persons, so-called domain experts. This is particularly important in the area of technical diagnostics, due to the fact that the modern technical objects are very often complicated and the design the diagnostic system by the small group of people may be very difficult.

## III. Requirement engineering

In literature, there are available many different definitions of the term requirement e.g. in [12], [16] or [17]. For the purpose of presented studies, the following statement may be assumed: *Requirement is a formalized description of function/atributte, that designed object should realize/meet.* Just as in the literature exist many definition of the term requirement, the different divisions and classifications of requirements exist also. However, two groups of requirements i.e. functional and nonfunctional requirements are usually distinguished. Functional requirements describe the basic functions of the system, i.e. the way in which the system operates, colloquially what the system should to do. This, how the particular functions of the system should be implemented is described by the nonfunctional requirements. Very often there are also called as a quality requirements due to the fact that they describe the operation of the system (implementation of particular functional requirements) from the quality point of view. Repeatedly, an overall evaluation of the developed system and the recognition that the system has been developed according to the assumptions depend from them [12], [16].

Generation of the set of possible solutions
Criteria
Selection of optimal solution

Fig. 1. Scheme of the proposed diagnostic systems design process

## IV. Notation of the set of requirements

The use of requirements for the purpose of formalized description of the need, requires the introduction some additional assumptions, that are not seen in the software engineering area. These assumptions are connected with the necessity of adoption of a specific manner of notation of defined requirements. This notation is caused by the specific properties of the area that is the technical diagnostics. Namely, the detection of individual faults is considered as the major functionality of the diagnostic system. In order to achieve this task, certain diagnostic rules (symptoms of faults) should be applied. Each diagnostic rule may be realized with using some measurement methods e.g. measurement and analysis of temperature, vibration measurement etc., which include various types of sensors, measurement cards etc. All of these elements must be saved as a component of the established definition of the requirement.

Taking into account the mentioned remarks, each functional requirements $req_i$ may be recorded as

$$req_i =< c_r, attr_r, pf_r, drule >, \qquad (2)$$

where:
$c_r$ – content of requirement, $attr_r$ – attributes of requirement, $pf_r$ – preference factor, $drule$ – diagnostic rule.
The content of the requirement is the description of the functionality of the diagnostic system. It is related with the necessity of detection on specific fault e.g. *The necessity to*

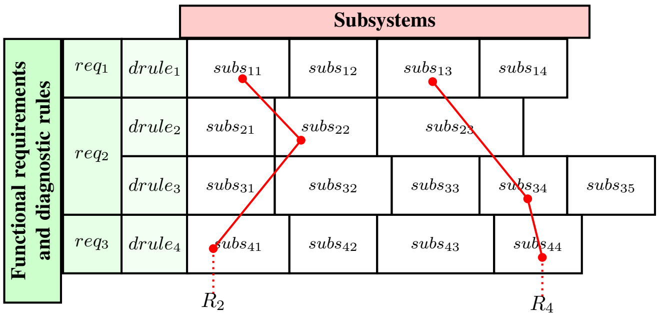

Fig. 2. Morphological table with the set of possible solutions of diagnostic system project

*detect breakage of the gear tooth*. For each requirement it is possible to assignment some set of attributes,

$$attr_r = \{attr_{r1}, attr_{r2}, ...\}, \tag{3}$$

which are used to detail the description of this requirement and are the basis for evaluating the usability of the functionality which are described by this requirement. *Level of reduction the probability of fault occurrence described by the requirement*, or *level of reduction of costs associated with the occurrence of this fault* may the examples of these attributes. For each functional requirement, is possible to assign some value from the range $< 0; 1 >$, called the degree of preference. It expresses the need to take into account this requirement in the final solution of the diagnostic system. Preference factor may be considered as a subjective assessment of the suitability of the given requirement to the achieve by the diagnostic system the established goal, which is the minimization of technical risk. For each functional requirement is possible to define the set of possible diagnostic rules:

$$drule = \{drule_1, drule_2, ...\}, \tag{4}$$

which are used to detect the specific fault. Each diagnostic rule is expressed as:

$$drule_i =< c_{dr}, attr_{dr}, pf_{dr}, subs, ko > . \tag{5}$$

Scheme of marks is similar like in the case of requirements. So $c_{dr}$ is a verbal description of the rule, e.g. *exceeded the root mean square value of vibration signal*, $attr_{dr}$ is a set of possible attributes, that may be used to accurately describe each of the rule e.g. *level of the false alarms*, and $pf_{dr}$ is a degree of preference assigned to each rule. Each of the diagnostic rules may be fulfilled by using different measurement systems, for the purpose of this study, called subsystems. Each subsystem $subs_i$ may be expressed as:

$$subs_i =< elem, attr_s, pf_s >, \tag{6}$$

where:
$elem$ – subsystem elements, $atrr_s$ – attributes of subsystems, $pf_s$ – preference factor.
Each element of subsystem may be considered as:

$$elem_i =< elem_{type}, elem_{value}, attr >, \tag{7}$$

where $elem_{type}$ is a type of element, e.g. relative vibration sensor, measurement card (DAQ card) etc. and $elem_{value}$ is a possible items of the specific element type, that is, e.g. specific sensors from catalogues of certain producent. These elements may be described by numerous attributes $attr$ e.g. measurement range, sensitivity, cost etc. For the purpose of limiting the applicability of the selected elements included in the subsystems, it is possible to define a set of limiting criteria $ko$ that are assigned to each diagnostic rules $drule_i$. Diagnostic rules and subsystems assigned to them may be regarded as non-functional requirements defined for selected functional requirements, that describe the necessity to detection of individual faults.

Requirements (i.e. hierarchically saved elements $req_i$, $drule_i$ and $subs_i$), that are gathered by using the proposed method, describe in the formalized manner the project's need. Based on this formalized need, it is possible to generate the set of possible solutions of the diagnostic system. To perform this operation it is necessary to use the catalog of possible elements that are the part of subsystems $subs_i$, and take into account the limiting criteria. In this way, for the defined combination of functional requirement - diagnostic rule, is generated a set of possible subsystems. These three elements i.e. functional requirement, diagnostic rule and subsystem are the component of the project of the diagnostic system. Morphological table [18] (see example in Fig. 2) may be used for easier presentation the set of possible solutions of this diagnostic system.

In order to use the proposed method of formalization of project's need, it is necessary to answer on two fundamental questions. First of all, how to acquire the necessary set of requirements. And the second, how to evaluate the generated set of possible solutions so as to choose the optimal solution. The answer to these two questions is contained in two successive chapters.

## V. Requirements acquisition

The process of gathering the requirements for the purpose of design diagnostic system is not an easy task. As in the software engineering area [12], [16], it depends on many factors, including the availability of knowledge about the possible faults of object, methods of their diagnosis etc., [5]. The process of obtaining the relevant requirements, should therefore be adaptive aided by using different kinds of knowledge banks, catalogues of elements, etc. In general case, for each technical object it is possible to develop a so-called catalog of hazardous events, which includes the possible faults of its individual components. For individual fault, it is possible to estimate the risk (probability/frequency of occurrence of the event, the potential costs of the consequences of this event) associated with their occurrence. Based on this set of faults, it is possible to define the set of diagnostic rules, that include typical symptoms of individual faults. For the purpose of describing the subsystems that are used to provide various diagnostic rules, it is possible to create a catalog of elements in the form of pairs: element type - a list of elements.

Using data banks prepared in this way, is possible to perform the process of requirements acquisition, that assumes the defining of following elements that are included in the definition of requirements, in hierarchical order, i.e. functional requirement, diagnostic rule and subsystem, whereby during this stage, it is possible to use the pre-defined knowledge banks. It is assumed that, depending on the needs and the technical possibilities (see Sec. VII) for individual objects may be assigned different attributes. These attributes are the basis for assessment of the suitability of individual requirements, and also allow to generate a set of possible solutions of the diagnostic system. Additionally, it is assumed that during the stage of defining the diagnostic rules, it is possible to define the limits (limiting criteria) that must be met by the subsystems used to implement the specific diagnostic rule. However, the limiting criteria must refer to the attributes assigned to individual elements.

An important advantage of using this approach is the possibility of a separate preparation knowledge banks and acquiring the set of requirements. Both of these stages can be performed not only independently, but also by different persons, such as domain experts. The entire process of obtaining requirements can be further simplified by making the decomposition of the technical object and define the requirements for such separate components.

## VI. Requirements evaluation

In the software engineering area the process of evaluation of obtained requirements takes many forms. However, it usually amounts to the negotiation between the customer that order the project and its potential developer. Each of them articulate own needs and expectations. After a series of conversations, they together agree a final set of established requirements [8]. This approach, due to the several factors cannot directly be used in the case of designing the diagnostic systems. The first of them is the lack of explicit customer for the requirements negotiation process. A person who contracts or expresses the need to perform diagnostic system in many cases not have complete knowledge about the considered technical object. Therefore, this person will not be able to correctly assess the whole set of requirements. Additionally, in many cases the knowledge about technical object, particularly the knowledge about the manner of its diagnosis may not be fully accessible and good quality. So, it is necessary to apply a some software system, that will be support the process of evaluation of requirements based on the collected data. This system may be treated as a virtual customer, that represents the technical object and articulates the necessary requirements.

The overall objective of the stage of the requirements evaluation, is to determine the answer for two fundamental questions, namely:

- what should be the functionalities of the diagnostic system, i.e. which faults should be detected by the diagnostic system and which diagnostic rules should be applied for this purpose,
- what should be the structure of the diagnostic system, i.e. which subsystems that carrying out specific diagnostic rules should be applied and which items from available element types should be used.

For the purpose of carrying out the mentioned above activities, it seems reasonable to develop an expert system. It allows not only to carry out the process of inference about the usefulness of individual requirements, taking into account the existing data/information, but also the assessment of individual solutions of the diagnostic system in order to select an optimal solution.

The basic components of a typical expert system is a knowledge base, database, inference algorithm and the user interface, through which is provided the access to the individual components of system [14]. The use of expert system for the described purposes, requires the develop of the knowledge base in the appropriate form. This is due to the necessity to take into account the numerous set of attributes, based on which will be performed the process of evaluating of individual requirements. For the purpose of developing the knowledge base the graphic models e.g statement networks [4] or belief network [9], [11] can be used. In considered case the belief networks are used.

Belief network is a directed graph $G$ in which the set of nodes $N$ and set of directed edges $V$ may be distinguished. Nodes of this network are used to represent the available information on observed facts and made observations. Causal relationships between the selected facts are represented by defined edges between the relevant nodes. The size of the impact of individual nodes to each other is determined in the conditional probabilities tables that are defined for each of nodes.

In the presented case, the structure of required belief networks is constant. Example of the structure of the required network that is necessary to represent the knowledge associated with the functional requirements is shown in Fig. 3. Nodes of four classes i.e. *requirements*, *attributes for requirements*, *criteria*, and *auxiliary nodes* exist in this structure. The attributes and criteria for attributes are the input nodes, while the functional requirements are the output nodes. As the values of the *attributes* nodes, qualitative data collected at the stage of defining requirements are introduced. *Criterion* node determines whether the attribute is important from the point of view of the project of a diagnostic system. Conditional probability tables are fixed for nodes within each group and may be elaborated based on available literature data or expert's knowledge. In the same way the network for diagnostic rules can be defined. As a result of the inference process, for the individual functional requirements and diagnostic rules the preference factor is assigned. The value of this factor indicates about whether the certain solution (requirement or diagnostic rule) is desirable in the designed diagnostic system.

The stage of assessment of subsystems is the next process that can be performed by using expert system. It is assumed, that based on the obtained database of elements and defined constraints imposed on the subsystems, is possible to generate very large set of potential subsystems. The process of their evaluation involves the use of optimization functions, that

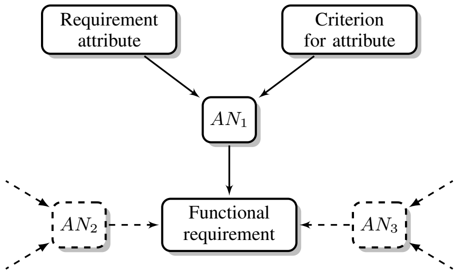

Fig. 3. Structure of belief network for considered task, $AN_i$ – auxiliary node

looking for the best solution. The most commonly used functions minimize or maximize the value of one or more attributes assigned to the individual elements e.g. cost minimization. In this way the set of desirable functional requirements and rules and within their the optimal subsystems are determined. The optimal structure of the diagnostic system is generated by the choice of a certain subset of functional requirements (e.g. those for which the appointed degree of preference is greater than the certain predetermined value) and iterative merge of selected subsystems. The iterative merge assumes, that is possible to omit certain elements of subsystems, for example measurement cards, because they are already elements of another subsystems and can be used repeatedly. This approach allows in many cases to simplify the structure of the diagnostic system as well as to reduce its cost.

## VII. Short example of proposed approach

For the purpose of presentation described in this article the method of aided the development of diagnostic systems process, one simple example will be presented. A simple technical object which is typical rotating machine equipped with the ball bearings is considered. For this object it is possible to define the needs that may be written as: *determine the current technical state of the object*. As it has already been mentioned, this need may be met by developing appropriate diagnostic system. For such defined problem, it is possible to begin the process of defining requirements. As a result of this process, the set of functional requirements may be defined. Examples of these requirements may be given as follows:

- $req_1$ – the need to detect the wear of the bearing raceway,
- $req_2$ – the need to detect crack of the outer raceway of the bearing.

These requirements may be described by the following attributes:

- the level of reduction of the probability of fault occurrence,
- the level of reduction of cost associated with occurrence of fault,
- downtime of the object after fault occurrence,
- the applicability of the requirement in other projects of the diagnostic systems.

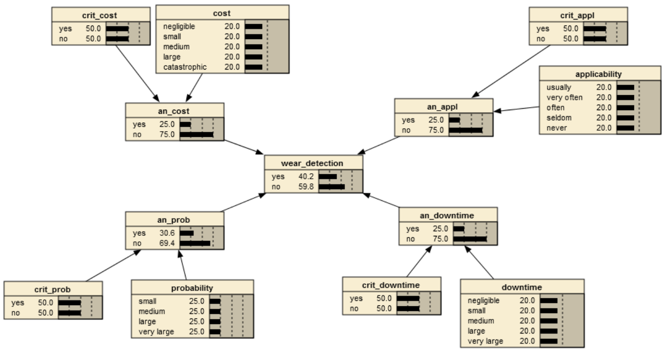

Fig. 4. Belief network with elementary data

Considering only the requirement $req_1$, it is possible to define for it a diagnostic rule written as, $drule_1$ – *exceeding the allowable root mean square value of vibration signal in the bearing*, and the limiting criterion for the subsystem on the content: *measuring range up to 10kHz*. Diagnostic rule $drule_1$ can be realized by the subsystem of the structure: absolute vibration sensor, connecting cables, measuring card and software for signal analysis. Fragment of a possible catalog of available sensors may include for example such elements as: CMSS 2100, CMSS 2100T, CMSS 2200, CMSS 780C, CMSS 2100 etc. all of these sensors are produced by the SKF company. Described process of requirements defining should be carried out in the same way for the remaining functional requirements. For the purpose of the presentation the inference process with using the belief networks the Netica environment was used. The defined statements network for the elementary data is shown in Fig. 4. The network structure is consistent with the assumptions shown in Fig. 3 and described in Sec. VI. After entering to the network the data related with: the probability of occurrence of considered fault, possible cost of the fault occurrence and information about the necessity to take into account some attributes, the value of preference factor for the considered requirement will be appointed (see Fig. 5). The next stage of the assessment involves the selection of the optimal form of the subsystem. For this purpose, based on the available sets of items and the defined limiting criterion, the set of possible solutions is generated. In this set the solution characterized by the minimum cost is now sought.

Taking into account that for the considered technical object, it is possible to define large set of requirements, the described the way of proceeding should be carried out for each of them. At the end, it is necessary to carry out the optimization of the whole structure of diagnostic system, to exclude repeating items.

## VIII. Environment for diagnostic systems design process

Presented in this article, the method of elaborating of the projects of the diagnostic systems, may be aided by using a dedicated software environment. Four main modules, i.e. requirements acquisition module, requirements evaluation module, presentation module as well as database may be dis-

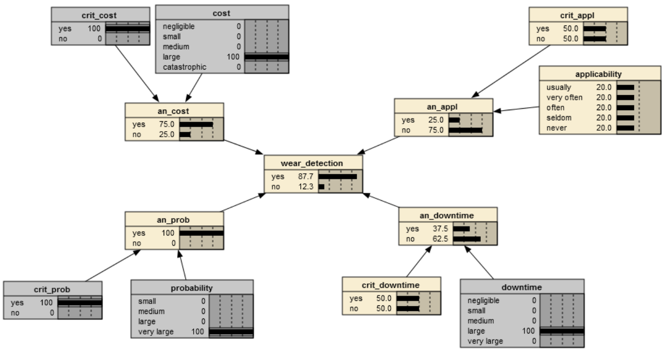

Fig. 5. Belief network after entering the obtained data

tinguished in the structure of this environment. Requirements acquisition module is responsible for collecting and storing requirements that describe developed diagnostic system. It cooperates with the banks of knowledge, in which are recorded information about known collections of faults, possible diagnostic rules, and known catalogues of elements in the form of pairs type of element - element. Based on the defined functional requirements and diagnostic rules the knowledge base for expert system is generated. The inference process will be carried out by using the package *REx* that is developed in R programming language [6]. The preference factot is assigned to each functional requirements and diagnostic rules as the result of inference process. The process of evaluating the individual subsystems and integration of the overall project of the diagnostic system will be performed in the evaluation module. For the purpose of presentation of the results the presentation module will be used, while the individual data, knowledge, etc. will be stored in the suitably developed database. Currently this environment is under construction.

## IX. Conclusion

The process of designing the diagnostic systems is a very complex task. In many cases these systems are prepared for the critical machines e.g. turbines of power plant, etc. that appropriate diagnosis is essential. During the design process of these systems is necessary to take into account numerous factors including available knowledge, existing limitations etc. In order to properly management of the available data, it is necessary to support the process of defining the diagnostic systems. For these purposes the set of requirements may be used. The used requirements may formalize the notation of the main project need. The formalized notation of the need assumes that exist three elements i.e. functional requirements, diagnostic rules and subsystems. Each of these elements can be developed based on existing catalogues of faults, measurement systems or catalogues of elements of those systems. Based on the formalized project need it is possible to generate the set of possible solution of the diagnostic systems. Because the evaluation of these solution, there is the selecting of the optimal solution is a challenging task, the additional software environment so-called expert system may be used. As a result of the use of expert system the optimal solution of the designed diagnostic system is isolated. Each of the necessary stages of the proposed approach may be performed by using specialized environment which is currently being developed. Future work will be related to the testing of this environment and removing possible inconveniences and drawbacks of the proposed method.

# Process Approach to Management Knowledge Objects Managerial Expertise for Distance Learning

Krzysztof Hauke
Wroclaw University of Economics
Komandorska 118/120,
53-345 Wrocław, Poland
Email: krzysztof.hauke@ue.wroc.pl

***Abstract*— One of the basic features of the information society is a constant acquisition of information. This information can be obtained from various sources. One source is the Internet environment. In this environment, you can use the standard communication of information on the web. The disadvantage of this approach is the lack of assessment of knowledge by the recipient. If you want to professionally lead the learning process then we have to use distance learning technologies. The use of distance learning systems, forcing the recipient to the following activities: acquire new knowledge and its evaluation. Note, however, that the knowledge in the course offered must be current. Then it makes sense to use distance learning systems.**

***The paper will be presented process approach to management knowledge objects managerial expertise for distance learning systems. Process management is carried out in the following steps. knowledge acquisition, knowledge Locating, developing knowledge, preservation of knowledge, knowledge sharing, knowledge utilization. The use of learning objects taking into account the process approach to improving the quality of the courses offered in the form of e-learning.***

***Keywords:* e-learning, knowledge, knowledge management, knowledge object, knowledge management process approach.**

## I. Introduction

The traditional model of the teacher - student knowledge transfer becomes quite a big limitation. The limitation is due to lack of time and logistic reasons. However, keep in mind that this model is good especially when you consider news aspect of their contents. In order to try to alleviate the constraints are involved with information technology solutions such as e-learning. From the point of view of the process of communicating, content society is already so educated, that it does not have much of a problem. The problem, however, lies in the interior of such a system. Didactic units are created by traditional human team. Immediately after completion of the work related to the availability of content is generally rated very well. However, after some time, a substantive assessment related to the content will be increasingly lower until it can be quite inadequate to the environment and the existing state of knowledge in the field. In order to avoid this uncomfortable situation a didactic unit or course must be constantly evaluated. Any derogation as to the content on a regular basis must be corrected to prevent such a situation that learners will use the outdated knowledge without this awareness. However, to improve the content can not be consistently implemented from the outset. Such an approach leads to a significant prolongation update the content of the course. The speed associated with upgrading the content is inherent to the process of knowledge management. If you consider elements of knowledge management in this course including activities associated with the creation or update it, will no longer be time-consuming. Note, however, that implemented elements of knowledge management in e-learning systems will not eliminate the traditional mentor in preparation for the actual content of educational material [1] [2].

## I. Learning objects in educational materials

The information society is a new type of society, which is characterized by information processing. One of the sectors which is engaged in information processing is education. Traditionally provided education requires challenges for mentors returning knowledge through lectures, exercises, conservatories and laboratories. Progressive growth of information generated by the various institutions of this society compels members to look into the issue of the organization of knowledge. In the eighties of the last century we had seen very rapid growth in the use of information technology in teaching [3]. Mentors began to prepare classes with the use of tools. It was noted unsatisfactonary with these solutions related to the teaching process. There were tools (course management systems), which in a comprehensive manner solved the problems of teaching. However, even here there are problems. Each of the mentors worked out on an individual didactic material for the course. The development of such a course would be individual to the issue and was of the author. In addition, be aware of the dynamics of the environment from the point of view:

- time that provides more and more information in the following units of time,
- a place that generates information specific to their environment.

But the uniqueness of feature associated with the time to create such a course. The preparation of such teaching

978-83-60810-66-8/$25.00©2015, IEEE

material that takes into account any change of scene and adjusts to the time and place is very difficult. This problem can be solved by developing courses using the components. Components of the so-called learning objects (learning object - LO). The concept of learning objects was first described in the work of Gerard in 1967. Initially, this concept does not use the term object of knowledge. The first time the concept of learning object was used 1994 by Wayne Hodgins, who created a working group Computer Education Management Association (CEdMa) dealing with objects of knowledge [12].

In the literature you can find many definitions of learning objects.

General Definition - the object of knowledge is any element constituting a whole (entity) in digital form or not, which can be used in the process of learning, teaching or training.

This learning object is the smallest independent structural elements comprising three components:

- purpose - specifying expected outcomes of learning / teaching;
- activity - that this part of the knowledge element, which achieves the objective pursued;
- evaluation - allows an indication of how the expected objective has been achieved.

According to Mr Shepherd - the object of knowledge is a small, digital reusable component that can be used - alone or in combination with others - using computer software by the creator of the content or independently by the learner, for educational purposes [5].

According to S. Mills - the object of knowledge can be used to meet the teaching and the intended results can be borrowed from a different educational environment. Knowledge reusable objects are associated with electronic educational sources that can be used by different learning environments [14].

Definition author - learning objects are self-contained and independent objects that describe a reality that can be used an infinite number of times in various educational courses.

The creation of such an object is very difficult. Creating a learning object should take into account quality of universality. This will ensure that the use of such a universal object in other educational materials.

The object of knowledge is an independent piece of information, which might function independently, designed for reuse, used to create a lecture held at a distance. The object of knowledge is associated with:

- content / object content,
- metadata (tags) that describe the object keywords,
- educational material management systems LMS / LCMS (Learning Management System / Learning Content Management System).

The figure below (Fig. 1) shows the relationship between the object of knowledge, metadata and educational material management systems.

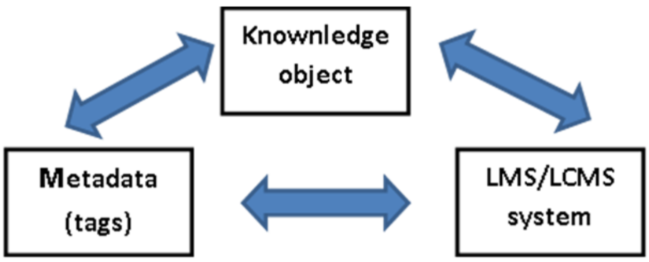

Fig. 1. Environment the object of knowledge

Source: Own study based on: http://www.itpedia.pl/index.php/Grafika:E-lear_5.jpg

From the above considerations the common elements of knowledge object definition can be derived::

- content - the purpose of training, content and actions in the area of knowledge transfer needed to achieve this goal and objective assessment reflecting the training,
- size or time needed to take advantage of knowledge - party knowledge that assimilation takes no more than 15 minutes,
- context and characteristics - knowledge that can operate independently and be delivered to the listener, if necessary, exactly on time and in sufficient quantity,
- labeling and remembering - the part of knowledge that describes a standardized set of tags.

Fig. 2. Schematic combining learning objects into a finished course

Source: Own study based on http://www.itpedia.pl/index.php/Grafika:E-lear_6.jpg

The object of knowledge can be represented by: text, graphic image, animation, multimedia audio, video [4]. a combination of these elements [13].

Learning objects are managed via the Learning Management System (LMS). Learning objects can be grouped into thematic repositories individually determined by the management of these facilities.

Repository - the place for orderly storage of documents, all of which are designed for sharing. The concept identified with the main storage, the central, but designed in such a way that access to all of its resources was equally easy. In the era of information technology there is also a term used in relation to all sorts of digital resources (databases, set of packages or source code), for example on the Internet [14].

Repository relates primarily to storage, and no sharing. It is a storage at the same time: the main, central, current and easily accessible.

Knowledge repository - a repository of documents with specific subject matter, with a specific to the field of mechanisms that facilitate access to information, or / and mechanisms for synthesizing additional information based on content stored documents.

Repository of domain, also called thematic repository and the repository of knowledge, according to. Lexicon Distance learning: the repository is a storage place structured domain knowledge, intended for repeated use in different contexts. Knowledge is presented in the form of a portion called - LO (Learning Object) In other words, it is a specialized computer system, which performs the functions of storing, sharing and modifying structured domain knowledge.

Features a repository of knowledge

- completeness - chronological, thematic, etc,
- timeliness - the new data may change old,
- relationships - mapped data relationships,
- searchability - FTS, taxonomies,
- accessibility - digital form, the Internet, PDAs, Epaper.

In the picture above (Fig. 2) learning objects are divided into two repositories:

- practical (Pn) - contains objects resulting from the observation of reality, case studies, calculations, collected empirical material
- theoretical (Tn) - contains objects resulting from the theory related to the matter, definitions, concepts, structure, interpretations, which are contained in the books, published in the form of compact or posted on websites.

This approach allows the use of multiple learning object developed in various courses. It was only at the stage of designing the course designer can benefit from such a facility in order to obtain a particular course.

## II. The Evolution of Knowledge

The organization of the knowledge allows you to achieve new opportunities. Accordingly the strategy of its organization can contribute to a rapid response to stimuli from the environment. The strategy becomes a tool for organizing the accumulated knowledge from a particular individual. Be aware of the fact that the ordering of knowledge should be fully aware of the act and the result of a desire to dominate over its generation by a number of individual and collective objects. Mastering the body of knowledge related to the functioning of the matter may become the primary factor leading to success. We must realize that today's information society generates enormous amount of information even in the smallest unit of time. Organizing them as a whole would be an extremely difficult issue to pursue. Information technology organization is trying to help this knowledge as a whole. You can mention the concept of big data, which lets you store knowledge objects. At present, it is a challenge for the information society, which must determine the direction of its activities for the coming years. Currently, a better solution is to adopt a strategy for organizing knowledge in very limited areas, resulting from specialization. Such organized knowledge will be useful for potential people who would want to solve the problems of an individual or for the environment. Such an approach requires a focus on a very narrow area of activity. This leads to specialization of an individual or collective entity in the field of influence. The limited approach to knowledge organization for the area allows you to assign its high utility value. The big economic corporations using so organized knowledge can make decisions of a strategic nature. Of course, because of the dynamics of the environment when making strategic decisions should take into account current knowledge and adapt in activities that may result in the future.

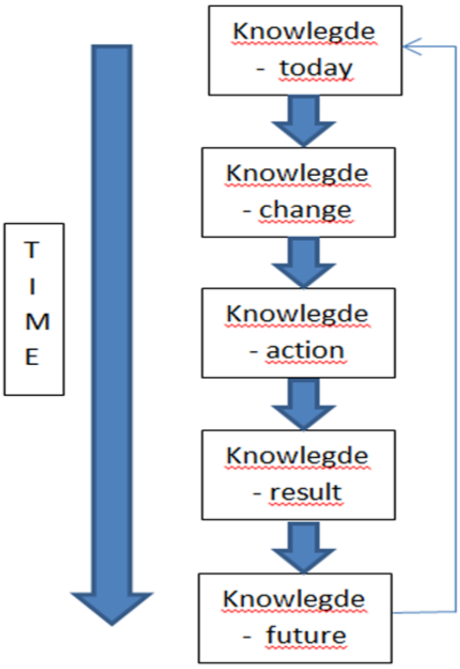

Fig. 3. The evolution of knowledge
Source: Own study

The process of evolution of knowledge is dependent on time. In the figure above (Fig. 3) the process of evolution is shown in five steps:

- Knowledge today - it is the state of knowledge on a specific state of our reality.
- Change of knowledge - a process based on the fact that by comparing the state of knowledge in the information system with real environment arising.
- Action on knowledge - declare that appeared in the environment or you may receive new knowledge forces administrators to system.
- Measurement of knowledge - at this stage the control of the state of knowledge in the information system of the update knowledge of the environment.
- Knowledge in future - it reaches the result of this step is to ensure comparability of knowledge in the system and the knowledge derived from the environment. After this stage, your "future" knowledge becomes "today" and may be used by the public.

The evolution of knowledge is an iterative process. Depending on the knowledge of frequency witch be very different. Knowledge can be changed in very short periods of time.

## III. Process approach to knowledge management

In a process approach the following are taken into account by G. Prost, S. Raub, K. Romhardt:

- locating knowledge,
- acquisition knowledge,
- developing knowledge,
- preserving knowledge,
- sharing knowledge,
- using the knowledge (Fig. 4)[11] [7]

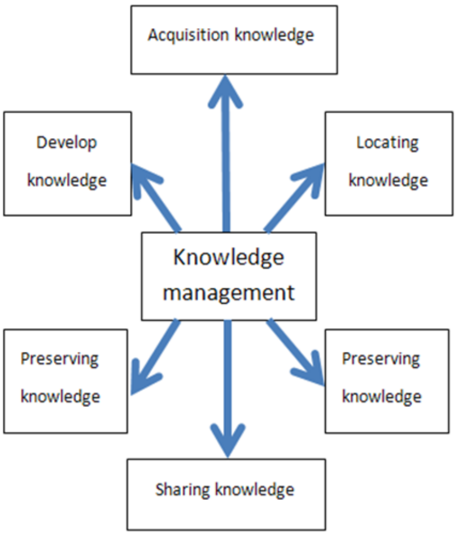

Fig. 4. Elements of knowledge management
Source: Own study [11]

**Locating of knowledge** - a basic function of solving the above problems. However, you will notice that the users in defining the demand for expertise in early stage have very big problems with identifying what knowledge they need.

**Acquisition knowledge** - knowledge can come from different sources. Each of the entities in the end generates a knowledge of the differentiated value.

**Developing knowledge** - it is the process of acquiring complementary expertise. The mere knowledge acquisition over time due to turbulence of the environment can lead to stagnation of the acquired knowledge.

**Preserving knowledge** - can work the right tools and means of media in order to replay, as well as activities undertaken in the field of detention experienced and skilled employees, as the most severe form of loss.

**Sharing knowledge and its dissemination** - this is one of the most difficult processes of knowledge management. Because of the development of the information society consciousness more and more we appreciate its value.

**Using the knowledge** - is a process that is used to achieve the objective of the organization. The organization wanting to accomplish their goal should seek to use the findings obtained.

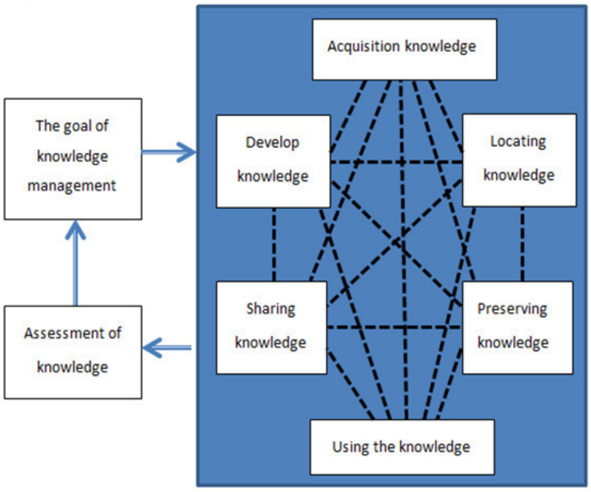

Fig. 5. Knowledge management environment
Source: Own study [11]

The activation of any of the six elements determines the assessment of knowledge. If the assessment of knowledge is inadequate to the knowledge of the environment it must be restored to its desired state - founded at the beginning of the creation of educational material.

The proposed approach will allow for an immediate reaction on outdated knowledge in the e-learning system.

## IV. LCMS as an example of a process approach to managerial knowledge management

Learning Content Management System (LCMS) is a software application that allows content management training. The LCMS helps you to create, use, locate, deliver, manage and improve training content.

The LCMS is able to locate and deliver to the end user the personalized training unit to cater to a single request, or to provide more elements of the course. Fig. 6 shows the managerial knowledge management process through e-learning system - Learning Content Management System (LCMS) [8].

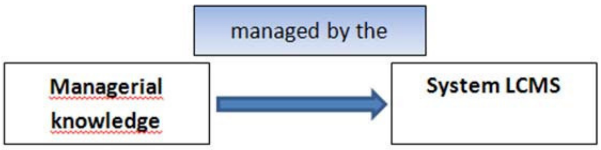

Fig. 6. Knowledge management environment
Source: Own study

Each course is a complex system, which (in the design) can be divided into small separate objects, called "learning objects" and that after the merge create the course content. Fig. 6 shows how you can create repositories managerial knowledge specific to the operating level, management and strategic management of the organization [6].

The basic components of the system LCMS are:

- **Repository of learning objects** - it is a centralized database in which content knowledge are stored and managed. Content can be made available to users as a single object of knowledge, in the form of larger modules or as an entire course, according to individual requirements.
- **Automated authentication application** - it is used when creating reusable learning objects, which are available from the repository using templates containing scenarios, training design principles. It supports both authors, slingshots automates the development of learning objects.
- **Dynamic publishing interface** - provides learning objects based on profiles, preliminary tests and / or user queries.
- **Administration** - it is used to manage lists of users sharing directories courses with courses, tracking and reporting the progress of the participants [9].

Functional modules of LCMS (Learning Content Management System):

- **The object repository** - the module object repository is a central database in which are stored all the elements included in the course. From this place objects that make e-learning training they are sent to the students.
- **The module automates build courses** - in this module to create the objects included in the rate (SCO - Sharable Content Objects) module facilitates work by providing templates, as well as the full list of existing objects. which can be re-utilization, processed, copied.
- **The distribution of courses** - foreign distribution module allows you to share courses to students according to established profiles. It also allows you to track the progress of the trainee and reports the results of exercise testing questions.
- **Administration module** - it is used to manage the process of learning: account management trainees, providing them with courses, tracking the progress of science and carry out other administrative tasks [10]. The following figure (Fig. 8) shows the overall process of creating the course.

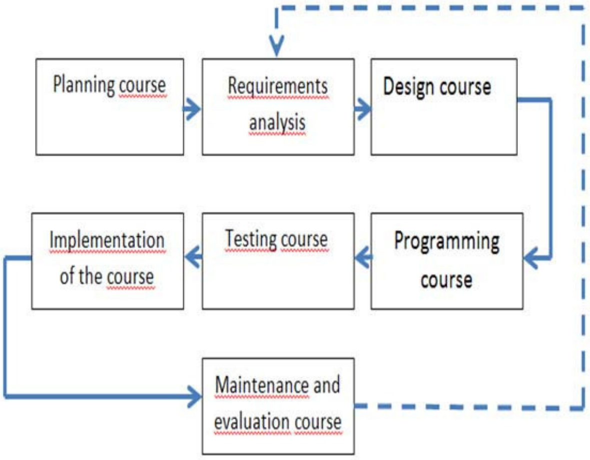

Fig. 8. The process of creating e-learning course
Source: Own study

In the process of building the e-learning course we should use the LCMS system. It will help to support the knowledge management function. Thanks to this course it will be able to quickly adapt to changes resulting from the dynamics of the environment. The figure below illustrates the LCMS system in the environment of knowledge management functions.

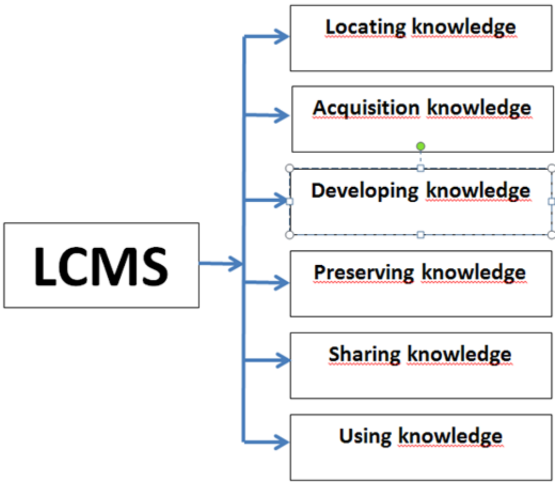

Fig. 9. LCMS in an environment of knowledge management function
Source: Own study

The following analysis will be carried out to present the LCMS system due to the components.

Components - **Repository of learning objects** - of the system LCMS supports:

- locating knowledge,

- acquisition knowledge,
- developing knowledge,
- preserving knowledge,
- sharing knowledge,
- using knowledge.

Components - **Automated authentication** application – of the system LCMS supports:

- locating knowledge,
- acquisition knowledge,
- developing knowledge,
- preserving knowledge,
- sharing knowledge,
- using knowledge.

Components - **Dynamic publishing interface** – of the system LCMS supports:

- acquisition knowledge,
- preserving knowledge,
- using knowledge.

Components - **Administation** – of the system LCMS supports:

- acquisition knowledge,
- develop knowledge,
- preserving knowledge,
- sharing knowledge,
- using knowledge.

The above analysis shows that the available LCMS system components can support knowledge management functions. As a result, knowledge management may be exercised by the systems to create e-learning courses, a mentor will be able to deal with the domain expertise in educational materials.

## V. Conclusion

Construction of knowledge and placing it in a repository that will be available to designers of e-learning will increase the quality of available educational materials. The disadvantages of data content in materials can be eliminated through a change in approach to lectures created. But it is not only the substantive dimension which must be taken into account. Although it is the most important. You should also pay attention to the efficiency of particular emphasis on funding. Stephen Downes in his work made a very simple economic calculations. These calculations should be taken into account by the designers of courses and organizations that are involved in creating e-learning courses.

These calculations are very simplistic but illustrate the scale of the economic problem. If you prepare one lesson which costs $ 100 and it will be used by 100 universities then the cost of this unit will be $ 1. If, however, the same teaching unit will be produced for each institution individually, the combined cost will be 10 000 $.

Financial calculations, however, should be in the background. Nothing can replace well-designed educational material with current professional knowledge. Recipients quickly assess the value of training that will be fully up to date, discussed the current problems of reality [9].

Managerial knowledge management is very difficult. Its variability over time is the cause of failure of e-learning in the process of transferring knowledge to the recipient. This can be eliminated by a proper design of such a course. The inclusion of knowledge management functions will create the course, which will be able to quickly incorporate the changes in the domain knowledge from the environment.

The use of a process approach to managerial knowledge management can contribute to the improvement of the course prepared for the recipient. Taking into account this approach with the capabilities of the system Learning Content Management Systems - LCMS implemented the tools to build the course which will help to improve the quality of substantial exchange of managerial knowledge.

# Supervised Context Classification Methods for an Industrial Machinery

Mateusz Kalisch
Silesian University of Technology
Institute of Fundamentals of Machinery Design
ul. Konarskiego 18a, 44-100 Gliwice, Poland
Email: mateusz.kalisch@polsl.pl

***Abstract*—The paper describes a method of supervised context classification for an industrial machinery. The main objective of this study is to compare single and ensemble classifiers in order to classify groups of contexts which are based on an operating state of the device. The applied research was conducted with the assumption that only classic and well-practised classification methods would be adopted. The comparison study was carried out using real data recorded from an industrial machinery working underground in a mine in Poland. The achieved results confirm the effectiveness of the proposed approach and also show its limitations.**

## I. Introduction

THE INCREASING complexity of recent industrial objects causes that fault diagnosis is one of the most important directions of research in the fields of robotics and modern automatic controls [1], [2], [3]. There are a lot of areas where technical systems and processes are required to be safely and reliably operated, such as aircraft, spaceships, automotive or the mining industry. A large majority of the methods implemented for fault detection and isolation are based on simple approaches [4], because these are easy to implement and fast, but the final result can be unsatisfactory because of limitations e.g. too slow system reactions. More complex solutions can be used to achieve better results for more difficult cases but it can be impossible for even an expert to build this kind of the system. One solution is to create a fault detection and isolation system based on the classifiers which are used to prepare and classify datasets, but it is difficult to extract real data fragments connected with a faulty state, and as a consequence, the training data are not good enough for the classifiers. Another solution is context based reasoning [5]. A system based on this approach can be focused on the list of the contexts which are connected with e.g. working conditions of an examined device. Simpler models of the classifiers and more efficient results of the fault detection and isolation process can be considered as advantages of the system based on the context. However there are some problems connected with this approach like when and what kind of context occurs in a specific period of time and how to use context based approach in the fault detection and isolation process.

The rest of the paper is organized as follows. In Section 2 the context based approach with regards to machine learning is described. The next section includes a detailed description of the proposed method. In particular, there are investigations of the classification methods. Section 4 contains a case study description and the more interesting results of the verification experiments. The last section is devoted to concluding remarks and suggestions for future work.

## II. Context in machine learning

In a classification task, it is possible to distinguish three types of features: primary, contextual and irrelevant [6]. Primary features are useful for classification, without regard to the other features. The irrelevant features are not useful for classification, either when combined with the other features or when they are considered alone. Contextual features cannot be used directly by a classifier, but can be useful when they are combined with other features. The primary features can be also divided into context-sensitive and context-insensitive features. In the case of a machine diagnosis, the context variable could be connected with a number of factors e.g. weather conditions. In another paper [5], the author used contextual variables such as humidity, barometric pressure and external temperature for a gas turbine engine diagnosis. Speech recognition is another example of an area which can use contextual features to improve the efficiency of classification [7]. A speaker's sex, nationality or age may have a strong influence on the relevance of various features but without the primary features the contextual features are useless for these methods. Another type of contextual variable is unknown context which can be identified from data by means of a method based on an evolutionary algorithm [8], [9]. In the final implementation, the context can be acquired directly from the data base or distinguished from the data by the classifier.

The contextual variable is a continuous or discrete variable connected with a specific object. In the case of a discrete contextual variable, the contextual value is equal to one of all the available contextual variants describing this variable. The contextual variant can be obtained from a continuous contextual variable by using the classifier. In the case of an expert system, the context may be connected with text information, where the first part of the message is connected to the contextual variable and the object related to this variable. The second part of the message is connected to the contextual variant. An example of a contextual message could be the contextual variable which refers to wind velocity. The first part of the message connected with the variable might be *Wind*

978-83-60810-66-8/$25.00©2015, IEEE

*velocity is* and the second part (connected with the variant) might be *too low* or *too high*.

In the literature some of the concepts for the usage of the context with machine learning algorithms are described [10], [11]. Peter Turney in [6], [5] described five strategies which show how context can be used: *Contextual normalization*, *Contextual expansion*, *Contextual classifier selection*, *Contextual classification adjustment* and *Contextual weighting*. The extraction of the context during a reasoning process is one part of the context based method of the classification. The context can be available as an additional variable in the dataset or can be hidden in the data. In the second approach, it is necessary to implement an algorithm which can extract this context from the data in the dataset. The context can occur as single context but also as group of contexts, where each context from the group can also occur independently.

## III. Methods of context classification

In the next part of the article, the author describes two methods of classification for groups of contexts. Each context can be described as a binary variable whose value is equal to 0 or 1. All contexts can be connected together and be presented as a decimal value obtained from the binary representation of all contexts (e.g. six binary contexts connected together can be presented as a binary value 010010, which is equal to 16 in decimal notation). It is possible to define a list of all the available combinations of contexts in the group and to create a list of all possible decimal values. This approach (Figure 1) lets us create only one multi-class classifier and the final result of the classification can be decoded to a binary representation to see the state of each binary context in the group.

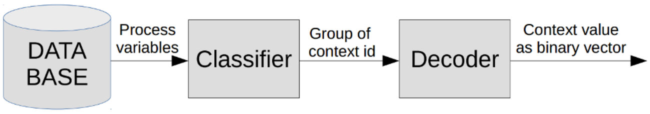

Fig. 1. A scheme for context classification using a single classifier

The advantage of the first method is that the result of the classification can be connected with only one of the known combination of the contexts, because all possible combinations are defined in the training data. The second method (Figure 2) is based on a bank of the binary classifiers where each of them is trained to detect different contexts. When six contexts are available during the reasoning process, it is necessary to implement six binary classifiers in the scheme.

In both methods, each context in the group can be used independently for fault detection and an isolation system. However in the second method, there is a possibility of reaching a result which is not correct. A more detailed description of this problem is presented in the next section of the article.

### A. Used classifiers

In this paper the author compares four different classifiers based on various approaches: *Bayesian Network*, *Naive Bayes*, *Decision Tree* and *Artificial Neural Network*. Each of these classifiers returns a label for a chosen class and a degree of belief for all predicted classes. The best result occurs when one of the classes is characterised by the belief level equal to 1 and the rest of them are equal to 0. This gives us a 100% certainty that a new element should be classified as belonging to this particular class. In the next subsections, more precise descriptions of the selected methods are given.

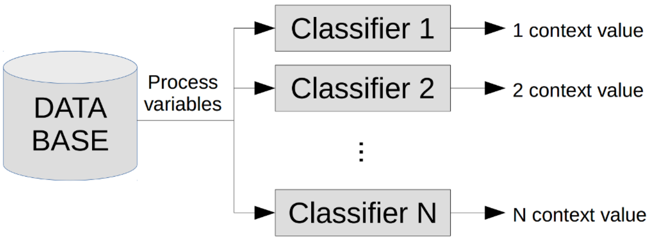

Fig. 2. A scheme of context classification using group of binary classifiers

*1) Bayesian Network:* Bayesian Network, also called *Belief Network* or *Casual Network*, is a graphical model for representing the conditional independences between a set of random variables. Each node in the network represents a variable [12], [13]. Each connection between the nodes is represented by the Bayesian equation 1 where $P(d_i|V_1, \cdots, V_n)$ is often known as the posterior probability of $d_i$ given $V_1, \cdots, V_n$. $P(V_1, \cdots, V_n|d_i)P(d_i)$ is often referred to as the likelihood of $d_i$ given $V_1, \cdots, V_n$, $P(d_i)$ is the prior or marginal probability of $d_i$ and $P(V_1, \cdots, V_n)$ is a normalizing term.

$$P(d_i|V_1, \cdots, V_n) = \frac{P(V_1, \cdots, V_n|d_i)P(d_i)}{P(V_1, \cdots, V_n)} \quad (1)$$

*2) Naive Bayes:* Naive Bayes is a simple probabilistic classification method which is based on Bayesian theory. However, the Naive Bayes classifier considers each of the existing features independently. Taking into account this assumption, the Bayesian equation (1) can be transformed to (2), where the denominator of the equation is replaced by a constant $C$ and the conditional probability is calculated by the multiplication.

$$P(d_i|V_1, \cdots, V_n) = C \cdot P(V_1|d_i) \cdot ... \cdot P(V_n|d_i) \cdot P(d_i) \quad (2)$$

The degrees of beliefs for the classification results are equal to the probability values obtained from the Bayesian equation.

*3) Decision Tree:* A Decision Tree is a classifier based on a tree-like graph created by nodes and the connections between them, where each end node is called a *leaf* and the rest of the nodes have conditions. The result of a decision tree application depends on a chosen leaf. In the algorithm, different split evaluation criteria (e.g. ratio gain in C4.5; information gain in ID3; the Gini impurity measure in CART; etc.) can be used [14], [15]. The confidence levels for the classification results are calculated separately for all leaves of the tree during the learning process. Sometimes, when the learning data is very complex, the results of the decision tree may be uncertain since some of the leaves may be connected to more than one class. The class which is described by more elements then others (in a specific leaf) is chosen as the main class for this leaf. The ratio between the number of elements for available classes is used to calculate the of probability for each class for the leaf.

*4) Artificial Neural Network:* The classifier is a feedforward neural model in which multiple layers of neurons with nonlinear activation functions allow the network to learn nonlinear or linear relationships between input and output vectors [16]. In this paper, a multiple-layer network is used which consists of three layers including $n^1$ neurons in the input layer, with $n^2$ and $n^3$ neurons in the first and the second hidden layers, respectively. In this case, the neural computation can be represented by the following equation:

$$y = \mathbf{LW}^3\mathbf{f}^2\left(\mathbf{LW}^2\mathbf{f}^1\left(\mathbf{LW}^1\mathbf{u}+\mathbf{b}^1\right)+\mathbf{b}^2\right)+b^3 \qquad (3)$$

where $\mathbf{LW}^{\{1,2,3\}}$ correspond to the weight matrices of the input layer and the first/second hidden layer, $\mathbf{b}^{\{1,2,3\}}$ are vectors of the biases, $\mathbf{u}$ is the input signal, and $\mathbf{f}^{\{1,2\}}$ are nonlinear transform operators consisting of tangensoidal activation functions.

## IV. Case Study

A longwall shearer working in a coal mine in Poland is the subject of this study. Longwall mining is underground mining where a long wall of materials is removed in a single slice. The longwall mining method extracts ore along a straight front having a large longitudinal extension. The mining technology involves a longwall shearer, a machine 15 metres long, and weighting 100 tonnes, that has picks attached to two drums which rotate atat a speed of $30{-}40 rev/min$. A longwall face is the mined area from which the materials are extracted. The shearer removes coal by traversing the face at approximately 25 minutes intervals. Traditionally, longwall mining equipment is controlled manually, and the face is aligned in a straight line [17], [18].

### A. Data analysis

Available datasets consist of 36 signals including values of the currents, oil and water pressures, temperatures and rotational speeds of the left and right drums of the longwall shearer. Redundant signals were removed from the dataset after a statistical analysis and the final number of signals was reduced to 21. One of the variables was the operational state which contained information about the current state of the longwall shearer. Information for this variable is represented as binary value and each bit is connected with a specific state. The available dataset covering a few days was divided into the smaller datasets connected with single days. In each dataset the author calculated the number of empty rows and the rows containing data. The results of this calculation are presented in Table I.

TABLE I
Relation between the number of rows containing data and the size of the full dataset

| Date | Rows containing data | Total number of rows | Ratio |
|---|---|---|---|
| 18th October | 64783 | 106385 | 61% |
| 19th October | 72337 | 102470 | 71% |
| 20th October | 79719 | 105248 | 76% |
| 21st October | 77200 | 103746 | 74% |
| 22nd October | 44746 | 67080 | 66% |

It can be seen that all the datasets contained empty rows (with no values) and the size of these gaps was between 24% and 39% of all data.

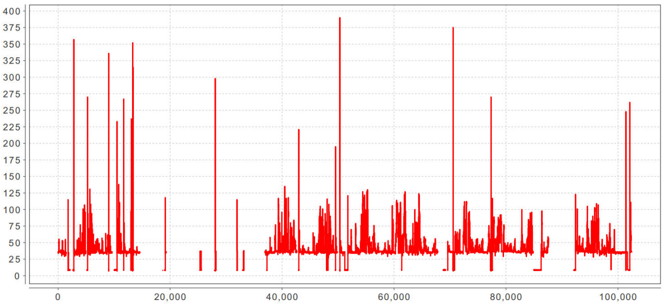

Fig. 3. Average current value of the drive engine

Figure 3 shows that gaps are placed in different fragments of the dataset and the lengths of the fragments of empty data and those filled with data are various. For the dataset from 19th October it is possible to distinguish 28 fragments filled the with the continuous data. Table II presents how many of these fragments filled with data lasted for specific periods of time.

TABLE II
Relation between the number of fragments of useful continuous data and their duration

| Duration | Number of fragments |
|---|---|
| 0 - 1 min | 2 |
| 1 - 10 min | 12 |
| 10 - 60 min | 7 |
| 1 - 3 h | 7 |

The author considered only the 7 datasets with the largest number of the samples. They contained in sequence 5031, 5362, 6461, 7351, 7680, 9937 and 10998 samples, so the duration of the series was between one hour and seven minutes and about two hours and thirty minutes. The higher number of the samples can delivered more samples connected with each operational state, providing more opportunities for the classifiers trained on this data to work properly.

### B. Operating states of the considered device

In the article operating states of the longwall shearer are considered as contexts described in the first part of the article. There are six operating states represented by binary value (0 or 1):

1) Breakdown,
2) Warning,
3) Operation of drives,
4) Drives turned off,
5) Drive to the left,
6) Drive to the right.

In the study presented in this article the operating states of the longwall shearer were recorded in the dataset by a monitoring system. Sometimes this kind of information is not recorded in the data base and it is necessary to discover it or to add additional information as defined by an expert. The operating state is available in the dataset as a decimal value and it is important to convert it to a binary representation to extract information about each operating state. Table III presents the list of the considered states and the possible combinations of them. The first row shows lists the states, where each state can be equal to 0 or 1. The first column presents a list of all possible combinations of the states represented by decimal values (4, 5, 8, 20, 36, 38) and their binary representations are presented in the central area of the table. The numerical values in the first row of the table correspond to the labels of the operating states in the list presented above.

TABLE III
BINARY REPRESENTATION OF ALL CONSIDERED COMBINATIONS OF THE OPERATING STATES

| | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|
| 4 | 0 | 0 | 1 | 0 | 0 | 0 |
| 5 | 1 | 0 | 1 | 0 | 0 | 0 |
| 8 | 0 | 0 | 0 | 1 | 0 | 0 |
| 20 | 0 | 0 | 1 | 0 | 1 | 0 |
| 36 | 0 | 0 | 1 | 0 | 0 | 1 |
| 38 | 0 | 1 | 1 | 0 | 0 | 1 |

Some of the combinations of the states are not correct and they cannot be considered as possible combinations of the states, e.g. it is not possible to set the bit numbers 5 and 6 to 1 at the same time, because bit 5 is connected with the task *Drive to the left* and bit 6 is connected with the task *Drive to the right*. As it is impossible to move the machine in both directions at the same time, but it is possible to stop the machine, then bit 5 and 6 are equal to 0.

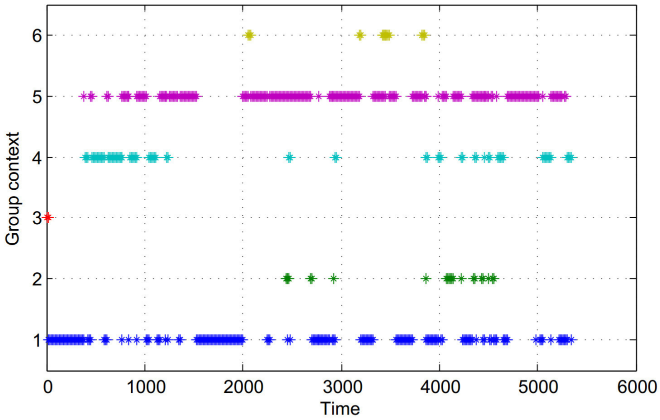

Fig. 4. Occurrence of possible groups of operating states in one dataset

Figure 4 presents the occurrence of the context groups in the fragment of the dataset where each context group id is connected with the following combinations of states:

1) *Operation of drives*,
2) *Breakdown* and *Operation of drives*,
3) *Drives turned off*,
4) *Operation of drives* and *Drive to the left*,
5) *Operation of drives* and *Drive to the right*,
6) *Warning*, *Operation of drives* and *Drive to the right*.

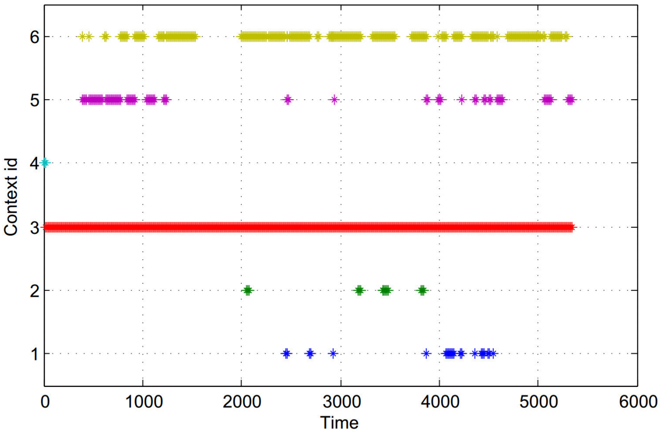

Fig. 5. Occurrence of considered operating states in the fragment of the dataset

Figure 5 shows the places were the specific states occurred in one of the considered datasets. It can be seen that the number of rows of data connected with each state is very various. ID values presented on the Y axis are connected with the list of considered operating states presented at the beginning of this section.

### C. Results

The author used seven different parts of datasets, all of them recorded on the 19th of October. The author compared the data using four various classifiers and two methods of classification. Each classifier in the first method (Figure 1) and all classifiers in the second method (Figure 2) were trained on one dataset and tested by the rest of them. Two measurements were considered to evaluate the effectiveness of the classification: accuracy and recall. Accuracy was the basic evaluation method of classification but its result may be not fully reliable in the cases where the data was not well balanced. The second measurement was used to reduce the influence of various numbers of states in the considered datasets.

To keep all results fully consistent, the final result of the second method (Figure 1) was considered correct only if all results of the binary classifiers (each classifier is connected with different state) were correct. Even if only one classifier made a mistake, the final result was treated as incorrect. This solution is fully comparable with first method, where the final result is presented as a group of the contexts.

Table IV shows the accuracy of all classifiers used in the two considered methods. The classifiers are presented in the table by their short names (DT - Decision Tree; NB - Naive Bayes; NN - Neural Network; BN - Bayesian Network). Each column is connected with a different training dataset and the values in the cells of the table show the average value of the test cases. It is clear that the bank of binary classifiers reached a much better result than the single multi-class classifier.

TABLE IV
ACCURACY RESULTS FOR ALL CLASSIFIERS AND METHODS

| Single classifier | | | | | | | |
|---|---|---|---|---|---|---|---|
| Dataset id | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| DT | 78.1 | 42.8 | 68.9 | 57.7 | 63.6 | 76.6 | 65.4 |
| NB | 30.4 | 45.3 | 55.2 | 48.2 | 72.0 | 56.7 | 37.6 |
| NN | 51.4 | 53.6 | 70, 2 | 65.2 | 75.6 | 75.5 | 51.3 |
| BN | 51.9 | 27.6 | 33.1 | 37.3 | 46.0 | 48.5 | 51.5 |

| Bank of binary classifiers | | | | | | | |
|---|---|---|---|---|---|---|---|
| Dataset id | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| DT | 89.4 | 86.8 | 89.9 | 90.8 | 91.0 | 88.5 | 89.4 |
| NB | 76.9 | 80.1 | 87.2 | 79.8 | 88.3 | 85.9 | 83.3 |
| NN | 83.3 | 86.7 | 92.6 | 82.9 | 92.4 | 92.1 | 88.8 |
| BN | 77.9 | 60.0 | 58.2 | 75.7 | 80.0 | 70.4 | 78.0 |

Accuracy is based on a ratio between all correctly classified rows and the number of all rows in the dataset, and it does not take into account the distinctness of each class in the testing dataset. The result based on the accuracy can not be used only as a measurement of the efficiency of the classification because of the unbalanced test datasets. The second measurement used in this test is mean recall. Recall was calculated for each class separately. The recall value is presented as a ratio of the number of all rows of data with a correctly predicted class to all data rows connected with a specific class. The final result is obtained as the average value of all recall values calculated for all available classes.

TABLE V
MEAN RECALL VALUES FOR ALL CLASSIFIERS AND METHODS

| Single classifier | | | | | | | |
|---|---|---|---|---|---|---|---|
| Dataset id | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| DT | 68.3 | 46.6 | 57.7 | 51.3 | 55.3 | 64.9 | 61.1 |
| NB | 27.0 | 29.7 | 35.8 | 29.2 | 46.8 | 35.3 | 32.1 |
| NN | 36.1 | 31.6 | 55.1 | 36.6 | 47.2 | 37.9 | 44.5 |
| BN | 35.8 | 27.4 | 27.9 | 35.8 | 37.9 | 38.9 | 43.0 |

| Bank of binary classifiers | | | | | | | |
|---|---|---|---|---|---|---|---|
| Dataset id | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| DT | 82.4 | 73.2 | 79.8 | 84.3 | 79.4 | 81.8 | 82.5 |
| NB | 58.1 | 61.1 | 63.9 | 59.0 | 65.9 | 64.1 | 58.2 |
| NN | 64.6 | 65.9 | 64.2 | 60.1 | 73.4 | 57.2 | 55.3 |
| BN | 65.2 | 53.1 | 60.1 | 66.9 | 66.8 | 67.8 | 66.1 |

The method based on the bank of binary classifiers reached much better results than the single classifiers. It can be seen that the values for mean recall are worse than the results for accuracy. This proves that the classifiers trained on unbalanced datasets were not evaluated properly by the accuracy measurement. The results for accuracy show that only two classifiers in each column reached the best results interchangeably: Decision Tree and Neural Network. The rest of the classifiers almost always reached worse results than the two mentioned above. The mean recall value shows that the algorithm based on a Decision Tree is able to work more properly with the unbalanced data, and in all columns it reached the best result. The classifier based on a Neural Network had a tendency to ignore classes with smaller numbers of examples.

TABLE VI
ACCURACY OF CLASSIFICATION OF EACH STATE OBTAINED BY DECISION TREE

| | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|
| 1 | 99.81 | 100.00 | 100.00 | 100.00 | 98.69 | 96.91 |
| 2 | 90.81 | 98.59 | 99.94 | 99.94 | 65.50 | 73.37 |
| 3 | 91.50 | 95.75 | 99.97 | 99.97 | 48.45 | 77.60 |
| 4 | 96.87 | 98.67 | 99.95 | 99.95 | 52.84 | 83.17 |
| 5 | 97.04 | 98.59 | 99.71 | 99.71 | 71.09 | 79.44 |
| 6 | 99.42 | 98.16 | 100.00 | 100.00 | 30.14 | 81.99 |
| 7 | 96.82 | 98.89 | 98.63 | 98.63 | 65.01 | 75.22 |

Table VI shows the accuracy result for the classification of each operating state (columns 1 to 6) for all available datasets (rows 1 to 7) by the bank of the binary classifiers based on a Decision Tree. Each value shows the result of one classifier from the bank, e.g. the value in the third row and second column (89.67) presents the primary accuracy result obtained by the binary classifier (based on a Decision Tree) whose task was to distinguish the operating state called *Warning* (the label of column 2). The label of each row indicates the dataset which was used during the verification test. It can be seen that the accuracy value for the first four states is high but for states 5 and 6 it is lower (except for the first row, because the classifier used in this example was trained by the first dataset).

TABLE VII
RECALL OF THE CLASSIFICATION OF EACH STATE OBTAINED BY A DECISION TREE

| | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|
| 1 | 97.42 | 100.00 | 100.00 | 100.00 | 95.98 | 96.72 |
| 2 | 73.59 | 99.29 | 97.92 | 97.92 | 76.02 | 72.10 |
| 3 | 50.40 | 89.67 | 99.99 | 99.99 | 62.51 | 77.00 |
| 4 | 56.08 | 94.92 | 93.18 | 93.18 | 66.33 | 80.30 |
| 5 | 50.50 | 83.83 | 95.15 | 95.15 | 77.75 | 76.95 |
| 6 | 58.11 | 75.11 | 100.00 | 100.00 | 53.32 | 82.11 |
| 7 | 48.84 | 77.29 | 91.48 | 91.48 | 61.15 | 71.93 |

The results for a recall of the same situation (Table VII) shows which states are more difficult to isolate and which are not. The classifier reached a high level of efficiency for the 3th and 4th state (*Operation of drives* and *Drives turned off*). The efficiency for the 2nd state (*Warning*) was a little bit lower. The classifier had some problems with the identification of the 5th and 6th states (*Drive to the left* and *Drive to the right*) and the reason for this problems could be the lack of clear information about the direction of movement of the longwall shearer in the dataset. There is no signal which could clearly show the direction of the movement. The classifier reached the worst results for the 1st state (*Breakdown*) because the number of examples connected with this state was very small and the classifier was not able to distinguish this state properly in the test dataset.

## V. CONCLUSIONS

It is possible to use different methods of classification to implement basic schemes of context identification. The author was able to increase the efficiency of classification by implementing groups of binary classifiers, instead of using a single multi-class classifier. The final decision of the presented schemes can be used in fault detection and isolation models implemented in an expert system.

The main advantage of the first method (Figure 1) of context classification is its simplicity. It requires only one multi-class classifier, and its result is always connected with a correct combination of states. But the classifier used in this method always reached a worse result than the classifiers used in the second method (Figure 2). Additionally the first scheme needed classified dataset which contained all possible combinations of states and sometimes it is impossible to prepare this kind of training dataset because some of the combinations might not occur in the recorded data. In the second method, it is not necessary to create a dataset with all possible combinations of contexts because each context is classified separately. It is therefore easier to prepare the appropriate training data. The scheme of this method is more complex, but the classification results are significantly more accurate than the results of the first method (Figure 1). Nonetheless, the results of this scheme cannot be fully correct because of the possibility of impossible combinations of contexts as a result of the classification (e.g. the longwall shearer moving in both directions at the same time).

### A. Future work

The next step in future research will be connected with other methods of context classification based on ensemble classifiers and meta-classification. Another step is the implementation of the described and future methods inside a fault detection and isolation system, in order to increase the quality of the system in comparison to a solution working without context. It is necessary to see how strong the influence of the context classifier is on the final result of the diagnosis system, because low efficiency of the context classifier could be a reason for high uncertainty levels of the final decision used in the fault detection and isolation system.

## Acknowledgment

The research presented in the paper was partially financed by the National Centre of Research and Development (Poland) within the frame of the project titled „Zintegrowany, szkieletowy system wspomagania decyzji dla systemów monitorowania procesów, urządzeń i zagrożeń" (in Polish) carried out in the path B of Applied Research Programme - grant No. PBS2/B9/20/2013. The part of the research was also financed from the statutory funds of the Institute of Fundamentals of Machinery Design.

***Abstract*—This paper deals with a method of faults detection and identification based on the clusterization of the multiple diagnostic signals. Various types of faults and character of their occurrence were simulated using DAMADICS Benchmark Process Control System. A great advantage of the applied approach based on self-organizing (Kohonen) maps is that even the smallest differences in signals allow for detection, isolation and identification of type of occurred faults with respect to the healthy condition of the investigated system based on the unsupervised learning. It was shown that in some cases the faults, which are undetectable during monitoring of simple heuristic and statistical parameters and other previously applied methods, are recognizable when the approach based on self-organizing maps is applied. The case studies presented in this paper show the faults detection procedure as well as clusterization of types and successful classification of almost all the unique faulty states of the investigated system.**

## I. Introduction

An increasing usage of control and automation systems in industrial applications influences on development of novel methods of fault diagnosis, particularly their detection, isolation and identification. Moreover, the industrial requirements for such procedures are to be sensitive even for the early stage of development of faults and should ensure the implementation of them in on-line monitoring systems. The specificity of the physical nature of some faults requires the application of new methods in order to detect and classify them with the lowest possible false alarms.

Recent studies in the area of the fault diagnosis are based on many different approaches. They can be classified, in general, into the quantitative and qualitative approaches. The most simple quantitative approach is an application of statistical measures to the diagnostic signals, observation and inference about a fault presence basing on these measures [1]. However, there is a large amount of research done with application of qualitative fault diagnosis, primarily using soft computing methods. Several authors used such methods in the fault diagnosis, in particular in [2], [3] the genetic programming for observer-based fault diagnosis and evolutionary learning of fuzzy models were used, while the authors of [4] used a fuzzy qualitative reasoning approach for the fault detection problem. A lot of studies are concerned with artificial neural networks (ANN) application to such a class of problems. In [5] the authors applied the group method of data handling (GMDH) neural networks, while in [6], [7] the authors used a neuro-fuzzy approach and ANN with decision trees, in [8] the hidden Markov model for the fault diagnosis was applied.

One of the novel and promising diagnostic tools is the group of approaches based on Kohonen self-organizing maps (SOM). SOM are very often used in problems of the analysis of large data structures e.g. in the problems of clustering or classification [9], [10], [11], [12], image processing [13], [14], [15], robotics [16], [17], time series forecasting [18], [19], [20] and faults detection and identification [21], [22], [23].

In the presented paper the authors analyzed and discussed the overall analysis of all faults using SOM-based approach, which diagnostic signals are able to be generated using the DAMADICS benchmark. The only previous study [24], which was carried out on DAMADICS data using the SOM-based approach, presented a possibility of application of SOM to the faults clusterization, but the results are limited to the analysis of three selected faults. In the present study the process signals were simulated basing on real measurements of diagnostic signals on the actuator system during the evaporisation process in the Lublin sugar factory (Poland) [25], [26]. In order to detect, isolate and identify the faults simulated using DAMADICS benchmark actuator system the SOM-based approach was applied.

## II. Description of the problem and the methodology

### A. The DAMADICS benchmark

The investigated problem of the faults detection and identification was based on sets of diagnostic signals, generated using the DAMADICS benchmark actuator system, which simulated various types of possible faults. The scheme of the investigated system is presented in Fig. 1 [27]. The actuator system consists of the pneumatic servo-motor $S$, a control valve $V$ and a positioner $P$. These three parts of a system are composed by a set of measured diagnostic signals: external controller output $CV$, flow sensor measurement $F$, input $P1$ and output $P2$ valve pressure, medium temperature $T$ and the rod displacement $X$.

Using the DABLib Simulink®-Matlab® library 19 fault types with a variable number of fault intensities (three stages

The publication is financed from the statutory funds of the Faculty of Mechanical Engineering of the Silesian University of Technology.

| $f19$ | Flow rate sensor fault |

of abrupt faults and the incipient fault) can be modelled, which gives total of 45 cases including the case with no faults occurrence. One should consider that not every fault simulation has physical foundation of existence, thus for some types of faults a limited number of intensity subcases existed. The complimentary list of faults that can be modelled and which were used in further analyses was presented with a description in Table I and Table II [27].

* Abrupt faults

### *B. Previous studies related to diagnosis using DAMADICS benchmark*

The problem of faults identification based on DAMADICS benchmark has been investigated by several scientific teams. The first studies were performed by the authors of the benchmark using various methods of faults detection, isolation and identification. One can notice the general tendency in these papers where the authors take into consideration only selected cases of faults. The authors of [28] performed the study on faults detection and isolation based on the analysis of residua using binary diagnostic matrices for single sets of signals for a given faults case as well as the pairs and triplets of such cases. The authors of [29] used timed automata approach and considered three selected faults in their identification procedure. The authors of [30] focused on the abrupt large faults available in the DAMADICS benchmark for faults detection using a spectral estimation approach. Other approaches were to consider GMDH neural networks [5], interval observers [31] fuzzy classifiers for fault detection and isolation [32], structural analysis [33] in order to evaluate fault isolability, etc. The only study, which considered the whole set of faults possible to simulate in the DAMADICS benchmark, was performed by the authors of [34]. They used an approach of qualitative reasoning coupled with fuzzy neural networks and basing on their results only two cases were not detected and isolated.

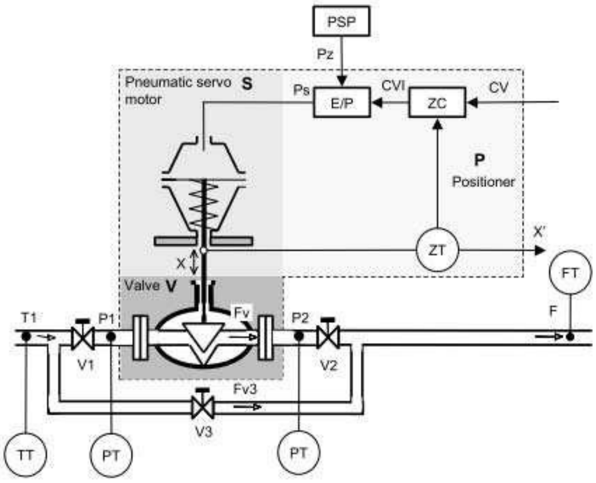

Fig. 1: The scheme of actuator system

The main goal of the studies on the DAMADICS benchmark was to find an appropriate methodology, which allows for detection, isolation and identification of all types of faults available in the benchmark and relations between them, which can be carried out within a single analysis procedure using all signals of all available faulty cases.

### *C. Data preparation*

The authors of [35] stated that the faults $f8$ and $f12$ have theoretical behaviour, i.e. the methods applied by the authors were not able to distinguish these faults from the healthy state. Results obtained by the authors of [34] show that the small type fault $f16$ and incipient type fault $f18$ are not detectable, while the authors of [33] stated that using their method the faults $f9$ and $f16$ are not detectable. The authors of [5] did not detected some types of faults: $f5$, $f8$, $f9$, $f12$ and $f14$ using the GMDH neural network-based approach. In the presented study all of the faulty cases were considered in the analysis. Considering initial analysis of signals generated from the DAMADICS benchmark, the signal $P2$ was removed from every set of tested cases due to the fact that this signal remained insensitive to the faults of a system. Moreover, following the previous studies in the fault detection problem on the DAMADICS benchmark data [4], [35], it is difficult to detect some of the faults due to their weak intensities (i.e. very small changes in the diagnostic signals) and/or very slow development. However, these faults cases were considered in further studies in order to investigate their detectability using the proposed methodology.

The sets of signals of each case listed in Table II were generated using the DABLib library. In each case the fault occurred after the 900th second of the simulation. Following this, the duration of the most of the generated sets of signals was limited to 2000 seconds. In some cases of slowly propagating incipient faults the duration of simulation was extended to 4600 seconds ($f17$) and to 86000 seconds ($f2$, $f3$, $f5$, $f6$, $f9$, $f11$ and $f18$) in order to achieve the full propagation history of a given fault until the fault index reaches the unity value.

During the performed researches four classes of faults: small, medium and large of abrupt and incipient faults, were considered. For the clarity of results presentation the numbers from 1 to 4 were assigned to the classes as the subscripts in the form: $fault_{class}$, e.g. the notation $(f2, f14)_4$ denotes that the faults $f2$ and $f14$ of incipient type, whereas $f3_{2,3}$ denotes that the fault $f3$ of medium and large abrupt types is considered.

### D. Simple statistics-based direct diagnostics

In the diagnostics of processes, the often applied approach for detection and isolation of faults is the direct diagnostics, which is based on simple signal processing and control of constraints. For this purpose the current values of the features of process variables such as mean value, root mean square, maximal and minimal values, variance and others, are determined. In the case of diagnosing of a system basing on the alarm thresholds the analysis is performed on the basis of a comparison of current signal value of a process with the assumed minimal and maximal values, between which the signal can change in the case of non-faulty condition. In the case of statistical features the estimators in the specified window are calculated and then compared with the appropriate values determined for the non-faulty condition.

In the investigated problem both approaches were applied. In the case of control of constraints the evaluation was performed basing on comparison of current values of signals of processes with maximal and minimal values of the signals representing non-faulty condition of a system. In the case of the analysis of statistical features the mean value and a variance were calculated for comparative procedures. For the comparison purpose of current signals with the signals for the non-fault condition the threshold of 5% of variability range was assumed. When the values of signals exceed the threshold the change is recognized as significant one, which indicates the damage. The results of damage detection using the above-described approaches were stored in Tables III, IV, V and VI. Each table refers to the intensity of a damage and the presented values denote the ability of detection of a given fault using the described approaches: 0 for the case of undetectable fault and 1 for the case of detectable fault.

Obtained results show that the detection of the following faults was not possible: small faults $(f10, f14, f16, f8)_1$, medium faults $(f10, f14, f16, f8)_3$, large faults $(f14, f8)_3$ and incipient faults $(f11, f2, f3, f4, f5, f6, f9)_4$. As can be noticed, the application of the described approaches for faults detection is possible only for a limited group of cases. The isolation of faults using these approaches is not possible in direct manner, but could be possible only after application of the algorithm, which allows for distinguish the faults. One of such extensions, which allows for distinguishing the faults, is the binary diagnostic matrix, however in numerous cases distinguishing of the faults was not possible. Therefore, it is necessary to develop appropriate approaches that would be sensitive to changes in the diagnostic signals and allow for their distinguishing and diagnostic inference about faults occurrence.

### E. Motivation

Considering the results of faults detection presented above it can be noticed that the simple statistical methods often remain insensitive to changes in signals and thus the faults could not be detected. In order to detect and identify the faults occurred during the investigated industrial process the more advanced techniques should be applied. The SOM seems to be an effective tool both for the faults detection and identification and has an adequate sensitivity to recognize even the tiny changes in the analysed signals. Moreover, the application of SOM allows for the analysis and comparison of sets of multiple signals, i.e. it is not necessary to preprocess the measurement data in order to find the signal containing information about the occurred fault.

## III. SOM AND METHODOLOGY

### A. Fundamentals on the self-organizing maps

The Kohonen SOM are a type of ANN with unsupervised learning. Two layers, input and output, can be distinguished in the structure of this network (see Fig. 2). The input layer is a vector of neurons, while the output layer is a multidimensional representation of neurons, commonly the two-dimensional (2D) or three-dimensional (3D) one. In the case of 2D representation a rectangular or hexagonal map can be used. A toroidal or cylindrical maps could be used in case of 3D representation. The number of neurons in the input layer is equal to the number of attributes that describe each input data. In case of output layer $5\sqrt{N}$ neurons, where $N$ is the number of input samples, was usually used [36]. But the practical size of this layer depends on nature of input samples. For diversified cases of input data bigger maps should be applied. Each neuron from input layer is connected with each neuron

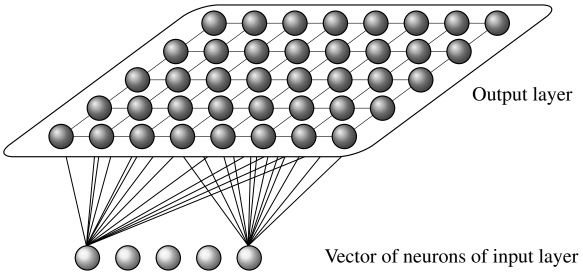

Fig. 2: The structure of the self-organizing map

of output layer [37]. For an arbitrary neuron $n_i$ from output layer it is possible to define some neighbourhood. For this purpose the radius $r$ is used. Based on this radius some area (called a neighbourhood) around considered neuron can be selected. The neighbourhood of the neuron $n_i$ is described by a function $h_{ci}[\bullet] \in [0; 1]_R$ called a neighbourhood's function. The values of this function are distributed from neuron $n_i$ along the radius $r$.

During the learning process of SOM for particular input data the best neuron from output layer is selected. In the literature this neuron is called a winner neuron or best matching unit (BMU). For the purpose of such selection some of the distance metrics e.g. Euclidean, Chebyshev, Manhattan, etc. can be used. In a learning process the weights of chosen neurons are updated according to the formula:

$$w_i(k+1) = w_i(k) + \eta(k) h_{ci}[x(k) - w_i(k)], \tag{1}$$

where $k$ is the number of iterations of the learning process, $\eta(k)$ is the learning coefficient, $h_{ci}$ is the value of the neighbourhood function of the neuron $n_i$ with respect to the neighbourhood of the winner neuron $n_c$ and $x(k)$ is the input vector inputted to the network during $k$-th iteration. Generally the learning process consists of two stages. The first of them is called Winner Takes Most (WTM). During this stage the weights of a winner neuron and its neighbours neurons are updated. Second stage is called Winner Takes All (WTA). In this case the radius $r = 0$, therefore the value of coefficient $h_{ci} = 1$, and only the weights of the winner neuron are updated.

### *B. The methodology*

For the purpose of carrying out the research described in this paper, the SOM Toolbox for Matlab® environment [38] was used. The input data was prepared basing on values of particular signals measures during occurrence of some faults. From each of considered signals (five signals without "$P2$, see the list in Sec. II-A) $N$ consecutive values were considered (e.g. from 100 s to $(100 + N)$ s). Based on these values the vectors of $5N$ elements that describe particular faults were created. Finally, the input matrix has a size of $M \times 5N$, where

$M$ is a number of considered fault cases plus one non-faulty exemplary case. During the conducted study different numbers of considered cases were being taken into consideration. The main settings of the SOM algorithm were as follows:

- type of output layer – 2D hexagonal maps of neurons,
- size of maps – from $10 \times 10$ for the simplest example to $100 \times 100$ for the most complicated examples,
- data normalization – variance was normalized to one,
- training algorithm – batch algorithm,
- number of training (WTM,WTA) iterations – from $(10, 10)$ to $(100, 80)$, depending on complexity of data,
- neighbourhood function – Gaussian function,
- distance measure – Euclidean metric.

For particular cases of input data the $U$-matrix maps were determined. An inspection of the obtained maps and quantization error were used for verification and evaluation of the quality of obtained results. For selected neurons of these maps the labels of considered faults or non-faulty case were assigned. Based on determined in this way maps the relevant conclusions about the possibility of detection, isolation and identification of particular faults were formulated.

In accordance with [39] the fault is detected when the difference in the set of signals with respect to an initial (healthy) state can be observed. As isolation stage we assume that the faults can be distinguished from each other and the identification stage allows us to identify a class and a type of a given fault. In this context we assume that basing on obtained SOM maps the fault is detected, isolated and identified when is located in separate cluster of map according to clusters related to the adequate non-faulty state or other fault cases. According to this assumption in Fig. 3 (subscript $s$ and $b$ in labels of faults denotes the small and big cases of fault, respectively) one can see that all faults are detectable. Faults $f2_s$ and $f2_b$ are detectable, but because they are located in the same cluster there are not isolated. Faults $f8_b$ and $f11_s$ are detectable and isolable as well since they are located in separate clusters. Finally, faults $f1_b$ and $f1_s$ are both detectable, isolable and identifiable. Additionally, based on obtained maps it is possible to conclude that some faults e.g. $f3_b$ could be weakly detectable.

In the most cases 1100 samples of each signal, starting from 901-th second (the onset of fault), were taken into account during the study. For several cases the number of considered samples was enlarged due to slow propagation of some of incipient faults. The analysis was realized following the standard two-step approach used during application of ANN. Firstly, the SOM was trained on standard data obtained from the generator following the description above. Then, three additional sets of data with modified character of noise distribution in signals were generated in order to validate the proposed approach during the testing stage.

## IV. Results

### A. Diagnosing process

At the beginning, all of the cases of faults were considered in order to evaluate their distinguishability. The resulted exemplary maps for this study are shown in Fig. 4. Two groups of faults: weakly and very well detected can be distinguished. The set of weakly detectable faults (the same cluster on the obtained map) contains the following faults: $(f8, f14, f16)_1$, $(f8, f14, f16)_2$, $(f8, f14)_3$, $(f2, f3, f5, f6, f9, f11, f18)_4$. On the other hand, the subset of very well detected faults contains the subsequent items: $f7_1$, $(f1, f7)_2$, $(f1, f2, f7, f15, f16)_3$, $(f13, f17)_4$.

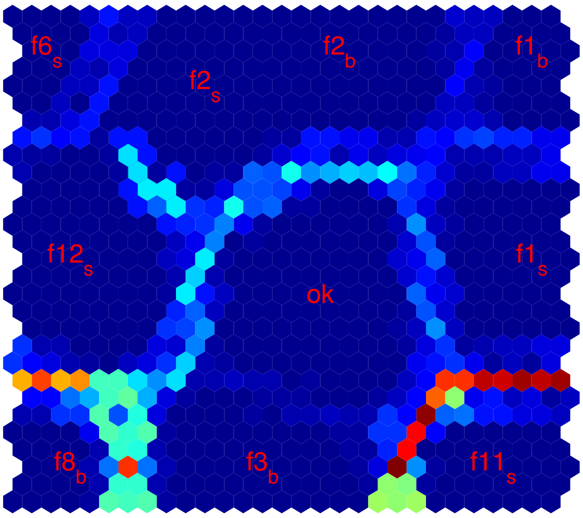

Fig. 3: Exemplary maps with associated faults for selected clusters

In the next stage of the analysis the faults in the context of their particular classes (three types of abrupt and one type of incipient faults) were considered. Examples of obtained maps are shown in Fig. 5. Based on the obtained results two groups of faults can be distinguished. In the first of them the weakly detectable faults such as $(f8, f14)_1$, $(f8, f14)_2$, $(f8, f14)_3$, $(f5, f6, f18)_4$ are assigned. A special case of assignment was obtained for $f14$, for which the same neuron as for non-faulty condition was assigned. Further analysis (search for the differences between the non-faulty and $f14$ signals) allows to conclude that the process signals of $f14$ were identical to the signals from the non-faulty condition of a system. The second group of faults contains the faults which are well detectable while taking into account the individual classes. The faults $(f1, f7, f13, f18)_1$, $(f1, f7, f13, f18)_2$, $(f2, f7, f15)_3$ and $(f4, f13, 17)_4$ can be assigned to this subset. Furthermore, it can be seen that some faults are very similar to each other, e.g. $f13_2$ and $f18_2$ as well as $f13_3$ and $f18_3$.

The consideration of the weakly detectable faults only, such as

$(f2, f3, f5, f6, f9, f11, f18)_4$, $f8_{1,2,3}$, (the faults $f14_{1,2,3}$ are not further considered), which were excluded during the previous analysis, allows to conclude that all of them are very well isolated with respect to the non-faulty case (see Fig. 6). Only the fault $f5_4$ is located in the same cluster as non-faulty case, thus this fault is very similar to this state.

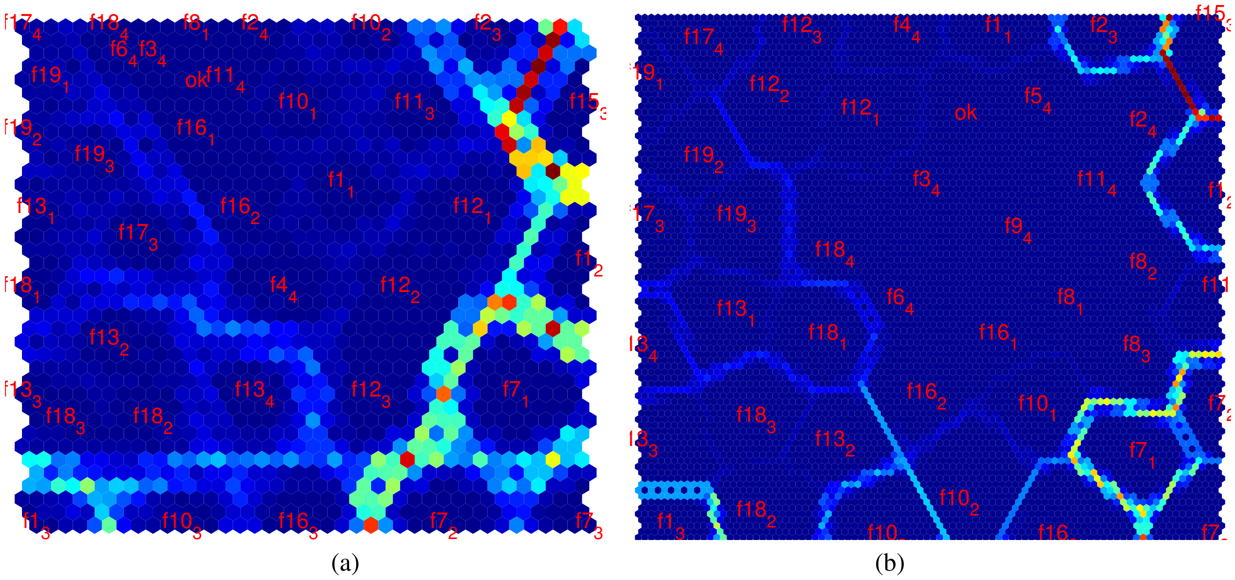

Fig. 4: Results obtained for all considered faults: (a) map size: 20 × 20, learning steps (WTM, WTA): (10, 10); (b) map size: 45 × 45, learning steps (WTM, WTA): (50, 30)

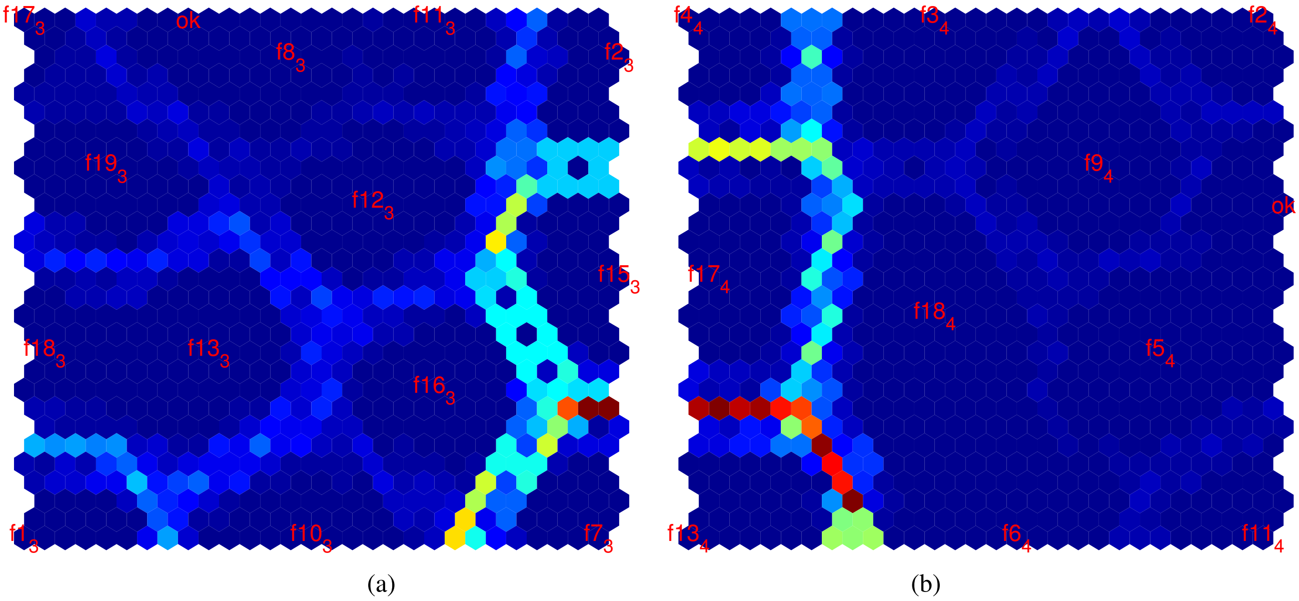

Fig. 5: Maps obtained for single classes of faults, map size: 15x15, learning steps (WTM, WTA): (30, 10): (a) large abrupt faults; (b) incipient faults

Further studies were concentrated on the sensitivity analysis with taking into consideration the shorter realizations of signals for the particular groups of faults. Two main groups: weakly detectable (listed above) and the remaining faults were considered. Exemplary maps are shown in Fig. 7. Based on the obtained results for these analyses, it is possible to conclude that the reduction of a length of signals influences on the quality of the results. The minimal period of time that makes possible the detection of selected faults equals 1 s. A vector of five elements (five signals were considered) describes each fault in these cases. Selected groups of faults (usually the intensities of particular faults) became indistinguishable from each other, e.g. $f7_{1,2,3}$, $f10_{2,3}$, $f18_{1,2,3}$.

Final summary of faults detection with division to the possible types is presented in Table VII.

### B. *Validation of a methodology*

Obtained SOM maps can be considered as a diagnostic pattern, based on which it is possible to conclude about technical

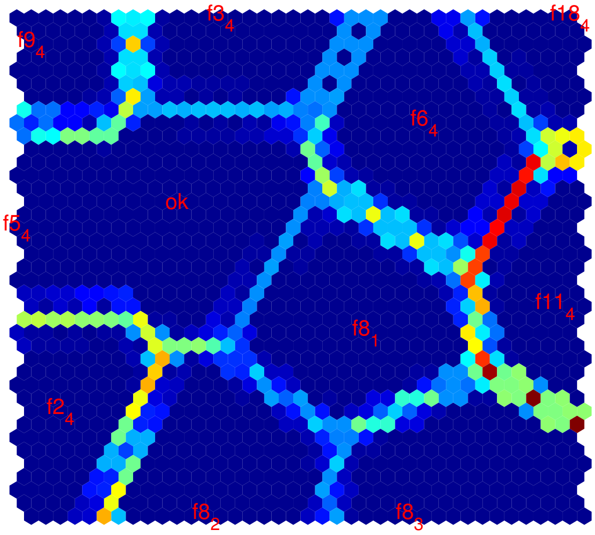

Fig. 6: Obtained maps for weakly detectable faults, map size: 20 × 20, learning steps (WTM, WTA): (20, 15)

TABLE VII: Results assigned to the possible classes of faults

| Type | Faults 1100 s |
|---|---|
| undetectable | $f14_{1,2,3}$ |
| weakly detectable (inside the classes of faults) | $f8_{1,2,3}$ $(f5, f6, f18)_4$ |
| weakly detectable (overall) | $f5_4$ |
| pair of not distinguishable faults | $(f13, f18)_2$ $(f13, f18)_3$ |
| very well detectable | $f1, f7, f13, f18)_{1,2}$<br>$(f2, f7, f15)_3$<br>$(f4, f13, f17)_4$ |

condition of the considered system. In order to validate this approach the new three sets of data for considered 44 faults were prepared (small modification of standard DAMADICS benchmark simulator was made). Obtained data was divided into five groups. The faults, according to the classes: small, medium and large abrupt and incipient, are included in the first four of them. The fifth class includes faults, which were obtained during previous analysis and assigned as the weakly detectable (see Figure 6). From the collection of numerous maps, which were generated previously, five maps were selected according to the particular groups of faults. Basing on these maps, for subsequent cases of new data the best neuron (BMU) from suitable map was determined. The considered fault was assigned as recognizable if the assigned neuron coincided with a neuron corresponding to the same fault from the basic map, or the neuron was located in the same cluster of a map. An example of assigned labels of large abrupt faults is shown in Figure 8, while a full summary of the results is posted in Table VIII. In the last three columns, the numbers of recognized cases of faults for individual groups are presented. It can be observed that the faults $f8_{1,2,3}$ i $f14_{1,2,3}$ are weakly recognizable. The best results are achieved for large abrupt faults, where for the most cases of considered faults the same neurons are assigned similarly as in the basic map.

TABLE VIII: Results of validation of methodology

| Groups of faults | Faults | 1st set | 2nd set | 3rd set |
|---|---|---|---|---|
| Small abrupt | 10 | 8 | 8 | 8 |
| Medium abrupt | 10 | 8 | 8 | 8 |
| Large abrupt | 14 | 12 | 12 | 12 |
| Incipient | 10 | 2 | 2 | 3 |
| Weakly detected | 10 | 4 | 5 | 7 |

## V. Conclusions

In the presented paper the novel approach to the process diagnosis problem based on self-organizing maps was presented. The authors used the DAMADICS benchmark for simulation of faults of various types and intensities, which was the basis of the investigated fault diagnosis problem. Using SOM-based approach and the simulation data it was shown that the faults can be not only precisely detected, but also isolated and identified basing on resulted BMU maps. As it was noticed, applied approach is very sensitive to changes between the signals, which allow to detect, isolate and identify almost all unique cases of faults and provides better results of faults detection and isolation than the previously applied methods for the DAMADICS benchmark problem. Moreover, using SOM it is possible to compare multiple to multiple signals, which improves much the methodology of fault diagnosis due to the lack of necessity to carry out preprocessing procedures of the process signals. In order to validate the presented approach additional datasets were generated from the DAMADICS benchmark simulator, which were slightly different than those generated for the main analysis. The validation procedures show that in the most cases the faults were appropriately classified to the particular clusters.

Presented studies is a part of on-going research. Several open problems, which were planned to solve in future, should be highlighted. The improvement of the distinguishability of faults is expected during the additional preprocessing of input diagnostic signals, e.g. their normalization. Additionally, the qualitative measure (e.g. a threshold), based on which the value of a neuron on the BMU map can be used for the identification of a fault, should be developed.

The application of SOM-based algorithm in process diagnostic systems has a great potential due to the very high sensitivity to the differences in signals and datasets and could be automated and successfully adapted for the industrial installations. Since the presented algorithm is time-consuming, it cannot be applied for real-time diagnosis, however further attempts will be made to optimize the SOM-based fault diagnosis algorithm in order to increase its effectiveness.

□

***Abstract*— An idea of contextual classifier ensembles extends the application possibility of additional measures of quality of base and ensemble classifiers in the process of contextual ensembles design. These measures besides the obvious classifier accuracy and diversity/similarity take under consideration the complexity, interpretability and significance. The complexity (the number of used measures and multi level measure structure), the diversity of the scales of used measures and the necessity of the fusion of different measures to one assessment value are the reasons for user support in contextual classifier ensembles design using fuzzy logic and multi criteria analysis. The aim for this paper is an idea of the framework of the process of contextual ensemble design.**

## I. Introduction

The contextual classifier ensemble other than, name it classical ensemble, gives the possibility to look more profoundly at problem under consideration and classifier ensemble design. The reason is context that is the criterion for diverse classifier creation. The contexts of the classification problem give the possibility to view it from different perspectives, to get more familiar with it, to choose the more appropriate contexts for each case.

This approach of classifier ensembles design extends the application possibility of additional measures of quality of the base and ensemble classifiers in the process of contextual ensemble design. These measures besides the obvious classifier accuracy and diversity/similarity take under consideration the complexity, interpretability and significance. The additional measures appear in the stages of the process of contextual ensemble design. This process and the idea of contextual classifier ensemble are introduced the section II.

The framework of contextual classifier ensembles design is included in the section III.

The complexity (the number of used measures and multi level measure structure that), the diversity of the scales of used measures and the necessity of the fusion of different measures in one assessment value for the given stage of process design are the reasons for applying fuzzy logic and multi criteria analysis. This methodology is introduced in section IV.

The first results of experiment that employs this idea contextual classifier design support is included in the section V. And finally the section VI gives some summary of the introduced idea.

## II. The Essentials of Contextual Classifier Ensemble

Classifier ensembles allow the different needs of a difficult problem to be handled by classifiers suited to those particular needs. Classifier ensembles provide an extra degree of freedom in the classical bias/variance tradeoff, allowing solutions that would be difficult, if not possible to reach with only a single classifier. Because of these advantages, classifier ensembles have been applied to many difficult real-world problems see: Oza and Tumer, 2008 [5], Patel and Nawathe 2013 [11].

The classifier ensemble is a set of base classifiers that together are solving the problem of the discrimination. There are three basic mechanisms of creation the classifier ensembles. The first is a mechanism of creation the base classifiers see: Dietterich, 2000 [2], Zhang and Ma, 2012 [9]. There are the following approaches:

– data manipulation - the models for different data subsets of the learning set or for different attribute subsets
– different techniques for modeling one learning data set
– the one kind of model with different parameter sets for one learning set.

Contextual classifier ensemble is a variant of classifier ensembles that is based on data

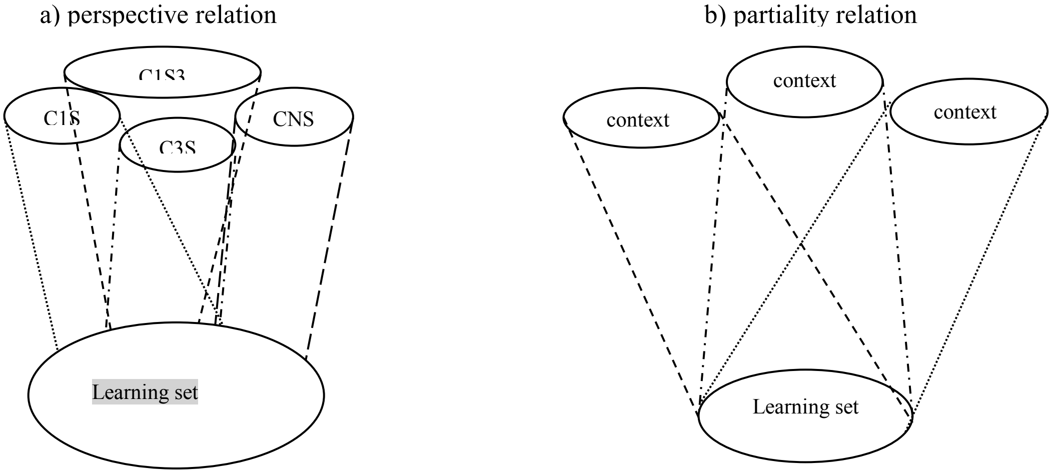
manipulation. Instead of random samples generation, or weighing examples according to correct classification in consecutive modeling step, contextual classifier ensemble generates attribute sets according known or discovered context from data that describe problem under consideration – compare: Jakubczyc, 2007 [3]. The most interesting situation is when the contexts are discovered in learning set. This case is a subject of this study. The context can be a single category i.e. localization with the urban and rural values that determine two contextual situations (localization=urban, localization=rural) or complex concept that is described by a set of attributes in the form of some kind of model for example decision tree. Each base classifier represents description of classification problem for single context or for single contextual situation. In the decision tree model each path from the root to the leaf indicates the contextual situation and the whole decision tree means the context. Whether it is context or contextual situation is determined by the type of relation between contexts and learning examples that represent problem under consideration are perspective and partiality (Figure 1). The perspective relation stands for possible contextual views on a problem. The partiality relation describes only subsets of more appropriate models of the problem for contextual situations. The last possible relation means partiality and perspective relation simultaneously (not presented in the Figure 1)



a) perspective relation

b) partiality relation

Figure 1. The relations between contexts and learning set of example

The type of relation that is used in creation contextual classifier ensembles is determined by the quality of contextual models. If the level of classification accuracy is acceptable for classifiers of identified contexts there is perspective relation. In this case the contextual classifier ensemble consists of models for each discovered contexts. On the contrary, unacceptable accuracy forces the one to take under consideration only some models for contextual situations that may guarantee the requested quality for each context. In this case there is partiality relation that may not cover the whole learning set. In this case the contextual classifier ensemble consists of models for the contextual situations not for whole context (for example in Figure1 C1S1 states for contextual situation 1 from context 1 model) with acceptable accuracy. It seems acceptable because the learning set may not be representative sample according to statistic theory.

There is also possible the mix relation that joins the first two. Our interest for now is in the first one that means the base classifiers are models for whole contexts (perspective relation). For now this focus allows us to exempt from the attendance of uncovered example by contextual classifier. It will be the subject of future research.

The selection of classifiers to the ensemble that solve the classification problem is the second mechanism. There are two problems: how many classifiers and which classifiers should be chosen.

The general answer for the first question is: “the more classifiers the better” according to the jury theorem of J.A. Marquis Condorcet - originally: Condorcet Marquis J.A.: Sur les elections for scrutiny, [in:] Histoire de l’Academie Royale des Sciences, 31-34, 1781 see: Cunnigham, 2007 [1] - but the empirical studies shows that even few classifiers may improve classification accuracy described compare: Abreu and Canuto, 2007 [10] Schiele, 2002 [7]. They have showed that ensemble of three or of five classifiers may bring much improvement too. In the case of contextual classifier ensemble the number of base classifiers in ensemble is limited to the number of identified contexts or the number of contextual situations.

The choice of the most appropriate base classifiers is generally based on two measures – applied by Kuncheva and Whitaker, 2003 [4]. The first measure is classification accuracy that should be above 50%. The second are the measures of diversity. Intuitively it means that chosen base classifiers should be mistaken on the different cases thus they can complement one another. Because the results of empirical studies are ambiguous, i.e. there is no linear relation between the diversity and accuracy, so the increase of diversity not necessary causes the increase of classification accuracy. So there is a need for additional measures that can support the choice of base classifiers. The contextual approach to creation classifier ensembles gives such possibility. The additional perspectives may be user evaluation of identified contexts and contextual base classifiers.

There is a need for additional measures also in the next step of combining single decisions of base classifiers into one final decision (it is the third mechanism). Applied techniques are determined by continuity or discreteness of class values. Since decision tree is chosen as the classification algorithm, we are dealing with nominal values of classes. In this case, the voting schemata are accessible techniques of the combination of the decision of base classifiers in this case. In simple voting schemata each classifier has one vote. But looking at different base contextual classifiers according to their quality, significance, comprehensibility, the equally assignment of votes is difficult to accept. The none-equivalence of base classifiers should be taken into account in global assessment of contextual ensemble.

The context as a criterion for creation classifier ensembles gives the possibility to look more profoundly at generated classifiers trough different contexts and at identified contexts alone. The profound assessment of the base contextual classifier and contextual ensemble needs the framework to account for the following aspects: identification of possible assessment criteria for single contextual classifier and for contextual classifier ensemble with different level of detail and aggregation, the possibility of evaluating simultaneously qualitative and quantitative assessments, contextual classifier ranking trough fuzzy multi-criteria analysis. The general framework with methodological approach is presented in the next section. The working example is shown in further section.

## III. The Framework for Contextual Classifier Ensemble

The proposition is aimed at more reasonable creation of classifier ensemble through the different, and not random criterion to build classifier ensembles. The contextual classifiers give the possibility of more profoundly evaluation of base and ensemble classifiers. The user active participation in this process of assessment is not to overestimate. The general framework of creation contextual ensembles is introduced at Figure 2. There is one global goal to choose the most appropriate contextual classifier ensemble and one intermediate goal to choose the best base contextual classifiers.

The classification problem is difficult so there is not possible to built the one model with acceptable level of accuracy. The possible solution is classifier ensemble, in this case with the contexts as criterion for building base classifiers.

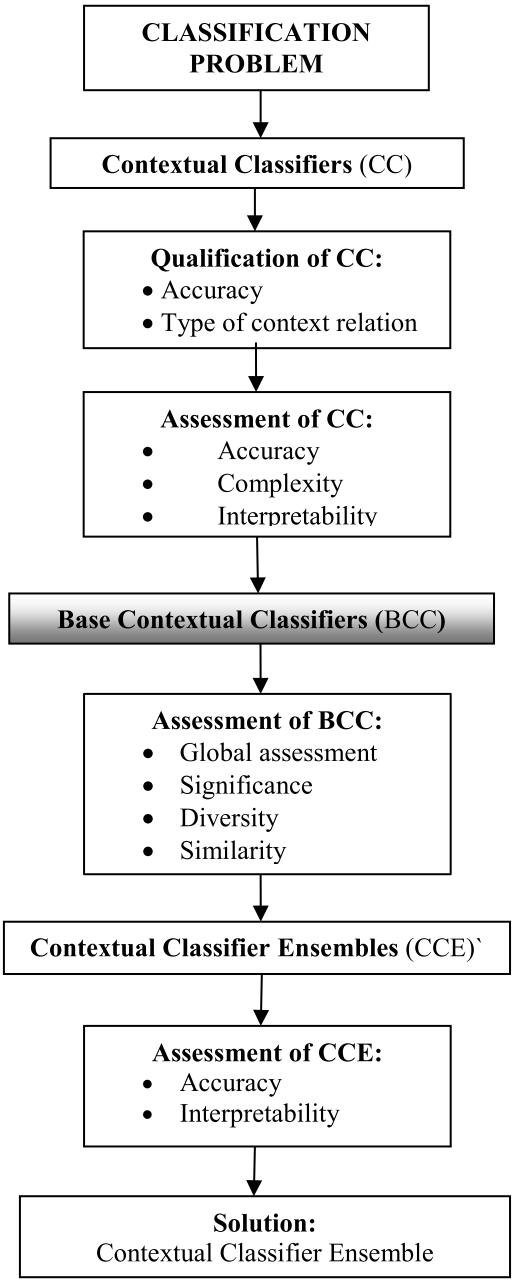


Figure 2. The general framework of creation contextual ensemble

The contextual classifiers to became the base contextual classifiers have to achieve the level of accuracy above 60% for each contextual situation (it takes place when the relation between contexts and learning set of examples is so called 'perspective relation') - presented in Figure 1 - and for each class. The contextual classifiers that have passed the qualification step are evaluated objectively according to accuracy and subjectively with support of detailed measures for complexity and interpretability (see Table 1.). To the ranking of base contextual classifiers are used two measures for each pair: similarity and diversity and user evaluation of classifier significance.

The similarity and diversity do not play a key role in process of evaluation since the number of base contextual classifiers are finite, so there can be used all possible combination of classifiers. The measures of similarity and diversity can be used to examine their quality influence.

The possible combinations of base contextual classifiers then are evaluated using objective measure of accuracy and subjective measure of interpretability. The ranking list of contextual classifier ensembles is the result of this process. The choice the most appropriate contextual classifier ensemble is up to the user. The detailed methodology used in the evaluation process is presented in the next section.

## IV. The Used Evaluation Methodology

The method for evaluation of base contextual classifiers and contextual classifier ensembles depends on character of the criteria and their properties (see Table 1). As we can see the criteria have the hierarchical structure, the different types of value (qualitative, quantitative), and different value scale. This imposes the use of fuzzy logic system introduced by L. Zadeh [8] as representing criteria values at all levels. The non-equivalence of identified criteria determines the use of pair wise matrices for the hierarchical structure of evaluation criteria means the need for gradual criteria aggregation at each higher levels.

The first step (the first column in Table 1) is the candidate qualification. To pass, the contextual classifier should have the level of accuracy above 60% and the context with perspective relation. The evaluation of contextual base classifier includes the three layers hierarchy of criteria and gradual way of evaluation.

The level 1 encompass four criteria. Each of them is represented as fuzzy membership function. The shape of these functions and key points are determined as result of analysis and requirement. The value of interpretability increase s when the value of 'novelty' decreases. There is assumed the 20% level of 'novelty' that does not influence the interpretability value.

Table  1. The criteria for assessment of base contextual classifier and classifier ensemble

| Contextual classifier | Base contextual classifier | | | Contextual classifier ensemble |
|---|---|---|---|---|
| | Level 1 | Level 2 | Level 3 | Level 4 |
| Accuracy<br>Type of context relation | Comprehensibility | Model interpretability | Base contextual classifier assessment | Accuracy<br>Interpretability |
| | Novelty | | | |
| | Number of descriptors | Model complexity | | |
| | Number of branches | | | |
| | | Model accuracy | | |
| | | | Similarity | |
| | | | Diversity | |
| | | | Significance | |

The value of ‘comprehensibility’ influences ‘interpretability the another direction: the higher ‘comprehensibility’ value the higher the value of ‘interpretability’. The range with full understanding is assumed in the interval 85-100%.

The fuzzy function of number of model descriptors has the two key points that determine the optimal range between 2 and 10 descriptors. The more descriptors indicate the more complexity of the classification model. Similarly is the matter with the ‘number of branches’ but with duplicated values.

The synthetic measure for base contextual classifier takes under consideration the non-equivalence of identified criteria. The pair wise comparison matrices (see: Saaty, 1977) are applied to derive implicit weights for a given set of criteria. The user has the possibility to introduce the significance weights for pair comparison matrix.

The model accuracy (Figure 3) has three key points. The first one indicate the minimal level of accuracy that is required for classifier ensemble i.e. 60%. The next two key points indicate the most desired range of accuracy i.e. 80%-95%. The values close to 100% are unacceptable.

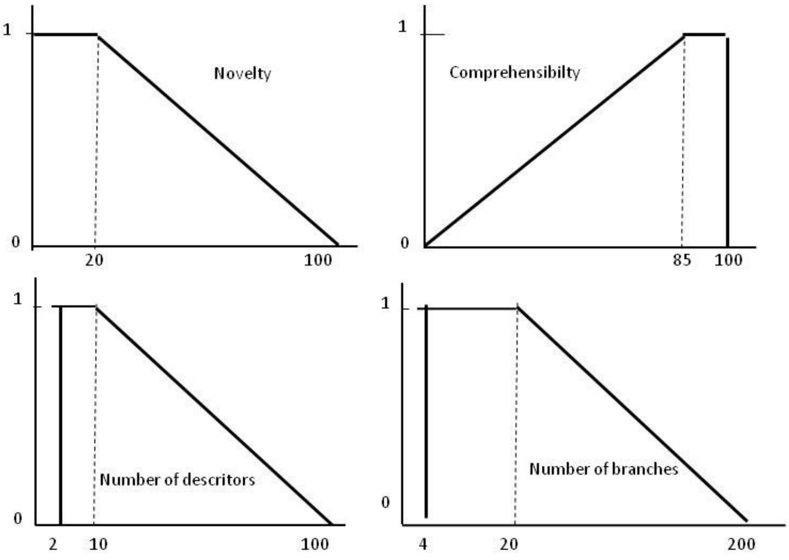

Figure 3. The shapes of fuzzy membership functions of the level 1 criteria

The complexity of contextual classifier is determined by detailed parameters of the number of descriptors and tree branches (Figure 4). The higher value of model complexity indicate the worst classifier quality. The first and second key point indicates the range of minimal level of complexity that may differ according to number of possible descriptors. After that , the quality of model decreases when the complexity increases. For different classification problem the user recommendation of key point may differ.

The interpretability indicates to what extent user understand and unexpected the classifier according to his knowledge. In this case the fuzzy membership function has the shape of monotonically increasing – the higher the value of interpretability the higher the quality of classifier.

The next level 3 takes into account synthetic evaluation of base classifier ensemble (interpretability, complexity and accuracy) and similarity and diversity measures and significance of base contextual classifiers.

The similarity measure is used as a means to eliminate the most similar classifiers from one ensemble. On the contrary the measure of diversity gives the possibility to include in one ensemble the most different contextual classifiers.

The weights assignment to particular base contextual classifier is the task for the user with his knowledge and experiences. So the assigned weights may differ from one user to another. The pair wise matrices are applied to this operation.

The calculation of synthetic measures takes place at level 2 for interpretability, complexity, and accuracy, at level 3 for base contextual classifier evaluation and at level 4 for contextual classifier ensemble.

All these calculation take into account non-equivalence of used criteria and identified contexts . This not-equivalence is measured by the general assessment of the base contextual classifier and the pair-relation of significance between contextual classifiers determined by the domain expert. Such approach allows for more precise choice of the most appropriate classifier ensemble for the problem under consideration. There are not a priori settled weights. The user each time introduces the values of the pair comparison between the base contextual classifiers. The system interface gives the possibility to view the all possible values with their interpretation.

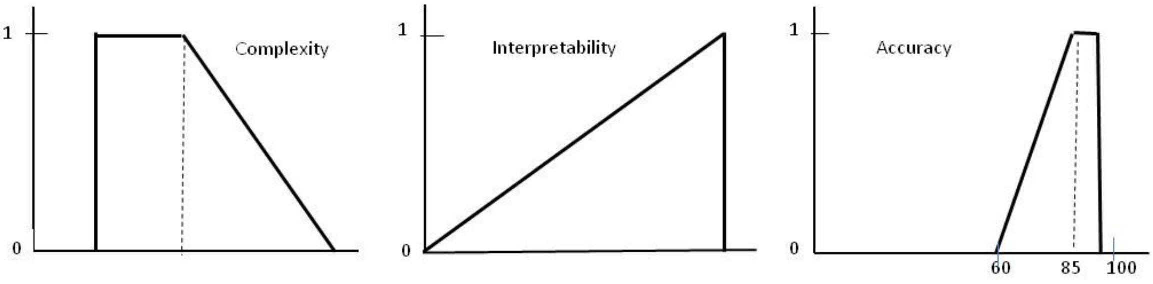

Figure 4. The shapes of fuzzy membership functions of the level 2 of criteria

The means for criteria aggregation are three following operators :

- maximum pessimism $D1 = \min(\mu_1(x_1)^{\alpha1}, \mu_2(x_2)^{\alpha2}, \dots, \mu_n(x_n)^{\alpha n})$
- multiplicative $D2 = \prod_{i=1}^{n} \mu_i (x_i)^{\alpha i}$
- additive $D3 = \sum_{i=1}^{n} \frac{\alpha_i * \mu_i(x_i)}{n}$

where:

$\mu_1(x_1),(\mu_2(x_2), \dots ,(\mu_n(x_n)$ - membership function,

$\{x_i\}$ – numerical and nominal criteria of classifier quality

$\alpha_1, \alpha_2, \dots, \alpha_n$ – the relative significance of the criteria and in the case of global criteria assessment the relative significance of base contextual classifiers.

The global assessment of contextual classifier and contextual classifier ensemble is determined by the three criteria: maximum pessimism (D1) multiplicative (D2), additive (D3) to observe the relation between them. D2 and D3 have the propriety of little value compensation of one criterion by the increasing the other criteria. The conformity of the obtained results for D1, D2, D3 increases the confidence of study results. All of them gives the global value in the range of 0 and 1 (the higher the better).

## V. WORKING EXAMPLE

The experiment was conducted on the problem of the banks client behavior and the estimation of clients behavior. The classification task was to predict whether the client is active or non-active. This problem is very important for each bank management If the client is non-active there is an indication to take pro-active action to the client to keep him as an stable bank client for the future and do not let him switch the bank for example. The bank provided 24 000 examples in learning set. The Bank is providing 24 000 representation data. There were nine discovered context that were the basis for contextual classifier design.

Our experiment aimed at two issues. The first is to verify the usability of the proposal of the framework and applied methodology. It proved to be appropriate and flexible. The flexibility concerns the automatic or manual design of contextual classifier ensemble. Because of the subjectivity of some used measures, as for example interpretability and comprehension, assumption in automatic process for these measures default values was not the best idea.

The second aspect refers to view the classification problem according to discovered contexts and knowledge/experience of the user. Generally the designed contextual ensemble by the various users were different but their quality quite similar. They differ from the weights assignment to significance of contexts and contextual models. Each of users built own fuzzy rule set and used the possibility to design few contextual ensemble to choose the best one. It results of knowledge and experience of the users.

## VI. Summary

The context as criterion for creation classifier ensembles gives the possibility to consider more profoundly classification problem under consideration. The user activation seems to be important too, although the interactive problem solving do not forces the user to join the process. But from our current experiments with the user the solutions were more reasonable. The applied approach proved to be adequate. The applied methodology showed to be appropriate too. Additionally the users fast get familiar with it.

We observed how the level of diversity changes the quality of classifier ensemble, how the knowledge and experiences influence the solutions. But it is too few experiments to conclude more general conclusions. Our work is going on.

*Abstract—* **The main objective of conducting this study is to shed light on the benefits and role of data warehouse (DW) as a source of knowledge acquisition in enhancing the process of decision-making. It is believed and assumed that meaningful and significant information can be acquired from DW which provides valuable knowledge to support business process and decision-making.**

**The theoretical assumptions are supported by the results of a questionnaire survey, which was conducted on top management of Jordanian firms. The questionnaire was developed based on the findings from related literature and other related research questionnaires. Over 250 firms, which were listed on Amman Stock Exchange (ASE) at the time of data collection, were involved in the survey. The researchers arrived at scores of significant and remarkable results regarding DW and its benefits and role in enhancing the process of decision-making. In general, the respondents had a positive attitude towards the use of DW.**

## I. Introduction

Today's organizations face a very hard time, largely as a result of competition, globalization, automation and scarcity of resources. As the business environment is changing. At the same time, those companies are likewise evolving. In this changing environment, companies are much more eager in getting immediate and accurate information to make better decisions. Successfully supporting managerial decision-making has become critically dependent upon the availability of integrated and high quality information organized and presented to managers in a timely and easily understood manner ([1]; [2]; [3]).

In such environments it is important to assure decision-makers of the quality of data they use ([13; [12]). [16] claim that Data warehouse (DW) hastens the process of retrieving information needed for decision-making. DW technology has emerged as a key source and powerful tool for delivering and accessing information for decision-makers ([4]; [1]; [5]; [6]; [7]; [3]). Since the 1990s ([8]; [9]), DWs have been an essential information technology (IT) strategy component for large and medium-sized global organizations [8].

Despite the recognition of data warehousing as an important area of practice and research, there is little empirical research ([3]; [17]) about implementation of DW in general ([18]; [14]; [17]; [3]).

Timely and informed decision-making is becoming crucial for the long-term success of businesses [20]. [21] claims that business decisions must be made with speed and accuracy if organizations are to remain competitive. There is quasi-consent that DW provides more detailed and accurate information for decision-makers to improve their decisions. Considering the usefulness of DW there has been little research in Jordan on DW, i.e. it has been comparatively less investigated in Jordan (exceptionally our last paper during KAM'14 – see [76]. Therefore, the main focus of this study is on the advantages and benefits of DW as a provider of information to the process of decision-making. It investigates mainly the relation between decision-making, the need for information and the employment of DW in Jordanian firms.

In addition, this study investigates how top management of Jordanian firms perceives the effectiveness (usefulness) of DW as a source of reliable and accurate information for decision-making.

## II. Aim of the Study

In this paper, a field study of DW and its benefits and role in easing and enhancing the process of strategic decision-making among top managers in Jordanian firms were investigated. Therefore, the main aim of this study is to investigate the benefits, which are provided by DW, in enhancing the process of decision-making.

It has been ascertained that DW is superior to traditional database and improves the process of decision-making. Therefore, the study's aim is to investigate empirically whether or not the DW provides better and more accurate information.

A study of a large number of data warehousing practitioners and experts by [24] showed that the implementation of DW was motivated more by internal pressures than external. A majority of the respondents said that the need was information related, including the need for better access to information, more accurate information and a single source of data. As the authors point out, organizations appear to initiate DW projects to provide decision-makers with accurate and effective information. [25] are of the opinion that improving access to information and delivering better and more accurate information are motivations for using DW.

## III. THE NOVELTY VALUE OF THE STUDY

This study was applied in Jordan, which is one of the developing countries in the Middle East. As Jordan's firms are not in isolation from the rest of the world, they are also influenced by the current competitive environment. The implementation of advanced and recent innovations, such as DW, is essential for the firms in developing economies, such as Jordan.

Despite the exaltation and adulation of DW, there is a need for evidences that the implementation of DW improves the quality and accessibility to information. Therefore, this study aims to practically investigate whether or not the implementation of DW improves the quality and accessibility to information and enhances the process of decision-making. Doherty and Doig in [26] drew attention to the role and importance of information accessibility. The authors claim that the information accessibility is a precursor of information quality-it has a significant impact on the information's usage, and consequently is an indicator of the DW's success in storing and processing information.

In addition to information's quality, previous literature and studies on DW have emphasized the importance of accessing information. The accessibility to information and their quality are crucial to the success of their use. It has been claimed that the use/ implementation of DW improves the quality and accessibility to information, and consequently leads to sound decisions. In other words, it leads to more fact-based decisions. DW has, according to DW literature, the ability to store a vast amount of data in a usable and appropriate form for the decision-makers' needs and uses. Although a wide range of primary and secondary sources has emphasized the importance and role of information quality and accessibility in enhancing the process of decision-making, little empirical research has been conducted so far. Such claims need to be tested empirically. It is essential, therefore, that the researchers investigate whether or not DW provides easy access to data and information, frequent, accessible and timely reports and more accurate, useful, reliable, complete and relevant information to decision-makers.

Based on extensive literature review, the researchers have identified that firms are often unsuccessful due to a lack of appropriate information or more precisely their inability to get the right information to the right person at the right time. The availability of apposite information to decision-making helps mangers in taking reliable decisions, which improve the firm's performance.

Additionally, the researchers have not found and are completely unaware of any empirical studies regarding the implementation of DW in Jordan. Therefore, it is hoped that the findings of this study give the readers and those who are interested in these issues practical insights into DW's field in Jordan. To some extent, it is one of the academic contributions. It contributes to our understanding of the DW in general and in Jordan in particular, and may form a basis and motivation for future research in the important fields. It is also believed that the final outcome of this paper adds up to the improvement and development in DSS, such as DW, by helping their users and developers to be more aware of the data and information's quality.

## IV. RESEARCH METHODOLOGY

The writing of this paper is passed in different phases. In the initial phases of the study, renowned journals, publications, conferences proceedings and books were reviewed. In addition to these sources, the findings of numerous empirical studies were researched and analyzed. As the researchers previously pointed out, the sample of the study comprises all the 277 firms, which are listed on ASE at the time of the data collection. Thus, a questionnaire was found to be the best instrument for collecting the data in this study. During the next phases, therefore, a survey questionnaire was conducted with the top managers of Jordanian firms. The questionnaire, which is used in this study, is based on previous studies and the researchers' assessments and discretion and adapted to suit the objectives and requirements of the study.

The data, which were collected, is very quantitative in nature. Therefore, in the final phases of the study, the data were statistically analyzed by employing Statistical Package for the Social Sciences (SPSS) in order that proper descriptive and inferential statistics to analyze the results and draw conclusions can be reached, including means, frequencies, standard deviation,.

## V. LITERATURE REVIEW

The concept of data warehousing has evolved out of the need for easy access to a structured store of quality data that can be used for decision-making [27 p. 5]. Organizations have vast amounts of data but have found it increasingly difficult to access it and make use of it [27 p. 5].

As an attempt to solve the problem, DWs were introduced. DWs have become the focal point for decision support in organizations today [28]. [27 p. 5] claim that the data warehousing offers a better approach. Data warehousing implements the process to access heterogeneous data sources; clean, filter, and transform the data; and store the data in a structure that is easy to access, understand, and use. The data is then used for query, reporting, and data analysis [27 p. 5]. [29] also claim that the data warehousing has emerged as an effective mechanism for converting data into useful information.

DW systems offer efficient access to integrated and historical data from heterogeneous sources to support managers in their planning and decision-making [30]. [31] also claim that data warehousing provides an infrastructure that enables businesses to extract, cleanse, and store vast amounts of data. Most medium to large organizations, according to [32], operate DWs.

It has been claimed that the main DW's role is to support decision-making. However, the role of DWs has been broadened. [33] state that DW provides information from external data sources for decision-making. DW has the potential to create radical changes to existing business processes and is often viewed within the context of business process reengineering [18]. Accordingly, [34] claims that DW gives business' users the ability to analyze data. [35] also claim that DWs enable organizations to exploit decision-making.

According to [36], DWs provide the basis for management reports and decision support. In support of the above mentioned claims participants to a study by [6] agreed that the Return on Investment (ROI) for the DW was well justified through considerable gains in productivity and enhanced quality of customer service. Moreover, in an independent detailed study of 62 organizations worldwide ([34]; [37]), the major findings of International Data Corporation (IDC) based upon 62 case studies of organizations that have successful DWs in use are an average three-year ROI of 401percent was realized by organizations building DWs. Although this study is primarily focused on quantitative information, there are several qualitative benefits ([34]; [37]), such as providing standardized, clean and value-added data to create information from disparate sources. In addition, the DW makes the data available across corporate organizations and provides the needed information quickly.

The DW is developed in order to support the integration of external data sources ([38]; [39]) for the purpose of advanced data analysis. [40 p. 35] argues that a DW produces tangible impacts to the quality of day-to-day business transactions. Previous research on DW has produced some encouraging findings about its benefits and indicated that a DW can offer several benefits to an organization [18], such as enabling effective decision support; ensuring data integrity, accuracy, security, and availability; easing the setting and enforcing of standards, facilitating data sharing, and improving customer service [35]. [41] presented time savings for data suppliers and for users, more and better information, better decisions, improvement of business processes, and support for the accomplishment of strategic business objectives as benefits from data warehousing.

Furthermore, [5], who examined data warehousing at the Housing and Development Board (HDB) in Singapore, found that the main benefits of the DW, which were developed by HDB, are enabling the users to have access to consistent and reliable data in a timely fashion which facilitated forecasting and planning efforts and improved decision-making. In addition, a study by [42] revealed that DW appears to be used more to improve the flow of information in an organization than to change the way the organization does business. The authors found that more and better data is the greatest realized benefit from DW. Moreover, a study by [43] identified time savings, new and better information, and improved decision-making as benefits of DW.

[44] conducted an explanatory case study at a financial services organization to investigate how DW provides decision support to individual decision-makers. The results showed that the organizations successfully automated the retrieval and input of data for front-end users. [40 p. 33-34], who interviewed people from seven companies, found that the benefits of implementing DW were improving asset management, reducing customer support costs, auditing billing practices, terminating unprofitable product, reducing staff requirements and running the business. [28], who described the DW implementation at Blue Cross and Blue Shield of North Carolina (BCBSNC), claim that the DW had resulted in many organizational benefits, including better data analysis and time savings for users. [45], who looked at the DW of Egypt's Cabinet Information and Decision Support Center, found that the DW provides a lot of benefits to the users, including ease of access to the information, fast and more consistent reports, support the decision-makers and integrating the data from various sources.

Additionally, [7], who conducted a laboratory experiment in 2006, found that the implementation and use of DW improves the DSS users' decision performance, by which he means improving the quality of the DSS by adding a DW can improve information availability and quality and enhance DSS users' decision performance. In conclusion, the study showed that DW can have a positive impact on decision-making.

[46], who described an example of implementing DW in medical institutions, found that the DWs provide the users access to important information. [47], who conducted a survey to find out how DW assists decision-making process in healthcare, found that the DW provides better accessibility to data, integrated disparate data sources and improved decision-making. [48] found that all companies, which are studied, recognized some benefits such as cost reduction, reach-out to other markets, increase in sales, time saving in amount and preparation of reports and more effective decision-making based on the obtained information. [49], who conducted two case studies on American Airlines and Hallmark Cards, found the easy to use, speedy information retrieval, more information, better quality information, improved productivity, and better decisions as benefits of DW. [50], who examined the implementation of DW in public security, found that the DW is very important in improving the comprehensive ability of leadership and decision-making. In addition, it quickly and efficiently integrates heterogeneous data sources.

Previous literature on DW, such as [42] and [30], claims that the DW does not create value by itself; the value comes from the use of the data in the DW. [30] claim that improved decision-making results from the better information available in the DW. By making the right information available at the right time to the right decision-makers in the right manner, DWs empower the users with the ability to make the right decisions [51]. [42] also claim that this use can result in numerous benefits, including more and better information, improved user ability to produce information and reduced effort by developers to produce information. [52] also maintain that DWs have tremendous potential to present information. The greatest potential benefits of the DW occur when it is used to redesign business processes and to support strategic business objectives [41].

[53] also identified many different measures of success; these include benefits such as data accuracy, useful information, accurate information, ease of use, user satisfaction, time to make decision and increased revenue. However, [54] claims that despite clear evidences that many DW projects have resulted in interesting business benefits, there are also many examples of cost and schedule overruns and dissatisfaction regarding the results from these projects. [55] argue that DW is one of the key developments in the IS field and has plentiful benefits. In addition, [56] indicates that the introduction of a new IS into an organization should deliver multiple benefits.

Since the early 1990s, DWs have become the technology of choice for building data management infrastructures [8] and been investigated and implemented around the world in many areas and by many researchers, authors, and scholars [57]. According to [58] p. 13, the early successful implementation of DW dates back to mid-1980s at ABN AMRO Bank (Netherlands). The author claims that the end-user's needs were the key feature behind the implementation. As a result, those requirements were modeled rather broadly, and all available data was stored in the DW. In fact, in the first few years of general use, its usage had grown at an annual rate of 50%, and by 1995 the DW had supported some 3,000 end-users. [58 p. 17] also mentioned that a study of 62 DW projects, which was conducted in 1996, showed an average return on investment (ROI) of 321% for these enterprise-wide implementation in an average payback period of 2.73 years.

In addition, [59], who investigated whether lodging companies are involved with DW technology through a sample of twelve large lodging corporations, found that the most of hotel corporations in the study were using their DWs to support market analysis. However, [13], who conducted a survey on a large Australian public organization, found that 60% of the users were with limited or no usage (or were anticipating the use in the future) of the DW. The data also helped the users to make informed decisions and the data, which was retrieved from the DW, was also presented to the senior management and other strategically oriented sections in the form of reports i.e. annual and quarterly reports.

Similarly, [18], who surveyed DW's managers and data suppliers from 111 organizations in different regions of the United States (US), also found that all companies had operational DW and nearly all of them considered that their initiative is successful. In other words, 26% of the respondents considered it runaway success. Another survey by Forrester showed that 878 IT decision-makers in the US enterprises were somewhat satisfied with the accessibility and quality of customer information; 82% of these respondents are satisfied or very satisfied [60]. [35] also found that about 55% of 196 respondents firms (107) in two major states in the US had already adopted and used DWs.

Similarly, [23] p.192-196 found that 60% of the respondents consider the functionality of their DW below expectations. 40% of the dissatisfied group was actually still using it. This means that 80% of the respondents were still using their internal DW, which is a good indication of the overall degree of satisfaction.

In addition to those studies, [61], who reported the results of a survey which was conducted at The Data Warehousing Institute (TDWI) World Conference in New Orleans 2003, found that 45% of the respondents had been already in production with their current DW or implementing a second or third release.

The 2007's IBM Data Warehousing Satisfaction Survey showed that 56% of those questioned were very successful with their DW (200 end-user enterprises were participated), however, 43% of the respondents acknowledged the need for improvement, as there are still a number of business and technical challenges confronting the enterprises which make use of DWs according to the survey [64]. The success of DW's implementation, according to [64], is growing as 56% of the respondents were very successful and satisfied. [65], who conducted a survey on 84 users of DW, found that the majority of respondents (73%) in the surveyed firm were successful in obtaining and accessing the needed data and information from the DW, only two respondents indicated that they were not at all successful, while 56% indicated somewhat successful and 13% indicated very successful. In addition to these results, 67% and 33% of the respondents rated the importance of the obtained information in performing their job better as vital and somewhat important respectively.

Numerous studies have also shown successful implementation of DW. For example, [66] used a case study and conducted a series of interviews at Continental Airlines. The results showed that the organization has realized an enviable level of DW maturity and significant cumulative benefits. [67], who surveyed 244 members of TDWI, found that 51.2% of the respondents had at least one DW application and 30.3% were still in development stage. 17.2% were still in planning stage and 1.2% of respondents had no any efforts made in their organizations to implement the DW. This result showed that more than 80% of respondents had implemented DW.

According to [14], there is a scarcity of empirical studies that examine the DW success. Therefore, this paper investigates the extent to which Jordanian firms implemented DW and the benefits for implementing DW. It is aimed at providing empirical evidence, thereby extending the body of research regarding the implementation of DSSs in general and DW in particular.

## VI. Results, Findings and Discussion

As mentioned earlier, the study's sample consists of the Jordanian firms' top management. The results of the study's sample analysis are shown in the figure below (Figure 1). In this figure, the sample results are broken down by responses.

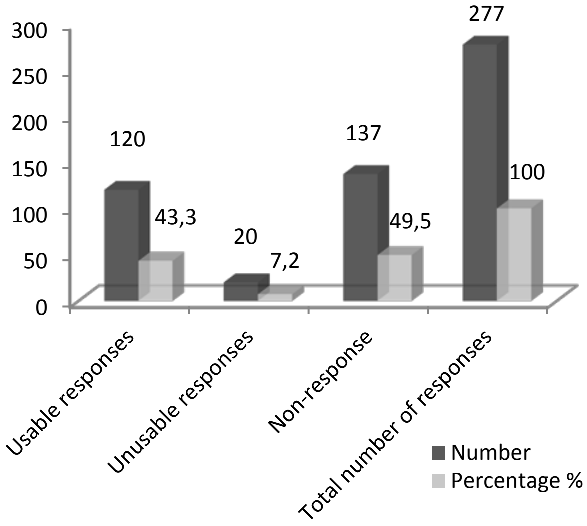

**Fig. 1.** The analysis of the study's sample (Source: the figures are based on the responses to the questionnaire).

As can be seen from these results, 140 completed questionnaires were returned to the researcher's address with a response rate of 50.5%. According to these figures, usable questionnaires accounts for 43.3% of the total sample. 20 of the questionnaires were discarded as unreliable, i.e. there were many essential questions missing from the questionnaires. To sum up, all the firms (277), which were listed on ASE at the time of data collection, were selected. 140 filled questionnaires were returned generating 50.5 %. This response rate somehow on average comparison to many similar studies such as ([69]; [70]).

The reliability, internal consistency and validity of the Likert scale questions are assessed by using Cronbach's alpha. It was found that Cronbach's alpha is the most popular method for assessing the reliability of scales.

It has been used by many researchers, including [71]. Cronbach's alpha determines the internal consistency of the items in a survey instrument (questionnaire) to assess its reliability. Figure 2 shows Cronbach's alpha for the Likert-scale question. In addition, the figure demonstrates the mean, SD, sum of item variances (V) and standard error (SE) for the rating scale question. As can be seen from these figures, Cronbach's alpha coefficient is more than 0.9.

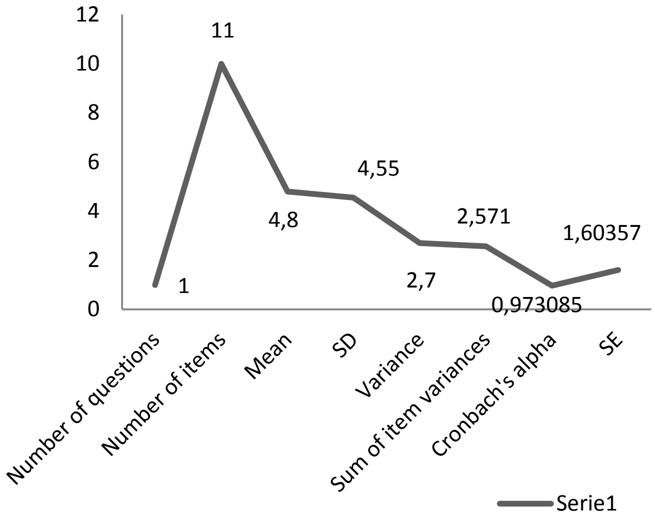

**Fig. 2.** The statistical analysis of reliability and validity (Source: the figures are based on the responses to the questionnaire).

The respondents, who their firms implemented DW (42 respondents), were solicited for their opinions regarding the actual benefits (which their firms have realized) of implementing the DW. The likely and expected benefits, which were measured on a seven-point scale ranging from 1 (strongly disagree) to 7 (strongly agree), are shown in table (1).

The table shows the mean and SD for all the select benefits. As can be seen from these results, the role of DW's information in enhancing and facilitating the process of decision-making (mean=6.38) was the most important benefit of implementing the DW in the Jordanian firms involved. From the data in the above table, it is apparent that the improvement to decision-making process is the second most widely mentioned benefit of implementing DW.

Other important benefits of implementing DW include more accurate, useful, reliable, complete and relevant information to decision-makers (mean= 6.28), helping decision-makers in taking fact-based decisions (mean= 6.26) and more efficient and successful decisions (mean= 6.23). Moreover, the figures show clearly that the DW has provided many benefits, including frequent, accessible and timely reports and information to decision-makers (mean=6.11), improved the quality of decisions (mean=6.04), easy access to data and information (mean=6.04) and DW's information is used as a basis for decision-making. According to these figures, Increase in competitive capability (mean=5.57) and better performance measurement (mean= 5.54) were the least important benefits of implementing DW.

TABLE I.
THE BENEFITS OF IMPLEMENTING DW

| Benefits of implementing DW | No | Min. | Max. | Mean | SD |
|---|---|---|---|---|---|
| DW has improved the quality of the decisions | 42 | 4 | 7 | 6.04 | 1.01 |
| DW's information has helped decision-makers in taking fact-based decisions | 42 | 4 | 7 | 6.26 | 0.83 |
| Better performance measurement | 42 | 3 | 7 | 5.54 | 1.26 |
| Easy access to data and information | 42 | 5 | 7 | 6.04 | 0.79 |
| DW has provided more accurate, useful, reliable, complete and relevant information to decision-makers | 42 | 5 | 7 | 6.28 | 0.81 |
| DW has provided frequent, accessible and timely reports and information to decision-makers | 42 | 4 | 7 | 6.11 | 0.99 |
| DW's information is used as a basis for decision-making in your firm | 42 | 4 | 7 | 6.02 | 0.92 |
| Increase in competitive capability | 42 | 1 | 7 | 5.57 | 1.67 |
| Improvement to decision-making process | 42 | 5 | 7 | 6.31 | 0.71 |
| DW has led to more efficient and successful decisions | 42 | 4 | 7 | 6.23 | 0.93 |
| DW's information enhances and facilitates the process of decision-making | 42 | 5 | 7 | 6.38 | 0.76 |

Source: The figures are based on the responses to questionnaire.

In conclusion, the figures clearly lead to the conclusion that the select benefits are highly rated. These results are entirely consistent with other earlier research on DW. For example, [10], who investigated the adoption of DW in Small and Medium Enterprises (SME) In Zimbabwe, found that DW provides a variety of benefits, including the reduction in the overall effort concerning data analysis and reporting, improvements to the reports' quality, more flexible reaction to new information needs and improvement to business decisions through more precise as well as more current data analyses.

Park and Kim [11], who presented a DSS for the management of sewer infrastructure using DW technology, found that the managers, by using DW, could significantly reduce the burden of collecting unnecessary information, easily retrieve managerial information and achieve effective data management. Consequently, the proposed DSS could provide flexible storage of valuable information, reduce subjectivity in decision-making processes, accelerate the pace of data flow, improve the consistency in decision-making processes (consistent decisions), and better environment for strategic operation of infrastructure.

## VII. CONCLUSION

The evidences, which are obtained by analyzing the data from the questionnaires, reveal exceptionally remarkable facts, first of all and to some extent, the success of implementing DW in Jordanian firms was a direct result of the benefits which were reaped from using the DW by the managers of Jordanian firms. One consequence of implementing DW was the great role of DW's information in enhancing and facilitating the process of decision-making. The results also showed that the Jordanian firms benefited greatly from implementing DW: These benefits reflected well on the process of decision-making. The results also revealed that the DW is a fruitful source of information. Moreover, the implementation of DW proved to be a success through helping decision-makers in taking fact-based decisions. Based on some of the study's findings, it can be concluded that the implementation of DW did provide frequent, accessible and timely reports and information to decision-makers and easy access to data and information. Furthermore, the DW was lauded by the users for the successful use of its information as a basis for decision-making.

This study has humbly contributed to the field of scientific research in general and the field of decision support systems (DSS) in particular in many ways, first of all, the studies on the implementation of DW were nearly all in developed countries. This study was applied in Jordan, therefore, the results of this study made a humble contribution to the existing knowledge in the field of implementing DW worldwide in general and in Jordan in particular.

Second, there is a need for evidences that the DW improves the quality and accessibility to information. Therefore, this study practically investigated whether or not the implementation of DW improves the quality and accessibility to information and facilitates the decision-makers' tasks. Lastly, Based on extensive literature review, the researchers have identified that firms are often unsuccessful due to a lack of appropriate information. For this reason, this study is one of the few empirical studies which have attempted to examine the effect of DW on decision effectiveness. In addition, previous research has not empirically tested its effectiveness in DSS contexts in Jordanian firms "to the researchers' knowledge".

Despite the usefulness and positive contributions of the study's results, these results should be treated and interpreted with caution. In fact, the study's sample included only the Jordanian firms which are listed on ASE. As a consequence, this might severely restrict the generalization of the results. It is believed that the results of this study might have been dissimilar, if all Jordanian firms have been surveyed. Therefore, prospective researchers are recommended to broaden the scope of their investigation to include all Jordanian firms.

Email: Maciej.Pondel@ue.wroc.pl

*Abstract*—**This paper describes the author's concept for universal enterprise platform that allows to benefit from modern approaches to data analysis based on Business Intelligence and Big Data technologies. This idea is based on SOA architecture that enables workflow to coordinate the business processes and communicate domain applications with bespoke Business Intelligence and Big Data Solutions. Whole platform is designed the way that can be provided in a cloud environment.**

## I. Introduction

IN current times business requires scalable IT platforms supporting whole business processes from the beginning till the successful finish. Due to a huge complexity of the processes they require very often several domain applications like ERP, CRM, DMS and many more. In most cases those processes are handled manually and need human interaction between various IT Systems. Such approach leads to mistakes or inconsistencies in processes. Business Intelligence systems and Big Data solutions in current world provide essential information and knowledge for managers on the strategic or tactical level. The most important challenge defined in this paper is to take advantage of them also on the operational level of a business.

## II. Big data and Business Intelligence

There are several definitions of Big Data and Business Intelligence solutions. Some of them emphasize that Big Data is a modern concept replacing older approach defined as Business Intelligence [1], [2].

We can also find the approach stating that Big Data resolves new problems, brings new opportunities and meets new challenges that are different or complementary to the known Business Intelligence and Data Warehouses areas of usage [3], [4].

Author of this paper claims that both Big Data and Business Intelligence solutions meets similar problems when we look at it from the very general perspective. In details they have slightly different foundations and some problems could be better satisfied with multidimensional approach based on data warehouse and Business Intelligence solutions (OLAP, reporting, querying) and some problems are better satisfied with Big Data approach (NoSQL data structures, map reduce parallel processing).

We have to remember that Business Intelligence is no only a technology or a set of IT tools. It is considered a management strategy used to create a more structured and effective approach to decision making [5]. Of course, to fulfill this strategy, we need IT tools providing an access to data and capabilities allowing analysis and presentation of information. We can consider traditional BI based on ETL Process, data warehouses, data marts, OLAP, dashboards, scorecards and analytics. The Business Intelligence approach is still evolving. We can mention Business Intelligence 2.0 that includes following Features [5]:

- Proactive alerts and notifications.
- Event driven/ real time/ instant access to information.
- Advanced analytics.
- Enterprise Integration.
- Mashups and portal integration.
- Mobile/ Ubiquitous access.
- Improved visualization, Rich Interfaces (RIA).
- BI as a service (SOA and SaaS)
- In-memory analytics
- Open Source BI.

We can also meet (mainly on the BI Vendors websites) the term Business Intelligence 3.0. Author of this paper couldn't find a consistent scientific definition of the term. Different sources define Business Intelligence 3.0 as another evolution of BI systems that focus on the user interface, that is so intuitive to the regular user, that little or no training is necessary to explore data. We can list the following terms that appear when we consider this new approach: Data Discovery, Advanced Visualization, Visual Analytics, Business Discovery, Self-Service Business Intelligence. Example tools delivered by the top vendors are [7]:

- Visual Insight by MicroStrategy,

978-83-60810-66-8/$25.00©2015, IEEE

- Visual Intelligence by SAP,
- Visual Analytics by SAS,
- PowerPivot, Power View Power BI by Microsoft,
- Cognos Insight by IBM,
- Endeca by Oracle.

Also, it's important to highlight that there are two kinds of self-serve BI user:

- Analytics Power Users who create visual apps from multiple data sources – both internal and external.
- Regular Users that can fully explore the visual apps created by power users or IT.

Literature also mentions that BI 3.0 focuses on mobile devices. Mobile devices are here treated as the interface of data visualization but also as a source of the data together with other sensor-based Internet-enabled devices equipped with RFID, barcodes, and radio tags (the "Internet of Things") [8].

According to the quoted key factors of Business Intelligence 3.0 we can state that it is not a completely new concept but more development of Business Intelligence 2.0 with emphasized selected features. In some cases BI 3.0 concentrates on the same data sources as Big Data approach.

From the author's point of view the main difference between Business Intelligence and Big Data concept regards the following:

- Business area: Business Intelligence tools and Warehouses are concentrated on business transactions (sales, costs, money transfers) [13] and Big Data stores the records describing all the activities leading to the transaction or leading to the decision about transaction (tracking the customer path in on-line or off-line shop, social activity)
- Data quality – in most cases data in warehouses come from transactional databases that are consistent, stable and there is no room for any errors. In case of Big Data systems that are loaded very often with social content, by devices (Internet of Things) or server logs, the quality of data can be lower. In any case the lower data quality doesn't contradict the value of Big Data solutions. If there is an error in the data describing transaction in data warehouse it can result with the serious problems in financial / tax reports. The outcome of the missing or incorrect items the Big Data system usually do not affect the business so much (of course it the wrong data do not represent the majority of data).
- Data structure – the structure of data warehouses is based on relational structures and usually are denormalized multidimensional star or snowflake structure. Basing on such structure we can easily build the OLAP cubes. Big Data system store data in non-relational databases.

## III. Workflow Based platform

Workflow systems are considered mainly as tools supporting business processes. A workflow application implements a business process model. The model describes the process steps to be performed to achieve a specific business goal, business rules for coordination of those steps and responsibilities of process participants[9]. The steps include tasks that should be performed by agents that can be human, computer systems or combination of both [10]. Workflow systems, with the benefits of efficient and flexible process modelling and process automation, have been widely used for managing business processes [11]. The main advantages of using workflow platforms are:

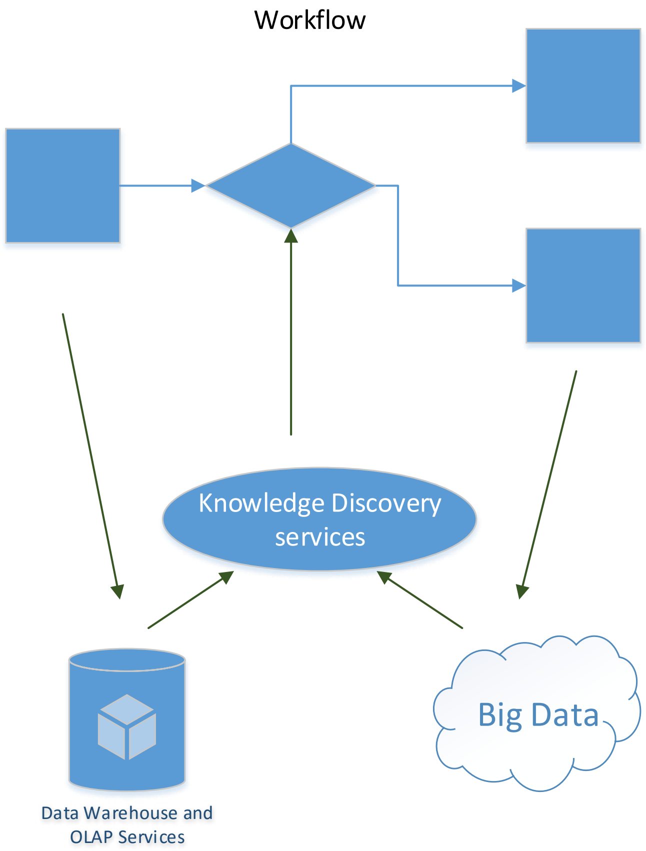
- Ability to model and deploy processes by a business user without engagement of software developers and deployment procedures.
- Ability to measure the performance of the processes and the whole business area related to the process.
- Full control over processes. Every step must be undertaken during the process and whole process (there is no possibility to forget some activity) has to be performed according to the business rules (no risky shortcuts allowed). Workflow makes processes less dependent on users mistakes and faults.
- Workflow can automate both business critical processes and also those back-office and automation makes processes to consume less time and resources.

Workflow activities execute programs that consume and produce data (parameters values and files). An output data produced by an activity can be consumed as input data to another activity, establishing a dependency relation between those activities [12].

## IV. Concept of BI and Big Data platform that is workflow driven

Being aware that steps in workflow produce some data it seems natural that they could be connected directly to the data storage such us data warehouse or big data repositories. Such approach can change the current well known and stable ETL approach (Extract Transform and Load).

Regarding to the consumption data by workflow activities we can assume that beside the data produced on the earlier stages of the process, the activity can be also fed with the data or information coming from data warehouses or even knowledge produced by a knowledge discovery modules of both BI and Big Data Systems.



Workflow
Knowledge Discovery services
Big Data
Data Warehouse and OLAP Services

**Figure 1. Concept of workflow and Big Data and Warehouse communication**

Some key items of the system's architecture are visualized on the Figure 1. There we can business process supported by workflow tool. Some steps (decision blocks) can use the Knowledge acquired in Knowledge Discovery module. Other steps (actions) can load the data into:

- Data Warehouse
- Big Data repository

The compound layer called Knowledge Discover services is working on the collected data and in this layer the Data Mining models are prepared. We can use well the known methods of data discovery like:

- Artificial neural networks
- Machine learning
- Naïve Bayes networks
- Collaborative filtering
- Clustering
- Association rules

and any other that can produce the valuable conclusions in the business environment.

The most important assumption regarding this layer is accessibility to its actions through SOA protocols like SOAP and REST. Regarding the actions it is meant mostly executing the models on the real object to gather the classification or assign the object to the cluster. Author assumes that through the service model we could also launch the training, testing or validation processes.

In SOA architecture we can efficiently send data for the technology different:

- Workflow platform
- Data loading services
- Knowledge discovery services

Example of a workflow driven combination of such activities can be the sales process in an example company. During the process, the customer goes the path (live or virtual) among various products and stops to watch some of them. The information about user focusing on the product and making decision regarding putting it to the basket or not is a valuable item to store in big data repository. After the user makes some particular activity, we can ask the conclusion model (bulid on previous customers behaviors) if it is efficient to present the customer directed proposal (or any other marketing message). If the recommendation of conclusion model is positive we can communicate with customer by:

- sending him message on his mobile (using sms, mms or push notification in the bespoke mobile app),
- presenting him the message on the screen visible in the market,
- make the shop assistant to approach the customer and ask some more information and present the dedicated offer.

We can imagine many more ways the store is communicating the customer to make the offer more suitable for him and optimize the income and turnover from the customer service.

Of course the areas of usage of such platform are not limited only to sales and marketing processes, although it is probably the most efficient and most obvious to use data mining based on big data and Business Intelligence modules there.

The important remark regarding the proposal of workflow using Big data and BI states that such workflow can automate nearly every process in the company (both Front Offices and Back Office as well). Workflow is able to communicate not only with Knowledge Discovery services but also with any application working in the enterprise environment that is build using Service Oriented Architecture approach.

## V. Project of Platform Implementation in Enterprise Environment

Due to various business processes and the logic of existing IT environment in enterprises we cannot assume that the implementation of proposed platform may be done in a standard way and be processed easily. Of course whole platform will contain a set of coupled services, ready to cooperate, but they all will need to be integrated with enterprise data sources and configured to fulfill the business requirements.

The project of the platform implementation will contain the following stages:

1. Identification of business goals. The processes or business areas of efficiency improvement must be defined. We can imagine a whole variety of platform usage like:
    a. Sales processes
    b. Customer relation and loyalty management
    c. Logistic processes
    d. Back office processes

    And many more
2. Information and data sources identification. We should investigate the possible sources of data required to acquire sufficient knowledge useful in chosen processes improvement. In current approach the data may come from:
    a. The classic electronic sources like:
        i. IT systems databases.
        ii. Server logs describing usage of the IT tools.
        iii. Search engines' queries corresponding to the knowledge flows and users' needs.
        iv. Social media activities of internal users and external individuals (customers, suppliers, fans, competitors). Social systems are now full of interesting information. We can distinguish 2 ways of social systems:
            1. Open – like Facebook, Twitter, Youtube, LinkedIn and many more
            2. Internal – available only for internal users or intentionally invited externals – like Yammer, HighQ, eXo Platform and many more.
    b. The electronic sources emerging especially to feed the database of implemented platform. They can register activities of individuals that have not been registered yet eg.:
        i. Sensors identifying paths of customers movement around market or employees in a warehouse.
        ii. Barcode scanners, RFID tags / readers.
        iii. Mobile devices (tablet/smartphones) equipped with applications to register some facts that have not been registered previously (Customer assistant may register the conclusion of conversation with customer eg. Customer has just bought a house and soon he will need pieces of furnishings or the logistics employee may calculate the time every activity takes and register that)
        iv. Stationary machines allowing customers to give a feedback or provide a satisfaction survey in a simple way.
3. Verification of individuals acceptance for registering the data describing individuals and their behavior. If customers feel surveilled they can avoid the services or the company that implemented platform. Internal employees who are aware of continuous tracking may feel strange and not work fully efficient. Another important aspect is validation of law and regulatory compliance. Personal data is protected by the law and we should verify if the data we gather can be processed without breaking the law.
4. Data load processes design. We can distinguish in here:
    a. ETL (Extract, Transform and Load) processes – mainly for data coming from traditional electronic sources.
    b. Services design (SOAP/REST) – mainly for data describing events that were when event occurred. In such approach the database is filled immediately

5. Data structures design that will include:
    a. Data warehouse structure in the form of multidimensional structure (star or snowflake). Basing on the structure we can build OLAP cubes structure or we can process a data mining models.
    b. Non – relational database that can be much more efficient while storing the behavioral data. We can distinguish in here:
        i. Column database like Cassandra or HBase
        ii. Document database like MongoDB or HyperDex
        iii. Key-value like FoundationDB or CouchDB

    NoSQLdatabases are more efficient for huge data sets processing and the performance of data loading is much higher.
6. Validation of the data designed structure especially it's adaptation to the business goals that were discovered on the earlier stage. Verification of the data quality must also be made.
7. To build the knowledge discovery services it is crucial to choose the correct data exploration

methods that fits best to business problem solutions. The huge topic is extraction of the algorithms parameters and their adjustment for models to generate the best possible results.

8. Since the main concept is based on the fact, that business processes using knowledge services and feeding them with data should be supported by workflow tool – it is important on the design stage of the project to model the business processes and automate them in the workflow software.

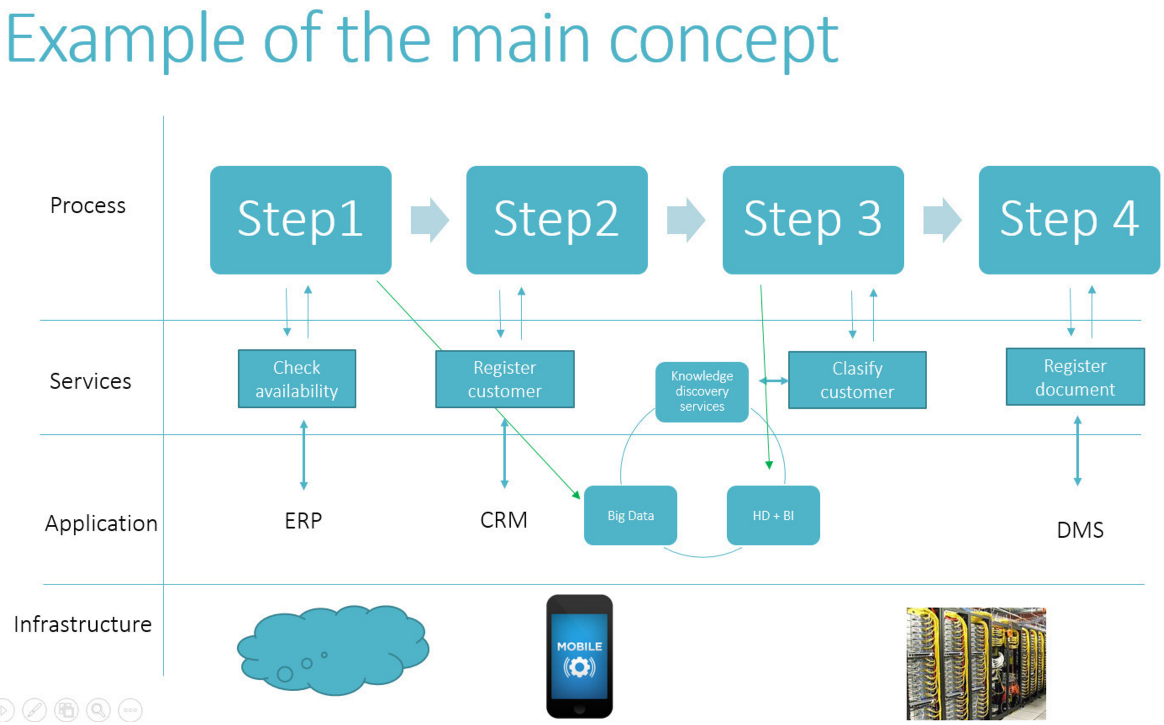
## VI. Platform Structure Assumptions

In the current state the platform is technology independent. The necessary components like:

- Data warehouse
- NoSQL databases
- Services (SOAP/REST) protocols
- ETL tools
- Workflow Engines
- Data exploration algorithms

have implementation in various operating systems and software development platforms, that is why from today's perspective it is not crucial to select the final technology.

Figure 2 . presents the example of the concept platform architecture basing on real life examples of use cases.



Example of the main concept

**Figure 2. Example of concept platform**

## VII. Challenges

Without a doubt, implementation of presented platform is a risky project and includes a lot of challenges. Among them we can distinguish:

- Performance – the knowledge discovery services and intended to respond on-line for process requests. If there is any significant delay – it may harm the efficiency of core business processes.
- Data mining models' relevancy – it is crucial to acquire valuable knowledge form data and provide it to the business scenarios supported by presented platform.
- Business efficiency – implementation of the platform is high cost affair. If we choose wrong processes or wrong methods of knowledge discovery and usage - the return of investment bay be not rewarding
- Stability of the platform - some of the technologies / solutions intended to be used in the platform are modern and in some cases may be unstable. It may influence the stability of the whole platform.

## VIII. Conclusions

The article presents modern approach for building enterprise platform, that could be used in majority of enterprises. The advantages of such approach are the expected high performance and most efficient usage of analytical platform (BI and Big Data) not only on a strategic level as management support systems but also on an operational level where business processes supported by knowledge can be most efficient from a business perspective. The future researches will concentrate on choosing example technologies and implementation of pilot atomic use cases to prove the correctness of proposed approach.

***Abstract*—We address the problem of the access to the results of scientific publications in the agri-food domain. We focus on the description of main contributions of the papers treating them as accepted or rejected beliefs of their authors expressed in the form of scientific laws. We define the structure of different kinds of scientific laws present in the domain in the form of an ontology. The main concern of the paper is a process in which we proceed from the abstracts of papers to the ontological representation of laws. Moreover, we present examples of SPARQL queries which show how the resulting knowledge base can be used. Among the uses we point out discovering new scientific hypotheses and incoherencies among scientific laws.**

***Index Terms*—ontology, scientific law, knowledge extraction, scientific hypotheses, incoherency**

## I. Introduction

In RECENT years the number of scientific publications has increased significantly. It is common knowledge in scientific community that there are so many works published every year that it is not possible for one person to read all of them, even if that person limits themselves to a narrowed specialization. The situation of professionals who are working at the crossroads of science and practice is even worse because they must not only struggle through countless scientific papers but they must also cope with the difficult scientific language in which these papers are written. This problem gets even more serious when it comes to scientific projects where research is being conducted in many loosely connected disciplines.

Some of the journals are already providing structured abstracts within the papers published there. One of the possible structures of such abstracts is to divide the abstract into three sections: background, results, and conclusion. And, additionally, there are keywords at the end[1] [1]. Another way to facilitate access to the content of a paper is using so called *highlights* which are “a short collection of bullet points that convey the core findings and provide readers with a quick textual overview of the article”.[2] There are also semantic solutions addressing this problem. For example, the authors of the Nanopublication and the Micropublications projects have created models to represent statements and argumentation from scientific papers. We shall discuss the projects in the section dedicated to related works.

The research presented in the paper was conducted within ProOptiBeef[3] project, oriented towards increasing the level of innovation in Polish beef sector. One of the tasks of the project is creating a knowledge base (henceforward KB) of recent results published in the top journals relevant to the domain of beef production and consumption. These results were selected by the community of the experts involved in the project. One of the main goals of constructing the KB is to help scientists decide which experiments should be conducted in order for the research to be innovative.

In order to transfer knowledge from the papers to our KB, we have created an ontology called Science. It is designed to represent proved and disproved statements extracted from scientific papers stored in the database of the ProOptiBeef project. We shall informally describe the Science ontology in section II of this paper. In section III we shall present the way in which we fill the KB with the information from scientific papers. The final element of our KB is a reasoning part. This element enables us to perform some reasoning algorithms on our KB in order to discover new scientific hypotheses and to detect incoherency among scientific laws which have already been represented. We shall present an implementation of three of these algorithms in the SPARQL query language in section IV. In section V we shall shortly describe related works. The last section, section VI, contains summary and describes our planned future work related to the project described in this paper.

## II. Ontology of scientific laws

As mentioned above, the project’s KB is structured according to Science ontology (see [2], [3] for the formal structure of the ontology and [4] for the philosophical sources of the ontology). The ontology is expressed in OWL and is composed of two parts: TBox and ABox. TBox (terminological component) consists of a taxonomy of scientific laws (see figure 1) and provides a formal characterization of each class of the

[1] See also http://www.nlm.nih.gov/bsd/policy/structured_abstracts.html. Journal of Biomedical Semantics can serve as an example.

[2] See: http://www.elsevier.com/journal-authors/highlights.

[3] Full name of the project: *ProOptiBeef – Optimizing beef production in Poland according to strategy “from fork to farm”*. Web page: http://prooptibeef.pl.

978-83-60810-66-8/$25.00©2015, IEEE

taxonomy[4]. Laws from different classes differ in their structure and therefore require different representation specified by the ontology. The top distinction in the taxonomy is between *quantitative and qualitative laws*[5]. Quantitative Law concerns the dependency between *qualities* of an entity that can be measured (e.g., time of (beef) aging influences (beef) pH value) while Qualitative Law concerns *perdurants* or *endurants* describing directly their properties or comparing them with respect to their qualities (e.g., meat of bulls housed in groups before slaughter was less tender than meat of bulls individually housed).

The meaning of terms "endurant", "perdurant" and "quality" comes from the DOLCE ontology [5] which is used as a foundational ontology for Science. The terms are to be understood as follows:

- endurants are wholes that endure in time, e.g., beef, pasture, food;
- perdurants are entities that "happen in time"; they can have temporal parts or spatial parts, e.g., feeding, slaughtering, cooking;
- qualities are entities that can be perceived or measured, e.g., height, weight, age, protein content.

Quantitative Law is further divided into Correlation Law and Functional Law. Correlation laws state that there is a correlation between the values of the qualities, but the details of the correlation are unknown, i.e. it is not possible to determine the function (direction) of it (e.g., there is a significant correlation between sarcoplasmic protein solubility and both expressible moisture and color parameters). Functional laws say that there is a dependency between the values of two qualities. One of the qualities is called an independent parameter and the other one is called a dependent parameter. A functional law states that the value of a dependent parameter is a function of the value of an independent parameter (e.g., aging influenced instrumental hardness). If the function describing dependency in a law is monotonic (i.e., it is either increasing or decreasing), this law is an instance of Monotonic Law (e.g., fat reduction results in higher cooking losses).

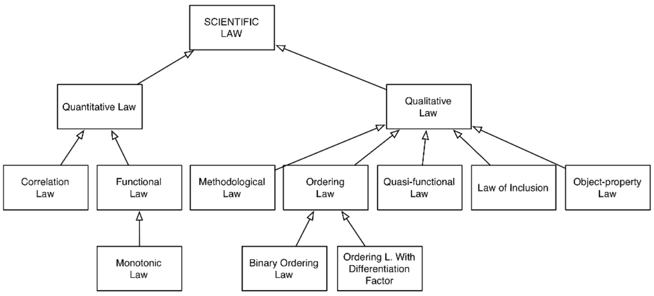

Fig. 1. The backbone of Science ontology.

There are five subcategories of Qualitative Law: Methodological Law, Quasi-functional Law, Law of Inclusion, Object-property Law and Ordering Law. A methodological law states that a method is used to measure a certain property (e.g. Multiple Linear Regression is used to measure beef tenderness). A quasi-functional law—similarly to a functional law—expresses the dependency between two qualities but one of the qualities is qualitative (e.g., the sex of an animal has influence on the tenderness of its meat – "sex" here is a qualitative quality). A law of inclusion states that one class of objects is a subclass of the other (e.g. meat color is a meat quality). An object-property law states that an object possesses a quality (e.g., red meat is an important source of vitamin D). Ordering Law is divided into two subcategories: Binary Ordering Law and Ordering Law with Differentiation Factor. Each instance of Ordering Law has some ordering basis according to which classes of objects are compared. Binary ordering laws compare two classes of objects (e.g., dairy cow lean has a longer display color life than beef cow lean) with respect to some quality playing the role of order basis (e.g., display color life). Each instance of Ordering Law with Differentiation Factor describes a change of some quality of an object after the object has undergone some modification (e.g., magnesium decreased in beef during cooking).

It is also worth noting that the term "scientific law" which is used by us in the paper covers proved and disproved statements described in scientific papers. Proved and disproved statements are instances of classes: Accepted Scientific Law and Rejected Scientific Law, respectively (see figure 2). It suggests that we treat scientific laws similarly to beliefs. Referring to [6] we assume that each scientific law has its "owners", who are the authors of the paper which the scientific law comes from. The paper is also a source in which the law is exemplified. So modelling author role and the paper as the context in which a scientific law appears is very important for our representation ([7], [8]).

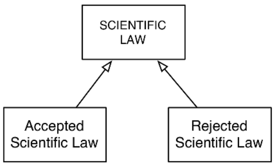

Fig. 2. Each scientific law is either accepted or rejected in a scientific paper.

ABox of our KB is simply a set of individuals (i.e., concrete scientific laws extracted from concrete scientific papers) which are represented in accordance to the TBox just described.

Below we shall describe the process of extraction of scientific laws from the scientific papers and their translation into the language of Science ontology.

[4] The TBox of Science ontology can be browsed here: http://onto.kul.pl/webprotege/.

[5] The way the laws are represented in Science has been widely described in [2], [3].

## III. Knowledge Acquisition

### *A. Extraction of knowledge from scientific papers by domain experts*

ABox contains a significant number of 8k scientific laws adequately representing the content of selected scientific articles. The selection of papers from the top journals—in the opinion of researchers involved in the ProOptiBeef—was prepared in the earlier phase of the project. Thus, the remaining task was to present the information from the selected papers in the form designed to represent scientific laws.

For an efficient realization of the task we decided to use abstracts of the papers as the main source of information. The UNESCO guide for the preparation of scientific papers for publication [9] states that "[t]he abstract should contain the results and conclusions of the paper in brief detail adjusted to the size allowed to the abstract and should, within these limits, refer to any new information which it contains. The abstract should not contain information or claims not contained in the body of the paper, nor should it include inessential details. [...] "*New information* should include observed facts, conclusions of an experiment or argument, the essentials of new methods or apparatus, etc." Moreover, the guide postulates that "[t]he abstract should be *self-contained*". In the light of these principles an abstract should contain enough information about the main results of the papers to reconstruct scientific laws.

Our experience shows that the practice in the journals from the agri-food domain in principle agrees with these postulates. However, authors use there technical vocabulary and discipline's folklore. That makes them difficult to be accessed by non-specialists. Thus, the participation of agri-food science specialists in the process of extracting knowledge from abstracts is inevitable.

On the other hand most specialists are not familiar with the formal and computational tools of knowledge representation. After a short introduction to our schema of the representation of scientific laws the specialists invited to the project were aware of the key conceptual distinctions (object, qualities) and the key elements of the representation of theses – the influences between factors and correlations. However, to encourage them to co-operate we had to allow them to present the results of their analyses in a form quite close to natural language with only some structural restrictions.

As a result we introduced a multi step process whose main steps are:

- agri-food specialists extract information from abstracts and write them down in a semi-structured way,
- information is automatically transferred to a database,
- the database is further elaborated by ontologists and (this is itself a multi step process described below)
- finally the information is automatically converted into OWL ontology.

Let us now trace the process in detail.

*a) STEP 1:* An abstract (earlier divided into sentences that are numbered for easier reference) of a scientific paper goes to the so called *Raiders of The Theses* (most of them are PhD students of broadly understood agri-food science). Their work is controlled and approved by senior members of the project team. The work with the abstract is based on a text form covering the following elements:

- a list of objects
- a list of properties (qualities)
- a thesis formulation from the abstract
- a new elaborated formulation of the thesis

The first two lists constitute a conceptual structure in which the laws presented in the article can be expressed. The description of the list of objects is usually rather complex and is a subject of further ontological elaboration. An example is presented later in the paper when we discuss the work of ontologists (see section III-B). The list of properties is rather simple and is directly transferred into a database where each quality is connected to the article and the thesis it comes from.

*Example 3.1:* Now let us concentrate on the formulation of theses and analyze an example. The original formulation from the abstract is as follows[6]: "W normalnej atmosferze, fotooksydacja była powierzchowna, ponieważ zaobserwowano odwrotną korelację między wagą plastra mięsa i stężenie COP na podłożu lipidowym, w przeciwieństwie do atmosfery bogatej w tlen (32%)." ("In normal atmosphere, photo[o]xidation was a superficial process, since an inverse correlation between meat slice weight and COPs content on a lipid basis was observed, unlike in a highoxygen (32%) atmosphere.")

The specialist disambiguated the formulation and divided it into elementary facts forming laws of one of the type from our ontology. The statement from our example is presented as the two following facts:

- "Wraz ze spadkiem masy plastrów surowej wołowiny, poddanych pakowaniu w atmosferze powietrza, zwiększa się stężenie produktów oksydacji cholesterolu." ("In normal atmosphere, with the decrease of meat slice weight the COPs content increses.")
- "Wraz ze spadkiem masy plastrów surowej wołowiny, poddanych pakowaniu w atmosferze bogatej w tlen (32%), zmniejsza się stężenie produktów oksydacji cholesterolu." ("In a highoxygen (32%) atmosphere, with the decrease of meat slice weight the COPs content decreses.")

### *B. Pre-ontological elaboration of statements, qualities and objects*

*a) STEP 2:* Statements formulated in *STEP 1* were automatically transferred to a database for further elaboration by the ontological staff of the project. Within this process all statements are annotated with unique identifiers. The two above statements from our example received numbers: t_652_3 and t_652_4 respectively. We shall further refer to them using these identifiers.

[6] Specialists worked on Polish translation – we present both Polish and English versions.

*b) STEP 3:* Each statement, whether proved or disproved, has an attributed type of thesis from Science.

For the selected types of scientific laws it is also necessary to determine the monotonic type. There are two main monotonic types: positive and negative. They express the direct or inverse proportion between qualities for the monotonic laws, increase or decrease of quality values for ordering laws. In special cases of ordering laws, additional monotonic types were introduced which are "equal", "different" or "no monotonic type". Exceptions, related to additional monotonic types, refer to these in which values of qualities are equal/stay unchanged or values are said to differ but the exact value differences are unknown. The latter exceptions refer to the ordering laws with differentiation factor, where the value of qualities is unknown.

At this point it is also determined for a particular thesis whether it is proved or disproved, by marking it as "accepted" or "rejected".

*Example 3.2:* Let us describe this on the example of thesis t_652_3 (it is a continuation of example 3.1). The statement is proved, so we mark it as "accepted". It describes dependency between weight and concentration of cholesterol oxidation products. Both qualities are quantitative qualities and quality dependence is known; therefore the thesis should be assigned as an instance of Monotonic Law. Monotonic laws require determining monotonic type. At this case decreasing the weight causes increasing the concentration of cholesterol oxidation products, that indicates an inverse proportion between qualities: "negative" monotonic type.

*c) STEP 4:* The next step of the development refers to relating the qualities to particular scientific laws. The qualities were listed by the domain specialists in the earlier phase (see *STEP 1*), but the list was linked to a particular article not to a thesis (see *STEP 2*). So if there were a few theses extracted from one article (which was almost always the case) there was a need of selecting the qualities for each thesis. A particular thesis needs to have not only proper qualities attributed but also (if possible) their role determined. The latter depends on the type of thesis. To attribute qualities to a thesis, the proper qualities are selected from the list. The proposed names of qualities must precisely describe the qualities mentioned in the thesis. In other case they should be corrected together with their English translation.

For all scientific laws qualities can be attributed; the only exception might be the laws of inclusion, which may refer to two or any quality. If a statement expresses any kind of influence between two or more qualities, then we should characterize the roles of these qualities in the statement. It is so in the case of all functional, monotonic and quasi-functional laws. In such statements dependent and independent qualities are distinguished. For methodological, ordering and object-property laws single qualities are attached to the statement. The special cases are laws of inclusion and correlation laws. As it was said, the laws of inclusion might refer to two or any quality. In the first case two qualities are assigned to a thesis in the following way: the first quality is a specialization of the second one. For correlation laws the direction of influence is unknown, for this reason each quality is assigned a number that corresponds to the order of its occurrence in the thesis.

*Example 3.3:* In our example (it is a continuation of example 3.2) two qualities: stężenie produktów oksydacji cholesterol (concentration of cholesterol oxidation products) and masa (weight) were extracted from the abstract (to which refers thesis t_652_3). Both of them refer to the statement t_652_3. Since the statement belongs to Monotonic Law, qualities dependency must be characterized. Hence, "weight" should be attributed to the statement as independent quality and "concentration of cholesterol oxidation products" as a dependent quality.

*d) STEP 5:* In the next step the elaborated data are automatically translated into an OWL ontology. The result is the Science ontology with classified instances of scientific laws. Each concrete scientific law was assigned qualities in appropriate roles, monotonicity (if applicable), the identifier of the article it comes from, the original sentence from the abstract of the article which expresses the law, its Polish translation and expert's elaboration.

*e) STEP 6:* The last part of the work is related to the description of objects (the experimental materials) the theses are about. The objects for the theses were described by the domain experts. Example 3.4 shows a description of the object for the aforementioned theses t_652_3 and t_652_4.

*Example 3.4 (Objects for theses t_652_3 and t_652_4):*

- mięso wołowe (beef)
- plastry surowej wołowiny poddane działaniu światła fluorescencyjnego (raw beef slices exposed to fluorescent light)
- pakowane w: atmosferze powietrza / bogatej w tlen atmosferze (packed in: normal atmosphere / oxygen-rich atmosphere)
- tlenek cholesterolu 7k (cholesterol oxide 7k)
- tlenek cholesterolu 7-$\beta$-OH (cholesterol oxide 7-$\beta$-OH)
- tlenek cholesterolu 7-$\alpha$-OH (cholesterol oxide 7-$\alpha$-OH)
- tlenek cholesterolu $\beta$-epoksydowy (cholesterol oxide $\beta$-epoxy)

At this level, the concepts of objects are developed according to the top categories of DOLCE (endurants, perdurants, qualities) and established (for this domain) types of relations. At the first step of the formalization, all classes of endurands, perdurants, qualities, their instances and relations between them are extracted from the object description prepared by the domain experts. They are written out with the assigned serial numbers and a shortcut describing the type of category (endurant "e", quality "c", relation "r"). Each object has its English translation in brackets (see example 3.5 below).

*Example 3.5 (Pre-ontological description of objects):*

1.e. mięso (beef)
2.e. bydło (cattle)
3.c. surowe (raw)
4.c. pokrojone w plastry (sliced)
5.e. światło fluorescencyjne (fluorescent light)
6.r. pakowane w (packed in)
7.e. normalna atmosfera (normal atmosphere)
8.e. bogata w tlen atmosfera (oxygen-rich atmosphere)
9.e. tlenek cholesterolu 7k (cholesterol oxide 7k)
10.e. tlenek cholesterolu 7-$\beta$-OH (cholesterol oxide 7-$\beta$-OH)
11.e. tlenek cholesterolu 7-$\alpha$-OH (cholesterol oxide 7-$\alpha$-OH)
12.e. tlenek cholesterolu $\beta$-epoksydowy (cholesterol oxide $\beta$-epoxy)
$\langle 1, o, 2 \rangle$
$\langle 1, q, 3 \rangle$
$\langle 1, q, 4 \rangle$
$\langle 1, tr, 5 \rangle$
$\langle 1, 6, 7 \rangle$
$\langle 1, 6, 8 \rangle$

Next the relations between objects (with use of given shortcuts) are written out in angle brackets. Firstly, the relations might occur between different objects. In that case we use triples: $\langle o_1, r, o_2 \rangle$, where "$o_1$", "$o_2$" describe objects and "$r$" the relation between them (see example 3.5 above). In some cases we also use quadruples. It is the case for relations such as "is aged for", "is stored in temperature", and any other relation which refers to a quality and its value with a proper unit. The pattern for quadruple is the following: $\langle o, r, v, u \rangle$, where "$o$" describes object, "$r$" – relation, "$v$" and "$u$" respectively value and its unit.

For some frequently repeated relations special symbols were established. In our case those symbols are "$o$" and "$tr$", which describe respectively the relation of "obtained from" (otrzymany z) and "is treated with" (potraktowany).

*f) STEP 7:* From the pre-ontological representation we automatically obtain the description of objects in OWL by translating tuples into axioms of the Science ontology.

## IV. Knowledge Management

After the process described in section III is finished, the Science ontology is populated by scientific laws with their formal description. Then by performing SPARQL queries we may obtain many interesting results.

*a) query 1:* For instance by SPARQL queries we are able to find accepted (IRI so:c0000001) monotonic laws which refer to the same qualities in the same roles but having different monotonicity (see query 1).

```
query 1

PREFIX rdf:<http://www.w3.org/1999/02/22-rdf-syntax-ns#>
PREFIX owl:<http://www.w3.org/2002/07/owl#>
PREFIX xsd:<http://www.w3.org/2001/XMLSchema#>
PREFIX rdfs:<http://www.w3.org/2000/01/rdf-schema#>
PREFIX so:<http://onto.beef.org.pl/science/>

SELECT ?class1 ?class2 ?thesis1 ?thesis2 ?m1 ?m2
WHERE {
?c1 rdfs:subClassOf [rdf:type owl:Restriction;
owl:onProperty so:isIndependentParameterIn;
owl:hasValue ?thesis1];
rdfs:subClassOf [rdf:type owl:Restriction;
owl:onProperty so:isIndependentParameterIn;
owl:hasValue ?thesis2].

?c2 rdfs:subClassOf [rdf:type owl:Restriction;
owl:onProperty so:isDependentParameterIn;
owl:hasValue ?thesis1];
rdfs:subClassOf [rdf:type owl:Restriction;
owl:onProperty so:isDependentParameterIn;
owl:hasValue ?thesis2].

?thesis1 rdf:type so:c0000015; so:hasMonotonicType ?m1;
rdf:type  so:c0000001.
?thesis2 rdf:type so:c0000015; so:hasMonotonicType ?m2;
rdf:type so:c0000001.

?c1 rdfs:label ?class1. ?c2 rdfs:label ?class2.
FILTER(lang(?class1) = "en"). FILTER(lang(?class2) = "en").
FILTER(?thesis1 != ?thesis2). FILTER(?m1 != ?m2).
}
```

The query gives 16 results in our KB (so 8 pairs of laws); four of them can be seen in table I. For instance the first row of the table informs that the class with english label "weight"@en is an independent parameter in theses with IRI so:t_652_3 and so:t_652_4 and the class with the English label "concentration of cholesterol oxidation products"@en is a dependent parameter in theses with IRI so:t_652_3 and so:t_652_4. But the thesis so:t_652_3 states that weight has a negative impact on concentration of cholesterol oxidation products, while so:t_652_4 states that the impact is positive. This result makes us curious about the reason for the change of monotonicity of the influence from "negative" to "positive". Having access to the bearers of the mentioned qualities we can learn that weight and cholesterol oxidation products are qualities of meat slices and that in the experiment they were divided into two groups which were packed differently: one in normal atmosphere and the other in highoxygen (32%) atmosphere. So the interesting information is: the way in which meat slices are packed has impact on the direction of influence of weight on the concentration of cholesterol oxidation products.

*b) query 2:* By querying the ontology we are also able to find new laws, i.e. not explicitly expressed in the scientific articles. For instance, the theses which are linked with classes of qualities by so:isIndependentParameterIn and so:isDependentParameterIn roles can be examined in the following way (see query 2): find two functional laws which share the same class of qualities, lets call it a "transitive_class", such that it is a dependent parameter in the first law and independent in the second; if they are found, the other classes appearing in the two laws—i.e. an independent parameter of the first, lets call it "class1", and a dependent parameter of the second, lets call it "class2" — create a new law.

```

Table II presents four out of 704 results the query brings about in our KB. In the first row we find a new scientific law stating that tenderness (column ?class1) influences color value (column ?class2). The law is obtained from the two laws: so:t_837_8 and so:t_278_4. The first states that tenderness has impact on pH ultimate value and the second that color value depends on pH ultimate value.

*c) query 3:* We can also ask about qualities which have an influence on a selected quality, for instance a quality with the label "tenderness"@en (see query 3 below).

```
query 3

PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>

}
```

In table III we see partial results of the query. We get the information that aging time, total collagen content, country origin and the amount of connective tissue influence the tenderness of meat. It is also worth noting that in table III we find three different articles which support the existence of correlation between the amount of connective tissue and tenderness.

## V. Related works

At least a few attempts have been made to address the problem which we have presented in the introduction. Now, we are going to present some of these works which are, in our opinion, interesting and relevant to our work. Firstly, we shall present the SWAN project which “aims to develop a practical, common, semantically structured framework for biomedical discourse initially applied, but not limited, to significant problems in Alzheimer Disease (AD) research” [10, p. 739]. The ontology called SWAN was created within this project. The goals of the SWAN ontology are: 1) to be the schema of a knowledge base in AD research; 2) to link the information from this knowledge base with information from other sources. These goals are intended to be achieved by using the following groups of concepts of the SWAN ontology: people and organizations, discourse elements, bibliographical information, concepts from the domain of interest, and others. The SWAN ontology allows for a representation in which, for example, there is a hypothesis from a scientific publication connected with some journal article by the relation “citesAsEvidence”, with claims by “contains”, and with a person by “authoredBy”. In turn, one of these claims can be connected with another claim by the relation “inconsistentWith”. It is possible, of course, to create these “epistemic” connections among concepts automatically, but in the cited paper the authors seem that they want them to be represented manually. In turn our KB allows for detecting inconsistency between statements automatically.

The second example which we would like to discuss here is the Nanopublications project [11]. The authors of this project argue that the lack of context (i.e. experimental data, citations, argumentation) of a statement (extracted from a scientific paper) which is intended to be represented is a serious problem, because “the statement can only be validated scientifically if you take into consideration its context” [11, p. 51]. And because it is common practice in the Semantic Web to represent a statement without its context (which, traditionally, is implicitly included in a source document), it is important to enable people to add a context to the represented statement.

The authors of the project created the nanopublications – a way to connect a statement with its context. A nanopublication is a "set of annotations that refer to the same statement and contains a minimum set of (community) agreed-upon annotations" [11, p. 52]. An annotation is a triple in which the subject is a statement. A statement, in turn, is a triple which can be uniquely identifiable. In such a triple there are three concepts in three different roles (positions): subject, predicate, and object. According to the authors, this model can be realized through the use of Named Graphs which enable adding a URI to a given RDF graph. A statement is a Named Graph and "all annotations belonging to a nanopublication should be part of the same Named Graph" [11, p. 53]. A nanopublication should represent the information from a source publication. In the SWAN ontology the statements were treated as independent components, here the authors of the project laid emphasis on the fact that a publication is a whole, but may still be connected to other publications. The usage of triples for representing statements is a well known practice. In one of the previous sections we have used triples (and, in fact, quadruples) for describing objects. But here we have an additional use of Named Graphs which allows for connecting statements with URIs in triples.

Another example is the Micropublication project within which "a layered metadata model of scientific argumentation and evidence" [12, p. 2] was created in order to "organize, verify, assess, combine and absorb this information [from the world's biomedical literature] in a comprehensive way" [12, p. 2]. The authors designed this model in such a way that it is able to represent both minimal and maximal forms of publications. In [12] the authors present nine use cases of this model. These use cases show that the model is very flexible and enables a wide range of possible usages: from a simple representation of a citable claim with supporting reference to a representation of a claim with a full chain of supporting evidence, citations etc. Also, the micropublication model allows for expressing statements in a natural language due to the fact that it is easier for scientists to annotate their work in that way.

Although the above mentioned approaches are interesting, they fail to take into account our specific need, i.e. the ability to represent information in a very specific manner. It is due to the fact that we would like to conduct automatic reasoning on our knowledge base. The SWAN ontology is intended to represent "lonely" statements in a simple formal manner, more or less the same applies to nanopublications. Micropublications can be represented both in formal and natural languages. We want our statements to be not only composed from a few concepts, but they should also be internally structured. This is provided by the taxonomy of scientific laws. And in our representation it is also possible to connect a law with a statement in natural language (e.g. by data property) and with a sentence from the abstract.

## VI. CONCLUSION AND PERSPECTIVES

We have presented an ontological representation of the main results of scientific articles from agri-food domain. The knowledge base consists of a TBox in which we define the structure of different kinds of scientific laws present in the domain and an ABox containing over 8k of particular laws. We have described in detail a way in which we proceed from abstracts of journal papers to assertions in ontology.

The work on the knowledge base is still in progress. It can be used as a core element of scientific information systems for the domain. We have not developed any such system in full by now but we have presented in the paper several SPARQL queries that show the kind of information that can be obtained from the knowledge base. The development of applications based on the knowledge base is one of the directions of future works.

The information extracted from the abstracts contains the detailed description of objects to which the laws pertain. The objects are connected to these laws in ontology. However, we have not developed algorithms that make extensive use of them. Tackling this task is another direction of future work.

Yet another challenge is concerned with the unification of the present results with the earlier ontological works within ProOptiBeef project. They resulted in the Domain ontology [13], [14] containing concepts that were used as keywords in the scientific papers from the projects database. The set of concepts from Domain and the set of objects and features used in Science ABox overlap. We believe that it is worth to merge both ontologies.

## Acknowledgment

Research was realized within the Project no. WND-POIG.01.03.01-00-204/09 Optimizing of Beef Production in Poland According to "from Fork to Farm" Strategy co-financed by the European Regional Development Fund under the Innovative Economy Operational Programme 2007 – 2013.

# Joint Agent-oriented Workshops in Synergy

JOINT Agent-oriented Workshops in Synergy is a coalition of agent-oriented workshops that come together to build upon synergies of interests and aim at bringing together researchers from the agent community for lively discussions and exchange of ideas. For the first time JAWS was organized during the 2011 FedCSIS Conference. Workshops that constitute JAWS in 2015 are:

- ABC:MI'15 - 10th Workshop on Agent Based Computing: from Model to Implementation
- MAS&S'15 - 9th International Workshop on Multi-Agent Systems and Simulations
- SEN-MAS'15 - 4th International Workshop on Smart Energy Networks & Multi-Agent Systems

# 10th Workshop on Agent Based Computing: from Model to Implementation

THE FIELD of agent technology is rapidly maturing. One of key factors that influence this process is the gathered body of knowledge that allows in-depth reflection on the very nature of designing and implementing agent systems. As a result, there is now significant knowledge on how to design and implement them. There is also a deeper understanding of the most important issues to be addressed in the process. Therefore, on the top-most level a progress in development of methodologies for design of agent-based systems can be seen. Furthermore, these methodologies are usually supported by tools that allow not only top level conceptualization but guide the process towards implementation (e.g. by generating at least some code). Next, it can seen that new languages for agent based systems are created, e.g. AML or API Calculus. Separately, tools/platforms/environments that can be used for design and implementation of agent systems have been through a number of releases, eliminating problems and adding new, important features. Resulting products are becoming truly robust and flexible. Furthermore, open source products (e.g. JADE) are surrounded by user communities, which often generate powerful add-on components, further increasing value of existing solutions.

## Topics

The Workshop primarily focuses on all aspects of the process that leads from the model of the problem domain to the actual agent-based solution. These aspects will cover both principled approaches and established practices of software engineering aimed at producing high quality software. In this context, research into the application of agent-based solutions to key challenges faced by software engineering (e.g. reduction of costs and delivery times, coping with a larger diversity of problems) will be of primary importance. ABC:MI Workshop welcomes submissions of original papers concerning all aspects of software agent engineering.

Topics include but are not limited to:

- Methodologies for design of agent systems
- Multi-agent systems product lines
- Modeling agent systems
- Agent architectures
- Agent-based simulations
- Simulating and verifying agent systems
- Agent benchmarking and performance measurement
- Agent communication, coordination and cooperation
- Agent languages
- Agent learning and planning
- Agent mobility
- Agent modeling, calculi, and logic
- Agent security
- Agents and Service Oriented Computing
- Agents in the Semantic Web
- Applications and Experiences

*Abstract*— **Formal methods offer a great potential for early integration of verification in the design process. These are based on theories and mathematical notations that allow the formal specification of a program and check its implementation. They offer a global vision and a high-level structure and system organization. In addition, the software architecture plays a key role as a pivot point between the requirements of a system and its implementation. In this paper, we present a formal approach based on Bigraphical Reactive Systems for specifying and verifying the main features of the Multi Agent Systems (MAS) architectures based on the Belief-Desire-Intention (BDI) agent model. The proposed approach supports both the static and dynamic aspects of BDI-MAS architectures at different levels of abstraction. Further, we use automatic proof tool BigMc to analyze the specifications and verify system properties.**

**Keywords**: Multi-Agent Systems, software architecture description language, Bigraphical Reactive System, formal specification, reconfiguration, formal verification, Bigraphical Model Checker.

## I.Introduction

The emergence of large-scale IT networks has given rise to numerous distributed applications. These applications require a strong interaction between different entities distributed on the network that may share the same resources and the same goals. Several distributed development models for these applications have been proposed in the literature. However, the importance of the issue, is to be convinced of the legitimacy and trust granted to IT applications. These concerns have led to methods of development and verification. Lately software systems tend to be more distributed, open and concurrent. This evolution of computing has changed the way of thinking but also the design of such systems. Multi-Agent Systems (MAS) are particularly suitable for developing these kinds of systems. However, the diversity and complexity of the basic concepts that characterize multi-agent systems involve a difficulty in understanding and designing of such systems.

Formal methods offer a great potential for early integration of verification in the design process, these are based on theories and mathematical notations allowing both to formally specify the program, to check and prove that its implantation's compliance with all the properties described in the specification. This is called proper implementation with respect to the specification and formally verified program. Formal methods are recognized by standard references, so that the seventh and final confidence level of the Common Criteria [1] is granted to applications built with them. The awareness of the importance of checking more carefully the programs and the maturity of tools dedicated to this task has generated a considerable growth of programs formal verification in the last decade. Offering a global vision and a high-level structure and organization of a system, the software architecture plays a key role as a pivot point between the requirements of a system and its implementation.

The diversity of design concerns in general and particularly in MAS, request support on formal techniques, which offer enough flexibility and expressiveness to rigorously specify MAS architecture at both the static and dynamic level.

In our previous work [2] we proposed a new approach for modeling and analyzing MAS architectures called BDI MAS architecture in which Bigraphical Reactive Systems (BRS) [3] are adopted as a semantic framework to formalize MAS architectures that are based on the Belief-Desire-Intention (BDI) agent model [4] which is the most commonly used approach for representing agent internal state and it also has been used to build a number of significant real-world applications (i.e. web applications,...). Therefore, Milner's BRS are very suitable to formalize MAS fundamental architectural aspects and their reconfiguration.

Thus, in this work we argue that in addition to their graphical aspect and rigorous basis, BRS are capable of representing both locality and connectivity constituting main concepts of MAS architecture then we propose our a bigraph-based model in order to reason about their properties for that we use the automatic proof tool BigMC to analyze the specifications and verify system properties during configuration. The rest of the paper is organized as follows. In section 2, we introduce Bigraphical Reaction Systems (BRS) and the automatic proof tool BigMc . Section 3 and 4 present the related works and then our bigraphical specification of BDI-MAS architecture. The given

978-83-60810-66-8/$25.00©2015, IEEE

formalization approach is verified and validated by the BigMC tool through examples in section IV. Finally, some concluding remarks and ongoing work finish the paper.

## II. Bigraphs and Bigraphical Model Checker

### A. *Bigraphs*

Bigraphical Reactive Systems were initially introduced by Milner [3] to provide a completely graphical intuitive formal model capable of representing at the same time connectivity and locality of distributed entities which is very close to MAS concepts. The proposal of BRS provides a model for information systems with mobile placing and mobile linking, in which real-world pervasive and distributed systems can be described and analyzed. Further, it provides the unification of existing process calculi for concurrency and mobility (such as π-calculus, Petri nets, λ calculus, and so on) in a simpler way [5].

Structural Aspects: A bigraph is the combination of two independent structures place and link graphs. The place graph represents system entities geographical distribution. The link graph is a hypergraph representing interconnections between these entities. Within a BRS, system entities are represented by nodes and interactions between them are represented by edges (see Fig. 1.). A node can be dotted with ports representing connexion points to edges or inner/outer names.

Each node has a control, which is an identifier belonging to a set that is called a signature (usually denoted as S). Each control indicates how many ports the node has, whose controls are atomic (node empty), and which of the non-atomic controls are active (node permitting reaction inside) or passive. The inner names and outers names of a bigraph indicate connecters to which other bigraphs or roots (i.e. regions) can be connected. Such interconnection is possible only if the outer name of a bigraph or root is equal to the inner name of another bigraph. Sites represent holes into which a root or node can be nested. They are considered as an abstraction indicating the presence of other elements.

Definition [3]: a bigraph is formally defined by $G = (V, E, ctrl, G^P, G^L) : I \rightarrow J$, $I = <m, x>$, $J = <n, y>$, where:

- $V$ and $E$ represent finite sets of nodes and edges respectively.
- $ctrl : V \rightarrow K$ a control map that assigns a control to each node. The signature $K$ is a set of controls.
- $G^P$ and $G^L$ are Place and Link graphs respectively.
- $I$ and $J$ represent inner and outer names (interfaces) respectively of the bigraph $G$.

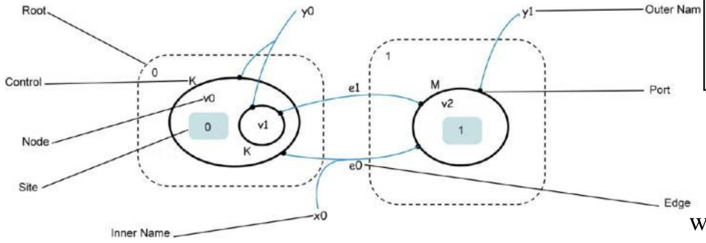

Fig. 1 The anatomy of bigraphs

Bigraph can also be expressed by term language. In [5] Milner axiomatises the structure of bigraphs, to prove that the theory is complete, the algebra of bigraphs structure is surprisingly simple, the primary operations and elements used in this paper are summarized in Table 1.

TABLE 1. TERMS LANGUAGE FOR BIGRAPHS.

| Term | Signification |
|---|---|
| $U \mid\mid V$ | Juxtaposition of roots |
| $U \mid V$ | Juxtaposition of nodes |
| $U \circ V$ | Composition |
| $U . V$ | Nesting( U contains V) |
| $/x . U$ | U with outer name x replaced by an edge |
| $x /y$ | Connection inner names y to outer name x |

Dynamical aspects: Bigraphs structural dynamics is expressed through a BRS (Bigraphical Reactive System) consisting of a category of bigraphs and a set of reaction rules; each one defines a redex bigraph to be transformed to a reactum bigraph. Formally, a reaction rule takes the form$(R,R',n)$ where $R : m \rightarrow J$ is a redex, $R' : m' \rightarrow J$ is a reactum and $n : m' \rightarrow m$ is a map of ordinals [3]. The category of all bigraphs and their reaction rules constitute a BRS.

### B. *Bigraphical Model Checker (BigMC)*

The use of formal methods allows rigorous verification of computer systems. There exist a number of formal verification techniques, model checking [6, 7] is one of many and BigMC (Bigraphical model checker) [8] is one of the few model checking tool devoted to the verification of models encodes as a Bigraphical Reactive System. BigMC ensures that the system's behavior meets the expected properties. This verification is fully automated and consists in exploring all the possible cases. The result of this analysis is to confirm that each property is verified, or not. In the latter case, and this is one of the main interests of this tool, the model checker returns a counter-example. Fig. 2 shows the full BigMC bigraph term:

$$\begin{aligned}
&M ::= E; M \mid E\\
&E ::= \%passive\ k :\ arity\\
&E ::= \%active\ k :\ arity\\
&E ::= \%rule\ n\ T \rightarrow T\\
&E ::= \%property\ n\ P\\
&E ::= T \rightarrow T \mid T\\
&T ::= K.T \mid T \mid T \mid T \mid\mid T \mid \$n \mid K \mid nil\\
&K ::= k[names] \mid k\\
&names ::= n, names \mid n\\
&n ::= [a - zA - Z][a - zA - Z0 - 9] * \mid -\\
&P ::= matches(T) \mid terminal() \mid !P
\end{aligned}$$

Fig. 2 BigMC terms language

Using the grammar in Fig. 2, we can specify a model M which may be a composed of another model or an expression E or both. In turn an expression E can be composed of nodes (being active or passive and assigning an arity to each one of them), reaction rules (whose form is as follows T -> T) and properties denoted by P (which are expressed as a logical formula). In this work, we will use the BigMC grammar to specify our proposed BDI-MAS architecture model in order to check and validate some properties.

## III.MULTI AGENT SYSTEMS BIGRAPH BASED SPECIFICATION

To better understand the multi agent system development, we have reviewed the literature related to Architecture description languages (ADLs) and those of MAS. Therefore, in our previous work [2] we have captured the fundamental concepts to better ensure the specification, evolution and the verification of MAS architecture. This modeling has studied both the structural and dynamic dimension of multi-agent systems architectures. These two dimensions (structural and dynamic) will be developed in this section to show how the proposed framework based on the BRS as a formal notation, express the multi-agent architectures.

At a high level of abstraction, multiagent system is considered as a set of computing entities (a set of agents) that are distributed across multiple sites, and are often referred to as nodes. In Table 2, we summarize fundamental elements intervening in a BDI-MAS architecture.

TABLE 2. CORRESPONDENCE BETWEEN MAS AND BRS CONCEPTS.

| MAS architectural element | Bigraph element |
|---|---|
| Agents, Beliefs module, Desires module, Intention module, plans. | Node |
| Physical or logical location the agents | Root |
| Various type of links between the different elements | Edge/Hyper Edge |
| Abstract elements | Site |

### A. Structural description of the BDI-MAS model

Our BDI-MAS architecture model structure follows core principles, which we organize in two levels of abstraction: (i) internal (or agent) level; (ii) social (or MAS) level. The former describes the internal structure and state of the agent (i.e. the basic construct elements of the MAS) and the second describes the assembly and interaction among agents that compose the MAS architecture. A multi-agent system does not reduce to a centralized computer system; it consists of a set of interconnected agents. Where each agent can initiate communication, generate messages, and respond to other agent's messages, in order for agents participating in these interactions to achieve overall system goals [9].

#### *a) Agent level:*

The Fig. 3 shows our BDI agent and its internal structure. Each agent (denoted by AG) is composed of three principal nodes, which in turn contains other nodes that structure them. In what follows, we will take a closer look on the nodes that compose the agent AG1, for more details see [2].

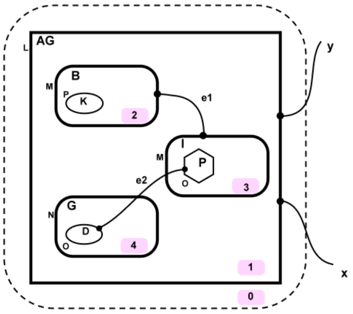

Fig. 3 Bigraphical model of BDI Agent.

The signature associated to a BDI-MAS bigraph is as follows:
K = { L: (2, active), M: (1, active), N :( 0, active), O :( 1, atomic), P :( 0, atomic)}, L, M, N, O and P represent controls associated to different nodes. The different nodes types used in the model and their associated controls are summarized in Table 3.

TABLE 3. NODES TYPES OF BDI-MAS ARCHITECTURE.

| Node | Control | Attribute | Arity | Meaning |
|---|---|---|---|---|
| AG | L | Active | 2 | Agent |
| B | M | Active | 1 | Beliefs Module |
| G | N | Active | 0 | Goal Module |
| I | M | Active | 1 | Intention Module |
| P | O | Atomic | 1 | Plan |

#### *b) Social level:*

The model presented provides notations for describing the structure of MAS in terms of hierarchical configurations of interacting components. It provides an explicit and common basis for describing MAS architectural configurations (see Fig. 4).

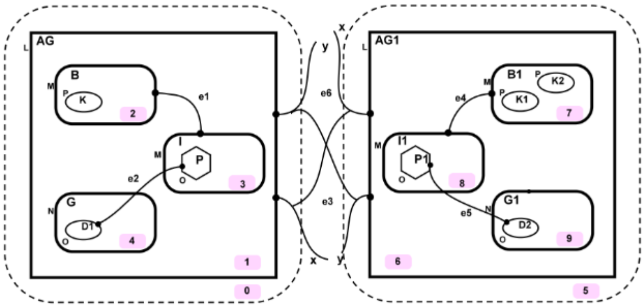

Fig. 4. Bigraphical model of BDI-MAS configuration.

### *B. Modeling BDI-MAS Architectural Reconfiguration*

As defined in our previous work [2] the BDI-MAS architecture dynamics is formalized using reaction rules expressing changes of form in terms of shape shifting while preserving architectural constraints. In this subsection, we give some reaction rules samples defined to model BDI-MAS internal and external behavior and reconfiguration. Table 4 depicts how we defined the behavioral model, based on reaction rules.

**TABLE 4.** MODELLING MULTI AGENT SYSTEM DYNAMICS.

| Multi Agent System | BRS |
|---|---|
| Configuration *MAS*. | Bigraph : $G_{MAS}= (V_{MAS}, E_{MAS}, crtl_{MAS}, G_{MAS}\,p\,, G_{MAS}\,L\,)$ |
| Reconfiguration from *MAS* to *MAS'* | Meta reaction rule: $RL = (MAS, MAS', m' \rightarrow m)$ |

**Example RL1:** Resolution of an internal goal reaction rule

$$AG_{x\,y}\ .(B_{e1}.(K \mid d2) \mid G.(D1 \mid d4) \mid I_{e1}\,.(P \mid d3) \mid d1) \mid d0$$
$$\rightarrow$$
$$AG_{x\,y}\ .(B_{e1}.(K \mid K1 \mid d2) \mid G.(D1_{e2} \mid d4) \mid I_{e1}\,.(P_{e2} \mid d3) \mid d1) \mid d0$$

**Example RL2:** Resolution of an external goal (collaboration) reaction rule

$$AG_{xy}.(B_{e1}.(K|K1|d2)|G.(D1|d4)|I.(d3)|d1)|AG1_{xy}.(B1_{e2}.(K2|d7)|G1.(D3|d9)|I1_{e2}.(d8)\ |d6)$$
$$\rightarrow$$
$$AG_{xy}\ .(B_{e1}.(K \mid K1 \mid K3 \mid d2) \mid G.(D1_{e6} \mid d4) \mid I.(P2_{e6} \mid d3) \mid d1) \mid AG1_{xy}.(B1_{e2}.(K2 \mid K3 \mid d7) \mid G1.(D3 \mid d9) \mid I1_{e2}.(d8) \mid d6)$$

## IV. FORMAL ANALYSIS OF PROPERTIES

Software verification becomes essential to the development of computer systems. Indeed, the use of formal methods allows to prove that a system satisfies a given specification. In fact, these methods appear one of the main solutions for the development of high quality and safe systems at a reasonable costs and time span. Further, the use of these methods in the development process allows the verification and validation of the specification and facilitates the passage to the implementation. These techniques are accompanied by powerful tools that can be used to automate various stages of verification. The use of rather conventional design methods (composition, aggregation, etc.) in the development cycle has paved the way for the smooth introduction of techniques such as model checking.

In our case, we use BigMC a Bigraphical Model Checker to check properties such as deadlock and some violations that the model should not allow to happen during its execution. First, we specify the structural aspect (i.e., nodes and their signature and outer and inner interfaces …) then the dynamic aspect (i.e., reaction rules ex internal resolution of goal …) using the BigMC syntax term language. Then we formulate the properties that we would like to verify on each example. Finally, we will analyze and validate the resulted output given by the BigMC tool.

### *A. Reachability checking*

In this section, we would like to verify the soundness of our model. For that purpose, we decide to start with the building blocks of our model's dynamic, which are no other than the reaction rules for the resolution of an internal, external goal resolution and the reconfiguration example of adding a new agent to the system specified in the section 4.

Fig. 5 describes, how our BDI agent is able to solve an internal goal, as it may be seen in the redex, the presence in the node G of a desire D1 to satisfy, one can also notice the presence into the node B of a knowledge node denoted by K, which is necessary for triggering the rule. In the reactum one can first see the appearance of a node P, which is the best plan among plans that can satisfy the desire D1 (choosing the best possible plan remains tied to heuristics that cannot appear in the architectural level). Secondly, the creation of a link e2 between the node D1 and P specify that the desire D1 could be satisfied by the execution of the plan P. Finally, the execution of P induces two possible cases either: (1) adding / removing knowledge at the node B (2) beliefs of the agent do not change [2].

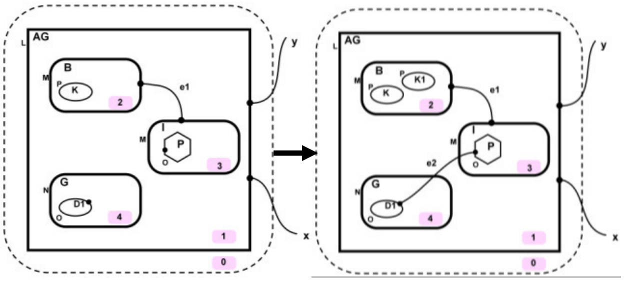

Fig. 5. Internal goal resolution reaction rule.

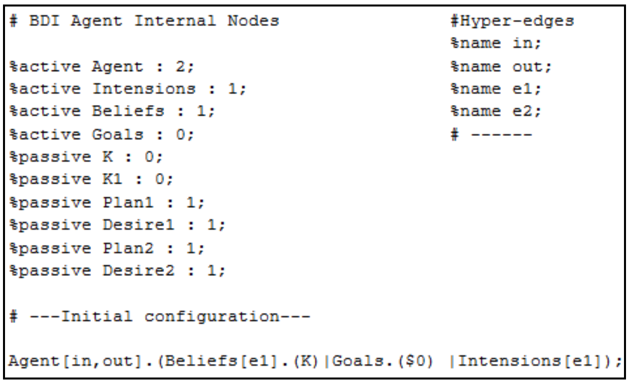
Fig. 6 below represents the structural bigraphical specification of the resolution of an internal goal in BigMC term language.



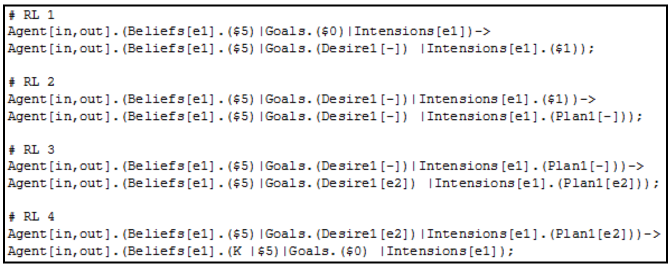
```
# BDI Agent Internal Nodes                        #Hyper-edges
                                                  %name in;
%active Agent : 2;                                %name out;
%active Intensions : 1;                           %name e1;
%active Beliefs : 1;                              %name e2;
%active Goals : 0;                                # ------
%passive K : 0;
%passive K1 : 0;
%passive Plan1 : 1;
%passive Desire1 : 1;
%passive Plan2 : 1;
%passive Desire2 : 1;

# ---Initial configuration---

Agent[in,out].(Beliefs[e1].(K)|Goals.($0) |Intensions[e1]);
```

Fig. 6 Internal goal resolution in BigMC term language

Fig. 7 shows the dynamics of our example, through the presentation of a sequence of meta-reaction rules written in BigMC, we can also see that there are two types of reactions of rules linking and placing reaction rules. The former is responsible for creating or deleting links between nodes while the second type is responsible for creating, moving or deleting nodes in our BDI-MAS Agent.



```
# RL 1
Agent[in,out].(Beliefs[e1].($5)|Goals.($0)|Intensions[e1])->
Agent[in,out].(Beliefs[e1].($5)|Goals.(Desire1[-]) |Intensions[e1].($1));

# RL 2
Agent[in,out].(Beliefs[e1].($5)|Goals.(Desire1[-])|Intensions[e1].($1))->
Agent[in,out].(Beliefs[e1].($5)|Goals.(Desire1[-]) |Intensions[e1].(Plan1[-]));

# RL 3
Agent[in,out].(Beliefs[e1].($5)|Goals.(Desire1[-])|Intensions[e1].(Plan1[-]))->
Agent[in,out].(Beliefs[e1].($5)|Goals.(Desire1[e2]) |Intensions[e1].(Plan1[e2]));

# RL 4
Agent[in,out].(Beliefs[e1].($5)|Goals.(Desire1[e2])|Intensions[e1].(Plan1[e2]))->
Agent[in,out].(Beliefs[e1].(K |$5)|Goals.($0) |Intensions[e1]);
```

Fig. 7. Internal goal resolution dynamics

Now that we have specified our model structural and dynamical aspects in BigMC the penultimate stage before the checking is to specify or formulate the property to check on our example. For this purpose, BigMC provides a set of predefined predicates using the syntax showing in Fig. 2, in the following example, we will use two of them, the first property that we would like to verify named violation_free uses the predicate !match(T) which states that we must not find a match to the expression between brackets during our system execution. The second property is deadlock_free which uses the predicate !terminal() the predicate as transcribed here states that there will be a possible future state reachable by a step of reaction rule from the current one. For more elaborated properties the common boolean operator such as AND, OR and NOT are used.

%property secure !matches(Agent[in,out].(Beliefs[e1].(K | K1 | $2)|Goals.(Desire1[-] | $0) |Intensions[e1].(Plan1[-] | $1 )));

%property deadlock_free !terminal();

The result of the model checking is shown in the figure after 20 steps the model checker reached successfully the intended state and does not report any property violation (due to the lake of space intermediate rewriting steps are omitted) .

## V.Related work

There is an important core of work regarding to the design and development at the architectural level as mentioned in [9] and [10], several works propose different languages, formal and semi-formal, Architecture Description Language (ADL). Such as Darwin, Rapide, Dynamic-Wright [11] and π-ADL[12] for representing and analyzing software architectures in order to predict architectural qualities before the implementation, and guiding the design and coding process. Nonetheless, these works are labeled by a lack of coverage of concepts related to the definition of a multi-agent system, for example, the representation of the agent is generally limited by a single object devoid of the necessary concepts to express its autonomy and cognitive aspects (such as beliefs, knowledge and competences). As cited in [13] there exist various analysis techniques among the existing ADLs for testing, model checking, and evaluating performance based on architectural models. Bordini in [15, 16] has presented an approach for verifying multi-agent programs. In this approach, the system is written with the logic-based agent-oriented programming language AgentSpeak and automatically translated into either Promela or Java. This is an important work; however, the verification of MAS focuses on the program rather on the architecture. In [17] Walton address the verification of communication between agents participating in multi-agent web service systems, the approach is based on the application of model checking techniques. This approach is too specific, it is used to verify lightweight protocol language and it cannot be applied to a wide range of multi agent systems and neither at the architectural level. In [18] and [19] are abstract formal models for developing formal specifications of multi-agent systems these approachs uses the Z notation as formal foundation. However, the Z language cannot model in an effective way the interaction, distribution and the concurrence in a MAS. Fisher in [20] describes the first steps towards a formal specification and verification of multi-agent systems using Concurrent METATEM and the temporal belief logics. This approach suffers from a low level of abstraction and does not take into account the reconfiguration of the system at the architectural level.

## VI.Conclusion

In this paper, we have described our proposed formal modeling approach of the BDI-MAS architecture. The system has been specified at both individual (agent) and social (MAS) levels. The BDI-MAS bigraph simplifies considerably the MAS architectures readability. A MAS architecture is seen as a hierarchical configuration of interacting nodes. The model emphasizes on both locality and connectivity that can be used to represent the location and interconnection of MAS architectures. On the other hand, reaction rules allow developers to correctly analyze the BDI-MAS architecture features, including modeling the behavior of the BDI agents and describing reconfigurations that could be added to the architecture. Further, the use of bigraphs as formal basis in the development process allows the verification and validation of the specification. Using the BigMC tool we have shown that our BDI-MAS architecture model through its Meta reaction rules are free of violations and deadlock. Our aim is to have a graphical intuitive solid formal foundation for modeling MAS architecture in order to handle the complexity of the systems in general, adopting a high level of abstraction that removes unnecessary details regarding all the expected properties and facilitates the passage to the implementation.

In the perspectives of this work, we plan to:

- Formally analyze and verify some non-functional properties such as security of the BDI-MAS architectures model.
- Provide a tool that generates executable implementation from our BDI-MAS architecture model,
- Develop a methodology around the model in order to guide the development of MAS.

***Abstract*—The number and type of digital sources storing healthcare data is increasing more and more, rising the problem of collecting actually dispersed information about a single patient. In this paper we propose an agent-based system to support integration of health-related data extracted from both structured (HIS) and semi-structured (websites and social networks) sources. Integrated data are exported in HL7 format to finally feed personal health record (PHR).**

## I. Introduction

DIGITAL healthcare data dramatically increased during last years [1]; this is mainly due on one hand to data stored into Health Information Systems (HIS) [2][3] as medical records and clinical exams, while on the other hand a significant contribution comes from specialized websites (e.g. online medical forums) and social networks as FaceBook and Twitter, where doctors and patients post their personal experiences and opinions about various health related topics e.g. illnesses, symptoms, treatments, side effects [4][5].

The number and type of such data sources poses the problem of collecting actually dispersed healthcare information for a single patient, therefore the extraction and integration of such data into a standard repository arise.

Data integration is a well-known and quite old issue [6][7], however it still requires a significant effort, especially when information are extremely sensitive for privacy issues, as it occurs for medical information [8].

In this paper we propose an agent-based systems whose goal is the integration of health related data coming from different sources; as cited before, we consider both HIS (i.e. SQL based data sources) as well as websites (HTML-based data sources) and social networks (in particular, Twitter).

These are used to populate official medical documentation known as Electronic Medical Records (EMR), Electronic Health Records (EHR) and Personal Health Record (PHR). In more detail, EMR/EHR [9][10][11] is the digital collection of a person's health related documents used within HIS to provide an effective, reliable and costs saving health management, contains the standard medical and clinical data and is managed only by health care providers, whereas in the PHR [12] the person can directly manage his personal medical-related information and therefore it can also contain data coming from website and social networks cited previously (i.e. unstructured or semi-structured). In the rest of this paper, we will use the term PHR only, implicitly including also EMR/EHR.

Since our goal is the gathering of *personal* health-related data, we suppose that all information can be accessed on a per-user basis according to authentication mechanisms whenever present, i.e. agents should be granted access to personal profiles to extract data.

Moreover, for an effective integration a common reference terminology is needed; to this purpose, we exploit the SNOMED-CT [13], currently the most comprehensive medical terminology worldwide adopted, to discover medical terms and properly manage, match and integrate synonyms, hyponyms and hypernyms.

Together with standard database terminology, we also include a list of additional informal terms to be searched if nothing is found within SNOMED-CT, indeed it is possible that within unofficial medical data sources (as in the case of social networks and websites) people use words like ”headache” that are not explicitly stored into SNOMED-CT, where ”headache” is indeed referred as ”migraine”; the additional list allows to cope with such real situations.

Finally, a common output format for PHR data is advisable; a widely accepted format is HL7 [14], a standard for information exchange between medical applications and healthcare providers. HL7 includes several recommendations for conceptual representation, documents (included the PHR), applications and messaging standards, and is available as v2.x and v3.0. The v2.x version is a non-XML proposal where data is organized in segments (lines), each containing proper fields and subfields. The v3.0 HL7 messaging protocol leverages XML to provide data structure and also provides support for healthcare workflows.

Other works deal with integration issues, for instance in [15] an OWL ontology is developed to integrate specific medical documents (CCD) authors focus on, whereas in [16] a complete method for ontology based schema and data integration for clinical and genomic databases is presented. Our goal is to provide a tool for extracting and integrating any (neither specific nor structured) medical information without creating a new ontology (rather, exploiting existing ones). Using social forums in healthcare has been investigated e.g. in [17], where answer for medical queries in unresolved posts is provided via similar thread retrieval; to the best of our knowledge, no data gathering from social forum for PHR has been considered so far. Joining virtual social networks and healthcare recently led to neologisms as *Infodemiology* and *Infoveillance* [18]; also Twitter has been exploited in this sense, for instance in [19] the micro-blog is used to detect flu trends, whereas in [5] Ailment Topic Aspect Model is applied to tweets to track public health over time; in [20] authors tracked and

978-83-60810-66-8/$25.00©2015, IEEE

examined disease transmission in particular social contexts via Twitter data, while in [4] social media use improves healthcare delivery by encouraging patient engagement and communication. Apart all these proposals however, no specific use of Twitter data for PHR currently exist. A preliminary and partial study of the work presented in this paper can be found in [21] and [22].

The paper is organized as follows. In section II we describe the overall architecture of our proposal, and how the data extraction and integration are performed for each data source. In section III we show an application to a real case, providing concluding remarks and future works in section IV.

## II. Agent-based gathering system

In fig. 1 our agent-based model is shown. The three main data sources categories we consider are the so-called *database*, that represents standard HIS where official medical personal data are stored (usually, according to a well structured schema), and the *website* and *social*, indicating respectively HTML-based and text-based data sources as described in previous section; in our experiments in particular we looked at online medical forums for the "website" category and Twitter for the "social". Considering agents, the first set (named *wrapper agents*) is devoted to gather personal data from each data source, while *text mining agents* filter previous data to extract medical information. The integration module collect all such data and performs proper integration also exploiting both the SNOMED-CT terminology and an additional dictionary of "common" medical terms (e.g. "headache") that are not stored as official medical terms in the SNOMED-CT. The same references are used by the text mining agents to detect medical information. After this, *feeding agents* are used to populate user's PHR with his relevant medical data. *User agents* collaborate to compare information gathered from different users but semantically related, allowing to build a user network; similarly, *disease agents* cooperate to correlate detected diseases. In the following each component of the proposed architecture is described in more detail.

### A. Wrapper agents

All sources are managed by wrapper agents, that are used to isolate and collect information referring to the same user; in the case of database this is quite trivial and can be accomplished via standard SQL based queries, even if each real HIS has its schema and probably both proprietary solutions as well as authentication issues must be tackled. The question is somehow different for what concern websites and social network. In the case of websites indeed, in particular considering online medical forums we focused on, sometimes all messages are directly available on a per-user basis, therefore the extraction performed by the agent still remains feasible, whereas when forums provide a thread/topic based classification the wrapper agent has to browse all threads/categories and collect all messages for each single user to contribute as much as possible in populating his medical profile; forums where total anonymous messages are allowed are then not considered here (i.e. registered nicknames only). In social networks as Facebook or Twitter, the same approach can be applied since they generally adopt the same organization of traditional websites, i.e. personal messages somehow identifiable even in the case of a topic-based arrangement. Note that the term *person* here refers to a distinguishable user_id or nickname, i.e. the agent stores data together with the *(user_id, source_id)* pair so that each text refers to a single user. Since the nickname should be associated to a real person, this requires he/she should grant the permission for his/her data in order to fulfill privacy issue and related laws; here we suppose that persons do not prevent their personal data to be extracted by agents.

### B. Text mining agents

The next step is the extraction of all medical related data (concerning a given person), discarding other information; this task is performed by text mining agents shown in fig. 1. This agent is not present in the case of HIS since it is likely that such a data source exclusively stores medical related information; conversely, websites and social networks may also include non medical data, also thanks to their semi-structured or unstructured nature, i.e. HTML and text based data posted by common people (not necessarily doctors or medical personnel). Online medical forum and social networks are managed following the same approach, except for a preliminary step in websites, where pure text is extracted from HTML, therefore these sources both provide text data (either webpages or tweets). The first operation we apply is the language recognition, since all further text-mining actions (e.g. stemming) strictly depend on the specific language; in this sense, we discard then all non English text portion. Then, the text mining agent searches for statements containing medical terms; this is accomplished using Natural Language Processing (NLP) techniques [23], in particular first removing irrelevant information (as hyperlink text for web pages, or retweet details and usernames for tweets) and then applying standard text processing operations as tokenization, stopwords removal, stemming and indexing [24]. If the index terms list contains at least a medical term, the statement that term belongs to is preserved, otherwise we discard the statement.

In the last step, we leverage sentiment analysis [25][26] in order to evaluate the remaining statements (those containing medical terms), e.g. if the person suffers a disease cited in a tweet, or if an intolerance to some food specified in a forum question is still present or not. Sentiment analysis or opinion mining [27] leverages NLP, text analysis and computational linguistics to extract subjective information, as the mood of the people regarding a particular product or topic; basically, the sentiment analysis can be viewed as a classification problem of labelling a given text (statement within a tweet or extracted from online forum) as *positive*, *negative* or *neutral*, in our case if the result of classification is positive or negative, the text mining agent passes this information to the integration module to enrich personal medical profile.

To understand how it works, let us consider the text "Last night was too rainy, this morning my headache is stabbing but

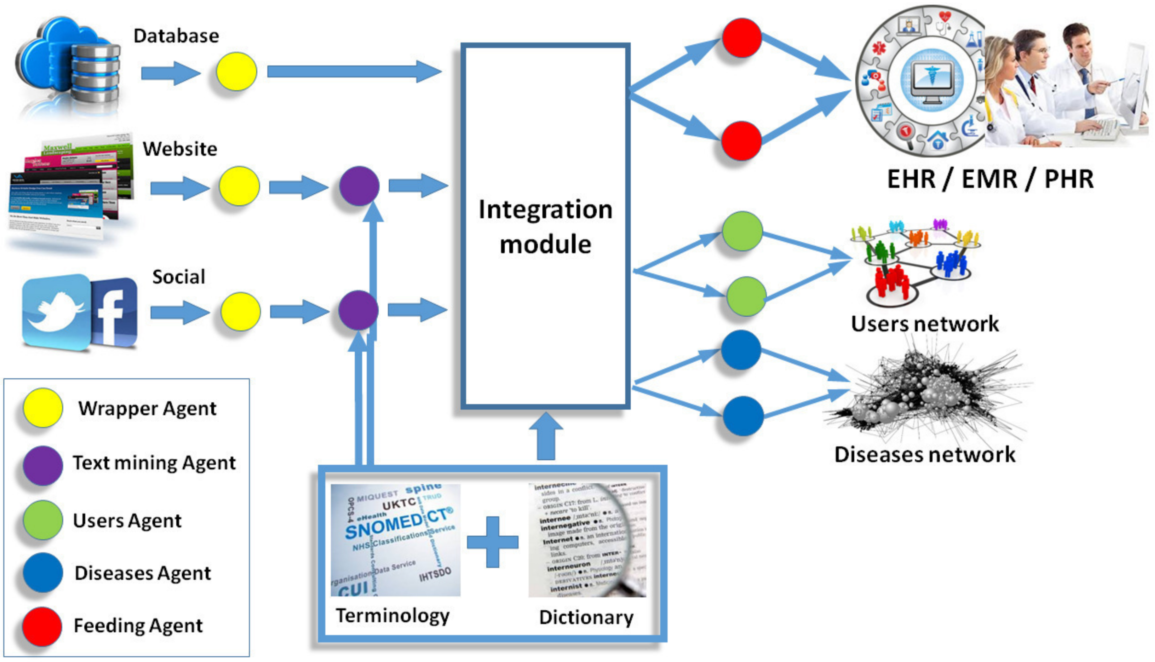

Fig. 1. Application architecture

fortunately I will not go at work" that can come from a social as well as from a website source. Using the NLTK chunking package [28], we first identify short phrases (clusters) like noun phrases (NP) and verb phrases (VP); the text portion cited above in particular produces the following chunks:

”Last night”(NP)
”was” (VP)
”too rainy” (NP)
”this morning” (NP)
”my headache” (NP)
”is stabbing” (VP)
”but fortunately” (NP)
”I” (NP)
”will not go” (VP)
”at work” (NP).

The sentiment analysis exploits the chunking technique first to isolate clusters, then we discard those without medical terms (in the example only ”headache” is present, therefore clusters ”Last night was too rainy” and ”I will not go at work” are discarded), finally trying to assess the meaning of remaining clusters by using a proper list of *positive* and *negative* verbs, so the cluster ”this morning my headache is stabbing” is labelled as *positive* or, in other words, we got the information that person has the headache.

### C. SNOMED-CT and dictionary

In order to discard statements that do not contain any medical term, we search each index term extracted by text mining agent in the SNOMED-CT terminology. To better clarify how this search is performed, we briefly cite the SNOMED-CT core components (details can be found in [29]) that are:

- *concepts*, that represent all entities that characterize health care processes; they are arranged into acyclic taxonomic hierarchies (according to a *is-a* semantics)
- *descriptions*, explaining concepts in terms of various clinical terms or phrases; these can be of three types, Fully Specified Names (FSNs) that is the main (formal) definition, Preferred Terms (PTs), i.e. the most common way of expressing the meaning of the concept, and Synonyms.
- *relationships* between concepts, e.g. the concept (disease) ”Staphylococcal eye infection” has ”Causative agent” relationship with ”Staphylococcus” (different types of relationships exist depending on concepts type)
- *reference sets* used to group concepts e.g. for cross-maps to other standards purposes.

In this work, the first two items are considered, in particular among all concepts hierarchies we focus in the ”disorder/disease” since our goal is to detect tweets about diseases, therefore we do not consider other specific hierarchies (e.g. ”surgical procedures”). Inside the disorder hierarchy, we search each index term extracted from tweets as a FSN, PT or synonym; if found, that tweet is further processed in order to establish whether the specified disorder is present using sentiment analysis (see below).

As indicated in the introduction, to guarantee that all medical terms can be successfully detected, a list of additional informal terms is searched if nothing is found within SNOMED-CT, for instance if the index term is the word ”flu”, this has positive match in the synonym list of ”influenza” disease (the FSN), but the (also quite common) term ”headache” is not explicitly present when browsing SNOMED-CT [30], where this disorder is instead referred as ”migraine” both as FSN and its synonym. Including ”headache” in an additional list (*dictionary* in fig. 1) is the simple solution we adopted; this list is considered just if nothing is found within SNOMED-CT.

Also note that several diseases are defined as a group of words (e.g. ”Viral respiratory infection”), therefore during the indexing phase we also retain N-grams with N=2 and 3; diseases with more than three words can be easily disambiguated even with 3 words since not all words are generally significant (e.g. in ”Disease due to Orthomyxoviridae” the first and the last words are enough for correct matching).

Finally, detected diseases may be hierarchically related, e.g. ”influenza” and ”pneumonia” are both children of ”Viral respiratory infection” according to the ”is-a” semantics. This information could be used for instance by replacing both children with their common parent, in order to build a more generalized, global view of diseases named in the given geographic area during the chosen time period. We choose however to preserve the best level of detail by not using a common ancestor as in the example, while on the other hand we will substitute all terms that represent the same disease with its FSN as indicated in SNOMED-CT, for instance if different tweets refer to ”flu”, ”grippe” and ”influenza” they will be all considered as tweets about ”influenza”.

### *D. Integration module*

The integration of all data concerning the same person into his PHR is performed by the *integration module* after it receives data by wrapper and/or text mining agents. The process is not fully automatic at this stage, so the scenario the user is presented to includes a set of pieces of information that could refer to the same person and have to be somehow integrated.

In particular, the wrapper (or text mining for semi-structured data) agents deliver a set of triples *(user_id, source_id, data)* each referring to a given user, though distinct user_ids, say *UID1* and *UID2* could refer to the same physical person since such triples come from different sources. Whenever *UID1* is literally identical to *UID2*, the system suggests to integrate all related *data* into the same set for further processing, and the user simply can confirm this decision; if however the user believes that although identical those pieces of information do not refer to the same person, for instance when the first *data* is about menopause (female) and the second is about prostate cancer (male), the system stores this decision and rename the second id differently (i.e. *UID2_*) in order to allow disambiguation for further data. In the case *UID1* and *UID2* are different, the user has to decide whether these ids actually represent the same person or not; again, the system stores the decision, therefore if *UID1* is ”Robert Stanton” and *UID2* is ”RBTSTN” and the user establishes that the latter is a portion of ”Robert Stanton”'s fiscal code, all further triples having ”RBTSTN” will automatically incorporated into the same set of ”Robert Stanton” pieces.

After all pieces of health-related information belonging to the same person have been collected into the same set *S*, the integration module tries to integrate *data* present in triples, again through a semi-automatic process. It is important to highlight however that a definitive standard for PHR currently does not exist at all, therefore we do not aim at defining a schema all data should adhere to, rather our goal is to integrate to some extent data concerning the same information.

In particular we first focus on structured data, where the presence of a schema means that *data* in a triple is usually represented as a table, i.e. a query result coming from HIS (databases). Different tables can be integrated first from a structural point of view (e.g. merging ”patient_ID” and ”patient_CODE” columns into a single one) and then from a semantic perspective (e.g. collapsing ”migraine” and ”headache” into the same term); the problem is quite complex but really not new and several solutions already exist [31] [6] [7]. In our first implementation, the user can specify whether he wants a single schema or not; if so, for each table the user has to select which columns are considered (or discarded) and whether columns from different tables must be joined together into a single one; the data type of an output column that mixes two or more existing columns will be the largest data type among those of existing columns being integrated (e.g. float and integer are integrated to float). At the end of the process, a single table comes as output of the integration module and its definition will be XML based, according to HL7 v3.0 format cited in the introduction. Note that data belonging to tables are not integrated in our implementation, rather we simply insert all pieces of information into the single table; if the user do not wish a real integration, all tables are simply preserved and passed as output.

Considering the case of semi-structured data, i.e. website and/or social in fig. 1, *data* stored in a triple is not a relational-like tables, rather it is a labeled statement where the person (identified by the *user_id* element) suffers a given disease (as the headache in the example cited in the text mining module) or has been screened with a given clinical examination etc. In this case the integration we implemented allows to collapse several pieces of information whenever they actually coincide, for instance if we have the statements ”this morning my headache is stabbing” and ”the diagnosis was acute migraine” both labelled as positive and belonging to the same set *S* concerning a given person *user_id*, the system allows the user to discard one of the two statements since they represent the same information. Note that the system recognizes the statements as comparable since it exploits SNOMED-CT and the dictionary of informal terms to map all medical terms (in this case, ”headache” and ”migraine”) into the same term (in this case, the FSN ”migraine”); if such a mapping does not occur, statements are supposed to be different, but the system always allows the user to collapse a set of statements into a single one manually if this is the case.

### *E. Feeding agent*

After the integration process has been performed, a (possibly reduced) set of triples *(user_id, source_id, data)* is provided by the integration module for PHR feeding. The way

PHR is actually stored and accessed has not been definitively standardized [32], however in our architecture PHR should be available as web services to guarantee an easy and uniform access. In this sense, a number of platforms have been proposed, as the Microsoft's HealthVault [33], PatiensLikeMe [34] or other proprietary solutions, in addition to institutional approaches, e.g. [35]. Since each one of them has its features, we specify only general guidelines of the actual implementation of the feeding agent, in particular each agent is devoted to a specific solution and has to manage authentication issues as well as data format and communication protocol; we suppose however that supporting HL7 v3.0 as XML-based data format is the best choice

### *F. User and disease agents*

*Users agents* are devoted to build and manage the network of users whose data have been extracted. The network can be built according to different criteria, for instance two users may be considered as *linked* if they "share" the same disease, or they were admitted at the same hospital. Similarly, a set of *Diseases agents* can build a network of diseases somehow related, e.g. a link between two diseases may represent a co-occurrence of both diseases in a significant number of data concerning the same user, or the fact that they are cited by related users and so on; the establishment of such network leverages the SNOMED-CT to tackle semantic-related issue (e.g. synonyms, homonyms, hypernyms). At this stage these two set of agents are considered for future works and have not been implemented.

## III. Results

In this section we show an example of how the architecture works. In particular, we considered a small group of persons who suffer different diseases and are in treatment at the same medical center; in fig. 2 we show one of them with two so-called *medical problems*, i.e. diabetes and osteoporosis. The Health Information System used in this centre was actually a customized version on the OpenEMR software [36], whose data access were granted to the wrapper agent through an API-based connection to the underlying MySQL database. The wrapper agent submitted an SQL query with users names, in order to get information about their exams; in fig. 3 we show the resulting table for the same person of fig. 2; for the sake of simplicity, we omitted query details, i.e. the foreign keys used to join patient with medical problems tables, and only significant columns are shown in fig. 2 (patient name and related medical problems). As specified in the previous section, the table will be the *data* field in the triple *('Rebecca Greenfield', 'SRC#002', data)* extracted from MySQL database for that person by the wrapper module and delivered to the integration module. Note that to get results, we supposed (as specified in the introduction) that the person in fig. 2 grants the wrapper agent to access her data, in order to overcome authentication issues.

Similarly, other wrapper agents search on websites and/or social networks, in particular we considered [37] (a medical forum) as "website" data source, and, supposed that we are able to associate (even manually) the name stored in the HIS to the nickname "rebgreen46", we allow the wrapper agent to extract from HTML the text contained within posts (fig. 4 shows one of them). The text is further processed by the text mining agent, as discussed in previous section, therefore we get the following triples:

- *('rebgreen46', 'SRC#003', ('back', 'hurts', POSITIVE))*
- *('rebgreen46', 'SRC#003', ('legs and shoulders', 'aches', POSITIVE))*
- *('rebgreen46', 'SRC#003', ('pain', 'is getting worse', POSITIVE))*

These triples represent therefore additional pieces of information about that person, i.e. from the database emerges that she suffers diabetes and osteoporosis, whereas from this forum the presence of aches for back, legs and shoulders is detected. According to the procedure described in the previous section, the integration module allow to associate these three triples with the table (in this case, manually specifying that 'Rebecca Greenfield' is the same *user_id* as 'rebgreen46'); one or more feeding agents will finally connect to the platform(s) where these pieces of information will be added to the Personal Health Record for that patient. Apart the simple example shown so far, we are currently undergoing on a more significant test with a relevant number of patients (about 200) also considering Twitter as "social" data source.

## IV. Conclusions

The work described in this paper outlines an agent-based architecture for feeding PHR with data extracted from structured and semi-structured (databases and website/social networks, respectively) sources. Our proposal is currently at an early stage, and we believe that the first implementation will provide us with results confirming prosiming expectations. Moreover, the implementation will allow to assess the effectiveness of our approach, expecially when a relevant number of data sources as well as a relevant number of patients to extract data about will be gathered; this validation is also required to evaluate the quality of integrated infomation with respect to that stored into original sources (e.g. redundancy, completeness and so on).

Some future works are planned:

- a useful extension concerning the integration module is the possibility of specifying a mapping function so that the system can be trained a-priori to associate different *user_id* into the same person, for instance the mapping function can be a regular expression acting as a bijective function to convert *UID1* to *UID2* and viceversa. More complex function could be defined to allow automatic integration.
- the integration module presented in this paper is quite elementary; we are considering more effective solutions, e.g. a classifier (supervised or not) that tries to aggregate health data without the user's intervention or reducing this as much as possible. Besides, more effective data

I have where I cant walk very far my back hurts so bad I break out in a sweat. I cant stand up very long with out the pain. if I can sit down for a while it stops. and my legs and shoulders aches. is this my osteoporosis. I have bern diagnosed with it but the pain is getting worse. what is the best medication to take?

Tags: Pain, medication, hurts

Fig. 4. A post extracted from a forum webiste by wrapper agent

integration mechanisms for either structured or semi-structured data sources (or both) should be investigated, as for instance agent-based approaches, also in order to fully exploit the cooperation of agents we outlined in the main architecture to provide effective automation in the integration process

- finally, a significant further work is required to implement both user and disease agents and to explore how to leverage corresponding networks to improve integration and the quality of health-related information.

# 9th International Workshop on Multi-Agent Systems and Simulation

MULTI-AGENT systems (MASs) provide powerful models for representing both real-world systems and applications with an appropriate degree of complexity and dynamics. Several research and industrial experiences have already shown that the use of MASs offers advantages in a wide range of application domains (e.g. financial, economic, social, logistic, chemical, engineering). When MASs represent software applications to be effectively delivered, they need to be validated and evaluated before their deployment and execution, thus methodologies that support validation and evaluation through simulation of the MAS under development are highly required. In other emerging areas (e.g. ACE, ACF), MASs are designed for representing systems at different levels of complexity through the use of autonomous, goal-driven and interacting entities organized into societies which exhibit emergent properties The agent-based model of a system can then be executed to simulate the behavior of the complete system so that knowledge of the behaviors of the entities (micro-level) produce an understanding of the overall outcome at the system-level (macro-level). In both cases (MASs as software applications and MASs as models for the analysis of complex systems), simulation plays a crucial role that needs to be further investigated.

## Topics

MAS&S'15 aims at providing a forum for discussing recent advances in Engineering Complex Systems by exploiting Agent-Based Modeling and Simulation. In particular, the areas of interest are the following (although this list should not be considered as exclusive):

- Agent-based simulation techniques and methodologies
- Discrete-event simulation of Multi-Agent Systems
- Simulation as validation tool for the development process of MAS
- Agent-oriented methodologies incorporating simulation tools
- MAS simulation driven by formal models
- MAS simulation toolkits and frameworks
- Testing vs. simulation of MAS
- Industrial case studies based on MAS and simulation/testing
- Agent-based Modeling and Simulation (ABMS)
- Agent Computational Economics (ACE)
- Agent Computational Finance (ACF)
- Agent-based simulation of networked systems
- Scalability in agent-based simulation

***Abstract*—Agent Based Modeling and Simulation (ABMS) is considered an effective approach for conducting simulation studies in many fields. In order to develop high quality simulation models, methodological approaches are demanded. In such direction we are moving by proposing a heuristic for the formalization of agent based simulation problems. The proposed heuristic is based on some guidelines developed for identifying the main elements of the problem domain description by analysing verbs and their common taxonomy in grammar.**

## I. Introduction

SIMULATIONS are used in several contexts for evaluating the behaviour of complex systems and for understanding how the numerous variables constraint the performance of such systems. Especially, a simulation model gives the opportunity to make experiments and to identify errors in such a way that would often be infeasible in the real world. A simulation study is a process that allows to define a simulation model of a real system and to make experiments with that model.

Among simulation models, Agent Based Modelling and Simulation (ABMS) is becoming a widely used approach for conducting simulation studies in many disciplines (such as social sciences, economy, traffic and transportation) that deal with complex systems characterized by the presence of autonomous and active entities [1, 2, 3, 4, 5, 6, 7].

Such increasing interest is mainly due to the possibility to include in such models some aspects that are commonly not considered by traditional approaches, such as local interactions, entity organizations, impact of environmental changes on entity behaviours, entity heterogeneity and so on.

Whether on the one hand these features make the ABMS paradigm very useful for the representation of highly quality models, on the other hand it requires appropriate methodological approaches for addressing such a kind of simulation study. At present, there are some proposals in such direction but several issues are still open and a comprehensive methodological approach is still lacking.

The work we present in this paper is part of a more ambitious objective: the development of a complete methodological approach (we named MAMAS, *Methodological Approach for Multi-Agent Simulations*) that covers the entire life cycle of a simulation study taking into account each facet of the agent based modelling paradigm. In so doing, the experience we collected in the latest years about methodological approaches in the field of agent oriented software engineering (hereafter AOSE) consolidated our opinion that a solid foundation for design processes lies on the use of system metamodels. This is also recognized in the field of agent based simulations where some proposals about system metamodels [8, 9, 10, 11] for creating a common ground for several agent based simulation domains are proposed. For these reasons, we are defining MAMAS approach starting from the metamodel we proposed in [11]. Specifically we are specializing the set of activities that are commonly defined for generic simulation studies in the ABMS context by using the metamodel as activity's benchmark. Thus we are defining specific guidelines and work products for these activities wherever are not defined yet.

The importance of the problem formalization in order to produce complete and well defined simulation models is well recognized in literature [12, 13]. In our work, problem formalization assumes a very important role for the identification of simulation goals and all the multi-agent system goals influencing the simulation goal itself. The concept of goal, in our approach, spreads over the whole MAMAS process. For this reason we spent a great effort in studying a formalized way for identifying and modelling goals. We also studied how they influence the whole simulation study, starting from the very early stages of simulation analysis i.e. the *problem formalization*.

In such a landscape, the aim of this paper is to provide guidelines for performing a core activity of MAMAS process: *Problem Formalization*; the proposed contribution lies on the heuristic developed for identifying the main elements of the problem domain by using verbs and their common taxonomy in grammar.

The rest of the paper is organized as follows: in section II we detail the motivations for our work against the related works in literature, in section III we present a brief overview on the MAMAS process; in section IV we illustrate the proposed heuristic and finally some discussions and conclusions are drawn in section V.

## II. Motivation and Related Work

The advantages of simulation models for studying the behaviour of complex and dynamic systems are widely known. In particular multi agent models are among the most interesting ones due to some useful properties showed by this type of modelling [6]. Moreover, multi agent simulations is considered one of the killer applications of agent oriented technology [14]. Nevertheless, as far as we know, to date there is no comprehensive methodological approach that can provide guidelines for the development of such models. Indeed, traditional approaches are conceived for generic simulation studies and they do not adapt well to agent based simulations because they overlook some essential aspects that are fundamental in an ABMS approach, such as for example the role of the environment or agent interactions.

Only to cite a few, Balci in [15] suggests a process based on 10 phases and 13 credibility assessment stages. The credibility assessment starts from the first phase of problem formulation until the last phase of the presentation of simulation results. In [16] instead Balci states the importance of the VV&T (Validation Verification and Testing) techniques throughout the life cycle of a simulation study showing how they are categorized. Although these two works established a baseline for the development of credible simulation studies they are conceived for generic simulation approaches. We think that, from the perspective of agent-based simulations, the life cycle of a simulation study has to take into account some typical features of agent oriented technology. For example, it is important to focus on the environment model that plays a fundamental role in such kind of simulations where it commonly represents the real context in which the real actors work.

In [12] John S. Carson defines the human actors that have to compose the simulation team relating them to the common steps of a simulation study and providing some useful hints in order to conduct the activities of the process. Just to give an example, Carson states that during *Problem Formulation* the team should develop a list of specific questions the model should address and he also states that it has to focus on model boundary and scope, level of detail and project scope. While during the *Model Development* phase he suggests two main activities have to be performed: *(i)* development of data structures to represent the data needed by the model and *(ii)* translation of the modelling assumptions in a specific document written in the language or representation required by the adopted simulation package. Hence, although the guidelines of *Problem Formulation* are surely helpful also in the context of agent based simulations, the second one is not applicable due to the different technological simulation paradigm.

In [13] Averill M. Law proposes a seven-step approach for conducting a simulation study. In his work, Law highlights the importance of the validity of a simulation model. Thus, he presents practical techniques and guidelines for developing valid and credible models. In particular, he declares that the keystone for building valid and credible models lies on (i) formulating the problem precisely; (ii) interacting with the decision-maker on a regular basis throughout the simulation project to ensure that the correct problem is being solved and to promote model credibility; (iii) using quantitative techniques to validate components of the model; (iv) performing sensitivity analysis to determine important model factors; (v) comparing model and system results for an existing system (if any); (vi) using a Turing test to compare model and system output data; (vii) reviewing of model results and animations to see if they appear to be reasonable. As well as the process proposed by Balci in [15], the process proposed by Law covers the whole life cycle of a simulation study providing right-minded guidelines for each activity. But as the previous ones, such guidelines are not effective enough for agent based simulation studies because too general.

At the same way, as far as we know, the methodological approaches currently proposed for agent oriented modelling give a rundown of the overall life cycle of a simulation study and only in some cases they focus on single steps, such as for example model definition and validation.

In [17] the authors present a model-based methodological framework for designing multi-agent simulations. The aim of the authors in this paper is the introduction of a consistent use of the agents during the entire life cycle of a simulation study. In particular they individuate three roles involved in a MABS (Multi-Agent Based Simulation) the thematicians that are practically the domain experts, the modellers that have the responsibility to design the model and finally the computer scientist that have to implement the model. Each role deals with abstractions of the agent at different levels (i.e: real agents, conceptual agents and computational agents) thus defining the specific kind of model related to the level he belongs to (i.e: domain model, design model and operational model). At that time, in their operational model the computational agents do not own the peculiar features of agents such as proactivity or autonomy due to the lack of development language supporting them. At the time was common the use either object-oriented or procedural or functional languages to implement the specifications described in the conceptual agents. These deficiencies are nowadays overcome by the several agent-oriented development paradigm. Hence according to Drogoul *et.al*, we believe that a methodological approach for simulation study has to be based on model transformations from different levels of abstractions but we also want to fill the gap between the conceptual model and the operational one.

In [18] the authors proposed a standard protocol for conceiving agent-based models, named ODD (Overview, Design concepts, Details). Such protocol provides guidelines in order to structure the information needful for agent-based models in an established sequence following a top down approach. It is composed of seven steps grouped in three main blocks: Overview, Design concepts and Details. The core of the protocol is the description of the design concepts following a detailed check-list of questions that allow to examine particular aspects of the system to be simulated such as emergence, adaptation, prediction etc...

The easyABMS methodology [19] is based on an iterative process that covers the common activities of a simulation study and produces several models according to the specific phase of the simulation study. Such models are produced according to a reference meta-model that is characterized by elements that are quite common in the AOSE context. It lacks of explicit representation of space, entity features and organizational structure.

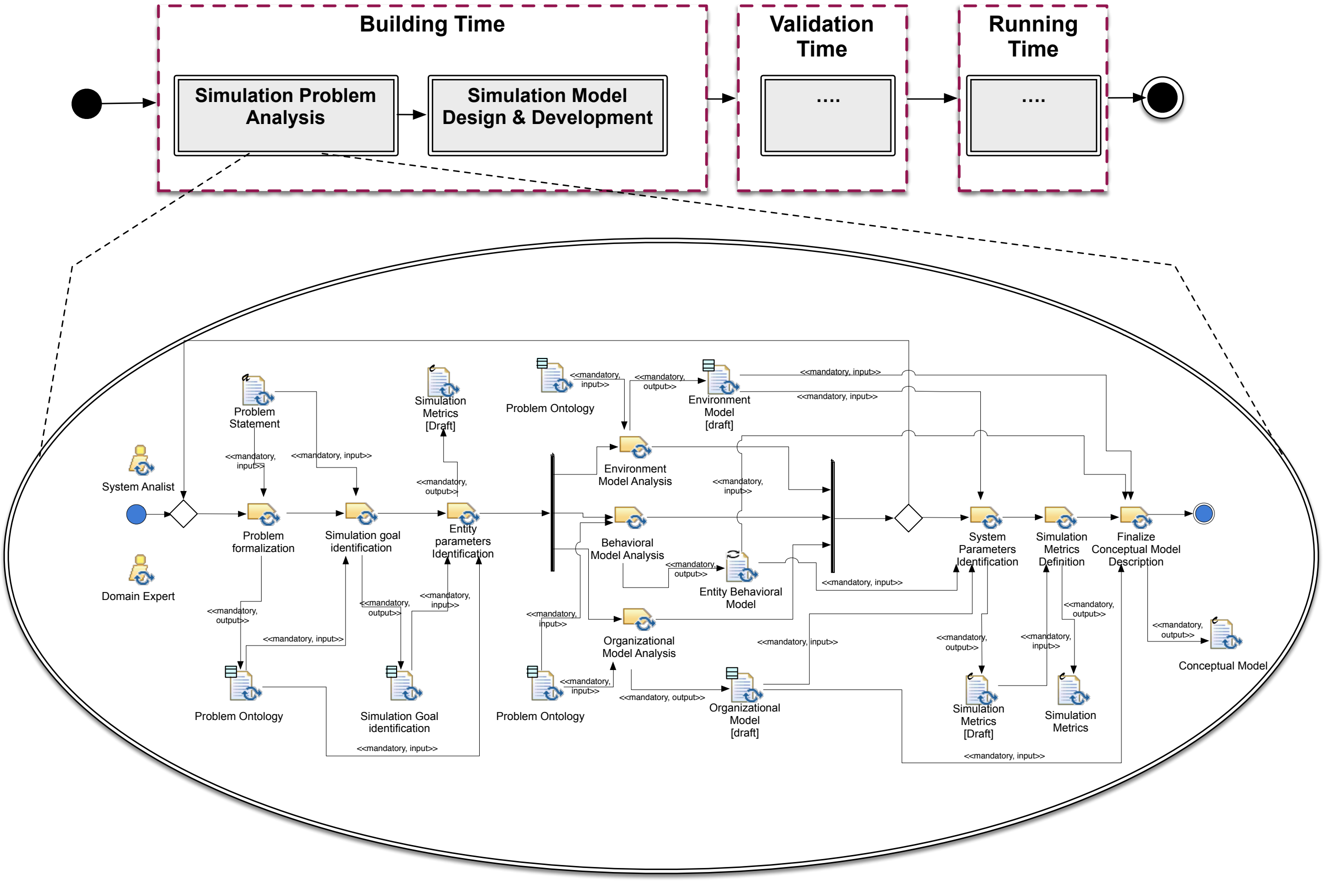

Fig. 1. A sketch of MAMAS process with zooming on Simulation Problem Analysis Phase

In [20] Cioffi introduces a general methodology for social simulations. It is an iterative process that begins with a referent system in the real world (he names *explanandum*). Then techniques of abstraction, formalization, programming are used to develop a simulation model (he names *explanans*). As well as techniques for Verification and Validation are reported such as Code Walk-Through, Parameter Sweeps, Histograms and so on. Social simulations find a natural representation by means of agent oriented techniques. As Cioffi states, agent based models have a more sophisticated landscape and actors that come closer to emulating humans through various aspects of reasoning, decision- making, and behaviours. But he only focuses on three main components of the agent based model (i.e: agents, rules, and environments) thus adapting the methodology only for this aspects.

Agent-Based Social Simulations are also the core of MAIA [21]. MAIA is a framework based on a meta-model that supports conceptualization of a agent-based simulations. It provides some guidelines in order to adequately capture, analyse, and understand the domain of application. It helps the modellers to explicitly report the motivations behind modelling choices. Such framework is focused on social and institutional structures and its meta-model aims to describe those systems where the key components are individuals and institutions. We think that some other model components have to be considered when we address agent based simulation studies. In [11] we conducted a study that highlighted the presence of an organizational aspect in many practical agent based simulations. According to the authors of [20] and [21] we claim that a methodological approach should certainly consider agents, rules, norms and environments but also other aspects such as the organizational one.

In [22] the focus is on the use of simulation in biological systems. In such a context the authors propose a revision of the Agent and Artifact (A&A) metamodel for adaptation to the Systems Biology, they made experiments using the case study of glycolysis and shown how to model and simulate the metabolic pathway.

In [23] the authors propose a method to integrate simulation-based approach within AOSE methodologies as a new fragment of the methodology. The main idea behind the use of simulation in the software engineering process is that the simulation can be used to predict the dynamics of the system to be developed and also the run-time properties that can be induced by design, before the system is completely developed.

From the literature it arises that several issues have to be still addressed for the definition of an appropriate methodological approach for agent based simulation studies. This work goes in such direction by addressing a crucial aspect: the *Problem Formalization*.

## III. AN OVERVIEW OF MAMAS PROCESS

In order to understand the aim of this paper we need to briefly introduce the context in which this contribution is plugged in. As we previously said, we are working on the development of a complete methodological approach for addressing agent based simulation studies (hereafter MAMAS) taking into account specific facets of agent based simulation paradigm.

From a literature review (see Section II), it arises that the main stages of a generic simulation study are: *(i)* the simulation model development, *(ii)* its validation and *(iii)* the execution of experiments on such model with the related analysis. We have defined in the MAMAS process three macro phases according to the stage they refer, we named them respectively *Building Time*, *Verification&Validation Time* and *Running Time* (see Fig. 1).

For the scope of this paper, let us focus on the *Building Time* phase. The final aim of this phase is to produce the agent based simulation model. This usually requires the transition from real-world system to a simulated one throughout four main artefacts:

- the *Problem Domain Description*, also called *Problem Statement*, containing an informal description both of the real-world problem to be addressed by the simulation study and of the simulation objectives;
- the *Domain Model*, also called *Conceptual Model*, that is the model of the system to be simulated emerging from the study of the *Problem Domain*. This model contains a more formalized form of knowledge about the *Problem Domain*. In particular, it may contain knowledge about real-world agents, behaviours, rules and so on;
- the *Design Model* is the model derived from the Domain Model by describing the details of the architecture of the agent based system that have to be realized for simulating the real system. A Design Model contains knowledge about design agents, interaction, behaviours that is a formal refinement of the previous one.
- the *Computational Model* is the implementation of the Design Model on a specific agent platform. It handles the computational agents that are implementation on a specific agent platform.

For supporting this transition in a systematic way, several activities are necessary. In MAMAS process, we grouped them in two phases: *Simulation Problem Analysis* and *Simulation Model Design & Development* respectively. The former supports the transition between the *Problem Domain Description* to the *Domain Model*, while the second produces the *Design Model* and the *Computational Model*. These last phase could be performed by using classical AOSE approach.

Now, let us focus on the *Simulation Problem Analysis* phase (see the zooming of Fig.1). According to the ABMS literature, we recognize the importance of the problem formalization as a mean for producing well defined simulation models. We have already experienced (see [24]) in the AOSE context how to perform the problem formalization through the use of ontological approaches in a way useful for identifying goals of multi agent systems that are the leading elements for the development of design models. Such goal identification approach is based on the definition of a *Problem Ontology* starting from the *Problem Statement* of the multi agent system to be developed.

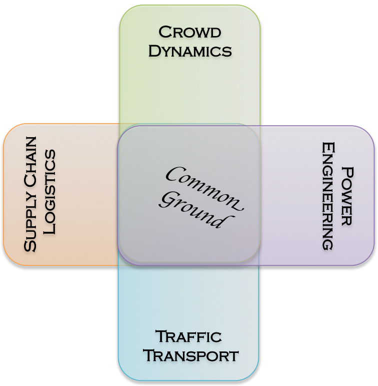

Fig. 2. Several simulation problem domains share a common ground that aims to provide a starting point for the development of an agent based simulation model.

In the same way, we think that in the ABMS context simulation goals along with agent goals are leading elements for the development of the conceptual model. Thus we are adapting the approach proposed in [24] for the identification of simulation goals and all the agent goals that influence the simulation goals itself. It is worth noting that in this context the concept of goal assumes different meanings. Commonly in generic simulation studies the term *goal* is used for referring to the simulation objectives, namely what are the real issues the simulation has to address. In such a sense, simulation goals are linked to the interest that the simulation team sees in the results of the simulation study. Conversely, agent goals refer to the states of the world an agent wants to achieve. Thus, they are linked to the interest the single entities have in the system they live in. This system is the means the simulation approach uses to achieve the intended simulation goals.

Thus, in order to adapt the approach we proposed in [24] in the context of ABMS, we need to define appropriate guidelines for building the *Problem Ontology* starting from the *Problem Domain Description* of a simulation study. Such guidelines are founded on the metamodel for agent based simulation problems proposed in [11] that will be presented in the following sections.

A detailed description of all the activities shown in Fig.1 is out of the scope of this paper, however it is important to note the role of the problem Ontology as input of several activities thus making necessary the problem formalization we propose.

## IV. PROBLEM FORMALIZATION

In [11] we already addressed the definition of a metamodel for agent based simulation problems. In that work we adopted a systematic approach to review the existing literature about agent-based simulation studies in order to identify what elements are commonly used for describing simulation problems and what elements are used in specific application domains. In

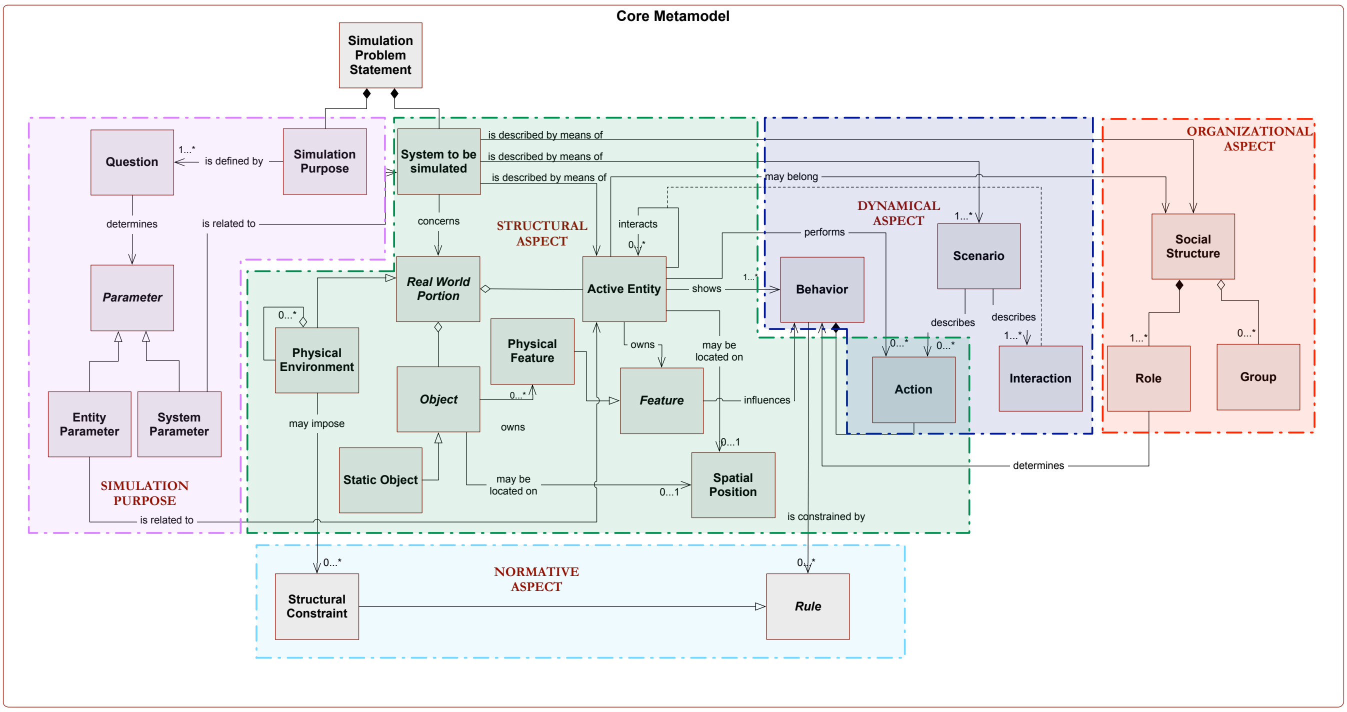

Fig. 3. The Core metamodel for agent based simulation problem.

so doing, we identified and analysed some problem domains where agent based simulations are frequently employed, thus determining a common ground formalized in a *Core Metamodel* that contains all the elements shared among the domains under analysis. Fig.2 illustrates the domains we covered in that review and the result is the metamodel shown in Fig.3. Such a metamodel shows that real-world systems commonly simulated by means of multi agent systems share some features we grouped in five key categories:

- the *Simulation Purpose* grouping elements that are related to the questions defining the goal of the simulation;
- the *Structural Aspect* namely the configuration of the real world influencing the simulation problem;
- the *Dynamical Aspect* represented by actions, interactions performed by someone/something for producing something or for achieving a particular end;
- the *Organizational Aspect* represented by the element that defines the social structure by means of group and roles;
- the *Normative Aspect* given by regulations that commonly constrains the dynamic or physical aspects of the system such as structural constraints or social norms.

Such metamodel underpins the *Simulation Problem Analysis* phase and each activity is devoted to manage some portion of it (see zooming of Fig.1). In particular, in this paper we detail the *Problem Formalization* activity that is devoted to instantiate the elements belonging to the structural aspect of the *Problem Ontology*. In the following we introduce the guidelines for performing this activity by means of a case study.

### A. Case Study

During the latest years we carried out several experiments in the field of goods management within logistic districts, studying how to store them in metropolitan distribution centres and the way to efficiently deliver them throughout the city. By working on this problem we had the possibility to conduct several experiments on agent based methodological approaches for simulation studies The focus of our studies was on one single node of the supply chain; the node was responsible for managing containers automatically unloaded by means of some AGVs (Automatic Guided Vehicle) provided with forklift for pallet handling; that is representative for a large number of real logistic warehouse-related problems.

Throughout the following subsections we use this case study in order to illustrate the proposed approach to problem ontology definition; an excerpt of the Problem Statement document is reported below.

*a) Problem Statement:* A logistic district is a large area composed of several warehouses where some freight forwarders may deliver their container. Inside a logistic district, several articulated lorries, coming from extra urban areas, arrive all the time and are arranged in warehouse bays. Each articulated lorry transports one 40-foot standard ISO (*International Organization for Standardization*) type container. Whenever a lorry reaches the warehouse, it docks into a bay for unloading its cargo. Commonly, a container holds several kinds of goods contained in boxes and grouped in pallets. These latter are *EUR pallets* (a standard ISO pallet measures 800x1200 mm). Each pallet must be unloaded from the container and carried into a well defined warehouse area dedicated to the sorting of goods, this operation is carried by the AGVs. In this area, each pallet is opened and its contents (packages of goods) placed on different sorters according to their destinations. These operations averagely last 5 minutes per pallet.

Commonly, a real logistic warehouse is basically composed of the following elements: gates, recharging areas (for AGVs), sorting areas, sorter places, buffer areas, paths and waypoints. The *Gate* corresponds to the warehouse bay and it is holds an unloading platform; lorries park here waiting for unloading their cargo (pallets). The *recharging area* is a specific area provided with sockets for recharging AGV's batteries when necessary, in particular the AGV moves towards the nearest free recharging area when its battery has depleted to a specific level. The *Sorting Area* is the place in which goods, contained in the pallets, are processed by the Sorter, an automatic device able to collect incoming goods and to forward toward a new destination. AGVs deliver goods to the Sorter using several input points (called *Sorter Places*). Goods are placed on hold when the Sorter is busy (all Sorter Places occupied by AGVs delivering some good) in the *Buffer Area*, this area is also used for temporarily parking AGVs that are waiting for a new mission. AGVs move following some *Paths* realized by means of optical guides connecting particular floor markers (*Waypoints*). AGVs have a value for their speed, their turning radius, loading capacity and type of guidance and lie in a particular area called parking area when unused.

A Waypoint has a unique ID and may be recognized by an AGV during its movement; a Waypoint is positioned outside each area of interest (Sorting Areas, entrance of unloading platforms and so on) or two meters before each cross between optical guides thus pointing out a stopping position for each AGV willing to pass a cross.

Paths are divided in path sections that are delimited by waypoints; there may be two kind of waypoints: waypoints positioned at the end of a path and the one positioned in the mid of a path, in the first case the waypoint is adjacent to one other waypoint only in the second case to two ones.

An automatic warehouse may be configured with several physical layouts (different disposition of optical lines, different number of entrances or exits, etc.) and equipped with some machinery. Each layout may impose limits to the use of different resources, the number of AGVs working simultaneously may be bounded by the set of available optical paths and their lengths; at the same time, specific equipment (i.e. the number and the performance of the AGVs, sorter capacity, etc...) and the choice of specific business strategies, such as path reservation strategy or AGVs scheduling, may constraint the performance of the warehouse thus greatly limiting its ability to quickly unloading arrived trucks.

Smaller vehicles (eco-friendly trucks) move packages out of the warehouse to their new destination (usually in town). The transport of pallets toward the sorting area is committed to AGVs with optical guidance; AGVs move, in order to load or unload pallets, by following the guidelines painted on the floor and engage a path between two adjacent waypoints, only one AGV at a time may engage such a path.

Given a warehouse made as described above the main aim of this simulation study is: how may we improve the throughput (the number of pallets unloaded per hour) of the warehouse?

### B. Guidelines for Problem Formalization

The aim of the Problem Formalization activity is to identify and instantiate all the metamodel elements composing the *Structural Aspect* of the domain under study hence all the real world concepts, or part of it, influencing the simulation problem. The result is a structural diagram, an UML class diagram, that we call Problem Ontology. This activity is deeply grounded on the analysis of the problem statement, hence on the analysis of portions of text from which the analyst has to identify the following elements: *active entity*, *object*, *feature*, *physical feature*, *spatial position* and *action*.

Before going on in the activity description, let us illustrate a verbs classification (shown in Table I) that proved useful in analysing the text for creating the Problem Ontology diagram.

| | | | | |
|---|---|---|---|---|
| **Dynamic Verbs (or Action Verbs)** | Dynamic verbs normally describe action that can be done or something that happens. They also describe action or events that may have a beginning and an end. | Transformational | They indicate events *without* a temporal extension and entail a *state change*. | wake up, leave, die… |
| | | Continuous | They indicate events *with* a temporal extension and they *have not* an implicit *goal* to reach. | sleep, work, help, improve… |
| | | Resulting | They indicate events *with* a temporal extension and they *finish* when a specific *goal* is reached. | lern, fall, build, complete… |
| **Stative Verbs** | Stative verbs refer to not changing or static condition. | Perception | They indicate perceptive processes | see, like, feel, listen, sound,.. |
| | | Cognition | They indicate cognitive process such as thinking, imaging, remembering and so on | think, suppose, remember,… |
| | | Relation | They indicate a relationships among objects or person | have, consist of… |

TABLE I. VERBS TAXONOMY

In grammar, verbs may be grouped in two main categories: dynamic verbs and stative verbs. A dynamic verb is a verb having a duration and referring to a continuous and progressive action of the subject, this is the opposite of stative verbs. Dynamic verbs are moreover distinguished in verbs showing a changing in the state of the element they refer to and/or verbs that make clear reference to a goal, an objective, to reach (for instance, work, help, sleep ...). In contrast, stative verbs refer to situations in which there is no obvious action (for instance, think, suppose, listen ...) or that relate different elements in a sentence (for instance, have, be, consist of, composed of ...).

We use this classification in order to identify in a text the elements of interest for our problem domain. As already said, the main focus when analysing a problem statement during a simulation study is on all those elements having an influence on the simulation goals. This verb classification allows us to retrieve from the text elements who performs an action when that action is intentionally performed by some active entity in order to cause a state change in the domain. It is also useful for discriminating among all the entities that actively produce a state change and all the ones that may be considered objects, resources or everything else is also used to reach a specific goal. Moreover, the focus on verbs allows us to identify the right relations among entities in the domain and above all the qualities and parameters belonging to entities that have to be taken into account when identifying all the goals of the simulation study and the metrics to be used for measuring their fulfillment. Although the latest part of the previous statement is not in the scope of this paper, it is worth underlining that the construction of a complete and well built problem ontology is the foundation, in our approach, for representing the domain as well as for identifying the system goals that purposefully influence the simulation goal; we already reported our work on the retrieval of goals from ontology in [24].

The heuristic we propose for identifying the metamodel elements from the problem statement prescribes to analyse the problem statement text in order to retrieve nouns, adjectives, verbs and relationships among them. This approach may resemble the well known Abbot's technique for identifying objects and their attributes/operations/relationships from use cases description (see [25]). Moreover, particular kinds relationship, such as aggregation or composition, may be identified also through the genitive or possessive case.

The following subsections report the guidelines for implementing the heuristic, they start from the identification of *active entities*, *objects* and *actions* that are related and identifiable through subjects, verbs and direct objects in sentences. *Active entities*, *objects* and *actions* are drawn by means of classes. [1]

It is worth noting the proposed guidelines help in identifying nouns, verbs, etc. that are candidate to become active entities, objects, actions and so on. The final decision whether they are really to be inserted in the Problem Ontology with that specific meaning is always left to the designer. The guidelines are not intended to define an algorithm for the automatic (i.e. non-supervised) production of a Problem Ontology diagram.

Fig. 8 reports a part of the Problem Ontology for the analysed problem statement. In the following subsections such ontology will be built step-by-step by applying the proposed guidelines.

*1) Preliminary Step-Nouns Identification:* A preliminary step is required: it prescribes to analyse the problem statement and to prepare a list of all nouns present in the text. Obviously, not all the nouns found during this work are relevant for the problem, we are constructing a model hence a view on a specific area of interest. The problem domain we are analysing as a case study falls in the area of the simulation of processes. It takes place in a warehouse, and it aims to improve its throughput. Hence, we may say, for instance, that *logistic district* is not a noun of interest because we are focusing on the warehouse that is a part of logistic district. The same is for *urban area* because, in this case, it clearly does not influence the real process in the warehouse and consequently our simulation study. It is also frequent that synonyms are used in the text. This is to be avoided when possible and existing synonyms are to be reported only once with the most immediately recognizable name. For instance, in the case study problem description text, it is possible to note that bay is used as a synonym of gate. The result of this activity in the reported case study produces the following list of nouns: lorry, pallet, AGV, path, gate, sorting area.

*2) Active Entity Identification:* The identification of active entities is performed in the following way:

```
For each noun in the previous list

-   analyze sentences in which it is the
    subject of a verb

-   if there exists at least one sentence
    in which it is the subject of a
    dynamic verb (or it is in some kind of
    relationship with a dynamic verb)
      -   analyze the verb
      -   if it is a resulting or a
          transformational verb (Table I)
          the considered noun is an active
          entity
```

Some active entities may be in composition/aggregation, specialization or association relationship with other active entities, this kind of relationships are identified by means of stative verbs, relation kind.

In the presented case study there are not evidences of stative verbs such as cognition and perception verbs, however, generally speaking, they both may be verbs whose subject is an active entity.

The result of this activity in the reported case study brings to the identification of sentences like:
"*AGVs move*, in order to *load* or *unload* pallets, by following guidelines (hence paths) painted on the floor"
"*Lorries park* here (ref. gates)"
"*AGV moves* towards the nearest recharging area"

In these sentences two active entities may be identified: *AGV* and *Lorry* (the use of the singular form of the nouns is advisable). A first portion of Problem Ontology Diagram may now be built by reporting in it the two identified active entities (see Fig. 4).

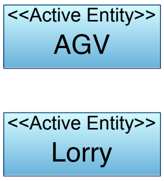

Fig. 4. Problem Ontology-Step 2 (active entities)

[1] It is worth noting that the guidelines for performing Problem Formalization may be associated to every kind of notation, we choose UML class diagram because its extended usage makes it easier to understand the composition of the Problem Ontology diagram.

*3) Actions Identification:* The identification of actions is performed in the following way:

> For each previously identified active entity, associate the corresponding action in the sentence and draw them in the diagram.

This step may be performed in a iterative fashion with the previous one (active entities identification).

The result of this activity in the reported case study brings to the identification of the following actions: move, load, unload, follow, park.
Such elements are reported in the Problem Ontology diagram thus obtaining its new release as reported in Fig. 5.

The notation we adopt for this diagram prescribes the direction of the relationships went from the active entity (the actor performing an action) towards the performed action.

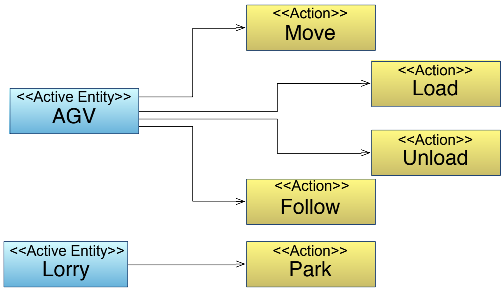

Fig. 5. Problem Ontology-Step 3 (actions)

*4) Objects Identification:* The identification of objects is performed in the following way:

> All nouns that are direct objects in sentences where an active entity is a subject are *objects*. All the other nouns that are not active entities are candidate objects. Candidate objects that are subject of stative-relation or dynamic-continuos verbs are *objects*.

In order to definitively identify all the *objects*, the designer has to examine the structure of sentences and to analyse if a candidate object is related to another one or if it is related to adjectives, anyway she has to look through which kind of verbs they are related to. This is complemented by the following step. Moreover, as for active entities, objects may be related by association, composition/aggregation and generalization relationships.

The result of this activity in the reported case study brings to the identification of sentences like:
"AGVs move, in order to load or unload *pallets*, by following guidelines (hence *paths*) painted on the floor"
"Lorries park here (ref. *gates*)"
"AGV moves towards the nearest *recharging area*"
"Paths *are divided* in path sections that *are delimited* by waypoints; there *may be* two kind of waypoints..."

In these sentences the following objects may be identified: *Recharging Area*, *Pallet*, *Path*, *PathSection*, *Waypoint*, *MidWayPoint*, *FinalWayPoint*, *Gate*. Some of them are related by composition/generalization relationships as described in the new release of the Problem Ontology diagram reported in Fig. 6.

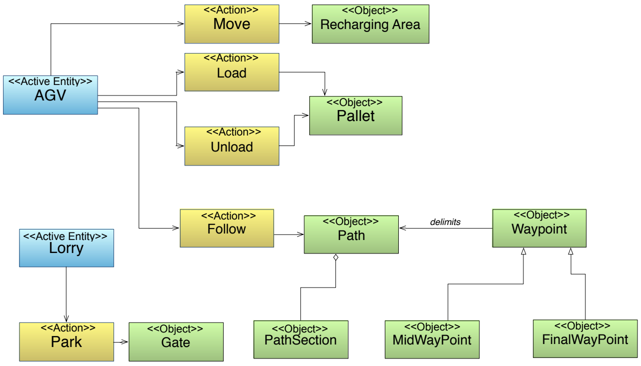

Fig. 6. Problem Ontology-Step 4 (objects)

*5) Feature Identification:* The identification of features is performed in the following way:

> For each candidate object analyse if it is related to other candidate objects through relation or continuous verbs. We may find two cases:
>
> - noun + relation or continuous verb + adjectives, the noun is an *object* and the relationship with the adjective is described with a predicate
> - noun + relation or continuous verb + noun, the first noun is an *object*, the second one may be represented through another *object*, related with UML relationships, or through attributes.

The choice between representing relations as attributes rather than other objects depends on what the analyst wants to underline and on the specific problem domain. In the presented case study, for instance, speed is represented as an attribute of AGV and not as an object because we found not necessary to represent speed as an object while simulating processes in warehouses. The contrary happens for Sockets that in the real word own a specified position and physical attributes that, in the designer's understanding, may influence the simulation goal (warehouse throughput optimization).

The result of this activity in the reported case study brings to the analysis of sentences like:
"in the first case the waypoint is adjacent to one other waypoint only in the second case to two ones."
"AGVs have a value for their speed, their turning radius, loading capacity and type of guidance."
"The recharging area is provided with sockets for recharging AGV's batteries when necessary"

The first sentence brings to the identification of the IsAdjacent predicate between two waypoints. The second one lists some attributes of AGVs (speed, turning radius,...), the last one identifies two new objects (Socket and Battery) and the relationship between Socket and Battery.

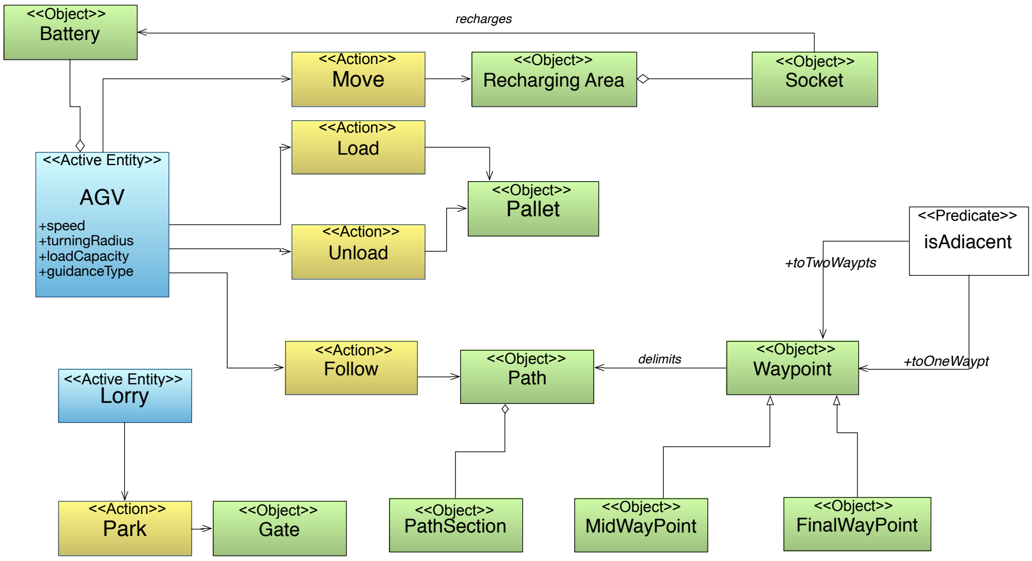

Fig. 7. Problem Ontology-Step 5 (Features)

Such elements are reported in the Problem Ontology diagram thus obtaining its new release as reported in Fig. 7.

*6) Spatial Position Identification:* The identification of features is performed in the following way:

Guidelines in this case are the same of *Feature*, the designer has to look at continuous or relation verbs denoting positioning of objects in the space and choose if they may be treated as objects, attribute or predicates.

The result of this activity in the reported case study brings to the analysis of sentences like:
“a Waypoint is positioned outside each area of interest”
“AGVs lie in a particular area called parking area when unused”

The first sentence allows to identify two relations, the first between the concepts Waypoint and InterestPoint whereas the second between the concepts AGV and ParkingArea; see Fig. 8 where, as already anticipated, the complete resulting Problem Ontology is reported.

## V. Conclusions

Simulation studies conducted by using agent based modelling and simulation approaches had reported in the latest period good results, however they still lack a rigorous methodological approach for going, step by step, from simulation problem analysis to the implementation of the agent based simulation system. We may say that in the case of simulation studies the development of agent based systems is a part that resides within the overall simulation study and its requirements are greatly affected from the simulation requirements themselves. In this context an important role is covered by the simulation problem analysis phase that aims at identifying and describing the domain under study along with the simulation goals.

We claim that simulation goals descending from the problem domain, are greatly related to the goals of the agent based systems, although they cover a different scope with respect to agent goals. Indeed, simulation goals are related to the interest that the simulation team sees in the results of the simulation study. Whilst agent goals refer to the states of the world an agent wants to achieve in the system they live. This system is the means the simulation approach uses to achieve the intended simulation goals. Thus, simulation goals constraint the scope of the problem to be addressed by the simulation study and they guide the definition of the problem elements that are useful to model.

In this context it is of high importance to have some guidelines for extracting the goal of the simulation and the system goals from the description of the problem domain. In some previous work [24] we already experienced how to extract goals from a formalized description of the problem domain and we want to somehow apply the same approach for the future development of our work on agent based simulation study.

In this paper we explore the step before the identification of goals and provide a set of guidelines for modelling the structural aspect, hence the configuration of the real word influencing the simulation goal, of the problem domain. We propose an heuristic based on the analysis of verbs and nouns in the problem statement.

This work is the logic progression of what reported in [11] where we identified which elements have to be present in the problem statement of a simulation study; the result of that work was a metamodel whose elements (the part related to the structural aspect) are instantiated in the simulation problem analysis phase by means of the guidelines we propose in the proposed contribution.

For the future, we are going to complete all the activities of the simulation problem analysis phase as well as the whole methodological approach for multi agent simulation study.

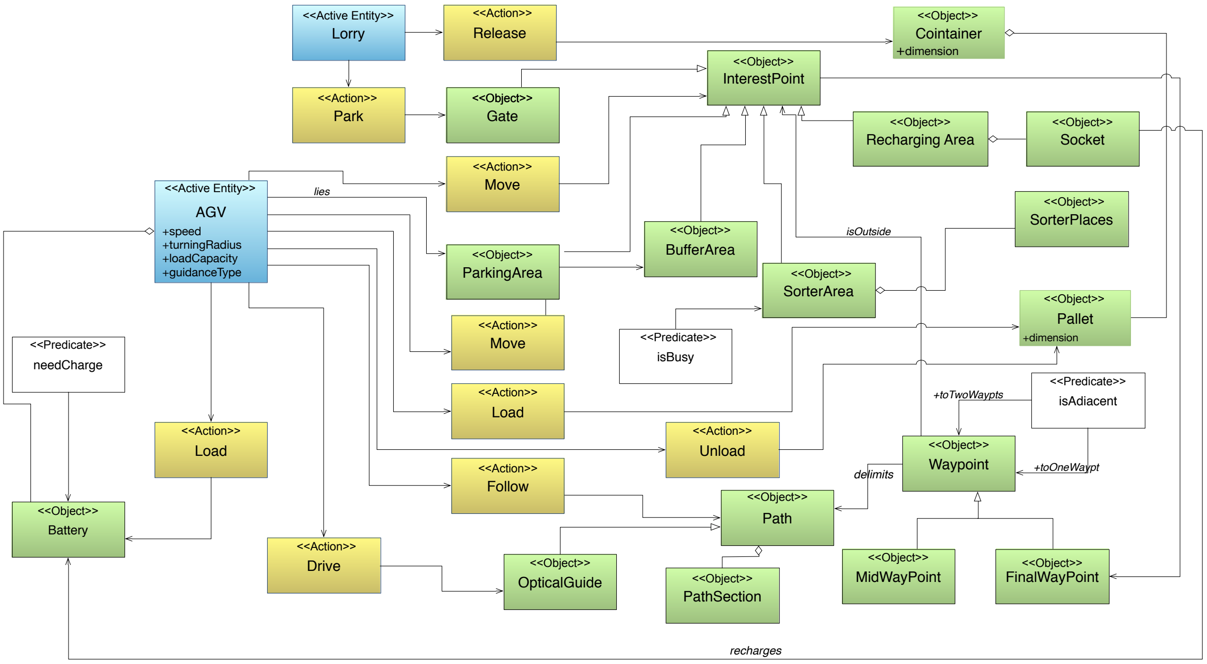

Fig. 8. The Problem Ontology diagram resulting from the application of the proposed heuristic for Logistic Warehouse case study.

# Developing an Integrative Modelling Language for Enhancing Road Traffic Simulations

Alberto Fernández-Isabel
Rubén Fuentes-Fernández
{afernandezisabel@estumail, ruben@fdi}.ucm.es
Universidad Complutense de Madrid
Madrid, Spain

***Abstract*—Road traffic is a pervasive aspect in modern societies that affects millions people. The study of its multiple aspects is a very demanding task. Due to its complexity, traffic simulations become a key tool. Their development demands multidisciplinary teams, where communication problems are frequent. Model-driven engineering alleviates this situation providing graphical instruments for designing Modelling Languages (MLs) and semi-automatic transformations. This work presents a model-driven infrastructure composed by an integrative ML, a model editor, and a code generator. The ML is based on related literature and facilitates modelling different theories and simulations based on them. It considers the roles of individuals involved in road traffic, and partially adopts agent-based methodologies to model their decision-making. A case study shows how to produce a simulation specification adapting an existing traffic theory to the ML, and adjust this specification to a simulation platform for testing. It provides the basis for comparison with related work.**

## I. Introduction

ROAD traffic is a complex phenomenon. Its study requires considering a large amount of variables, and it affects a variety of aspects, such as pollution, economical factors, leisure organisation, and health issues. The individuals involved play multiple roles in a broad range of scenarios, being able to establish complex relationships among them. These features make difficult studies based on experiments in real settings, which leads researchers to limit the variables considered and focus only on very specific aspects. In order to alleviate these restrictions, traffic simulations appear as a possible solution. Nevertheless, simulations present their own weak points [1]. Some of the most relevant are related to the difficulties to align (and check this alignment) the theories, goals, code, and results of the simulation, particularly because of the different backgrounds of people involved and the use of implicit information.

Approaches based on Model-Driven Engineering (MDE) [2] have been proposed to deal with these issues. They are organised around *models*, which are compliant with MLs, and generate other artefacts via semi-automatic *transformations*. MDE processes are usually incremental and iterative, allowing introducing improvements and modifications at any part of their workflows. MDE requires an initial effort for developing the elements of its infrastructure. This effort is higher than just implementing a simulation, but it compensates it with reusability (i.e. the resources can be used as a basis for other projects) and the explicit description of all the information (with MLs, models, and transformations).

Our approach provides a complete and integrative MDE infrastructure for road traffic simulations, focused on modelling individual behaviours. It introduces a Traffic Modelling Language (TML) and two development tools. A graphical editor supports describing the specifications, and a code generator helps to produce the semi-automatic transformations to generate the source code for a target simulation platform from those specifications.

The TML pursues being able to integrate (i.e. support the modelling and combination of) different theories related to road traffic. It considers the multiple viewpoints of the involved individuals (i.e. drivers, pedestrians, and passengers) and the roles in development teams (e.g. traffic expert and programmer). In this sense, it is a Domain-Specific ML (DSML) for this kind of problem. Faced to the traditional dichotomy in MLs between general and specific ones [3], our work chooses limiting the applicability of the approach to traffic simulations in order to provide better support in terms of guidance and tools to experts. The language is also intended to be platform-independent, so the details of the target platform can be considered just in late design tasks.

Following common practices in MDE, a metamodel describes the TML. It is organised using inheritance and composition hierarchies. The inheritances provide specialisation of concepts, while compositions are based on relationships of purpose, functional groups, physical links, or similarity. The metamodel is divided into three clusters: a *Mental cluster* where the different features of individuals are considered, an *Environmental cluster* to specify environment information, and an *Interactive cluster* to represent the interactions among individuals and the environment and the decision-making.

The *Mental cluster* considers the psychological features of individuals [4]. It plays a role similar to the mental state of the agent paradigm [5]. It adopts the BDI model [6], incorporating some of its knowledge concepts to model the current information that an individual or group possesses.

The *Environmental cluster* is based on the Driver-Vehicle-Environment (DVE) [7] approach. It considers that individuals can interact among them or with the environment, either directly or using their means of transport. These dynamic interactions influence the individual behaviours. This assumption

978-83-60810-66-8/$25.00©2015, IEEE

fits with Agent-Based Modelling (ABM) [8], where agents are intentional entities that can establish communications among them for different purposes (e.g. collaborate or interact).

The *Interactive cluster* models the decision-making of the individuals. It adapts this aspect from methodologies based on Agent-Oriented Software Engineering (AOSE) (e.g. INGENIAS [9] or Tropos [10]). *Goals* represent the people's objectives, and *tasks* are the instructions to execute in order those satisfy goals. These elements are considered in a *perceive-reason-act* cycle [11].

Regarding the development tools, the graphical editor allows designing the model instances compliant with the TML. The code generator takes as input these instances, and provides a set of functionalities to generate source code and adapt it to the target traffic simulation platform.

A case study shows the suitability of the MDE infrastructure to develop traffic simulations. It specifies the work in [12] using the ML. The graphical editor tool supports and guides this process, which produces a model specification and default source code templates for the primitives of the ML. These artefacts are the input of the code generator tool. It supports the completion of these templates with graphical wizards that assist users. This code is finally adapted to a specific traffic simulation platform, MATSim [13]. For this purpose, the code generator allows adding specific classes and code snippets to modify available code (e.g. using libraries or algorithms).

The rest of the paper is organised as follows. Section II presents the basic concepts of MDE and the related tools. The TML is introduced in Section III through its metamodel and clusters. Section IV presents the two development tools based on the TML, the model editor and the code generator. The case study in Section V illustrates the application of the approach. Then, Section VI compares this with related work. Finally, Section VII discusses some conclusions and future work.

## II. Model-Driven Engineering

MDE [2] is a development methodology that is composed around *models*, in contrast to traditional approaches that are based on source code. The development process is focused on the production of iterative and incremental specifications of models going to abstract to accurate, where developers refine and add new elements to them at each step. During this process, *transformations* are introduced in order to automate repetitive modifications in models. For instance, generating patterns or concrete specialisations to target platform in order to produce models. Other related elements (e.g. source code or documentation) are compliant to these considerations, as they can be obtained from models using manual settings and transformations.

This development approach is based on modelling languages. In the case of graph-oriented languages, which are the most popular ones [14], the main instrument to achieve these definitions is the metamodel. Metamodels are commonly selected to describe their abstract syntax, but also they can be used to define their specific syntax or semantics [15]. Also, these metamodels are defined using meta-modelling languages. The Meta-Object Facility (MOF) [16] provided by the Object Management Group (OMG) is the standard in the domain. Nevertheless it presents some limitations. The absence of extensive tool support promotes that users frequently choose alternative languages or develop their own related tools. The Ecore meta-modelling language [17] is considered as an alternative as it is supported by multiple Eclipse modelling tools. These tools are organised around the Eclipse Modelling Framework (EMF) [17] and the Graphical Editing Framework (GEF) [18]. Also, Ecore adopts the Object Constraint Language (OCL) [19] to define model constraints and it is almost compliant to Essential MOF (EMOF). EMOF is a part of MOF focused on object oriented concepts and able to specify reflective operations. These features encourage this approach to select Ecore as its meta-modelling language in order to develop the TML.

Fig 1 shows the principal primitives of Ecore. An instance of *EClass* plays the role of its similar entities at the model level (i.e. classes). It clusters *EAttribute* and *EReference* elements. *EAttribute* instances provide features coming from *EDataTypes* (i.e. primitive types) to *EClass* instances. These primitive types include the most common (e.g. integer, char or string). An *EReference* instance symbolises a binary relationship in only one direction among two *EClass* instances. It allows creating containment and non-containment relationships. The *EReferenceType* of a specific *EReference* instance is indicated by its target *EClass*. Multiple *EClass* instances can be considered by *ESuperType* relationship in order to express inheritance among them. *EPackage* instances contemplate the possibility of grouping the structures of the metamodel.

Regarding the transformations, they are the other core instrument of MDE. They present different types of inputs and outputs, being able to be classified in [20]: Model-to-Text (M2T), Text-to-Model (T2M) and Model-to-Model (M2M) [21]. These transformations can be developed using general-purpose programming languages or transformation languages. In the first case, a module uses programming structures to manage its inputs and outputs. In the second case, the module is developed using a specific language for transformations and presents an engine that executes it in order to accomplish the process.

In this work, a module defined by a general-purpose programming language (i.e. Java) is adopted (see Section IV), as it can use techniques from reflection-based programming [20] and integrates several wizards that assist developers.

## III. Traffic metamodel

Road traffic is a pervasive phenomenon that involves elements and situations. In order to study it, there are different theories that consider its aspects from multiple backgrounds and purposes. The same situation occurs with traffic simulations, where infrastructures differ on their modelling approach and goals.

In order to facilitate the integration and modification of elements in the TML and its study, this approach uses a metamodel [17] defined with Ecore.

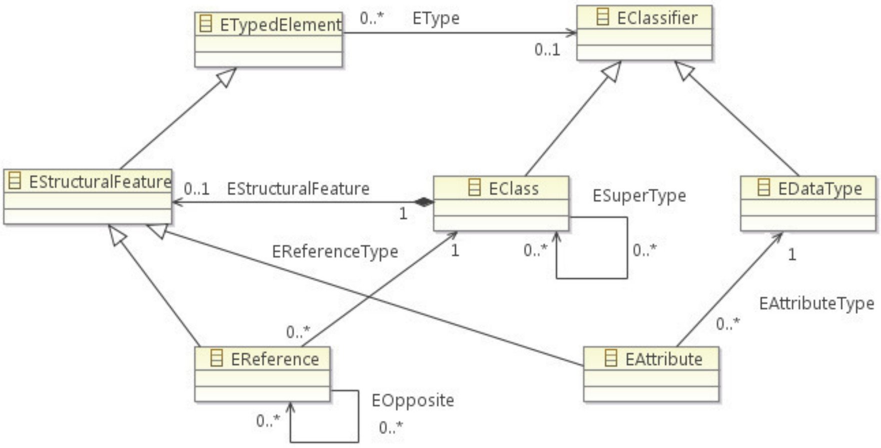

Fig. 1. Extract of the Ecore model selected from [17]

Regarding the concepts of the TML,they are mainly based on ABM [8] and structured into three clusters. The *Mental* and *Environmental* clusters gather the different concepts obtained from traffic literature. The *Mental cluster* represents the inner state of the participants in traffic [4]. The *Environmental cluster* includes the DVE approach [7]. These clusters have similar structures (see later in this section). The *Interactive cluster* is focused on representing the goals and actions of people involved in traffic. It is based on the guidelines of methodologies coming from Agent-Oriented Software Engineering (AOSE), integrating a *perceive-reason-act* cycle [11].

The core concept of the metamodel is the *Person* meta-class. It represents the types of people involved in traffic. According to their means of transport, they can be drivers, passengers, or pedestrians. These *Person* instances can interact with an *Environment* instance. This interaction is direct (in the case of pedestrians), or indirect when a *Vehicle* instance is used for it (for drivers and passengers). People' features are modelled with *Profile* instances, and the information they possess with *Knowledge* instances. Their acts are motivated by *Goal* instances, and the potential ways to achieve them are represented by *Task* instances. *Evaluator* instances determine how people have actually to act according to the circumstances, and *Actuator* instances execute the planned tasks.

The previous elements are arranged in inheritance hierarchies, adding the needed specialisation and structure to the metamodel. All concepts inherit from the *GeneralElement* meta-class (see Figs. 2 and 3). This meta-class provides the *EInherits* reference in order to represent inheritance among elements of the same type in model instances. The *GeneralRelationship* meta-class (see also Figs. 2 and 3) supports the introduction of relationships (e.g. affects or influences) among other elements. The *RInherits* reference allows its specialisation. Both types of references are constrained by expressions written with OCL [19]. For instance, constraints only allow inheritance among instances of the same type of meta-classes (e.g. a *Knowledge* instance only extends another *Knowledge* instance using a *EInherits* reference).

The internal structure of the *Mental* and *Environmental* clusters allows composition hierarchies using the *XComponent* (e.g. *KComponent* or *VComponent*) meta-classes. These meta-classes can be decomposed into others of their same types. All these compositions are constrained by OCL expressions. For instance, a *Profile* instance can be decomposed only into *PComponent* instances, while these *PComponent* instances can be only decomposed into others of the same type.

The meta-classes of the metamodel include attributes and predefined methods. Attributes can be specific for certain meta-classes or common (with similar name and meaning) to several meta-classes. An example of the first case is the *AvailableArea* attribute in the *Environment* meta-class; the *XValues* attributes (e.g. *PValues* or *EValues*) for storing the impact that an element has in the rest of the elements of a model instance are examples of the second group. Methods are placeholders for specifications that describe behaviour or attributes derived from others. For instance, code snippets can be attached to these methods in the model specification for code generation.

Next sub-sections discuss these aspects in detail. Subsection III-A describes the mental state and features of participants in traffic. Subsection III-B focuses on concepts to describe the traffic setting according to the DVE model [7], i.e. vehicles and the environment. Subsection III-C introduces the concepts to represent interactions among the previous elements and decision-making.

### *A. Mental cluster*

The *Mental cluster* (see Fig. 2) represents the different concepts that can appear in the road traffic domain influencing the behaviour of individuals [4]. These concepts are classified as features of people or their current state.

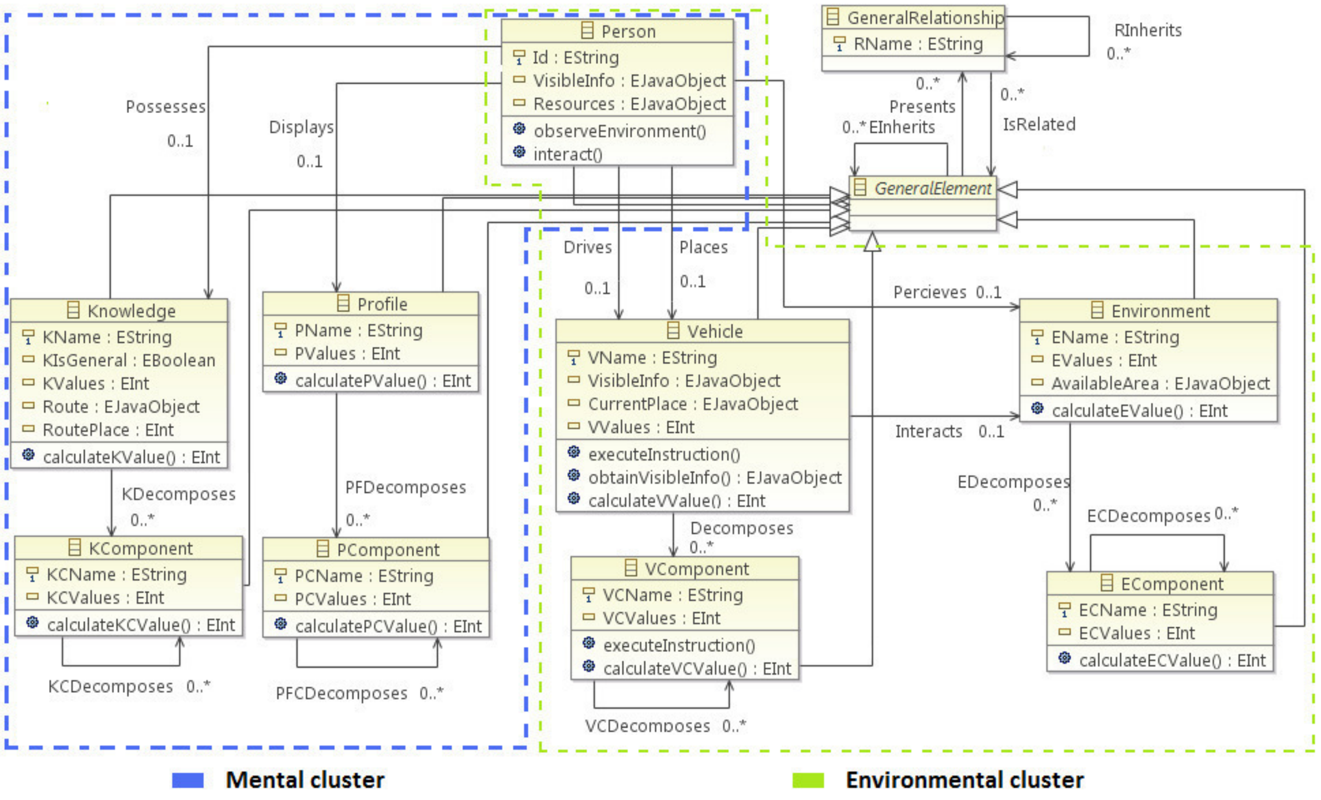

Fig. 2. Excerpt of the *Mental* and *Environmental* clusters of the metamodel.

The cluster includes three main meta-classes: *Person*, *Profile*, and *Knowledge*. *Profile* represents the different features of people in traffic. *Knowledge* considers the current mental state (but the goals) that a *Person* uses when dealing with traffic. It can be factual (e.g. traffic signs), procedural (e.g. how to overtake a vehicle), and normative (e.g. drivers should respect safe distances with other vehicles) knowledge. *Profile* instances describe people features (e.g. age or fatigue).

Both knowledge and features of people can specify information that does not change in simulation time (e.g. gender or meaning of signs), or does it (e.g. stress or mood). Proper *calculate* methods and their associated attributes must be specified to describe how to calculate them later.

The instances of the *Knowledge* meta-class and their composition meta-classes can represent information belonging to individuals (e.g. the current route), or global information available for every participant in the simulation (e.g. the speed limit in a specific type of road). The *KIsGeneral* attribute differentiates both uses.

This cluster is closely related to the agent paradigm [5]. For instance, the *Knowledge* meta-class can consider the *Beliefs* of people involved in road traffic, which are contemplated in the BDI model [6].

### B. *Environmental cluster*

The *Environmental cluster* (see Fig. 2) adapts the concepts of the DVE model [7], as this is focused only on the driver role and the TML considers others. Thus, here it is considered that an individual can get information from the environment (any participating person) and the vehicle (only drivers and passengers). These elements can be extended to facilitate the potential accommodation of other theories.

The cluster considers how individuals relate to their means of transport and environment. It comprehends three main meta-classes: *Person*, *Environment*, and *Vehicle*. *Environment* represents the place where people (i.e. *Person* instances) interact, including the physical conditions that can occur (e.g. weather and road conditions). A model specification has a unique *Environment* instance shared by all the individuals. The *Vehicle* represents the means of transport, considering the different roles of people in road traffic (i.e. driver, passenger, and pedestrian). Drivers and their passengers relate to the *Environment* through their vehicles, but only drivers can use them to act on it. In the case of pedestrians, they have a direct relationship with the environment.

The mutual influences among *Person*, *Environment*, and *Vehicle* instances because of their relationships are partially represented in the metamodel with some attributes. The *Environment* meta-class has an *AvailableArea* attribute. It indicates the part of the environment that can be perceived. The *Person* and *Vehicle* meta-classes include the *VisibleInfo* attribute to specify which information from the *Environment* instance can be perceived in or through their instances.

### C. Interactive cluster

The *Interactive cluster* (see Fig. 3) describes how *Person* instances act on the traffic situations considered by the *Mental* and *Environmental* clusters (see Sections III-A and III-B). Its components are organised into two groups. The first one describes the objectives of people and their capabilities to achieve them. The second one represents the elements that carry out the acting cycle.

The first group includes the *Goal* and *Task* elements. These two concepts come from Multi-Agent Systems (MAS) [22], and agent-based methodologies. These methodologies include a specific acting architecture where agents play multiple roles and try to meet the requirements of their different goals. These goals are enabled according to the agents' mental states and are directly related to task elements that can satisfy them. These goals can be decomposed into others, generating *OR* or *AND* compositions. Tasks can be decomposed in a similar way in order to describe complex jobs.

In our work, the *Mental cluster* represents the mental state of agents, and the *Environmental cluster* provides information from the environment and the vehicle (only in the case of drivers and passengers). The *Goal* meta-class represents a state of some traffic elements a person aspires to keep or reach, and the *Task* meta-class models person's capabilities. Both meta-classes hold specific attributes to characterise them. *Goals* have *Satisfaction* attributes that represent their satisfaction conditions. *Tasks* include *Instructions* attributes to specify the atomic actions that implement them.

These meta-classes can be decomposed into others of their type (constrained with OCL expressions), following the structure already seen for sub-components in the other two clusters. However, semantics are different. Here, they are related to satisfaction instead of determining the features of a component. The *Goal* and *Task* meta-classes present the *GType* and *TType* attributes in order to specify the type of compositions (e.g. *OR* or *AND*). The *GType* attribute represents the type of goal satisfaction compositions, while the *TTYpe* attribute indicates if the current task is accomplished by completing one or all its sub-tasks. These semantics are flexible, as both attributes could be modified to support different structures and classifications.

The second group represents those elements of a person that are in charge of evaluating the actual known state and executing actions. It follows a classical *perceive-reason-act* cycle [11] with evaluators and actuators (based on [23]). The information perceived from the environment is stored in the elements of the *Environmental cluster* (including the *Person* meta-class), the reasoning is carried out by *Evaluator* instances, and the acting is achieved with *Actuator* instances.

*Evaluator* instances can be decomposed into others using the *EVDecomposes* reference, being able to distribute the liabilities among them. In the case of *Actuator* instances, they cannot be decomposed into others. They can use inheritance through *EInherits* references, but each *Person* instance (i.e. a person type modelled) can only present one *Actuator* instance related to it (see the *Utilizes* reference in Fig 3).

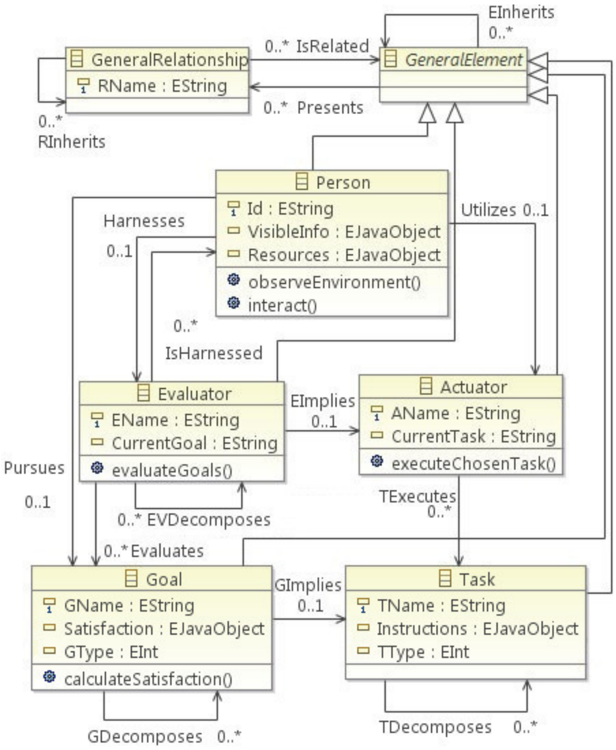

Fig. 3. Excerpt of the *Interactive cluster* of the metamodel.

*Evaluator* instances assess the information obtained from the *Environment* and *Vehicle* instances, the elements they are composed, and the available relationship instances linked to their *Person* instance. From that, they update the internal state of the *Person* instance. All this information determines the current state of goals. Once a candidate goal is selected, an *Actuator* instance picks its associated tasks. It executes these *Task* instances through its *Instructions* or subtasks.

## IV. Development tools

The MDE approach presented in this paper is supported by two main tools: a graphical editor where the model specifications are developed, and a code generator where multiple operations to produce source code from models are achieved through semi-automatic transformations. Their implementation is based on the Eclipse Modelling Framework (EMF) [17] and the Graphical Editing Framework (GEF) [18].

The graphical editor is an Eclipse plug-in that guides users in the development of model specifications. It generates models compliant with the TML through a visual interface. This interface provides a canvas and a palette for displaying the model and the concepts of the metamodel. The model generated can be validated to ensure its compliance.

The code generator tool takes as input the model specifications produced by the graphical editor. In a first step, it associates to the classes in the model the source code EMF generates automatically for their meta-classes. Also, it provides options to integrate other external files, e.g. specific libraries coming from the target platform or even the entire simulation with its associated dependencies. This can be used later to modify the preliminary code.

Over that input, the tool presents a graphical interface for displaying the information captured in the model specifications, allowing an intuitive navigation of them. The information about a selected element instance includes the methods associated (original and newly created), the decomposed elements it presents, the *GeneralRelationship* instances where it acts as the origin, and the elements from which it inherits (see Fig.4).

The code generator implements operations related to source code transformation and model adaptation, and operations related to specialisation to target simulation platform. Most of them are partially automated through wizards in order to provide guidance to users. A text editor, an internal graphical editor, and a compiler are integrated in the infrastructure in order to support these features.

Regarding the code transformation, main functionalities are: source code injection for platform adaptation, design and storage of self-contained *Interactive clusters* (see Section III-C), and cluster integration.

The injection of source code offers two alternatives. They are based on techniques from reflection-based programming [20] in order to modify and compile dynamically the default EMF implementation. The first one redefines only the body of the methods of the classes adding different instructions, using suitable code snippets for the target simulation platform. The second one is more complex, being able to complete the entire class or extending it from another one of the same type previously redefined. This allows adding new attributes and methods. As these operations require some programming skills, the graphical interface and the integrated modules (i.e. text editor and compiler) assist to examine the metamodel and model elements, and their code. This facilitates these tasks and produces a more intuitive development environment. There is also on-line help and examples to guide users in this point.

The design and storage of self-contained *Interactive clusters* uses the integrated graphical editor. It provides (in a similar way to the graphical editor plug-in explained above) a canvas and a palette to create the multiple elements (i.e. *Goal*, *Task*, *Evaluator*, *Actuator*, and *GeneralRelationship* instances) and a validation tool. After that, the generated cluster can be loaded into the tool in order to perform other tasks, such as code injection or storage of the development stage. In the last case, a wizard creates a compressed file including the current stage and the model designed, which allows continuing with the graphical design in the future.

The cluster integration functionality is linked to the previous one. It merges a model specification only with elements from the *Mental* and *Environmental* clusters previously loaded in the tool, and a stored self-contained *Interactive cluster*. A graphical wizard facilitates the process showing to users the available elements in each cluster in order to link them through references from the TML. Also, *GeneralRelationship* instances can be added or completed (i.e. relationships with origin in elements of *Mental* and *Environmental* clusters and destination in elements of *Interactive cluster* or vice versa). This functionality is particularly useful since models of the *Interactive cluster* can frequently be reused with different models of the *Mental* and *Environmental* clusters. Moreover, their attached code is the most depending on the target platform. Once the integration is completed, the rest of the tool functionalities can be used taking the new integrated model specification as the current one.

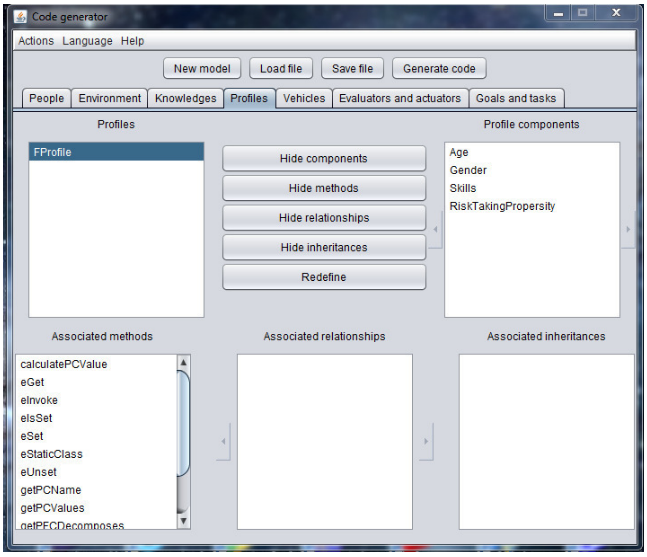

Fig. 4. Graphical interface of the code generator tool.

Regarding the platform adaptation, the code generator tool presents two main functionalities that promote the specialisation of the design and a better integration between the model specification and the target traffic platform: a dynamic compiler insertion and new classes generation.

The dynamic insertion assists in the attachment of libraries provided by the target platform (i.e. as external files) to the code generator, making them available to the compiler. Once the library or libraries are selected, the process is internally managed by the tool making it transparent to users. It allows producing platform-related elements in the source code of a model specification class.

The new class generation functionality supports the creation of new classes extending the original ones coming from these external libraries. It uses a wizard that eases the selection among the available classes. These classes are inserted dynamically in the path of the compiler and can be used as the others. This allows the creation of new objects of these classes in the model specification classes or vice versa.

Finally, when both the code transformation and platform adaptation are completed, the final file is produced. It can be generated using two different approaches: a specific plug-in and a new adjusted platform, being both supported by wizards to make the process more intuitive. The specific plug-in approach builds a compressed file packaging the model specification, the dependencies, and the classes generated that could be used or inserted into the target platform. The new adjusted platform approach integrates the entire target simulation platform and their dependencies (if they are needed), using external libraries, with the model specification and the classes modified and generated. The result is a runnable compressed file that contains the target platform. This platform is able to develop simulations considering the model specification inserted.

In both cases, configuration files can be created by another wizard. These files can be added to the compressed files in order to indicate parameters related to the simulation that must be considered.

The functionalities of these tools support our MDE approach for traffic simulation. They facilitate the process allowing the graphical examination of elements and the integration of multiple artefacts (e.g. model specifications or code snippets). Also, they encourage reusability and incremental development, reducing manual coding.

## V. Case study

The case study shows the use of the MDE infrastructure (i.e. the TML and the development tools) in order to produce a road traffic simulation. It integrates a model specification (compliant with the TML) that adapts a theory of the domain with the specialisation to a target traffic simulation platform.

In this case, the selected traffic theory [12] describes a classification of potential risk factors for drivers, and how these factors can influence their behaviour. It is modelled with the proposed TML, and uses the resulting model for generating source code through a semi-automatic process. Specific code snippets and classes are inserted for generating an adaptation that can run a simulation using the MATSim platform [13].

The original classification of risk factors presents multiple aspects structured around two main concepts: *Individual differences* and *Situational factors*. This classification does not follow the DVE [7] approach required by the TML, but its adaptation seems feasible, as both cover common aspects. For instance, the *Vehicle size* factor in [12] can be represented through the *VComponent* meta-class, the *Age* factor with the *PComponent* meta-class, and the *Trip purpose* factor using the *KComponent* meta-class.

The first step to model the traffic theory is focused on elaborating a *modelling plan*. This describes an initial evaluation of the elements coming from the traffic theory to model that can match with the types of the metamodel. Once this task is completed, these elements are mapped to the selected types of the *Mental* and *Environmental* clusters (see Sections III-A and III-B) that fit properly with them. This planning produces a *starting schema* as a result. These guidelines are represented as a model using the graphical editor tool as follows.

Users start producing a simple structure that contains only the needed instances from the root meta-classes of the metamodel to represent the concepts of the theory (i.e. the starting schema). In this case, the *FPerson* class (an instance of the *Person* meta-class) is the root of the model design. The other classes are related to it using their appropriate references, e.g. connecting the *FEnvironment* class (an instance of the *Environment* meta-class) and the *FKnowledge* class (an instance of the *Knowledge* meta-class) to the *FPerson* class.

The previous structure is the basis to integrate the rest of the theory. After creating it, users add the elements of the TML that represent the other factors considered in [12], and link them with the relevant main elements following the *modelling plan*. The *FProfile* class acts as a root of its own tree substructure, being decomposed into two *PComponent* children. They represent *Individual Differences* and *Individual* factors from the theory. Each one of them is in turn decomposed into several children (e.g. *Individual Differences* into *Age* and *Gender*; and *Individual* into *Impairment* and *Hurry/Distraction*). The *FKnowledge* class is decomposed into two *KComponent* children (i.e. *Trip purpose* and *Length of drive*). The *FVehicle* class is decomposed into two *VComponent* children (i.e. *Size* and *Performance Characteristics*). Finally, the *FEnvironment* class is decomposed into four *EComponent* children (e.g. *Weather* and *Road condition*). This completes the adaptation of the original model to the TML (see Fig. 5).

Once the model specification based on the *Mental* and *Environmental* clusters is completed, the next step is designing the elements of the *Interactive cluster*. This can be done with the graphical editor tool adding the elements previously defined, or with the graphical editor integrated in the code generator tool. In order to show how models can be reused, the second option is chosen, developing a self-contained model specification.

A self-contained specification is an independent model that comprises only elements of the *Interactive cluster* and *GeneralRelationship* instances. These components can be developed according to the requirements of a particular simulation platform, promoting their specialisation. The resulting model can be merged with other models based on the *Mental* and the *Environmental* clusters, which facilitates the integration of multiple traffic theories with the target platform.

In this case, the self-contained model takes as basis the approach presented in [23]. It provides a *Goal* and *Task* tree structure with *AND* and *OR* compositions. That comes from agent-based methodologies and the BDI model [6]. This tree structure presents tasks associated with most of the goals. These tasks achieve the actions of the individuals following a set of instructions.

The root goal called *ArrivedFastDestination* represents the basic goal of individuals involved in traffic. It is decomposed into two sub-goals that must be fulfilled (i.e. *AND* composition): *Actuated* and *EndedRoute*. In turn, the *Actuated* goal is decomposed into a set of alternative goals (i.e. *OR* composition) that represents the different actions individuals can choose while they are interacting in road traffic (see Fig. 6). These goals are decomposed into the alternatives to achieve them (e.g. the *SearchedObstacle* goal is decomposed into the *SearchedOnLeft* or *SearchedForward* sub-goals). When any of these goals that represent actions is satisfied, the *Actuated* goal is satisfied too. Meanwhile, the end of the route is

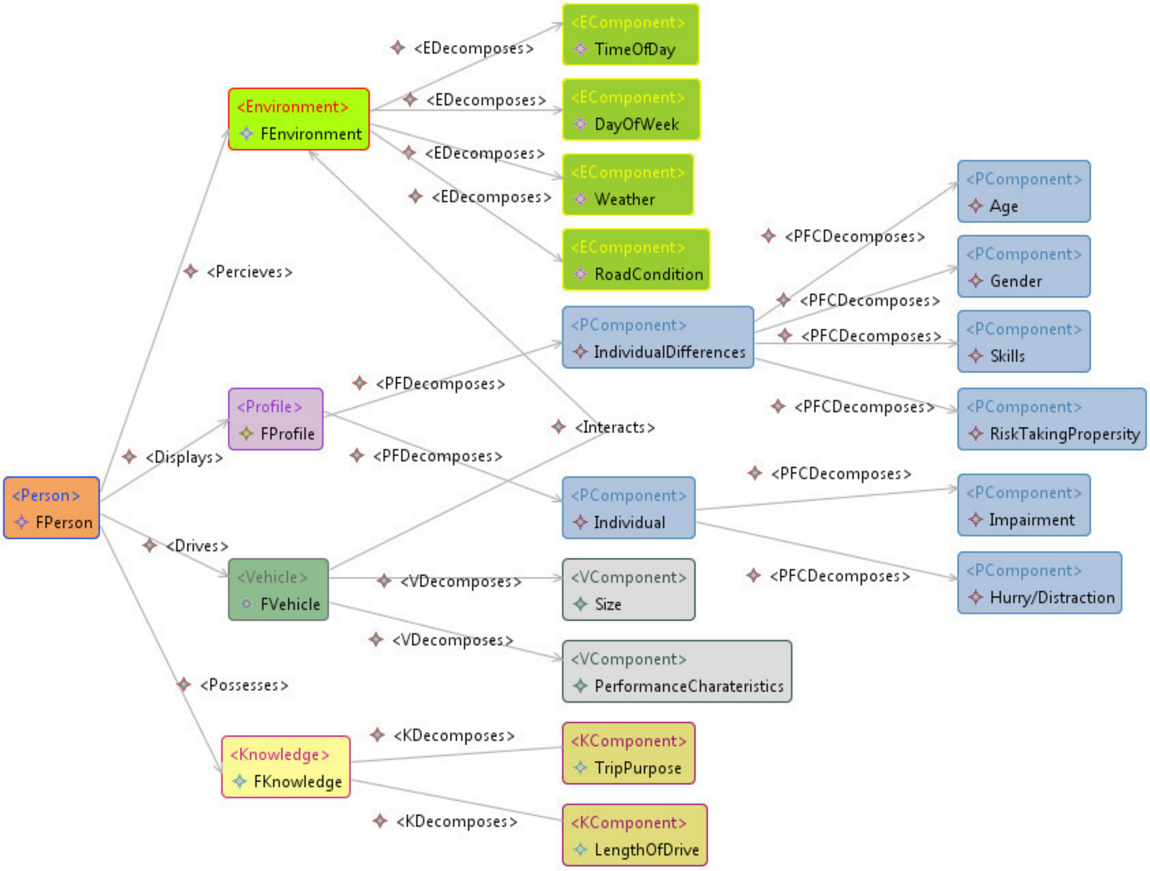

Fig. 5. Excerpt of the TML specification of the *Factors* model.

checked (*EndedRoute* goal satisfaction). If the *EndedRoute* goal is satisfied, then individuals have achieved their purpose, satisfying the *ArrivedFastDestination* root goal; if not, the process starts again. This sequence of actions models the processes in real-life, and assumes that at least one action must be done to reach the root goal.

In this self-contained model specification, *Goal* and *Task* instances present their own attributes and methods to manage these type of compositions. In *Goal* instances, the *GType* attribute indicates the type of goal composition (i.e. *AND* or *OR*). Code snippets are inserted into the body of the *calculateSatisfaction* method. These code snippets check if the sub-goal elements are satisfied. In *Task* instances, the *TType* attribute indicates the type of task composition (i.e. *AND* or *OR*), while code snippets complete the body of the *setInstructions* method. These code snippets validate if the associated sub-tasks and the atomic instructions are achieved successfully.

The *Interactive cluster* of the metamodel provides the means to model a *perceive-reason-act* cycle [11] of people. It uses the *Evaluator* and *Actuator* meta-classes based on [23].

In this case, *Evaluators* have a hierarchical decomposition that follows the goal tree. The root *Goal ArrivedFastDestination* is considered only by the *EvaluateDestination Evaluator* instance, the *EndedRoute Goal* is checked only by the *EvaluateRoute Evaluator* instance, and the *Actuated Goal* and the rest of *Goals* related to actions are controlled by the *EvaluateActions Evaluator* instance. This last *Evaluator* is in charge of selecting the best *Goal*. It considers the input parameters provided by both the *Mental* and the *Environmental* cluster, or the other two *Evaluator* instances. It also evaluates if the satisfaction of the selected *Goal* is produced in order to check if its parent *Goal* instances can be satisfied.

Once the structure in charge of evaluating the goals is completed, an *Actuator* instance is added to the self-contained model specification. It considers every task, executing its instructions when the appropriate evaluator selects its associated goal.

After that, this part of the model specification must be stored using the corresponding wizard of the code generator tool to generate a compressed file. In turn, the model based on the *Mental* and *Environmental* clusters generated in the graphical editor is loaded as input by the code generator tool. Then, navigating through the elements of the model specification, code snippets can be inserted into the *setXValues* body method of each one of the elements with the purpose of redefining the

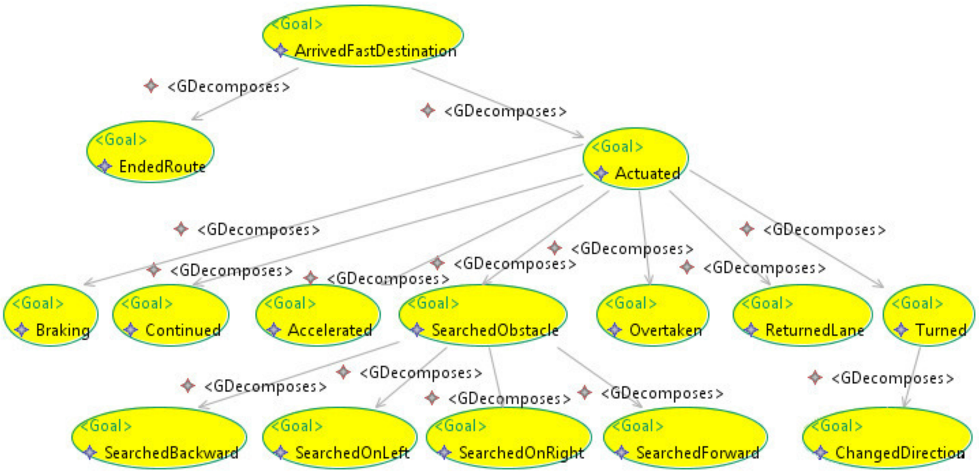

Fig. 6. Excerpt of the goal tree structure of the self-contained model specification.

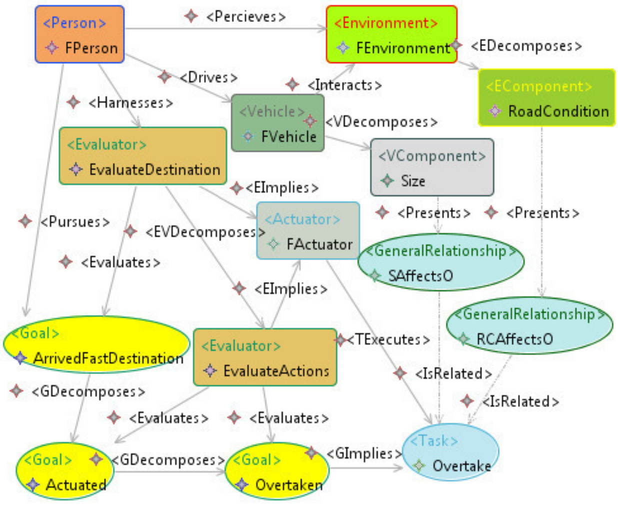

Fig. 7. Excerpt of the elements implicated in the overtaken interaction.

calculation procedure of the *XValue* attributes (see Section III). In this case, the code snippet applies a formula based on Fuzzy logic [24]. The value of an element is obtained adding every value of the children and its own value and dividing this result by its number of children plus one, establishing a relationship among the children components and the parent. This step can be changed to consider other formulas and theories.

This model based on the *Mental* and *Environmental* clusters can be stored using the appropriate code generator functionality. This allows reusing the fuzzy formula and the structure generated in other projects.

As soon as the fuzzy logic is inserted into the model, the wizard in charge of the cluster integration functionality can be selected to apply it. The wizard links the *FPerson* instance with the root *Goal* instance of the self-contained model specification (i.e. *ArrivedFastDestination*) through a *Pursues* reference. Then, the *FPerson* instance is linked to the *Evaluator* root instance (i.e *EvaluateDestination*) and vice versa using the references *Harnesses* and *IsHarnessed* respectively. Finally, the *Actuator* instance is connected to the *FPerson* instance by means of *Utilizes* reference. When the process is completed and every reference is established, both clusters become a single model specification.

The same wizard supports the integration of *GeneralRelationship* instances among both clusters of the single model specification. These *GeneralRelationship* instances indicate the influence of target elements over the *Task* instances associated with each *Goal* instance. These *GeneralRelationships* are considered by the appropriate *Evaluator* instance in order to select the best candidate *Goal*. It evaluates the *Xvalues* attributes (previously configured using Fuzzy logic) of each related element of the *Mental* and *Environmental* clusters in order to generate real-time decisions.

Here, the addition of *GeneralRelationship* instances follows the factors structure. *Environment* factors (i.e. *RoadCondition* or *TimeOfDay*) directly affect *Overtake* or *Brake* instances, establishing multiple *GeneralRelationship* instances among them (see example in Fig.7). *IndividualDifferences* factors (i.e. *Age* or *RiskTakingPropensity*) affect *Accelerate* or *ReturnLane Task* instances. *Individual* factors (i.e. *Impairment* or *Hurry/Distraction*) affect *SearchObstacle* or *Accelerate Task* instances. *Vehicle* factors (i.e. *Size* or *PerformanceCharacteristics*) affect *Accelerate* or *Turn Task* instances. *Knowledge* factors (i.e. *TripPurpose* or *LengthOfDrive*) affect *Overtake* or *SearchObstacle Task* instances.

When the integration of these *GeneralRelationship* instances is completed, all these concepts and other possible evaluation criteria must be considered by the *Evaluator* instances. For this, the appropriate code snippets must be inserted into the body of the *evaluateGoals* method.

In order to illustrate how the code generator tool generates specific source code for a target platform, this case study considers MATSim. This agent platform presents different functionalities, but it only supports route configuration and optimisation using a path to follow (i.e. the interactions of individuals are not considered). It is made available to the code generator tool as an external compressed file, adding all its libraries and dependencies to the compiler.

The integration requires developing and adding a new class using the related wizard. This class is in charge of merging the model specification and the platform by establishing communications between them through programming procedures (i.e. the model specification is encapsulated being able to be integrated as a class in the MATSim source code).

Some classes of the MATSim platform need to be extended in order to consider the model specification structure. The original classes only plan the route, and now they must also consider, for instance, overtaking or lane changes. The new classes are integrated into the project, being considered by the compiler of the code generator.

The *Instructions* attribute of *Task* instances must be adapted and redefined to the way of functioning and the source code provided by MATSim. This allows generating the proper platform-specific actions to get the intended behaviour.

Once the specialisation is achieved, a configuration file is generated through the corresponding wizard of the code generator tool. The initial parameters of the *XValues* attributes are defined. These parameters can be modified with the purpose of obtaining different influences of elements. Also, another class is developed in the code generator and integrated into the path of its compiler in order to load this configuration file when the road traffic simulation starts.

Finally, the code generator tool produces a compressed file. It directly runs the MATSim platform with the embedded model specification generated and integrating the configuration file.

## VI. Related work

Road traffic simulation is related to multiple areas of research. The presented approach considers the modelling of people's behaviour and environmental features affecting traffic, and the development process of simulations.

Existing road traffic simulation platforms are mainly based on multiple drivers that follow paths, though some of them allow random behaviours. The differentiation of their features, the decision-making and the interaction among them or with the environment are considered only in limited ways [13], [25].

Pedestrians and the influence of people around (e.g. passengers) over drivers are also important elements to evaluate, but frequently disregarded. For instance, [26] can model pedestrian interacting with the environment and drivers, but passengers and their possible impact are not contemplated.

The proposed metamodel considers the different roles of the individuals involved in traffic (i.e. drivers, pedestrians and passengers). It corresponds to microscopic models, as it models the multiple individual artefacts involved in road traffic (e.g. instances of *Person* and *Vehicle*). Although not fully considered now, mesoscopic models (i.e. those combining the individual and group levels), could also be integrated in the ML. The ABM approach adopted in the ML facilitates this extension, as it is frequently adopted for such kind of models [27]. The metamodel structure improves existing approaches in order to embody multiple social features. Most of approaches consider a fixed set of these features and their relationships, e.g. [9]. *Knowledge* instances are designed to be specialised and combined, providing instruments to add facts that affect groups of entities or the overall simulation.

Regarding the internal modelling of individual participants involved in traffic, there is not a widely accepted approach. Models range from simple, mainly reactive ones, to quite complex, usually deliberative. For instance, in [28] agents use simple logical rules to interact with the environment. This environment is mainly composed of crossroads where agents react to the behaviour of others. A more complex approach appears in [29], where driver's actions are decomposed into workflows considering the multiple situations that can occur during their execution.

The decisions achieved by agents in the previous approaches can be combined in hierarchical architectures, where there are several abstraction layers that organize acting. An example of this is the Michon's hierarchical control model for drivers [30]. The metamodel supports the hierarchical composition of most of its elements, but not the definition of abstraction layers as required by hierarchical architectures.

Another point of discussion in literature is related to which of the features of participants and the environment have influence on road traffic. Approaches such as [31], [32] review some of these features. The metamodel is intentionally open in this aspect. Meta-classes such as *Vehicle* and *Environment* in the *Environmental cluster*, and *Knowledge* and *Profile* in the *Mental cluster*, present sub-components to classify other related elements or characteristics. The metamodel also allows introducing additional concepts (i.e. through the *GeneralElement* meta-class) and relationships (i.e. through the *GeneralRelationship* meta-class), and extending them using the different inheritance hierarchies. These aspects entail that the TML is highly customisable for the multiple requirements of the road traffic domain.

Regarding the development process, most of reviewed works do not cite the approach they follow. Those that do it, in general assume common development processes focused on source code, where models play only a documentation and communication role. The advantages of MDE in this scenario have been already discussed in the related literature [33]: explicit representation of the information, higher involvement of experts, enhanced model validation, and reusability.

## VII. Conclusions

This paper has presented a metamodel that defines a TML to support a MDE approach for the development of road traffic simulations. It defines this extensible ML focused on the behaviour of individuals. Development tools compliant with the metamodel are provided to support the process. The adoption of MDE facilitates the exchange of information among groups of experts with different backgrounds. It also promotes the reutilisation of artefacts between projects, as there is a clear separation of concerns and all the information is explicit. For instance, this facilitates deployments in multiple platforms. It also encourages the incremental development, as models and transformations can be more easily modified than code.

The metamodel is designed with the purpose of being able to integrate multiple theoretical works from the domain. It follows an ABM [8] approach in order to consider the social interactions of the individuals involved in road traffic. It has three main clusters: a *Mental cluster*, an *Environmental cluster*, and an *Interactive cluster*. The first one includes the different psychological attributes that can influence the behaviour of individuals [4]. These concepts are classified into two groups: the features of people and their current state. It considers aspects of the mental state in the agent paradigm [5], particularly the BDI model [6]. The second cluster is based on the DVE approach [7] for modelling the different interactions of the individuals involved in road traffic, considering the relationships among vehicles, environment, and people. Many of the existing studies can fit their concepts into this structure, as it includes widely accepted notions to describe traffic settings. The last cluster uses concepts like goal and task. A *perceive-reason-act* cycle [11] is integrated through the evaluator and actuator concepts.

The meta-classes of the metamodel are designed to support internal hierarchical substructures, e.g. the container *Profile* meta-class and its sub-components with the *PComponent* meta-class. Inheritance between elements of the same type is introduced to make possible specialisations. Other types of relationships among elements are also considered.

Development tools are based on Eclipse facilities [17], [18]. The graphical editor provides a visual interface and a palette for describing the model specifications. These specifications can be validated to guarantee its compliance with the ML. The code generator provides a set of functionalities that guide users in the production of source code for a given target traffic simulation platform.

The case study exemplifies the use of the complete MDE infrastructure. The development tools support the design of a model specification according to a theory, its specialisation to the MATSim platform, and the generation of the source code associated. The MATSim platform presents a route optimisation feature to simulate individuals involved in traffic. This feature does not consider interactions among individuals and only generates a path to follow. Here, it is improved adding decision-making actions based on [23] through a goal-task hierarchical structure with *OR* and *AND* compositions. A tailored *perceive-reason-act* cycle [11] is integrated using the *Evaluator* and *Actuator* meta-classes. Also, the resulting model integrates a taxonomy related to the traffic domain based on the risk factors for drivers [12]. Individual actions are influenced by the related factors, producing different behaviours in individuals when those factors change.

The presented approach has several open issues. The TML must be tested with other types of road traffic theories (e.g. interactions among drivers and pedestrians) in order to check its primitives and structure. The development tools must also be used to generate source code specialisations for other traffic agent platforms (e.g. SUMO [25] or VISSIM [26]). The introduction of social norms, the influence of traffic signals (e.g. crossings or traffic lights) and the types of vehicles (e.g. ambulances or motorbikes) could be considered.

## ACKNOWLEDGMENT

This work has been done in the context of the project "Social Ambient Assisting Living - Methods (SociAAL)" (grant TIN2011-28335-C02-01) supported by the Spanish Ministry for Economy and Competitiveness, and the research programme MOSI-AGIL-CM (grant S2013/ICE-3019) supported by the Autonomous Region of Madrid and co-funded by EU Structural Funds FSE and FEDER.

***Abstract*—This paper presents a flexible agent decision model for the simulation of indoor scenarios. There are different kind of applications with varying requirements, from the typical emergency evacuation where the physical interaction of crowds of agents are more relevant, to those that demand more sophisticated agent decision models as when testing smart environment applications. Existing tools usually focus on one of these issues, looking for efficiency in the solutions.**

**The agent decision model in this paper tries to get a balance between efficiency and flexibility in the specification of the agent behavior in simple and complex situations. This is applied in a simulation framework for indoor scenarios, although it could be extended to other settings.**

## I. Introduction

TESTING APPLICATIONS for smart environments is a difficult task. It requires the installation of sensors and actuators, the communications and the software for the control system, and the participation of persons who have to play the different scenarios. This is costly, both in economic sense as well as in time. Also, there are some situations that cannot be tested for practical reasons (e.g., a fire, people accidents). Furthermore, from the point of view of the developers, who are used to iterative processes, it is difficult to repeat the tests if they have to perform these with persons. At least for these reasons it is interesting to use simulation tools that provide some support for the development of smart environment applications.

A relevant aspect to be considered in this kind of tests is the modelling of the behavior of humans under different situations. The behavior for these scenarios requires at least the following: interactions among agents, with the environment, and the process for decision making.

There are several tools for simulation and design of how people behave in indoor scenarios (some of them commercial) [1]–[6]. They focus on the design of spaces and 3D appearance, where the agents are seen more like a crowd that can be characterized by simple behaviors with a fixed number of parameters, instead of considering them as individuals. Although they are appropriate to simulate specific scenarios, it is important to consider the human and social behavior of individuals when simulating how people interact with their environment, including other individuals.

Other works have better addressed the specification of the agent behavior, such as [7]–[13]. However, they have not sufficiently taken into account the methodological aspects for a design process when developing the agents' behavior. This is relevant when the simulation framework has to be used for different purposes and by other developers. In those cases, there is a need for a clearer agent model, with some support for the design at a higher level of abstraction that can be easily translated to an implementation. This is the purpose of MASSIS (**M**ulti-**A**gent **S**ystem **S**imulation of **I**ndoor **S**cenarios), a framework for modelling and simulation of the decision-making process of agents in multiple situations in indoor scenarios domain.

The rest of the paper is structured as follows. Section II describes the MASSIS framework. Section III explains how is modelled the agent's behavior. Section IV shows a case study to illustrate the approach. Finally, Section V presents our conclusions.

## II. The MASSIS framework

MASSIS is an agent-based simulation framework for indoor scenarios. It has a component-based architecture, built on open-source software components. An overview of the framework is shown in Figure 1.

Graphical modelling of the indoor environment is supported by SweetHome3D [14]. This is a well known package that is used to model all components involved in the simulation environment, such as walls, doors, stairs, people, etc. (see Fig. 2). Sweet Home 3D allows to design buildings with enough realism, in a relatively short time. It also allows the integration of extensions, providing significant flexibility when adding new features. MASSIS adds a set of plugins for this application, which lets the user to specify the characteristics of the elements of the building that will act as agents. In the case of people, can be weight, speed, inherent characteristics of the person (fear, courage, etc.) and link to their behavior. It is also possible to specify elements of the environment, such as sensors and actuators, which will have a reactive behavior.

When the building is created, the SweetHome3D representation of the building is transformed inside the simulation engine, which adapts it to the internal representation of MASSIS. One of the important issues when modeling

This work has been developed in the context of the project MOSI-AGIL-CM (with grant S2013/ICE-3019, by the Directorate General for Universities and Research of CAM) and by the Programa de Financiación de Grupos de Investigación UCM-Banco Santander with reference GR3/14.

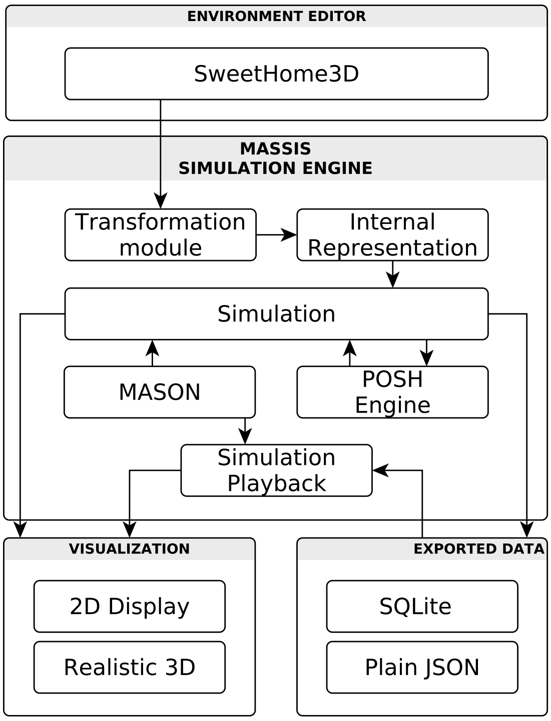

Fig. 1. MASSIS framework overview

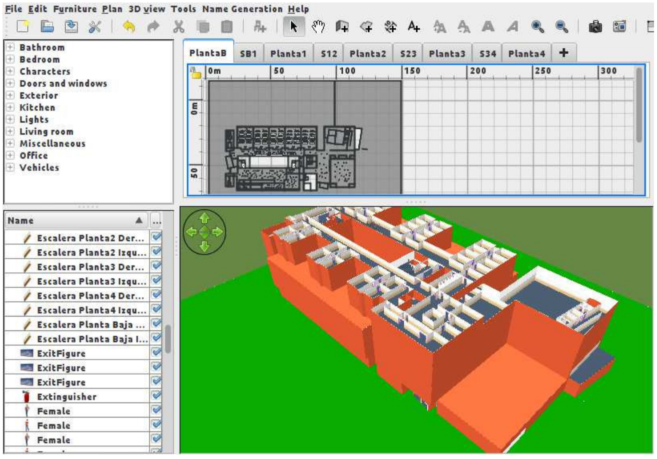

Fig. 2. Screenshot of the MASSIS's 3D editor, based on SweetHome3D.

indoor scenarios is the accuracy of the representation. Inside a building it is very common to have various elements at very small distances. If the elements of space are assigned to cells, the accuracy is reduced considerably. To solve this problem, MASSIS represents the elements in the building without discretizing the space; each element is represented as a polygon. For efficient computation of the locations of agents, data structures appropriate to this representation are used, such as different models of quadtree and polygon meshes. These data structures are used both for locating agents, perception and pathfinding.

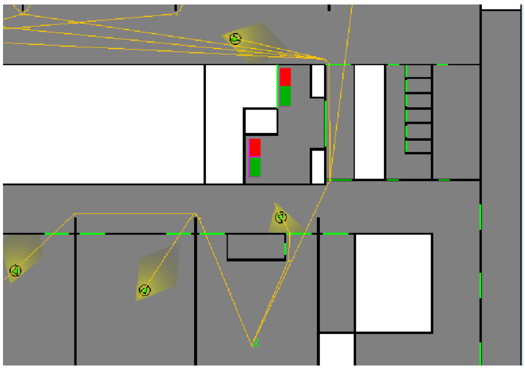

Fig. 3. Standard schematic display of MASSIS, showing bodies radio, vision areas and paths (*black circles green arrows*, *yellow polygons* and *yellow lines*, respectively). The green lines are doors, and the red and green squares are stairs.

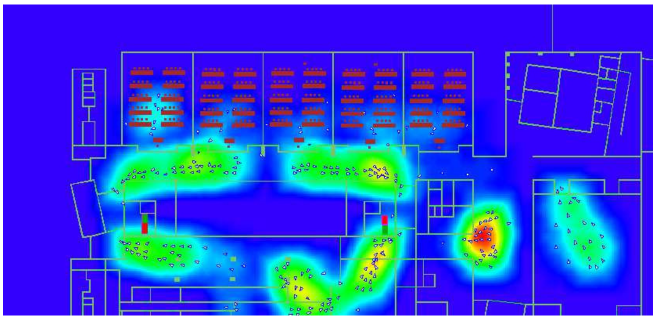

Fig. 4. Example of an user-defined schematic display: crowd density.

As simulation engine, MASSIS uses MASON [15], a lightweight multi-purpose agent-based simulation library. MASON has been chosen because it provides a good support for agent-based simulation platform, with well proven efficiency. Also, the clear separation of the simulation core and the GUI, allows MASSIS to use the MASON simulation core, while using its own display system.

The agents' behavior is controlled with the Pogamut's [16] POSH engine. (See Section III for more details)

All the changes made in the environment are reflected in real time by MASSIS' 3D (Fig. 9) and 2D (Fig. 3) displays, and can be logged in JSON format (Listing. 1), as a single zipped file or in a SQLite database for further analysis. Although 3D display is more realistic, the 2D view is useful for analysis and debugging. Also, the 2D visualization API allows the creation of user-defined layers (Fig. 4).

Once a simulation is performed, the exported data can be used to playback all events that have occurred during the execution of the simulation, i.e., the agents will behave in the same way they did during the simulation.

## III. Agent Decision Model in MASSIS

The aspects of human behavior that are of interest for modelling indoor scenarios in the MASSIS framework are the mechanisms that humans use to deal with problems reasoning

from context, making use of collective intelligence, and how this intelligence is used in problem solving.

Each agent in MASSIS has its own behavior, which is computed at a high-level (reactive plans) and at a low level (speed, position, angles, density, etc.)

When the high level decides *what to do next*, the action is executed by the low-level module, which carries all the necessary operations (movement, animation, etc.) Both high-level and low-level behaviors are affected by the state of the agent, altering the decision making process (e.g., a *scared* agent may choose a different route to reach a target, probably a longer one) and the action execution (it will be moving faster).

### A. Low-level behavior

The low-level module deals with the perception of the environment and a set of basic behaviors for interacting with it. These behaviors are mostly a set of *steering behaviors* [17], which control the most basic movement component of the agent.

Using a simple force model, steering behaviors produce smooth, life-like movements, providing agents the ability to navigate around the environment in a realistic manner. The forces applied to the agent can be combined in order to create more complex behaviors (e.g. collision avoidance, path-following, leader following, queuing, etc.). Fig. 5 shows the forces present in the basic *Seek and Flee* behavior.

Steering
Path following, alignment, queuing, separation, collision avoidance...
Locomotion
Motion

Fig. 6. MASSIS 's human behavior agent model.

### B. High-level behavior

The high-level behavior deals with decision making, learning and communications with other agents and makes decisions based on the knowledge of the environment, which is provided by the low-level module.

The architecture of this behavior follows the BOD (Behavior Oriented Design) method [18]. This method for building agents combines the advantages of Behavior Based AI [19], [20] and object-oriented design approaches.

In MASSIS this is applied to facilitate the design of agents that are capable of running in parallel and of generating a behavior that can satisfy multiple objectives that may conflict with each other.

The difficulty of making an autonomous agent is that many of the goals that the agent wants to be accomplished must be carried out at the same time. An agent may have the desire to be loved, be promoted at work and having breakfast in the morning.

Additionally, these goals must be achieved in an unpredictable environment, which can complicate or even make easier the way in which the agent tries to accomplish its goals. Developing a system of agents under BOD involves dividing the implementation into two different parts:

1) A library of Behavior modules. They consist of a set of classes representing a set of modules for perception, action and learning. These are *primitives*, actions and senses that can be called from the mechanism of action selection. They also provide a place where certain states and knowledge can be stored in order to perform those actions, and they contain code that describes any sense that needs to be carried out to acquire that state and

```java
public ActionResult run() {
    boolean isInLoc;
    SimulationObject target=getTarget();
    Location tLoc=target.getLocation();
    isInLoc=agent.approachTo(tLoc);
    if (isInLoc) {
        return ActionResult.RUNNING_ONCE;
    }
    else {
        return ActionResult.FINISHED;
    }
}
```

Listing 2. Example of the primitive action *Go to target*

```
(C search-for-object
vars($type, $storeFlag="IS_NEAR_TARGET")
(elements
 ((has-target (trigger ((HasTarget))) approach
    ))
 ((is-object-visible
  (trigger ((SeesElement($attr=$type,$value=1)
      true ==)))
  setTarget($target="?LAST_SEEN_OBJ")))
((search ExploreAction)))
)
```

Listing 3. POSH code of parametrized competence *search-for-object*. *ExploreAction* is a primitive action, *approach* is a competence and words preceded by *$* are variables.

knowledge. In brief, they determine *how* to do something. These senses and actions are created in the native language for the problem space (in the case of MASSIS, Java; see for instance the code in the listing 2)

2) POSH Dynamic action selection scripts. These allow to determine priorities between modules. The BOD architecture uses a POSH dynamic plan when an action should be carried out.
A POSH(Parallel-rooted, Ordered Slip-stack Hierarchical) plan is a prioritized set of conditions and the related actions to be performed when the conditions have been met.
It consists of drive collections, competences, and action patterns.
    - Drive collections are the root of every POSH plan. On the action selection step, the drive collections select which goal the agent must try to accomplish. They can be seen as a set of conditional rules, that are evaluated from highest to lowest priority.
    Every time the condition of the drive collection with highest priority is satisfied (a higher rule interrupts a lower one), the POSH engine executes the corresponding action pattern or competence.
    - Competences are a set of nested if-then conditional trees, which can be reused several times inside the reactive plan. They differ from the drive collections in the way they are executed; rules they do not interrupt each other.

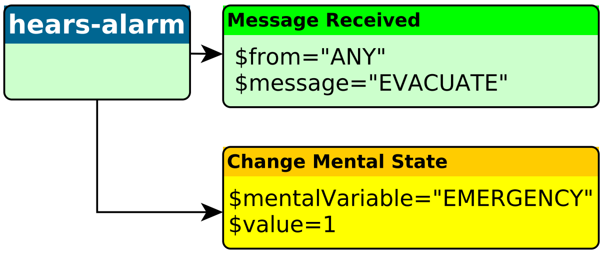

Fig. 7. *Mental state* modification in a POSH plan (*yellow*), triggered by the sense "Message Received" (*green*) on the Drive Element "hears-alarm"(*blue*)

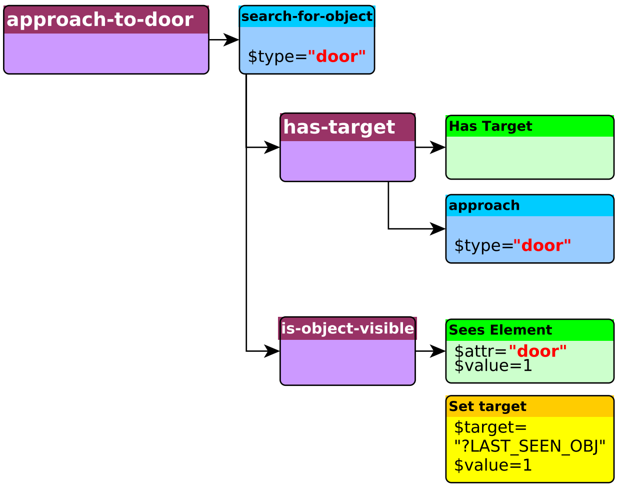

Fig. 8. Propagation of the value "door" in the parametrized competence of searching an object. **Note**: Some elements were omitted for clarity.

    - Action Patterns are simple sequences of actions. Although they are not very flexible, they provide a layer of abstraction very useful when grouping actions.

MASSIS encourages the use of variables and the agent's *Mental State* in POSH plans. *Mental States* are intended for representing the knowledge of the agent about its environment as a set of key-value pairs, but can be used for any other purpose, such as storing control variables in order manage the plan execution (see Fig. 7).

Also, as MASSIS uses the Pogamut's extension of the POSH language, *actions*, *senses*, *action patterns* and *competences* can be parametrized. This provides considerable flexibility, allowing the reuse of elements in the reactive plans (see Fig. 8 and Listing 3).

## IV. Case study: Emergency simulation

Public buildings have some protocols for dealing with emergency situations, which may involve, for instance, evacuation of the building. Testing these protocols requires some planning and cost. Simulation can help to this task. This case study addresses this kind of situation for the building of the Facultad de Informática at UCM. In this scenario, a teacher is responsible for guiding students safely to the building's exit in case of emergency. For illustrating purposes, this is the protocol for a teacher in an emergency situation:

> *When the alarm sounds the teacher of the group should go to the classroom door and order the students to close the windows if there is a fire. If instead of a fire there is a bomb threat, windows and doors should be left open. Students will leave the classroom through the door and they will be waiting for the teacher outside. The teacher will be the last person to leave the classroom. Once there is nobody in the classroom, the teacher will place a chair at the entrance of it,as an indication that the room has been evacuated entirely. Then the teacher will guide students toward the nearest exit.*

Modelling the teacher agent involves the following basic skills:

- Hearing and vision capabilities.
- Ability to communicate with other agents by voice.
- Movement.
- Interaction with objects in the environment: Taking an object, carrying it , dropping it.

These skills are candidates to be *primitive* actions and senses. These primitives, such as the movement one (Listing 2), are used by the reactive plan as *Triggers* of *Drive Elements*, components of *Action Patterns*, or they form part of one or more *Competences*. Figure 10 shows part of the teacher's reactive plan. Figures 9 and 11 show the initial state of the simulation. When the alarm sounds, and the teacher goes to the door (using *go-to-nearest-door* competence). Figure  12 illustrates the moment when the teacher tells the students that they must close the windows (*act-windows* competence). When the windows are closed, and the students outside (Fig. 13), the teacher takes the first chair he sees and he moves it to the

door. After that, the teacher guides his students to the nearest exit (cf. Fig. 14).

## V. Conclusion and Future Work

This paper has presented MASSIS, a multiagent-based simulation framework that supports the decision making process of humans when solving problems. Agent behavior is structured in low-level and high-level behavior components, extending Pogamut's POSH implementation model, with the addition of features that facilitate the separation of decision-making process and low level actions. MASSIS provides a rich set of low-level behavior components for the simulation of indoor scenarios. This has required to MASSIS the extension of the SweetHome3D environment with plugins for linking agent's behavior in the simulation. In order to apply MASSIS to other kind of scenarios (e.g., a city), new low-level behavior components should be implemented and integrated with another graphical design package that supports the definition of the new environment. In this sense, MASSIS can be easily extended. MASSIS provides as well a rich log capability, which can be the basis for further analysis of the scenarios. The integration of existing analysis tools is one of the most relevant issues for the next version ofthis framework.

## Acknowledgment

A special thanks to P.R. Hijas for her comments that greatly improved the development of the MASSIS' framework.

# Simulation as a Service: A Design Approach for large-scale Energy Network Simulations

Thomas Preisler, Tim Dethlefs and Wolfgang Renz
Faculty of Engineering and Computer Science,
Hamburg University of Applied Sciences,
Berliner Tor 7, 20099 Hamburg, Germany
Email: {thomas.preisler,tim.dethlefs,wolfgang.renz}@haw-hamburg.de

*Abstract*—**In the ongoing GEWISS project it is planned to implement a geographical heat information and simulation system. It shall provide a planning and simulation tool for the interlinking of urban development and district heating network development to support the political decision making process in the City of Hamburg. The system shall combine macroscopic and microscopic simulations to a co-simulation system. The simulation as a service approach is presented as a loosely-coupled scalable solution to realize large-scale energy network simulations. It is based on cloud computing technologies for the optimal utilization of computing resources in heterogeneous simulation-infrastructures. This approach can be used to realize simulation systems integrating Multi-Agent System (MAS) based simulations and other simulation technologies. For practical evaluation, two implementation approaches based on a MAS platform as a service-oriented solution will be presented and compared to an approach involving standard web-service technologies.**

## I. Introduction

SIMULATIONS take a significant stake in finding intelligent solutions and concepts for future Smart Energy Networks. They are vital to test the suitability of such concepts and solutions and therefore, needed before an actual realization can take place. This regards today's energy grid that undergoes a structural change towards the so-called *Smart Grid* as well as other energy networks as e.g., *heat supply systems*. Besides the realization of control and coordination strategies for the Smart Grid, the uniformed planning of both urban development and energy network development is essential. The holistic contemplation of such a *Smart City* requires the combination of different simulation concepts. Regardless of the domain, it is essential to test operational concepts with respect to their cost effectiveness and to optimize them if necessary [1], [2]. Contrasting to the test of operational concepts, which often requires fine-granular simulations with consideration of microscopic aspects, in terms of planning questions for urban and energy network development macroscopic simulations are of concerns.

The *simulation as a service* approach presented in this paper is related to the *GEWISS* project [3]. The goal of this project is to develop a geographical information and simulation system in order to support the political decision making in terms of an interlinking between urban development and district heating network development. It shall combine macroscopic modeling approaches from urban development regarding the evolution of building structures in a quarter, with microscopic simulations of the heat energy demand of buildings respectively building blocks. A multi-agent based co-simulation system is envisioned, where the microscopic behavior of single buildings or building blocks will be modeled as agents and the selection of appropriate sub-simulations will be mapped to agent-based goal deliberation. The latter will not be part of this paper. This paper focuses on presenting a possible approach to support large-scale co-simulations of macroscopic and microscopic simulation components, that can be rolled out to a heterogeneous IT-infrastructure. The goal of the proposed approach is to utilize cloud computing technologies and service-oriented design concepts in order to build loosely-coupled simulation systems, that integrate different simulation types and models in a service-oriented fashion. Cloud computing technologies and approaches should be used to form a private cloud on heterogeneous university IT-infrastructure, consisting out of different types of servers, in order to utilize the available computation resource optimally and to integrate slow but cheap computers like, e.g., *Raspberry Pi* single-board computer meaningfully.

The remainder of this paper is structured as follows. Section II describes current cloud computing infrastructures and related simulation frameworks and approaches as well as a related approach in the domain of modeling and simulating the heat energy demand of buildings. In Section III the GEWISS project will be described in more detail before the concept of simulation as a service will be described in Section IV. Section V describes and discusses possible implementation alternatives and challenges, followed by Section VI where the implementation alternatives will be evaluated in terms of their scalability. Finally, Section VII concludes the paper.

## II. Related Work

This Section introduces examples for state of the art cloud computing technologies, and describes related simulation approaches and frameworks, as well as related work in terms of the *GEWISS* Project.

### A. Cloud Computing Technologies

Cloud computing [4] is seen as a new approach to IT infrastructure management, facilitating a pay-as-to-go usage model. Computational resources are made available on a demand-driven basis instead of statically dedicated physical systems.

978-83-60810-66-8/$25.00©2015, IEEE

Therefore, the approach minimizes idle times and optimizes the utilization of resources, which leads to a minimization of resource dissipation. The authors of [5] bring forward the argument, that by adapting cloud computing ideas for optimal resource utilization, it is reasonable that existing computers in a company or university network could contribute their spare resources in a private cloud. This approach is picked up to propose the *simulation as a service* concept to realize large-scale simulations as required in the *GEWISS* project, that scale well and support optimal utilization of a heterogeneous IT-infrastructure. Cloud applications can be built on the *Infrastructure as a Service* (IaaS) or the *Platform as a Service* (PaaS) layer. On the IaaS layer, access to the cloud is granted by virtual machines that allow fine-grained control of the software stack and provide low-level aspects like operating systems. On the PaaS layer, a cloud operator establishes a new software layer with a dedicated middleware programming interface, and thus, lower level details are abstracted. PaaS facilitates the development of applications on top of the given platform, but restricts the types of applications to those which are supported by the platform. The *Software as a Service* (SaaS) layer are user-ready applications running in the cloud, which are typically built upon the IaaS or PaaS layer. There are many different approaches and technologies for the implementation and operation of cloud applications. This Section will focus on two different PaaS solutions and describe them exemplary. PaaS solutions are more suitable for the realization of simulations as a service than IaaS approaches, as they abstract from the operating system level and offer an Application Programming Interface (API) for the realization of scalable applications on top of a cloud infrastructure. The *Mesos* platform [6] offers a thin resource sharing layer, that enables fine-grained sharing across diverse cluster computing frameworks by providing a common interface for accessing cluster resources. *Mesos* focuses on providing shared commodity clusters between diverse cluster programming frameworks like *Hadoop* [7] or *MPI* [8] to improve cluster utilization. Resources are shared in *Mesos* to allow frameworks to achieve data locality by taking turns in reading data stored on each machine. It introduces a distributed two-level scheduling mechanism called *resource offers*. A resource offer encapsulates a bundle of resources that a framework can allocate on a cluster node to run tasks. *Mesos* decides how many resources it offers each framework, while the frameworks decide which resources they accept and which computations are executed. *Mesos* delegates the control over the scheduling to the frameworks. This decentralized scheduling model may not always result in globally optimal scheduling, but according to [6] it performs well in practice and allows the frameworks to meet goals such as data locality near perfectly. While *Mesos* focuses on resource-sharing in datacenters, *JadexCloud* [5] is a PaaS infrastructure to develop, deploy and manage distributed applications with a strong focus on distribution transparency. It is based on a Multi-Agent Systems (MAS) platform and allows to build cloud-based agent applications with service-oriented communication. The key concept is a three layered model, that helps separating responsibilities and managing complexity. A daemon layer provides a node infrastructure for managing cloud resources. It automatically detects and announces nodes joining and leaving the network. The platform layer on top supports application related management tasks including the automatic deployment of application artifacts on different nodes as well as starting and stopping of components. Finally, the application layer facilitates the application development by providing the API and tools for debugging. The current version of the provided PaaS infrastructure [9] supports the management of non-functional requirements. It allows to define non-functional properties for services that are monitored automatically, e.g., a wait-queue property that counts the request currently waiting to be answered. Based on this non-functional properties the service selection can be automated by defining non-functional requirements like, e.g., finding the service with the smallest wait-queue. Due to its focus on cloud-components offering services (agents), and the automatic deployment of application artifacts to dynamically joining and leaving network nodes, *JadexCloud* seems to be well suited to realize the simulation as a service approach.

### *B. Simulation and Modeling as a Service Approaches*

In [10] it is described how simulation software can be accessed as service (SimSaaS) in a service-oriented architecture (SOA) approach. It is stated that carrying out an experiment can be achieved by connecting multiple simulation services to form a work-flow which represents how the experiment proceeds. The authors of [10] state that simulation services differ from regular web services as concepts of time and state are essential, thus, viewing them as stateful services, that treat each service request as a series of dependent transactions that are related to the previous requests as well as the model's current state. Therefore, different communication and synchronization paradigms are described and assessed in terms of their suitability to interconnect stateful simulation services. The approach presented in this paper adopts the ideas from [10] by combining them to a design approach for large-scale energy network simulation with the extension that stateless simulation services may also be suitable for the realization and integration of small sub-simulation models. A survey about current trends and technologies in the field of modeling and simulation as a cloud service is given in [11]. It defines the term Modeling and Simulation as a Service (MSaaS) as a model for provisioning modeling and simulation (M&S) services on demand from a cloud service provider (CSP), that keeps the underlying infrastructure, platform, and software requirements and details hidden from the user. In this case the CSP is responsible for licenses, software upgrades, scaling the infrastructure, and providing grade of service and quality of service as specified in service level agreements. The SaaS model provides access to hosted applications in a cloud environment, allowing users to access services at low cost and scale as needed. This model was extended in [12] to include high-performance hosted simulation and modeling services. The described *Polymer Portal* is a first-generation simulation and modeling as a service (SMaaS) platform. Contrasting to the approach presented in this paper, where the simulation as a service approach is presented as a modeling approach to build distributed, scalable simulation systems, the approach presented in [12] focuses on ready to use simulation- and modeling-services that users can access for a fee.

### C. *Simulation Frameworks and Approaches*

There exist many different tools and frameworks that developers can use to built simulations upon. Some of these simulation frameworks focus on specific application domains and thus, support the developers by providing domain specific models and tools, while other frameworks focus on a broader application-domain independent scope and support simulations in general. While application-domain specific frameworks take some of the implementation work from the developer and often allow a faster implementation, they restrict developers in terms of implementational freedom and limit them, if their problem does not fit into the domain specific scope of the framework. Examples for domain specific simulation frameworks are, e.g., *Mosaik*, a flexible Smart Grid co-simulation framework [13] and *RinSim*, a simulator for logistics problems [14]. An example for a general simulation framework is the *Jadex* project [15]. When it comes to providing simulation functionality as a service there a two practicable ways. The first one is to implement the simulation using an application-domain dependent or independent simulation framework (or of course implementing it completely from scratch). In this case, the implemented simulation system will be considered as a black box with defined input and output parameters when it is encapsulated by a service component, that provides the simulation functionality as a service method. An example for this implementation scheme is given in [16] where 4GL Matlab simulation models are encapsulated by service components, to provide their functionality via REST (Representational State Transfer) web-services. The other implementational alternative is to implement the whole simulation with service-based technology. In this case it is possible to provide both, the macroscopic functionality of the simulation itself, as well as the microscopic functionality of single simulation components out of the box, without the need to encapsulate it first. An example for such a simulation system is given in [17], where a Multi-Agent based self-healing resource-flow system was built that used services to provide the functionality of the simulated robots. The standardization of simulation interoperability resulted in the *High Level Architecture* (HLA), an IEEE standard for modeling and simulation [18]. The HLA is a technical architecture developed to facilitate the reuse and interoperability of different simulation systems and assets. It provides a general framework, which can be used by developers to structure and describe their simulation systems and to interoperate them with other simulation systems. But due to its complexity it is hardly used outside the military domain [19].

### D. *Modeling Urban Energy and Heat Demand*

In terms of modeling the urban energy and heat demand the approach presented in [20] and [21] is related to the undertaking in the *GEWISS* project. Both projects aim at modeling the energy respectively heat demand of urban buildings and building structures. But while the *GEWISS* project will follow a Multi-Agent based simulation approach, modeling the building and building structures as microscopic agents the approach presented in [20] and [21] uses 3D city models to calculate the heat demand of whole district areas. It uses the OGC Standard *CityGML* [22], an open, multi-functional model that can be used for geospatial transactions, data storage, and database modeling, for the modeling of 3D buildings. Based on the surface of the 3D models of whole building blocks their energy and heat demand is calculated as a macroscopic approach.

## III. Introducing the GEWISS Project

The requirements for the simulation as a service approach are derived from the *GEWISS* project. In this project a geographical heat information and simulation system will be developed to support the analysis of heat demand and urban development for the City of Hamburg (Germany). The goal is the development of a simulation tool (framework) that supports the interlinking of urban development and district heat network development by providing a planning tool for different scenarios.

### A. *Project Description*

In order to utilize the potential of climate protection and to allocate available resource with high cost-effectiveness, the strategic heat planing must be interlinked with urban development projections (and vice versa). In this case, an abstraction of the spatial location of existing buildings is for obvious reasons not possible. Aspects such as the conversion of urban areas, infill, redevelopment or demolition as well as renovation of buildings or building groups should be tailored to the local available heat sources. Conversely, this means that the grid-based heat supply should be planned with respect to existing and future building stock. For this indentation it is necessary that data will be collected and analyzed with respect to spatial location. The combination of data and analysis to the heat demand and urban development should take place in a geographic information system (GIS). The goal of the *GEWISS* project is to extend such a GIS with geographic heat information and simulation capabilities in order to provide planning assistance for future developments.

Therefore, a framework should be develop that allows users to simulate the medium and long-term development of a heat supply system. Here, the specification of both external conditions (e.g., the development of energy prices) as well as municipal political measures (e.g., regulations or financial incentives for certain structural measures) should be supported and also the analysis of their effectiveness. The goal hereby is to explore business models as well as different urban development plans in a systematic fashion. This should help the City of Hamburg to find measures to achieve an optimal solution to match environmental protection objectives in the heating sector. From the overall project goal a set of scientific and technical working tasks are derived, which are relevant for the functional and non-functional requirements of the simulation and information system to be built:

- The strategic conception of heat planning and urban development should be integrated, so that energy and emission reductions can be implemented efficiently.
- All areas of a heating system (generation, transmission, storage and demand) should be considered through a participatory modeling and simulation approach that involves all relevant stakeholders.
- As a core, an agent-based simulation with visualization capabilities should be realized.

### B. Simulation Requirements

A series of functional and non-functional requirements unfolds from the mentioned project goals. For example, the design of the simulation entities must consider all areas of the heating system, taking into account production, transport, storage and demand. This means, that the simulation tool must be able to support large-scale simulations with more than 100,000 simulation entities (agents). The agents that are designed to model buildings or building blocks may be required to support a rule-based temporal evolution. The considerations of important stakeholders implies on the one hand influences on the design of simulation scenarios, but allows on the other hand the scenario-dependent modeling of rule-based descriptions for the automatic simulation through autonomous agents. The validation of these descriptions is to be ensured against separate micro-simulations. In order to fulfill this requirements a simulation tool that supports the realization of co-simulations based on a service-oriented middleware is envisioned. Co-simulation is a prominent method to solve multi-physic problems. Such simulations combine well-established and specialized simulation tools for different fields [23]. In the context of the *GEWISS* project a co-simulation is distinguished by a distributed simulation as well as a distributed modeling (defined by the usage of different modeling tools). A distributed simulation in this context is understood as the integration of multiple, self-contained simulations. Additional information about the strong impact of non-functional requirements on large-scale systems can be found in [24].

## IV. The Concept of Simulation as a Service

The concept of the simulation as a service approach derives from the simulation requirements of the *GEWISS* project. The goal is to use cloud computing ideas and technologies to built loosely-coupled large-scale simulation systems. By adapting the SaaS concept to the simulation domain, simulations will be provided as services in a cloud infrastructure. The conceptual architecture and approach is depicted in Fig. 1. The idea is that simulations will be contained within a Simulation Service Component. This component encapsulates the functionality of the simulation and provides a service interface to execute it in a service-oriented fashion. This approach unifies the invocation of different simulation types while also allowing the combination of different implementation models and programming languages. Fig. 1 exemplifies two different simulation types that can be combined and invoked in an unified way following this approach.

A common modeling technique in the engineering domain is the usage of fourth generation languages (4GL). These are programming languages focusing on rapid application development. The expression was coined by [25]. Recently, they have gained new attention through the introduction of model based software development [26]. Examples for 4GL are MATLAB, Simulink, Modelica, GAMS (General Algebraic Modeling System). These languages are used in many research projects for rapid prototyping as well as the realization of models or algorithms, e.g., for demand side management and the integration of regenerative energy resources into smart grids [27]. Although they reduce the overall development effort through the usage of comprehensible application-oriented paradigms, the integration of such 4GL models into large-scale simulations is a considerable challenge [16]. Encapsulating their functionality by a Service Simulation Component allows to execute them in an unified way, while also enabling their execution in a scalable cloud infrastructure.

The other depict simulation type is a MAS based simulation. They are well-known and widely spread [28]. Here, different types of agents are used to model the reality and to examine different problems. Such simulations exhibit different grades of complexity and inter-simulation dependencies. If a simple MAS based simulation that is executed on a single network node is considered, it can easily be encapsulated by a Simulation Service Component as a whole. This will provide an unified service-oriented way of invocation and control the execution and the life-cycle of the simulation as a whole. If a more complex, distributed MAS based simulation is considered, a possible integration approach is to encapsulate a dedicated starting component with a Simulation Service Component, which starts the distributed application and collects the results to return them.

Simulation Nodes

Fig. 1. Simulation as a Service Conceptual Architecture and Approach

Simulations that are encapsulated by a Simulation Service Component can either by called by clients directly if they require a specific simulation functionality, or more complex simulations can be composed out of multiple simulation services. In this case a simulation component can use the services offered by other simulation components, if they require the results provided by these simulation components as a sub-simulation. An example for this use-case is the realization of a mesoscopic co-simulation where a macroscopic simulation requires results from microscopic simulation components. This will be the case in the *GEWISS* project, were questions regarding the development of district heat networks shall be examined with regards to macroscopic simulations regarding urban development and microscopic simulations regarding the heat demand of households. If the composition of different simulation services is of concern, approaches like the Web Service Business Process Execution Languages (WS-BPEL) respectively the Business Process Model and Notation (BPMN) for the orchestration of web-services might be adoptable to the simulation domain.

Basically there are two main paradigms for the composition of simulation services. Fig. 2 depicts the hierarchical composition and execution of simulations as an UML sequence diagram. It illustrates the execution of a simulation $A$. During its execution, the simulation requests services of the sub-simulations $B$ and $C$, while sub-simulation $C$ requires the results from sub-simulation $D$ in order to answer the request from Simulation $A$. The hierarchical structure depict in Fig. 2 resembles the envisioned structure of the simulation system in the *GEWISS* project, where a main simulation (macroscopic) requires results from microscopic sub-simulations. Thereby, the sub-simulations are only active when their simulation services are called by the main simulation. The simulated time in this case can either be managed by the encapsulating root simulation and passed on to the sub-simulations or each sub-simulation can handle it's own time model, which allows to model interacting simulation with different time-scales (microscopic and macroscopic).

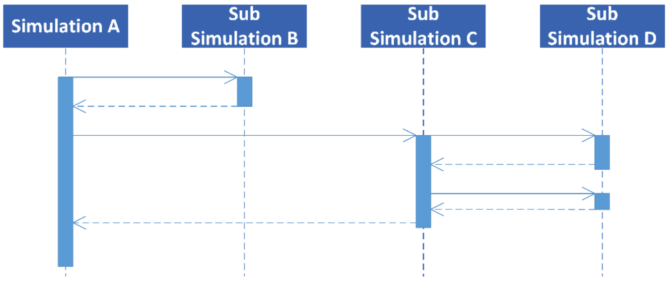

Fig. 2. UML sequence diagram: Hierarchical composition and execution of simulation services.

A different composition paradigm is depict in Fig. 3 where two simulations are executed parallel while exchanging data. This paradigm resemble the one described in [10] where it is stated that simulation services differ from web services as they have to be considered as stateful services, that treat each service request as a series of dependent transactions that are related to the previous requests as well as the model's current state. Regarding this composition paradigm of interlinked simulations it has to be ensured that their time model is synchronized, so that events are processed in a correct order.

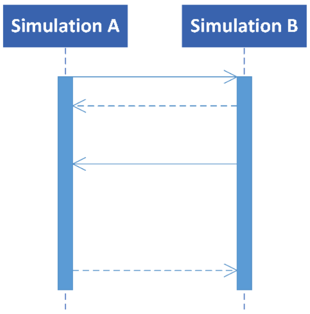

Fig. 3. UML sequence diagram: Parallel composition and execution of simulation services.

## V. Implementation Alternatives and Challenges

In general it is reasonable to facilitate established service-oriented technologies to provide simulations as a service. If distribution transparency, scalability and robustness properties should be adopted for the provided simulation services, it is reasonable to facilitate established cloud computing technologies as well. If the simulation is considered as a black box and not implemented with explicit cloud distribution in mind it might be more feasible to use the IaaS approach to abstract from the physical hardware in order to achieve the previous mentioned cloud computing properties. In this case the IaaS approach excels the PaaS approach, because the later one requires the application to be built on top of API of the according platform. Although it is also possible to encapsulate a black box simulation with a component regarding the API of the PaaS platform, but in this case the simulation does not profit from the distribution, scalability or robustness properties of the PaaS platform. So if an already existing simulation system should be provided as a cloud simulation service, a solution built upon a IaaS platform is advantageous. If the simulation is built from scratch or the simulation model is a simple one with a small footprint, it is beneficial to built it against the PaaS API respectively to encapsulate the simple model with a component that is built against the API.

The next Section will provide an evaluation of three different implementation alternatives and evaluate them in terms of their scalability. A case study was ventured, in order to show how a simulation as a service component could be built based on different technologies. A 4GL-model simulating the energy demand of a single household equipped with an electrical heater was used for this case study. In the following, the three implementation alternatives are described briefly before they are evaluated in the next Section.

**REST Webservices:** The first implementation follows the approach presented in [16] and encapsulated the 4GL-model with a REST web-service. In order to provide scalability, a load balancer was connected upstream to distribute the request based on a round-robin scheduling mechanism among multiple simulation nodes.

**Jadex NFP Service Selection:** The second implementation facilitated the approach for elastic component-based cloud applications presented in [9]. This approach introduces the concept of service selection based on non-functional properties. Again the 4GL-model is encapsulated by a service component. In this case the service is equipped with a non-functional property observer that observes the length of the wait queue of this service. If the simulation service is going to be requested by a client, a non-functional property evaluator evaluates the mentioned waiting queue size property and selects the best service (lowest number of waiting clients). Thus, an optimal distribution of client calls is achieved.

**JadexCloud Service Pool:** The third implementation uses the *JadexCloud* PaaS middleware [5]. Like other PaaS solutions it simplifies the construction of a cloud application by providing common base abstractions, tool sets and an API. The *JadexCloud* infrastructure has two main advantages for the development and deployment of distributed application. Any service offered by a component can be made available in a platform-controlled service pool. The utilization of the service pool deliberates the developer from starting and handling the life-cycle of the service-components himself. The service pool will start new service-components automatically if new resources are needed to handle incoming requests. Therefore, the service pool acts as a proxy handling all incoming service-requests and forwards them to service-components with free resources. The usage of the service pool, does not only simplifies the development of scalable services but also supports the dynamical deployment of service-components to remote platforms. If the service pool detects new *JadexCloud* platforms in the network range, it automatically deploys the governed service-components on this platforms and starts new instances on the remote platform, in case such are required to handle incoming service requests. So following this implementation scheme, the service component encapsulating the 4GL-model was equipped with a service pool to handle the automatic deployment on a cluster of *JadexCloud* nodes and to handle the life-cycle and load-balancing in order to achieve scalability.

## VI. Simulation and Evaluation of Implementation Alternatives

In order to evaluate the three proposed implementation alternatives in terms of their scalability three implementation prototypes were realized. Each of the three simulation setups will be described briefly before the results of the scalability analysis will be discussed. The simulation setup for the implementation based on REST web-services (1) is depicted in Fig. 4. Similar in all three setups is a client (a HTTP web-service client in this case) that places $n$ parallel requests. For this example, the 4GL-model simulating the energy demand of a single household is encapsulated by a REST web-service. The service is deployed to five homogeneous workstations running *Apache Tomcat 7*[1] as an application container. On one of these workstations the *Apache HTTP Server*[2] equipped with the *mod_jk*[3] Tomcat connector is used as a load-balancer. It uses a round-robin scheduling mechanism to distribute the calls to the simulation services in an equal way. For the purpose of testing the scalability and distribution properties only one service-component was deployed on each of the network nodes.

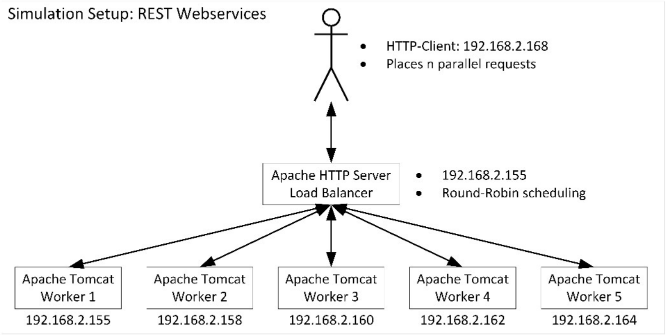

Fig. 4. Simulation Setup: REST Webservices.

The simulation setup for the service selection based on non-functional requirements (2) is depicted in Fig. 5. Again a client places $n$ parallel service calls. In this setup the simulation service encapsulating the 4GL-model is realized as a *Jadex* service and is equipped with a non-functional property monitor, that monitors the size of the service's wait-queue. For each of the service calls, the client queries the service monitors and uses a non-functional property evaluator to evaluate them with regards to quality criteria. The best service (lowest number of waiting requests) is selected and then called directly. Thereby, an optimal degree of capacity utilization is achieved as it is ensured that always the service with the lowest capacity utilization is ensured.

The simulation setup for the utilization of a service pool and the *JadexCloud* infrastructure (3) is depicted in Fig. 6. It uses the same client and simulation service component as described before, but contrasting to the previous described service selection based on non-functional properties, a global

[3] http://tomcat.apache.org/connectors-doc/ (accessed September 25, 2015)

service pool is used to act as a proxy between the actual services and the client. The service pool deploys the service code automatically to all five workstations and handles the execution of one service-component on each workstation. Due to comparability reasons with the two other setups, only one service-component was started on each of the *JadexCloud* platforms, although it is possible to configure the service pool accordingly to make use of more components. Comparable to the first simulation setup the service pool use a round-robin based scheduling mechanism to distribute the service requests equally to all pooled services. The service distribution is completely transparent for the clients, as they only interact with the proxy.

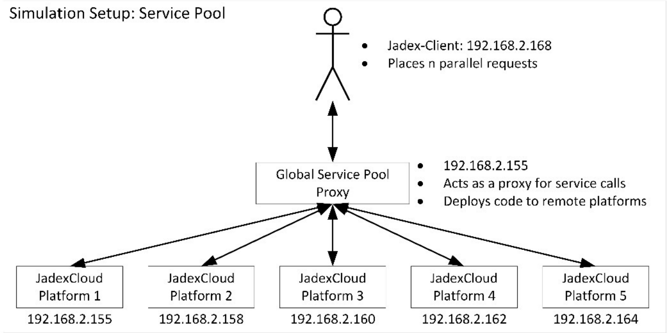

Fig. 6. Simulation Setup: Service Pool.

In order to analyze the scalability properties of the three presented implementation alternatives a number of experiments were conducted. The results of this analysis are shown in Fig. 7. The x-axis depicts the number of parallel calls on a logarithmic scale and the time in milliseconds it took to serve all the parallel requests is depicted on the y-axis (logarithmic scale as well). In order to dampen spikes for each number $n$ of parallel calls 10 experiments were ventured and the mean values were used for the evaluation. For $n = 10, 100, 1000$ parallel calls the three implementation alternatives perform quite similar and all three show a linear scalability. This behavior differs for $n = 10000$ parallel service requests. The implementation utilizing the non-functional property based service selection still scales linear. But both, the implementation using REST web-services and the *JadexCloud* service pool scale considerably worst. Therefore further experiments for these two implementations were conducted. As shown in the graph for $n = 2000, 3000, 4000$ parallel calls they still perform nearly linear. When the number of parallel calls reaches $n = 5000$ they lose this scalable behavior. We assume that this deviation between the three approaches is because the according load balancer (Apache HTTP Server or Jadex Service Pool) became saturated. If a large amount of parallel calls has to be processed by a load balancer it may become overloaded. Therefore, the load balancer itself could be the bottleneck of the system. This behavior differs from the service selection based on non-functional properties, as in this case the client itself evaluates the degree of capacity utilization of the offered services and selects the best. Therefore, the required distribution effort is shifted to the client. In order to further investigate this behavior, future work will analyze the scalability behavior of the three implementation alternatives on a System-on-a-Chip cluster. This cluster is characterized by a larger amount of machines with less computational power each in comparison to the workstation cluster used in this experiment. Thus, the scalability and load-balancing properties of the implementation alternatives will become more relevant.Also a combination of the non-functional property selection approach with the service pool approach is envisioned. Even if the scalability properties of the non-functional property selection approach excels the ones from the service pool approach, the dynamically deployment properties of the service pool approach are of great value, especially if an application is executed on dynamic infrastructure with joining and leaving network nodes. Therefore, a combination is envisioned where the default round-robing scheduling mechanism of the service pool is going to be replaced by one selecting the service based on non-functional properties like, e.g., the size of the wait-queue.

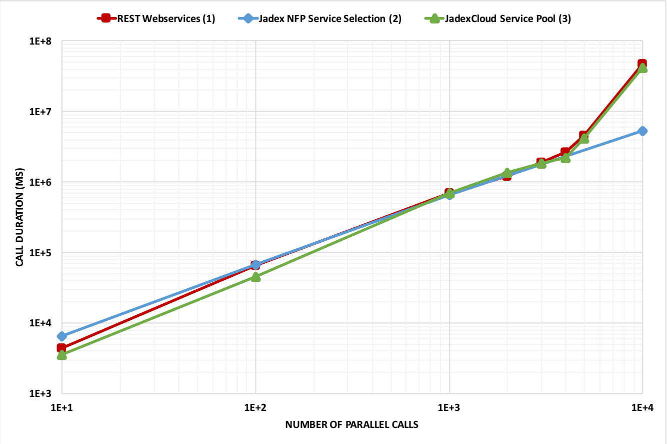

Fig. 7. Results of the Scalability Analysis.

## VII. Conclusion

In this paper we presented the concept of simulation as a service as a promising approach for the realization of large-scale smart-energy network simulations. It was described how the approach will be used to implement a geographical heat information and simulation system in the *GEWISS* project. The goal is to provide a planning and simulation tool for the interlinking of urban development and district heat network development in order to support the political decision making process in the City of Hamburg. The envisioned system will combine macroscopic and microscopic simulations to a co-simulation system. The simulation as a service approach was presented as loosely-coupled and scalable solution to realize a large-scale simulation system based on cloud computing technology in order to optimal utilize the computing resources of a heterogeneous university IT-infrastructure. Three different implementation alternatives were described and evaluated in terms of their scalability. The results encouraged the usage of the *Jadex* PaaS platform. A MAS platform that allows to built agent-based cloud application with service-oriented communication and supports the execution and deployment with service pools, service selection based on non-functional requirements and the automatic deployment of components (agents) and services to fluctuating network nodes.

## ACKNOWLEDGMENT

We would like to thank Lars Braubach and Alexander Pokahr for their input and support while implementing the simulation prototypes based on the *Jadex* platform, as well as our partners in the *GEWISS* project.

***Abstract*—A major challenge in swarm robotics is to minimize energy and time costs. We focus in this paper on multi-agent foraging algorithms that uses ant-like agents with limited energy. By considering energy consumption, we propose a new Energy aware Cooperative Switching Algorithm for Foraging (EC-SAF) that optimizes the whole system search and transport operations needed to collect resources over time. Unnecessary moves are avoided according to the following two premises: (1) Quick search and optimal paths provided by Stigmergic Multi-Ant Search Area (S-MASA) algorithm; (2) Quick homing provided by using the optimal paths created while searching. Results indicate that EC-SAF is promising in reducing swarm energy consumption compared to an energy-aware version of the c-marking algorithm (Ec-marking).**

## I. Introduction

SWARM robotics is concerned with the design of artificial robot swarms based upon the principles of swarm intelligence [1] [2] [3]. Promising solutions are expected by using numerous simple robots [4] [5] [6]. The collection carries out complex tasks based on simple rules, without spending much computational power and much physical energy [7]. Foraging robots are mobile robots that search for objects, and transport them to one or more storage points. It is a benchmark problem used in swarm robotics for several reasons: (1) It integrates several complex sub-tasks such as exploration, navigation, manipulation and transport; (2) It constitutes a canonical problem for the study of robot-robot cooperation; and (3) Many real-world applications are instances of foraging robots (like cleaning, harvesting, searching and rescuing) [8]. Foraging robots perform tasks that consumes energy, and must have a means of obtaining more energy to complete missions successfully. The most common strategies for powering long-lived autonomous robots are: (1) Capture ambient energy directly from the environment, also known as energy scavenging; or (2) Transfer energy from a recharging station [9]. Several options are possible in the last case: (1) Working robots perform their work until their energy falls below a given threshold. At this time, they return to recharging station, to recharge their energy [10] [11]; (2) Working robots can stay at the working site permanently, while special dock robots visit them periodically to provide them with energy [9] [12]; (3) Robots could transfer the energy also between them by comparing their energy's level [8]; and (4) Robots have to decide between search and transport, where transport can be applied to different resources. Even if resources are unknown at the beginning, as robots can be recruited by others, robots have sometimes to choose between carrying resources to the nest, carrying resources to another location in the field or searching for new resources, according to minimize the global energy consumption and maximize the global resources collected (that are equivalent to the accumulated energy) [13].

In this paper, we study the energy expenditure in the Cooperative Switching Algorithm for Foraging (C-SAF) [14] by addressing and analyzing two points:(1) What is the impact of collective exploitation of food provided by recruitment in C-SAF algorithm on energy consumption? (2) Does the division of search space (by using multiple sinks) in C-SAF improves energy efficiency? C-SAF robots are ant-like agents with limited computing and memory capacities. C-SAF provides quick search by using S-MASA algorithm [15] as search strategy, and quick exploitation by recruiting agents. Results are better than the standard reference algorithm and performances are emphasized with cooperation [16]. In this work, we propose to enhance foraging algorithms efficiency by taking energy into account. Individual energy and overall swarm energy are considered during resources location and exploitation.

The remainder of the paper is organized such as follows: in Section II we present the EC-SAF algorithm, its Finite State Machine (FSM) and a description of different states and we present the Ec-marking algorithm, an enhanced version of the c-marking algorithm [16], with which we compared the obtained results. In Section III, we present the performance indices used, describe the scenarios used for simulations and compare obtained results of the two algorithms. We finish with a conclusion in Section IV and some future works.

## II. An Energy-aware Multi-Agent Foraging Algorithm

In this Section, we present the EC-SAF algorithm, the FSM of our foraging agents and a description of different states. We present the Ec-marking algorithm, with which we compare the obtained results.

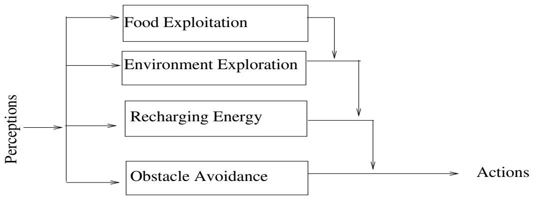

Fig. 1: Subsumption architecture of our foraging agents

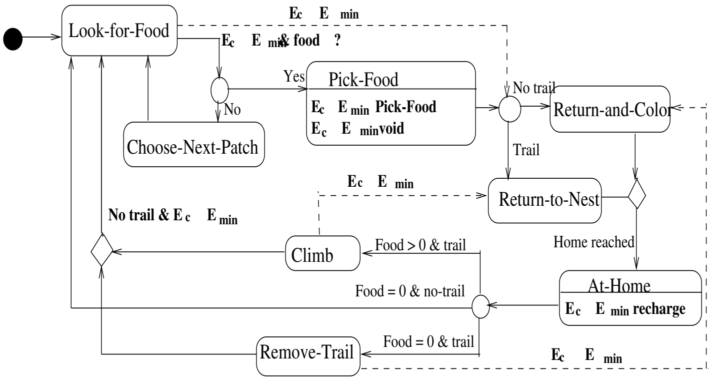

Fig. 2: State transition diagram of a foraging agent. Dotted arrows are the added transitions related to the recharging behavior of agents

### A. EC-SAF Algorithm

Our foraging agents use a four layered subsumption architecture [17] where each layer implements a particular behavior: *Environment exploration* is the lowest priority layer in this architecture. It consists in exploring the environment, therefore, it includes the states *Choose-Next-Patch* and *Look-for-Food*. *Food exploitation* consists in exploiting food when it is found, it envelops the states *Pick-Food*, *Return-to-Nest*, *Return-and-Color*, *At-Home*, *Climb* and *Remove-Trail*. *Recharging energy* consists of the set of states that allow agents to return home to recharge when their energy falls below a threshold, it includes the states *Return-to-Nest*, *Return-and-Color*, *Remove-Trail* and *At-Home*. *Obstacle avoidance* is the higher priority layer, it implements the obstacle avoidance behavior. Higher priority layers are able to subsume lower levels in order to create viable behavior (see Figure 1 for an illustration of the architecture). The behavior of our foraging agents is enhanced from [14] to deal with energy limitation. It is shown by the state transition diagram in Figure 2 where dotted arrows represent the new transitions used when the current energy of an agent ($E_c$) falls below the fixed threshold ($E_{min}$). States are described below and the enhanced algorithm is given by Algorithm **??**:

**Look-for-Food:** If $E_c > E_{min}$ and there exists a food here, agent executes *Pick-Food* state, while if there exists no food it executes *Choose-Next-Patch* state. If its $E_c <= E_{min}$, it turns to *Return-to-Nest* state if there exists a trail, or to *Return-and-Color* state, if there exists no trail.

**Choose-Next-Patch:** If an obstacle is detected, the agent calls the procedure Avoid_Obstacle(). If no obstacle is there, the agent climbs the brown trail to reach the food location if there exists one, it spreads then the information to its left cell. It lays a limited amount of pheromone $\mathbb{P}$ in current cell, adjusts its heading by executing S-MASA Algorithm [15] and moves one step forward. It turns automatically when finished to *Look-for-Food* state.

**Pick-Food:** If $E_c > E_{min}$, agent picks a given amount of food and spreads the information to its left cell. However, If $E_c <= E_{min}$ it does not pick food. It executes in the two cases *Return-to-Nest* state, if there exists a trail or *Return-and-Color* state if there exists no trail.

**Return-to-Nest:** The agent moves to one of colored neighboring cells with the lowest $\mathbb{P}$ value. It remains in this state until home is reached, it turns then to *At-Home* state.

**Return-and-Color:** The agent moves to one of the four neighboring cells with the lowest $\mathbb{P}$ value and marks its trail with yellow and remains in this state until it reaches the home; it turns then to the *At-Home* state.

**At-Home:** The agent unloads food if it carries one. If its current energy *($E_c$)* is below *($E_{min}$)*, it recharges its energy to the maximum amount $E_{max}$. It goes to *Climb* state if there exists one and the amount of food is $> 0$. If amount of food is $= 0$, it executes *Remove-Trail* state, else it turns to *Look-for-Food* state.

**Climb:** Agent moves to one of its four colored neighbors with a $\mathbb{P}$ value greater than the $\mathbb{P}$ value of the current cell. It remains in this state until no colored cell (yellow trail) exists and its $E_c > E_{min}$, it turns then to the *Look-for-Food* state. If its $E_c <= E_{min}$ and since there exists a trail, it executes the *Return-to-Nest* state in order to return home for recharging its energy.

**Remove-Trail:** The agent moves to a colored cell with the greatest $\mathbb{P}$ value and resets its color to the default color (black). It remains in this state until no colored cell is found and $E_c > E_{min}$, it turns then to the *Look-for-Food* state. If $E_c <= E_{min}$, the agent returns to home to recharge and executes the *Return-and-Color* state since it already removed the existing trail and to keep track of the last position from where he will continue removing after it recharges its energy.

The modeling of the components of our multi-agent system are detailed below:

- *Environment Model:* an N X N grid world. It contains a set of agents, food, nest and obstacles.
- *Agent Model:* agents have limited processing power and memory, simple sensors, do not know the position of food nor the map of environment.
- *Pheromone Releasing and Evaporation:* Two types of pheromone have no diffusion and evaporation properties and they are used either to mark a transport or recharging trails or a recruitment trail. The third one is used to mark already visited cells.

### B. Ec-marking Algorithm

The Ec-marking algorithm, which is an enhanced version of the c-marking algorithm [16] to deal with energy limitation,

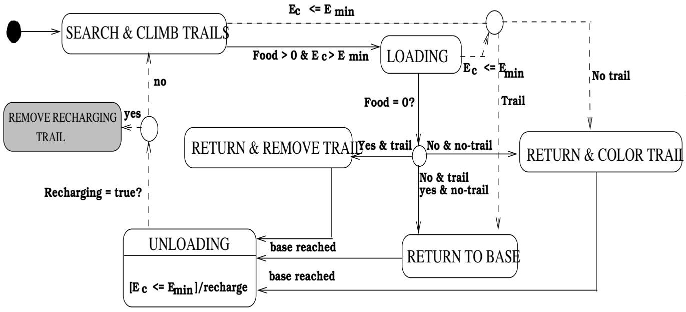

Fig. 3: State transition diagram of an Ec-marking agent, where colored state, dotted transitions and bold guards are related to energy-aware behavior of agents

is given by Figure 3. Agents while exploring the environment build simultaneously paths between food and nest which results in building an ascending Artificial Potential Field (APF) incrementally. An Ec-marking agent is always in one of the states depicted by Figure 3, where the enhancements made represented by filled states, dotted transitions and bold guards. This set of states is described below:

**SEARCH & CLIMB TRAIL:** If food >0 and $E_c > E_{min}$, the agent executes the *LOADING* state. If $E_c <= E_{min}$, it looks for trail, if there exists one it executes *RETURN TO BASE*, else if there exists no trail it executes *RETURN & COLOR TRAIL*, else it moves to food if it is found and if not it moves to a neighboring cell not marked yet.

**LOADING:** The agent picks a given amount of food and food here is exhausted and there exists a trail, it executes *RETURN & REMOVE TRAIL*, if food is not exhausted and there exists no trail, it executes *RETURN & COLOR TRAIL*, else it executes *RETURN TO BASE.*

**RETURN & COLOR TRAIL:** The agent moves to one of the four neighboring cells with the lowest $APF$ value and changes its color to a trail color, it remains in this state until it reaches the home; it turns then to the *UNLOADING* state.

**RETURN & REMOVE TRAIL:** The agent moves to one of the four neighboring cells with the lowest $APF$ value and changes its color to the default one (black), it remains in this state until it reaches the home; it turns then to the *SEARCH & CLIMB TRAIL* state.

**RETURN TO BASE:** The agent moves to a colored neighboring cell with value minimal to its current value, until it reaches the home; it turns then to the *SEARCH & CLIMB TRAIL* state.

**UNLOADING:** The agent unloads the food at home. If $E_c <= E_{min}$, it recharges its energy to $E_{max}$ and if its statue is recharging it changes state to the *REMOVE RECHARGING TRAIL*, else it changes to the *SEARCH & CLIMB TRAIL.*

**REMOVE RECHARGING TRAIL:** The agent moves to a colored neighboring cell with higher $APF$ value and resets its color to the default one, until no colored cell is found it changes then to the *SEARCH & CLIMB TRAIL.*

## III. Simulation Results

Three performance indices are used to compare the algorithms (*Total food returned*, *Energy efficiency* and *Total energy*). Through simulations, we compared the four algorithms (EC-SAF [Algorithm **??**], C-SAF [14], c-marking [16] and Ec-marking [Figure 3]) on the basis of *Total food returned*, to verify if an energy-aware management can improve performances. After that, the two energy-aware algorithms proposed in this paper (EC-SAF and Ec-marking) are compared between each other on the basis of *Energy efficiency* ($E_{eff}$) and *Total energy* performance indices.

- **Total food returned**: is the total amount of food (in units) returned over some elapsed time.
- **Energy efficiency**: it is the energy spent while foraging one food location. It is calculated according to equation 1.

$$E_{eff} = \frac{TotalEnergyOfConsumedFood}{NumberOfReturnedFood} \qquad (1)$$

  Where *Total Energy Of Consumed Food*, is the sum of each agent energy spent in exhausting one food location starting from finding the food until it is exhausted. *Number Of Returned Food* is the quantity of units of food returned;
- **Total energy**: is the total energy spent by all agents to search and exhaust all the food locations.

The energy consumption of an agent at each state is defined on the basis of the power of real equipment (such as motor, sensor and processor) required to achieve that state. It is inspired by the B-swarm model [10]. Agent consumes 1 unit of energy per simulation update for the states that do not need hard work (such as *Climb* and *Return-to-Nest*), while in states that need hard manipulation such as: depositing pheromone (in *Choose-Next-Patch* state), loading food (in *Pick-Food* state), unloading food (in *at-Home* state), pick-up pheromone (in *Remove-Trail* state), and deposit pheromone (in *Return-and-Color* state), the agent consumes 5 units of energy per simulation update. However, for the *Avoid-Obstacle ()*, agent changes its direction only and consumes 3 units of energy per simulation update. For the Ec-marking, the energy consumed is: 5 units of energy per simulation update for states *SEARCH*, *LOADING*, *RETURN & COLOR TRAIL*, *RETURN & REMOVE TRAIL*, *UNLOADING*, *REMOVE RECHARGING TRAIL* and 1 unit of energy per simulation update for states *CLIMB TRAIL*, *RETURN TO BASE* and 3 units of energy per simulation update for the *avoid obstacle()*. Simulation is based on Netlogo [18]. The simulation results are the average of ten simulations. Four kinds of simulations are reported in this paper. In each simulation several related parameters are to be fixed: agent parameters (number and capacity), world parameters (size, complexity and sinks number) and food parameters (density and concentration) where: *Agent's number* is the number of agents that participate at each simulation, *Agent's capacity* is the amount of food (units) that an agent can transport at each time. *World size* is the dimension of the search space, it is a grid of *N X N cells*, the world is obstacle-free or obstacle represent the *world complexity*, *sinks number*

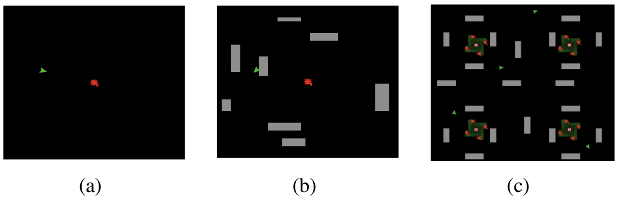

Fig. 4: World setups used in simulations (a) obstacle-free environment (b) obstacle environment (c) environment with 4 sinks, where red arrows are agents, green arrows are food locations, gray blocks are obstacles and pink squares are sinks

TABLE I: Parameters of scenario 1, scenario 2, scenario 3 and scenario 4

| Parameter | | Value |
|---|---|---|
| **Scenario 1** | *Total food returned Analysis* | |
| World size | | 40 X 40 cells |
| Number of agents | | 8 |
| Food density | | 2 sites |
| Food concentration | | 50 units |
| Agent's capacity | | 1 unit |
| Sinks number | | 1 |
| **Scenario 2** | *Energy Efficiency Analysis* | |
| World size | | 40 X 40 cells |
| Number of agents | | 5 – 30 |
| Food density | | 1 site |
| Food concentration | | 20 units |
| Agent's capacity | | 1 unit |
| Sinks number | | 1 |
| **Scenario 3** | *Energy Efficiency Analysis* | |
| World size | | 80 X 80 cells |
| Number of agents | | 48 |
| Food density | | 1 site |
| Food concentration | | 20 units |
| Agent's capacity | | 1 unit |
| Sinks number | | 1 – 16 |
| **Scenario 4** | *Total Energy Analysis* | |
| Number of ticks | | 50 – 300 |
| World size | | 40 X 40 cells |
| Number of agents | | 15 |
| Food density | | 1 site |
| Food concentration | | 20 units |
| Agent's capacity | | 1 unit |
| Sinks number | | 1 sink |

is the number of the home or base station to where agents store food and recharge energy. *Food density* is the number of food locations (sites), distributed randomly in the environment. *Food concentration*, indicates the amount of food that each site contains (we refer to it as unit in the paper). At first stage, we wanted to test if energy-aware can improve efficiency of our C-SAF algorithm or not, therefore, we proposed scenario 1 (see TABLE I), where we calculate the total amount of food returned over some elapsed time. The obtained results with the four algorithms (C-SAF, EC-SAF, c-marking and Ec-marking) are depicted by Figure 5.

From Figure 5, we observe that in C-SAF and c-marking algorithms, the total food returned increases with the increase in ticks (below 300 ticks) because agents still have energy, when their energy is exhausted, agents die and the total food returned does not increase (over 300 ticks). While the total food returned keep increasing in the energy-aware versions of the algorithms (EC-SAF and Ec-marking), because agents return to recharge when their energy falls below the fixed threshold and resumes their tasks. From this experimental results, we conclude that an energy-aware version are needed to improve performances.

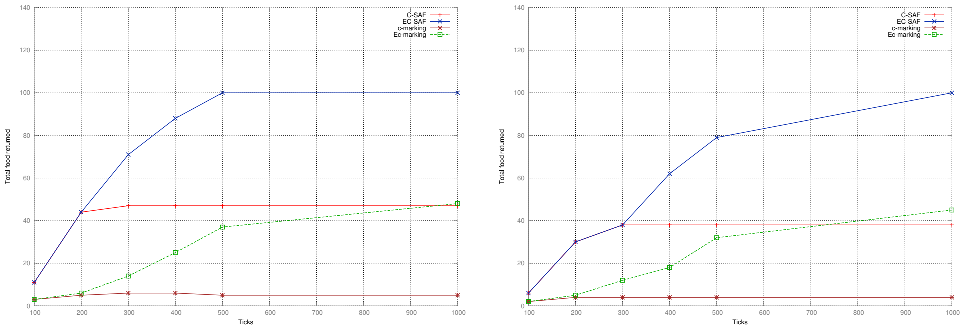
The EC-SAF algorithm is also compared with the Ec-marking one, in order to test if it can improve energy consumption or not. We proposed therefore, Scenario 2, scenario 3 and scenario 4, where the two first ones are used to test the impact of varying agent's number and sink's number (search space division) on energy efficiency. While in scenario 4, we observe the whole energy consumed over some elapsed time, to test whether the algorithm consumes much or less energy when operating (see TABLE I for the description of the three scenarios). The three world setups that are used for simulations including positions of nest, food, obstacles and agents, are reported in Figure 4.

### A. *Results in Scenario 2*

The energy efficiency in EC-SAF does not change when changing the number of agents. In opposite to the number of ticks that is reduced with the increase of agents number, the energy consumed by one agent is the same consumed by multiple agents that participate at food exploitation. However, the energy efficiency in c-marking decreases with each increase in agents number. The energy consumed depends on the length of path that relays the food and the home. In Ec-marking algorithm, the paths are not optimal when number of agents is small thus energy consumption is great, with the increase of agent's number the length of paths will be reduced and the energy consumption decreases. Because of the optimal paths provided by S-MASA algorithm [15], EC-SAF gives better results than the Ec-marking one (see Figure 6(a)). Results in obstacle environment are similar to the ones in obstacle-free environment configuration, with additional steps needed to avoid obstacles (see Figure 6(b)).

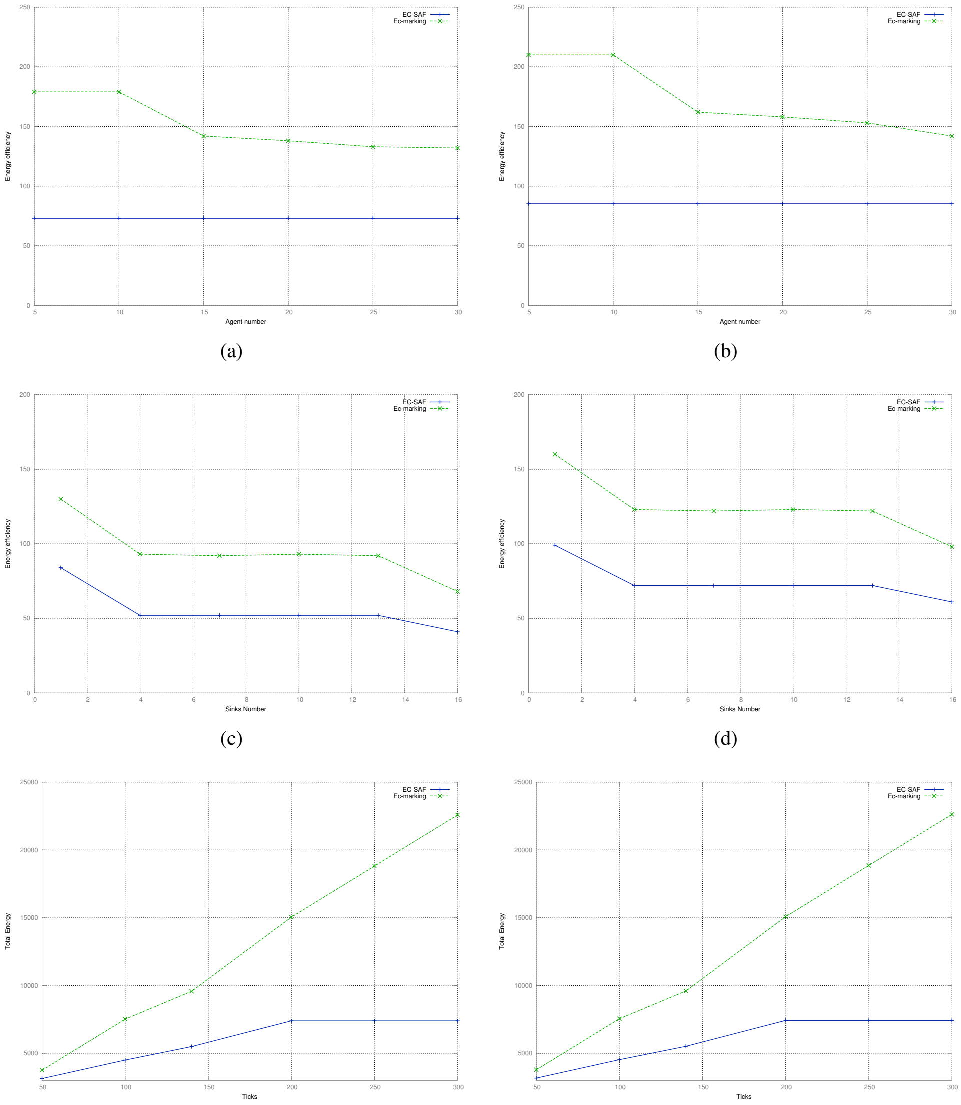
### B. *Results in Scenario 3*

Using multiple sinks divide the whole search-space into sub-search spaces with smaller size. When increasing the the number of sinks the number of sub-spaces is increased too and the size is reduced more. The path length to food is reduced each time we increase the number of sinks (food takes fixed position in all simulations). In EC-SAF less consumption of energy is reached with 16 sinks, where the size of sub-spaces is the smallest and the path length to the food is the smallest (6 cells). The energy consumption is greater with 4, 7, 10 and 13 sinks (the path length to food is 8 cells). However, it is the greatest with 1 sink, because the search-space size is the greatest and the path length to food is the longest (14 cells). In Ec-marking, the energy consumption is great with



(a) (b)

Fig. 5: Simulation results of scenario 1 in : (a) obstacle-free environment, (b) obstacle environment.



(a) (b)

(c) (d)

(e) (f)

Fig. 6: Simulation results in obstacle-free and obstacle environment of: (a), (b) scenario 2. (c), (d) scenario 3. (e), (f) scenario 4

1 sink because the search-space size is the greatest, the path length to food is the longest and paths are not optimal. It is reduced with 16 sinks, since the path length to food is reduced. ES-CAF provide less energy consumption rather than Ec-marking because of the optimal paths induced by the S-MASA algorithm [15]. Figure 6(c) shows the results comparison between the two algorithms. Results in obstacle environment are same as in obstacle-free environment configuration, with additional steps needed to avoid obstacles (see Figure 6(d)).

### C. Results in Scenario 4

The total energy increased with increasing the number of ticks as shown in Figure 6(e). It is stable in EC-SAF above 200 tick because the agents reach the boundaries of the search world (the finish time of the foraging is 140 ticks). However, the finish time of foraging in Ec-marking is 300 ticks and until this time the total energy continue to increase. Also in this scenario EC-SAF provides a less consumption of energy in comparison to Ec-marking one. Also in obstacle environment, the total energy in the two algorithms increased with increasing the number of ticks but it is more in Ec-marking algorithm than in EC-SAF algorithm (see Figure 6(f)).

## IV. Conclusion

We investigated in this paper the energy efficiency and the total energy consumed of the EC-SAF algorithm as changing the number of agents (to test the benefit of collective foraging), changing the sinks number (to test the benefit of dividing search space) and calculating total energy consumed over ticks (to test the impact of the search strategy used). Simulation results show that energy efficiency in EC-SAF, does not change when changing agents number because the set of agents execute the same states as one agent and thus consume the same energy consumed by one agent. It can be reduced when using multiple sinks, and it depends on the path length between food and home, if the path is reduced with search space division the energy efficiency is even reduced (and vice versa). While the total energy increased with the increase in number of ticks, it stops changing and becomes stable when all food is foraged and the search space boundaries are reached. EC-SAF gives better results than the enhanced c-marking one, because of the optimal paths and the quick search provided by S-MASA algorithm [15].

In the future, we intend to explore other environment configurations and examine other possibilities to reduce the energy consumption in EC-SAF.

# 4th International Workshop on Smart Energy Networks & Multi-Agent Systems

THE EMERGING smart infrastructure in energy networks represents a major paradigm shift in resource allocation management with the aim to extend the centralised supply management model, towards a decentralised supply-and-demand management that is expected to enable more efficient, reliable and environment-friendly utilisation of primary energy resources.

Together with this vision, there are new and complex tasks to manage, in order to ensure safe, cost-reducing and reliable energy network operations. This includes the integration of various renewable energy systems, like the photovoltaic or the wind energy, which are able to reduce the greenhouse gas emissions but that are working under greater uncertainty; as well as the interaction of transport and storage systems for energy that are envisioned through techniques like 'Power to Gas' and fuel cells, which are using the electrical and the gas transportation network.

Further tasks can be found in the fact that the market participants (e.g. simply households) are becoming more autonomous and intelligent through technologies like smart metering, which requires a coordinated demand side management for millions of producers, consumers or, if this applies, prosumers by means negotiations and agreements.

Information and communication technologies are key enablers of the envisioned efficiencies, both on the demand and the supply sides of the smart energy networks, where the agent-paradigm provides an excellent first modelling approach for the distributed characteristic in energy supply systems. On the demand side they aim at supporting end-users in optimising their individual energy consumption, e.g. through the deployment of smart meters providing real-time usage and cost of the energy and the use of demand-response appliances that can be controlled according to the user preferences, energy cost and carbon footprint. On the supply side they aim at optimising the network load and reliability of the energy provision, e.g. through active monitoring and prediction of the energy usage patterns, and proactive control and management of the reliable energy delivery over the networks. It is also envisaged that they will be able to influence the demand through the dynamic adjustments of the energy price in order to influence the end user behaviour and energy usage patterns throughout and across the energy networks for electricity, gas and heat.

Although a significant effort and investment have been already allocated into the development of smart grids, there are still significant research challenges to be addressed before the promised efficiencies can be realised. This includes distributed, collaborative, autonomous and intelligent software solutions for simulation, monitoring, control and optimization of smart energy networks and interactions between them.

## Topics

The SEN-MAS'15 Workshop aims at providing a forum for presenting and discussing recent advances and experiences in building and using multi-agent systems for modelling, simulation and management of smart energy networks. In particular, it includes (but is not limited to) the following topics of interest:

- Experiences of Smart Grid implementations by using MAS
- Applications of Smart Grid technologies
- Management of distributed generation and storage
- Islands Power Systems, Microgrid Applications
- Real time configurations of energy networks
- Distributed planning process for energy networks by using MAS
- Self-configuring or self-healing energy systems
- Load modelling and control with MAS
- Simulations of Smart Energy Networks
- Software Tools for Smart Energy Networks
- Energy Storage
- Electrical Vehicles
- Interactions and exchange between networks for electricity, gas and heat
- Stability in Energy Networks
- Distributed Optimization in Energy Networks

## I. Introduction

***Abstract*—We present in this paper GRENAD, a Multi-Agent System based framework for the simulation and piloting of power-grids and particularly smart grids. Exploiting a component-based approach, it allows a flexible design of complex smart grid applications by providing a generic canvas where extensible, modular and reusable components, defined on the basis of their functionalities, can be easily combined and connected. Thanks to Multi-Agent approach, a set of such components can naturally be integrated into a coherent economical agent. GRENAD makes no assumption on the energy definition and eases the development of MAS control algorithms for smart grids. The level of details of the energy-related information is controllable. This information is computed either through internal physical models or by interfacing with external simulators. We present here our model, illustrate its features with a rich example which exhibits its genericity, and demonstrate how a coordination protocol can easily be integrated to it.**

ENERGY supply is at the core economy while being also one of the major items of expenditure. Decreasing fossil energy supplies as well as rising concerns about climate made it critical to change in the near future the way energy is produced, distributed and consumed. Smart grids are highly automated power networks that possess fine grained monitoring and control capabilities, from the power plant to the domestic appliance. Easy access to information and autonomous decision making allow smart grids to save energy by quickly reacting to changes in the environment and reorganising demand, production and distribution. Smart grid are also meant to allow the massive integration of distributed renewable energy resources (DER) as well as new equipments such as combined heath and power (CHP) generation and energy storage. As such smart grids are called to play a crucial role in the coming years for the efficient control of power systems.

Hardware for production, monitoring and storage in smart grids already exist. While still not being widely deployed, the penetration of such equipments is constantly progressing and increasingly supported by legislations. However they raise new challenges. Indeed, as opposed to the traditional power grids approches, energy flows may be intermittent and/or bidirectional. Moreover smart grids technologies also foster a radical change in the business of energy supply, by allowing the energy to be islanded, it is to say produced, sold and consumed locally. Lastly, increased interconnection and information exchange between actors enables them to coordinate more closely, providing thus a new opportunity to reach higher efficiency and revenues.

One of the most challenging aspects of smart grids is thus at the engineering and at the logical level: the development of efficient control and coordination algorithms that are able to fully exploit their different potentialities. In order to tackle these challenges the use of a Multi-Agent Systems (MAS) approach is particularly relevant as the structure of MAS closely match the structure and behaviour of smart grids: They are constituted of a set of interconnected distributed autonomous actors, each aiming at maximising their respective goals through coordination. Also, a given smart grid is composed by interconnecting differents components (production, distribution or storage) that may be used, as is, on another smart grid. It is thus relevant to adopt a modular approach for modeling the equipments in a reusable, and thus capitalizable, way. Therefore a key driver for the deployment of smart grids is the conception of a dedicated platform that ease their development by exploiting both oriented-component paradigm for equipment modelisation aspects and oriented-agent paradigm for coordination and optimisation aspects.

In the context of the Resilent FP7 project [20], we have developed such a platform, GRENAD, which stands for "`Gestion des Ressources ENergétiques, Autonome et Distribuée`" (Autonomous and Distributed Management of Energetic Resources). GRENAD presents two main aspects. The first is a feature rich API and Domain Specific Language (DSL) based on JADE [11] which allows to construct component-based JADE agents. As such it benefits of all the features and standard compliance of JADE and can natively be used in conjunction with other JADE-based applications. The second is a generic smart grid model implemented on top of this DSL. Thanks to these two aspects, it is possible to easily capitalize and reuse developed software across different smart grid applications.

While most MAS publications in the smart grid domain focus on the connection with a simulator or the conception of a new control algorithm, our contribution is a platform that offer enough flexibility to allow an easy interfacing with simulators and an easy implementation of control algorithms. Also, each

component defining the smart grid can natively be monitored, or even controlled, either by an agent, a GUI, or a remote optimisation algorithm.

In Section II we present a smart grid scenario exhibiting all critical features for the applications we are interested in. In Section III we present the related work and how they answer to the objectives highlighted by our scenario. In section IV we present the GRENAD agent and smart grid models and we describe how to implement the scenario with them. In Section V we show how to easily integrate a smart grid optimization algorithms in GRENAD.

## II. A Rich Scenario

In this section we present a district energy system scenario. The richness of this scenario allows us to demonstrate the capabilities of our MAS based tool to model complex energy management systems at the district-level. This scenario exhibits most of the main characteristics that challenge today the design of smart grid energy management systems [19]:

- Interdependence of several energy flows (electricity, heat and gas)
- Distributed generation and storage capabilities
- Interaction with the main energy grids (electricity and gas)
- Local renewable energy generation capabilities
- Prosumers
- Diverse consumption profiles

In the scenario, the considered components (producers, distribution grid, consumers/prosumers and storage systems) are modelled as autonomous agents that interact with the intention of providing real time management at the district level and optimizing the energy production and distribution in the district, in conjunction with the main energy networks.

### A. Business and organizational models

The behaviors of the different components are defined by their individual roles and their internal characteristics (physical, economical, quality of service, *etc.*). Those behaviors are constrained by the business and organizational models of the system as well as by the interconnection mode to the main grid (an energy system can work either in *connected or islanded mode* w.r.t the main energy grids). In our scenario we considered a system connected to the main gas and power grids (represented as components 3 and 4 in Figure 1).

Among the different existing business and organizational models we can list:

- **Free markets**: the components are competitors and interact via a market mechanism [12];
- **Virtual Power Plant (VPP)**: combination of production storage and consumption resources. A VPP [18] is adapted when all the resources belong to or are managed by a single actor;
- **Cooperative Virtual Power Plant (CVPP)**: In a CVPP [3] different actors manage/own the different components, they coordinate in a cooperative way to use shared resources (for instance centralized storage systems, the distribution network, etc.) and provide global services (for instance: grant the energy balance, the security of the network and/or the quality of service).

All these different organizational models can be considered in our approach. In our scenario we model interactions between components as a free market.

### B. Roles

The main roles that we support are *producer, storage, consumer, prosumer and distribution*. The different constraints and characteristics associated to those roles are described below:

*1) Producer components:* The characteristics of the generation of energy provided by producers depend on several aspects:

- **Internal physical constraints**: the nominal power (max power capabilities), start/stop conditions (time to be operational/off operation), their efficiency (it is the rate between the output generated energy and the input primary used energy), and for renewables the variability and the intermittence.
- **Controllability**: The controllability of a given generator depends on the primary energy source that it uses and on internal state variables. Most of renewable-energy sources (e.g. wind, solar) are considered non-controllable, it is, their availability and level of energy cannot be controlled. Nevertheless, some renewable based generators can adapt their internal state (i.e. orientation of wind turbines or solar trackers) in order to secure and optimally generate energy according to the primary-source real time conditions. Generators whose primary energy supply can be controlled provide different control levels, for instance some generators can only provide on/off control while others can provide intermediate levels of functioning.

In our scenario we consider two producers (the components 1 and 2 in Figure 1): a set of wind turbines for power generation and a Combined Heating and Power (CHP) generator that generates both power and heating from combustion of gas. Gas is provided by the main gas grid (component 3 in

Figure 1) and can be stored nearby the CHP. The system is also connected to the main power grid (component 4 in Figure 1). The gas and the power main grids are considered in our model as controllable producers, it is, we consider that the quantity of gas or the power drawn from the main grids can be controlled. In the real system only the gas flow can be directly controlled, the drawn power from the main grid is indirectly controlled and corresponds to balance needed power, it is, the consumed power minus the local producer power.

*2) Storage components:* The behavior of a storage component depends mainly on its nominal capacity, its rate of charge/discharge and its instantaneous state of charge (SoC). Other important variables are the efficiency of the conversion in the charge and discharge phases and the self-discharge rates. The usage of some storage systems, for instance batteries, is constrained by the charge/discharge cycling conditions that optimize their efficiency and increase their lifetime. In our scenario we consider a thermal storage component (see component 6 in Figure 1).

*3) Distribution components:* The distribution of energy generates losses due to the physical characteristics of the transportation system used (i.e. transmission capabilities, dissipation rates, etc.) and the distances of transmission of the energy. In general, at the district level, the electricity losses due to distribution are negligible while the heating and hydraulic (heating network related) losses are not. Some distribution components (as valves in heating networks and some types of transformers) allow the dispatching of input energy among different outputs. While the availability of energy over electrical networks is instantaneous (electricity is transmitted at about the speed of light), the transmission of energy over heating and cooling networks, due to the transport inertia, needs significant time (several minutes per km) to go from the injection to the consumption points. In our scenario we consider local heating and power networks: all the production and consumption components considered in the scenario are connected to at least one of these distribution networks.

*4) Consumer components:* The characteristics of the energy consumed, basically their load curves, depend mainly on the buildings physical characteristics (i.e. thermal inertia, storage capabilities), the behaviors of the inhabitants (presence/absence, used services) and the comfort constraints (e.g. ambient temperature set points). In our scenario we consider two consumers, the components 7 and 8 in Figure 1.

*5) Prosumer components:* Besides the characteristics that define the load curves of the consumer components, prosumers can partially or totally cover their needs in energy and under some conditions produce energy surplus that can be injected into the main or local energy grids. In our scenario we consider one prosumer (component number 5 in figure 1), that locally produces power thanks to the PV solar panels installed on its roof. It uses part of this energy for self-consumption and is able to inject part of this energy into the power distribution network.

### C. Planing and operation

Due to the temporal inertia of most of the components (e.g. time to start or change generator command level; thermal inertia on houses and distribution networks; time to charge/discharge storage systems) and the use of non-controllable sources (that are intermittent and variable), the energy usage needs to be planned before actual generation and delivery. In our approach, we consider *planning strategies* that are combined to *real-time operation strategies*. *Planning* is based on estimation of the consumption loads and generation capabilities and allows to establish negotiated (i.e. agreed by all parties) generation, storage and consumption schedules. For the renewable based generators, the estimation depends on weather and generation capabilities forecasting. For end consumers, the estimation depends mainly on weather and usage forecasting, as well as on thermal inertia evaluation. Those different forecasting based estimations lead to inaccuracies at the planning phase. In order to maintain the balance between consumption and generation and minimize the use of external generated energy, we implement and operate a mechanism that allows the near real-time correction of energy schedules when deviations of generation and load are detected (monitored or forecasted). This mechanism can be seen as a capacity market where global flexibility is provided by the combined individual flexibility capabilities (e.g. deferrable load, dedicated storage capabilities, etc.)

### D. Real-Time payment

Smart-Grid also aims to adapt the consumption to the energy production capacity. This is particularly critical when some producers are not controllable (e.g. weather dependant renewable energy source). By exploiting for instance a building thermal inertia, it is possible to respect a required comfort level while adapting the actual consumption.

A commitment of the consumer on how it will consume energy allows to optimise energy production and distribution during the planning. Several payment approaches [22] propose to impose penalties if such a commitment is not respected during operation phase. The actual payment of a consumer is thus computed by comparing its planned and operational consumption along with some other production-related and/or conventional parameters.

## III. Related Works

Actual testing and deployment of smart grid software require platforms able to directly support the execution of control software developed following as well as the ability simulate or even pilot power systems. Among the few available commercial systems that target specifically smart grids, only a bit of them follow the MAS approach.

The available commercial software that simulate and control traditional grids [15], [7], can to some extent be used to simulate parts of a smart grid, notably for the distribution aspect. However, smart grids possess several specificities that preclude the use of such software for the full chain control. On the other hand, smart grid software have not reached this level of maturity and are mostly experimental or at the level of academic research. Dedicated software solutions for smart grids exist independently, for different aspects presented in this scenario: storage simulation and dimensioning [10], DER integration [5], demand side management [9] and VPP [2]. While none of these commercial software uses a MAS approach, PowerMatcher [17] is an exception. It can perform simulation and piloting and uses auction protocols to interact over a market of flexibilities.

Among non commercial software, GridLab-D [4] is a notable one, it is a low level electrical simulation tool based on a MAS paradigm. It allows to assign different profiles of consumption to the devices on the network, but fails to represent economic actors and is not able to endow agents with advanced smart behaviours that react to change in their environment.

Most academic works in smart grids consider separately the development of a platform, a model and control algorithms. As such they provide very limited reusability and interoperability between the different layers. Platforms in the literature mostly act as a middleware and focus on the coupling of a MAS platform (JADE [11] being the most popular) with an electrical simulator and data exchange formats[1], [23], [21]. The designs provided in papers that present models [16], [8] fail to acknowledge either the simulation or the control aspects and often both of them, limiting their applicability. Finally, while most control algorithms are backed by experimental simulations, they are coded specifically for non smart grid environments and therefore fail to be reused and extended. We believe this shows a clear need for a generic and flexible tool for smart grid algorithms conception, testing and deployment.

In this paper we propose such a tool: a platform and a model that have been thought for reusability in smart grid applications and aims at supporting different smart grid applications at all levels. We demonstrate this by exhibiting the coupling of a state of the art distributed control algorithm. Previously mentioned works lack an abstract representation encompassing both the socio-economical actors and the physical devices, in GRENAD both are explicitly modeled.

The implementation of GRENAD is based on JADE. JADE is a widely popular generic purpose MAS execution platform providing primitives to ease the development of agents and deployment of agents [11]. This platform, by being generic, lacks support for smart grid elements needed to represent, simulate or even control a smart grid. GRENAD extends JADE and enrich its capabilities with additional communication mechanisms and smart grids specific objects and proposes a component based architecture.

## IV. Our Modular Agent-Based Smart-Grid Model

In this section we present and illustrate our contribution: an agent model implemented on top of JADE and a smart-grid model implemented on top of our agent model. The conception has been driven by the Design Pattern approach. For more information about Design Patterns please have a look at [6]. We first present our agent model, then we present our smart-grid model and last we describe how to formalize the scenario thanks to this model.

### A. Agent Model

GRENAD is implemented as an overlay of JADE. It provides a Domain Specific Language (DSL) that exploits a component-based approach in order to describe the agents and enhance JADE with a set of native services (agent building system, ergonomic agent messaging service, generalized support of a publish/subscribe system, ...). The agent building system simplifies the use of JADE for defining agents at compile time and runtime (initialisation step). The first class to understand in the agent building system is `GrenadAgent`. A `GrenadAgent<ID extends GrenadIdentifier>` can be viewed as a pair made of an **identifier** of type Id and a list of **components**. It is an implementation of the *builder pattern* from [6, p. 97]: the identifiers and components hold all the information required to build a JADE `Agent` exposing all the natively proposed features of JADE as well as non natively proposed ones.

A `GrenadIdentifier` is the specification of a JADE `AID` (the JADE *A*gent *ID*entifier): `GrenadIdentifier` allows to obtain the `AID` once the JADE agent is set up by JADE[1]. A component is a stateful and active object that is executed within the environment of the hosting agent. Such an environment provides access to a set of services shared by all the components of the same agent. We distinguish three groups of components:

- **Action components** are components that produce a list of JADE `Behaviour` objects that are to be added in the to-be-constructed JADE `Agent.`
- **Runtime components** allow to modify the way a `GrenadAgent` is handled by JADE. They can modify the `GrenadAgent` or execute side effects that depend on it, at agent set up or take down. They can specify actions to realise while cloning or moving the agent. They can also catch and handle exceptions issued by the agent execution, which is a functionality not natively proposed by JADE.
- **Composite components** are collections of components (as such they follow the *composite pattern* from [6, p. 163]). They allow to manipulate a bag of components as if it was a single one. From the agent point of view, loading a `Composite component` is equivalent to loading each component of the collection it represents.

By definition a component is an independent piece of software: it has its own state (set of constants, variables and methods) and has no access to the other components of the hosting agent (except for certain Runtime Components, as it is their goal). Certain actions allow to specify their state in a separate class and thus easily share it with other components

[1] JADE agent life cycle starts by building the agent, then executes the method `setup` once the agent is alive. It then executes the method `takeDown` if the agent is required to terminate, and finally kills it

of the same agent. The goal is to enhance component re-usability by separating configuration/decision aspects to action/communication ones. For example, different behaviours or protocols may require at some point to have access to the agent launch date, its neighbourhood, its preferences or abilities such as computing an optimal path. Exploiting the *Template Method Pattern* from [6, p. 325] allows to identify those methods that ought to be placed in interfaces implemented by the component state. It is then the responsibility of the agent to globally implement them in states shared by its components, thus ensuring both coherence of its actions and efficient factorisation of its code.

Let us consider, for instance, an auction about a certain type of objects that runs between an auctioneer and several bidders. In this process each bidder is characterized by the value it attributes to the objects. Except for this *decision function*, all other actions executed during this auction process are conventions specified by the auction rules. A correctly factorized implementation would thus define a component that encodes the behaviours resulting from those rules and exploits the evaluation function on the considered bidders, implemented in a separated state. Let us suppose now that one of these same bidders has latter participates in a different kind of auctions about the same type of objects. The expected behaviour for this agent is to evaluate the objects in the same way. Our "correctly factorized" approach does it naturally since the agent will only need to share the previously used state with the component executing this new process.

Please note that we strongly recommend to avoid data mutability in this approach by only sharing constants and methods. If the state has variables, it is up to the programmer to ensure, when building the agent, that the different components that exploit it do not modify them in an incoherent way.

Besides, all the components of a same agent share three services :

- Access to the unique identifier of the agent.
- Access to the agent communication service, which allows to send messages and have access to the mailbox.
- Access to the publish/subscribe service of the agent.

The *Publish/Subscribe Pattern* (also known as the *Observer Pattern*, see [6, p. 293]) is natively proposed by GRENAD, because it provides an efficient way to decouple communication, as opposed to the natural approach of message sending. In the *Publish/Subscribe Pattern*, an agent, the publisher, publishes whenever it decides any information it finds relevant. It does not know *a priori* who is interested by this information. A published information is identified by its type, a name set by the publisher, and the identifier of the publisher. A subscriber agent knows *a priori* which publication of which publisher it is interested in. It thus subscribes to it, and indicates at the same time the action it will execute upon the reception of a new publication (how it will *react*). It may stop this behaviour at any time by unsubscribing.

Simple direct message exchange and the *Publish/Subscribe Pattern* are opposed approaches to communication: in the former, the receiver of the message is decided by the sender, while in the latter the sender of a message is decided by the receiver. Natively proposing both approaches brings a great flexibility in the way of establishing communication neighbourhoods. *Publish/Subscribe Pattern* is also well suited for the event-driven approach that characterizes reactive agents.

The approach proposed so far achieves modularity in the production of multi-agent systems by applying the *Builder Pattern* on a class that encapsulates its own strategy (*i.e.* the list of components), thus allowing to get rid of the "extends" keyword for varying the characteristics of the instantiated agent. Indeed the *Strategy Pattern*, by promoting encapsulation, is more suited than inheritance when it comes to flexibility, re-usability and modularity. Modularity comes from the fact that a component can informally be seen as a full and independent functionality. It can be assembled with other components in order to easily define a complex agent. Component independence is the first root of re-usability. The second root lies in the ability to delegate the responsibility of the configuration or decision methods to the agent rather than to the components. Hence, given a set of already implemented components, it is possible to build heterogeneous agents by varying their preferences, planning methods, *etc.*. Lastly, flexibility is provided by the simultaneous native support of traditional mail-box based message sending and reactive *Publish/Subscribe Pattern*, which avoids imposing constraints upon the initial coupling of neighbours.

## B. *Smart-Grid Model*

On the basis of the agent structure presented in section IV-A, we propose here a model that allows to describe, simulate and pilot complex smart-grids. In order to do so, it exploits physical models of atomic components as well as simulators of groups of components. It allows a fine-grained remote monitoring and control of the energy distribution given information about consumption, production and a "configuration" of each component (*i.e.* an instantiation of its actuators). Also, actuators can be remotely controlled, thus allowing the smart-grid to be controled by a user interface (GUI, service web, ...) or an autonomous decision mechanism. Considered energy information is projected over time and includes generic multi-flow energy demand, generic offer characteristic and whether the offer can meet the demand at each point of the grid. Relevant physical model can simulate the propagation of blackouts or brownouts. Also several simulations can run simultaneously on the same smart-grid, made mutually dependent (*e.g.* planning and operation) and easily compared (*e.g.* real-time payment).

The model proposed here has been implemented in GRENAD as a collection of components (see Section IV-A). Hence it can naturally be integrated with other components and distributed over a network in order to be used in various situations. For instance, it can get its values and set its actuators from and to a physical smart-grid ; it can be used as an isolated simulator ; it can be used in conjunction with a coordination protocol ; encapsulating agents may interact with real clients ; encapsulating agents may negotiate on stock market, ...

In this section we present the different aspects of our smart-grid model: how energy is represented by the different roles, how information about energy is stored and updated, how it is transmitted between the agents and projected over time.

*1) Energy and Roles:* We consider three roles.

- **A consumer** expresses a *demand* as an *amount* of energy on the different flows considered (*e.g.* heat, electricity, ...).
- **A producer** expresses an *offer*, as a function that, given a demand, returns whether it can be produced. If so, it returns also what would be the *Quality of Service* (QoS) (*e.g.* $CO_2$ impact (in $kgCO_2$), base cost (in euros), ...).
- **A distributor** distributes the energy among its neighbours. It associates with each consuming neighbour an offer and each producing neighbour a demand.

A given component has a specific representation of the energy. This representation is structured among two aspects: amount and QoS. No constraints at all are put on these objects: they are only defined w.r.t. the information required by the physical models and the simulators used in the considered application. However, some components require a manipulation function to be provided. For this reason, we consider a dedicated algebra over amounts or QoS. This algebra allows the component to manipulate energy information as a black box, thus ensuring genericity. For instance, let $\mathcal{A}$ be an amount, $\oplus^{\mathcal{A}} : \mathcal{A} \times \mathcal{A} \mapsto \mathcal{A}$ is an additive operator over $\mathcal{A}$. It allows to compute the overall demand of two consumers. $\emptyset^{\mathcal{A}}$ represent a null amount, *i.e.* the neutral element of $\oplus^{\mathcal{A}}$. The same goes for QoS.

A `Demand<`$\mathcal{A}$`>` is a container of several flows of energy of type $\mathcal{A}$. We implements a flow as a class that extends the class $\mathcal{A}$. A `Demand<`$\mathcal{A}$`>` can be manipulated, given an aforementioned algebra over $\mathcal{A}$ by simply applying it independently on each of its flow.

An offer `Offer<`$\mathcal{A}, \mathcal{QoS}$`>` is a function from a `Demand<`$\mathcal{A}$`>` to an `Optional<`$\mathcal{QoS}$`>`. An `Optional<`$\mathcal{QoS}$`>` can either be a value *of* type $\mathcal{QoS}$, if the producer has the capacity to satisfy the demand, or be *empty* if it cannot.

*2) State, Fields and Internal Model:* The state of a smart-grid component is defined as a collection of a dedicated class of fields, `SGField<A>`. An `SGField<A>` allows to handle asynchronicity by outputting four types of values: (1) an object of type `A` if it has been correctly instantiated (in this case, the field is said to be *valued*), (2) `NotReady` if some information is still missing or some computation is still running on, (3) `IncoherentNeighbourhood` if an information received from some neighbour is incoherent and (4) `InvalidInternalState` if the instantiation of the state of the component is invalid w.r.t. the internal model. Note that we do not throw any exception, since the states 2, 3 and 4 can come from a delay of communication due to asynchronicity or distribution. For instance, if two neighbours are required to modify their configuration, the first that receives the request may define an `IncoherentNeighbourhood` while it has not received the updated information of the other component.

We distinguish five types of `SGField`. The first, `Fixed<A>`, has a constant value and, thus, should always be valued. The second and third fields have dynamic values and exploit the Publish/Subscribe pattern: `Output<A>` is an observable field that is observed by a `Sensor<A>` field of a neighbour. Whenever a new value is set in an `Output<A>`, it is published. The neighbour's `Sensor<A>`, upon the reception of the publication, will trigger the occurrence of a new event within the component. This will typically result to the call of the internal model of the component, which may in turn update some outputs, thus propagating the information. The fourth field, `Actuator<A>`, is an `Output<A>` that can be remotely controlled by the fifth field, `Controller<A>`, which is a `Sensor<A>` that may send a request to implement a new value on the actuator it observes, thus modifying the configuration of the smart-grid.

Each class representing a smart-grid role (consumer, producer or distributor) is associated in one hand to a set of fixed, outputs, sensors and actuators (its state) and, in another hand, to an internal model. As stated above, the internal model is triggered upon the reception of a new event, either a new value observed by some sensors, or the modification of some actuators. When called, the internal model will read the value of the fixed fields, the sensors and the actuators and update the outputs. The internal model is an abstract method whose implementation is application specific and may rely on some simple Java models or complex external physical simulators.

*3) Links and Information Propagation:* In our smart-grid model, the neighbourhood relation is defined using outputs and sensors: each component associates an output to each of its neighbours. It also defines a sensor for each output that has been associated to him.

Sensors may transform the observed information. This allows to easily implement link losses or maximal capacity. Sensors may also change the type of the information. Hence, given a function from `A` to `B`, an `Output<A>` can be observed by a `Sensor<B>`. This allows to easily connect heterogeneous components.

Note that each component is associated to a group. Only outputs and sensors of the same group can interact. This allows a same agent to load different instances of the same component, each being uniquely identified by its group. Thanks to this architecture, it is easy to do simultaneously the current *operation* phase and tomorrow *planning* phase on a same agent. The latter may easily compute its real-time payment by comparing the outputs of its *planning* and *operation* components.

The three roles (consumer, producer or distributor) rely on a strict neighbourhood architecture. Figure 2 presents the neighbourhood relation between the roles. Next to the role is represented the type of its output; each output is mirrored by a sensor of the neighbour. For clarity, we always consider in this article homogeneous components: they use the same energy representation, $(\mathcal{A}, \mathcal{QoS})$.

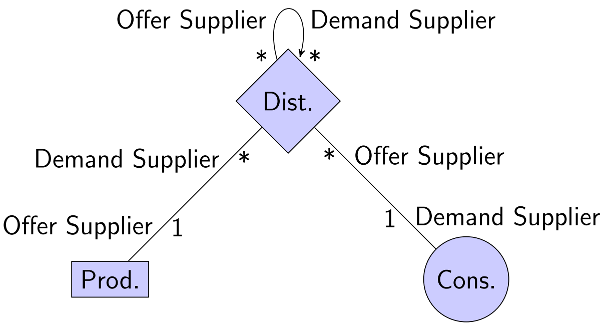

Fig. 2. Relation between roles

Consumers and producers are seen as clients of the distributing network. For this reason, they have exactly one neighbour, which is a distributor. They are responsible for defining either their demand (consumers) or their offer (producers), which is then observed by the distributor. A distributor may have several neighbours, either consumers or producers. The result of the distributed propagation of energy information is that every distributor outputs an offer to each of its neighbour consumer and a demand to each of its neighbouring producer. A distributor may also have several distributor neighbours. For each couple of distributor neighbours, one must be consuming and the other producing. The attribution of the role results from the internal models that may rely, for instance, on the value of actuators. Indeed, the distributor neighbour which consumes outputs a demand and observes an offer, and conversely for the producing one. If the neighbours disagree on their respective roles, they will output an `IncoherentState`. We refer to a distributor neighbour that has the consumer (rep. producer) role as a consumer (resp. producer) neighbour of a distributor. We refer to a distributor neighbour that is either the consumer (rep. producer) or a distributor that is consuming (resp. producing) as a consuming (resp. producing) neighbour of a distributor.

This model has been designed in order to perfectly separate the responsibility of each role. Consumer internal models are only concerned by the definition of the demand. Producer internal models are only concerned by the definition of the offer. Distributor internal models take as input the demand and the offer and are only concerned about their distribution. This abstract model is the basis of our components. Concrete classes require to implement specific internal models. Such models exploit specific actuators or outputs/sensors. Controllers allow a dynamic reconfiguration of actuators, by either a distributed or centralised algorithm, in order to optimize the energy distribution.

*4) Projection over time:* In Section IV-B2, we presented an `SGField<A>` as a container of either `A`, `NotReady`, `IncoherentNeighbourhood` or `IncoherentInternalState`. However, it is a more complex class. Indeed, it is a planning, *i.e.* a function, that, given a date, returns one of those four values or `Undefined` if no value is associated to the date. We propose several implementations of the inner function model, which is set at construction time (see *strategy pattern*). For instance, a *constant* will return the same value for all the dates, a *scatter graph* is only defined on a discrete set of date, a *step function* is defined on a range of dates .... Many other models can be thought of, however, in order to be exploitable they have to implement the following set of methods.

Let us consider `FV<A>` (FV stands for Field Value), an abstract class that can only be instantiated as one of the five types of value that can be returned by an `SGField<A>`. An `SGField<A>` delegates from its inner function model[2]:

- `SGField<B>` `map(Function2<Date,FV<A>,FV<B> >` f), a function that transforms a `SGField<A>` to a `SGField<B>`, given a function that takes a date, a `FV<A>` and output a `FV<B>`.
- `SGField<C>` `zipWith(SGField<B>` that, `Function3<Date,FV<A>,FV<B>,FV<C> >` f), a function that aggregates a `SGField<A>` and a `SGField<B>` into a `SGField<C>`, by applying a function on the couple of values associated to each date.

Both functions aim to provide required generic features, while preserving the fact that the inner model is a black box. `map` allows to modify the content of an `SGField`. For example, you can trigger a “maximum of capacity” for a planning of offers or “losses” on link transmission by mapping the appropriate function into the initial planning. `zipWith` allows to combine two `SGField` objects into one. For example, a planning of demand and a planning of offer can be combined into a planning of `Optional<`$\mathcal{QoS}$`>`, which results, at each date, from the application of the demand to the offer. If the `f` parameter of `zipWith` is a binary operator (*i.e.* `A` equals `B` equals `C`), `zipWith` may be used to fuse a collection of `SGField<A>` into one `SGField<A>`.

Note that the `f` parameters of `zipWith` and `map` take the date as argument. This allows to implement time-dependent operations which is critical for any application that depends on the weather. For example the losses on a heat pipe may be dependent on the external temperature, which can be predicted with weather information.

Note that there exist several ways to simplify the `f` parameters of `zipWith` and `map`. First, if you do not consider a time-dependent application, you can build a function $f : Date \times A \rightarrow B$ from a function $f' : A \rightarrow B$ by simply returning the application of $A$ to $f'$ whatever the date is. Second, you can consider a conventional way of handling `NotReady`, `IncoherentNeighbourhood` and `InvalidInternalState` by order of criticality. If the mapped initial value (or one of the zipped value) is an `InvalidInternalState`, the resulting value is an `InvalidInternalState`. Or if it is an `IncoherentNeighbourhood` the resulting value is an `IncoherentNeighbourhood` since the internal state is valid but not w.r.t a neighbour internal state. If it is `NotReady` the resulting value is a `NotReady` since it means that there is

[2] this approach is inspired from the category pattern[13]

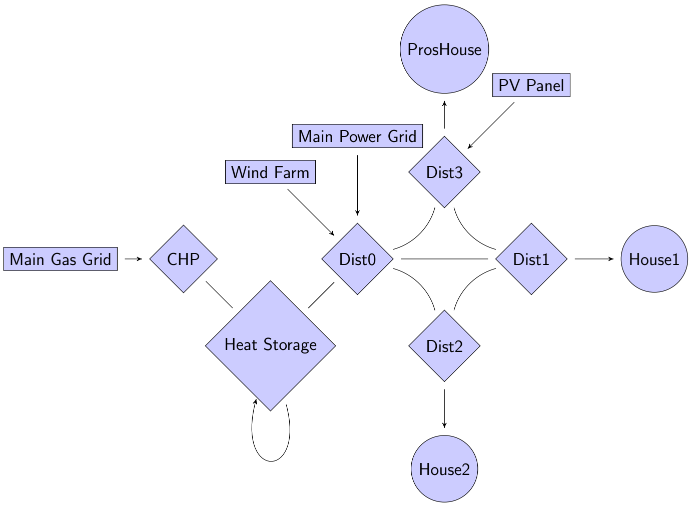

Fig. 3. Formalisation of Figure 1 scenario

*a priori* no error, but a computation is going on and we should wait for its completion. Hence, it is possible, using these rules, to automatically build a `Function<FV<A>,FV<B> >`, from a `Function<Optional<A>,Optional<B> >` where `Optional<A>` is of type `A` if a value is associated to the considered date or of type empty if no value is associated (*i.e.* type `Undefined`). The third and last way of simplifying the `f` parameter is to consider that if the mapped value or one of the zipped value is `Undefined`, the result is `Undefined`. This allows to get rid of the `Optional`.

Hence, given those three simplifying rules, to manipulate an `SGField<A>` one can rely most of the time on `SGField<B> map(Function<A,B> f)` and `SGField<C> zipWith(Function2<A,B,C> f)` for time-independent application and on `SGField<B> map(Function2<Date,A,B> f)` and `SGField<C> zipWith(Function3<Date,A,B,C> f)` for time-dependent applications. The richness of our model allows however more fine-grained control on relevant cases.

### C. Implementing the scenario

Figure 3 is the formalisation of the scenario of Figure 1 described in Section II. Figure 3 uses the same convention as Figure 2: producers are boxes, consumers circles and distributors diamonds. One can verify that Figure 3 is conform to the specification of Figure 2.

Economic actors are modelled using different components, each one characterising one functionality of the actor. Components House1 and House2 define the consumption of the elements 7 and 8 of Figure 1. They are respectively associated to Dist1 and Dist2, which define the quality of production of the energy they are supplied with. CHP and Heat Storage are distributors since they both consume and supply energy.

The links model interactions between actors; arrows are oriented from production to consumption. Both links and components are multiflow. There is a neighbourhood relation in form of a ring, the heating network, that goes along Dist0, then Dist3 then Dist1 then Dist2 to go back to Dist0. Simultaneously, there is a tree shaped network, the electricity network, that connects the root, Dist0 to Dist1, Dist2 and Dist3. For instance, the link between Dist0 and Dist1 only transmits electricity information, the one between Dist3 and Dist1 only heating information and the one between Dist0 and Dist3 convey both. We choose to connect all the main power producers into a single distributor, Dist0, however, Dist0 may hide a complex subnetwork. Indeed, it is possible to fuse several distributors into one distributor. For instance, one could have modelled Figure 1 with only one distributor instead of Dist0, Dist1, Dist2 and Dist3 or even including Heat Storage and CHP. The same operation is feasible with consumers (or producers) connected to a same distributor. Please note that, in this case, one looses direct access to some information. For example, if one fuses every distributor into a single one, GRENAD will provide an easy access to all the information from and to the producers and consumers but not necessarily the information between the distributors. This feature allows to design the application with total control of the level of details. This is particularly useful for delegating the computation of the distribution of energy of certain local parts of the system to an external simulator.

We will now detail the implementation of the components.

*1) Consumers:* Consumers (*a.k.a* House1, House2 and ProsHouse) may be implemented in different ways. Each implementation should provide an output that defines a demand at any time and is aware of the neighbour distributor offer. Also, an enhanced consumer may implement a mechanism similar to the one described in Section V in order to adapt its consumption by coordinating, during the planning phase, with its distributor neighbour. Besides, thanks to the controller of a dedicated actuator, one can provide a total control to a remote end-user during the operation phase.

*2) Common distributor:* The distributors Dist0, Dist1, Dist2 and Dist3 have as sole function to distribute the energy coming from the producers to the consumers. The stability of a grid requires electricity to respects the Kirchoff law: the flow in must equal the flow out[3]. For this reason, we propose a generic distributor class, the `KirchoffStar`. This distributor is characterized by an actuator that indicates the part of the overall demand associated to each of the producing neighbours. Hence, this actuator holds a map that associates, to each producer and distributor neighbour, $n$, a number $p_n \in [0, 100]$. $p_n$ is the percent of the sum of the consumer neighbour demands that the producing neighbour $n$ has to satisfy. The actuator values, at each time point, is valid if it respects the Kirchoff law, that is to say the sum of the $p_n$ equals 100. Note that if a distributor neighbour $n$ is consuming, $p_n$ will be null.

Reciprocally, we associate to each consumer the QoS that corresponds to the part of its consumption w.r.t. the overall consumption. For example, let us suppose that three consumers

[3] Note that as explained in Section IV-B3, losses, or any link related modification of the energy, are handled during the communication between an output and its sensor

with a demand expressed on the considered flow at the considered time point, as 3, 2 and 5 kWh. Let us suppose that there are two producers, the first assuming 30% of the consumption and the second 70%, as such, the first will assume 3 kWh and the second 7. Let us suppose that the first producer emits 4 $kgCO_2$ for producing 3 kWh and the second 6 for producing 7 kWh. Hence, the first consumer demand will be associated to a QoS of 3 $kgCO_2$, the second to a QoS of 2 $kgCO_2$ and the third to a QoS of 5 $kgCO_2$

However, our model requires the distributor to output not a QoS but an offer, that is to say, a function that associates to any demand a QoS, if this demand is satisfiable. The offer output to each consumer is computed under the hypothesis that it is the only one changing its demand. Let $prod_{dist}$ be the offer function associated of a given distributor, $dist$. A given demand $a$ is distributed by $dist$ to each of its producing neighbor, $n$, according to their associated $p_n$. This offer is computed for the demand $a$ as the sum of the QoS returned by each those neighbours for their associated part of the demand. Let $Producing_{dist}$ be the set of the considered producing distributor neighbours,

$$\forall a \in Demand < \mathcal{A} >, prod_{dist}(a) = \begin{cases} empty & \text{if some neighbour can't supply it's part} \\ \sum_{n \in Producing_{dist}} offer_n(a \times p_n) & \text{else} \end{cases} \quad (1)$$

The offer output to a consumer $cons$, $output_{cons}$, considers $prod_{dist}$ as if all other consumers had already consumed. Let $Consuming_{dist}$ be the set of the considered consuming distributor neighbours, and, for any $c \in Consuming_{dist}$, let $a_c$ be its demand,

$$\forall a \in Demand < \mathcal{A} >, output_{cons}(a) = prod_{dist}\Big(\sum_{c \in Consuming_{dist} \backslash cons} c_a \oplus a\Big) \quad (2)$$

Please note that this approach is coherent with the above mentioned examples. It also provides more information and allows to still use a simple model that only considers two types of information, demand and offer.

*3) Prosumer:* The prosumer house with PV panel needs to be separated into 3 components. One defining the offer (PV Panel), the other the demand (ProsHouse) and the third the distribution (Dist3). Please note that, in case the PV panel does not have any actuator and provides energy only to the house, it is possible to remove this component and only use a "gain" on the links, implemented thanks to the sensors (see Section IV-B3). In this case, the sensors of Dist3 and ProsHouse both transform the observed output over time by applying the weather-dependent prediction of the production of the PV Panel. If it is not the case, a separate element is required, either to be able to receive actuator modifications or to be seen by Dist 3 as a source of energy that can be distributed to the network.

*4) Storage:* The Storage unit is a distributor with two neighbours that can be decomposed as three internal components. It holds a consumer, which defines a demand, an internal state, which holds the information about the stored energy, and a producer, which defines an offer. The demand is output to one of the neighbours and the offer to the other.

The decision related to the storage is about how much energy is stored and at which time, this is why the storage demand is held by an actuator. The internal state is a private output that holds the stored energy in the form of a demand, which may be initially not null. It is updated by the storage demand, which adds energy, and the observed consuming neighbour demand, which subtracts energy. Also a special function defines losses by modifying the internal state accordingly.

The maximum capacity offer is defined by the internal state. The QoS of energy offered to the storage consuming neighbour is independent of the consuming neighbours demand. Indeed, the offered energy has already been produced at the time it is stored. Hence, the consuming neighbours are informed of this QoS even if their demands are null. For any time point $t$, let $QoS^t_{stor}$ be the QoS returned by the application of the demand of the storage at time $t$ to the offer of its producing neighbour at time $t$ (assuming this demand is sustainable). Let $stored^t$ be a demand indicating the stored energy at time $t$ (*i.e.*, the internal state). For any demand $a^t$ of the consuming neighbour, the storage can assume $a^t$ if $a^t$ is inferior to $stored^t$, and the offered QoS is always equals to $QoS^t_{stor}$.

Note that, if necessary, you can encode the fact that the storage unit can not simultaneously store and deliver by triggering an `InvalidInternalState` whenever a positive value of the demand actuator matches a positive value of the observed demand of the consuming neighbour.

*5) Main Grids:* Main gas and power grids are typically producers that are out of the scope of control of the considered smart-grids. Hence, they do not provide any actuators. If GRENAD is used as a simulator, they will be implemented with a predefined offer to output. If it is used as a piloting tool, they exploit the *interface pattern* for two purposes. Firstly, to get the information from the external system they represent and construct from it an offer, and secondly, ot transmit the demand computed by GRENAD in the appropriate format.

*6) CHP:* The CHP unit offers energy both on the heat and the electricity flows. It is a distributor since it transforms energy by consuming it from the main gas grid and supplying it to Dist0. The CHP offer to Dist0 is computed from the main gas grid offer, and an internal actuator that indicates how much of the energy consumed is used to produce electricity and how much is used to produce heat. CHP demand to the main gas grid is computed back from Dist0 demand given the internal actuator value.

*7) Wind Farm:* In our scenario, the orientation of the wind farm turbines is controlled by the application. Hence, the wind farm producer provides a collection of actuators, each one defining the orientation of the turbine it is associated with, along the time. Those actuators can either be manually controlled by a remote end-user or dynamically optimised by a coordination mechanism run by GRENAD (see for instance Section V).

In the application we are considering, the objective is typically to optimise the energy production, distribution, and consumption as a whole. The optimisation of the wind farm production is not about maximising independently their production but coordinating the production of the different producers (main grids and CHP) as well as the storage units in order to optimise the overall QoS of the energy supplied to the consumer. One may also wants to include the consumer in order to match the consumption with the production capacities. GRENAD ergonomically supports the implementation of such a coordination protocol by exploiting the *state pattern* coupled with the natively proposed *publish subscribe pattern*, as described in the next section. However, the definition of such a protocol in the complex case of this rich scenario is behind the scope of this article.

## V. Optimisation of energy distribution

In order to present the genericity and flexibility of GRENAD we describe in this section the port in GRENAD of a distributed algorithm that performs an optimal distributed dispatching of electrical power over radial networks. The presented algorithm solves a distributed constraint optimisation problem and is a part of [14], the port to GRENAD introduces some modifications. First, GRENAD generic way of handling energy allows to easily apply the presented algorithm in a more general context than [14] (see Section V-B). Second, the combination of the *State Pattern*, from [6, p. 305], with the natively implemented publish/subscribe pattern allows a simple description and implementation of the distributed algorithm. In particular, no effort have to be put on the communication, one only needs to focus on how each component reacts to the observed state of its neighbourhood.

We first expose an overview of the distributed algorithm, then we describe some hypothesis on the production, and last, we details the two phases of the algorithm.

### A. Overview of the Distributed Algorithm

The application cases of the algorithm are composed of consumers and producers with a static demand and offer. All of them can be directly represented using the proposed model, the nodes being modeled as distributors, which extend the `KirchoffStar` class. We also use the sensor/output algorithm, described in Section IV-B3 to implement maximum capacity of the links. The solution computed by the algorithm defines: for each producer, the demand it will have to deliver, for each consumer, the QoS resulting from its demand, and, for each distributor, the percent of the overall demand of its consuming neighbours it will require from each of its producing neighbours. At the end, if the offer can answer the demand, an optimal distribution will be implemented, otherwise all consumers will be informed that the network is overused. The use of the `KirchoffStar` class either ensures that the demand is satisfied or detects any demand that would violate the flow conservation constraint or the capacity.

The algorithm requires the network to be tree shaped (*e.g.* electric network), and proceeds in two phases. In the first, the *collect phase*, information is going from the leaves to the root: each node acquires and transmits to its parent the overall consumption and production information about its subtree. In the second, the *propagation phase*, information is going from the root to the leaves: each node decides an optimal power dispatching given the one of its parent.

Implementing this algorithm in GRENAD is done in the following way: each distributor possesses an actuator named *proposal* for each of its distributor neighbours, and observes with a sensor the proposals of these respective neighbours. This communication network allows the information required by the *proposal phase* to be transmitted from point to point. Each actuator is updated by the optimisation algorithm. GRENAD allows transparently this optimisation algorithm to be either located at the level agent or in a remote controller. For the sake of clarity, in this section, we refer to the initial state of sensors and outputs of the `KirchoffStar` as *regular* sensors and outputs.

The implementation exploits the *state pattern*: a given behavior is associated to a certain instantiation of the *proposal* and *regular* sensors, output and actuator. We distinguish three states:

1) *Not Ready* distributor: the distributor did not already receive enough information from its neighbours to be able to act. It is therefore waiting.
2) *Collect Ready* distributor: all but one of the distributor neighbours has instantiated their *proposal* actuator, the only neighbour that has not instantiated its proposal is then considered as its parent and the others as its children. When a distributor is in this state, it computes and instantiates its *proposal* actuator.
3) *Propagation Ready* distributor: all distributor neighbours have instantiated their *proposal* actuator. The distributor has then enough information to compute an optimal distribution between itself and its neighbours. The optimal distribution for this component is implemented by instantiating its *regular* outputs. Also, it is propagated by providing instructions to its children by the mean of its *proposal* outputs.

In the next section we detail how a proposal is computed and how the optimal configuration is determined.

### B. Production Characteristics

In order to compute an optimal distribution, certain hypothesis have to be made on producers. We consider a smart-grid where the energy demand is modeled as an amount $\mathcal{A}$ and the quality of production as $\mathcal{QoS}$. We consider the following algebra over $\mathcal{A}$ and $\mathcal{QoS}$, required by the computation of the following sections:

- $\oplus^{\mathcal{A}}$ is a binary operator over $\mathcal{A}$,
- $\oplus^{\mathcal{QoS}}$ is a binary operator over $\mathcal{QoS}$

- $\succ^{\mathcal{A}}$ is a preorder over $\mathcal{A}$.
- $\succ^{\mathcal{QoS}}$ is a preorder over $\mathcal{QoS}$.

In this section, a producer refers to a tuple $(p, maxP_p, \propto_p, offer_p)$, where $p$ is its identifier, $maxP_p$ is the maximum amount of energy it can produce, $\propto_p$ is a comparable object that allows to compare producers with respect to their quality of production and $offer_p$ is their offer function. A higher $\propto$ (given $\succ^{\propto}$) is equivalent to a better quality of production, i.e. :

$$\forall p, q \text{ producers}, \forall a \in \mathcal{A}, a \prec^{\mathcal{A}} maxP_p \wedge a \prec^{\mathcal{A}} maxP_q, \\ \propto_p \succ^{\propto} \propto_q \iff offer_p(a) \succ^{\mathcal{QoS}} offer_q(a) \quad (3)$$

In [14] the author considers a single energy flow whose amount is expressed in $kWh$, and encodes $\propto$ as the slope of a linear function that associates a $CO_2$ impact to the production of a given amount of energy.

In this setting, given a set of producers, an optimal distribution is obtained by saturating the production of producers in decreasing order of $\propto$. This is done by $dist^{opt}$, a function that considers a set of producers and an amount of energy that returns for each producer the amount of energy it must produce in the optimal distribution. $\hat{dist}^{opt}$ is a function that exploits the result of $dist^{opt}$ and returns the part of the consumption attributed to each producer in the optimal distribution, in order to instantiate the actuator of the `KirchoffStar`.

### C. Collect Phase

A proposal is computed by a *Collect Ready Distributor* and transmitted to its parent, which will have to decide the flow of energy between them. The information provided by a *Collect Ready Distributor* in a proposal to its parents is (1) the list of producers of its subtree, composed of the producer neighbours listed in its children proposals and its own producer neighbours, and (2) the overall demand of the consumers of its subtree, computed from the overall demand provided by its children proposals and the demand of its consumer neighbours. Given this proposal, the parent has to decide, during the implementation phase, whether it considers neighbouring distributors to be producing or consuming. It also has to decide of the amount of energy demanded to producers, the remaining energy of the overall consumption being assumed by the producers of the subtree. Please note that the transmitted energy between a distributor and its parent cannot exceed the maximum capacity of their power line. Hence, proposals are modified so that the overall demanded consumption does not exceed this limit. Exceeding energy is deduced from the subtree producers offer.

The proposal of a *Collect Ready Distributor*, $d$, is a tuple ($Prop_d^{Offer}$,$Prop_d^{Demand}$) where $Prop_d^{Offer}$ is a list of producers and $Prop_d^{Demand}$ a demand. They are computed as follow: Let $Cons_d$ be the set of consumer neighbours of $d$, $Prod_d$, the set of its producer neighbours, and $Child_d$, the set of its distributor neighbours that have defined their proposals. To say that $d$ is a *Collect Ready Distributor* is equivalent to say that $Child_d$ refers to all but one of its distributor neighbours, $\dot{d}$, which is its parent. The overall demand of $d$ subtree[4] is computed as the sum of the demands of its consumer neighbours and its children proposals. The list of producers of $d$ subtree is computed as the union of both its producer neighbours and the producers listed in its children proposals.

Let $Excess_d$ be the difference between the line capacity and the overall demand of $d$ subtree. Two cases are possible: (1) $Excess_d$ is negative or null, in which case the parent can answer the demand without any restriction. In this case, the proposal of $d$ is defined as the list of producers and the overall demand of its subtree; (2) $Excess_d$ is positive, in which case the answer of the parent is limited by the transmission line. The exceeding amount has then to be assumed by the subtree. In this case, $d$ proposal demand is defined as the line transmission capacity. The exceeding power is dispatched in an optimal way using $dist^{opt}$ on $d$ subtree list of producers. For each producer $p$ of $d$ subtree, let $local_p$ be the demand attributed to $p$ by the aforementioned call of $dist^{opt}$. $d$ proposal offer is then a modified list of producers of its subtree. First, for any $p$, $local_p$ is subtracted from $maxP_p$. Second, for any $p$, $offer_p$ is modified into $offer'_p$ by assuming that $local_p$ is produced, *i.e.* :

$$\forall a \in Demand < \mathcal{A} >, offer'_p(a) = \\ offer_p(a \oplus^{Amount} local_p) \quad (4)$$

### D. Propagation Phase

A distributor, $\dot{d}$, is in the *Propagation Ready* state if all of its neighbours have either defined their proposal (*i.e.* they are its children) or they outputs (*i.e.* there is exactly one, which is its parent in the network tree or zero if it is the root of the network). Such a distributor has the responsibility to determine a globally optimal distribution to each of its neighbour by instantiating its outputs. To do so it considers the overall demand and the list of producers of its subtree. Those information are computed from the children proposals, the consumer and producer neighbours and the possible parent, which can either be seen as a producing or as a consuming neighbour.

For each producer $p$ of its subtree, let $prod_p^{opt}$ be the demand it must assume in an optimal distribution. $prod_p^{opt}$ is computed by $dist^{opt}$ applied on the overall demand and the list of producers of $\dot{d}$ subtree. To each child $d$ of $\dot{d}$, is attributed the total amount of energy, $Prod_d^{opt}$, the child should supply in a globally optimal solution. $Prod_d^{opt}$ is computed as the sum of $prod_p^{opt}$ for any $p$ belonging to $Prop_d^{Offer}$. Three cases are possible: (1) $Prod_d^{opt} = Prop_d^{Demand}$, which means that in an optimal solution $d$ subtree supports exactly its demand. No energy is transmitted between $d$ and $\dot{d}$. This subnetwork can be isolated; (2) $Prod_d^{opt} > Prop_d^{Demand}$, which means that in an optimal solution $d$ subtree supports its own demand and offers some exceeding energy. In this case $\dot{d}$ is configured so that it is demanding this exceeding

[4] the subtree of the network whom root is $d$

energy from *d;* (3) $Prod_d^{opt} < Prop_d^{Demand}$, which means that in an optimal solution *d* subtree does not support its own demand. In this case, $\dot{d}$ is offering the difference to *d,* $\dot{d}$ declares itself as a producer whose maximum production is the remaining demand. Please note that in this case, even if d does not support its own demand, some of its producers may no be used in the optimal configuration. However, a distributor always consumes first all the energy offered by its parent.

## VI. Conclusion

In this work, we have presented GRENAD, a JADE-based framework, that allows to describe, simulate and pilot smart power grids. The aim of GRENAD is to provide a great flexibility in the design and implementation of smart power grids applications, so that it can be used either as a standard basis to build and test such applications or as an interface to monitor and pilot actual grids. As such, it is compliant with the main business and organizationals models: it proposes the classical roles of production, consumption, prosumption, distribution and storage. GRENAD allows time-dependant monitoring and computation; it supports both internal physical models and connection to external ones; it provides flexibility in manual, automatic or autonomous processing of the computed energy-related information; and finally it eases the integration of distributed smart grid control algorithms. To meet these objectives, GRENAD exploits a combination of Multi-Agent and component-oriented paradigms. Such an approach allows to build complex agents using simple reusable components and, thus, capitalize the development of applications.

We also have proposed a model of smart-grid that handles demand and offer and rely on the most general interpretation of consumption, production and distribution. The information about energy exchanged by the agents is complex. Indeed, it does not impose any assumption on the energy definition, which can be a combination of several flows and it is projected over time. Also, its management handles asynchronicity of computations and incoherence of states. The use of algebras and the category pattern[13] allows an efficient and ergonomic processing of this information. Also, GRENAD does not require to deal with communications, since it implements a transparent event-driven approach for information exchange, supported by the publish-subscribe pattern. Lastly, we demonstrated the ease of implementation of a generic sophisticated optimization distributed algorithm thanks to this architecture and the state pattern.

Future works include the development of more component libraries, of simulator interfaces and of dedicated optimization algorithms. Another interesting line of development would be to improve the reliability of the platform by integrating model checking capabilities.
